The Albigeois is a small town about twenty seven miles in length, and twenty in breadth, abounding in corn, wood, grapes, farron, plums, and sheep: and the inhabitants drive a great trade in dried prunes, grapes, a coarse sort of cloth, and wines of Guillac. These wines are the only fine hereabouts that are fit for exportation: they are carried down to Bourdeaux, and generally sold to the British. They have likewise several coal-mines.

ALBIGENSES, in church-history, a sect or party of reformers, about Toulouse and the Albigeois in Languedoc, who sprang up in the 12th century, and distinguished themselves by their opposition to the discipline and ceremonies of the Roman church.

This sect had their name, it is supposed, either by reason there were great numbers of them in the diocese of Albi, or because they were condemned by a council held in that city. In effect, it does not appear that they were known by this name before the holding of that council. The Albigeois were also called Albiani, Albigenes, Albi, and Albives, though some distinguish these last from them. Other names given to them are, Henriquenses, Abelardites, Bulgarians, &c. Some on account of the qualities they assumed; others on that of the country from whence it is pretended they were derived; and others on account of persons of note who adopted their cause, as Peter de Brins, Arnold de Breffe, Abelard, Henri, &c. Berengarius, on the other hand, himself, is by some ranked in the number. The Albigeois are frequently confounded with the Waldenses, from whom, however, they differ in many respects, both as being prior to them in point of time, as being found as to articles of faith, and only separating from the society of confessions and penances; maintained marriage unlawful; laughed at purgatory, prayers for the dead, images, crucifixes, &c. — There were likewise said to be two classes of them: the Perfect, and the Believers. The perfect boasted of their living in continence, of eating neither flesh, eggs, nor cheese. The believers lived like other men, and were even loose in their morals; but they were persuaded they should be faved by the faith of the perfect, and that none were damned who received imposition of hands from them. But from these charges also they are generally acquited by Protestants: who consider them as the pious inventions of the Roman church, whose members deem it meritorious by any means to blacken heretics.

However this be, the Albigeois grew so formidable, that the Catholics agreed upon a holy league or croifade against them. They were at first supported by Raimond, count of Toulouse. Pope Innocent III. de- ferous to put a stop to their progress, sent a legate into their country; which failing, he stirred up Philip Augustus, king of France, and the other princes and great men of the kingdom, to make war upon them. Upon this the count of Toulouse, who had sided with them, made his submission to the pope, and went over to the Catholics: but soon after, finding himself plundered by the croifaders, he declared war against them, and was joined by the king of Arragon. His army was defeated at the siege of Muret, where he himself was killed, and the defeat followed by the surrender of the city of Toulouse, and the conquest of the greatest part of Languedoc and Provence. His son Raimond succeeded him: who agreed with the king and the pope to set up the inquisition in his estates, and to extirpate the Albigenses. In an assembly held at Milan, the archbishop of Toulouse drew up articles, agreeable to which the court made a most ample declaration against them, which he published at Toulouse in 1253. From this time the Albigenses dwindled by little and little; till the times of the Reformation, when such of them as were left fell in with the Vaudois, and became conformable to the doctrine of Zuinglius and the disciples of Geneva.

ALBIGENSES is also a name sometimes given to the followers of Peter Vaud, or Waldo; and hence synonymous with what we more properly call Waldenses, or Poor Men of Lyons. In this sense the word is applied by Camerarius, Thuanus, and several other writers. The reason seems to be, that the two parties agreed in their opposition to the papal innovations and incroachments, though in divers other respects they appear to be different enough. The bishop of Meaux labours hard to support a distinction between the two sects, alleging that the Albigenses were heretics, and Manichaeans; whereas the Waldenses were only schismatics, not heretics; being found as to articles of faith, and only separating from the church of Rome on account of forms and discipline. Dr Allix endeavours to set aside the distinction, and shows, that both of them held the same opinions, and were equally condemned and held for heretics: and this not for points of faith, but for declaiming against the papal tyranny and idolatry, and holding the pope to be the Antichrist; which last, according to M. de Meaux, constitutes nothing less than the peculiar mark of Manichaeism.
Manicheism. In this sense the Lollards and Wickliffites in England were not only Albigenens but Manichees.

ALBINTEMELIUM, ALBINTEMELIUM, (Tactus;) or at full length, ALBIUM TEMELIUM, (Pliny, Strabo;) now Vivintimiglia, situated in the south-west of the territory of Genoa, near the borders of the county of Nice, with a port on the Mediterranean, at the mouth of the rivulet Rotta, almost about half-way between Monaco and S. Remo. E. Long. 7. 40. Lat. 43° 17'.

ALBIOCE, or ALBICE, (Pliny, Strabo;) otherwise called Rea Apliniarum, from their superstitious worship of Apollo; also Civitas Requinre; now Rie, in Provence, about 18 leagues to the north-east of Toulon, on the north side of the rivulet Verdon; was originally a Roman colony, (Inscription.) It was sometimes written Regium. The people were called Albici, (Caesar.) E. Long. 1. 0. Lat. 43° 20'.

ALBINI, in antiquity, the workmen employed in what was called Opus Albarium. They make a different profession from the dealers in whiteners. ALBINOS, the name by which the Portuguese call the white Moors, who are looked upon by the negroes as monsters. They at a distance might be taken for Europeans; but, when you come near them, their white colour appears like that of persons affected with a leprosy.

In Sauvage's Voyages dans les Alpes, is the following account of two boys, at Chamouni, who have been called Albinos. "The elder, who was at the end of the year 1785 about twenty, or one-and-twenty years of age, had a dull look, with lips somewhat thick, but nothing else in his features to distinguish him from other people. The other, who is two years younger, is rather a more agreeable figure; he is gay and sprightly, and seems not to want wit. But their eyes are not blue; the iris is of a very distinct rose-colour; the pupil too, when viewed in the light, seems decidedly red; which seems to demonstrate, that the interior membranes are deprived of the aures, and of that black mucous matter that should line them. Their hair, their eye-brows, and eye-lashes, the down upon their skin, were all, in their infancy, of the most perfect milk-white colour, and very fine; but their hair is now of a reddish cast, and has grown pretty strong. Their sight too is somewhat strengthened; though they exagerrate to strangers their aersion for the light, and half-shut the eye-lids, to give themselves a more extraordinary appearance. But those who, like me, have seen them in their infancy, before they were tormented to this deceit, and when too few people came to Chamouni to make this affection profitable to them, can attest that then they were not very much offended with the light of day. At that time, they were so little de- fiers of exciting the curiosity of strangers, that they hid themselves to avoid such; and it was necessary to do a fort of violence to them before they could be prevailed on to allow themselves to be inspected. It is also well known at Chamouni, that when they were of a proper age they were unable to tend the cattle like the other children at the same age; and that one of their uncles maintained them out of charity, at the time of life when others were capable of gaining a subsistence by their labour.

I am therefore of opinion, that we may consider these two lads as true Albinos: for if they have not the thick lips and flat noses of the white negroes, it is because they are albino of Europe, not of Africa. This infirmity affects the eyes, the complexion, and the colour of the hair; it even diminishes the strength, but does not alter the configuration of the features. Besides, there are certainly in this melady various degrees: some may have less strength, and be less able to endure the light; but these circumstances in those of Chamouni are marked with characters sufficiently strong to intitle them to the unhappy advantage of being classed with that variety of the human species denominated Albino.

When nature presents the same appearance often, and with circumstances varied, we may at last discover some general law, or some relation which that appearance has with known causes: but when a fact is so singular and so rare, as that of those Albino, it gives but little scope to conjectures; and it is very difficult to verify those by which we attempt to explain it.

I at first imagined that this disease might be referred to a particular port of organic debility; that a relaxation of the lymphatic vessels within the eye might offer the globules of the blood to enter too abundantly into the retina, the aures, and even into the retina which might occasion the redness of the iris, and of the papil. The same debility seemed also to account for the intolerance of the light, and for the whitening of the hair.

But a learned physiologist, M. Blumenbach; professor in the university at Göttingen, who has made many profound observations on the organs of sight, and has conferred with great attention the albino of Chamouni, attributes their infirmity to a different cause. "The study of comparative anatomy has furnished him with frequent opportunities of observing this phenomenon; he has found it in brutes, in white dogs, and in owls; he says, it is generally to be seen in the warmed blooded animals; but that he has never met with it in those with cold blood.

From his observations, he is of opinion, that the redness of the iris, and of the other internal parts of the eye, as well as the extreme sensibility that accompanies this redness, is owing to the total privation of that brown or blackish mucus, that, about the fifth week after conception, covers all the interior parts of the eye in its found flate. He observes, that Simon Pontius, in his treatise de Coloribus Oculorum, long ago remarked, that in blue eyes the interior membranes were less abundantly provided with this black mucus, and were therefore more sensible to the action of light. This sensibility of blue eyes agrees very well, says M. Blumenbach, with northern people, during their long twilight; while, on the contrary, the deep black in the eyes of negroes enables them to support the splendor of the sun's beam in the torrid zone.

As to the connection between this red colour of the eyes and whiteness of the skin and hair, the same learned-physiologist says, that it is owing to a similarity of structure, confused in similitudine fabrice. He affirms, that this black mucus is formed only in the delicate cellular substance, which has numerous blood-vessels contiguous to it, but contains no fat; like the inside of the eye, the skin of negroes, the frontal palate of several domestic animals, &c. And, lastly, he says,
At the very time that L. Blumenbach was reading this memoir to the Royal Society of Gottingen, M. Buzzi, surgeon to the hospital at Milan, an able and celebrated anatomist, published, in the C. Pegio, Societ. de Medicina, 1784, tom. viii, p. 114, a very interesting memoir, in which he demonstrates by dissection what Blumenbach had only suppoosed.

"A peasant of about 30 years of age died at the hospital of Milan of a pulmonary disorder. His body being exposed to view, was exceedingly remarkable by the uncommon whiteness of the skin, of the hair, of the beard, and of all the other covered parts of the body. M. Buzzi, who had long defined an opportunity of dissection, sought a subject immediately seized upon him. He found the iris of the eyes perfectly white, and the pupil of a rose-colour. The eyes were disected with the greatest possible care, and were found entirely destitute of that black membrane which anatomists call the uvea; it was not to be seen either behind the iris, or under the retina: within the eye there was only found the choroid coat extremely thin and tinged, of a pale red colour, by vessels filled with discoloured blood. What was more extraordinary, the skin, when detached from different parts of the body, seemed also entirely destitute of the rete mucosum, which did not discover the least vestige of this, nor even in the wrinkles of the abdomen, where it is most abundant and most visible.

M. Buzzi likewise accounts for the whiteness of the skin and of the hair, from the absence of the rete mucosum, which, according to him, gives the colour to the cuticle, and to the hairs that are scattered over it. Among other proofs of this opinion, he alleges a well-known fact, that if the skin of the blackest horse be accidentally destroyed in any part of the body, the hairs that afterwards grow on that part are always white, because the rete mucosum which tinges those hairs is never regenerated with the skin.

The proximate cause of the whiteness of albinos, and the colour of their eyes, seems therefore pretty evidently to depend on the absence of the rete mucosum: But what is the remote cause?

"In the first place, it seems probable that men affected with this infirmity form a distinct species, for they are produced from parents that have dark skins and black eyes. What is it then that destroys the rete mucosum in such persons? M. Buzzi relates a singular fact, which seems to throw some light on this subject.

A woman of Milan, named Calcagni, had seven sons. The two eldest had brown hair, and black eyes: the third next had white skins, white hair, and red eyes; the last resembled the two eldest. It was said that this woman, during the three pregnancies that produced the albinos, had a continual and immediate appetite for milk, which she took in great quantities: but that when she was with child of the other four children, she had no such desire. It is not however ascertained, that this preternatural appetite was not itself the effect of a certain heat, or internal disease, which destroyed the rete mucosum in the children before they were born.

"The albinos of Chamouni are also the offspring of parents with dark skins and black eyes. They have three fathers by the same father and mother, who are also brunettes. One of them that I saw had the eyes of a dark brown, and the hair almost black. They are said, however, to be all afflicted with a weakness of sight. When the lads are married, it will be curious to observe how the eyes of their children will be formed. The experiment would be particularly decisive if they were married to women like themselves. But this faulty conformation seems to be more rare among women than among men; for the four of Milan, the two of Chamouni, the one described by Maupertuis, the one by Helvetius, and almost all the instances of these singular productions, have been of our sex. It is known, however, that there are races of men and women affected with this disease, and that these races perpetuate themselves, in Guinea, in Java, at Panama, &c.

"Upon the whole, this degeneration does not seem to be owing to the air of the mountains; for though I have traversed the greatest part of the Alps, and the other mountains in Europe, these are the only individuals of the kind that ever I met with."

ALBINUS, a Latin poet, whom Ovid sur-name the Divine. There is now nothing of his extant, except an Elegy on Drafus, and another on the Death of Mecenas.

ALBINUS (Bernhard Siegfried), a celebrated physician and anatomist, was born, of an illustrious family, at Francfort on the Oder in 1697. His father was then professor of the practice of medicine in the university of Francfort, but in the year 1702 he repaired to Leyden, being nominated professor of anatomy and surgery in that university. Here his son had an opportunity of studying under the most eminent masters in Europe, who, from the singular abilities which he then displayed, had no difficulty in prognosticating his future eminence. But while he was distinguished in every branch of literature, his attention was particularly turned to anatomy and surgery. His peculiar attachment to these branches of knowledge gained him the intimate friendship of Ruyffch and Rau, who at that time flourished in Leyden; and the latter, fortunately celebrated as a lithomaniac, is said to have seldom performed a capital operation without inviting him to be present. Having finished his studies at Leyden, he repaired to Paris, where he attended the lectures of Davernay, Vaillant, and other celebrated professors. But he had scarce spent a year there, when he was invited by the curators of the university of Leyden, to be a lecturer in anatomy and surgery in that place. Though contrary to his own inclination, he complied with their request, and upon that occasion was created Dr of physic without any examination. Soon after, upon the death of his father, he was appointed to succeed him as professor of anatomy; and upon being admitted into that office on the 9th of November 1721, he delivered an oration, De vera via ad fabricam humani corporis cognitionem ducere; which was heard with universal approbation. In the capacity of a professor, he not only beheld the greatest attention upon the instruction of the youth entrusted to his care, but in the improvement of the medical art. With this view, he published many important discoveries of his own; and by elegant editions, turned the attention of physicians to works of merit, which might otherwise have been neglected.
neglected. By these means his fame was soon extended over Europe; and the societies of London, Petersburg, and Harlem, cheerfully received him as an associate. In 1745, he was appointed professor of the practice of medicine at Leyden, and was succeeded in the anatomical chair by his brother Fréd. Bern. Albinus. He was twice rector of the university, and as often he refused that high honour when it was voluntarily offered him. At length, worn out by long service and intense study, he died on the 9th of September 1770, in the 74th year of his age.

ALBION, the ancient name of BRITAIN.

New Albion, a name given by Sir Francis Drake to California.

ALBIREO, (in Astronomy) a star of the third or fourth magnitude, in the constellation Cygnus.

ALBIS, (in anc. geog.) now the Elbe, which divided ancient Germany in the middle, and was the boundary of the ancient geography of Germany, so far as that country was known to the Romans: all beyond they owned to be uncertain, no Roman except Drusus and Tiberius having penetrated so far as the Elbe. In the year of the building of the city 744, or about six years before Christ, Domitius Ahenobarbus, crossing the river with a few, merited the ornaments of a triumph; so glorious was it reckoned at Rome to have attempted the passage. In the following age, however, the river that before occupied the middle of ancient Germany, became its boundary to the north, from the immigrations of the Sarmatiae, who policed themselves of the Tranfalb German. The Elbe rises in the borders of Silesia, out of the Rifenberg, runs through Bohemia, Mähia, Upper Saxony, Anhalt, Magdeburg, Bandenburg, Danneberg, Lauenburg, Holstein, and after being swollen by many other rivers, and pailing by Hamburg and Glückstadt, falls into the German, or North sea, to both which places the river is navigable by large vessels.

ALBISOLA, a small town belonging to the republic of Genoa: here is a porcelain manufacture, and several country-houses of the Genoese nobility. It was bombarded in 1745 by the English. E. Long. 8. 20. N. Lat. 44. 15.

ALBAGALERUS, in Roman antiquity, a white cap worn by the famo datus, on the top of which was an ornament of olive branches.

ALBORK, amongst the Mahometan writers, the beast on which Mahomet rode in his journeys to heaven. The Arab commentators give many fables concerning this extraordinary vehicle. It is represented as of an intermediate shape and size between an ass and a mule. A place, it seems, was secured for it in paradise at the intercession of Mahomet; which, however, was in some measure extorted from the prophet, by Albork's refusing to let him mount him when the angel Gabriel was come to conduct him to heaven.

ALBORO, in zoology, a name by which the erythrina, a small red fish, caught in the Mediterranean, is commonly known in the markets of Rome and Venice.

ALBOURG, a town of Denmark, in North Jutland, capital of the diocese of the same name, and a bishop's see. It has this name, which signifies seld-town, on account of the great number of cells taken here. It is seated on a canal, 10 miles from the sea, 30 north of Wiborgh, and 50 north of Arhys. It has an ex-change for merchants, and a safe and deep harbour.

ALBICANIAS. They have a considerable trade in herrings and corn; and an manufacture of guns, pistols, saddles, and gloves. E. Long. 29. 16. N. Lat. 56. 35.

ALBRICTUS, born at London, was a great philosopher, a learned and able physician, and well versed in all the branches of polite literature. He lived in the 11th century, and wrote several works in Latin, particularly, 1. Of the origin of the gods. 2. The virtues of the ancients. 3. The nature of poison, &c.

ALBUCA, BASTARD STAR-OF-BETHLEHEM: A genus of the monogynia order, belonging to the hexandra class of plants; and in the natural method ranking under the roth order, Coronariae. The characters are: The calyx is wanting: The corolla consists of six oval oblong petals, which are persistent: The flamina consists of six three-fided filaments the length of the corolla: Of these, three are fertile, with vertebrate antherae; three are barren, without antherae: The pistillum has an oblong three-fided germen: the stylus is three-fided: The pericarpiun is an oblong obulate triangular capsule, having three cells and three valves. The seeds are numerous, flat, and incumbent. Of this genus Linnaeus reckons only two. Species. 1. The major, or star-flow'wer, with spear-shaped-leaves. This is a native of Canada, and some other parts of North America: the root is bulbous; from whence shoot up eight or ten long, narrow, spear-shaped leaves. In the centre of these arises a flower-item, a foot or more in height, garnished with a loose spke of greenish yellow flowers. After the flowers are pan, the germen swells to a three-cornered capsule, having three cells and with flat seeds. 2. The minor, or African star-flow'er, is a native of the Cape of Good Hope. This hath also a pretty large bulbous root, from which arise four or five narrow awl-shaped leaves, of a deep green colour; the flower-item, which comes from the center of the root, is naked, and rarely arises more than eight or nine inches high, having five or six greenish-yellow flowers, growing almost in the form of an umbel at top: these are rarely succeeded by seeds in Britain.

Culture. The Canada albica is hardy: so the roots may be planted about four inches deep in a border of light earth, where they will thrive and produce their flowers late in the summer: but as the seeds do not often ripen in Britain, and the bulbs put out few offsets, the plants are not common in that country. The African generally flowers twice a year; first in March or April, and again in July or August: and if its roots are kept in pots filled with light earth; sheltered under a hot-bed frame, they will flower even in winter; but the best method is to have a border in the front of a green-house, or stove, where the roots of most of the bulbous flowers may be planted in the full ground, and fereened in winter from frost: in such situations they thrive much better, and flower stronger, than when kept in pots.

ALBUGINEA TUNICAE, in anatomy, the third or innermost coat or covering of the te€les: it is likewise the name given to one of the coats of the eye.

ALBUGINEUS, in anatomy, a term sometimes applied to the aqueous humour of the eye.

ALBUGO, or LEUCOMA, in medicine, a dieterper occasioned
occasioned by a white opaque spot growing on the cornea of the eye, and obstructing vision. See Medicine (Index).

**ALB**

ALBUM, in antiquity, a kind of white table, or register, wherein the names of certain magistrates, public transactions, &c. were entered. Of these there were various sorts; as the album decurionum, album senatorum, album praetorium, &c.

**ALBUM Decurionum**, was the register wherein the names of the decuriones were entered. This is otherwise called matricula decurionum.

**ALBUM Senatorum**, the list of senators names which was first introduced by Augusinus, and renewed yearly.

**ALBUM Praetorium**, that wherein the names of the persons of those decurio who judged at certain times, were entered.

**ALBUM praetoris**, that wherein the formula of all actions, and the names of such judges as the prætor had chosen to decide causes, were written.

The high-priest entered the chief transactions of each year into an album, or table, which was hung up in his house for the public use.

ALBUM is also used, in later times to denote a kind of table, or pocket-book, wherein the men of letters with whom a person has conversed, inscribe their names with some sentence or motto. The famous Albumazar, a learned Arabian physician of the tenth century, who wrote a treatise, Asudi de fapemon, has occasioned a table, which appears to be that anamolous unaccountable compilation wherein his house for the public use.

The white of an egg, according to Boerhaave, makes an extraordinary menstruum. Being boiled hard in the shell, and afterwards suspended in the air by a thread, it resolves and drops down into an impavid, white, milky liquor, which appears to be that inamolous unaccountable menstruum so much used by Paracelsus; and will, though it contain nothing sharp, oleaginous, or sapnaceous, make a thorough solution of myrrh; which is more than either water, oil, spirits, or even fire itself, can effect.

A little purulent white of egg taken into the stomach, occasions a nausea, horror, fainting, vomiting, diarrhoea, and gripes; it inflames the bile, excites heat, thirst, fever; and disfolves the humours like the plague. On the contrary, the white of fresh-laid eggs, if taken while warm from the hen, is extremely nourishing to the infirm; it may be taken in lukewarm milk; but if any other heat is applied to it, the nutritive quality will be destroyed. The fresh white of egg prevents burns from riling in blisters, if it is used immediately after the accident; it mitigates inflammations of the eyes, and preferves the face from sun-burning. In pharmacy, it is used as a medium to render balsams and turpentes, &c. miscible with aqueous fluids; but as it disagreee with many stomachs when thus taken, a medicile of gum arabe may supply its place, it being as good a medium in similar circumstances, and not apt to offend the tenderest stomach. - Whites of eggs are also useful for clarifying liquors; to which purpose, being mixed and incorporated with the liquors to be clariified, and the whole afterwards boiled, the whites of eggs are by this means brought together and hardened, and thus carry off the gross parts of the liquor along with them.

**ALBUQUERQUE**, a small city in Spain, in the province of Estremadura, is seated on an eminence, nine miles from the frontiers of Portugal. It is commanded by an almost impregnable fortress, built on a high mountain, and serving to defend the town. It carries on a great trade in wool and woollen manufactures. It was taken by the allies of Charles king of Spain, in 1705. W. Long. 7. o. N. Lat. 38. 52.

**ALBURN**, the English name of a compound colour, being a mixture of white and red, or reddish brown. Skinner derives the word, in this sense, from the Latin albus, and the Italian burro, from bruno, brown.

**ALBURNUM**, the soft white substance which in trees is found between the liber or inner bark and the wood, and in progress of time acquiring solidity, becomes itself the wood. From its colour and comparatively softness, it has been styled by some writers the fat of trees adeps arborum.

The alburnum is found in largest quantities in trees that are vigorous; though in such as languish, or are sickly, there is a great number of beds. In an oak six inches in diameter, this substance is nearly equal in bulk to the wood. In a trunk of one foot diameter, it is as one to three and a half; of two and a half feet diameter, as one to four and a half, &c. but these proportions vary according to the health and constitution of the trees. - The alburnum is frequently gnawed in pieces by insects which lodge in the substance, and are nourished from it.

**ALBURNUS**, in zoology, a species of the cyprinus of Linnaeus. See Cyprinus.

**ALCA**, or **AUK**, in ornithology, a genus of the order of anseres. The beak of this genus is without teeth, short, convex, compressed, and frequently furrowed transversely; the inferior mandible is gibous near the base; the feet have generally three toes. The species of the alca are 12; of which the most remarkable are,

1. The impennis, northern penguin, or great auk, with a compressed bill furrowed on each side, and an oval spot on each side of the eyes. According to Mr Martin, this bird breeds on the isle of St Kilda; appearing there the beginning of May, and retiring the middle of June. It lays one egg, which is six inches long, of a white colour; some are irregularly marked with purplish lines crossing each other, others blotched with black, and ferruginous about the thicker end: if the egg is taken away, it will not lay another that season. Mr Macaulay informs us that it does not visit that island annually, but sometimes keeps away for several years together; and adds, that it lays its egg close to the sea-mark, being incapable, by reason of the shortness of its wings, to mount higher. The length of this bird, to the end of its toes, is three feet; but its wings are 20 feet, as to be useless for flight; the length, from the tip of the longest quill-feathers to the
the first joint, being only four inches and a quarter.

This bird is observed by seamen never to wander beyond foundings; and according to its appearance they direct their measures, being then assured that land is not very remote. It sometimes frequents the coasts of Norway, the Ferroo isles, Iceland, Greenland, and Newfoundland; and feeds much on the lump-fish, father-lather, and other fish of that size. The young birds eat rofe-root, and other plants. The old ones are very rarely seen on shore, tho' the young ones are not unfrequently met with. It is a very shy bird. It walks ill; but dives well, and is taken in the manner used for the razor-bill and puffin. The skin between the jaws is blown into a bladder, and used for the darts of the Greenlanders, as is also that of some other birds. The skin of the body is supposed to be used by the Equinocuh Indians for garments.

2. The aile, little auk, or black and white diver, with a smooth conical bill, a white streak on the belly and wings, and black feet. The bulk of this species exceeds not that of a black-bird. It is not very common in Britain, being only met with now and then. It seems to be most plentiful towards the north, being met with in various parts as far as Spitzbergen. It is common in Greenland, in company with the black-billed species; feeds on the same food; and lays two bluish white eggs, larger than those of a pigeon. It flies quick, and dives well; and is always dipping its bill into the water while swimming or at rest on the water. It grows fat in the former season, from the waves bringing plenty of crabs and small fish within its reach; but from its size it is less sought after than the others. In Greenland it is called the Ice-bird, being the harbinger of Ice. This species is sometimes seen of a pure white.

3. The arctica, or puffin, with a compressed bill and four furrows; the orbit of the eyes and temples are white. The legs of this species are very small; and placed so far behind as to disqualify it from standing, except quite erect, resting not only on the foot, but the whole length of the leg. This circumstance makes the feet of the puffin from the ground very difficult, and it meets with many falls before it gets on wing; but when that is effected, few birds fly longer or stronger. These birds frequent the coasts of several parts of Great Britain and Ireland; but to place in greater numbers than Priests-holme, where their flocks may be compared to swarms of bees for multitude. These are birds of passage; they return there annually about the fifth or tenth of April, quit the place (almost to a bird), and return twice or thrice before they settle to burrow and prepare for ovation and incubation. They begin to burrow the first week in May; but some few have themselves that trouble, and dislodge the rabbits from their holes, taking possession of them till their departure from the ille. Those which form their own burrows, are at that time so intent on the work as to suffer themselves to be taken by the hand. This task falls chiefly to the share of the males; who also afflict in incubation. The first young are hatched the beginning of July. The old ones show vast affection towards them; and feed totally insensible of danger in the breeding season. If a parent is taken at that time, and suspended by the wings, it will in a fort of despair treat itself most cruelly, by biting every part it can reach; and the moment it is loosed, will never offer to escape, but infantly refer to its unfeigned young; for this affection ceases at the stated time of migration, which is most punctually about the 11th of August, when they leave such young as cannot fly to the mercy of the peregrine falcon, who watches the mouths of the house for the appearance of the little deferted puffins, which, forced by hunger, are compelled to leave their burrows. They lay only one egg. The eggs differ much in form: some have one end very acute; others have both extremely obtuse; all are white. Their flesh is excessively rank, as they feed on sea-weeds and fish, especially sprats: but when pickled and preferred with spices, are admired by those who love high-eating. Dr. Cates tells, that, in his days, the church allowed them in lent, instead of fish: he also acquaints us, that they were taken by means of ferrets, as we take rabbits: at present, they are either dug out, or drawn from their burrows by a hooked stick: they bite extremely hard, and keep such fast hold on whatever they fasten, as not to be easily disengaged. Their noise when taken, is very disagreeable; being like the efforts of a dumberson to speak. These birds are also common in Ireland; on the island Sherris, three leagues N. N. W. of Holyhead; and in the S. Stack, near Holyhead, they breed in plenty. They inhabit Iceland and Greenland; and breed in the extreme parts of the islands. It is found in the Ferroc isles, where it is called Landy; and in the Faroe isles, which is called Goder- nek, from the shape of the bill. It goes also by various other names; such as Golden-head, Battle-axe, and Halegug, in Wales; at Scarborough, Mullet; and in Cornwall, Pope. In America they are said to frequent Carolina in winter; and have been met with in Sandwich Sound by late voyagers: the natives ornament the fore parts and collar of their real-skin jackets with the beaks of them; and those of Aoonalakshka wear gowns of their skins, along with those of other birds. On the coast of Kamtschatka and the Kurilchik islands they are common, even on the Penchikski bay, almost as far as Ochotska: the nations of the two first wear the bills about their necks, and are fastened to fraps, being di- dging to the superstition of those people, their ransom or priest must put them on with a proper ceremony, in order to procure good fortune.

4. The torda, or razor-bill, with four furrows on the bill and a white line on each side running from the bill to the eyes. These birds, in company with the guillemot, appear in the British seas the beginning of February; but do not settle on their breeding places till they begin to lay, about the beginning of May. They inhabit the ledges of the highest rocks that impend over the sea, where they form a grotesque appearance; sitting close together, and in rows one above another. They properly lay but one egg a-piece, of an extraordinary size for the bulk of the bird, being three inches long: it is either white, or of a pale sea-green, irregularly spotted with black: if this egg is destroyed, both the auk and the guillemot will lay another; if that is taken, then a third; they make no nest, depositing their egg on the bare rock; and though such multitudes lay contiguous, by a wonderful instinctq each distinguishes its own. What is also matter of great amazement, they fix their egg on the smooth rock, with so exact a balance, as to secure it from rolling off; yet should
should it be removed, and then attempted to be replaced by the human hand, it is extremely difficult, if not impossible, to find its former equilibrium. According to Mr Latham, it is by means of a cement that the bird fixes its egg. The eggs are food to the inhabitants of the coasts they frequent; which they get with great hazard; being lowered from the top by ropes, trusting to the strength of their companions, whose footing is often so unstable that they are forced down the precipice, and perish together. These birds are found in the north of Europe, also in Iceland, Greenland, and on the coast of Labrador. In Europe they extend along the White Sea into the Arctic Atlantic shores, and from thence to Kamtschatka and the gulph of Ofschotka: it is the only one that reaches the inland Baltic; being found there on the Carls-Ozariles, near Gothland, and the island of Bondenoff Angermania.

5. The pica, or black-billed auk, has the bill of the same form with the torda, but is entirely black. The cheeks, chin, and throat, are white: in all other respects it agrees with the former species. Mr Pennant observes, that it is sometimes found on our coasts; but, according to Mr Latham, it is in the winter season only, when the common form has quitted them. They are said to be met with on the coast of Candia and other parts of the Mediterranean; "where, no doubt (Mr Latham observes) the complete old bird is likewise found, as I have been informed that they are common in the bay of Gibraltar, where it is curious to see their activity under water when pursuing the fish; for, as the water in the bay is sometimes clear for a great depth from the surface, these birds may be often seen as it were flying after their prey, with all the agility of a bird in the air, returning in every direction after the fish, with such wonderful address and dexterity as to elude them of their aim."

6. The eighata of Dr Pallas, or tufted auks, somewhat bigger than the common puffin, and the colours much the same: the bill is an inch and three-quarters in length, the same in depth at the base, and crossed with three furrows: over each eye arises a tuft of feathers four inches in length, which falls elegantly on each side of the neck, reaching almost to the back; and are white as far as they are attached to the head, but afterwards of a fine buff yellow: the legs are of a bright red; the claws black. The female is principally distinguished by having the bill crossed only with two furrows instead of three. This species inhabits the shores of Kamtschatka, the Kurile islands, and those intervening between Kamtschatka and America. In manners it greatly resembles the puffin; living all day at sea, but at no great distance from the rocks; it comes on shore at night; burrows a yard deep under ground, and makes a nest, with feathers and sea-plants; is monogamous, and lodges there the whole night with its mate. It lays one white egg, the end of May or beginning of June, which alone is thought fit to be eaten, the flesh of the bird itself being insipid and hard. It feeds on crabs, shrimps, and shell-fish, which last it forces from the rocks with its strong bill. Pallas remarks, that the Kamtschatkan girls imitate the tufts of these birds, which nature has supplied them with, by placing a similar strip of the white part of the glutton behind each ear, hanging down behind by way of ornament; and is a well-received present from a lover to his mistress. The bills both of this and the common puffin were formerly held by the natives as a charm, and worn by the priests as amulets; indeed at the present these have been seen fixed round their head dreads, but supposed now to be only effected as mere ornaments: the skins are however made use of for clothing, being fewed together. It is called in Kamtschatka, Mischaquarika, and in Ofschotka, ilema.

7. The puffacula, or perroquet auk, of Dr Pallas; is about the size of the little auk. The bill is much compressed on the sides, in shape convex both above and below, and of a bright red colour: from the remote corner of each eye is a very slender tuft of fine white feathers, hanging down the neck: the head and upper part of the body are dusky; the lower whiten, varied with black edges: the legs are of a dirty yellow; and the webs dusky. This species is found at Kamtschatka, in the isles towards Japan, and on the western shores of America. They are sometimes seen in flocks, but seldom far from land, except driven by storms. They build their harbours in the crevices of rocks. They lay an egg almost the size of a hen's, of a dirty white or yellowish colour spotted with brown; which they do about the middle of June, upon the bare rock or sand, for they make no nest. Like most of the tribe, they are stupid birds, as may be evinced by the ridiculous method of catching them:—One of the natives places himself under a loose garment of fur, of a particular make, with large open sieves, among the rocks, at evening; when the birds, returning to their lodging places, sit alone, run under the skirts, and up the arm-holes, for shelter during the night; and thus become an easy prey. Their stupidity likewise occasions them to fly aboard a ship at such times, mistaking it for a roosting-place; whereby navigators have been taught to avoid the danger of falling in too near with land, either of evenings, or on approaching storms. The eggs are esteemed good.

ALCIÆUS, a famous ancient lyric poet, born at Mitylene, in the island of Lesbos. Horace seems to think him the inventor of this kind of poesy:

Now the Roman muse inspire,
And warm the song with Grecian fire. Francis.

He flourished in the 44th Olympiad, at the same time with Sappho, who was likewise of Mitylene. Alcaeus was a great enemy to tyrants, but not a very brave soldier. He was present at an engagement, wherein the Athenians gained a victory over the Lesbians; and here, as he himself is said to have confessed in one of his pieces, he threw down his arms, and saved himself by flight. Horace, who, of all the Latin poets, most resembled Alcaeus, has made the like confession:

With thee I saw Philippi's plain,
Its fatal rout, a fearful scene!
And dropp'd, alas! th' ignobles shield,
Where valour's self was forc'd to yield;
Where foil'd in dust the vanquish'd lay,
And breath'd th' indignant soul away. Francis.

The poetical abilities of Alcaeus are indisputé; and though
Alcaic. 

Alcaeus, though his writings were chiefly in the lyric strain, yet his muse was capable of treating the sublimest subjects with a suitable dignity. Hence Horace says,

Alcaeus strikes the golden firings,  
And fees, and war, and exile sings.  
Thus while they strike the various lyre,  
The ghosts the sacred sounds admire:  
But when Alcaeus lifts the strain  
To deeds of war and tyrants slain,  
In thicker crowds the shadowy throng  
Drink deeper down the martial song. Francis.

Alcaeus, an Athenian tragic poet, and, as some think, the first composer of tragedies. He renounced his native country Mitylene, and passed for an Athenian. He left ten pieces, one of which was Passiphæa, that which he produced when he disputed with Aristophanes, in the fourth year of the 97th Olympiad.

There is another Alcaeus mentioned in Plutarch, perhaps the same whom Porphyrius mentions as a composer of faricales and epigrams, and who wrote a poem concerning the plagiarisms of Euphorus perhaps the same whom Persius, a poet of satirical iambics and epigrams, and who lived in the reign of Vespasian and Titus. We know not which of these it was who suffered for his宽容; a very large head, which Juvenal alludes to:

This is Alcaeus's tomb; who died by a radish,  
The daughter of the earth, and punisher of Adulterers.  
This punishment inflicted on adulterers, was thrusting one of the largest radishes upon the anus of the adulterer; or, for want of radishes, they made use of a fish with a very huge head, which Juvenal alludes to:

Quodquam multae et magis in trast. Sat. x.  
The mullet enters some behind.

Hence we may understand the menace of Catullus.

Ah! tua tu misera, malique fiat,  
Quem attrahis pedibus, pennis porta,  
Percurrent raphanum magnoque.  
Epig. xv.  
Ah! wretched thou, and born to luckless fate,  
Who art discover'd by the unfruit gate!  
If once, alas! the jealous husband come,  
The radish or the sea-fish is thy doom.

Alcaics, in ancient poetry, a denomination given to several kinds of verse, from Alcaeus, their inventor.

The first kind consists of five feet, viz. a spondee, or iambic; an iambic; a long syllable; a dactyl; another dactyl: such is the following verse of Horace,

Omnem eodem cognitum omnium
Verfum ur habet ferius ocular.  
Sors exiuitra.

The second kind consists of two dactyls and two trochees: as,

Exilium imposuit cymbae.  
Besides these two, which are called dactylic Alcaics, there is another dactylic Alcaic; consisting of an iambus, a choriambus; another choriambus; and a bacchus; the following is of this species,

Cur timent flatum Thierim tanger, cur olim sp.  

Alcaic Odes, a kind of many ode composed of several strophes, each consisting of four verses; the two first of which are always Alcaics of the first kind; the third verse is a diameter hypermetrical, or consisting of four feet and a long syllable; and the fourth verse is an Alcaic of the second kind. The following strophe is of this species, which Horace calls minores Alcaic canons.

Non posse dem multa vocaveris  
Relle beantum: relictus occupat  
Nomen beati, qui deorum  
Maneriis sapienter uti, &c.

Alcaid, Alcayde, or Alcalde, in the polity of the Moors, Spaniards, and Portuguese, a magistrat, or officer of justice, answering nearly to the French provost, and the British justice-of-peace. The alcaid among the Moors is vested with supreme jurisdiction, both in civil and criminal cases.

Alcala de Guadeira, a small town of Spain, in Andalusia, upon the river Guadeira. Here are the observances, from whence they convey water to Seville by an aqueduct. W. Long. 6. 10. N. lat. 37. 15.

Alcala de Henares, a beautiful and large city of Spain, in New Castile, seated upon the river Henares, which washes its walls. It is built in a very agreeable plain, and is of an oval figure. The streets are handsome and pretty straight; one of them is very long, running from one end of the city to the other. The houses are well built, and there are several squares, the largest of which is an ornament to the city; it is surrounded on all sides with piazzas, where tradesmen have their shops to expose several sorts of commodities to sale, of which there is a great plenty and variety as in most towns of Spain. The university was founded by cardinal Ximenes, archbishop of Toledo, about the beginning of the 16th century. The land about Alcala is watered by the Henares, well cultivated, and very fruitful, while that at a distance is dry and sterile: it yields grain in plenty, very good mufcat wine, and melons of a delicious kind. Without the walls is a spring, the water of which is so pure and so well tafted, that it is collected and sent up for the king of Spain's own use, from whence it is carried to Madrid. This city is 10 miles south-west of Guadalaxara, and 13 miles east of Madrid. W. Long. 4. 20. N. Lat. 40. 30.

Alcala Real, a small city of Spain, in Andalusia, with a fine abbey. It is built on the top of a high mountain, in a mountainous country; and the road to it is incommodious, rough, and unequal; but to make amends for this, here are several kinds of exquisite fruit and wine. W. Long. 4. 15. N. Lat. 37. 18.

Alcaly, or Alcali, Sec Chemisty, Index.

Alcanis, a town of Arragon in Spain, seated on the river Guadaloupe, twelve miles from Cape. It was formerly the capital of the kingdom of the Moors; but being taken from them, it was made a commendary of the order of Calatrava. Here is a very remarkable fountain, which throws up water through 42 pipes. It is surrounded with gardens and fruit-trees, and defended with a good fortef. W. Long. 6. 5. N. Lat. 41. 0.

Alcanna, in commerce, a powder prepared from the
the leaves of the Egyptian privet, in which the people of Cairo drive a considerable trade. It is much used by the Turkish women to give a golden colour to their nails and hair. In dying, it gives a yellow colour when steeped with common water, and a red one when infused in vinegar. There is also an oil extracted from the berries of alcanna, and used in medicine as a calmer.

Alcántara, a small, but very strong city of Estremadura, in Spain. It gives name to one of the three orders of knighthood. It is fleated on the banks of the Tajo, or Tagus, 21 miles from Coria, in a very fruitful soil, and is celebrated for its bridge over that river. This was built in the time of the emperor Trajan, as appears by an inscription over one of the arches, by the people of Lusitania, who were affeated to supply the expence. It is raised 200 feet above the level of the water; and though it consists but of six arches, it is 670 feet in length, and 28 in breadth. At the entrance of the bridge, there is a small antique chapel hewn in a rock by the ancient Pagans, who dedicated it to Trajan, as the Christians did to St. Julian. This city was built by the Moors, on account of the convenience of this bridge; which is at a place where the Tajo is very deep, running between two high steep rocks; for this reason, they called it Alcántara, which, in their language, signifies the Bridge. It was taken from them in 1214, and given to the knights of Calatrava, who afterwards assumed the name of Alcántara. It was taken by the Earl of Galloway, in April, 1706, and retaken by the French in November following. It is 45 miles from Madrid, and 125 from Seville. W. Long. 7° 12'. N. Lat. 39° 30'.

Knights of Alcántara, a military order of Spain, which took its name from the abovementioned city. They make a very considerable figure in the history of the expeditions against the Moors. The knights of Alcántara make the same vows as those of Calatrava, and are only distinguished from them by this, that the croc fleur de lys, which they bear over a large white cloak, is of a green colour. They possess 37 commanderies. By the terms of the surrender of Alcántara to this order, it was stipulated, that there should be a community between the two orders, with the same practices and observances in both; and that the order of Alcántara should be subject to be visited by the grand-master of Calatrava. But the former soon released themselves from this engagement; on pretence that their grand-master had not been called to the education of that of Calatrava, as had been likewise stipulated in the articles. After the expulsion of the Moors, and the taking of Granada, the sovereignty of the order of Alcántara and that of Calatrava was settled in the crown of Castile by Ferdinand and Isabella.—In 1540, the knights of Alcántara sued for leave to marry, which was granted them.

Alcázar, a small city of La Mancha, in Spain, defended by a strong castle, and remarkable for an ancient aqueduct. It stands near the river Guadarrama, and the soil about it is very fruitful. They have a breed of little running-horses, which are very fleet and strong. It is 25 miles north of the confines of Andalucía, 108 south of Cuenca, and 130 south-east of Madrid. W. Long. 1° 50'. N. Lat. 38° 28'.

Alcázar do Sal, a town of Portugal, in Estremadura, which has a castle said to be impregnable. It is indeed very strong, both by art and nature, being built on the top of a rock which is exceedingly steep on all sides. Here is a saltpit which produces very fine white salt, from whence the town takes its name. The fields produce large quantities of a sort of rushes, of which they make mats, which are transported out of the kingdom. W. Long. 9° 16'. N. Lat. 38° 18'.

Alcâsaar, a city of Barbary, seated about two leagues from Larache, in Algeciras, a province of the kingdom of Fez. It was of great note, and the seat of the governor of this part of the kingdom. It was built by Jacob Almanzor, king of Fez, about the year 1180, and designed for a magazine and place of rendezvous for the great preparations he was making to enter Granada in Spain, and to make good the footing Joseph Almanzor had got some time before. It is laid his father first invaded Spain with 300,000 men, most of whom he was obliged to bring back to Africa to quiet a rebellion that had broke out in Morocco. This done, he returned to Spain again with an army, as is said, of 200,000 horse and 300,000 foot. The city is now fallen greatly to decay, so that of fifteen miles from the confines of Spain, and to the south of Cuenca, and

It was of great note, and the seat of the governor of this part of the kingdom. It was built by Jacob Almanzor, king of Fez, about the year 1180, and designed for a magazine and place of rendezvous for the great preparations he was making to enter Granada in Spain, and to make good the footing Joseph Almanzor had got some time before. It is laid his father first invaded Spain with 300,000 men, most of whom he was obliged to bring back to Africa to quiet a rebellion that had broke out in Morocco. This done, he returned to Spain again with an army, as is said, of 200,000 horse and 300,000 foot. The city is now fallen greatly to decay, so that of fifteen miles from the confines of Spain, and to the south of Cuenca, and

ted to it likewise the declension of agriculture, it being imposed not only upon manufactures, but upon the rude produce of the land.

ALCAZAR LEGUE, a town of Africa, in the kingdom of Fez, and in the province of Idrarab. It was taken by Alphonsus, king of Portugal, in 1486; but soon after that, it was abandoned to the Moors. It is seated on the coast of the straits of Gibraltar.

W. Long. 5° 30'. N. Lat. 38° 0'.

ALCAZAR, a town of Spain, in New Castile, seated on the river Guadarrama, which has a fortress on a high hill for its defence, and lies in a very fruitful country. It is 700 miles north-west of Carthagena.

W. Long. 2° 10'. N. Lat. 38° 15'.

ALCE, ALCES, or EK, in zoology, the trivial name of a species of the cervus, belonging to the order of mammalia pecora. See CERVA.

ALCEA, the HOLLY-HOCK: A genus of the polyandrria order, belonging to the monadelphia class of plants; and in the natural method ranking under the 37th order, Columniferae. The characters are: The calyx is a double perianthium, monophyllous and perifephalous; the exterior one is five-cleft, the interior half five-cleft: the corolla consists of five petals, coaleced below into a five-cornered cylinder, loose above, and inferior into the corolla; the antherae are kidney-shaped: The pistillum has a roundish gnomen; a short cylindrical stylus: and numerous filiform stigma: The flower is of the same kind as a common flax flower, joined into a verticillum about a columnar depressed receptacle: The seeds are solitary, reniform, and deprived.

Species. Although Linneus mentions two distinct species of this genus, viz. the rubra and flofifolia, he thinks, that the latter may perhaps be only a variety of the former; but Mr Miller affirms them to be distinct species, whose difference in the form of their leaves always continues. The leaves of the first sort are round, and cut at their extremities into angles; those of the second are deeply cut into five or seven segments, so as to resemble a hand. Cultivation produces almost an infinite variety of this plant, such as double-flowered, single-flowered, deep red, pale red, blackish red, white, purple, yellow, and flesh-colour. The first species is a native of China, the second grows also in India. The natives of warm countries, they are hardly enough to thrive in the open air in Britain, and have for many years been some of the greatest ornaments in gardens, towards the end of summer; but they have the inconvenience of growing too large for small gardens, and requiring tall stakes to secure them from being broken by strong winds. In large gardens, however, when properly disposed, they make a fine appearance; for as their spikes of flowers grow very tall, there will be a succession of them on the same stems more than two months: the flowers on the lower part of the spike appear in July; and as their stalks advance, new flowers are produced till near the end of September. When planted in good ground, the stalks will often rise to the height of eight or nine feet; so that near six feet of each will be garnished with flowers, which, when double and of good colours, make a very beautiful appearance.

Culture. The holly-hock is propagated by seeds, which should be carefully sown from those plants whose flowers are double and of the best colours: for though the duplicity of the flowers, as well as their colour, are only accidental properties, yet the young plants will produce nearly the same kind of flowers with those from which the seeds are taken, provided no plants with single or bad-coloured flowers are permitted to grow near them; and as soon as such appear they ought to be removed from the good ones, that their fatina may not spread into the others, which would cause them to degenerate. The seeds ought to be gathered very dry, and remain in their capsules till springs; but care must be taken that no wet comes to them in winter, otherwise the covers would turn mouldy, and spoil their contents.—They should be sown in little hills, about the middle of April, on a bed of light earth, and covered with earth of the same kind about half an inch deep. When the plants have put out six or eight leaves, they should be transplanted into nursery-beds, observing to water them until they have taken good root; after which they will require no further care, but to keep them clean from weeds till October, when they should be transplanted where they are to remain.

ALCEDO, or KINGFISHER, in ornithology, a genus of the order of picas. The alcedo has a long, flat, thick, triangular bill; with a fleshy, plain, short, flat tongue.

Of this genus there are a great many species, with one or other of which almost every part of the world is furnished. Most of them frequent rivers, and live on fish, the singularity of catching which is admirable; sometimes hovering over the water, where a shoal of small fishes is seen playing near the surface; at other times waiting with attention, on some low branch hanging over the water, for the approach of a single one who is so unlucky as to swim that way; in either case dropping like a stone, or rather darting with rapidity on his prey; when seizing it crostwise in his bill, it retires to a retired place to feast on it; which it does piecemeal, bones and all, without reserve, afterwards bringing up the indigestible parts in pellets, like birds of prey. The wings of most of the genus are very short; yet the birds fly rapidly, and with great strength. It may be remarked, that throughout this genus, blue, in different shades, is the most predominant colour. The species found in the South Sea Islands are held in a kind of superstitious veneration by the natives of the places they severally inhabit, perhaps on account of their being frequently seen flying about the morais or burial-places. That which inhabits Otaheite, where it is called Enoro, is accounted particularly sacred, and not allowed to be taken or killed.

r. The ifipida, or common kings-fisher, is not much larger than a swallow; its shape is clumsy; the bill disproportionally long; it is two inches from the base to the tip; the upper cham black, and the lower yellow. But the colours of this bird alone for its inelegant form: the crown of the head and the coverts of the wings are of a deep blackish green, spotted with bright azure; the back and tail are of the most refulcent azure; the whole under-side of the body is orange-coloured; a broad mark of the same pales from the bill beyond the eyes; beyond that is a large white spot; the tail is short, and consists of twelve feathers of a rich deep-blue.
It was therefore necessary to place it in a tranquil sea, and to supply the bird with charms to allay the fury of a turbulent element during the time of its incubation; for it had, at that season, power over the seas and the winds.

May Halcyons smooth the waves, and calm the seas, and the rough south-east sink into a breeze; Halcyons, of all the birds that haunt the main, most lov'd and honour'd by the Nereid train.

These birds were equally favourites with Thetis as with the Nereids.

Dilectae Thetidæ Halcyones. VIRG. GEORG. I. 399.

as if to their influence these deities owed a repose in the midst of the storms of winter, and by their means were secured from those winds that disturb their submarine retreats, and agitated even the plants at the bottom of the ocean.

Such are the accounts given by the Roman and Sicilian poets. Ariosto and Pliny tell us, that this bird is most common in the seas of Sicily: that it sat only a few days, and those in the depth of winter; and during that period the mariner might fall in full security; for which reason they were styled Halcyon days.

Perque dies placidos hiberno tempore septem
Incubat Halcyone pendentibus aquore nidos:
Tum via tua maris: ventos uss fidet, et arce
Æolus egregius.

OVID. MET. lib. xi.

Alcyone, compress'd,
Seven days sits brooding on her watery nest,
A wintry queen; her fire at length is kind,
Calm's every form, and hushes every wind.

DRYDEN.

In after-times, these words expressed any season of prosperity: these were the Halcyon days of the poets; the brief tranquillity, the septem placent dies, of human life.

The poets also made it a bird of song. Virgil seems to place it in the same rank with the linnet;

Littoraque Halcyonem refonant, et Acantida dum.

GEORG. III. 338.

And Silius Italicus celebrates its music, and its floating nest:

Cum fonat Halcyone cantra, nidosque natantes
Immota gelat fissitis fluctibus unda.

Lib. xiv. 275.

But these writers seem to have transferred to our species, the harmony that belongs to the vocal alcódenote, one of the loft birds of the ancients.

As the ancients have had their fables concerning this bird, to have the modern vulgar. It is an opinion generally received among them, that the fleece of the kings-fisher will not corrupt, and that it will even banish all vermin. This has no better foundation than that which is said of its always pointing, when hung up dead, with its breast to the north. The only truth which can be affirmed of this bird when dead is, that

* Plin. lib. xxi. c. 8. of this seems to be founded on truth. The form of the nest is justly decried; and the materials which Ariosto says it was compofed of, are not entirely of his own invention. Whoever has seen the nest of the kings-fisher, will observe it fixed with the bones and scales of fish; the fragments of the food of the owner, and its young.—On the foundation laid by the philosopher, succeeding writers formed other tales extremely absurd; and the poets, indulging the powers of imagination, defribed the story in all the robes of romance. This nest was a floating one:

Incubat halcyonem pendentibus aequore nidos.

OVID. MET. lib. xi.
Alcedo. its flesh is utterly unfit to be eaten; while its beautiful plumage preferable to that of any other bird we know.

This bird is found not only in Britain, but throughout Europe, Asia, and Africa; as specimens have been received from both China, Bengal, and Egypt. Besong also remarks its having met with it in Romania and Greece; and Scopoli notices it as a bird of Carolina, where he says it remains the whole year as in different climates, being alfoil of its not alllIl by the block, and feeds on frogs, and thighs are whitish, marked with longitudinal broad stripes: and the claws are black. This species is found both in Guiana and Brazil, in the moist woods which it prefers to the more dry spots, for the sake of insects, on which it feeds. It is seldom seen exceptingle, as it is a very solitary bird, keeping for the most part in the thicker parts; its flight quick, but short; perches on branches of a middling height, where it sits all night, and frequently parts of the day, without flitting. Though these birds are solitary, yet they are far from scarce, as many may be met with. They are said to have a short and agreeable note. The natives of Guiana call this bird Venenore and the Creoles, Colibres grands bois. At Brazil their flesh is eaten by fome.

2. The rudis, or Egyptian kings-fisher, as described by Blauffe (*Egretta caudata*), is the size of the Roydon crow. The bill is blackish, more than half an inch broad at the base, and two inches in length: the head, shoulders, and back, are brown, marked with oblong ferruginous spots: the throat is of a ferruginous white: the belly and thighs are whitish, marked with longitudinal broad ferruginous spots: upper tail coverts are quite white: the quills spoted with white on the inner webs, chiefly at the tips: the tail is ash-coloured: the legs are of a palette green; and the claws blackish. It inhabits lower Egypt, about Cairo; builds in fycamore and date trees; and feeds on frogs, insects, and small fishes, which it meets with in the fields when they are overflood. Its cry is not unlike that of the common crow.

3. Le taparara of Buffon is about the size of a starling. The upper mandible of the bill is black; the lower red: the hind part of the neck, the back, and scapulars, are of an elegant blue; the rump and upper tail coverts bright beryl-blue: the under parts of the body are white: the wing coverts blue; and the legs red. It inhabits Cayenne and Guiana, at which last place the natives call all the kings-fishers tribe by the name Taparara. In this part of South America, which contains many rivers full of fish, kings-fishers, as might be expected, abound in vast numbers: but what is remarkable, they never herd together, always being found alone, except in breeding-time, which is about the month of September. They lay their eggs in the holes of banks, like the kings-fisher of Europe. The cry of this bird imitates the word Caraca.

4. The torquata, or cinereous kings-fisher, is about the size of a magpie, and fifteen inches and a half in length. The bill is three inches and a half long, and brown: the base of the lower mandible reddish: the head is crested: the upper parts of the head and body are blueish ash: the upper parts chefu: the throat is whitish, defending down the neck, and palling behind like a collar, ending towards the back in a pale green: the under tail coverts are of a plain fulvous, transfusely ftriated with black: the greater wing coverts varied with blueish, ash, black, and yellowish: the legs are red; and the claws blackish. It inhabits Martinique and Mexico; at which last it is called *darkula*_spinex*. This bird migrates into the northern parts of Mexico at certain seasons only, and is supposed to come there from some hotter parts.

5. The galbula, or green jacamar, is about the size of a lark. The bill is black, of a square form, a little incurvated and sharp at the point: the plumage in general, in the upper part of the body, is of a most brilliant green, glossed with copper and gold in different lights: the belly, throat, and vent, are rufous: the tail is composed of ten feathers, and shaped like a wedge: the legs are of a greenish yellow, very short and weak: the claws are black. This species is found both in Guiana and Brazil, in the moist woods which it prefers to the more dry spots, for the sake of insects, on which it feeds. It is seldom seen exceptingle, as it is a very solitary bird, keeping for the most part in the thickest parts; its flight quick, but short; perches on branches of a middling height, where it sits all night, and frequently parts of the day, without flitting. Though these birds are solitary, yet they are far from scarce, as many may be met with. They are said to have a short and agreeable note. The natives of Guiana call this bird Venenore and the Creoles, Colibres grands bois. At Brazil their flesh is eaten by fome.

6. The paradisaea, or paradise jacamar, is of the same size with the former, and has a similar bill: the throat, fore part of the neck, and under wing coverts are white: the rest of the plumage is of a deep dull green, in some lights appearing almost black, in other with a flight glos of violet and copper bronze: the tail is composed of twelve feathers of unequal lengths: the two middle ones longest: the legs are black; the toes are placed two before and two behind, and prettily united. It inhabits Surinam; and like the others, it feeds on insects; and sometimes, contrary to them, frequents open places. It flies farther at a time, and perches on the tops of trees: It is frequently found with a companion, not being quite so solitary a bird as the other. It also differs in the note, having a kind of soft whistle often repeated, but not heard a great way off.

Above 30 other species have been described by ornithologists.

ALCHEMILLA, or LADIES-MANTLE: A genus of the monogynia order, belonging to the tetradria class of plants; and in the natural method ranking under the 35th order *Seniciose*. The calyx is a single-leafed petiole, tubular, and persistent; the mouth, flat, and eight-parted: There is no corolla. The flower consists of four small erect tubular filaments placed in the mouth of the calyx; the anthers are rounded: The pistil has an egg-shaped germen: The flower is filiform, the length of the stamens, and inserted at the base of the germen. The stigma is globular. There is no perianth; but the neck of the calyx closed. The seed solitary, elliptical, and compressed. Of this genus there are three species.
ALCHYMIST. ALCHEMIST, a practitioner in alchemy.

ALCHEMISTRY, that branch of chemistry which had for its principal objects the transmutation of metals into gold; the panacea, or universal remedy; an alka-hef, or universal menstrum; an universal ferment; and many other things equally ridiculous.

Kircher, instructed in all the secrets of chemistry, has fully exposed the artifices and impostures of alchemists. An alchemist puts into a crucible the matter which is to be converted into gold; this he sets on the fire, blows it, sifts it with rods; and, after divers operations, gold is found at the bottom of the crucible, instead of the matter first put in: this there are a thousand ways of effecting, without any transmutation. Sometimes it is done by dexterously dropping in a piece of gold concealed between the fingers, sometimes by calling in a little of the dust of gold or silver disguised under the appearance of some elixir, or other indifferent matter; sometimes a crucible is used which has a double bottom, and gold put between the two; sometimes the rod used to sift the matter is hollow, and filled with the dust of the metal desired; at other times there is metal mixed with the charcoal, the ashes of the furnace, or the like. Mr Harris very properly distinguishes between alchemy and chemistry; and defines the former to be ars fere arte, exquisitio principiis effentiarum, medium laborare, et finis mendicare; and the latter has a proverb, non sibi fidare alchemista pro verbo o mediceo amalato. The ruin which has attended this delusion has occasioned several flats to make severe laws against pretences to alchemy. The Romans formerly banished all such as professed it; and the sacred censers like wife directed the thunder of their censure against them. Dioclian and Caesar directed all books which treated of this subject to be burnt. By modern furnishers with a licence for practicing alchemy, with all kinds of metals and minerals, granted to one Richard Carter in the year 1476 Rumm. Fec. tom. xii. Nevertheless, we have had severer laws against alchemy and multiplying of metals, as much for as against coin ing of dikes.

ALCIAT (Andrew), a great lawyer, who flourished in the 16th century, born at Milan. He mixed much of police learning in the explication of the laws, and happily drove out the barbarity of language which till then had reigned in the lectures and writings of lawyers; for which Thuanus highly praises him. He published a great many law-books, and some notes upon Tacitus. His Emblems have been much admired, and translated into French, Italian, and Spanish; and several learned men have written commentaries on them.

ALCIBIADES, an Athenian general. It was the fate of this great man to live at a time when his country was a scene of confusion. The Greeks, grown infatuated from their conquests in Persia, turned their arms against each other, and banded together under the conduct of the two most oppugnant states Athens and Lacedaemon. Alcibiades, in the midst of an expedition he had planned against the enemy of his country, was recalled home to answer some charge of a private nature; but fearing the violence of his enemy, instead of going to Athens, he offered his services at Sparta, where they were readily accepted. By his advice the Lacedaemonians made a league with Persia, which gave a very favourable turn to their affairs. But his credit in the republic raising jealousies against him, he privately reconciled himself to his country, and took again the command of an Athenian army. Here victory waiting as it were at his command, attended all his motions. The loss of seven battles obliged the Spartans to sue for peace. He enjoyed his triumphs, however, only a short time at Athens. One unsuccessful event made him again obnoxious to the malice of his citizens; and he found it expedient to retire from Athens. In his absence the Spartans again took the lead, and at the fatal battle of Areus entirely subdued the Athenian power. Alcibiades, though an exile, endeavored to restore the power of his country; of which the Spartans having intelligence, procured him to be assassinated. He was a man of admirable accomplishments, but indifferently principled: of great parts; and of an amazing veracity of genius.

ALCINOUS, king of the Phoenicians, in the island now called Corfu, was son of Nausithous, and grandson of Neptune and Peribea. It is by his gardens this king has chiefly immortalized his memory. He received Ulysses with much civility, when a storm had cast him on his coast. The people here loved pleasure and good cheer; yet were fruitful seamen; and Alcimus was a good Prince.

ALCMAER, a city of the United Provinces, seated in North Holland, about four miles from the sea, 15 from Haerlem, and 18 from Amsterdam. It is a handsome city, and one of the cleanest in Holland. The streets and houses are extremely neat and regular, and the public buildings very beautiful. It had formerly two parli-churches, dedicated to St Matthew and St Lawrence. The latter had to high a tower, that it served for a sea-mark to the ships that were in the open sea; but, in 1644, it tumbled down and damaged the other church so much, that they were both
broad demolished in 1470, and one church was built in
their stead, dedicated to the same saints. The Spaniards,
under the command of Frederick of Toledo, son of the
duke d'Alva, came to besiege it, after they had taken
Haarlem in 1573; but were forced to raise the siege,
after three months lying before it, as well on account
of the infection of the air as the stout resistance of the
inhabitants and soldiers; even the women signalized
themselves bravely in its defence. It is recorded in
the register of this city, that, in the year 1637, 120
tulips, with the off-sets, sold for 90,000 florins. The
town has a very good trade in butter and cheese, of
which a vast quantity is sold every year, and is effec-
tually held in Holland, E. Long. 4. 26. N. Lat.
52. 28.

ALCMAN, a lyric poet, who flourished in the 27th
Olympiad. He was born at Sparta; and composed
several poems, of which only some fragments are re-
maining, quoted by Athenaeus and some other ancient
writers. He was a very amorous: accounted the father
of gallant poetry; and is said to have been the first that
introduced the custom of singing love--songs in com-
pany. He is reported to have been one of the great-
citizens of his age; upon which Mr. Boyle remarks
that such a quality would have been extremely in-
convenient, if poetry had been at that time upon such
a footing as it has been once, not being desirable to
procure the poet bread. He died of a sanguine disease;
for he was eat up with lice.

ALCMANIAN, in ancient lyric poetry, a kind of
verse consisting of two dactyles and two trochees; as,-

Virginius putrifiquecuntu.

The word is formed from ALCMAN, the name of an an-
cient Greek poet, in great esteem for his erotic or
amorous composition.

ALCMIENA, the daughter of Eleersyo king of My-
ceniae, and wife of Amphiryon. Jupiter putting on the
shape of her husband while he was abroad in the wars,
begot Hercules upon her: he made that night as long
as three ordinary ones.

ALCock (John), doctor of laws and bishop of
Ely in the reign of king Henry VII. was born at Be-
verly in Yorkshire, and educated at Cambridge. He was
first made dean of Westminister, and afterwards ap-
pointed master of the rolls. In 1471, he was con-
secrated bishop of Rochester. 1476, he was trans-
ferred to the see of Worcester; and in 1486, to that of Ely,
in the room of Dr John Morton, preferred to the see
of Canterbury. He was a prelate of great learning and
piety; and so highly esteemed by king Henry,
that he appointed him lord president of Wales, and
afterwards lord chancellor of England. Alcock foun-
ded a school at King'ston upon Hull, and built the spa-
cious hall belonging to the episcopal palace at Ely.
He was also the founder of Jesus-college in Cambridge
for a master, six fellows, and as many scholars. This
house was formerly a nunnery, dedicated to St Rad-
gund; and, as Godwin tells us, the building being
decayed, and the revenues reduced almost to nothing,
the nuns had all forsworn it except two, whereupon bishop Alcock procured a grant from the
queen, and converted it into a college. But Camden
and others tell us, that the nuns of that house were
so notorious for their incontinence, that king Henry VII.
and pope Julius II. consented to its dissolution:

Bale accordingly calls this nunnery spiritualis here-
trium cum ordinis communitas, an community of spiritual harlots.

Bishop Alcock wrote several pieces; amongst which are
the following:

1. Nonn Perfectionis. 2. In Salmos nententialis. 3. Homilae Vulgares. 4. Meditations
Par. He died October 1, 1500; and was buried in
the chapel he had built at Kingston upon Hull.

ALCOHOL, or ALCOOL, in chemistry, spirit of
wine highly rectified. It is also used for any highly
rectified spirit. It is a strong antiseptic, and therefore em-
ployed to preserve animal substances.

ALCOHOL is also used for any fine impalpable
powder.

ALCOHOLIZATION, the process of rectifying
any spirit. It is also used for pulverization.

ALCOR, in astronomy, a small star adjoining to
the large bright one in the middle of the tail of arfa
major. - The word is Arabic. It is a proverb among
the Arabians, applied to one who pretends to see small
things, but overlooks much greater: Thou canst see Al-
cor and not yet see the full moon.

ALCORN, or AL-koran, the scripture, or bible,
of the Mahometans. The word is compounded of the
Arabic particle al, and koran or kara, from the verb
car or karas, to read. The word therefore properly signifies, the reading; or rather, that
which ought to be read. By this name the Mahometans
declare not only the entire book or volume of the Koran,
but also any particular chapter or section of it: just as
the Jews call either the whole scripture, or any part of
it, by the name of Karah, or Mikra, words of the
name origin and import.

Besides this peculiar name, the Koran is also honoured
with several appellations common to other books of
scripture: as, al Farkan, from the verb farka, to
divide or distinguish; not, as the Mahometan doctors
say, because those books are divided into chapters or
sections, or distinguished between good and evil; but in
the same notion that the Jews use the word Perek, or
Pirka, from the same root, to denote a section or portion
of scripture. It is also called al Mosbaf, the vo-
ume, and al-Kitab, the book, by way of eminence,
which answers to the Bible of the Greeks; and al
Dhikr, the adoration, which name is also given to the
Pentateuch and Gospel.

The Koran is divided into 114 larger portions of very
unequal length, which we call chapters; but the Ara-
bians name, in the singular fura; a word rarely used
on any other occasion, and properly signifying a row,
order, or a regular series; as a course of bricks in
building, or a rank of soldiers in an army; and is the
name in use and import with the Sura, or Tora, of the
Jews, who also call the fifty-three sections of the Pen-
tateuch Sedarim, a word of the same signification.

These chapters are not, in the manuscript copies, dis-
finguished by their numerical order, but by particular
titles, which are taken sometimes from a particular
matter treated of, or person mentioned therein; but
usually from the first word of note, exactly in the same
manner as the Jews have named their Sedarim; though
the word from which some chapters are denominated
be very far distant, towards the middle, or perhaps
the end, of the chapter: which seems ridiculous. But the
occasion of this appears to have been, that the verb of
passage
Alcoran. 
passage wherein such word occurs, was, in point of time, revealed and committed to writing before the other verses of the same chapter which preceded it in order; and the title being given to the chapter before it was completed, or the passages reduced to their present order, the verse from whence such title was taken did not always happen to begin the chapter. Some chapters have two or more titles, occasioned by the difference of the copies. 

Some of the chapters having been revealed at Mecca, and others at Medina, the noting this difference makes a part of the title: but the reader will observe, that several of the chapters are said to have been revealed partly at Mecca and partly at Medina; and, as to others, it is yet a dispute among the commentators to which of the two places they belong.

Every chapter is subdivided into smaller portions, of very unequal length also, which we customarily call verses; but the Arabic word is ajza, the same with the Hebrew ajza, and signifies figura or wonder: such as are the secrets of God, his attributes, works, judgments, and ordinances, delivered in those verses; many of which have their particular titles also, imposed in the same manner as those of the chapters. 

Besides these unequal divisions of chapter and verse, the Mahometans have also divided their Koran into sixty equal portions, which they call Abzah, in the singular Hash, each subdivided into four equal parts; which is also an imitation of the Jews, who have an ancient division of their Mithras into sixty portions called Mafheulah. But the Koran is more usually divided into thirty sections only, named Azasa, from the singular azas, each of twice the length of the former, and in the like manner subdivided into four parts. These divisions are for the use of the readers of the Koran in the royal temples, or in the adjoining chapels where the secrets of God, his attributes, works, judgments, and ordinances, delivered in those verses; many of which have their particular titles also, imposed in the same manner as those of the chapters.

Next after the title, at the head of every chapter, except only the ninth, is prefixed the following solemn form, by the Mahometans called the Bismillah, In the name of the most merciful God: which form they constantly place at the beginning of all their books and writings in general, as a peculiar mark or distinguishing characteristic of their religion, it being counted a sort of impolicy to omit it. The Jews, for the same purpose, make use of the form, In the name of the Lord, or, In the name of the great God; and the eastern Christians that of, In the name of the Father, and of the Son, and of the Holy Ghost. But Mahomet probably took this form, as he did many other things, from the Persian Magi, who used to begin their books in these words, Beinam Teydan kalbshahfigher dader; that is, In the name of the most merciful just God.

There are twenty-nine chapters of the Koran, which have this peculiarity, that they begin with certain letters of the alphabet, none with a single one, others with more. These letters the Mahometans believe to be the peculiar marks of the Koran, and to conceal several profound mysteries; the certain understanding of which, the more intelligent confefs, has not been communicated to any mortal, their prophet only excepted. Notwithstanding which, some will take the liberty of gueffing at their meaning by that species of Cabala called by the Jews Notarikon, and suppose the letters to stand for as many words, expressing the names and attributes of God, his works, his judgments, and decrees; and therefore these mystical letters, as well as the verses themselves, seem in the Koran to be called signify. Others explain the intent of these letters from their nature or origin, or else from their value in numbers, according to another species of the Jewish Cabala called Gematria: the uncertainty of which conjectures sufficiently appears from their disagreement. Thus, for example, five chapters, one of which is the second, begin with these letters A. L. M. which some imagine to stand for Allah latiff magid, "God is gracious and to be glorified," or, Allah minah, i.e. to me and from me, viz. belongs all perfection, and proceeds all good; or else for Ana Allah alam, "I am the most wise God," taking the first letter to mark the beginning of the first word, the second the middle of the second word, and the third the last of the third word; or for Allah, Gabriel, Mohammed, the author, revealer, and preacher of the Koran. Others say, that as the letter A belongs to the lower part of the throat, the first of the organs of speech; L to the palate, the middle organ; and M to the lips, which are the last organ; so these letters signify that God is the beginning, middle, and end, or ought to be praised in the beginning, middle, and end, of all our words and actions; or, as the total value of these three letters, in numbers, is seventy-one, they signify, that, in the space of so many years, the religion preached in the Koran should be fully established. The conjecture of a learned Christian is at least as certain as any of the former, who supposes these letters were set there by the amanenis, for Amar bi Mohammed, i.e. at the command of Mohammed, as the five letters prefixed to the nineteenth chapter seem to be there written by a Jewish scribe, for Coh yaz, i.e. Thus be commanded.

The Koran is universally allowed to be written with the utmost elegance and purity of language, in the dialect of the tribe of Koreish, the most noble and polite of all the Arabsians, but with some mixture, tho' very rarely, of other dialects. It is confessedly the standard of the Arabic tongue, and, as the more orthodox believe, and are taught by the book itself, inimitable by any human pen (though some fectaries have been of another opinion), and therefore infifted on as a permanent miracle, greater than that of raising the dead, and alone sufficient to convince the world of its divine original.

And to this miracle did Mahomet himself chiefly appeal for the confirmation of his mission, publicly challenging the most eloquent men in Arabia, which was at that time flocked with thousands whose sole study and ambition it was to excel in elegance of style and composition, to produce even a single chapter that might be compared with it (a).
To the pomp and harmony of expression本期 note all the force and effect of the Alcoran; which they consider as a sort of music, equally fitted with other species of that art to ravish and amaze. In this Mahomet succeeded so well, and so strangely captivated the minds of his audience, that several of his opponents thought it the effect of witchcraft and enchantment, as he himself complains. Others have attributed the effect of the Alcoran to the frequent mention of rewards and punishments; heaven and hell occurring almost in every page. Some suppose, that the few fulfial pleasures of paradise, so frequently set before the imaginations of the readers of the Alcoran, were what chiefly bewitched them. Tho' with regard to these, there is a great dispute whether they are to be understood literally or spiritually. Several have even allegorized the whole book.

The general design of the corporation was to unite the professors of the three different religions, then followed in the populous country of Arabia (who for the most part lived promiscuously, and wandered without guides, the far greater number being idolators, and the rest Jews and Chrisrians mostly of erroneous and heterodox belief), in the knowledge and worship of one God, under the sanction of certain laws, and the outward signs of ceremonies partly of ancient and partly of novel institution, enforced by the consideration of rewards and punishments both temporal and eternal; and to bring them all to the obedience of Mahomet, as the prophet and ambassador of God, who, after the repeated admonitions, promises, and threats, of former ages, was at last to establish and propagate God's religion on earth, and to be acknowledged chief pontiff in spiritual matters, as well as supreme prince in temporal.

The great doctrine then of the Alcoran, is the unity of God; to restore which point Mahomet pretended was the chief end of his mission; it being laid down by him as a fundamental truth, That there never was, nor ever can be, more than one true orthodox religion. For, though the particular laws or ceremonies are only temporary, and subject to alteration, according to the divine direction; yet the subsistence of it being eternal truth, is not liable to change, but continues immutably the same. And he taught, that, whenever this religion became neglected, or corrupted in essentials, God had the goodness to re-inform and re-admonish mankind thereof, by several prophets, of whom Moys and Jesus were the most distinguishing, till the appearance of Mahomet, who is their seal, and no other to be expected after him. The more effectually to engage people to hearken to him, great part of the Alcoran is employed in relating examples of dreadful punishments formerly inflicted by God on those who rejected and abused his messengers; several of which stories, or some circumstances of them, are taken from the Old and New Testaments, but many more from the apocryphal books and traditions of the Jews and Christians of those ages, set up in the Alcoran as truth in opposition to the scriptures, which the Jews and Chrisrians are charged with having altered: and indeed, few or none of the relations or circumstances in the Alcoran were invented by Mahomet, as is generally suppos'd, it being easy to trace the greatest part of them much higher, as the rest might be, were more of those books extant, and was it worth while to make the inquiry.

The rest of the Alcoran is taken up in prescribing necessary laws and directions, frequent admonitions to moral and divine virtues, the worship and reverence of the Supreme Being, and resignation to his will. One of their most learned commentators distinguishes the contents of the Alcoran into allegorical and literal; under the former are comprehended all the obscure, parabolical, and enigmatical passages, with such as are repealed, or abrogated: the latter, such as are clear, and in full force.

The most excellent moral in the whole Alcoran, interpreters say, is that in the chapter Al Airaf, viz. Shew mercy, do good to all, and dispute not with the ignorant; or, as Mr. Sale renders it, Use indulgence, command that which is just, and withdraw far from the ignorant. Mahomet, according to the authors of the Kûshaf, having begged of the angel Gabriel a more ample explication of this passage, received in the following terms: "Seek him who turns thee out, give to him who takes from thee, pardon him who injures thee; for God will have you plant in your souls the "roots of his chief perfections." It is easy to see that this commentary is copied from the gospel. In reality, the necessity of forgiving enemies, though frequently inculcated in the Alcoran, is of a later date among the Mahometans than among the Chrisrians; among those latter, than among the heathens; and to be traced originally among the Jews. (See Exodus xxxiii. 4, 5.) But it matters not so much who had it first, as who observes it best. The Caliph Hassam, son of Hali, being at table, a slave unfortunately let fall a dish of meat recking hot, which scalded him severely. The slave fell on his knees, rehearsing these words of the Alcoran, "Paraide is for those who refrain their anger." I am not angry with thee, answered the caliph. "And for those who forgive offences against them," continues the slave. I forgive thee thine, replies the caliph. "But above all, for those who return good for evil," adds the slave. I fet thee at liberty, rejoined the caliph; and I give thee ten dinars.

There are also a great number of occasional passages in the Alcoran, relating only to particular emergencies. For this advantage Mahomet had in the piecemeal method of receiving his revelation, that whenever he happened to be perplexed and grieved with anything, he had a certain resource in some new mod of revelation. It was an admirable contrivance of his, to engage people to hearken to him, great part of the Alcoran is employed in relating examples of dreadful punishments formerly inflicted by God on those who rejected and abused his messengers; several of which stories, or some circumstances of them, are taken from the Old and New Testaments, but many more from the apocryphal books and traditions of the Jews and Christians of those ages, set up in the Alcoran as truth in opposition to the scriptures, which the Jews and Christians are charged with having altered: and indeed, few or none of the relations or circumstances in the Alcoran were invented by Mahomet, as is generally suppos'd, it being easy to trace the greatest part of them much higher, as the rest might be, were more of those books extant, and was it worth while to make the inquiry.

The rest of the Alcoran is taken up in prescribing necessary laws and directions, frequent admonitions to moral and divine virtues, the worship and reverence of the Supreme Being, and resignation to his will. One of their most learned commentators distinguishes the contents of the Alcoran into allegorical and literal; under the former are comprehended all the obscure, parabolical, and enigmatical passages, with such as are repealed, or abrogated; the latter, such as are clear, and in full force.

The most excellent moral in the whole Alcoran, interpreters say, is that in the chapter Al Airaf, viz. Shew mercy, do good to all, and dispute not with the ignorant; or, as Mr. Sale renders it, Use indulgence, command that which is just, and withdraw far from the ignorant. Mahomet, according to the authors of the Kûshaf, having begged of the angel Gabriel a more ample explication of this passage, received in the following terms: "Seek him who turns thee out, give to him who takes from thee, pardon him who injures thee; for God will have you plant in your souls the "roots of his chief perfections." It is easy to see that this commentary is copied from the gospel. In reality, the necessity of forgiving enemies, though frequently inculcated in the Alcoran, is of a later date among the Mahometans than among the Chrisrians; among those latter, than among the heathens; and to be traced originally among the Jews. (See Exodus xxxiii. 4, 5.) But it matters not so much who had it first, as who observes it best. The Caliph Hassam, son of Hali, being at table, a slave unfortunately let fall a dish of meat recking hot, which scalded him severely. The slave fell on his knees, rehearsing these words of the Alcoran, "Paraide is for those who refrain their anger." I am not angry with thee, answered the caliph. "And for those who forgive offences against them," continues the slave. I forgive thee thine, replies the caliph. "But above all, for those who return good for evil," adds the slave. I set thee at liberty, rejoined the caliph; and I give thee ten dinars.

There are also a great number of occasional passages in the Alcoran, relating only to particular emergencies. For this advantage Mahomet had in the piecemeal method of receiving his revelation, that whenever he happened to be perplexed and grieved with anything, he had a certain resource in some new mod of revelation. It was an admirable contrivance of his, to engage people to hearken to him, great part of the Alcoran is employed in relating examples of dreadful punishments formerly inflicted by God on those who rejected and abusd his messengers; several of which stories, or some circumstances of them, are taken from the Old and New Testaments, but many more from the apocryphal books and traditions of the Jews and Christians of those ages, set up in the Alcoran as truth in opposition to the scriptures, which the Jews and Chrisrians are charged with having altered: and indeed, few or none of the relations or circumstances in the Alcoran were invented by Mahomet, as is generally suppos'd, it being easy to trace the greatest part of them much higher, as the rest might be, were more of those books extant, and was it worth while to make the inquiry.
of power, from whence Gabriel revealed it to Mahomet by parcels, some at Mecca, and some at Medina, at different times, during the space of 23 years, as the exigency of affairs required; giving him, however, the comission to show him the whole (which they tell us was bound in silk, and adorned with gold and precious stones of paradise) once a-year; but in the last year of his life he had the favour to see it twice. They say, that few chapters were delivered entire, the most part being revealed piecemeal, and written down from time to time by the prophet's amanuensis in such a part of each and such a chapter, till they were completed, according to the directions of the angel. The first parcel that was revealed is generally agreed to have been the first five verses of the 96th chapter.

After the new-revealed passages had been from the prophet's mouth taken down in writing by his scribe, they were published to his followers; several of whom took copies for their private use, but the far greater number got them by heart. The originals, when returned, were put promiscuously into a chest, observing no order of time; for which reason it is uncertain when many passages were revealed.

When Mahomet died, he left his revelations in the same disorder, and not digested into the method, such as it is, in which we now find them. This was the work of his successor Abu Beer; who, considering that a great number of passages were committed to the memory of Mahomet's followers, many of whom were slain in their wars, ordered the whole to be collected, not only from the palm-leaves and skins on which they had been written, and which were kept between two bits of leather, but also from the mouths of such as had gotten them by heart. And this transcript, when completed, he committed to the custody of Haffa the daughter of Omar, one of the prophet's widows.

From this relation it is generally imagined that Abu Beer was really the compiler of the Koran; though, for aught appears to the contrary, Mahomet left the chapters complete as we now have them, excepting such passages as his successor might add or correct from those who had gotten them by heart; what Abu Beer did, being perhaps no more than to range the chapters in the preëxisting order, which he seems to have done without any regard to time, having generally placed the longest first.

However, in the 50th year of the Hegira, Othman being then caliph, and observing the great disarrangement in the copies of the Koran in the several provinces of the empire; those of Irak, for example, following the reading of Abu Mafa al Affari, and the Syrians that of Madad Ebn Awaal: he, by the advice of the companions, ordered a great number of copies to be transcribed from that of Abu Beer; in Haffa's care, under the inspection of Zaid Ebn Thabet, Abd Allah Ebn Zobair, Said Ebn al As, and Ad'dalrahman Ebn al Hareth the Maklmunites; whom he directed, that, wherever they differed about any word, they should write it in the dialect of the Koreth, in which it was at first delivered. These copies, when made, were differed in the several provinces of the empire, and the old ones burnt and suppressed. Though many things in Haffa's copy were corrected by the above-mentioned revisers, yet some few various readings still occur.

In fact, the book of the Alcoran is held in the highest esteem and reverence among the Musselmans. They dare not to touch the Alcoran without being first washed, or legally purified; to prevent which, an inscription is put on the cover or label, Let none touch but they who are clean. It is read with great care and respect; being never held below the girdle. They swear by it; take omons from it on all weighty occasions; carry it with them to war; write sentences of it in their banners; adorn it with gold and precious stones; and knowingly suffer it not to be in the possession of any of a different religion. Some say that it is punishable even with death, in a Christian, to touch it; others, that the veneration of the Musselmans leads them to condemn the translating it into any other language as a profanation: but these seem to be aggravations. The Mahometans have taken care to have their scripture translated into the Persian, the Java, the Malay, and other languages; tho' out of respect to the original, these versions are generally, if not always, interlineated.

By the advocates of Mahometanism, the Koran, as already observed, has always been held forth as the greatest of miracles, and equally stupendous with the act of raising the dead. The miracles of Moses and Jesus, they say were transient and temporary; but that of the Koran is permanent and perpetual; and therefore far surpasses all the miraculous events of preceding ages. We will not detract from the real merit of the Koran: we allow it to be generally elegant, and often sublime; but at the same time we reject with disdain its arrogant pretense to any thing supernatural; all the real excellence of the work being easily referable to natural and visible causes.

In the language of Arabia, a language extremely loved and diligently cultivated by the people to whom it was vernacular, Mahomet found advantages which were never enjoyed by any former or succeeding impostor. It requires not the eye of a philosopher to discover in every foal and country a principle of national pride; and if we look back for many ages to the history of the Arabians, we shall easily perceive that pride among them invariably to have confounded in the knowledge and improvement of their native language. The Arabic, which has so justly effemed the most copious of the eastern tongues; which has effumed from the remotest antiquity; which has been established by numberless poets, and refined by the constant exercise of the natives; was the most successful instrument which Mahomet employed in planting his new religion among them. Admirably adapted by its unrivalled harmony, and by its endless variety to add painting to expression, and to perfume the imagination in its unbounded flight; it became in the hands of Mahomet an irresistible charm to blind the judgment, and to captivate the fancy of his followers.

"Of that description of men who first composed the adherents of Mahomet, and to whom the Koran was addressed, few, probably, were able to pass a very accurate judgment on the propriety of the sentiments, or on the beauties of the diction: but all could judge of the military abilities of their leader; and in the midst of their admiration it is not difficult to conceive, that they would ascribe to his compositions every imaginary beauty of inspired language.

"The shepherd and the folder, though awake to the
The prophet of Arabia had in this respect advantages peculiar to himself. His compositions were not to his followers the works of man, but the genuine productions of genius, and thus became the divine original, that which Mahomet delivered from the inspired lectures of that Being whom he revered as the object of his own imagination the stream which flowed through his polterity.

"But the prophet of Arabia had in this respect advantages peculiar to himself. His compositions were not to his followers the works of man, but the genuine productions of genius, and thus became the divine original, that which Mahomet delivered from the inspired lectures of that Being whom he revered as the object of his own imagination the stream which flowed through his polterity.

"In the first periods of the literature of every country, something of this kind has happened. The father of Grecian poetry very obviously influenced the taste and imitation of his countrymen. The modern nations of Europe all possess some original author, who, rising from the darkened mists of ages, has begun the career of composition, and tinctured with the character of his own imagination the stream which flowed through his polterity.

"When therefore we consider these peculiar advantages of the Koran, we have no reason to be surprised at the admiration in which it is held. But if, descending to a more minute investigation of it, we consider its perpetual insufficiency and absurdity, we shall indeed have cause for astonishment at that weakness of humanity which could ever have received such compositions as the work of the Deity.

"The first praise of all the productions of genius, is invention; that quality of the mind, which, by the extent and quickness of its views, is capable of the largest conceptions, and of forming new combinations of objects the most distant and unusual. But the Koran bears little impress of this transcendent character. Its materials are wholly borrowed from the Jewish and Christian scriptures, from the Talmudical legends and apocryphal gospels then current in the East, and from the traditions and fables which abounded in Arabia. The materials collected from these several sources are here heaped together, with perpetual and needless repetitions, without any settled principle or visible connection.

"When a great part of the life of Mahomet had been spent in preparatory meditation on the system he was about to establish, its chapters were dealt out slowly and separately during the long period of 23 years. Yet thus defective in its structure, and not less exceptionable in its doctrines, was the work which Mahomet delivered to his followers as the oracles of God.

"The most prominent feature of the Koran, that point of excellence in which the partiality of its admirers has ever delighted to view it, is the sublime notion of the nature and attributes of God. Its author had really derived these just conceptions from the inspiration of that Being whom they attempt to describe, they would not have been surrounded, as they now are on every side, with error and absurdity. But it might easily be proved, that whatever it justly defines of the divine attributes, was borrowed from our holy scripture; which even from its first promulgation, but especially from the completion of the New Testament, has extended the views and enlightened the understandings of mankind; and thus furnished them with arms, which have too often been ineffectually turned against itself by its ungenerous enemies.

"In this instance particularly, the copy is far below the great original, both in the propriety of its images, and the force of its descriptions. Our holy scriptures are the only compositions that can enable the dim sight of mortality to penetrate into the invisible world, and to behold a glimpse of the Divine perfections. Accordingly, when they would represent to us the happiness of Heaven, they describe it, not by any thing minute and particular, but by something general and great; something, that without depending to any determinate object, may at once by its beauty and immensity excite our wishes and elevate our affections. Though in the prophetic and evangelical writings the joys that shall attend us in a future state are often mentioned with a genteel admiration, they are expressed rather by allusion than similitude, rather by indefinite and figurative terms, than by any thing fixed and determinate.

"Eye hath not seen, nor ear heard, neither have entered into the heart of man, the things which God hath prepared for them that love him." 1 Cor. ii. 9.

What a reverence and astonishment does this passage excite in every hearer of taste and piety! What energy, and at the same time what simplicity, in the expression? How sublime, and at the same time how obscure, is the imagery.

"Different was the conduct of Mahomet in his descriptions of heaven and of paradise. Unaffected by the necessary influence of virtuous intentions and Divine inspiration, he was neither droll nor indeed able to exhibit the minds of men to sublime conceptions, or to rational expectations. By attempting to explain what is inconceivable, to describe what is ineffable, and to materialize what in itself is spiritual; he absurdly and improvidently aimed to feminize the purity of the Divine essence. Thus he fabricated a system of incoherence, a religion of depravity, totally repugnant indeed to the
The Persians are generally Alcoranists, as admitting the Alcoran alone for their rule of faith. The Turks, Tartars, Arabs, &c. besides the Alcoran, admit a multitude of traditions. The Alcoranists, among Mahometans, amount to much the same with the Textuates among the Jews. The Alcoranists can find nothing excellent out of the Alcoran; are enemies of philosophers, metaphysicians, and scholastic writers. With them the Alcoran is everything.

ALCOVE, among builders, a recess, or part of a chamber separated by an eltrade, or partition of columns, and other corresponding ornaments, in which is placed a bed of state, and sometimes seats to entertain company. These alcoves are frequent in Spain; and the bed is raised two or three ascents, with a rail at the foot.

ALCUINUS (Placentius), an ecclesiastic of the eighth century. Where he was born, is a matter of dispute; but, according to the most probable opinion, it was in Yorkshire. It is pretty certain, however, that he was educated at York, under the direction of archbishop Egbert, as we learn from his own letters, in which he frequently calls that greatprelate his beloved master, and the clergy of York the companions of his youthful studies. As he survived venerable bede about 70 years, it is hardly possible that he could have received any part of his education under him, as some writers of literary history have affirmed; and it is worthy of observation, that he never calls that great man his master, though he speaks of him with the highest veneration. It is not well known to what prerogatives he had attained in the church before he left England, though some say he was abbot of Canterbury. The occasion of his leaving his native country, was his being sent on an embassy by Offa king of Mercia to the emperor Charlemagne; who contracted so great an esteem and friendship for him, that he earnestly solicited, and at length prevailed upon him, to settle in his court, and became his preceptor in the sciences. Alcuinus accordingly instructed that great prince in rhetoric, logic, mathematics, and divinity; which rendered him one of his greatest favourites. "He was treated with so much kindness and familiarity (says a contemporary writer) by the Emperor, that the other courtiers called him, by way of eminence, the emperor's delight." Charlemagne employed his learned favourite to write several books against the heretical opinions of Felix Bishop of Urgel in Catalonia, and to defend the orthodox faith against the heresies, in the council of Franport, A.D. 804; which he performed to the entire satisfaction of the Emperor and council, and even to the conviction of Felix and his followers, who abandoned their errors. The Emperor consulted chiefly with Alcuinus on all things relating to religion and learning; and, by his advice, did many great things for the advancement of both. An academy was established in the imperial palace, over which Alcuinus presided, and in which the princes and prime nobility were educated; and other academies were established in the chief towns of Italy and France, at his instigation, and under his inspection. "France (says, one of our best writers of literary history) is indebted to Alcuinus for all the polite learning it boasted of in that and the following ages. The universities of Paris, Tours, Fulda, Soissons, and many others,
And truly, in his task of embellishment, some things are found in particular here and there, which seem not to favour of Alcyonius, but of some higher author.

The two orations he made after the taking of Rome, wherein he represented very strongly the injustice of Charles V. and the barbarity of his soldiers, were excellent pieces. There is also an oration ascribed to him on the knights who died at the siege of Rhodes.

ALDBOROUGH, a sea-port town in Suffolk, with a market on Saturdays. It is pleasantly situated, in a dale, between a high hill to the westward, on which its large old-built church stands; the sea to the east, and its river running south-west. It is a large, long, ordinary town, made up of two or three streets of low houses, running parallel to each other. A quarter of a mile to the south lies Slaughden, where they have a commodious key, with warehouses for ships; more fowtherly still, they have conveniences for drying their north-sea fish. Their employment in the fisheries is their chief business, which is considerable in the seafsons for catching herrings and sprats; and it is the only place in England for curing red sprats. It is a town corporate, and lends two members to parliament. Towards the sea, it has some pieces of cannon planted for its defence. It is 88 miles north-east from London. E. Long. 1. 32. N. Lat. 52. 50.

ALDBOROUGH, a market-town in the west riding of Yorkshire, seated on the river Ouse, 15 miles north-west of York, and 200 miles north of London. It lends two members to parliament. W. Long. o. 20. N. Lat. 54. 15. It was anciently a Roman city, called Isurium Brigantium; and several coins and monuments of the Saxons and Romans have been discovered here.

ALDEBARAN, in astronomy, a star of the first magnitude, called in English the bull's eye, as making the eye of the constellation Taurus. Its longitude is 6 deg. 32 min. 9 sec. of Gemini, and its latitude 5 deg. 29 min. 40 sec. north.

ALDER-tree, in Botany. See Betula.

ALDERHOLM, a pleasant island of Sweden, formed by the three arms of a river running thro' Gentle, a town of Norland, in Sweden. Here is a wharf, a repository for planks and deals, two packing houses, a large cutchouse for taking toll of the ships, an arsenal for cannon, and a granary.

ALDERMAN, in the British policy, a magistrate subordinate to the lord-mayor of a city or town-corporate. The number of these magistrates is not limited, but is more or less according to the magnitude of the place. In London they are 26; each having one of the wards of the city committed to his care. This office is for life; so that when one of them dies, or resigns, a ward-mote is called, who return two persons, one of whom the lord-mayor and aldermen choose to supply the vacancy. All the aldermen are justices of the peace, by a charter of 15 Geo. II. The aldermen of London, &c. are exempted from serving inferior offices; nor shall they be put upon salaries, or serve on juries, so long as they continue to be aldermen.

Alderman, among the ancient Saxons, was a degree of nobility answering to earl or count at present. Alderman was also used, in the time of king Edgar, for a judge or justice. Thus we meet with the
ALDERNEY, an island in the British Channel, subject to the crown of Great Britain. It is about eight miles in compass, and is separated from Cape la Hogue, in Normandy, by a narrow strait, called the Race of Alderney, which is a very dangerous passage in stormy weather when the two currents meet; otherwise it is safe, and has depth of water for the largest ships. Thro' this strait the French fleet made their escape after their defeat at La Hogue, in 1692. It is a healthy island, but has one church, is fruitful both in corn and pattle, and is remarkable for a fine breed of cows. The inhabitants, for their greater safety, live together in a town of the same name. The number of houses are said to be 200, and the inhabitants 1000. It has but one harbour, called Crably, which is at a good distance from the town; and is only fit for small vessels. To the west lie the range of rocks called the Gaffets, so dangerous to mariners. W. Long, p. 17. N. Lat. 49. 50.

ALDEHELM (St.), bishop of Sherburn in the time of the Saxon Heptarchy. He is said to have been the son of Kenred, brother to Ina, king of the West-Saxons; but, in the opinion of William of Malmbury, his father was no more than a distant relation to the king. Having received the first part of his education in the school which one Macduff, a learned Scot, had set up in the place where Malmbury now stands, he travelled into France and Italy for his improvement. At his return home, he studied some time under Adrian abbot of St. Augustine's in Canterbury, the most learned professor of the sciences who had ever been in England. In these different seminaries he acquired a very uncommon stock of knowledge; and became famous for his learning, not only in England, but in foreign countries: whence several learned men fent him their writings for his perusal and correction; particularly Prince Arcivill, a son of the King of Scotland, who wrote many pieces which he sent to Aldhelm, "in treating him to give them the last polish, by rubbing off their Scots raft." He was the first Englishman who wrote in the Latin language both in prose and verse, and composed a book for the instruction of his countrymen in the profody of that language. Besides this, he wrote several other treatises on various subjects; some of which are lost, and others published by Martin Delrio and Canisius. Venerable Bede, who flourished in the end of this and the beginning of the next century, gives the following character of Aldhelm: "He was a man of universal learning, having an elegant style, and being wonderfully well qualified in both philosophical and religious subjects." In fact, considering the cloud of ignorance by which he was surrounded, and the great difficulty of acquiring knowledge without proper instruction, Aldhelm was a very extraordinary man. From one of his letters to Icedda bishop of Winchester, concerning the nature of his studies whilst at Canterbury, he appears to have been indefatigably determined to acquire every species of learning in his power. For a copy of this curious epistle, see Henry's History, vol. ii. p. 320. King Alfred the Great declared, that Aldhelm was the best of all the Saxon poets; and that a favourite song, which was universally sung in his time, near 200 years after its author's death, was of his composition. When he was abbot of Malmbury, having a fine voice, and great skill in music as well as poetry, and observing the backwardness of his barbarous countrymen to listen to grave instructions, he composed a number of little poems, which he sung to them after masses in the sweetest manner; by which they were gradually instructed and civilized. After this excellent person had governed the monastery of Malmbury, of which he was the founder, about 30 years, he was made bishop of Sherburn, where he died A. D. 709. He wrote, 1. De oth vita pricipatibus. This treatise is extant in Bibliotheca Patrum of Canisius. 2. Epistola de vita et illustrativa. 3. De vita monachorum. 4. De laude sanctarum. 5. De piacio canonicum. 6. De aquae. 7. De astrologia. 8. A book against the mistake of the Britons concerning the celebration of Easter; printed by Soulis, 1576. 9. De laude virginitatis. Manuscript, in Bennet-college, Cambridge. Published among Bede's Opera. Besides many sonnets, epistles, and homilies in the Saxon language.

ALDPORT, an ancient name for Manchester.

See Manchester.

ALDRED, abbot of Tavistock, was promoted to the bishopric of Worcester in the year 1046. He was so much in favour with King Edward the Confessor, and had so much power over his mind, that he ordered him to be reconciled with the worst of his enemies, particularly with Swane son of the earl Goodwin, who had revolted against him, and came with an army to invade the kingdom. Aldred restored the union and friendship between king Edward and Griffin king of Wales. He took afterwards a journey to Rome, and being returned into England, in the year 1054, he was sent embassador to the emperor Henry II.; he laid a whole year in Germany, and was very honourably entertained by Herman archbishop of Cologne, from whom he learned many things relating to ecclesiastical discipline, which on his return he established in his own diocese. In the year 1058 he went to Jerusalem, where, no archbishop or bishop of England had ever done before him. Two years after he returned to England; and Kinian archbishop of York dying the 22d of December 1060, Aldred was elected in his stead on Christmas day following, and thought fit to keep his bishopric of Worcester with the archbishopric of Canterbury, as some of his predecevers had done. Aldred went soon after to Rome, in order to receive the pallium from the Pope: He was attended by Tofton earl of Northumberland, Gifo bishop of Wells, and Walter bishop of Hereford. The pope received To-
the prelate, unmoved at all this, answered calmly, "Good men, let him lie there, for he is not at Aldred's but at St Peter's feet; he must feel St Peter's power, since he dared to injure his vicegerent." Having thus reproved the nobles by his episcopal authority, he vouched to take the king by the hand, and to tell him the ground of his complaint. The king humbly excused himself, by saying he had been ignorant of the whole matter; and begged of the noblemen to intreat the prelate, that he might take off the curse he had pronounced Canute's, and change it into a blessing. Aldred was at last prevailed upon to favour the king thus far; but not without the promise of several presents and favours, and only after the king had granted him to take such a revenge on the governor as he thought fit. Since that time (adds the historian) none of the noblemen ever dared to offer the least injury. It may be questioned, which was more surprising here, whether the archbishop's haughtiness, who dared to treat his sovereign after so unbecoming a manner; or the king's stupidity, who suffered such insolence and audacity from a priest?—The Danes having made an invasion in the north of England in the year 1068, under the conduét of Harold and Canute the sons of king Swan, Aldred was so much afflicted at it, that he died of grief the 11th of September in that same year, having besought God that he might not see the desolation of his church and country.

ALDRICH (Robert), bishop of Carlile, was born at Burnham in Buckinghamshire about the year 1493, and educated at Eaton-school; from whence, in 1507, he was elected scholar of King's College, Cambridge, where he took his degree in arts, and was afterwards professor of the univercity at St Peter, and to him the faint's vicar, for the injury he had done them; adding, that if he refused to comply, the archbishop would make use of his apostolic authority against him, (intimating thereby that he would excommunicate him). The governor, offended at this proud message, used the persons whom the archbishop had sent him very ill, and returned an answer as haughtily as the message was. Aldred thereupon went to London to make his complaint to the king; but in this very complaint he acted with his wonted insolence; for meeting the king in the church of St Peter at Westminster, he spoke to him in these words: "Hearken, O William: when thou wast but a foreigner, and God, to punish the sins of this nation, permitted thee to become master of it, after having died a great deal of blood, I consecrated thee, and put the crown upon thy head with blessings; but now, because thou hast deferved it, I pronounce a curse over thee, instead of a blessing, since thou art become the perverter of God's church, and of his ministers, and hast broken the promises and oaths which thou

"madest to me before St Peter's altar." The king, terrified at this discourse, fell upon his knees, and humbly begged the prelate to tell him, by what crime he had deferved so severe a sentence. The noblemen, who were present, were enraged against the archbishop, and loudly cried out he deserved death, or at least bastinado, for having offered such an injury to his sovereign, and they pressed him with threatenings to raise the king from the ground. But the prelate, unmoved at all this, answered calmly, "Good men, let him lie there, for he is not at Aldred's but at St Peter's feet; he must feel St Peter's power, since he dared to injure his vicegerent." Having thus reproved the nobles by his episcopal authority, he vouched to take the king by the hand, and to tell him the ground of his complaint. The king humbly excused himself, by saying he had been ignorant of the whole matter; and begged of the noblemen to intreat the prelate, that he might take off the curse he had pronounced Canute's, and change it into a blessing. Aldred was at last prevailed upon to favour the king thus far; but not without the promise of several presents and favours, and only after the king had granted him to take such a revenge on the governor as he thought fit. Since that time (adds the historian) none of the noblemen ever dared to offer the least injury. It may be questioned, which was more surprising here, whether the archbishop's haughtiness, who dared to treat his sovereign after so unbecoming a manner; or the king's stupidity, who suffered such insolence and audacity from a priest?—The Danes having made an invasion in the north of England in the year 1068, under the conduét of Harold and Canute the sons of king Swan, Aldred was so much afflicted at it, that he died of grief the 11th of September in that same year, having besought God that he might not see the desolation of his church and country.

ALDRICH (Robert), bishop of Carlile, was born at Burnham in Buckinghamshire about the year 1493, and educated at Eaton-school; from whence, in 1507, he was elected scholar of King's College, Cambridge, where he took his degree in arts, and was afterwards professor of the university at St Peter, and to him the faint's vicar, for the injury he had done them; adding, that if he refused to comply, the archbishop would make use of his apostolic authority against him, (intimating thereby that he would excommunicate him). The governor, offended at this proud message, used the persons whom the archbishop had sent him very ill, and returned an answer as haughtily as the message was. Aldred thereupon went to London to make his complaint to the king; but in this very complaint he acted with his wonted insolence; for meeting the king in the church of St Peter at Westminster, he spoke to him in these words: "Hearken, O William: when thou wast but a foreigner, and God, to punish the sins of this nation, permitted thee to become master of it, after having died a great deal of blood, I consecrated thee, and put the crown upon thy head with blessings; but now, because thou hast deferved it, I pronounce a curse over thee, instead of a blessing, since thou art become the perverter of God's church, and of his ministers, and hast broken the promises and oaths which thou

"madest to me before St Peter's altar." The king, terrified at this discourse, fell upon his knees, and humbly begged the prelate to tell him, by what crime he had deferved so severe a sentence. The noblemen, who were present, were enraged against the archbishop, and loudly cried out he deserved death, or at least bastinado, for having offered such an injury to his sovereign, and they pressed him with threatenings to raise the king from the ground. But the prelate, unmoved at all this, answered calmly, "Good men, let him lie there, for he is not at Aldred's but at St Peter's feet; he must feel St Peter's power, since he dared to injure his vicegerent." Having thus reproved the nobles by his episcopal authority, he vouched to take the king by the hand, and to tell him the ground of his complaint. The king humbly excused himself, by saying he had been ignorant of the whole matter; and begged of the noblemen to intreat the prelate, that he might take off the curse he had pronounced Canute's, and change it into a blessing. Aldred was at last prevailed upon to favour the king thus far; but not without the promise of several presents and favours, and only after the king had granted him to take such a revenge on the governor as he thought fit. Since that time (adds the historian) none of the noblemen ever dared to offer the least injury. It may be questioned, which was more surprising here, whether the archbishop's haughtiness, who dared to treat his sovereign after so unbecoming a manner; or the king's stupidity, who suffered such insolence and audacity from a priest?—The Danes having made an invasion in the north of England in the year 1068, under the conduét of Harold and Canute the sons of king Swan, Aldred was so much afflicted at it, that he died of grief the 11th of September in that same year, having besought God that he might not see the desolation of his church and country.
Aldrich was a most universal scholar, and had a taste for all sorts of learning, especially architecture. Sir John Hawkins has favoured the public with several particulars relative to Dr Aldrich's skill in music; and on account of the Doctor's eminence in this respect, Sir John hath given his life, with his head prefixed. His abilities as a musician rank him, we are told, among the greatest masters of the science. He composed many services for the church, which are well known; and are also his anthems, nearly to the number of twenty. He adapted, with great skill and judgment, English words to many of the notes of Palestrina, Carissimi, Victoria, and other Italian composers for the church, some of which are frequently sung in the cathedrals as anthems.

By the happy talent which Dr Aldrich possest, of naturalizing the compositions of the old Italian masters, and accommodating them to an English ear, he increased the stores of his own college. Though the Doctor chiefly applied himself to the cultivation of sacred music, yet, being a man of humour, he could divert himself by producing pieces of a lighter kind. There are two catches of his; the one, "Hark the bonny Christ-church Bells," the other intituled, "A Smoking Catch," to be sung by four men smoking their pipes, which is not more difficult to sing than deviating to hear. His love of smoking was, it seems, so excessive as to be an entertaining topic of discourse in the university. Such was Dr Aldrich's regard for the advancement of music, and the honour of its professors, that he had formed a design of writing a history of the science; and the materials from which he proposed to compile it are yet extant in the library of his own college. It appears from these materials, that he had marked down every thing which he had met with concerning music and musicians; but that he had wrought no part of them into any kind of form.

Dr Aldrich is of some note as a Latin poet. In the Sylva Anglica, we find two elegant copies of verses by him; one on the accession of King William III. and the other on the death of the Duke of Gloucester. Sir John Hawkins hath preserved a humorous translation by him of the well-known English ballad,

"A soldier and a sailor," 
"A tink'er and a taylor," &c.

The following epigram, intitled "Canfa Bibendi," is likewise ascribed to Dr Aldrich:

"Si bene quid memini, Caufae fiant quinque bibendi, 
Hofpitis Adventus; praefent Sitis, arisque futura; 
Ant Vini Bonitas; que libet altera Canfa."

The epigram has been thus translated:

"If on my theme I rightly think, 
"There are five reasons why men drink; 
"Good wine, a friend, because I'm dry, 
"Or left I should be by and by, 
"Or any other reason why."

The translation is not equal to the original. It is evident, from the verses cited and referred to, that Dr Aldrich was a most skilful and pleasant turn of mind. Indeed, he is always spoken of as having been a man of wit; and as one who, to his great talents and virtues, joined those amiable qualities, which rendered him the object of general affection, as well as of general esteem and respect. Having never been married, he appropriated his income to works of hospitality and benificence, and in encouraging learning to the utmost of his power, of which he was a most munificent patron, as well as one of the greatest men in England, if considered as a christian or a gentleman. He had always the interest of his college at heart, whereby he was an excellent governor. And, as he was remarkable for modesty and humility, concealing his name to those several learned tracts he published, to his death he appointed to be buried without any memorial in the cathedral; which his thrifty nephew compiled with, depositing him on the south side of bishop Fell's grave, December 22, eight days after his decease; which happened in the 63d or 64th year of his age.

ALDROVANDUS (Ulysses), professor of philosophy and physic at Bologna, the place of his nativity. He was a most curious inquirer into natural history, and travelled into the most distant countries on purpose to form himself of their natural productions. Minerals, metals, plants, and animals, were the objects of his curious researches; but he applied himself chiefly to birds, and was at great expense to have figures of them drawn from the life. Aubert le Mire says, that he gave a certain painter, famous in that art, a yearly salary of 200 crowns, for 30 years and upwards; and that he employed at his own expense Lorenzo Bennini and Cornelius Swintus, as well as the famous engraver Christoper Coriolanus. These expenses ruined his fortune, and at length reduced him to the utmost necessity; and it is said that he died blind in an hospital at Bologna, at a great age, in 1665. Mr Bayle observes, that antiquity does not furnish us with an instance of a design so extensive and so laborious as that of Aldrovandus, with regard to natural history; that Pliny has treated of more kinds of subjects, but only touches lightly on them, saying but a little upon any thing, whereas Aldrovandus has collected all he could meet with. His compilation, or that compiled upon

3B his
his plan, consists of 13 volumes in folio, several of which
were printed after his death. He himself published
his Ornithology, or History of Birds, in three folio vol-
umes, in 1599; and his seven books Of Insects, which
make another volume of the same size. The volume
Of Serpents, three Of Quadrupeds, one Of Fishes,
that Of Exanguous Animals, the History of Monitors,
with the Supplement to that of Animals, the treatise
Of Metals, and the Dendrology or History of Trees,
were published at several times after the death of Al-
drovandas, by the care of several persons; and Aldro-
vandas is the sole author only of the first six volumes
of this work, the rest having been finished and compiled
by others, upon the plan of Aldrovandas: a most ex-
tensive plan, wherein he not only relates what he has
read in naturalists, but remarks also what historians
have written, legislators ordained, and poets regnied:
he explains also the different uses which may be made
of the things he treats of, in common life, in medicine,
architecture, and other arts; in short, he speaks of
morality, proverbs, devices, riddles, hieroglyphics,
and many other things which relate to his subject.

ALDROVANDA, in botany, a genus of the pen-
taerose order, belonging to the pentagonia class of
plants, of which there is but one species. The calyx
is divided into five parts; the petals are five; and the
capsule has five valves, with ten seeds. It is a native
of Italy and the Indies; and has no English name.

ALDUABIS (anc. geog.), a river of Celtic Gaul,
which rising from Mount Jura, separating the Sequani
from the Helveti, and running through the county of
Burgundy, or the Franche Comté, environs almost on
every side the city of Besançon; and running by Dole,
falls into the Saone near Chalone. In Caesar it is called
Madaugibus; in Ptolemy, Dobas; now le Droix.

A LE, a fermented-liquid obtained from an infusion
of malt, and differing from beer chiefly in having a less
proportion of hops. (See Brewing.) This liquor,
the natural substitute of wine in such countries as could
not produce the grape, was originally made in Egypt,
the first planted kingdom, on the diiference from the
east, that was suppos'disable to produce grapes. And,
as the Noachian colonies pierced further into the west,
they found, or thought they found, the same defect,
and filled it in the same manner. Thus the natives
of Spain, the inhabitants of France, and the aborigines
of Britain, all used an infusion of barley for their ordi-
ary liquor: and it was called by the various names of
Caeia and Crevis in the first country, Cerevisia in the
second, and Curtai in the last; all literally importing
only the strong water.

All the several nations (says Pliny) who inhabit
the west of Europe, have a liquor with which they in-
toxicate themselves, made of corn and water. The
manner of making this liquor is somewhat different in
Gaul, Spain, and other countries, and is called by
many various names; but its nature and properties are
everywhere the same. The people of Spain, in particu-
lar, brew this liquor so well, that it will keep good
a long time. So exquisite is the cunning of mankind,
in gratifying their vicious appetites, that they have
thus invented a method to make water itself intoxica-
care. The method in which the ancient Britons, and
other Celtic nations, made their ale, is thus described
by Luidoros and Orofius. "The grain is steeped in
water and made to germinate, by which its spirits are
excited and set at liberty; it is then dried and grind-
ed: after which it is infused in a certain quantity of
water; which being fermented, becomes a pleasing,
warmed, strengthening, and intoxicating liquor."

This ale was most commonly made of barley; but some-
times of wheat, oats, and millet.

Anciently the Welsh and Scots had also two kinds
of ale, called common ale and spiced ale; and their va-lue was thus ascertained by law: "If a farmer hath
no mead, he shall pay two casks of spiced ale, or four
casks of common ale, for one cask of mead."

By this law, a cask of spiced ale, nine palms in height,
and 18 palms in diameter, was valued at a sum of mo-
ney equal in efficacy to L. 7. 10s. of our present mo-
cy; and a cask of common ale, of the same dimen-
sions, at a sum equal to L. 3. 15s. This is a sufficient
proof, that even common ale in this period was an ar-
ticle of luxury among the Welch, which could only
be obtained by the great and opulent. Wine seems
to have been quite unknown even to the kings of Wales
in this period, as it is not so much as once mentioned
in their laws; though Giraldus Cambrensis, who flour-
ished about a century after the conquest, acquaints us,
that there was a vineyard in his time at Macnamer,
pembroke, in South Wales.

Ale was the favourite liquor of the Anglo-Saxons
and Danes, as it had been of their ancestors the an-
cient Germans. Before their conversion to Chrisli-
ty, they believed that drinking large and frequent
draughts of ale was one of the chief felicitics which
those heroes enjoyed who were admitted into the hall
of Odin.

There are various sorts of ale known in Britain,
particularly pale and brown: the former is brewed from
malt slightly dried; and is esteemed more virfid than
the latter, which is made from malt more highly dried
or roasted. Pale ale brewed with hard waters, as those
of springs and wells, is judged the most wholesome, in regard the
mineral particles tend to prevent the cohesion of those
drawn from the grain, and enable them to pass the pro-
per receptacles the better; softer waters, as those of ri-
vers, and rain, seem better suited to draw out the sub-
fiance of high-dried malts which retain many igneous
particles, be absorbed in a smooth vehicle.

In Staffordshire, they have a secret of fining ale in
a very short time. Plot conjectures it to be done by
adding alum, or vinegar, in the working.

Ale is prepared various ways, and of various ingre-
dients, as of wheat, rye, millet, oats, barley, the ber-
ries of the quick-bean, &c.

Some have found that the juice which bleeds from
the birch or fycamore is of great use on this occasion,
applied instead of water. It makes one bushel of malt
go as far as four in the common way.

Some have a method of preparing ale, so that it will
keep, carried to the East or West Indies. The secret
is, by mashing twice with fresh malt; boiling twice;
and, after straining it, putting to every five gallons two
new-laid eggs, whole, to remain therein. It is said,
that, in a fortnight's time, the shells will be dissolv-
ed; and the eggs become like wind-eggs; and that after-
wards the white will disappear and the yolk remain
untothed.

Ale
ALE is generally held to be more diuretic than beer, in regard it is smoother, more soothing and relaxing; so that when urine is to be promoted by facilitating the passage, ale is most likely to effect it.

Ale is flatulent; and hence sometimes produces colicky, and the cholera morbus; it is accecent; but it does not produce calcareous discharges, as has been asserted. If muli-liquor, of any degree of strength, is become flat and tarryish, as it is used, it should be drawn out of the cask into a jug, in which as many drams of powdered chalk is put as there are to be pints of liquor; thus a new ferment will be raised, a spirtuoue taste will be restored to the liquor, and its acidity will be destroyed. Tart liquors of this kind are apt to produce dysentery, frangury, or a gonorhoea; in which cases, a small quantity of branzy may be taken.

The consumption of ale in Great Britain is incredible. It was computed twenty years ago at the value of four millions yearly, including Great Britain and Ireland.

The duties on ale and beer make a principal branch of the revenue in Britain. They were imposed by the 12th of Car. II. and have been continued by several subsequent acts of parliament to first Geo. III. which lays an additional duty of 3d. per barrel. In the whole, the brewer of ale and beer for sale shall pay 8s. for every barrel of either, above 6s. a barrel; and for every barrel of 6s. or under, the sum of 1s. 4d.

Medicated Ales, those wherein medicinal herbs have been infused, or added during the fermentation. See Pharmacy, (Index.)

Gill-Ale, is that in which the dried leaves of gill or ground-ivy have been infused. It is esteemed absetive and vulnerary, and consequently good in disorders of the breast and obstructions of the viscer.

Ale-Connor, an officer in London, who inspects the measures used in public houses. There are four ale-conners, who are all chosen by liverymen in a common hall on midsummer-day.

Ale-Houses must be licensed by justices of the peace, who take recognizances of the persons licensed, and of their sureties, viz. 19d. each, that they will not suffer unlawful gaming, nor other disorderly practices in their houses. Every person, excepting those who fell ale in fairs, neglecting to procure a license, is liable to a penalty of 40s. for the first offence, 4l. for the second, and 6l. for the third, with all costs. The licence is granted on the first of September, or within twenty days after, at a general meeting of the justices for the division to which he belongs, upon his producing a certificate to his character, unless by living in a city or town-corporate, this last circumstance is dispensed with, and continues in force for one year only. Ale-house keepers, selling ale in short measure, are liable to a penalty not exceeding 40s. and not less than 10s. and likewise to a fine of 10s. for permitting tipping, &c.

By 29th Geo. II. c. 12. persons keeping ale-houses in Scotland shall be licensed as in England, and the justices there shall meet annually to license ale-houses; on each of which license a fee of 1s. is payable to the clerk of the peace. Magistrates of royal boroughs shall be yearly for the like purpose; but where there shall not be a sufficient number of magistrates to act in any royal borough, justices may grant licenses, to be in force for one year only. Ibid.

Persons in Scotland convicted of keeping unlicensed ale-houses shall forfeit for the first offence 5s. for the second 10s. for the third 20s. and to be disqualified; and for every subsequent offence 40s. to be levied by diftreys and sale, on oath to the informer, the other to the poor of the parish. Conviction to be intimated to the offender, and certified to the clerk of the peace, and recorded: but persons aggrieved may appeal to the quarter sessions. Ibid.

Licences for houses on the military roads in Scotland shall be issued on payment of 1s. only to the clerk of the peace; making out licences before the fame be sealed, is a penalty of 10l. and making them contrary to the intention of this act, 5l. and the same shall be vacated, unless the duty and fine be paid, and the receipt produced, and licence stamped. Ibid.

ALE-Silver, a tax paid annually to the lord-mayor of London, by all who fell ale within the city.

ALEA, in Roman antiquity, denotes in general all manner of games of chance; but in a more restricted sense, was used for a particular game played with dice and tables, not unlike our backgammon.

ALEANDER (Jerome), cardinal and archbishop of Brindisi, was born in 1480, and distinguis hed himself at the beginning of the reformation, by the opposition he made to Luther, for being sent into Germany as the pope's nuncio in 1539, he acted, as occasion served, in the character of both ambassador and doctor; and declared three hours together against Luther's doctrine before the diet of Worms, but could not prevent that celebrated reformer from being heard in that diet.

He published several works, and died at Rome in 1542.

ALEANDER (Jerome), a learned man of the fourteenth century, born in the principality of Friuli, of the same family with the preceding. When he went to Rome, he was employed as secretary under cardinal O Caesar Bandini, and discharged this office with great honour for almost twenty years. He afterwards, by the persuasion of Urban VIII. who had a great esteem for him, became secretary to Cardinal Barberini, whom he accompanied to Rome where he was, in the character of legate a latere, and in whose service he died in 1631. He was one of the first members of the academy of Humorists, wrote a learned treatise in Italian on the device of the society, and displayed his genius on many different subjects. Barberini gave him a magnificent funeral at the academy of Humorists; the academists carried his corps to the grave, and Gaspere Simeonibus, one of the members, made his funeral oration.

ALECTORO, one of the Furies, daughter of Acheron and Night, and as others would have it, of Pluto and Proserpine.

ALECTORIA, a stone said to be formed in the gall bladders of old cocks, to which the ancients ascribed many fabulous virtues. This is otherwise called Alectoria Lapis, sometimes Alectoroitha, in English the cock-stone. The more modern naturalists hold the ai-heros lapis to be originally swallowed down, not generated in, the stomach or gizzard of cocks and capons. It is known that many of the fowl-kind make a practice of swallowing pebbles, as it is supposed to be of service in the business of trituration and digestion.

ALECTOROMANTIA, in antiquity, a species of divination performed by means of a cock. This is otherwise...
otherwise called Aletheumany; of which there appear
to have been different species. But that most spoken
of by authors was in the following manner: A circle
being described on the ground, and divided into twen-
ty-four equal portions, in each of these spaces
was written one of the letters of the alphabet, and on each
of the letters was laid a grain of wheat; after which,
a cock being turned loose in the circle, particular no-
tice was taken of the grains picked up by the cock,
because the letters under them, being formed into a
word, made the answer desired. It was thus, accor-
ding to Zonaras, that Libanias and Jamblichs sought
who should succeed the emperor Valens; and the cock
eating the grains answering to the space AEGA, se-
veral whose names began with those letters, as The-
odosius, Theodolitis, Theodulphus, &c. were put to death,
which did not hinder, but promote, Theodolus to the
succession. But the story, however current, is but ill
supported: It has been called in question by some,
and refuted by others, from the silence of Marcellinus
Socrates, and other historians of that time.

A-LEE, in the sea-language, a term only used when
the wind, croffing or flanking the line of a ship's
course, presses upon the masts and sails so as to make
her incline to one side, which is called the lee-side: hence,
when the helm is moved over to this side, it is
said to be a lee, or hard-a-lee.

ALEGAMBE (Philip), a celebrated Jesuit, born at
Brussels in 1592, distinguished himself by publishing
a Bibliotheca of the writers of his order, and died
at Rome in 1652.

ALEGRETE, a small town of Portugal, in A-
lestejo, on the confines of Port Alegre, on the river
Caja, which falls into the Guadiana, a little below Ba-
jadoz, near the frontiers of Spanish Estremadura. It
is a very pretty town, and finely situated; seven miles
south-east of Port Alegre, and thirty miles north of

ALESIUS CAMPUS (anc. geog.), a plain in Cil-
cis, on this side the river Pyramus, near the mountain
Chimera, famous for Bellerophon's wandering and pe-
riphering there, after being thrown off Pegusus; which
is the reason of the appellation.

ALEMANIA, or ALLEMANIA, (anc. geog.) a name
of Germany, but not known before the time of the
Antonines, and then used only for a part. After the
Marcomanni and their allies had removed from the
Rhine, a rabble, or collection of people from all parts
of Gaul, as the term Allemanni denotes, prompted ei-
erly or poverty, occupied the Agri, called
Decumanus by Tacitus, because they held them on a
title; now supposing to be the duchy of Wirtzbergh.
Such appear to be the small beginnings of Alemania,
which was in after-times greatly enlarged: but still
it was considered as a distinct part; for Caracalla,
who conquered the Alemani, assumed the surname
both of Alemaniacs and Germaniacs.

ALEMBARD, and officer in the court of the Grand
Signior, who bears the green standard of Mahomet,
when the sultan appears in public on any solemn occa-
sions.

ALEMBERT (John le Rond d'), an eminent
French philosopher, was born at Paris in 1717. He
derived the name of John le Rond from that of the
church near which, after his birth, he was exposed as
a foundling. His father, informed of this circum-
stance, listened to the voice of nature and duty, took
measures for the proper education of his child, and for
his future subsistence in a state of ease and indepen-
dence.

He received his first education in the College of the
Four Nations, among the Janenists, where he gave
early marks of capacity and genius. In the first year
of his philosophical studies, he composed a Commen-
tary on the epistle of St Paul to the Romans. The
Jamenists considered this production as an omen that
portended to the party of Port-Royal a reformation to
some part of their ancient splendor, and hoped to
find one day in M. d'Alembert a second Pascal.
To render this remembrance more complete, they engaged
their rising pupil in the study of the mathematics; but
they soon perceived that his growing attachment to
this science was likely to disappoint the hopes they
had formed with respect to his future destitution;
they, therefore, endeavoured to divert him from this
line; but their endeavours were fruitless.

At his leaving college, he found himself alone and
unconnected in the world; and sought an asylum in
the house of his nurse. He comforted himself with
the hope, that his fortune, though not ample, would bet-
ter the condition and subsistence of that family, which
was the only one that he could consider as his own:
Here, therefore, he took up his residence, resolving
to apply himself entirely to the study of geometry: And
here he lived, during the space of forty years, with the
greatest simplicity, discovering the augmentation of his
means only by encreasing displays of his benevolence,
concealing his growing reputation and celebrity from
these honest people, and making their plain and uncoutch
manners the subject of good-natured pleantry and
philosophical observation. His good nurse perceived
his ardent activity: heard him mentioned as the writer
of many books; but never took it into her head that
he was a great man, and rather beheld him with a kind
of compassion. "You will never," said she to him one
day, "be any thing but a philosopher—and what is a
philosopher?—a fool, who toils and plagues himself during
his life, that people may talk of him when he is no more."

As M. d'Alembert's fortune did not far exceed the
demands of necessity, his friends advised him to think
of a profession that might enable him to augment it.
He accordingly turned his views to the law, and took
his degrees in that line; but soon abandoned this plan,
and applied to the study of medicine. Geometry,
however, was always drawing him back to his
former pursuits, and after many ineffectual efforts to
refit its attractions, he renounced all views of a lucrative
profession, and gave himself over entirely to ma-
thematics and poverty.

In the year 1741 he was admitted member of the
Academy of Sciences, for which distinguished literary
promotion, at such an early age, he had prepared the
way by correcting the errors of a celebrated work,
which was deemed classical in France in the line of ge-
ometry. He afterwards fitted himself to examining, with
deep attention and acendency, what must be the motion
of a body which passes from one fluid into another
more dense, in a direction not perpendicular to the
surface separating the two fluids. Every one knows
the phenomenon which happens in this case, and which
amuses.
A L E

ALEMBERT amuses children under the denomination of Ducks and Drakes; but M. d'Alembert was the first who explained it in a satisfactory and philosophical manner.

Two years after his election to a place in the academy, he published his Treatise on Dynamics. The new principle developed in this treatise conflicted in establishing equality, at each instant, between the changes that the motion of a body has undergone, and the forces or powers which have been employed to produce them; or to express the thing otherwise, in separating into two parts the action of the moving powers, and considering the one as producing alone the motion of the body, in the second instant, and the other as employed to destroy that which it had in the first.

So early as the year 1744 M. d'Alembert had applied this principle to the theory of the equilibrium, and the motion of fluids; and all the problems before solved by geometers became, in some measure, its corollaries. The discovery of this new principle was followed by that of a new calculus, the first trials of which were published in a Discourse on the general Theory of the Winds, to which the prize-medal was adjudged by the academy of Berlin in the year 1746, and which was a new and brilliant addition to the fame of M. d'Alembert. This new calculus of partial differences he applied the year following, to the problem of vibrating chords, whose solution, as well as the theory of the oscillations of the air and the propagation of sound, had been given but incompletely by the geometers who preceded him, and these were his masters or his rivals.

In the year 1749 he furnished a method of applying his principle to the motion of any body of a given figure; and he solved the problem of the precession of the equinoxes, determined its quantity, and explained the phenomenon of the nutation of the terrestrial axis discovered by Dr. Bradley.

In 1752, M. d'Alembert published a treatise on the Resistance of Fluids, to which he gave the modest title of an Essay, but which contains a multitude of original ideas and new observations. About the same time he published, in the Memoirs of the Academy of Berlin, Researches concerning the Integral Calculus, which is greatly indebted to him for the rapid progress it has made in the present century.

While the studies of M. d'Alembert were confined to geometry, he was little known or celebrated in his native country. His connections were limited to a small society of selected friends; he had never seen any man in high office except M. d'Argencon. Satisfied with an income which furnished him with the necessities of life, he did not aspire after opulence or honours; nor had they been hitherto bestowed upon him, as it is easier to confer them on those who solicit them, than to look out for men who deserve them. His cheerful conversation, his smart and lively fallacies, a happy knack at telling a story, a florid mixture of malice of speech with good-nights of heart, and of delicacy of wit with simplicity of manners, rendered him a pleasing and interesting companion, and his company consequently was much sought after in the fashionable circles. His reputation, as length, made its way to the throne, and rendered him the object of royal attention and beneficence. He received also a pension from government, which he owed to the friendship of Count d'Argencon.

The tranquillity of M. d'Alembert was abated when his fame grew more extensive, and when it was known beyond the circle of his friends, that a fine and enlightened taste for literature and philosophy accompanied his mathematical genius. Our author's eloquent alibis to envy, detraction, and to other motives nearly as ungenerous, all the disapprobation, or opinion, and curriculum that M. d'Alembert met with an account of the publication of the famous Encyclopædia Dictionary of Arts and Sciences, in conjunction with Diderot. None more will refuse the well-merited tribute of applause to the eminent displays of genius, judgment, and true literary taste, with which M. d'Alembert has enriched the great work now mentioned. Among others, the Preliminary Discourse he has affixed to it, concerning the rift, profligates, connections, and affinities of all the branches of human knowledge, is perhaps one of the most capital productions of which the philosophy of the present age can boast. Nor will it be disputed, that the master-builders of this new and stupendous temple of science, for the worship of Nature, had also really in view the advancement of human knowledge, and the improvement of the arts and sciences. This, no brute, no candid philosopher, will call in question. But that in the inner court of this temple there was a confederacy formed against all those who looked higher than nature, for the principal object of their veneration and confidence, is a fact too palpable, too boldly avowed, to stand in need of any proof.

Some time after this, d'Alembert published his Philosophical, Historical, and Philological Miscellanies. These were followed by the Memoirs of Christina Queen of Sweden; in which M. d'Alembert showed that he was acquainted with the natural rights of mankind, and was bold enough to assert them. His Essay on the Intercourse of Men of Letters with persons high in Rank and Office, wounded the former to the quick, as it exposed to the eyes of the public the ignominy of those servile chains, which they feared to shake off, or were proud to wear. A lady of the court hearing one day the author accused of having exaggerated the deplorableness of the great, and the submission they require, answered illy, If he had confined me, I would have told him still more of the matter.

M. d'Alembert gave very elegant speciments of his literary abilities in his translation of some select pieces of Tacitus. But these occupations did not divert him from his mathematical studies; for about the same time he enriched the Encyclopædia with a multitude of excellent articles in that line, and composed his Researches on several important Points of the System of the World, in which he carried to a higher degree of perfection the solution of the problem of the perturbation of the planets, that had several years before been presented to the Academy.

In 1759 he published his Elements of Philosophy: a work exulted as remarkable for its precision and perspicuity; in which, however, are some tenets relative both to metaphysics and moral science, that are far from being admirable.

The remonstrance that was kindled (and the disputes that followed it) by the article Cenusus, inserted in the Encyclopædia,
ALEMBERT

Encyclopædie, he well known. M. d'Alembert did not leave this field of controversy with flying colours. Voltaire was an auxiliary in the contest; but as, in point of candour and decency, he had no reputation to lose; and as he weakened the blows of his enemies, by throwing both them and the speakers into fits of laughter, the issue of the war gave him little uneasiness. It fell more heavily on d'Alembert; and exposed him, even at home, to much contradiction and opposition.

It was on this occasion that the late king of Prussia offered him an honourable asylum at his court, and the place of president of his academy; and was not offended at his refusal of these distinctions, but cultivated an intimate friendship with him during the rest of his life. He had refused, some time before this, a proposal made by the empress of Russia to intrust him with the education of the Grand Duke:—a proposal accompanied with all the flattering offers that could tempt a man, ambitious of titles, or desirous of making an ample fortune; but the objects of his ambition were tranquillity and peace.

In the year 1765, he published his Differtation on the Distillation of the Jesuits. This piece drew upon him a swarm of adversaries, who confirmed the merit and credit of his work by their manner of attacking it.

Beside the works already mentioned, he published nine volumes of memoirs and treatises, under the title of Opuscula; in which he has solved a multitude of problems relative to astronomy, mathematics, and natural philosophy; of which our Panegyrist gives a particular account, more especially of those which exhibit new subjects, or new methods of investigation.

He published also Elements of Music, and rendered, at length, the system of Rameau intelligible; but he did not think the mathematical theory of the invariable body sufficient to account for the rules of that art. He was always fond of music; which, on the one hand, is connected with the most sublime and learned researches of rational mechanics; while, on the other, its power over the senses and the soul exhibits to philosophers phenomena no less singular and still more inexplicable.

In the year 1772 he was chosen secretary to the French academy. He formed, soon after this preferment, the design of writing the lives of all the deceased academicians, from 1700 to 1772; and in the space of three years he executed this design, by composing 70 eulogies.

M. d'Alembert died on the 29th of October 1783. There were many amiable lines of candour, modesty, dignity, and benevolence, in his moral character, which are described, with a diffusive detail, in his eulogy, by M. Condorcet, Histoire de l'Académie Royale des Sciences, 1783.

ALEMBIC, a chemical vessel usually made of glafs or copper, formerly used for distillation. The bottom part, which contained the subject for distillation, is called, from its shape, the conus; the upper part, which receives and condenses the steam, is called the head; the neck of which is fitted into the neck of a receiver. Retorts, and the common mors, are now generally employed.

ALEMBROTH, in the writings of the alchemists, a word used for a sort of fixed alkaline salt, which had the power of the famous alkahest, in dissolving bodies, opening the pores of most or all known substances, and thence, as well as by destroying sulphurs, promoting the separation of metals from their ores.—It is also used for a compound of corrosive mercury and sal ammoniac. See Chemistry.

ALENIO (Julius), a Jesuit, born at Brefcia in the republic of Venice. He travelled into the eastern countries; and arrived at Macao in 1610, where he taught mathematics. From thence he went to the empire of China, where he continued to propagate the Christian religion for thirty-six years. He was the first who planted the faith in the province of Xanfi, and he built several churches in the province of Fokien. He died in August 1649, leaving behind him several works in the Chinese language.

ALENTEJO, a province of Portugal, between the rivers of Tagus and Guadiana: the soil is very fertile, and the inhabitants laborious and industrious. The principal town is Évora.

ALENZON, a large handsome town of France, in lower Normandy, with the title of a duchy. It is surrounded with good walls, and flanked with towers. The castle was formerly a place of great consequence, and has held out long sieges. It has but one parish church, which has a bold and noble front. Among the nunneries, that of St Clair is most remarkable. It is seated on the river Sarte, in a vast open plain, which produces all sorts of corn and fruit. Near it there are quarries of stone fit for building, wherein are found a sort like Brtilot stones. The linen made at Alençon is very good, and sells at Paris. It is 20 miles north of Mans, 63 south-by-west of Rouen, and 88 south-west of Paris. W. Long. 9. 10. N. Lat. 48. 25.

ALEPPO, or HALAB, the capital of the Pachalic, and of all Syria; and the ordinary residence of the pacha, is situated in the vast plain which extends from the Orontes to the Euphrates, and which towards the south terminates in the desert. It is built on eight hills or eminences, on the highest of which the castle is erected, and is supposed to be the ancient Beram. This mount is of a conic form, and forms in a great measure to be raised with the earth thrown up out of a deep broad ditch which surrounds it. The suburbs to the north-north-east are next in height to this, and those to the west-north-west are much lower than the parts adjacent, and than any other part of the city. The houses are large and commodious, having terraces on their tops, and generally sky-lights in form of a dome to let the light into the rooms, which from their loftiness, the gliding on the window-shutters, cupboard-doors, &c. have at first entrance a very grand and agreeable effect. They are all so equal in height, that there are seldom any steps to ascend or descend in going from one house to another; while several large vaulted streets increase the facility of communication, by affording a passage to every part of the city free from the embarrassments of the open streets. They are carefully paved; have gutters and a foot-pavement on each side; and the middle of the street is laid with brick, the small end upwards, for the convenience of the horses. There is also a cleanliness observed here unknown to the other cities of Turkey, and which is not attended with the trouble of scavengers, there being
being ass-drivers who go about the city and take up the rubbish and dust, which each inhabitant is obliged to sweep together; and though the heat of the climate renders this labour more easy, the same heat obliges them to greater cleanliness, in order to preserve the salubrity of the air.

The mosques in Aleppo are numerous, and some few of them magnificent. Before each of them is an area, with a fountain in the middle, designed for ablutions before prayers; and behind some of the larger there are little gardens. There are many large khanis, or caravanseras, consisting of a capacious square, on all sides of which are a number of rooms, built on a ground-floor, used occasionally for chambers, ware-houses, or stables. Above these there is a colonade or gallery on every side, in which are the doors of a number of small rooms, wherein the merchants, as well strangers as natives, transact most of their business.

The bazaars or market-places are long covered narrow streets, on each side of which are a great number of small shops, just sufficient to hold the trademen and his goods, the buyer being obliged to stand without. Each separate branch of bazaars has a particular name, which is locked up, as well as the streets, an hour and a half after sun-set; but the locks are of wood, though the doors are cased with iron. The skeleton-houses are in the suburbs, open to the fields. The tanners have a khan to work in near the river. To the southward in the suburbs they burn lime; and a little beyond there is a village where they make ropes all year, of white glass, in the winter only; for the north is so cold as to make such work impossible.

The situation of Aleppo, besides the advantage of a rich and fruitful soil, polishes all that of a stream of fresh water, which never becomes dry. This rivulet, which is as large as that of the Gobelin at Paris, or the New River near London, rises in the mountains of Atabat, and terminates four leagues below Aleppo, in a morass full of wild boars and pelicans. Near Aleppo, its banks, instead of the naked rocks which cover them in the upper part of its course, are covered with a fertile earth, and laid out ill gardens, or rather orchards, which, in a hot country, and especially in Turkey, cannot but be delightful. The city is in itself one of the most agreeable in Syria, and is perhaps the cleanest and best built of any in Turkey. On whatever side it is approached, its numerous minarets and domes present an agreeable prospect to the eye, fatigue with the continued sameness of the brown and parched plains. In the centre is an artificial mountain surmounted by a dry ditch, on which is a ruinous fortress. From hence we have a fine prospect of the whole city, and to the north discover the snowly tops of the mountains of Balian; and on the west, those which separate the Orontes from the sea; while to the south and east, the eye can discern as far as the Ephrates. In the time of Omar, this castle stopped the progress of the Arabs for several months, and was at last taken by treachery, but at present would not be able to retch the feeble assails. Its flight wall, low, and without a battery, is ruin; its little old towers are in no better condition; and it has not four canons fit for service, not excepting a culverine nine feet long, taken from the Persians at the siege of Baibars. Three hundred and fifty Janisaries, who should form the garrison, are busy in their shops, and the aga strongly finds room in it to lodge his retinue. It is remarkable that this aga is named immediately by the Porte, which, ever suspicious, divides as much as possible the different offices. Within the walls of the castle is a well, which, by means of a subterraneous communication, derives its water from a spring a league and a quarter distant. In the environs of the city, we find a number of large square stones, on the top of which is a turban of stone, which are so many tombs. There are many rising grounds round it, which, in cafe of a siege, would greatly facilitate the approaches of the assailants. Such, among others, is that on which the house of the Derviches stands, and which commands the canal and the rivulet: Aleppo, therefore, cannot be esteemed a place of importance in war, though it be the key of Syria to the north; but, considered as a commercial city, it has a different appearance. It is the emporium of Armenia and the Parthians; sends caravans to Bagdad and into Persia; and communicates with the Persian Gulf and India, by Baibars, with Egypt and Mecca by Damascus, and with Europe by Skardaron (Alexandretta) and La-Takita. Commerce is there principally carried on by barter. The chief commodities are raw or spun cottons, clumsy linens fabricated in the villages; silk stuffs manufactured in the city, copper, boners (coarse cloths) like those of Rouen, goats hair brought from Nalolia; the gall nuts of the Kourdfán, the merchandise of India, such as fawls and mufkins, and parsley nuts of the growth of the neighbourhood. The articles supplied by Europe are the Languedoc cloths, cochineal, indigo, fugar, and some other groceries. The coffee of America, though prohibited, is introduced, and serves to mix with that of Mocha. The French have at Aleppo a confidant and seven counting-houses; the English and the Venetians two, and the merchants of Leghorn and Holland one. The emperor appointed a consul there in 1784, in the person of a rich Jew merchant, who shewed his beard to assume the uniform and the sword. Rose-filla has also lent one very lately. Aleppo is not exceeded in extent by any city in Turkey, except Constantinople and Cairo, and perhaps Smyrna. The number of in inhabitants has been computed at 200,000; but in these calculations certainty is impossible. However, if we observe that this city is not larger than Nantes or Markilles, and that the houses consist only of one storey, we shall perhaps not think it probable they exceed 100,000. The people of this city, both Turks and Christians, are with reason esteemed the most civilized in all Turkey; and the European merchant no where enjoy so much liberty, or are treated with so much respect.

The air of Aleppo is very dry and piercing, but at the same time very exhilarating for all who are not troubled with asthmatic complaints. The city, however, and the environs, are subject to a singular endemical disorder, which is called the ringworm or pimple of Aleppo; it is in fact a small white pimple behind a pimple, inflammatory, and at length becomes an ulcer of the size of the nail. The usual duration of this ulcer is one year;
it commonly fixes on the face, and leaves a fear which disfigures almost all the inhabitants. It is alleged that every stranger who resides there three months is attacked with it: experience has taught that the best mode of treatment is to make use of no remedy. No reason is assigned for this malady: but M. Volney suspects it proceeds from the quality of the water, as it is likewise frequent in the neighbouring villages, in some parts of the Diarbekar, and even in certain districts near Damascus, where the soil and the water have the same appearances. Of the Christian inhabitants the greater number are Greeks, next to them the Armenians, then the Syrians, and lastly the Maonies; each of whom have a church in the city called Hadela; in which quarter, and the parts adjacent, most of them reside. The common language is the vulgar Arabic, but the Turks of condition use the Turkish. Most of the Armenians can speak the Armenian, some few Syrians understand Syrian, and many of the Jews Hebrew; but scarce one of the Greeks understands a word of Greek. The people in general are of a middle stature, and tolerably well proportioned; but they seem neither vigorous nor active. Both sexes are handsome when young; but the beard soon disfigures the men: and the women, as they come early to maturity, also fade soon; females are generally married from 14 to 18 years of age, and many under 14. The people of rank here are polite and affable, making allowances for that superiority which the Mahometan religion inculcated to them over all who hold a different faith. Their bread is generally of wheat flour made into thin cakes, but very ill prepared, and is generally eaten as soon as it comes out of the oven. The principal people have some loaves of a finer flour, which are well fermented and baked. Besides these, there are a variety of biscuits, most of which are fried on the top with some kind of seeds. The Europeans have very good bread, baked and prepared in the French manner. All the inhabitants of both sexes smoke tobacco to great excess; even the very servants have almost constantly a pipe in their mouths. Coaches or carriages are not used here; therefore persons of quality ride on horseback in the city, with a number of servants walking before them, according to their rank: ladies of the first distinction are even compelled to walk on foot in the city, or to any place at a moderate distance; in longer journeys they are carried by mules, in a kind of a couch clove covered up. There are a number of public bagnios in this city, which are used by people of all ranks, except those of the highest distinction, who commonly have baths and every other convenience in their own houses. Aleppo is 70 miles east of Scandaron, on the sea-coast, and 175 north-by-east of Damascus. E. Long. 37. 40. N. Lat. 36. 12.

ALEPPO (the Pachalie of), one of the five governments into which Syria is divided. It comprehends the country extending from the Euphrates to the Mediterranean, between two lines, one drawn from Scandaron to Beer, along the mountains; the other from Beles to the sea, by Marsa and the bridge of Shogor. This space principally consists of two plains; that of Amtiach to the west, and that of Aleppo to the east; the north and the sea coast are occupied by considerably high mountains, known to the ancients by the names of Amanus and of Rhoüs. In general, the foil of this government is fat and loamy. The lofty and vigorous plants which shoot up everywhere after the winter rains prove its fertility, but its actual fruitfulness is but little. The greatest part of the lands lie waste; scarcely can we trace any marks of cultivation in the environs of the towns and villages. Its principal produce consists in wheat, barley, and cotton, which are found especially in the flat country. In the mountains, they rather choose to cultivate the vine, mulberry, olive, and fig trees. The sides of the hills towards the sea-coast are appropriated to tobacco, and the territory of Aleppo to piñacchios. The pastureage is not to be reckoned, because that is abandoned to the wandering hordes of the Turkmen and Curds.

In the greater part of the pachalics the pacha is, as his title imports, at once the viceroy and farmer general of the country; but in that of Aleppo he does not possess the latter office. This the Porte has bestowed on a mollah, or collector, who is immediately accountable for what he receives. His lease is only for a year. The present rent of his farm is 800 purses (above L.40,000); but to this must be added the price of the babouch (Turkish flippers), or a present of three or four thousand pounds, to purchase the favour of the vizir and men in office. For these two sums the farmer receives all the duties of the government; which are, first, The produce of import and export duties on merchandise coming from Europe, India, and Constantinople, and on that exported in exchange. Secondly, The taxes paid by the herds of cattle brought every year by the Turkmen and Curds from Armenia and the Diarbekar, to be sold in Syria. Thirdly, The fifth of the salt-works of Djeboul. And lastly, the mir, or land-tax. These united may produce about L.60,000.

The pacha, deprived of this lucrative branch of the administration, receives a fixed allowance of about L.800. This revenue has always been inadequate to the expenses; for, besides the troops he is obliged to maintain, and the repairation of the highways and fortresses, the expenses of which he is obliged to defray, he is under the necessity of making large pre­fents to the ministers, in order to keep his place; but the Porte adds to the account the contributions he may levy on the Curds and Turkmen, and his extortions from the villages and individuals; nor do the pachas come short of this calculation. Abdi Pacha, who governed 13 or 14 years ago, carried off, at the end of 15 months, upwards of L.160,000, by laying under contribution every trade, even the very cleaners of tobacco-pipes; and very lately another of the same name has been obliged to fly for similar oppressions. The former was rewarded by the divan with the command of an army against the Russians; but if the latter has not enriched himself, he will be strangled as an extortioner. Such is the ordinary progress of affairs in Turkey!

In consequence of such wretched government, the greater part of the pachalics in the empire are impoverished and laid waste. 1 his is the case in particular with that of Aleppo. In the ancient dejters, or regis­ters of impotts, upwards of 320 villages were reck­oned; but at present the collector can scarcely find 400. Such of our merchants as have resided there 20 years, have themselves seen the greater part of the environs
ALE

A town was of such antiquity, that Diodorus Siculus relates it was built by Hercules. It is supposed to be the city of Ales, in the duchy of Burgundy, not far from Dijon.

ALET, a town of France, in Lower Languedoc, with a bishop's see. It is remarkable for its baths, and for the grains of gold and silver found in the stream which runs from the Pyrenean mountains, at the foot of which it stands. It is seated on the river Aude, 15 miles S. of Carcassonne, and 37 N. W. of Narbonne. E. Long. 2. 5. N. Lat. 42. 59.

ALETRIS, in botany, a genus of the monogynia order, belonging to the hexandria class of plants, and in the natural method ranking under the 10th order, Coronarie. The characters are: The corolla is monopetalous, funnel-shaped, hexangular, much corrugated, feathery, and persistent: The stamina consists of six filaments, the length of the corolla, and infixed into the base of the divisions of the corolla; the anther are oblong and erect: The pistils has an ovate, white, and hairy stigma: The pericarp is an ovated capsule, triquetrous, pointed, and triocular: The seeds are numerous. Of this genus botanical writers enumerate five.

Species. 1. The farinosa, a native of Virginia, and other parts of North America. 2. The capensis, a native of the Cape of Good-Hope. 3. The hyacinthoides, or Guiana aloe. 4. The zeylanica, or Ceylon aloe. 5. The fragrans, or tree-aloe, a native of Africa. Of these only the first is so hardy as to outlive the winter in Britain, unless placed in a flower; and even this requires to be sheltered under a frame. The flowers appear in June or July, of a white-green colour. The third and fifth produce fine spikes of white flowers; those of the third kind appearing in July, of the fifth in March or April. By proper management the last kind becomes a flatly plant, rising to the height of 12 or 14 feet; the flowers open wide in the evening, and perfume the air of the flower. These breed out one or two heads, or tubers, towards their tops, which may be cut off; and after they have lain a week in the flower to heal the wounded parts, they may be planted for increase. The other species seldom or never flower in Britain, nor does their appearance otherwise merit notice.

ALIUM, or ALES, (anc. geog.), a town of Celtic Gaul, now extinct. From its ruins arose St. Malo, in Brittany, at the distance of a mile. Its ruins are called Lauch Aeth in the British.

ALEUROMANCY, the name with what was otherwise called alphtomantrix, and eridhomantia, and means an ancient kind of divination performed by means of meal or flour.

ALEXANDER THE GREAT, king of Macedonia. His father Philip laid the plan of that extensive empire, which his son afterwards executed. Philip, having made himself master of Greece, began to cast his eyes upon Persia, with a view to retaliate upon that haughty empire the injuries of former times. It was the popular topic of the day. But this prince was cut off in the midst of his enterprise. Such, however, was the influence of Alexander in the assembly of the Greek states, that he was created general of their combined forces in the room of his father. Having made every needful
Alexander needful preparation, at the head of a veteran army he invaded Asia. The lieutenants of Darius, who was then king of Persia, opposed him at the river Granicus, where Alexander obtained a complete victory; after which he pursued his march through Asia. At Ilius, near Scandereroon, he was met by Darius in person, at the head of a prodigious army. Here he obtained a second victory; and took the camp of Darius, together with his family, whom he treated with the utmost humanity. Contrary to all the maxims of war, instead of pursuing Darius, he made an excursion into Egypt; and, as far as appears, through no better motives than those of vanity. Here he was acknowledged to be the son of Jupiter Ammon. In the mean time Darius recruited his strength, and got together an army superior to what he brought into the plain of Ilius. Alexander having finished his Egyptian expedition, traversed Asia, and passed the Euphrates. At Arbela, a town in Assyria, he met Darius. Here a decisive battle was fought, which put all Persia into the hands of Alexander. His ambition not being satisfied with the conquest of that vast country, he projected an expedition into India. Here he met with great opposition from Porus, a gallant prince, whom in the end he reduced. Beyond the Ganges lay a country still unfrequented. He notified it to his army, that he proposed to pass the river: But these veterans, harried with the fatigues, and seeing no end of their labour, mutinied, and refused to march further. The disappointed chief was therefore obliged to return. At Babylon he proposed to receive ambassadors, appoint governors, and settle his vast monarchy; but his ex cesses put an end to his life in the midst of his dignity, and in the flower of his age.

The character of this hero is so familiar to every body, that it is almost needful to labour to draw it. All the world knows, says Mr. Bayle, that it was equally composed of very great virtues and very great vices. He had no mediocrity in any thing but his fate: in his other properties, whether good or bad, he was all extremes. His ambition rose even to madness. His father was not at all mistaken in supposing the bounds of Macedon too small for his son: for how could Macedon bound the ambition of a man, who reckoned the whole world too small a dominion? He wept at hearing the philosopher Anaxarchus say, that there was an infinite number of worlds: his tears were owing to his desire of conquering them all, since he had not yet been able to conquer one. Livy, in a short digression, has attempted to enquire into the events which might have happened, if Alexander, after the conquest of Asia, had brought his arms into Italy? Doubtless things might have taken a very different turn with him; and all the grand projects, which succeeded so well against an effeminate Persian monarch, might easily have miscarried if he had had to do with rough hardy Roman armies. And yet the vast aims of this mighty conqueror, if seen under another point of view, may appear to have been confined in a very narrow compass: since, as we are told, the utmost wish of that great heart; for which the whole earth was not big enough, was, after all, to be praised by the Athenians: for it is related, that the difficulties which he encountered in order to pass the Hydaspes, forced him to cry out, "O Athenians, could you believe to what dangers I expose myself for the sake of being celebrated by Alexander?" But Bayle affirms, that this was quite consistent with the vast unbounded extent of his ambition, as he wanted to make all future time his own, and be an object of admiration to the latest posterity. Yet did not expect this from the conquests of worlds, but from books. He was perfectly in the right, says Bayle; "for if Greece had not furnished him with good writers, he would long ago have been as much forgotten, as the kings who reigned in Macedon before Amphitryon."

Alexander has been praised upon the score of continuency, yet his life could not lurely be quite regular in that respect. Indeed the fire of his early youth appeared to cold towards women, that his mother supposed him to be impotent; and, to satisfy her self in this point, did, with the consent of Philip, procure a very handsome courtezana to lie with him, whose car redresses, however, were all to no purpose. His behaviour afterwards to the Persian captives shows him to have had a great command over himself in this particular. The wife of Darius was a finifhied beauty; her daughters likewise were all beauties; yet this young prince, who had them in his power, not only bestowed on them all the honours due to their high rank, but managed their reputation with the utmost delicacy. They were kept as in a cloyster concealed from the world, and secured from the reach of every dishonourable (not only attack, but) imputation. He did not give the least handle to scandal, either by his visits, his looks, or his words: and for other Persian dames his prifoners, equally beautiful in face and figure, he contented himself with paying gaily, that they gave indeed much pain to his eyes. The amoun Thalestris could not obtain from him a compliance with her gallant request till after a delay of thirteen days. In the mean time, what are we to conclude from his cauing his favourite mistres Pancrate to be drawn naked by Apelles, tho' it is true he gave her to the painter, who fell in love with her? What of that immoderate love of boys, which Athenæus relates of him? What of that prodigious number of wives and concubines which he kept?

His excesses with regard to wine were notorious, and beyond all imagination; and he committed, when drunk, a thousand extravagancies. It was owing to wine, that he killed Clytus who saved his life, and burnt Persepolis, one of the most beautiful places of the East: he did this last indeed at the instigation of the courtezana Thalestris; but this circumstance made it only the more heinous. It is generally believed, that he died by drinking immoderately; and even Plutarch, who affects to contradict it, owns that he did nothing but drink the whole day he was taken ill.

In short, to sum up the character of this prince, we cannot be of opinion, that his good qualities did in any way compensate for his bad ones. Heroes make a noise: their actions glare, and make the senses forcibly; while the infinite destruction and misery they occasion lies more in the shade, and out of sight. One good legislator is worth all the heroes that ever did or will exist. See Macedon.
Alexander, afterwards at Rome; but he devoted all the time he could spare to the study of polite literature; and at length he entirely left the bar, that he might lead a more easy and agreeable life with the muses. The particular of his life are to be gathered from his work intitled Genialiam Diarium: We are there informed that he lodged at Rome, in a house that was his mother's, and he relates many surprising particulars about the ghost; he lays also, that when he was very young, he went to the lectures of Philo analytics, who explained at Rome the Tuscanian questions of Cicero; he was there also when Nicholas Perot and Domitius Calderinus read their lectures upon Martial. The particular time when he died is not known; but he was buried in the monastery of the Olivets. Tirioque wrote a learned commentary upon his work, which was printed at Lyons in 1587, and reprinted at Leyden in 1673, with the notes of Dennis Godfrey, Christopher Colerus, and Nicholas Mercerus.

Alexander (Neckham), an eminent English writer in the 12th and 13th centuries, born at St. Albans in Hertsfordshire. In 1215 he was made abbot of Exeter, and died in 1227. He wrote several works, which were never published; but they are to be found in manuscript in the libraries of England and other countries.

Alexander (Noel), an indefatigable writer of the 17th century, born at Roan in Normandy, 1639. After finishing his studies at Roan, he entered into the order of Dominican friars, and was professed there in 1655. Soon after he went to Paris, to go through a course of philosophy and divinity in the great convent, where he distinguished himself so, that he was appointed to teach philosophy there, which he did for 12 years. Mr. Colbert showed him many marks of his esteem: and being determined to omit nothing to perfect the education of his son, afterwards archbishop of Roan, he formed an assembly of the most learned persons, whole conferences upon ecclesiastical history might be of advantage to him. Father Alexander was invited to this assembly, where he exerted himself with so much genius and ability, that he gained the hand of young Colbert, who showed him the utmost regard as long as he lived. These conferences gave rise to Alexander's design of writing an ecclesiastical history: for, being desirous to reduce what was material in these conferences to writing, he did it with so much accuracy, that the learned men who composed this assembly, advised him to undertake a complete body of church-history. This he executed with great assiduity, collecting and digesting the materials himself, and writing even the tables with his own hand. He at last completed his work in 1686. Towards the latter part of his life, he was afflicted with the loss of his sight; a most inexpressible misfortune to one whose whole pleasure was in study, yet he bore it with great patience and resignation. He died merely of a decay of nature, 1724, in the 84th year of his age.

Alexander Severus, emperor of Rome, succeeded Hellogabalus about A.D. 222, when but 16 years of age. His mother's name was Mammæa, and by her advice he in a great measure regulated his conduct. He applied himself to the reformation of abuses, the state having been greatly disorderly by the vicious conduct of his predecessor; he was a most strict lover of justice, an encourager of learning and learned men, and to Alexander vorable to the Christians. He made a successful expedition against the Persians; but endeavouring to reform his troops, which had grown very licentious under the late bad government, they murdered him at the instigation of Maximinus in the 29th year of his age, together with his uncle, A.D. 1,192.

Alexander VI. (Pope), had four ballards when he was cardinal, for one of which he had so great affection, that he stuck at nothing to raise him. Designing to poison some cardinals, he was poisoned himself, A.D. 1503. See Borgia.

Alexander VII. (Pope), See Chigi.

Alexander Bishop of Lincoln in the reigns of Henry I. and Stephen, was a Norman by birth, and nephew of the famous Roger, bishop of Salisbury, who first made him archdeacon of Salisbury, and afterwards, by his interest with the king, raised him to the nitre. Alexander was consecrated at Canterbury, July 22, 1123. Having received his education under his uncle, the bishop of Salisbury, and been accustomed to a splendid way of living, he affected show and state more than was suitable to his character, or consistent with his fortunes. This failing excepted, he was a man of worth and honour, and every way qualified for his station. The year after his consecration, his cathedral church at Lincoln having been accidentally burnt down, he rebuilt it, and secured it against the like accident for the future by a stone roof. This prelate increased the number of prebends in his church, and augmented its revenues with several manors and estates. In imitation of the barons and some of the bishops, particularly his uncle the bishop of Salisbury, he built three castles; one at Banbury, another at Sleaford, and a third at Newark. He likewise founded two monasteries; one at Haverholm, for regular canons and nuns together, the other at Tame for white-friars. He went twice to Rome in the years 1142 and 1144. The first time, he came back in quality of the pope's legate, for the calling a synod, in which he published several wholeome and necessary canons. In August 1147, he took a third journey to the pope, who was then in France; where he fell sick through the excessive heat of the weather, and returning with great difficulty to England, he died in the 24 year of his prelacy.

Alexander (William), earl of Stirling, an eminent Scots statesman and poet in the reigns of James VI. and Charles I. who, after travelling with the duke of Argyle as his tutor or companion, wrote a poetical complaint of his unsuccessful love of some beauty, under the title of Aurora. He then removed to the court of James VI. where he applied to the more solid parts of poetry, forming himself upon the plan of the Greek and Roman tragedians. In 1607, he published some dramatic performances, intitled The Monarchic Tragedies, dedicated to king James; who was so well pleased with them, as to call him his philosophical poet. After this, he is said to have written A Supplement to [duplicate text removed] the third part of Sir Philip Sidney's Arcadia; and in 1613, he produced a poem called Doomsday, or the Great Day of Judgement. He was made gentleman-at-arms to prince Charles, and master of the requites; was knighted; and obtained a grant of Nova Scotia, where he projected the settlement of a colony, but afterward sold it to the French. In 1626, he was made secretary of state for Scotland;
ALE

Alexander Scottland; was created first viscount, and then earl, of Stirling; and died in 1640.

ALEXANDER I. (St), whom St Ireneus reckons the fifth bishop of Rome, succeeded St Evarifrus in the year 119, and died in the year 119. There is no account of his life; and the epistles which are attributed to him are spurious.

ALEXANDER II. king of Scotland, succeeded his father William in 1213, at 16 years of age. He made an expedition into England, to oppose the tyranny of King John; who returned the visit, and was offered battle by Alexander, but refused it. He took the city of Carlisle from Henry III. which was afterwards exchanged for Berwick. Alexander died in 1249, in the 51st year of his age, and 35th of his reign; and left for his successor, his son—

ALEXANDER III. who was crowned king of Scotland in 1249. The Cummings, lords of Scotland, took arms against him; and taking him prisoner, confined him at Stirling; but he was afterwards released by his subjects. He married the daughter of Henry III. king of England; and was at length killed by a fall from his horse, on the 10th of April 1290, after having reigned 42, or according to others 37 years.

ALEXANDERS, in botany. See SMYRNA.

ALEXANDREA, (anc. geog.) a mountain of Mylia, on the sea-coast, forming a part of mount Ida, where Paris gave judgment on the three goddesses.

ALEXANDRETTA, by the Turks called Scanderon; a town in Syria, at the extremity of the Mediterranean sea. It is the port of Aleppo, from which it is distant 28 or 30 leagues. It is now, properly speaking, nothing else but a village, without walls, in which the tombs are more numerous than the houses, and which entirely owes its existence to the road which it commands. This is the only road, in all Syria, where vessels anchor on a solid bottom, without their cables being liable to chance; but in other respects it has many inconveniences. It is infested, during winter, by a peculiar wind, called by the French sailors le Regnier, which blowing from the snowy summits of the mountains, frequently forces ships to drag their anchors several leagues. And when the snow begins to cover the mountains which surround the Gulf, tempestuous winds arise which prevent vessels from entering for three or four months together. The road also to Aleppo by the plain is infested by Cud robbers, who conceal themselves in the neighboring rocks, and frequently attack and plunder the strongest caravans. But the worst circumstance is the extreme unwholesomeness of the air, occasioned here by stagnant waters and mephitic exhalations. It may be affirmed, that this every year carries off one-third of the crews of the vessels which remain here during the summer; nay, ships frequently lose all their men in two months. The fever for this epidemic disorder is principally from May to the end of September; it is an intermitting fever of the most malignant kind; and is accompanied with obstructions of the liver, which terminate in a dropsy. To this baneful epidemic, Alexan- dretta, from its situation, seems to be irremediably condemned: for the plain on which the town is built is low and flat, that the rivulets, finding no declivity, can never reach the sea. When they are swelled by the winter rains, the sea, swelled likewise by tempests, hinders their discharging themselves into it; whence their waters, forced to spread themselves, form lakes in the plain. On the approach of the summer, the waters becoming corrupted by the heat, exhale vapours equally corrupt, and which cannot disperse, being confined by the mountains that encircle the gulf. The entrance of the bay besides lies to the west, which in those countries is the most unhealthy exposure when it corresponds with the sea.

The labour necessary to remedy this would be immense; and after all insufficient; and, indeed, such an undertaking would be absolutely impossible under a government like that of the Turks. A few years ago, Mr Volney informs us, the merchants of Aleppo, disgusted with the numerous inconveniences of Alexandretta, wished to abandon that port and carry the trade to Latakia. They proposed to the Paşa of Tripoli to repair the harbour at their own expense, provided he would grant them an exemption from all duties for ten years. To induce him to comply with their request, the agents they employed talked much of the advantage which would, in time, result to the whole country:—

"But what signifies it to me what may happen in time," replied the Paşa? "I was yesterday at Marach; to-morrow, perhaps I shall be at Djedda: Why should I deprive myself of present advantages, which are certain, for future benefits I cannot hope to parake?" The European factors were obliged therefore to remain at Scanderoon. There are three of these factors, two for the French, and one for the English and Venetians. The only curiosity which they have to amuse strangers with consists in six or seven marble monuments, sent from England, on which you read: Here lies such a one carried off in the flower of his age, by the fatal effects of a contagious air. The sight of these is the more disfavouring, as the languid air, yellow complexion, livid eyes, and droptical bellies of those who show them, make it but too probable they cannot long escape the same fate. It is true, they have some reissue in the village of Baslan, the pure air and excellent waters of which surprizingly restore the sick. The sea, for some years past, has applied the duties of the cemetary of Alexandretta to his own use, and rendered himself almost independent of the Pacha of Aleppo. The Turkish empire is full of such rebels, who frequently die in peaceable possession of their usurpations.

ALEXANDRIA, now Scanderon, by Athanasius called Xpore; a city of Lower Egypt, and for a long time its capital. This city was built by Alexander the Great, soon after the overthrow of Tyre, about 333 years before Christ. It is situated on the Mediterranean, twelve miles west of that mouth of the Nile anciently called Ganapium; and lies in E. Long. 30° 19'. N. Lat. 31° 10'.

Alexander is said to have been induced to build this city, on account of its being conveniently situated for a fine port; and so sudden was his resolution, that after he had directed where every public structure was to be placed, fixed the number of temples, and the duties to whom they should be dedicated, &c. there were no instruments at hand proper for marking out the walls, according to the custom of those times. Upon this, a workman advised the king to collect what meal was among the soldiers, and to lift it 1: lines upon the ground, whereby the circuit of the walls would be sufficiently marked out. This advice was followed;
Alexandria and the new method of marking out the walls was, by Arifander, the king's tooth-filer, interpreted as a preface of the city's abounding with all the necessities of life. Nor was he deceived in his prediction; for Alexandria soon became the staple not only for merchandise, but also for all the arts and sciences of the Greeks. Alexandria was a league and a half long, third in breadth, which made the circumference of its walls about four leagues. Lake Maroitis bathed its walls on the south, and the Mediterranean on the north. It was intersected lengthwise by straight parallel streets. This direction left a free passage to the northerly wind, which alone conveys coolness and refreshment into Egypt. A street of 2000 feet wide began at the gate of the sea, and terminated at the gate of Canopus. It was decorated by magnificent houses, by temples, and by public buildings. In this extensive range the eye was never tired with admiring the marble the porphyry, and the obelisks, which were destined at some future day to embellish Rome and Constantinople. This street, the handomest in the universe, was intersected by another of the same breadth, which formed a square at their junction of half a league in circumference. From the middle of this great place, the two gates were to be seen at once, and vessels arriving under full sail from the north and from the south.

A mole of a mile in length stretched from the continent to the isle of Pharos, and divided the great harbour into two. That which is to the northward preserved its name. A dyke drawn from the isle to the rock whereon was built the Pharos, secured it from the westerly winds. The other was called Eunostus, or the Safe return. The former is called at present the new, the latter the old harbour: a bridge that joins the mole to the city, served for a communication between them. It was raised on lofty pillars sunk into the sea, and left a free passage for ships. The palace, which advanced beyond the promontory of Lochias, extended as far as the dyke, and occupied more than a quarter of the city. Each of the Ptolemies added to its magnificence. It contained within its inclosure, the museum, an asylum for learned men, groves and buildings worth in royal majesty, and a temple where the body of Alexander was deposited in a golden coffin. The infamous Seccacus Clybotes violated this monument, carried off the golden coffin, and put a glass one in its place. In the great harbour was the little island of Anti-Rhodes, where stood a theatre, and a royal palace of residence. Within the harbour of Eunoios was a smaller one, called Kibotos, dug by the hand of man, which communicated with Lake Mareotis by a canal. Between this canal and the palace was the admirable temple of Serapis, and that of Neptune near the great place where the market was held. Alexandria extended Likewise along the southern banks of the lake. Its eastern part preferred to view the gymnasium, with its porticoes of more than 606 feet long, supported by several rows of marble pillars. Without the gate of Canopus was a spacious circus for the chariot races. Beyond that, the suburb of Nicopolis ran along the sea-shore, and seemed a second Alexandria. A superb amphitheatres was built there with a race-ground, for the celebration of the quinquennalia.

Such is the description left us of Alexandria by the ancients, and above all by Strabo.

The architect employed by Alexander in this undertaking was the celebrated Dicosrates, who had acquired much reputation by rebuilding the temple of Diana at Ephesus. The city was first rendered populous by Ptolemy Soter, one of Alexander's captains, who, after the death of the Macedonian monarch, being appointed as governor of Egypt, assumed the title of king, and took up his residence at Alexandria, about 304 years before Christ.

In the 30th year of Ptolemy Soter's reign, he took his son Ptolemy Philadelphus partner with him in the empire; and by this prince the city of Alexandria was much embellished. In the first year of his reign the famous watch-tower of Pharos was finished. It had been begun several years before by Ptolemy Soter; and, when finished, was looked upon as one of the wonders of the world. The same year, the island of Pharos itself, originally seven forlongs distant from the continent, was joined to it by a cuteway. This was the work of Desiphanes, who completed it at the same time that his son put the last hand to the tower. The tower was a large square structure of white marble; on the top of which fires were kept constantly burning, for the direction of sailors. The building cost 800 talents; which, if Attic, amounted to L. 165,000 sterling, if Alexandrian, to twice that sum.

The architect employed in this famous structure fell upon the following contrivance to usurp the whole glory to himself.—Being ordered to engrave upon it the following inscription, "King PTOLEMY to the Gods the Saviours, for the benefit of Sailors;" instead of the king's name he substituted his own, and then filling up the hollow of the marble with mortar, wrote upon it the above-mentioned inscription. In process of time, the mortar being wore off, the following inscription appeared: "SOSTRATUS the CNIEN, the son of DEXIPHANES, to the Gods the Saviours, for the benefit of Sailors."

This year also was remarkable for the bringing of the image of Serapis from Pontus to Alexandria. It was set up in one of the suburbs of the city called Rhodos, where a temple was afterwards erected to his honour, suitable to the greatness of that fatal and wondrous city. At Alexandria it was called and worshipped there, Serapeum. This structure, according to Ammianus Marcellinus, surpassed in beauty and magnificence all others in the world, except the capital at Rome.

Within the verge of this temple was the famous Alexandrian library. It was founded by Ptolemy Soter, for the use of an academy he instituted in this city; and, by continual additions by his successors, became at last the finest library in the world, containing no fewer than 700,000 volumes. The method followed in collecting books for this library, was, to seize all those which were brought into Egypt by Greeks or other foreigners. The books were transcribed in the museum by persons appointed for that purpose; the copies were then delivered to the proprietors, and the originals laid up in the library. Ptolemy Euergetes, having borrowed from the Athenians the works of Sophocles, Euripides, and Eschylus, returned them only the copies, which he caused to be transcribed in as beautiful a manner as possible; presenting the Athenians at the same time with fifteen talents (upwards of L. 300 Sterling) for the exchange.
As the museum was at first in that quarter of the city called Bucchion, near the royal palace, the library was placed there likewise; but when it came to contain 400,000 volumes, another library, within the Serapeum, was erected by way of supplement to it, and on that account called the daughter of the former. In this second library 500,000 volumes, in process of time, were deposited; and the two together contained the 700,000 volumes already mentioned. In the war carried on by Julius Caesar against the inhabitants of this city, the library in the Bucchion, with the 400,000 volumes it contained, was reduced to ashes. The library in the Serapeum, however, still remained, and here Cleopatra deposited 200,000 volumes of the Pergaman library, which Marc Antony preferred her with. These, and others added from time to time, rendered the new library at Alexandria more numerous and considerable than the former; and though it was often plundered during the revolutions and troubles of the Roman empire, it yet was again and again repaired, and filled with the fame number of books.

For 253 years Alexandria was held in subjection by the Ptolemies. Here is a list of these princes, with the dates of their respective reigns:

- Ptolemy the son of Lagus, named Soter, reigned 29 years, and died in the year 3720. Ptolemy Philadiphus reigned 35 years, and died in 3758. Ptolemy Euergetes reigned 25 years, and died in 3783. Ptolemy Philopater reigned 17 years, and died in 3800. Ptolemy Epiphanes reigned 24 years, and died in 3824. Ptolemy Philometer reigned 37 years, and died in 3861. Ptolemy Euergetes, or Phylcon, reigned 13 years, part with his brother Philometer and part alone. He died in 3888. Ptolemy La-thyrus reigned 36 years six months. He died in 3923. Cleopatra, the daughter of Lathyrus and wife of Alex­ander I, reigned six months. Alexander I, the nephew of Lathyrus, was established in 3924 and died in 3943. Alexander II, the son of Alexander I, was dispossessed by the Alexandrians in 3939. Ptolemy Nothus, or Auletes, the son of Lathyrus, reigned 13 years, and died in 3953. Ptolemy, named Dion­y­sius or Bacehos, reigned three years eight months, and died in 3957. Cleopatra reigned from 3957, and killed herself in 3974.

This city, as we have already observed, soon became extremely populous, and was embellished both by its own princes and the Romans; but, like most other noted cities of antiquity, had been the seat of terrible massacres. About 141 years before Christ, it was almost totally depopulated by Ptolemy Phylcon. That barbarous monster, without the least provocation, gave free liberty to his guards to plunder his metropolis and murder the inhabitants at their pleasure. The cruelties practised on this occasion cannot be expressed; and the few who escaped were so terrified that they fled into other countries. Upon this, Phylcon, that he might not reign over empty houses, invited other strangers from the neighbouring countries; by whom the city was repeopled, and soon recovered its former splendor. On this occasion many learned men having been obliged to fly, proved the means of reviving learning in Greece, Asia Minor, the islands of the Archipelago, and other places, where it was almost totally lost.

The new inhabitants were not treated with much more kindness by Phylcon than the old ones had been; for, on their complaining of his tyrannical behavior, he resolved on a general massacre of the young men. Accordingly, when they were one day assembled in the gymnasium, or place of their public exercises, he ordered it to be set on fire; so that they all perished, either in the flames, or by the swords of his mercenaries, whom the tyrant had placed at all the avenues.

Though Julius Caesar was obliged to carry on a war for some time against the city, it seems not to have suffered much damage, except the burning of the library already mentioned. Before Caesar left Alexandria, in acknowledgment of the assistance he had received from the Jews, he confirmed all their privileges there, and even engraved his decree on a pillar of bract. This, however, did not prevent the massacre of 50,000 of them in this city about the year of Christ 67.

The city of Alexandria seems to have fallen into decay soon after this, and to have forfeited many of its ancient privileges, the for what offence is not known; but when Adrian visited Egypt, about the year 145, it was almost totally ruined. He repaired both the public and private buildings, not only restoring the inhabitants to their ancient privileges, but heaping new favours upon them; for which they returned him their solemn thanks, and conferred upon him what honours they could while he was present; but as soon as he was gone, they published the most bitter and virulent lampoons against him.

The jele and fatirical humour of the Alexandrians was highly disliked by Adrian, though he inflicted no punishment upon them for it; but when they lampooned Caracalla, he did not let them escape so easily. That tyrant, in the year 215, when he visited their city, having become the subject of their foolish satires, ordered a general massacre by his numerous troops, who were dispersed all over the city. The inhuman orders being given, all were murdered, without distinction of age or sex; so that in one night’s time the whole city was filled in blood, and every house was filled with carcasses. The monster who occasioned this had retired during the night to the temple of Serapis, to implore the protection of that deity; and, not yet satisfied with destruction, commanded the massacre to be continued all the next day; so that very few of the inhabitants remained. As if even this had not been sufficient, he stripped the city of all its ancient privileges; suppressed the academy; ordered all strangers who lived there to depart; and that the few who remained might not have the satisfaction of seeing one another, he cut off all communication of one street with another, by walls built for that purpose, and guarded by troops left there.

Notwithstanding this terrible disaster, Alexandria soon recovered its former splendor. Her大战 was murdered a short time after. It was long esteemed the first city in the world, next to Rome; and we may judge of its magnificence, and the multitude of people contained in it, from the account of Diodorus Siculus, who relates, that in his time (44 years before Christ) Alexandria had on its rolls 300,000 freemen. Towards the middle of the sixth century, Ammon Ibn el Aas, Omar’s general, took it by storm, after a siege
Alexandria of 14 months, and with the loss of 23,000 men. Heraclius, the emperor of Constantinople, did not send a single ship to its assistance. This prince affords an example very rare in history; he had displayed some vigour in the first year of his reign, and then suffered himself to be lull'd into idlenes and effeminacy. Awakened suddenly from his lethargy by the noise of the conquerors of Contra, that scourge of the east, he put himself at the head of his armies, distinguished himself as a great captain from his very first campaign, laid waste Persia for seven years, and returned to him capital covered with laurels: he then became a theologian on the throne, lost all his energy, and amused himself the rest of his life with disputing upon Monotheism, whilst the Arabs were robbing him of the finest provinces of his empire. Deaf to the cries of the unfortunate inhabitants of Alexandria, he had been too athe of the people of Jerusalem, who defended themselves for two years, he left them a sacrifice to the fortunate ascendency of the indefatigable Amrou. All their intrepid youth perished with their arms in their hands.

The victor, astonished at his conquest, wrote to the caliph, "I have taken the city of the west. It is of an immense extent. I cannot describe to you how many wonders it contains. There are 4000 palaces, 12,000 baths, 12,000 dealers in fresh oil, 12,000 gardeners, 40,000 Jews who pay tribute, 400 comedians," &c.

At this time according to the Arabian historians, Alexandria consisted of three cities, viz. Menna, or the port, which included Pharos, and the neighbouring parts; Alexandria, properly so called, where the modern Scanderia now stands; and Nektis, probably the Necropolis of Josephus and Strabo.

At that time John, surnamed the grammatian, a famous Peripatetic philosopher, living in the city, and in high favour with Amrou Ebn Al Aas the Saracen general begg'd of him the royal library. Amrou replied, that it was not in his power to grant such a requisit; but that he would write to the Khalif on that head; since without knowing his pleasure, he dared not to dispose of a single book. He accordingly wrote to Omar, who was then Khalif, acquainting him with the request of his friend: To which the ignorant tyrant replied, That if those books contain the same doctrine with the Koran, they could be of nought, for the Koran contained all necessary truths; but if they contained any thing contrary to that book, they ought not to be suffered: and therefore, whatever their contents were, he ordered them to be destroyed. Pursuant to this order, they were distributed among the public baths; where, for the space of six months, they served to supply the fires of those places of which there was an incredible number in Alexandria.

After the city was taken, Amrou thought proper to pursue the Greeks who had fled farther up the country; and therefore marched out of Alexandria, leaving but a very slender garrison in the place. The Greeks, who had before fled on board the ships, being apprised of this, returned on a sudden, surpriz'd the town, and put all the Arabs they found therein to the sword: but Amrou, receiving advice of what had happened, suddenly returned, and drove them out of it with great slaughter; after which the Greeks were frightened, that he had nothing farther to fear from them.—A few years after, however, Amrou being deprived of his government by the Khalif Othman, the Egyptians were so much displeased with his diminution that they inclined to a revolt; and Constantine the Greek emperor, having received intelligence of their dissatisfaction, began to meditate the reduction of Alexandria. For this purpose, he sent one Manuel, an eunuch, and his general, with a powerful army, to re-take that place; which, by the assistance of the Greeks in this city, who kept a secret correspondence with the imperial forces while at sea, and joined them as soon as they had made a descent, he effected, without any considerable effusion of Christian blood. The Khalif, now perceiving his mistake, immediately restored Amrou to his former dignity. This step was very agreeable to the natives; who having had experience of the military skill and bravery of this renowned general, and apprehending that they should be called to an account by the Greeks for their former perfidious conduct, had petitioned Othman to send him again into Egypt. Upon Amrou's arrival, therefore, at Alexandria, the Copts or natives, with the traitor Al-Mokawkas (who had formerly betrayed Amrou the forrers of Meid) at their head, not only joined him, but supplied him with all kinds of provisions, exciting him to attack the Greeks without delay. This he did; and, after a most obstinate dispute which lasted several days, drove them into the town, where, for some time, they defended themselves with great bravery, and repuls'd the utmost efforts of the besiegers. This so exasperated Amrou, that he swore, "If God enabled him to conquer the Greeks, he would throw down the walls of the city, and make it as easy of access as a bawdy-house, which lies open to every body." Nor did he fail to execute this menace; for having taken the town by storm, he quite dismantled it, entirely demolishing the walls and fortifications. The lives of the citizens, however, were spared, at least as far as lay in the general's power; but many of them were put to the sword by the soldiers on their first entrance. In one quarter particularly, Amrou found them butchering the Alexandrians with unrelenting barbarity; to which, however, by his reasonable interposition, he put a stop, and on that spot erected a mosque, which he called the "mosque of mercy."

From this time Alexandria never recovered its former splendor. It continued under the dominion of the Khalif's till the year 924, when it was taken by the Magrebians, two years after its great church had been destroyed by fire. This church was called by the Arabs Al Kasfara, or Caperna; and had formerly been a pagan temple, erected in honour of Saturn by the famous queen Cleopatra.

The city was soon after abandoned by the Magrebians; but in 928 they again made themselves masters of it: their fleet being afterwards defeated by that belonging to the Khalif, Abul Kafem, the Magrebian general retired from Alexandria, leaving there only a garrison of 300 men; of which Thosall, the Khalif's admiral, being apprised, he in a few days appeared before the town, and carried off the remainder of the inhabitants to an island in the Nile called Abukair. This was done, to prevent Abul Kafem from meeting with any entertainment at Alexandria, in case he should think proper to return. According to Eutychius, above 200,000...

Alexandria. 200,000 of the miserable inhabitants perished this year.

What contributed to raise Alexandria to such a prodigious height of splendor as it enjoyed for a long time, was its being the centre of commerce between the eastern and western parts of the world. It was with the view of becoming master of this lucrative trade, that Alexander built this city, after having extirpated the Tyrians, who formerly engrossed all the East-India traffic. Of the immense riches which that trade afforded, we may form an idea, from considering the Egyptians, especially the Alexandrians; and after the defeat of Zenobia, there was a single merchant of Alexandria who undertook to raise and pay an army out of the profits of his trade. The Greek emperors drew prodigious tributes from Egypt, and yet the caliphs found their subjects in good circumstances as to screw up their revenues to three hundred millions of crowns.

Though the revolutions which happened in the government of Egypt, after it fell into the hands of the Moors, and was frequently ravaged by different tribes, did not utterly extinguish Alexandria, yet it lost the excellence of its port, and the innumerable conveniences resulting from the East-India trade, to whomsoever were masters of Egypt, preferred Alexandria from total destruction, even when in the hands of the most barbarous nations. Thus, in the 13th century, when the barbarism introduced by the Goths, &c. began to wear off from the commerce, and they acquired a taste for the elegancies of life, the old mart of Alexandria began to revive; and the port, though far from recovering its former magnificence, grew once more famous by becoming the centre of commerce: but having fallen under the domination of the Turks, and the pillage round the Cape of Good Hope being discovered by the Portuguese in 1499, a fatal blow was given to the Alexandrian commerce, and the city has since fallen into decay.

At present the city of Alexandria is reckoned to have about 14,000 or 15,000 inhabitants; a strange colluvi of different nations, as well as from various parts of the Turkish empire. They are in general given to thieving and cheating; and (like their predecessors) seditions above all others, were they not kept in awe by the severity of their government. The British and French carry on a considerable commerce with them, and have each a consul residing here. Some Venetian ships also fail thither yearly, but with French colours, and under the protection of France. The subjects of those kingdoms which keep no consul here, are subject to a tax by the Grand Signior; but the Jews have found out the method of indemnifying themselves for this disadvantage; namely, by selling their commodities cheaper than other foreigners can afford. They are also favoured by the farmers of the revenue; who, knowing, that if they do not pay some private regard to them, the Jews have it their power to cause fewer merchandizes come into their port during the two years that their farm lasts.

The present city is a kind of peninsula situated between the two ports. That of the westward was called by the ancients the Portus Eunobius, now the Old Port, and is by far the best; Turkish vessels only are allowed to anchor there: the other, called the New Port, is for the Christians at the extremity of one of the arms of which stood the famous Pharos. The New Port, the only harbour for the Europeans, is clogged up with Alexandria sand, insomuch that in stormy weather ships are liable to bilge; and the bottom being also rocky, the cables from chafe and part; so that one vessel driving against a fagond, and that against a third, they are perhaps all lost. Of this there was a fatal instance 16 or 18 years ago, when 42 vessels were dashed to pieces on the mole in a gale of wind from the north-west, and numbers have been since lost there at different times. If it be asked, Why do they not repair the New Port? the answer is, That in Turkey they destroy every thing and repair nothing. The old harbour will be destroyed likewise, as the ballast of vessels has been continually thrown into it for the last 200 years. The spirit of the Turkish government is to ruin the labours of past ages, and destroy the hopes of future times, because the barbarity of ignorant despotsipem never considers to-morrow.

In time of war, Alexandria is of no importance; no fortification is to be seen; even the Farillon, with its lofty towers, cannot be deemed a great garrison. There is not a cannon fit for service, nor a gunner who knows how to point them. The 500 janizaries, who should form the garrison, reduced to half the number, know nothing but how to smoke a pipe. But Alexandria is a place of which the conquest would be of no value. A foreign power could not maintain itself there, as the country is without water. This must be brought from the Nile by the kalidj, or canal of 12 leagues, which conveys it thither every year at the time of the inundation. It fills the vaults or reservoirs dug under the ancient city, and this provision must serve till the next year. It is evident, therefore, that were a foreign power to take possession, the canal would be shut, and all supplies of water cut off. It is this canal alone which connects Alexandria with Egypt; for from its situation without the Delta, and the nature of the soil, it really belongs to the deserts of Africa. Its environs are sandy, flat, and sterile, without trees and without houses; where we meet with nothing but the plant which yields the kail, and a row of palm-trees which follows the course of the kalidj or canal.

The city is governed like others in the same kingdom. (See Egypt.) It has a small council of elders, part of which are Janizaries and Almifs; who are very haughty and insolent, not only to strangers, but to the mercantile and industrious part of the people, tho' ever so considerable and useful. The government is so remiss in favour of these wretches, that Mr Norden informs us, one of them did not hesitate to kill a farmer of the customs, for refusing to take lets of him than the duty imposed, and went off unpunished; it being a common salvo among them, that what is done cannot be undone.

The present condition of Alexandria is very deplorable, being now so far ruined, that the rubbish in many places overtops the houses. The famous tower of Pharos has long since been demolished, and a castle, called Farillon, built in its place. The caufway which joined the island to the continent is broken down, and its place supplied by a stone bridge of several arches.

Some parts of the old walls of the city are yet standing, and present us with a masonry-piece of ancient magnificence. They are flanked with large towers, about 200 paces distant from each other, with small ones in the middle.
Alexandria, middle. Below are magnificent censers, which may serve for galleries to walk in. In the lower part of the towers is a large square hall, whose roof is supported by thick columns of Thebaic stone. Above this are several rooms, over which there are platforms more than 20 paces square. The ancient reconverts, vaulted with so much art, which extend under the whole town, are almost entire at the end of 2000 years.

Of Caesar’s palace there remain only a few porphyry pillars, and the front, which is almost entire, and looks very beautiful. The palace of Cleopatra was built upon the walls facing the port, having a gallery on the outside, supported by several fine columns. Not far from this palace are two obelisks vulgarly called Cleopatra’s Needles. They are of Thebaic stone, and covered with hieroglyphics. One is overturned, broken, and lying under the sand; the other is on its pedestal. These two obelisks, each of them of a single stone, are about 60 feet high, by seven feet square at the base. Towards the gate of Rosetta, are five columns of marble on the place formerly occupied by the porticos of the Gymnasion. The rest of the colonnade, the design of which was discoverable 1600 years ago by Mallet, has since been destroyed by the barbarism of the Turks.

But what most engages the attention of travellers is the Pillar of Pompey, as it is commonly called, situated at a quarter of a league from the southern gate. It is composed of red granite. The capital is Corinthian, with palm leaves, and not indented. It is nine feet high. The shaft and the upper member of the base are of one piece of 90 feet long, and 0 in diameter. The base is a square of about 15 feet on each side. This block of marble, 60 feet in circumference, rests on two layers of stone bound together with lead; which, however, has not prevented the Arabs from forcing our several of them, to search for an imaginary treasure. The whole column is 144 feet high. It is perfectly well polished, and only a little flivered on the eastern side. Nothing can equal the majesty of this monument; from a distance, it overtops the town, and serves as a signal for vessels. Approaching it nearer, it produces an affonishment mixed with awe. One can never be tired with admiring the beauty of the capital, the length of the shaft, nor the extraordinary simplicity of the pedestal. This last has been somewhat damaged by the instruments of travellers, who are curious to posele a relic of this antiquity; and one of the volutes of the column was immediately brought down about 12 years ago, by a prank of some English captains, which is thus related by Mr. Irwin.

These jolly fons of Neptune had been pulling about the canoe on board one of the ships in the harbour, until a strange freak entered into one of their brains. The eccentricity of the thought occasioned it immediately to be adopted; and its apparent impossibility was but a spur for the putting it into execution. The boat was ordered; and with proper implements for the attempt, the seers exploring heroes pined away, to drink a bowl of punch on the top of Pompey’s pillar! At the spot they arrived; and many contrivances were proposed to accomplish the desired point. But their labour was vain; and they began to despair of success, when the genius who struck out the frolic happily fig-
ALEXANDRIA (anc. geog.), a city of Arachosia, called also Alexandria, on the river Arachosus (Stephanus, Iliodorus Characenus).—Another Alexandria in Geæroia, built by Leonatus, by order of Alexander (Pliny).—A third Alexandria in Aria, situated at the lake Arias (Poolemy), but, according to Pline, built by Alexander on the river Arias.—A fourth in the Bactriana (Pliny).—A fifth Alexandria, an inland town of Carmania (Pliny, Ptolemy, Ammian).—A sixth Alexandria, or Alexandria, in the Sogdiana (Iliodorus Characenus).—A seventh in India, at the confines of the Accanes and Indus (Arrian).—An eighth called also Alexandretta, near the finus Ilicus, on the confines of Syria and Cilicia, now Scanderbon (see Alexandria), the port-town to Aleppo. —A ninth Alexandria of Margiana, which being demolished by the barbarians, was rebuilt by Antiochus the son of Seleucus, and called Alexandria Julianopolis (Pliny, Arrian).—A twelfth Alexandria in Baœria, called Troas and Antigonia (Pliny).—A thirteenth on the Iaxartes, the boundary of Alexander's victories towards Scythia, and the left that he built on that side.

ALEXANDRIAN, in a particular sense, is applied to all those who professed or taught the sciences in the school of Alexandria. In this sense, Clesmus is denominated Alexandrinus, though born at Athens. The name was, however, claimed by Apion, who was born at Oasis, and Aretarchus, by birth a Samothracian. The chief Alexandrian philosophers were, Ameinocles, Plotinus,
ALEXANDRIA, the name given by the Moors to a fort of vermicelli, which they make of flour and water and are very fond of in their entertainments.

ALEF, in old Latin, a letter of the alphabet, which was represented by a triangle with a point downwards.

ALEXANDRIA, or Alexandria, in poetry, a kind of verse consisting of twelve, or of twelve and thirteen syllables alternately: so called from a poem on the life of Alexander, written in this kind of verse by some French poet. Alexandria is peculiar to modern poetry, and seem well adapted to epic poems. They are sometimes used by most nations of Europe; but chiefly in the French, whose tragedies are generally composed of Alexandrines.

ALEXICACUS, something that preserves the body from harm or mischief. The word amounts to the same as alexiterial.

ALEXIPHARMICS, in medicine, are properly remedies for expelling or preventing the ill effects of poison, but some of the moderns having imagined, that the animal spirits, in acute信息化, were affected by a malignant poison, the term has been understood to mean medicines adapted to expel this poison by the cutaneous pores, in the form of sweat. In this sense, alexipharmics are the same as sudorifics.

ALEXIS, a Piedmontese. There is a book of "Secrets," which for a long time has gone under his name. It was printed at Basl 1576, in 8vo, and translated from Italian into Latin by Wecker; it has also been translated into French, and printed several times with additions. There is a preface to the piece, wherein Alexis informs us, that he was born of a noble family; that he had from his most early years applied himself to study; that he learned the Greek, the Latin, the Hebrew, the Chaldee, the Arabian, and several other languages; that having an extreme curiosity to be acquainted with the secrets of nature, he had collected as much as he could during his travels for 57 years; that he piqued himself upon not communicating his secrets to any person; but that when he was 82 years of age, having seen a poor man who had died of a sickness which might have been cured had he communicated his secret to the surgeon who took care of him, he was touched with such a remembrance of confidence, that he lived almost like a hermit; and it was in this solitude that he ranged his secrets in such an order as to make them fit to be published. The hawksers generally carry them, with other books, to the country fairs. These, however, contain only the select remedies of Seignor Alexis of Piedmont; the entire collection would make too large a volume for them.

ALEXITERIAL, among physicians, a term of much the same import with alexipharmic; though some times used in a synonymous sense with amulet.

ALEYNE, (Charles), an English poet in the reign of Charles I. In 1631, he published two poems on the famous victories of Cressey and Poictiers. He succeeded his father as clerk of the ordnance, and was commissary general of the artillery to the king at the battle of Edgehill. The next piece he wrote was a poem in honour of Henry VII, and the victory that gained him the crown of England. In 1636, the year before he died, he translated the history of Eurialius and Lucretia, from the Latin epistles of Enneas Sylvius.

ALFANDIGA, the name of the customhouse at Lisbon.

ALFAQUES, among the Moors, the name generally used for their clergy, or those who teach the Mahometan religion; in opposition to the Morabites, who answer to monks among Christians.

ALFATERNA (anc. geogr.), the last town of Campania, beyond Vesuvius (Diodorus); the name with Nocera, which fce. The inhabitants Alfaferi, Piny.

ALFDOUGH, a name given by the Moors to a market town in Lincolnshire, with a market on Tuesdays for provisions and corn; and two fairs, on Whit-Tuesday, and November 8, for cattle and sheep. It is seated on a small brook that runs through the town, and is a compact place. A small spring was discovered here in 1670, from the pigeons which flew thither in great numbers to drink the water; those birds being known to be fond of salt. It contains a purging salt, together with a portion of sleet. It is strongly purgative. It is recommended as cooling, cleansing, and attenuating. As a good remedy in the scurvy, jaundice, and other glandular obstructions. It also promotes urine and sweat, and therefore is good in gravelly and other disorders of the kidneys and bladder; and in complaints arising from obstructed perspiration. Alford is six miles from the sea, and 20 N. of Boston. E. Long. 0. 13. N. Lat. 53. 30.
ALFRED, or Elfred, the Great, king of England, was the fifth and youngest son of Æthelwulf, king of the West Saxons, and was born at Wantage in Berkshire in 849. He distinguished himself, during the reign of his brother Ethelred, in several engagements against the Danes; and upon his death succeeded to the crown, in the year 871, and the 22d of his age. At his ascending the throne he found himself involved in a dangerous war with the Danes, and placed in such circumstances of distress as called for the greatest valour, resolution, and all the other virtues with which he was adorned. The Danes had already penetrated into the heart of his kingdom; and before he had been a month on the throne, he was obliged to take the field against these formidable enemies. After many battles gained on both sides, he was at length reduced to the greatest distress, and was entirely abandoned by his subjects. In this situation, Alfred, conceiving himself no longer a king, laid aside all marks of royalty, and took shelter in the house of one who kept his cattle. He retired afterwards to the Isle of Athelney, in Somersetshire, where he built a fort for the security of himself, his family, and a few faithful tenants who repaired thither to him. When he had been about a year in this retreat, having been informed that some of his subjects had routed a great army of the Danes, killed their chiefs, and taken their magical standard, he filled his letters, giving notice where he was, and inviting his nobility to come and confound with him. Before they came to a final determination, Alfred, putting on the image of a harper, went to the enemy's camp, where without suspicion, he was every where admitted, and had the honour to play before their princes. Having thereby acquired an exact knowledge of their situation, he returned in great secrecy to his nobility, whom he ordered to their respective homes, there to draw together each man as great a force as he could; and upon a day appointed there was to be a general rendezvous at the great wood, called Chipstead, in Wiltshire. This affair was transacted so secretly and expeditiously, that, in a little time, the king, at the head of an army, approached the Danes, before they had the least intelligence of his design. Alfred, taking advantage of the surprise and terror they were in, fell upon them, and totally defeat-ed them at Athelstane, now Eddington. Those who escaped fled to a neighbouring castle, where they were soon besieged, and obliged to surrender at discretion. Alfred granted them better terms than they could expect. He agreed to give up the whole kingdom of the Earl-Angles to such as would embrace the Christian religion, on condition they would oblige the rest of their countrymen to quit the island, and, as much as it was in their power, prevent the landing of any more foreigners. For the performance thereof he took hostages; and when, in pursuance of the treaty, Guthrum the Danish captain came, with thirty of his chief officers, to be baptized, Alfred answered for him at the font, and gave him the name of Æthelfrith; and certain laws were drawn up between the king and Guthrum for the regulation and government of the Danes settled in England. In 884, a fresh number of Danes landed in Kent, and laid siege to Rochester; but the king coming to the relief of that city, they were obliged to abandon their design. Alfred had now great success; which was chiefly owing to his fleet, an advantage of his own creating. Having secured the seas, he fortified the rest of the kingdom, with castles and walled towns; and he beleaguered and recovered from the Danes the city of London, which he resolved to repair, and keep as a frontier (a).

After some years respite, Alfred was again called into the field: for a body of Danes, being wonted in the west of France, came with a fleet of 200 vessels on the coast of Kent; and having landed, fixed themselves at Apple-tree; shortly after, another, fleet of 50 vessels coming up the Thames, the men landed, and built a fort at Middleton. Before Alfred marched against the enemy, he obliged the Danes, settled in Northumberland and Essex, to give him hostages for their good behaviour. He then moved towards the invaders, and pitched his camp between their armies, to prevent their junction. A great body, however, moved off to Essex; and crossing the river, came to Farnham in Surry, where they were defeated by the king's forces. Mean-while the Danes settled in Northumberland, in breach of treaty, and notwithstanding the hostages given, equipped two fleets; and, after plundering the northern and southern coasts, failed to Exeter, and besieged it. The king, as soon as he received intelligence, marched against them; but before he reached Exeter, they had got possession of it. He kept, them, however, blockaded upon all sides; and reduced them at last to such extremities, that they were obliged to eat their horses, and were even ready to devour each other. Being at length rendered desperate, they made a general rally on the besiegers;

(a) "This (says Sir John Spelman) was a banner with the image of a raven magically wrought by the three sisters of Hinguar and Hobba, on purpose for their expedition, in revenge of their father Lodmarch's murder, made, they say, almost in an instant, being by them at once begun and finished in an antiochite, and believed by the Danes to have carried great fatality with it, for which it was highly esteemed by them. It is pretended, that being carried in battle, towards an good success it would always seem to clap its wings, and make it if it would fly; but towards the approach of mischief, it would hang down and not move." Life of Alfred, p. 61.

The Danes had poisined themselves of London in the time of his father; and had held it till now as a convenient place for them to land at, and fortify themselves in; neither was it taken from them but by a close siege. However, when it came into the king's hands, it was in a miserable condition, scarce habitable, and all its fortifications ruined. The king, moved by the importance of the place, and the desire of strengthening his frontier against the Danes, restored it to its ancient splendor. And observing, that, through the confusions of the times, many, both Saxons and Danes, lived in a loose disordered manner, without owning any government, he offered them now a comfortable establishment, if they would submit and become his subjects. This proposition was better received than he expected; for multitudes growing weary of a vagabond kind of life, joyfully accepted such an offer. Chron. Sax. p. 89. .
The king's contrivance is thought to have produced the meadow between Hertford and Bow; for at Hertford was the Danish fort, and from thence they made frequent excursions on the inhabitants of London. Authors are not agreed as to the method the king purposed in laying dry the Danish ships: Dugdale supposes that he did it by straightening the channel; but Henry of Huntington alleges, that he cut several canals, which exhausted its water.
net-College library, at Cambridge. 3 *Instituta gueudem, lib. 1, Certain Institutes, in one book. This is mentioned by Pitts, and seems to be the second counterpart with Guthrum. 4. Contra judices iniquos, lib. 1. An Inveigle against Unjust Judges, in one book. 5. *Alta Magnificaturn fioron*, lib. 1. Acts of his Magnificates, in one book. This is supposed to be the book of judgments mentioned by Horne; and was, in all probability, a kind of reports, intended for the use of succeeding ages. 6. Regnum fortune variae, lib. 1. The various Fortunes of Kings, in one book. 7. Dier- ta feplentum, lib. 1. The Sayings of Wise Men, in one book. 8. Parabola et folus, lib. 1. Parables and pleasant sayings, in one book. 9. *Collectiones chroni- corum. Collections of Chronicles. 10. Epitome ad Wulf- figum Episcopum*, lib. 1. Epistles to Bishop Wulfigs, in one book. 11. *Manuale meditationum. A Manu- al of Meditations.* Besides these original works, he translated many authors from the Latin, &c. into the Saxon language, viz. 1. Bede's History of England. 2. Paulinus Orosius's History of the Pagans. 3. St Gregory's Fastoral, &c. The first of these, with his pauses, was published at London in 1644. The second, with his laws, were printed at Cambridge, 1644. His laws are likewise inferred in Spelman's Councils. 4. *Boetius de Confola- tione*, lib. V. Boetius's Consolations of Philosophy, in five books. Dr Plot tells us, king Alfred translated it at Woodstock, as he found in a MS. in the Cotton Library. 5. *Epopea Fabulae, Epope Fables*: he is said to have translated from the Greek both into Latin and Saxon. 6. *Pfalterium Davidicum, lib. I. David's Psalter, in one book. This was the last work the King attempted, death surprizing him before he had finished of May, 1764; and ordered his own mausoleum, with this inscription to be fixed upon it: *Hic jacet* a man whose root, leaf, and limbs are alone. Under this description are comprehended all the sea-weeds, and some other aquatic plants. In the sexual system, they constitute the 3rd order of the 24th class Cryptogamia; in Tournefort, the second genus of the second section, Marineae, aut fluviatiles, of the 17th class Alpinoe volgo habitae; and the 57th order in Linnaeus's Fragments of a Natural Method. The discoveries made in this part of the vegetable kingdom are uncertain and imperfect; and the attempts, in particular, to arrange flags by the parts of the fruitification, have not been attended with great success. Dillenius has arranged this order of plants from their general habit and structure; Michelius from the parts of fruitification.—Each has considerable merit.

**ALGAROIA**, a small sea-port town in the island of Corica, fortified with walls and bastions. It was almost destroyed by the mal-content in 1731, but has since been repaired. E. Long. 9. 45. N. lat. 42. 20.  

**ALGAROT**, in chemistry, an Arabic term for an emetic powder, prepared from regulus of antimony, dissolved in acids, and separated by repeated lotions in warm water.

**ALGAROTTI (Cont) a celebrated Italian, was born at Padua; but the year is not mentioned. Led by curiosity, as well as a desire of improvement, he travelled early into foreign countries; and was very young when he arrived in France in 1736. Here he composed his *Newtonian Philosophy for the Ladies,* as Fontenelle had done his Cartesian Astronomy, in the work entitled, *The plurality of worlds.* He was noticed by the king of Prussia, who gave him marks of the esteem he had for him. He died at Pisa the 23d of May, 1764; and ordered his own mausoleum, with this inscription to be fixed upon it: *Hic jacet* Alga- rotti, *rostis, fed non omnis.* He is allowed to have been a very great connoisseur in painting, sculpture, and architec- ture. He contributed much to the reformation of the Italian opera. His works which are numerous, and upon a variety of subjects, abound with vivacity, elegance, and wit: a collection of them has lately been made, and printed at Leghorn.

**ALGARVA**, a province in the kingdom of Por-ugal, 67 miles in length and 20 in breadth: bounded on the W. and S. by the sea, on the E. by the river Guadiana, and on the N. by Alentej. It is very fertile in figs, almonds, dates, olives, and excellent wines; besides, the fishery brings in large sums. The capital town is Pharo. It contains four cities, 12 towns, 67 parishes, and 61,000 inhabitants.

**ALGEBRA.** A method of computation, wherein signs and symbols, commonly the letters of the alphabet, are used to represent numbers, or any other quantities.

This science, properly speaking, is no other than a kind of shorthand, or ready way of writing down a chain of mathematical reasoning on any subject whatsoever; so that it is applicable to arithmetic, geometry, astronomy, menedication of all kinds of solids, &c. and the great advantages derived from it appear manifestly to arise from the conciseness and perspicuity with which every proposition on mathematical subjects can be written down in algebraic characters, greatly superior to the tedious circumlocutions which would be necessary were the reasoning to be written in words at length.

With regard to the etymology of the word *algebra*, it is much controverted by the critics. Menage derives it from the Arabic *algobaras,* which signifies the restitution of any thing broken; supposing that the principal part of *algebra* is the consideration of broken numbers. Others rather borrow it from the Spanish, *algebris,* a person who replaces dislocated bones; ad-
that algebra has nothing to do with fraction. Some, with M. d'Herbelot, are of opinion, that algebra takes its name from Geber, a celebrated philosopher, chemist, and mathematician, whom the Arabs call Giaber, and who is supposed to have been the inventor. Others from geber, a kind of parchment made of the skin of a camel, whereon Ali and Grifer Sakak wrote, in mystic characters, the fable of Mahometanism, and the grand events that were to happen till the end of the world. But others, with more probability, derive it from geber: a word whence, by prefixing the article al, we have formed algebra; which is pure Arabic, and properly signifies the reduction of fractions to a whole number. However, the Arabs, it is observed, never used the word algebra alone, to express what we mean by it; but always added to it the word macabelah, which signifies opposition and comparison: thus algebra-macabelah, is what we properly call algebra.

Some authors define algebra, The art of solving mathematical problems; but this is rather the idea of analysis, or the analytic art. The Arabs call it, The art of reflection and comparison; or, The art of resolution and equation. Lucas de Burgo, the first European who wrote of algebra, calls it, Regula rei et confit: that is, the rule of the root and its square; the root with them being called rei, and the square confit. Others call it Species Arithmetic; and some Universal Arithmetic.

It is highly probable that the Indians or Arabians first invented this noble art: for it may be reasonably supposed, that the ancient Greeks were ignorant of it; because Pappus, in his mathematical collections, where he enumerates their analysis, makes no mention of any thing like it; and, besides, speaks of a local problem, begun by Euclid, and continued by Apollonius, which none of them could fully resolve; which doubtless they might easily have done, had they known any thing of algebra.

Diaphantus was the first Greek writer of algebra; who published 13 books about the year 800, though only six of them were translated into Latin, by Xylander, in 1575; and afterwards, viz. anno 1721, in Greek and Latin, by M. Buchet and Ferret, with additions of their own. This algebra of Diophantus only extends to the solution of arithmetical indeterminate problems.

Before this translation of Diophantus came out, Lucas Paccilius, or Lucas de Burgo, a Minorite friar, published at Venice, in the year 1694, an Italian treatise of algebra. This author makes mention of Leonardus Piusius, and some others, of whom he had learned the art; but we have none of their writings. He adds, that algebra came originally from the Arabs, and never mentions Diophantus; which makes it probable that that author was not then known in Europe. His algebra goes no farther than simple and quadratic equations.

After Paccilius appeared Silfius, a good author; but neither did he advance any farther.

After him came Scipio Ferrarius, Cardan, Tartaglia, and some others, who reached as far as the solution of some cubic equations. Bombelli followed these, and went a little farther. At last came Nanneus, Ramus, Schoner, Salignac, Clavius, &c. who all of them took different courses, but none of them went beyond quadratics.

In 1590, Vieta introduced what he called his Species Arithmetic, which consists in denoting the quantities, both known and unknown, by symbols or letters. He also introduced an ingenious method of extracting the roots of equations, by approximations; since greatly improved and facilitated by Ralphson, Halley, Maclaurin, Simpson, and others.

Vieeta was followed by Oughtred, who, in his Clavis Mathematica, printed in 1621, improved Vieta's method, and invented several compendious characters, to show the sums, differences, rectangles, squares, cubes, &c.

Harriot, another Englishman, contemporary with Oughtred, left several treatises at his death; and among the rest, an Analysis, or Algebra, which was printed in 1631, where Vieta's method is brought into a still more commodious form, and is much esteemed to this day.

In 1657, Des Cartes published his geometry, where he made use of the literal calculus and the algebraic rules of Harriot; and as Oughtred in his Clavis, and Marin. Ghetaldus in his books of mathematical composition and resolution published in 1650, applied Vieta's arithmetic to elementary geometry, and gave the construction of simple and quadratic equations; so Des Cartes applied Harriot's method to the higher geometry, explaining the nature of curves by equations, and adding the contractions of cubic, biquadratic, and other higher equations.

Des Cartes's rule for constructing cubic and biquadratic equations, was farther improved by Thomas Baker, in his Clavis Geometriae Catholica, published in 1684; and the foundation of such contructions, with the application of algebra to the quadratures of curves, questions de maximis et minimis, the centrobaric method of Guldinus, &c. was given by R. Snellius, in 1668; as also by Fermat in his Opera Mathematica, Roberval in the Mem. de Math. et de Philos., and Barrow in his Lectiones, 17-8, algebra was applied to the laws of chance and gaming, by R. de Montmort; and since by de Moivre and James Bernoulli.

The elements of the art were compiled and published by Merian in 1671; and afterwards, inferius, &c. were applied to the solution of algebra to geometry; which defect is supplied by Guinée in a French treatise expressly on the subject published in 1704, and by Oughtred, in his Clavis Mathematica, published in 1665, which contains a variety of examples: the whole substance of Diophantus is here delivered, and many things added concerning mathematical composition and resolution from Ghetaldus. The like has been since done by Puffert in 1654, and by Oyama in 1703; but these authors omit the application of algebra to geometry; which defect is supplied by Guinée in a French treatise expressly on the subject published in 1704, and by Oughtred, in his Clavis Mathematica, published in 1665.

The rules of algebra are also comprehended by Sir Isaac Newton, in his Arithmetica Universalis, first published in 1707, which abounds in useful examples, and contains several rules and methods invented by the author.

Algebra has also been applied to the consideration and calculation of infinites; from whence a new and extensive branch of knowledge has arisen, called the Doctrine of Fluxions; or Analysis of Infinites, or the Calculus Differentials.
A QUANTITY which can be measured, and is the object of mathematics, is of two kinds, Number and Extension. The former is treated of in Arithmetic; the latter in Geometry.

Numbers are ranged in a scale, by the continued repetition of some one number, which is called the Root; and, in consequence of this order, they are conveniently expressed in words, and denoted by characters. The operations of arithmetic are easily derived from the established method of notation, and the most simple reasonings concerning the relations of magnitude.

Investigations by the common arithmetic are greatly limited, from the want of characters to express the quantities that are unknown, and their different relations to one another, and to such as are known. Hence letters and other convenient symbols have been introduced to supply this defect; and thus gradually has arisen the science of Algebra, properly called Universal Arithmetic.

In the common arithmetic too, the given numbers disappear in the course of the operation, so that general rules can seldom be derived from it; but, in algebra, the known quantities, as well as the unknown, may be expressed by letters, which, through the whole operation, retain their original form; and hence may be deduced, not only general canons for like cases, but the dependence of the several quantities concerned, and likewise the determination of a problem, without exhibiting which, it is not completely resolved. This general manner of expressing quantities also, and the general reasonings concerning their connections, which may be founded on it, have rendered this science not less useful in the demonstration of theorems than in the solution of problems.

If geometrical quantities be supposed to be divided into equal parts, their relations, in respect of magnitude, or their proportions, may be expressed by numbers; one of these equal parts being denoted by the unit. Arithmetic, however, is used in expressing only the conclusions of geometrical propositions; and it is by algebra that the bounds and application of geometry have been of late so far extended.

The proper objects of mathematical science are number and extension; but mathematical inquiries may be intituted also concerning any physical quantities that are capable of being measured or expressed by numbers and extended magnitudes: And, as the application of algebra may be equally universal, it has been called The science of quantity in general.

DEFINITIONS.

1. QUANTITIES which are known are generally represented by the first letters of the alphabet, as $a$, $b$, $c$, &c. and such as are unknown by the last letters, as $x$, $y$, $z$, &c.

2. The sign $+$ (plus) denotes, that the quantity before which it is placed is to be added. Thus $a+b$ denotes the sum of $a$ and $b$; $x+y$ denotes the sum of $x$ and $y$, or $8$. When no sign is expressed, $+$ is understood.

3. The sign $-$ (minus) denotes, that the quantity before which it is placed is to be subtracted. Thus $a-b$ denotes the excess of $a$ above $b$; $6-2$ is the excess of $6$ above $2$, or $4$. Note. These characters $+$ and $-$, from their extensive use in algebra, are called the signs; and the one is said to be opposite or contrary to the other.

4. Quantities which have the sign $+$ prefixed to them are called positive or affirmative; and such as have the sign $-$ prefixed to them are called negative.

5. Quantities which have the same sign, either $+$ or $-$, are also said to have like signs, and those which have different signs are said to have unlike signs. Thus $+a, +b$, have like signs, and $+a, -c$, are said to have unlike signs.

6. The juxtaposition of letters as in the same word, expresses the product of the quantities denoted by those letters. Thus $ab$ expresses the product of $a$ and $b$; $bc$ expresses the continued product of $b, c$, and $a$. The sign $+$ also expresses the product of any two quantities between which it is placed.

7. A number prefixed to a letter is called a numerable coefficient, and expresses the product of the quantity by that number, or how often the quantity denoted by the letter is to be taken. When no number is prefixed, unit is understood.

8. The quotient of two quantities is denoted by placing the dividend above a small line and the divisor below it. Thus $\frac{18}{3}$ is the quotient of $18$ divided by $3$, or $6$.

9. $\frac{a}{b}$ is the quotient of $a$ divided by $b$. This expression of a quotient is also called a fraction.

10. A quantity is said to be simple, which consists of one part or Term; as $a+a$, $-abc$; and a quantity is said to be compound, when it consists of more than one term connected by the signs $+$ or $-$. Thus $a+b$, $a-b+c$, are compound quantities. If there are two terms, it is called a binomial; if three, a trinomial, &c.

11. Simple quantities, or the terms of compound quantities, are said to be like, which consist of the same letter or letters, equally repeated. Thus $+ab$, $-5ab$, are like quantities; but $+ab$, and $+a$, are unlike.

12. The equality of two quantities is expressed, by placing the sign $=$ between them. Thus $x+y=z$, means that the sum of $x$ and $y$ is equal to the excess of $y$ above $z$.

When quantities are considered abstractly, then $+$ and $-$ denote addition and subtraction only, according to Def. 2. and 3. and the terms positive and negative express the same ideas. In that case, a negative quantity by itself is unintelligible. The sign $-$ also is unnecessary before simple quantities, or before the leading term of a compound quantity which is not negative; though, when such a quantity or term is to be added to another, $+$ must be placed before it, to express that addition; and hence in Def. 2. it is said, that $+$ is understood when no sign is expressed.
terms in the quantity to be added may be united, so as to render the expression in the sum more simple.

**PROB. II. To Subtract Quantities.**

General Rule. Change the signs of the quantity to be subtracted into the contrary signs, and then add it; so changed, to the quantity from which it was to be subtracted (by Prob. I.); and the sum arising by this addition is the remainder.

Examp. From $4a$ Subtract $3a$ $3ab-4mb$

Rem. $+2a$

From $5a-7b+9c+3$

Subt. $2a-4b+9c-d$

Rem. $3a-3b+8+d$

When a positive quantity is to be subtracted, the rule is obvious from Def. 3: In order to how it, when the negative part of a quantity is to be subtracted, let $e-d$ be subtracted from $a$, the remainder, according to the rule, is $a-e-d$. For if $e$ is subtracted from $a$, the remainder is $a-e$ (by Def. 3.); but this is too small, because $e$ is subtracted instead of $e-d$, which is less than it by $d$; the remainder therefore is too small by $d$; and $d$ being added, it is $a-e+d$; according to the rule.

Otherwise If the quantity $d$ is to be added to these two quantities $a$ and $e-d$, the difference will continue the same; that is, the excess of $a$ above $e-d$ is equal to the excess of $a+d$ above $e-d+d$; that is, to the excess of $a+d$ above $e$, which plainly is $a+d-e$, and is therefore the remainder required.

**PROB. III. To multiply Quantities.**

General Rule for the Signs. When the signs of the two terms to be multiplied are like, the sign of the product is +; but, when the signs are unlike, the sign of the product is -.

**Cafe 1.** To multiply two terms.

Rule. Find the sign of the product by the general rule; after it place the product of the numerical coefficients, and then set down all the letters one after another, as in one word.

| Mult. $+a$ | $+5b$ | $-5ax$ |
| By $+b$ | $-3e$ | $-7ab$ |
| $+ab$ | $-15bc$ | $+35abx$ |

The reason of this rule is derived from Def. 6, and from the nature of multiplication, which is a repeated addition of one of the quantities to be multiplied as often as there are units in the other. Hence also the letters in two terms multiplied together may be placed in any order, and therefore the order of the alphabet is generally preferred.

**Cafe 2.** To multiply compound quantities.

Rule. Multiply every term of the multiplicand by all the terms of the multiplier, one after another, according to the preceding rule, and collect all the products into one sum; that sum is the product required.

Examp.
The reason of that rule will appear by proving it, as applied to the last mentioned example of \( a-b \) multiplied by \( c-d \), in which every case of it occurs.

Since multiplication is a repeated addition of the multiplicand as often as there are units in the multiplier, hence, if \( a-b \) is to be multiplied by \( c-d \), \( a-b \) must be added to itself as often as there are units in \( c-d \), and the product therefore must be \( ca-cb-ad+db \) (Prop. I).

But this product is too great; for \( a-b \) is to be multiplied, not by \( c-d \), but by \( c-d \) only, which is the excess of \( a \) above \( b \) times \( c-d \) therefore, or \( ca-cb-ad+db \), has been taken too much; hence this quantity must be subtracted from the former part of the product, and the remainder, which (by Prop. II.) is \( ca-cb-ad+db \), will be the true product required.

Def. 13. The products arising from the continual multiplication of the same quantity are called the powers of that quantity, which is the root. Thus, \( aa, aaa, aaaa, \&c. \) are powers of the root \( a \).

14. These powers are expressed, by placing above the root, the right hand, a figure, denoting how often the root is repeated. This figure is called an index, or exponent, and from it the power is denominated. Thus,

\[
\begin{align*}
\text{Power of the root} & = a^n, \\
\text{where} & = \text{index, or exponent}.
\end{align*}
\]

The 2d and 3d powers are generally called the square and cube; and the 4th, 5th and 6th, are also sometimes respectively called the biquadrate, sest Hibatic, and subcubes.

Cor. Powers of the same root are multiplied by adding their exponents, Thus, \( a^1 \times a^2 = a^3 \), or \( aaa \times a = aaaa \), \( b^2 \times b^2 = b^4 \).

Scholium.

Sometimes it is convenient to express the multiplication of quantities, by letting down with the sign \( \times \) between them, without performing the operation according to the preceding rules; thus \( a \times b \) is written instead of \( a^1 \times b^1 \), and \( a-b \times c-d \) expresses the product of \( a-b \), multiplied by \( c-d \).

Def. 15. A vinculum is a line drawn over any number of terms of a compound quantity, to denote those which are understood to be affected by the particular sign connected with it.

Thus, in the last example, it shows that the terms \( +a \) and \( -b \), and also \( c \) and \( -d \) are all affected by the sign \( (\times) \). Without the vinculum, the expression \( a-b \times c-d \) would mean the excess of \( a \) above \( b \) and \( c \); and \( a-b \times c-d \) would mean the excess of the product of \( a-b \) by \( c-d \). Thus also \( a+b \) expresses the second power of \( a+b \), or the product of that quantity multiplied by itself; whereas \( a+b \) would express only the sum of \( a \) and \( b \); and so of others.

By some writers a parentheses ( ) is used as a vinculum, and \( a+b \) is the same thing as \( (a+b) \).
A L G E B R A.

Part I.

403

Rule 1. The terms of the dividend are to be ranged according to the powers of some one of its letters; and those of the divisor, according to the powers of the same letter.

Thus, if \( a^2 + 2ab + b^2 \) is the dividend, and \( a + b \) the divisor, they are ranged according to the powers of \( a \).

2. The first term of the dividend is to be divided by the first term of the divisor (observing the general rule of the signs); and this quotient being set down as a part of the quotient wanted, is to be multiplied by the whole divisor, and the product subtracted from the dividend. If nothing remain, the division is finished; the remainder, when there is any, is a new dividend.

Thus, in the preceding example, \( a^2 \) divided by \( a \), gives \( a \), which is the first part of the quotient wanted; and the product of this part by the whole divisor \( a + b \), viz. \( a^2 + ab \) being subtracted from the given dividend, there remains in this example \( ab + b^2 \).

3. Divide the first term of this new dividend by the first term of the divisor as before, and join the quotient to the part already found, with its proper sign: then multiply the whole divisor by this part of the quotient, and subtract the product from the new dividend; and thus the operation is to be continued till no remainder is left, or till it appear that there will always be a remainder.

Thus, in the preceding example, \( 4ab \), the first term of the new dividend divided by \( a \), gives \( b \); the product of which, multiplied by \( a + b \), being subtracted from \( ab + b^2 \), nothing remains, and \( a + b \) is the true quotient. The entire operation is as follows.

\[
\begin{align*}
  \frac{a^2 + 2ab + b^2}{a + b} &= a + ab + b^2, \\
  a + b &= a + b, \\
  ab + b^2 &= ab + b^2, \\
  &\quad \vdots \quad * \quad * \\
  3a^2 - b^2 &= 3a^2 - 12a^2 + 4a^3 + 3ab - 2b^3, \\
  &\quad \vdots \quad \vdots \quad \vdots \\
  &\quad \vdots \quad 1 - a = 1 + a + a^2 + a^3, & \text{&c.} \\
  1 - a &= 1 - a. \\
\end{align*}
\]

It often happens, as in the last example, that there is still a remainder from which the operation may be continued without end. This expression of a quotient is called an infinite series; the nature of which shall be considered afterwards. By comparing a few of the first terms, the law of the series may be discovered, by which, without any more division, it may be continued to any number of terms wanted.

Of the General Rule.

The reason of the different parts of this rule is evident; for, in the course of the operation, all the terms of the quotient obtained by it are multiplied by all the terms of the divisor, and the products are successively subtracted from the dividend till nothing remain: that, therefore, from the nature of division, must be the true quotient.

Note. The sign \(-\) is sometimes used to express the quotient of two quantities between which it is placed; Thus, \( a^2 + x^2 \div a + x \), expresses the quotient of \( a^2 + x^2 \) divided by \( a + x \).

§ 2. Of Fractions.

Definitions.

1. When a quotient is expressed by a fraction, the dividend above the line is called the numerator; and the divisor below it is called the denominator.

2. If the numerator is less than the denominator, it is called a proper fraction.

3. If the numerator is not less than the denominator, it is called an improper fraction.

4. If one part of a quantity is an integer, and the other a fraction, it is called a mixed quantity.

5. The reciprocal of a fraction, is a fraction whose numerator is the denominator of the other; and whose denominator is the numerator of the other. The reciprocal of an integer is the quotient of 1 divided by that integer. Thus, \( a \div b \) is the reciprocal of \( a \); and \( b \) is the reciprocal of \( m \).

The distinctions in Def. 2, 3, 4, properly belong to common arithmetic, from which they are borrowed, and are scarcely used in algebra.

The operations concerning fractions are founded on the following propositions:

If the divisor and dividend be either both multiplied or both divided by the same quantity, the quotient is the same; or, if both the numerator and denominator of the fraction be either multiplied or divided by the same quantity, the value of that fraction is the same.

Thus, let \( \frac{a}{b} = c \); then \( \frac{ma}{mb} = c \). For, from the nature of division, if the quotient \( \frac{a}{b} (= c) \) be multiplied by the divisor \( b \), the product must be the dividend \( a \). Hence \( \frac{a}{b} \times b = c \), and likewise \( \frac{ma}{mb} = c \), and dividing both by \( mb \), \( \frac{ma}{mb} = c \). Conversely, if \( \frac{ma}{mb} = c \), then also \( \frac{a}{b} = c \).

3 E 2  Cor.
Cor. 1. Hence a fraction may be reduced to another of the same value, but of a more simple form, by dividing both numerator and denominator by any common measure.

Thus, \[
\frac{30ax - 5a^2y}{12ab} = \frac{5x - 9y}{2b}.
\]

\[
\frac{8a^2 + 6bc}{4a^3} = \frac{a^2 + 3c}{2a}.
\]

Cor. 2. A fraction is multiplied by any integer, by multiplying the numerator, or dividing the denominator by that integer; and conversely, a fraction is divided by any integer, by dividing the numerator, or multiplying the denominator by that integer.

PROB. I. To find the greatest common Measure of two Quantities.

1. Of pure numbers.

Rule. Divide the greater by the less; and, if there is no remainder, the less is the greatest common measure required. If there is a remainder, divide the last divisor by it; and thus proceed, continually dividing the last divisor by its remainder, till no remainder is left, and the last divisor is the greatest common measure required.

The greatest common measure of 45 and 63 is 9; the greatest common measure of 187 and 391 is 17. Thus,

\[
\begin{array}{c|c}
45 & 63 \\
45 & 187 \\
18 & 391 \\
18 & 187 \\
9 & 187 \\
18 & 187 \\
0 & 0 \\
\end{array}
\]

From the nature of this operation, it is plain that it may always be continued till there be no remainder. The rule depends on the following principles:

1. A quantity which measures both divisor and remainder must measure the dividend.

2. A quantity which measures both divisor and dividend must also measure the remainder.

For a quantity which measures two other quantities, must also measure both their sum and difference; and, from the nature of division, the dividend consists of the divisor repeated a certain number of times, together with the remainder. By the first it appears, that the number found by this rule is a common measure; and, by the second, it is plain there can be no greater common measure: for, if there were, it must necessarily measure the quantity already found less than itself, which is absurd.

When the greatest common measure of algebraical quantities is required, if either of them be simple, any common simple divisor is easily found by inspection. If they are both compound, any common simple divisor may also be found by inspection. But, when the greatest compound divisor is wanted, the preceding rule is to be applied; only,

2. The simple divisors of each of the quantities are to be taken out, the remainders in the several operations are also to be divided by their simple divisors, and the quantities are always to be ranged according to the powers of the same letter.

The simple divisors in the given quantities, or in the remainders, do not affect a compound divisor which is wanted; and hence also, to make the division succeed, any of the divisors may be multiplied by a simple quantity. Besides the simple divisors in the remainders not being found in the divisors from which they arise, they may be divided by this operation.

Thus, the greatest common measure of \(8a^2b^2 - 10ab^3 + 2b^2\), and \(9a^4b - 9a^3b^2 + 3a^2b^3 - 3ab^4\). The simple divisors being taken out, viz. } 2b out of the first, it becomes \(4a - 5ab + b^3\); and } 2b out of the second, it is \(3a^2 - 3ab + b^2\). As the latter is to be divided by the former, it must be divided by \(a\), to make the operation succeed, and then it is as follows:

\[
\begin{align*}
a^2 - 5ab + b^2 & \quad 12a^2 - 12ab + 4b^2 - ab^3 \quad (3a) \\
& \quad 12a^2 - 15ab + 3b^2 \\
& \quad 3a^2 + 2b^3 - ab^2 \\
\end{align*}
\]

This remainder is to be divided by \(b\), and the new dividend multiplied by \(3\), to make the division proceed. Thus,

\[
\begin{align*}
3a^2 + ab - 4b^2 & \quad 12a^2 - 15ab + 3b^2 \quad (4) \\
& \quad 12a^2 + 4ab - 16b^2 \\
& \quad 19ab + 19b^2 \\
\end{align*}
\]

and this remainder, divided by \(19b\), gives \(a - b\), which being made a divisor, divides \(3a^2 + 4ab - 4b^2\) without a remainder, and therefore \(a - b\) is the greatest compound divisor: but there is a simple divisor \(b\), and therefore \(a - b\times b\) is the greatest common measure required.

PROB. II. To reduce a Fraction to its lowest Terms.

Rule. Divide both numerator and denominator by their greatest common measure, which may be found by prob. I.

Thus, \(75abc - 2\alpha^2\), \(25bc\) being the greatest common measure, \(a\), \(a^2\), \(a + b\) also,

\[
9a^2b - 9a^3b^2 + 3a^2b^3 - 3ab^2 = 9a^2 + 3ab^2 \quad 8a + 2b^2 \quad \text{the greatest common measure being } a - b \times b, \text{ by Prob. I.}
\]

PROB.
Part I. ALGEBRA.

Fundamental operations.

PROB. III. To reduce an Integer to the Form of a Fraction.

Rule. Multiply the given integer by any quantity for a numerator, and let that quantity under the product for a denominator.

Thus, \( \frac{ma}{n} \). \( a+\frac{b}{a-b} \). \( \frac{a^2-b^2}{2a} \).

Cor. Hence, in the following operations concerning fractions, an integer may be introduced; for, by this problem, it may be reduced to the form of a fraction. The denominator of an integer is generally made 1.

PROB. IV. To reduce Fractions with different Denominators to Fractions of Equal Value, that shall have the same Denominator.

Rule. Multiply each numerator, separately taken, into all the denominators but its own, and the products shall give the new numerators. Then multiply all the denominators into one another, and the product shall give the common denominator.

Example. Let the fractions be \( \frac{a}{b} \), \( \frac{c}{d} \); they are respectively equal to \( \frac{ad}{bd} \), \( \frac{bf}{df} \).

The reason of the operation appears from the preceding proposition; for the numerator and denominator of each fraction are multiplied by the same quantities; and the value of the fractions therefore is the same.

PROB. V. To add and subtract Fractions.

Rule. Reduce them to a common denominator, then add or subtract the numerators, and the sum or difference be over the common denominator is the sum or remainder required.

Ex. Add together \( \frac{2}{b} \), \( \frac{c}{d} \), the sum is \( \frac{ad+bf+bd}{bd} \).

From \( \frac{a}{b} \) sub. \( \frac{c}{d} \), the difference is \( \frac{ad-bc}{bd} \).

From the nature of division it is evident, that, when several quantities are to be divided by the same divisor, the sum of the quotients is the same with the quotient of the sum of the quantities divided by that common divisor.

In like manner, the difference of two fractions having the same denominator, is equal to the difference of the numerators divided by that common denominator.

Cor. 1. By Cor. Prob. 3, integers may be reduced to the form of fractions, and hence integers and fractions may be added and subtracted by this rule. Hence also what is called a mixt quantity may be reduced into the form of a fraction, by bringing the integral part into the form of a fraction, with the same denominator as the fractional part, and adding or subtracting the numerators as the two parts are connected by the signs + or -.

Thus, \( \frac{b}{d}+\frac{c}{d} \) and \( a-\frac{a^2-b^2}{2a} \) = \( \frac{2a^2-a^2+b^2}{2a} \).

Cor. 2. A fraction, whose numerator is a compound quantity, may be divided into parts, by dividing the numerator into several parts, and setting each over the original denominator, and uniting the new fractions (reduced if necessary) by the signs of their numerators.

Thus, \( \frac{a^2-2ab+b^2}{2a} \) \( a^2+ab+b^2 \) = \( \frac{a}{2a} \). \( \frac{a-b}{2a} \). \( \frac{a+b}{2a} \).

PROB. VI. To multiply Fractions.

Rule. Multiply their numerators into one another, to obtain the numerator of the product; and the denominators, multiplied into one another, shall give the denominator of the product.

Ex. \( \frac{a}{b} \), \( \frac{c}{d} \) \( \frac{ac}{bd} \) \( a+b \) \( \frac{a-b}{c} \) \( \frac{a^2-b^2}{c} \).

For, if \( \frac{a}{b} \) is to be multiplied by \( \frac{c}{d} \), the product is \( \frac{ac}{bd} \) but if it is to be multiplied only by \( \frac{a}{d} \) the former product must be divided by \( d \), and it becomes \( \frac{ac}{bd} \) (Cor. 2. to the preceding problem.)

Or, let \( \frac{a}{b} \equiv m \), and \( \frac{c}{d} \equiv n \). Then \( ac=bdm \), and \( ec=dam \), and \( ac-bd \equiv mn \). \( \frac{ac}{bd} \) = \( \frac{mn}{b} \).

PROB. VII. To divide Fractions.

Rule. Multiply the numerator of the dividend by the denominator of the divisor; their product shall give the numerator of the quotient. Then multiply the denominator of the dividend by the numerator of the divisor, and their product shall give the denominator.

Or, Multiply the dividend by the reciprocal of the divisor; the product will be the quotient wanted.

Thus, \( \frac{a}{b} \) \( \frac{c}{d} \) \( \frac{bc}{b} \) \( \frac{a}{d} \).

For, if \( \frac{c}{d} \) is to be divided by \( a \), the quotient is \( \frac{c}{ad} \) but \( \frac{c}{d} \) is to be divided, not by \( a \), but by \( \frac{a}{d} \), therefore the former quotient must be multiplied by \( b \), and it is \( \frac{bc}{ad} \).

Or, let \( \frac{a}{b} = m \), and \( \frac{c}{d} = n \); then \( ac=bdm \), and \( c=d \equiv n \) also \( ad=bdn \) and \( b=bd \); therefore \( \frac{b(\frac{c}{bd})}{ad} \). \( \frac{ac}{bd} \).

Scholium.

By these problems, the four fundamental operations may be performed, when any terms of the original quantities, or of those which arise in the course of the operation, are fractional.

Ex.-
Of Proportion. Example. 

\[
\text{Mult. } \frac{a^2}{2x} = \frac{3ax}{26},
\]

By \(ab = 4x\)

\[
\frac{a^2}{2x} = \frac{a^2}{2x} - 2a^2 + 6ax^2
\]

\[
a + x) (a + x) \frac{a^2}{2x} - 2x^2 - \frac{2x^2}{a}, \text{ &c.}
\]

\[
a + x
\]

\[
ax + x^2
\]

\[
2x^2
\]

\[
2x^2 + 2x^2
\]

\[
a
\]

\[
\frac{ax}{a}
\]

\[
\frac{2x^2}{a}
\]

\[
\frac{2x^3}{a^2}
\]

\[
+ 2x^4
\]

\[
a + x^2, \text{ &c.}
\]

This quotient becomes a series, of which the law of continuation is obvious, without any farther operation.

In such cases, when we arrive at a remainder of one term, it is commonly set down with the divisor below it, after the other terms of the quotient, which then becomes a mixed quantity. Thus the last quotient is also expressed by \(a - x + \frac{2x^3}{a + x}\).

\[\text{C H A P. II.} \]

Of Proportion.

By the preceding operations quantities of the same kind may be compared together.

The relation arising from this comparison is called ratio or proportion, and is of two kinds. If we consider the difference of the two quantities, it is called arithmetical proportion; and if we consider their quotient, it is called geometrical proportion. This last being most generally useful, is commonly called simply proportion.

1. Of Arithmetical proportion.

Definition. When of four quantities the difference of the first and second is equal to the difference of the third and fourth, the quantities are called arithmetical proportionals.

Cor. Three quantities may be arithmetically proportionals, by supposing the two middle terms of the four to be equal.

Prop. In four quantities arithmetically proportionals, the sum of the extremes is equal to the sum of the means.

Let the four be \(a, b, c, d\). Therefore from Def. \(a - b = d\); to these add \(b + d\) and \(a + d = b + c\).

\[\text{Cor. I. Of four arithmetical proportionals, any three being given, the fourth may be found.}\]

Thus, let \(a, b, c\), be the 1st, 2nd, and 4th terms, and let \(x\) be the third which is sought.

Then by Def. \(a + x = b + x\), and \(x = a + c - b\).

\[\text{Cor. II. If three quantities be arithmetical proportionals, the sum of the extremes is double of the middle term; and hence, of three such proportionals, any two being given, the third may be found.}\]

2. Of Geometrical Proportion.

Definition. If of four quantities, the quotient of the first and second is equal to the quotient of the third and fourth, these quantities are said to be in geometrical proportion. They are also called proportionals. Thus, if \(a, b, c, d\), are the four quantities, then \(\frac{a}{b} = \frac{c}{d}\), and their ratio is thus denoted \(a : b : c : d\).

Cor. Three quantities may be geometrical proportionals, viz. by supposing the two middle terms of the four to be equal. If the quantities are \(a, b, c\), then \(\frac{a}{b} = \frac{c}{d}\), and the proportion is expressed thus, \(a : b : c\).

Prop. I. The product of the extremes of four quantities geometrically proportionals is equal to the product of the means; and conversely.

Let \(a : b : c : d\).

Then by Def. \(\frac{a}{b} = \frac{c}{d}\);

and multiplying both by \(bd\), \(ad = bc\).

If \(ad = bc\), then dividing by \(bd\), \(\frac{a}{b} = \frac{c}{d}\); that is, \(a : b : c : d\).

Cor. 1. The product of the extremes of three quantities, geometrically proportional, is equal to the square of the middle term.

Cor. 2. Of four quantities geometrically proportional, any three being given, the fourth may be found.

Ex. Let \(a, b, c\), be the three first; to find the 4th. Let it be \(x\), then \(a : b : c : x\), and by this proposition, \(\frac{ax}{a} = \frac{bc}{d}\);

and dividing both by \(a\), \(x = \frac{bc}{a}\).

This coincides with the Rule of Three in arithmetic, and may be considered as a demonstration of it. In applying the rule to any particular case, it is only to be observed, that the quantities must be so connected and so arranged, that they be proportional, according to the preceding definition.

Cor. 3. Of three geometrical proportionals, any two being given, the third may be found.

Prop. II. If four quantities be geometrically proportional, then, if any equimultiples whatever be taken of the first and third, and also any equimultiples whatever of the second and fourth; if the multiple of the first be greater than that of the second, the multiple of the third will be greater than that of the fourth; and if equal, equal; and if less, less.

For, let \(a, b, c, d\), be the four proportionals. Of the
Part I.

**ALGEBRA.**

**Of Equations.**

The first and third, $ma$ and $mc$ may represent any equimultiples whatever, and also $nb$, $nd$, may represent any equimultiples of the second and fourth. Since $a : b : c : d$, $ad=bc$; and hence multiply by $mn$, $mnad=mc$, and therefore (Conv. Prop. 1.) $ma : nb : mc : nd$; and from the definition of proportionals, it is plain, that if $ma$ is greater than $nb$, $mc$ must be greater than $nd$; and if equal, equal; and if less, less.

Prop. III. If four quantities are proportionals, they will also be proportionals when taken alternately or inverely, or by composition, or by division, or by conversion. See Def. 13. 14. 15. 16. 17. of Book V. of Euclid, Simson's edition.

By Prop. II. they will also be proportionals according to Def. 5. Book V. of Euclid; and therefore this proposition is demonstrated by propositions 16, B. 18, 17, E. of the same book.

Otherwise algebraically.

Let $a : b : c : d$, and therefore $ad=bc$.

Altern. $a : c : b : d$

Invert. $b : a : d : c$

Divid. $a-b : b-c : d : c$

Comp. $a+b : b+c : c+d : d$

Convert. $a : a-b : c : c-d$

For since $ad=bc$, it is obvious, that in each of these cases the product of the extremes is equal to the product of the means; the quantities are therefore proportionals. (Prop. 1.)

Prop. IV. If four numbers be proportionals, according to Def. 5. B. V. of Euclid, they will be geometrically proportionals, according to the preceding definition.

1st. Let the four numbers be integers, and let them be $a, b, c, d$. Then if $b$ times $a$ and $b$ times $c$ be taken, and also $a$ times $b$ and $a$ times $d$, since $bc$ is the multiple of the first is equal to $ab$ the multiple of the second, $bc$ the multiple of the third, must be equal to $ad$ the multiple of the fourth. And since $bc=ad$, by Prop. 1. $a, b, c$, and $d$, must be geometrical proportionals.

2nd. If any of the numbers be fractional, all the four being multiplied by the denominators of the fractions, they continue proportionals, according to Def. 5. B. V. Euclid (by Prop. 4. of that book); and the four integer quantities produced being such proportionals, they will be geometrical proportionals, by the first part of this prop.; and therefore, being reduced by division to their original form, they manifestly will remain proportionals, according to the algebraical definition.

**CHAP. III.**

**SECT. I. Of Equations in general, and of the Solution of Simple Equations.**

**Definitions.**

1. Any Equation may in general be defined to be a proposition asserting the equality of two quantities; and is expressed by placing the sign $=$ between the quantities.

2. When a quantity stands alone upon one side of an equation, the quantities on the other side are said to be a value of it. Thus in the equation $x=4+y-d$, $x$ stands alone on one side, and $b+y-d$ is a value of it.

3. When an unknown quantity is made to stand alone on one side of an equation, and there are only known quantities on the other, that equation is said to be unsolved; and the value of the unknown quantity is called a root of the equation.

4. Equations containing only one unknown quantity and its powers, are divided into orders, according to the highest power of the unknown quantity to be found in any of its terms.

If the highest power of the unknown quantity is $1$, the unknown quantity is called a Simple Equation.

If the highest power of the unknown quantity is $2$, the equation is called a Quadratic.

If the highest power of the unknown quantity is $3$, the equation is called a Cubic, &c.

But the exponents of the unknown quantity are supposed to be integers, and the equation is supposed to be cleared of fractions, in which the unknown quantity, or any of its powers, enter the denominators.

Thus, $x^3-5=12$, when cleared of the fraction by multiplying both sides by $2x$, becomes $6x^4-10=24x$; a quadratic.

$x^3-2x^2+x=20$ is an equation of the fifth order, &c.

As the general relations of quantity which may be treated of in algebra, are almost universally either that of equality, or such as may be reduced to that of equality, the doctrine of equations becomes one of the chief branches of the science.

The most common and useful application of algebra is in the investigation of quantities that are unknown, from certain given relations to each other, and to such as are known; and hence it has been called the analytical art. The equations employed for expressing these relations must therefore contain one or more unknown quantities; and the principal business of this art will be, the deducing equations containing only one unknown quantity, and resoluing them.

The solution of the different orders of equations will be successively explained. The preliminary rules in the following section are useful in all orders, and are alone sufficient for the solution of simple equations.

§ 1. Of Simple Equations, and their Resolusion.

Simple equations are resolved by the four fundamental operations already explained; and the application of them to this purpose is contained in the following rules.

**Rule 1. Any equation may be transposed from one side of an equation to the other, by changing its sign.**

Thus, if $3x-10=2x+5$

Then, $3x-2x=10+5$ or $x=15$

Thus also, $5x+6=2x+2x$

By transp. $3x=-5$.

This rule is obvious from prob. 1. and 2.; for it is equivalent to adding equal quantities to both sides of the equation, or to subtracting equal quantities from both sides.

**Cor.**
Cor. The signs of all the terms of an equation may be changed into the contrary signs, and it will continue to be true.

Rule 2. Any quantity by which the unknown quantity is multiplied may be taken away, by dividing all the other quantities of the equation by it.

Thus, if \[ ax = b \]
\[ x = \frac{b}{a} \]

Also, if \[ mx + nb = am \]
\[ x = \frac{am - nb}{m} \]

For if equal quantities are divided by the same quantity, the quotients are equal.

Rule 3. If a term of an equation is fractional, its denominator may be taken away, by multiplying all the other terms by it.

Thus, if \[ \frac{ab + c}{x} \]
\[ x = \frac{ab + c}{a} \]

Also, if \[ \frac{x - c}{x} \]
\[ x = \frac{x - c}{b} \]

And by trans. \[ x = \frac{a}{b} \]

And by div. \[ x = \frac{a}{b} \]

For if all the terms of the equation are multiplied by the same quantity, it remains the true proposition.

Corollary to the three last Rules.

If any quantity be found on both sides of the equation, with the same sign, it may be taken away from both. (Rule 1.)

Also, if all the terms in the equation are multiplied or divided by the same quantity, it may be taken out of them all. (Rule 2 and 3.)

Ex. If \[ 3x + 4 = a + b, \] then \[ 3x = b. \]
If \[ 2ax + 3ab = am + a, \] then \[ 2x + 3b = m + a. \]

If \[ \frac{x - 4}{3} = \frac{16}{3} \]
then \[ x = 16. \]

Any simple equation may be resolved by these rules in the following manner. \( \frac{1}{2} \) All fractions may be taken away by R. 3. \( \frac{1}{2} \) All the terms including the unknown quantity, may be brought to one side of the equation, and the known terms to the other, by R. 1. \( \frac{1}{2} \) If the unknown quantity is multiplied by any known quantity, it may be made to stand alone by R. 2, and the equation will then be resolved. Def. 3.

**Examples of Simple Equations resolved by these Rules.**

**I.**

If \[ 3x + 5 = x + 9 \]
R. 1. \[ x = 4 \]
R. 2. \[ x = \frac{4}{2} = 2 \]

**II.**

If \[ 5x - 5x + x = 2x + 26 \]
R. 1. \[ x = \frac{26}{2} = 13 \]
R. 2. \[ 30x - 15x = 8x = 84 \]

§ 2. Solution of Questions producing Simple Equations.

From the resolution of equations we obtain the resolution of a variety of useful problems, both in pure mathematics and physics, and also in the practical arts founded upon these sciences. In this place, we consider the application of it to those questions where the quantities are expressed by numbers, and their magnitude alone is to be considered.

When an equation, containing only one unknown quantity, is deduced from the question by the following rules, it is sometimes called a final equation. If it be simple, it may be resolved by the preceding rules; but if it be of a superior order, it must be resolved by the rules afterwards to be explained. The examples in this chapter are so contrived, that the final equation may be simple.

The rules given in this section for the solution of questions, though they contain a reference to simple equations only, are to be considered as general, and as applicable to questions which produce equations of any order.

**General Rule.** The unknown quantities in the question proposed must be expressed by letters, and the relation of the known and unknown quantities contained in it, or the conditions of it, as they are called, must be expressed by equations. These equations being resolved by the rules of this science, will give the answer of the question.

For example, if the question is concerning two numbers, they may be called \( x \) and \( y \), and the conditions from which they are to be investigated must be expressible by equations.

Thus, if it be required that the sum of two numbers found by \( x + y = 60 \) be 60, that condition is expressed thus

If their difference must be 24, then \( x - y = 24 \)
If their product is 1640, then \( xy = 1640 \)
If their quotient must be 6, then \( \frac{x}{y} = 6 \)
If their ratio is as 3 to 2, then \( \frac{x}{y} = \frac{3}{2} \), and therefore \( 2x = 3y \)

These are some of the relations which are most easily expressible. Many others occur which are less obvious; but as they cannot be described in particular rules, the algebraical expression of them is best explained by examples, and must be acquired by experience.
Part I.

A distinct conception of the nature of the question, and of the relations of the several quantities to which it refers, will generally lead to the proper method of stating it, which in effect may be considered only as a translation from common language into that of algebra.

Case I. When there is only one unknown quantity to be found.

Rule. An equation involving the unknown quantity must be deduced from the question (by the general rule). This equation being resolved by the rules of the last section, will give the answer.

It is obvious, that, when there is only one unknown quantity, there must be only one independent equation contained in the question; for any other would be unnecessary, and might be contradictory to the former.

Examp. 1. To find a number, to which if there be added a half, a third part, and a fourth part of itself, the sum will be 50.

Let it be $z$; then half of it is $\frac{z}{2}$, a third of it $\frac{z}{3}$, &c. Therefore $2z + \frac{z}{3} + \frac{z}{4} = 50$.

If the operation be more complicated, it may be useful to register the several steps of it, as in the following.

Examp. 2. A trader allows L.100 per annum for the expences of his family, and augments yearly that part of his stock which is not so expended by a third of it; at the end of three years his original stock was doubled. What had he at first?

By R. 3.

By R. 1.

By R. 2.

Therefore his stock was L.1480; which being tried, answers the conditions of the question.

Case II. When there are two unknown quantities.

Rule. Two independent equations involving the two unknown quantities, must be derived from the question. A value of one of the unknown quantities must be derived from each of the equations; and these two values being put equal to each other, a new equation will arise, involving only one unknown quantity, and may therefore be resolved by the preceding rule.

Two equations must be deduced from the question: for, from one including two unknown quantities, it is plain, a known value of either of them cannot be obtained, more than two equations would be unnecessary; and if any third condition were affirmed at pleasure, most probably it would be inconsistent with the other two, and a question containing three such conditions would be absurd.

It is to be observed, however, that the two conditions, and hence the two equations expressing them, must be independent; that is, the one must not be deducible from the other by any algebraical reasoning: for, otherwise, there would in effect be only one equa-

Vol. I.
Examp. 4. A gentleman distributing money among some poor people, found he wanted 10£. to be able to give 5s. to each; therefore he gives each 4s. only and finds he has 45s. left. To find the number of shillings and poor people.

If any question such as this, in which there are two quantities sought, can be resolved by means of one letter, the solution is in general more simple than when two are employed. There must be, however, two independent conditions; one of which is used in the notation of one of the unknown quantities, and the other gives an equation.

Let the number of poor be $x$.

The number of shillings will be $y = x - 10$.

By 2 and 3.

The operation might be a little shortened by fabricating the 4th from 5th and thus $14 = y + z$; and hence $y = 21$. Therefore (by 6th) $x = (3y - 14) = 49$.

Examp. 5. A courier sets out from a certain place, and travels at the rate of 7 miles in 3 hours, and 8 hours after, another sets out from the same place, and travels the same road, at the rate of 5 miles in 3 hours. I demand how long and how far the first must travel before he is overtaken by the second.

Let the number of hours which the first travelled be $y$.

Then the second travelled $y + 8$.

The first travelled seven miles in 5 hours, and therefore in $y$ hours $3(5:7::y:z).$ 7 miles

In like manner the second travelled $5y - z$, miles.

But they both travelled the same number of miles; therefore by 3, and 4.

Malt.

The first then travelled $5y$ hours, the second ($y - 8 = z$) 42 hours.

The miles travelled by each $\left(\frac{7y}{5} = \frac{5y - 40}{3}\right) = 70$.

Examp. 7. To find a number consisting of three places, whose digits are in arithmetical proportion; if this number be divided by the sum of its digits, the quotient will be 48; and if from the number be subtracted 198, the digits will be inverted.

Let the 3 digits be $x, y, z$.

Then the number is $100z + 10y + x$.

If the digits be inverted, it is $100x + 10y + z$.

The digits are in ar. prop.

therefore $4x + z = 2y$.

By question $100x + 10y + z = 48$.

By question $x + y + z = 2y$.

From 6 and trans. $790x = 992 + 198$.

Divid. by 99 $8x = z + 2$.

From 4 $x = 2y - z$.

8 and 9 $10y - z = y + 2$.

Trans. $11y = 2y + 4$.

Malt. $5x + 10y + 5z = 48y + 48y + 48y$.

Trans. $52z = 38y + 47x$.

8 and 11 sub. $7x + 10y = 8y + 38 + 47z$.

Trans. $15y = 66$.

Divid. $16y = 2.6$.

The number then is 432, which succeeds upon trial.
Part I. A L G E B R A. 411

Of Equations. It sometimes happens, that all the unknown quantities, when there are more than two, are not in all the equations expressing the conditions, and therefore the preceding rule cannot be literally followed. The solution, however, will be obtained by such substitutions as are used in Ex. 7 and 9, or by similar operations, which need not be particularly described.

Corollary to the preceding Rules.

It appears that, in any question, there must be as many independent equations as unknown quantities; if there are not, then the question is called indeterminate, because it may admit of an infinite number of answers, since the equations wanting may be assumed at pleasure. There may be other circumstances, however, to limit the answers to one, or a precise number, and which, at the same time, cannot be directly expressed by equations. Such are the fact, that the numbers must be integers, squares, cubes, and many others. The solution of such problems, which are also called diophantine, shall be considered afterwards.

Scholium.

On many occasions, by particular contrivances, the operations by the preceding rules may be much abridged. This however, must be left to the skill and practice of the learner. A few examples are the following.

1. It is often easy to employ fewer letters than there are unknown quantities, by expressing some of them from a simple relation to others contained in the conditions of the question. Thus, the solution becomes more easy and elegant. (See Ex. 4. 5.)

2. Sometimes it is convenient to express by letters, not the unknown quantities themselves, but some other quantities connected with them, as their sum, difference, &c. while from which they may be easily derived. (See Ex. 1 of chap. 5.)

In the operation also, circumstances will suggest a more easy road than that pointed out by the general rules. Two of the original equations may be added together, or may be substracted; sometimes they must be previously multiplied by some quantity, to render such addition or subtraction effectual, in exterminating one of the unknown quantities, or otherwise promoting the solution. Substitutions may be made of the values of quantities, in place of quantities themselves, and various other such contrivances may be used, which will render the solution much less complicated. (See Ex. 3, 7 and 9.)

Sect. II. General Solution of Problems.

In the solutions of the questions in the preceding part, the given quantities (being numbers) disappear in the last conclusion, so that no general rules for like cases can be deduced from them. But if letters are used to denote the known quantities, as well as the unknown, a general solution may be obtained, because, during the whole course of the operation, they retain their original form. Hence also the connection of the quantities will appear in such a manner as to discover the necessary limitations of the data, when there are any, which is essential to the perfect solution of a problem. From this method, too, it is easy to derive a synthesis demonstration of the solution.

When letters, or any other such symbols, are employed to express all the quantities, the algebra is sometimes called literal or literal.

Examp. 8. To find two numbers, of which the sum and difference are given.

Let \( s \) be the given sum, and \( d \) the given difference. Also, let \( x \) and \( y \) be the two numbers sought.

\[
\begin{align*}
&x + y = s, \\
&x - y = d
\end{align*}
\]

Whence \[
\begin{align*}
x &= \frac{s + d}{2}, \\
y &= \frac{s - d}{2}
\end{align*}
\]

Thus, let the given sum be 124, and the difference 24. Then \( x = \frac{124 + 24}{2} = 74 \) and \( y = \frac{124 - 24}{2} = 50 \).

In the same manner may the canon be applied to any other values of \( s \) and \( d \). By reversing the steps in the operation, it is easy to show, that if \( x = \frac{s + d}{2} \) and \( y = \frac{s - d}{2} \), the sum of \( x \) and \( y \) must be \( s \), and their difference \( d \).

Examp. 9. If \( A \) and \( B \) together can perform a piece of work in the time \( a \), \( A \) and \( C \) together in the time \( b \), and \( B \) and \( C \) together in the time \( c \), in what time will each of them perform it alone?

Let \( A \) perform the work in the time \( x \), \( B \) in \( y \), and \( C \) in \( z \); then as the work is the same in all cases, it may be represented by unity.

\[
\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = \frac{1}{a} \cdot \frac{1}{b} + \frac{1}{c}
\]

By

\[
\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = \frac{1}{a} \cdot \frac{1}{b} + \frac{1}{c}
\]
## Algebra

**Of Equations.**

If particular values be inserted for these letters, a particular solution will be obtained for each case. Let them denote the numbers in Example 5.

Then \( x = \frac{gra}{qr - ps} = \frac{5 \times 5 \times 8}{5 \times 5 - 7 \times 3 - \frac{200}{4}} = 50 \).

Here it is obvious, that \( qr \) must be greater than \( ps \), else the problem is impossible; for then the value of \( x \) would either be infinite or negative. This limitation appears also from the nature of the question, as the second courier must travel at a greater rate than the first, in order to overtake him. For the rate of the first courier is to the rate of the second as \( x \) to \( y \), that is, as \( ps \) to \( qr \); and therefore \( qr \) must be greater than \( ps \).

**Scholium.**

Sometimes when there are many known quantities in a general solution, it may simplify the operation to express certain combinations of them by new letters, still to be considered as known.

**Of Involution and Evolution.**

### LE_\text{mma.}

The reciprocals of the powers of a quantity may be expressed by that quantity, with negative exponents of the same denomination. That is, the series \( a, \frac{1}{a}, \frac{1}{a^2}, \frac{1}{a^3}, etc. \), may be expressed by \( a^1, a^{-1}, a^{-2}, a^{-3}, etc. \)

For the rule for dividing the powers of the same root to subtract the exponents; if then the index of the divisor be greater than that of the dividend, the index of the quotient must be negative.

Thus, \( a^2 = a^{1-1} = a^{-1} \). Also, \( a^{1/2} = \frac{1}{a^{1/2}} \).

And, \( \frac{a^n}{b^n} = a^{n-m} = a^m \). And, \( \frac{a^m}{b^n} = a^{m-n} \), etc.

### Cor. 1.\text{ Hence any quantity which multiplies either the numerator or denominator of a fraction, may be transposed from one to the other, by changing the sign of its index.}

Thus, \( \frac{x}{y} = y \cdot x^{-1} \). And \( \frac{a^x}{y^1} = a^x \cdot y^{-1} \), etc.

### Cor. 2. From this notation, it is evident that these negative powers, as they are called, are multiplied by adding, and divided by subtracting their exponents.

Thus, \( a^{-1} \cdot a^{-1} = a^{-2} \). Or, \( \frac{1}{a^1} \cdot \frac{1}{a^1} = a^{-2} \).

Or, \( \frac{a^{-1}}{a^{-1}} = a^{-1} \). Or, \( \frac{a^{1/2}}{a^{1/2}} = a^{1/2} \).
Part I.

A L G E B R A.

I. Of Involution.

To find any power of any quantity is the business of involution.

Case 1. When the quantity is simple.

Rule. Multiply the exponents of the letters by the index of the power required, and raise the coefficient to the same power.

Thus, the 2d power of \( a^4 \) is \( a^{4\times2} = a^8 \).

The 3d power of \( 2a^4 \) is \( 8a^4 \times 3 = 8a^{12} \).

The 3d power of \( 3ab^4 \) is \( 27a^4 \times b^4 \times 3 = 27a^4b^4 \).

For the multiplication would be performed by the continued addition of the exponents; and this multiplication of them is equivalent. The same rule holds when the signs of the exponents are negative.

Rule for the signs. If the sign of the given quantity is \(+\), all its powers must be positive. If the sign is \( -\), then all its powers whose exponents are even numbers are positive; and all its powers whose exponents are odd numbers are negative.

This is obvious from the rule for the signs in multiplication.

The last part of it implies the most extensive use of the signs \(+\) and \( -\), by supposing that a negative quantity may exist by itself.

Case 2. When the quantity is compound.

Rule. The powers must be found by a continual multiplication of it by itself.

Thus, the square of \( x + a \) is found by multiplying it into itself. The product is \( x^2 + 2ax + a^2 \). The cube of \( x + a \) is got by multiplying the square already found by the root, &c.

Fractions are raised to any power, by raising both numerator and denominator to that power, as is evident for the rule for multiplying fractions in Chap. I. § 2.

The involution of compound quantities is rendered much easier by the binomial theorem; for which see Chap. VI.

Note. The square of a binomial consists of the squares of two parts, and twice the product of the two parts.

II. Of Evolution.

Evolution is the reverse of involution, and by it powers are resolved into their roots.

Def. The root of any quantity is expressed by placing before it \( \sqrt{\text{ }} \) (called a radical sign) with a small figure above it, denoting the denomination of that root.

Thus, the square root of \( a \), is \( \sqrt{a} \) or \( a^{\frac{1}{2}} \).

The cube root of \( bc \), is \( \sqrt[3]{bc} \).

The 4th root of \( a^b - b^a \), is \( \sqrt[4]{a^b - b^a} \).

The \( n \)th root of \( e^{ax} \) is \( e^{\frac{ax}{n}} \).

General Rule for the Signs.

1. The root of any positive power may be either positive or negative, if it is denominated by an even number; but if the root is denominated by an odd number, it is positive only.

2. If the power is negative, the root also is negative, when it is denominated by an odd number.

3. If the power is negative, and the denomination of the root even, then no root can be assigned.

This rule is easily deduced from that given in involution, and supposes the same extensive use of the signs \(+\) and \( -\). If it is applied to abstract quantities in which a contrariety cannot be supposed, any root of a positive quantity must be positive only; and any root of a negative quantity, like itself, is unintelligible.

In the last case, though no root can be assigned, yet sometimes it is convenient to set the radical sign before the negative quantity, and then it is called an impossible or imaginary root.

The root of a positive power, denominated by an even number, has often the sign \( = \) before it, denoting that it may have either \( + \) or \( - \).

The radical sign may be employed to express any root of any quantity whatever; but sometimes the root may be accurately found by the following rules; and when it cannot, it may often be more conveniently expressed by the methods now to be explained.

Case I. When the quantity is simple.

Rule. Divide the exponents of the letters by the index of the root required, and prefix the root of the numeral coefficient.

1. The exponents of the letters may be multiples of the index of the root, and the root of the coefficient may be extracted.

Thus, the square root of \( a^4 = a^2 = a^{\frac{2}{4}} \).

\( \sqrt{27a^9} = 3a^3 = 3a^{\frac{3}{1}} \).

\( \sqrt{a^{6b^2}} = a^{3b} \cdot b^{\frac{1}{2}} = \frac{3a^{3b}}{2} \).

2. The exponents of the letters may not be multiples of the index of the root, and then they become fractions; and when the root of the coefficient cannot be extracted, it may also be expressed by a fractional exponent, its original index being understood to be 1.

Thus, \( \sqrt[4]{16a^2b^2} = 4ab \).

\( \sqrt[3]{7ax^2} = \frac{7}{x} a^x = \frac{7}{2} x a^{\frac{1}{2}} \).

As evolution is the reverse of involution, the reason of the rule is evident.

The root of any fraction is found by extracting that root out of both numerator and denominator.

Case II. When the quantity is compound.

1. To extract the square root.

Rule. 1. The given quantity is to be ranged according to the powers of the letters, as in division.

Thus,
Thus, in the example \(a^2 + 2ab + b^2\), the quantities are ranged in this manner.

2. The square root is to be extracted out of the first term (by preceding rules), which gives the first part of the root fought. Subtract its square from the given quantity, and divide the first term of the remainder by double the part already found, and the quotient is the second term of the root fought.

Thus, in this example, the remainder is \(2ab + b^2\); and \(2ab\) being divided by \(2a\), the double of the part found, gives \(b\) for the second part of the root.

3. Add this second part to double of the first, and multiply their sum by the second part: Subtract the product from the last remainder, and if nothing remain, the square root is obtained. But, if there is a remainder, it must be divided by the double of the parts already found, and the quotient would give the third part of the root; and so on.

In the last example, it is obvious, that \(a+b\) is the square root fought.

The entire operation is as follows.

\[
\frac{a^2 + 2ab + b^2}{a^2} = 2a + b + \frac{2ab + b^2}{2a + b}
\]

\[
x^2 - ax + a' = \frac{x^2 - a}{2}
\]

\[
x^2 - 2ax + a^2 = \frac{x^2 - 2a + a^2}{4}
\]

\[
x^2 - 2ax + a^2 = \frac{x^2 - 2a + a^2}{4}
\]

\[
x^2 - 2ax + a^2 = \frac{x^2 - 2a + a^2}{4}
\]

The reason of this rule appears from the composition of a square.

2. To extract any other root.

Rule. Range the quantity according to the dimensions of its letters, and extract the said root out of the first term, and that shall be the first member of the root required. Then raise this root to a dimension lower by unity than the number that denominates the root required, and multiply the power that arises by that number itself. Divide the second term of the given quantity by the product, and the quotient shall give the second member of the root required—in like manner are the other parts to be found, by considering those already got as making one term.

Thus, the fifth root of

\[
a^5 + 5a^4b + 10a^3b^2 + 10a^2b^3 + 5ab^4 + b^5 = (a + b)
\]

\[
5a^4 + 5a^3b
\]

And \(a+b\) raised to the 5th power is the given quantity, and therefore it is the root fought.

In evolution it will often happen, that the operation will not terminate, and the root will be expressed by a series.

Thus, the square root of \(a^4 + x^4\) becomes a series.

\[
\sqrt{a^4 + x^4} = \frac{a^2 + x^2}{2a + x}
\]

\[
x^2 = \frac{x^2}{4a^2}
\]

\[
\sqrt{a^4 + x^4} = \frac{a^2 + x^2}{2a + x}
\]

The extraction of roots by series is much facilitated by the binomial theorem (Chap. vi. Sect. 3.) By similar rules, founded on the same principles, are the roots of numbers to be extracted.

III. Of Surds.

Def. Quantities with fractional exponents are called surds, or imperfect powers.

Such quantities are also called irrational; in opposition to others with integral exponents, which are called rational.

Surds may be expressed either by the fractional exponents, or by the radical sign, the denominator of the fraction being its index; and hence the orders of surds are denominated from this index.

In the following operations, however, it is generally convenient to use the notation by the fractional exponents.

\[
a^\frac{1}{2} = \sqrt{a}, \sqrt{4ab^2} = 2ab.
\]

The operations concerning surds depend on the following principle: If the numerator and denominator of a fractional exponent be both multiplied or both divided by the same quantity, the value of the power is the same. Thus \(a^m = a^n\); for let \(a^m = b\); then \(a^n = b^m\), and \(a^n = b^m\), and extracting the root \(n\), \(a^\frac{m}{n} = \frac{b^m}{b^n}\).

Lem. A rational quantity may be put into the form of a surd, by reducing its index to the form of a fraction of the same value.

\[
a^\frac{1}{2} = \sqrt{a}, a^\frac{3}{4} = \sqrt{a^3}.
\]

Prob. I. To reduce surds of different denominations to others of the same value and of the same denomination.

Rule.
Part I. 

ALGEBRA.

Rule. Reduce the fractional exponents to others of the same value and having the same common denominator.

Ex. \( \sqrt[3]{a^2} \), \( \sqrt[3]{b^3} \) or \( a^\frac{2}{3}, b^\frac{1}{3} \)

but \( a^\frac{1}{2} = \sqrt[2]{a} \) and \( b^\frac{1}{2} = \sqrt[2]{b} \).

therefore \( \sqrt[3]{a} \) and \( \sqrt[3]{b} \) are respectively equal to \( a^\frac{1}{3} \) and \( b^\frac{1}{3} \).

PROB. II. To multiply and divide surds.

1. When they are surds of the same rational quantity, add and subtract their exponents.

Thus, \( a^\frac{1}{2} \times a^\frac{1}{2} = a^{\frac{1}{2} + \frac{1}{2}} = a\sqrt{a} \)

\( \sqrt{a^2 - b^2} = \sqrt{a^2 - b^2} \)

\( a + b \) and \( a^\frac{1}{2} \times b^\frac{1}{2} = a^{\frac{1}{2}} b^{\frac{1}{2}} \)

\( \sqrt{a^2 - b^2} = \sqrt{a^2 - b^2} \)

\( a^\frac{1}{2} b^\frac{1}{2} = a^{\frac{1}{2}} b^{\frac{1}{2}} \)

If the surds have any rational coefficients, their product or quotient must be prefixed. Thus, \( a\sqrt{m} b\sqrt{n} = ab\sqrt{mn} \). It is often convenient, in the operations of this problem, not to bring the surds of simple quantities to the same denomination, but to express their product or quotient without the radical sign, in the same manner as if they were rational quantities. Thus, the product in Ex. 1. may be \( a^{\frac{1}{2}} b^{\frac{1}{2}} \), and the quotient in Ex. 3. \( a^\frac{1}{2} b^\frac{1}{2} \).

Cor. If a rational coefficient be prefixed to a radical sign, it may be reduced to the form of a surd by the lemma, and multiplied by the problem; and conversely, if the quantity under the radical sign be divisible by a perfect power of the same denomination, it may be taken out, and its root prefixed as a coefficient.

\( a\sqrt{b} = a\sqrt{b} \times 2 \times \sqrt{\frac{b}{2}} \)

\( \text{Conv. } a\sqrt{b} = ab \sqrt{\frac{b}{a}} \sqrt{\frac{a^2 - b^2}{b}} = 2a\sqrt{1 - \frac{b}{a}} \).

Even when the quantity under the radical sign is not divisible by a perfect power, it may be useful sometimes to divide surds into their component factors, by reversing the operation of this problem.

Thus \( \sqrt{a^2 - b^2} = \sqrt{a + b} \times \sqrt{a - b} \times \sqrt{\frac{b}{a + b}} \times \sqrt{\frac{a}{a - b}} \)

\( \times \sqrt{a + x} = \sqrt{a + x} \times \sqrt{a + x} \times \sqrt{a + x} \times \sqrt{a + x} \).

PROB. III. To involve or resolve Surds.

This is performed by the same rules as in other quantities, by multiplying or dividing their exponents by the index of the power or root required.

The notation by negative exponents, mentioned in the lemma at the beginning of this chapter, is applicable to fractional exponents, in the same manner as to integers.

Scholium.

The application of the rules of this chapter to the resolving of equations, shall be explained in the succeeding chapters, which treat of the solution of the different classes of them; but some examples of their use in preparing equations for a solution are the following.

If a member of an equation be a surd root, then the equation may be freed from any surd, by bringing that member first to stand alone upon one side of the equation, and then taking away the radical sign from it, and raising the other side to the power denominated by the index of that surd.

This operation becomes a necessary step towards the solution of an equation, when any of the unknown quantities are under the radical sign.

Example. If \( 3\sqrt{a^2 - x^2} = 3x = x + y \)

Then \( 3\sqrt{a^2 - x^2} = x + y \)

and \( 9\times \sqrt{a^2 - x^2} = x^2 - 2xy + y^2 \).

If the unknown quantity is found only under the radical sign, and only of the first dimension, the equation will become simple, and may be resolved by the preceding rules.

Thus, if \( \sqrt{4x^2 + 10x + 5} = 9 \)

Then \( \sqrt{4x^2 + 16x + 9} = 4 \)

And \( 4x + 16 = 4 \)

\( 4x = 48 \)

And \( x = 12 \).

If \( m\sqrt{a^2 - b^2} = x \)

Then \( a^\frac{1}{2} b^\frac{1}{2} x = a^\frac{m}{a^\frac{1}{2} b^\frac{1}{2}} \)

\( x \times \frac{a^m}{a^\frac{1}{2} b^\frac{1}{2}} \).

If the unknown quantity in a final equation has fractional exponents, by means of the preceding rules a new equation may be substituted, in which the exponents of the unknown quantity are integers.

Thus, if \( \sqrt{x^2 + 3x^2} = 10 \)

by reducing the surds to the same denomination, it becomes \( x^2 + 3x^2 = 10 \)

and if \( x = 2x^2 = 10 \); and if this equation be resolved from a value of \( x \), a value of \( x \) may be got by the rules of the next chapter. Thus, if \( x^2 + 2x^2 = 100 \)

If \( x^2 = z \), this equation becomes \( z^2 + 2z^2 = 100 \).

In general, if \( x^2 + x = a \), by reducing the surds to the same denomination \( \frac{a}{a^\frac{1}{2}} + \frac{x}{a^\frac{1}{2}} = a \), and if \( x = \frac{a}{a^\frac{1}{2}} \), then the equation is \( \frac{a}{a^\frac{1}{2}} + \frac{x}{a^\frac{1}{2}} = a \), in which the
EQUATIONS were divided into orders according to the highest index of the unknown quantity in any term. (chap. 3.)

Equations are either pure or affected.

Def. 1. A pure equation is that in which only one power of the unknown quantity is found.

2. An affected equation, is that in which different powers of the unknown quantity are found in the several terms.

Thus, \( a^2 + ax = b^2 \), \( ax - b \equiv x^2 \), \( ax - b \equiv m^2 + x^4 \) are pure equations.

And \( x^2 - ax = b^2, x^2 + x^4 = 17 \), are affected.

1. Solution of pure Equations.

Rule. Make the power of the unknown quantity to stand alone by the rules formerly given, and then extract the root of the same denomination out of both sides, which will give the value of the unknown quantity.

Examples.

If \( a^2 + ax^2 = b^2 \), \( ax^2 = b^2 - ax \), \( ax^2 - a^2 = b^2 - b \),

Then by Ex. 8, chap. 3.

The proportions are

\[ \frac{a + x}{2} : \frac{b + y}{2} : \frac{b - y}{2} : \frac{a - z}{2} \]

Mult. by 2 and still

\[ a + x : b + y : b - y : a - z \]

From the three first-

\[ a + x : b + y : b - y : a - z \]

From the three last-

\[ a + x : b + y : b - y : a - z \]

3d added to 4th

\[ 2ab - 2y = 2b + 2y \]

4th subtr. from 3d

\[ 2ab - 2y = 2b + 2y \]

6th reduced

\[ 2b + 2y \]

7th subtr. for \( z \) in 5th

\[ 2b + 2y \]

Transp. and divide 8th by \( \frac{5}{2} \)

\[ \frac{a + b}{2} \]

In numbers

\[ \frac{a + b}{2} \]

Hence the four proportionals are 5, 6, 2, 1; and it appears that \( b \) must be greater than \( a \), otherwise the root becomes impossible, and the problem would also be impossible; which limitation might be deduced also from prop. 25. V. of Euclid.

2. Solution of affected Quadratic Equations.

Affected equations of different orders are resolved by different rules, successively to be explained.

An affected quadratic equation (commonly called a quadratic) involves the unknown quantity itself, and also its square; it may be resolved by the following rules.

1. Transpose all the terms involving the unknown quantity to one side, and the known terms to the other; and so that the term containing the square of the unknown quantity may be positive.

2. If the square of the unknown quantity is multiplied by any coefficient, all the terms of the equation are to be divided by it, so that the coefficient of the square of the unknown quantity may be 1.

3. Add to both sides the square of half the coefficient of the unknown quantity itself, and the side of the equation involving the unknown quantity will be a complete square.

4. Extract.
Part I.

Equation. 4. Extract the square root from both sides of the equation, by which it becomes simple, and by transferring the abovementioned half coefficient, a value of the unknown quantity is obtained in known terms, and therefore the equation is resolved.

The reason of this rule is manifest from the composition of the square of a binomial, for it consists of the squares of the two parts, and twice the product of the two parts. (Note, at the end of Chap. IV.)

The different forms of quadratic equations, expressed in general terms, being reduced by the first and second parts of the rule, are these:

1. \( x^2 + ax = b^2 \)
2. \( x^2 - ax = b^2 \)
3. \( x^2 - ax = b^2 \)

Cafe 1. \( x^2 + ax + \frac{a^2}{4} = b^2 + \frac{a^2}{4} \)
\[ x + \frac{a}{2} = \sqrt{b^2 + \frac{a^2}{4}} \]
\[ x = \sqrt{b^2 + \frac{a^2}{4}} - \frac{a}{2} \]

Cafe 2. \( x^2 - ax + \frac{a^2}{4} = b^2 + \frac{a^2}{4} \)
\[ x - \frac{a}{2} = \sqrt{b^2 + \frac{a^2}{4}} \]
\[ x = \sqrt{b^2 + \frac{a^2}{4}} + \frac{a}{2} \]

Cafe 3. \( x^2 - ax = b^2 - \frac{a^2}{4} \)
\[ x - \frac{a}{2} = \sqrt{b^2 - \frac{a^2}{4}} \]
\[ x = \sqrt{b^2 - \frac{a^2}{4}} + \frac{a}{2} \]

Of these cases it may be observed,
1. That if \( a \) be supposed, that the square root of a positive quantity may be either positive or negative, according to the most extensive use of the signs, every quadratic equation will have two roots, except such of the third form, whose roots become impossible.
2. It is obvious, that in the two first forms, one of the roots must be positive, and the other negative.
3. In the third form, \( a \) or the square of half the coefficient of the unknown quantity, be greater than \( b^2 \), the known quantity, the two roots will be positive. If \( a \) be equal to \( b^2 \), the two roots then become equal.

But \( a \) in this third case \( \frac{a}{4} \) is less than \( b^2 \), the quantity under the radical sign becomes negative, and the two roots are therefore impossible. This may be easily shown to arise from an impossible supposition in the original equation.

4. If the equation, however, expresses the relation of magnitudes abstractly considered, where a contrariety cannot by supposition to take place, the negative roots cannot be of use, or rather there are no such roots:

Vol. I.

for then a negative quantity by itself is unintelligible, Equation, and therefore the square root of a positive quantity must be positive only. Hence, in the two first cases, there will be only one root; but in the third, there will be two. For in the third case, \( ax^2 = b^2 \), or \( ax = x^2 \), it is obvious that \( x \) may be either greater or less than \( a \), and yet \( x \) may be positive, and hence \( ax = x \) is also positive, and may be equal to a given positive quantity \( b^2 \); therefore the square root of \( x^2 = ax + b^2 \) may be either \( x + \frac{a}{2} \) or \( x - \frac{a}{2} \), and both these quantities also positive.

Let then \( x = \frac{a}{2} = \sqrt{b^2 - \frac{a^2}{4}} \), and hence \( x = \frac{a}{2} - \sqrt{b^2 - \frac{a^2}{4}} \), and these are the same two positive roots as were obtained by the general rule.

The general rule is usually employed, even in questions where negative numbers cannot take place, and then the negative roots of the two first forms are neglected. Sometimes one only even of the positive roots of the third case can be used, and the other may be excluded by a particular condition in the question. When an impossible root arises in the solution of a question, and if it be resolved in general terms, the necessary limitation of the data will be discovered.

When a question can be so stated as to produce a pure equation, it is generally to be preferred to an affected. Thus the question in the preceding section, by the most obvious notation, would produce an affected equation.

2. Solution of Questions producing Quadratic Equations.

The expression of the conditions of the question by equations, or the stating of it, and the reduction likewise of these equations, till we arrive at a quadratic equation, involving only one unknown quantity and its square, are effected by the same rules which were given for the solution of simple equations in Chap III.

Examp. 2. One lays out a certain sum of money in goods, which he told again for 24.24, and gained as much per cent. as the goods cost him: 1 demand what they cost him?

If the money laid out be \( x \), then \( x + \frac{x}{100} = 24.24 \), and \( x = \frac{24.24 \times 100}{101} \).

The gain will be \( \frac{x}{100} \), and \( x + \frac{x}{10} = 24.24 \).

Therefore by question

And by rule and \( \frac{24.24 \times 100}{101} \). Completing the square

Extr. the root

Transp.

The answer is 20, which succeeds. The other root, 120, has no place in this example, a negative number being here unintelligible.

Any quadratic equation may be resolved also by the general canons at the beginning of this section. That
By inferring numbers, \( x = 71 \) or 29 and \( a - x = 29 \) equations, or 71, so that the two numbers sought are 71 and 29. Hence it is to be observed, that \( b \) must not be greater than \( a' \), else the roots of the equation would be impossible; that is, the given product must not be greater than the square of half the given sum of the numbers sought. This limitation can easily be shown from other principles; for, the greatest possible product of two parts, into which any number may be divided, is when each of them is a half of it. If \( b \) be equal to \( a' \), there is only one solution, and \( x = \frac{a}{2} \), also \( a - x = \frac{a}{2} \).

Example 5. There are three numbers in continual geometrical proportion. The sum of the first and second is 10, and the difference of the second and third is 24. What are the numbers?

Let the first be \( x \), the second will be \( 2(x - x^2) \), and the third \( \frac{34 - x}{2} \).

Since \( x + 10 = z \):
\[
\begin{align*}
4x^2 - 20x + 100 &= 34z - 2^2 \\
\text{Transp.} & \\
2z^2 - 54z &= -100 \\
\text{Divid.} & \\
6z^2 - 27z &= -50 \\
\text{Comp., the square} & \\
7z^2 - 27z + \frac{27^2}{2} &= \frac{27^2}{4} - 50 = \frac{529}{4} \\
\text{Extract the \( \sqrt{\frac{529}{4}} \)} & \\
8z - 27 &= \frac{23}{2} \\
\text{Transp.} & \\
9z &= 27 - \frac{23}{2} = 25 \text{ or } 2.
\end{align*}
\]

But though there are two positive roots in this equation, yet one of them only can here be of use, the other being excluded by a condition in the question. For as the sum of the first and second is 10, 25 cannot be one of them; 2 therefore is the first, and the proportional will be 2, 8, 32.

This restriction will also appear from the explanation given of the third form, to which this equation belongs. For \( z \) may be less than \( \frac{27}{2} \), but from the first condition of the question it cannot be greater; hence the quantity \( x - 27z + \frac{27^2}{2} \) can have only one square root, viz. \( \frac{27 - z}{2} \); and this being put equal to \( \sqrt{\frac{529}{4}} \), we have by transposition \( z = \frac{27 - 23}{2} = 2 \), which gives the only just solution of the question.

From the other root, indeed, a solution of the question may be represented by means of a negative quantity. If the first then be 25, the three proportional will be 25, -15, 9. These also must answer the conditions, according to the rules given for negative quantities, though such a solution has no proper meaning.

Besides, it is to be observed, that if the following question be proposed, 'To find three numbers in geometrical proportion, so that the difference of the 1st
and 2d may be 10, and the sum of the 2d and 3d may be 24; the equation in step 6th will be produced; for, if the 1st be 2, the second is $z-10$, and the third $34-z$, and therefore $34-z=z^2-20z+100$, the very same equation as in step 4th. In this question it is plain that the root 25 only can be useful, and the three proportions are 25, 15, 9.

But the necessary limitations of such a problem are properly to be derived from a general notation. Let the sum of the two first proportions be $a$, and the difference of the two last $b$. If $a$ is not greater than $b$, the first term must be the least; but if $a$ be greater than $b$, the first term must be either the greatest or the least.

When the first term is the least, the proper notation of the three terms is $z$, $a-z$, $a+b-z$, and the equation when ordered is $z^2-3a+b z-a^2$. If the first term be the greatest, and then $a$ is greater than $b$, the notation of the terms is $z$, $a-z$, $a+b-z$, and the corresponding equation is $z^2-3a+b z+a^2=0$.

Of the first of these equations it may be observed, that whatever be the value of $a$ and $b$, the square of $\frac{3a+b}{4}$, viz. of half the coefficient of $z$, is greater than $\frac{a^2}{4}$, and therefore the roots are always possible. If the square be completed, and the roots extracted, they become

$$z=\frac{3a+b}{2} \pm \frac{\sqrt{36+8b^2-a^2}}{2},$$

$$z=\frac{3a+b}{4} \pm \frac{\sqrt{36+8b^2-a^2}}{4}.$$  

But in this case $z$ is the least of the three terms, and therefore $a$ is greater than $2z$, or $\frac{a}{2}$ greater than $z$; and therefore the second root only can be admitted, and $z=\frac{3a+b}{4} \pm \frac{\sqrt{36+8b^2-a^2}}{4}$ is the only proper solution.

The second equation, since $a$ is greater than $b$, $\frac{3a-b}{4}$ must be always positive, and therefore the equation is necessarily of the third form. But the roots are possible only when $\frac{3a-b}{4}$ is not less than $\frac{a}{2}$ that is, when $a^2+b^2$ is not less than $6ab$, or when $a-b$ is not less than $2\sqrt{ab}$. When the roots are possible, $z$ may be either greater or less than $\frac{3a-b}{4}$, and hence each root gives a proper solution; therefore, $z=\frac{3a-b}{4} \pm \frac{\sqrt{36+8b^2-a^2}}{4}$.

Ex. Let $a=40$ and $b=6$. The first term in this case may be assumed either as the greatest or the least. And, first, if $z$ be the greatest; the roots of the equation will be possible, since $(a^2+b^2)=1636$ is greater than $(6ab)=1440$. The two values of $z$ are 32 and 25, and the proportions are either 32, 8, 2, or 25, 15, 9. 2df, If $z$ be assumed the least of the proportions, the two roots of the equation are possible, but Equations, one of them only can be applied; which is 17.635 nearly, and the three proportions are 17.635, 22.365, and 28.365, nearly, the roots of the equation being incommensurate.

In like manner may the limitations of the other question abovementioned be ascertained.

The same would have been got, by substituting in the general theorem $w=\frac{z}{2}, a=3$, and $b=10$, or, if the least number had been called $z'$, the equation would not have had fractional exponents.

Examp. 15. To find two numbers, of which the product is 100, and the difference of their square roots 3.

Let the less be $x$, the greater is 100.

By question

$$x^2-3x-100=0$$

$$x^2-\sqrt{x}=3$$

$$x^2=3 \pm \sqrt{9}$$

$$x^2=9$$

$$x=\pm 3$$

If $x=3$, the other number is 25; and this is the proper solution, for $x$ was supposed to be the least. In this case, indeed, the negative root of the equation being applied according to the rules for negative quantities, gives a positive answer to the question; and if $x=25$, the other number is 4.

The same would have been got, by substituting in the general theorem $w=\frac{z}{2}, a=3$, and $b=10$, or, if the least number had been called $x'$, the equation would not have had fractional exponents.

Of Indeterminate Problems.

It was formerly observed (Chap III.), that if there are more unknown quantities in a question than equations.
ALGEBRA.

Part I.

1, or a number divisible by 4. Then \(\frac{z+v}{2}\) and \(\frac{z-v}{2}\) are the numbers sought.

For the product of two odd numbers is odd, and that of two even numbers is divisible by 4. Also, if \(z\) and \(v\) are both odd or both even, \(\frac{z+v}{2}\) and \(\frac{z-v}{2}\) must be integers.

Ex. 1. If \(z=27\), take \(v=1\), then \(z=27\); and the squares are 196 and 169. Or \(z\) may be 9 and \(v=3\), and then the squares are 36 and 9.

2. If \(z=12\), take \(v=2\), and \(v=6\); and the squares are 16 and 4.

Ex. 3. To find a sum of money in pounds and shillings, whose half is just its reverse.

Note. The reverse of a sum of money as 81. 12s. is 12l. 8s.

Let \(x\) be the pounds and \(y\) the shillings.

The sum required is \(20x+y\)

Its reverse is \(-20x+y\)

Therefore \(-\frac{20x+y}{2}=20x+y\)

\[x:y=(59:18:1)\]

In this equation there are two unknown quantities; and, in general, any two numbers of which the proportion is that of 13 to 6 will agree to it.

But, from the nature of this question, 13 and 6 are the only two that can give the proper answer, viz. 13l. 6s. for its reverse 6l. 13s. is just its half.

The ratio of \(x\) and \(y\) is expressed in the lowest integral terms by 13 and 6; any other expression of it, as the next greater 26 and 12, will not satisfy the problem, as 12l. 26s. is not a proper notation of money in pounds and shillings.

CHAP. VII.

Demonstrations of Theorems by Algebra.

ALGEBRA may be employed for the demonstration of theorems, with regard to all those quantities concerning which it may be used as an analysis; and from the general method of notation and reasoning, it possesses the same advantages in the one as in the other.

The three first sections of this chapter contain some of the most important properties of series which are of frequent use; and the last, miscellaneous examples of the properties of algebraical quantities and numbers.

I. Of Arithmetical Series.

Def. When a number of quantities increase or decrease by the same common difference, they form an arithmetical series.

Thus, \(a, a+d, a+2d, a+3d, \&c\), \(x\), \(-a\), \(-a-2d\), \&c.

Also, \(1, 2, 3, 4, 5, 6, \&c\) and \(8, 6, 4, 2, \&c\).

Prop. In an arithmetical series, the sum of the first and
Part I.

**ALGEBRA.**

**Prop. I.** The product of the extremes in a geometrical series is equal to the product of any two terms, equally distant from the extremes.

Let the first term be \( a \), the last \( l \), and \( b \) the common difference; then \( b+\ell \) will be the second, and \( x-b \) the last but one, &c.

Thus, \( a, a+b, a+2b, a+3b, a+4b, \&c. \)

It is plain, that the terms in the fame perpendicular rank are equally distant from the extremes; and that the sum of any two in it is \( a+x \), the sum of the first and last.

Cor. 1. Hence the sum of all the terms of an arithmetical series is equal to the sum of the first and last, taken half as often as there are terms.

Therefore if \( n \) be the number of terms, and \( s \) the

\[ s = \frac{a+b}{2} \cdot n. \]

If \( a = 0 \), then \( s = \frac{n^2}{2} \).

Cor. 2. The fame notation being understood, since any term in the series consists of \( a \), the first term, together with \( b \) taken as often as the number of terms preceding it, it follows, that \( x = a + b \cdot \frac{n-1}{2} \cdot b \), and hence \( s = \frac{2an+nb^2}{2} \) or by multiplication, \( s = \frac{2an+nb^2}{2} \).

Therefore from the first term, the common difference, and number of terms being given, the sum may be found.

Ex. Required the sum of 50 terms of the series 2, 4, 6, &c.

\[ s = \frac{2 \cdot 50 \cdot (50+1)}{2} = 2550. \]

Cor. 3. Of the first term, common difference, sum and number of terms, any three being given, the fourth may be found by resolving the preceding equation: \( a, b, t, \) and \( n \), being successively considered as the unknown quantity. In the three first cases the equation is simple, and in the last it is quadratic.

II. Of Geometrical Series

**Def.** When a number of quantities increase by the same multiplier, or decrease by the same divisor, they form a geometrical series. This common multiplier or divisor is called the common ratio.

Thus, \( a, ar, ar^2, \&c. \)

\[ a, \ \frac{a}{r}, \ \frac{a}{r^2}, \ \frac{a}{r^3}, \ \&c. \]

**Prop. II.** The sum of a geometrical series, when the first term is \( a \) and the last \( l \) is equal to the sum of \( l \) and \( a \) multiplied by the common ratio.

For, assuming the preceding notation of a series, it is plain, that

\[ \frac{a}{r} + \frac{a}{r^2} + \frac{a}{r^3} + \ldots = \frac{a}{r} + \frac{a}{r^2} + \frac{a}{r^3} + \ldots \]

Cor. 1. Therefore \( s \) being the sum of the series, \( \frac{s}{ar} = \frac{1}{a} \). And \( r = \frac{a}{s} \).

Hence \( r \) can be found from \( a, y, \) and \( r \); and any three of the four being given, the fourth may be found.

Cor. 2. Since the exponent of \( r \) in any term is equal to the number of terms preceding it; hence in the last term its exponent will be \( n-1 \); the last term, therefore, \( y = or \), and \( s = ar^{n-1} = \frac{ar^n}{r} \).

Hence in these four, \( s, a, r, n \), any three being given, the fourth may be found by the solution of equations. If \( n \) is not a small number, the cases of this problem will be most conveniently resolved by logarithms; and of such solutions there are examples in the appendix to this part.

Cor. 3. If the series decreases, and the number of terms is infinite; then, according to this notation, \( a \)

the least term will be \( 0 \), and \( s = \frac{ar^r}{r-1} \), a finite sum.

Ex. Required the sum of the series \( 1, \frac{1}{2}, \frac{1}{4}, \&c. \)

Here \( y = 1 \), and \( r = 2 \). Therefore \( s = \frac{1 \cdot 2^r}{r-1} = 2 \).

What are called in arithmetic repeating and circulating decimals, are truly geometrical decreasing series, and therefore may be summed by this rule.

Thus \( \frac{333}{10}, \&c. = \frac{3}{10} + \frac{2}{100} + \&c. \) is a geometrical series in which \( y = \frac{3}{10} \) and \( r = 10 \); therefore \( s = \frac{y}{r-1} = \frac{y}{r-1} \).

Thus, also \( \frac{2424}{33}, \&c. = \frac{8}{33} \) for here \( y = \frac{24}{100} \) and \( r = 100 \); therefore \( s = \frac{y}{100} = \frac{24}{100} \).

III. Of Infinite Series.

It was observed (Chap. I. and IV.), that in many cases, if the division and evolution of compound quantities be actually performed, the quotients and roots can only be expressed by a series of terms, which may be continued ad infinitum. By comparing a few of the first terms, the law of the progression of such a series
Theorem. Any binomial \((a+b)\) may be raised to any power \((n)\) by the following rules.

1. From inspecting a table of the powers of a binomial obtained by multiplication, it appears that the terms without their coefficients, are \(a^n, a^{n-1}b, a^{n-2}b^2, \ldots\) This is the celebrated binomial theorem deduced here by demonstration, though upon evolvement, and devolution, fractional, positive, or negative; hence the signs of the terms of the \(n\)th term is \(\pm a^{n-1}b^{n-1}, \pm a^{n-2}b^{n-2}, \ldots, \pm a^{n-n}b^n, \pm a^0b^n\), &c. This is the celebrated binomial theorem. It is deduced here by induction only; but it may be rigidly demonstrated, though upon principles which do not belong to this place.

Cor. As \(m\) may denote any number, integral or fractional, positive or negative, hence the division, involution, and evolution, of a binomial, may be performed by this theorem.

Ex. 1. Let \(m = \frac{1}{1-r}\), then \(a+br = a^r + \frac{a^{r+1}}{2} - b + \frac{a^{r+2}}{4} - \ldots\). This being applied to the extraction of the square root of \(a^r + x^r\) (by inferring \(a^{r/2}\) for \(a\) and \(x^{r/2}\) for \(x\)), the same series results as formerly. (Chap. IV.)

Ex. 2. If \(\frac{1}{1-r}\) is to be turned into an infinite series, since \(\frac{1}{1-r} = 1\times\frac{1}{1-r}\), let \(a = 1, b = -r, and m = -1\); and the same series will arise as was obtained by division (Chap. I).

In like manner \(\sqrt[n]{\frac{a^n}{r^n}} = (\sqrt[n]{r^{n-1}} + 2x\sqrt[n]{2x^2-2x+1})^{\frac{1}{n-1}}\) may be expressed by an infinite series, by supposing \(a = 2x^n, b = -2x^n, and m = -1\), and then multiplying that series by \(r^n\).

Cor. 2. This theorem is useful also in discovering the law of an infinite series produced by division or evolution. Thus, the series expressing the square root of \(a^2 + x^2\), consists of \(a, together with a series of fractions; in the numerators of which are the even powers of \(x\), and in the denominators the odd powers of \(a\). The numerical coefficients of the terms of the whole series, as deduced by the theorem, will be: \(1, 1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}\), &c.

Note. If the binomial is \(a - b\), the signs of the terms of any power are all positive; if it is \(a - b\), the alternate terms are negative, beginning at the second. This theorem may be applied to quantities the sum or difference of more than two parts, by supposing them distinguished into two, and then substituting for the powers of these compound parts their values, to be obtained also, if required, from the theorem. Thus, \(a + b + c = a^2 + ab + ac + b^2 + bc + ca + c^2\).

Scholium.

An infinite series may itself be multiplied or divided by another; it may be involved or evoluted; and various other operations may be performed upon it which are necessary in the higher parts of algebra. The methods for finding the sum depend upon other principles.

IV. Properties of Numbers.

Theor. I. The sum of two quantities multiplied by their difference is equal to the difference of their squares.

Let the quantities be represented by \(a\) and \(b\), then \(a + b \times a - b = a^2 - b^2\). as appears by performing the operation.

Cor. If \(a\) and \(b\) be any two quantities of which the sum may be denoted by \(s\), the difference by \(d\), and their product by \(p\), then the following propositions will be true.

1. \(a + b = s, a - b = d\)
2. \(a^2 - b^2 = 2p\)
3. \(a + b = s, a - b = d\)
4. \(a^2 + b^2 = 2p + d\)
5. \(a + b = s, a - b = d\)
6. \(a^2 - b^2 = 2p - d\)

It is unnecessary to express these propositions in words, and the demonstrations are very easy, by raising \(a + b\) to certain powers, and making proper substitutions.

Theor. II. The sum of any number of terms \((n)\) of the odd numbers \(1, 3, 5, \ldots\) beginning with \(1\), is equal to the square of that number \((n^2)\).

In the rule for summing an arithmetical series, let \(a = r, b = 2a, and n = n\), and the sum of this series will be \(\frac{2an + n^2}{n} = a + \frac{n^2}{n}\). Q. E. D.
Part I.

**Algebra.**

**Theor. III.** The difference of any two square numbers is equal to the sum of the two roots, together with twice the sum of the numbers in the natural scale between the two roots.

Let the one number be \( p \), and the other \( p+n \), the intermediate numbers are \( p-1, p-2, \ldots, p-n-1 \).

The difference of the squares of the given numbers is \( 2p+2n \); the sum of the two roots is \( 2p+r \), and twice the sum of the series \( p-1 + p-2 + \ldots + p+n-1 \) is (by Cor. 1. 3d Sect. of this Chap.) \( 2(2p+n-1) \), viz. the sum of the first and last multiplied by the number of terms, and it is plain that \( 2p+n+2p+n-1 = 2pn+n^2 \). Therefore, &c.

**Lem. 1.** Let \( r \) be any number, and \( n \) any integer, \( r-n \) is dividible by \( r-1 \).

The quotient will be \( r-n + r^{n-1} \), &c. till the index of \( r \) be 0, and then the last term of it will be 1; for if this series be multiplied by the divisor \( r-n \), it will produce the dividend \( r^n-1 \).

It will appear also by performing the division, and inferring for any number.

**Lem. 2.** Let \( r \) be any number, and \( n \) any integer odd number, \( r^n \) is dividible by \( r+1 \). Also, if \( n \) is any even number, \( r^n \) is dividible by \( r+1 \).

The quotient will be \( r^n + r^{n-1} \), &c. till the exponent of \( r \) be 0, and the last term of the quotient will be 1. It will appear also by performing the division, and inferring for any number.

**Theor. IV.** If from any number in the general scale now described, the sum of its digits be substratcled, the remainder is dividible by 9.

The number is \( a+b+c+d+e+\ldots \), &c. and the sum of the digits is \( a+c+e+\ldots \), &c. Subtracting the latter from the former, the remainder is \( b+d+f+\ldots \), &c. But, (by Lem. 1.) \( r^n-1 \) is divisible by \( r-1 \), whatever integer number \( r \) may be, and therefore any multiple of \( r-1 \) is also divisible by \( r-1 \); Hence each of the terms, \( b+c+\ldots \), &c. is divisible by \( r-1 \), and therefore the whole is divisible by \( r-1 \).

**Cor. 1.** Any number, the sum of whose digits is divisible by \( r-1 \), is itself divisible by \( r-1 \). Let the number be called \( N \), and the sum of the digits \( D \); then by this prop. \( N-D \) is divisible by \( r-1 \), and \( D \) supposed to be divisible by \( r-1 \) ; therefore it is plain that \( N \) must also be divisible by \( r-1 \).

**Cor. 2.** Any number, the sum of whose digits is divisible by an aliquot part of \( r-1 \), is also divisible by that aliquot part. For, let \( N \) and \( D \) denote as before; and since \( N-D \) (Theor. 4.) is divisible by \( r-1 \), it is also divisible by an aliquot part of \( r-1 \); but \( D \) is divisible by an aliquot part of \( r-1 \), therefore \( N \) is also divisible by that aliquot part.

**Theor. V.** In any number, if from the sum of the coefficients of the odd powers of \( r \) the sum of the coefficients of the even powers be subtracted, and the remainder added to the number itself, the sum will be dividible by \( r+1 \).

In the number \( a+b+c+d+e+\ldots \), &c. the sum of the coefficients of the odd powers of \( r \) is \( b+d+f+\ldots \), &c. If the latter sum be subtracted from the former, and the remainder added to the given number, it makes \( a+b+c+d+e+\ldots \), &c. But (by Lem. 1.) \( r^n-1 \), \( r^n+1 \), \( r^n+1 \), &c. are each dividible by \( r+1 \), and therefore any multiples of them are also dividible by \( r+1 \), hence the whole number is dividible by \( r+1 \).

**Cor. 1.** If the difference of the sum of the even digits, and the sum of the odd digits of any number be dividible by \( r+1 \), the number itself is dividible by \( r+1 \).

Let the sum of the even digits (that is, the coefficients of the even powers of \( r \)) be \( D \), the sum of the odd digits be \( d \), and the number be \( N \). Then by the theorem \( N+D-d \) is dividible by \( r+1 \), and it is supposed that \( D-d \) is dividible by \( r+1 \); therefore \( N \) is dividible by \( r+1 \).

**Cor. 2.** In like manner, if \( D-d \) is dividible by an aliquot part of \( r+1 \), the number itself is dividible by \( r+1 \).

**Cor. 3.** If a number want all the odd powers of \( r \), or if it want all the even powers of \( r \), and the sum of its digits be dividible by \( r+1 \), that number is dividible by \( r+1 \).

**Cor. 4.** In the common scale \( r+1=11 \), which therefore will have the properties mentioned in this theorem, and the corollaries. Thus, in the number 6934, the sum of the even digits is 7, the sum of the odd digits is 18, and the difference is 11, a number dividible by 11, the given number therefore (Cor. 1.) is dividible by 11; Thus also, the sum of the digits of 704308 is dividible by 11, and therefore the number is dividible by 11 (Cor. 3.)

**Scholium.**

These theorems relate to any scale whatever, and therefore the properties of \( r-1 \) in Theor. 4. would in a scale of eight belong to seven, and those in Theor. 5. to nine. If twelve was the root of the scale, the former properties would belong to eleven, and the latter to thirteen.

**Appendix to Part I.**

**Algebra** may be employed in expressing the relations of magnitude in general, and in reasoning with regard to them. It may be used in deducing not only the relations of number, but also those of extension, and hence those of every species of quantity expressible by numbers or extended magnitudes. In this appendix are mentioned some examples of its application to other parts of mathematics, to physics, and to...
the practical calculations of business. The principles and suppositions peculiar to these subjects, which are necessary in directing both the algebraical operations, and the conclusions to be drawn from them, are here alluded as just and proper.

1. Application of Algebra to Geometry.

Algebra has been successfully applied to almost every branch of mathematics; and the principles of these branches are often advantageously introduced into algebraical calculations.

The application of it to geometry has been the source of great improvement in both these sciences: on account of its extent and importance it is here omitted, and the principles of it are more particularly explained in the third part of these elements.

In this place shall be given an example of the use of logarithms in resolving certain algebraical questions.

Note. When logarithms are used, let \( \log \) denote the logarithm of any quantity before which it is placed.

Ex. To find the number of terms of a geometrical series, of which the sum is 511, the first term 1, and the common ratio \( r \).

From sect. 2. chap. 6. it appears that \( s = \frac{a(1 - r^n)}{1 - r} \), and in this problem, \( s, r, \) and \( a \) are given, and \( n \) is to be found. By reducing the equation \( r^n = \frac{1}{1 + s/a} \) and from the known property of logarithms \( n \log x = \log \frac{x^n}{a} \), we have

\[
\log n = \log \frac{1}{1 + s/a} - \log a.
\]

Here \( s = 511, a = 1, r = 2 \), and \( n = \frac{\log 1/0.512}{\log 2} \).

\[
\frac{2.7093700}{0.3010299} = 9.
\]

In like manner may any such equation be resolved, when the only unknown quantity is an exponent, and when it is the exponent only of one quantity.

Ex. 2. An equation of the following quadratic form \( a\sqrt{x} - b\sqrt{y} = c \) may be resolved by logarithms. \( \sqrt{x} \) by the logarithms of Chap. V. \( x^2 = b^2 - 4ac \). And then \( x \) is discovered in the same manner as in the preceding example. Thus, let \( a = 2, b = 10, c = 96 \), and the equation \( 2\sqrt{x} - 10\sqrt{y} = 96 \).

\[
\sqrt{x} = 12 \pm 8. \quad \text{If } 2x = 8 \text{ then } x = \frac{8}{2} = 3 \text{ and } 2 - \frac{3}{4} = 2.512 \text{ and } 2.512^2 = 6.31 \text{ is a true equation. If } 2x = 12 \text{ then } x = \frac{12}{2} = 6.3121813 = 3.5849 \text{, and this number being solved for } x \text{ in the given equation, by means of logarithms, will answer the conditions.}
\]

Ex. 3. The sum of 2000, has been out at interest for a certain time, and 500l. has been at interest double of that time, the whole arrear now due reckoning 4 per cent. compound interest, is 600l. What were the times?

By the rules in the third part of this appendix for compound interest, it is plain that if \( R = 1.04 \), and the time at which the 2000l. is at interest be \( x \), the arrear of it will be 2000\( x \). The arrear of the 500l. is 500\( x \), and hence 500\( x \)\( R \), and 2000\( x \)\( R \), is 6000. This

\[
R = 1.04, x = \frac{2}{l.04} = 17.67, \text{ nearly, that is, 17 years and 8 months nearly, and the double is } 35 \text{ years and } 4 \text{ months; which answer the conditions.}
\]

11. Application of Algebra to Physics.

Physical quantities which can be divided into parts, that have proportions to each other, the same as the proportions of lines to lines, or of numbers to numbers, may be expressed by lines and numbers, and therefore by algebraical quantities. Hence these mathematical notations may be considered as the measures of such physical quantities; they may be reagented upon according to the principles of algebra, and from such reagentings, new relations of the quantities which they represent may be discovered.

In those branches of natural philosophy, therefore, in which the circumstances of the phenomena can be properly expressed by numbers, or geometrical magnitudes, algebra may be employed, both in promoting the investigation of physical laws by experience, and also in deducing the necessary consequences of laws investigated and prefixed to be just.

It is to be observed likewise, that if various hypotheses be assumed concerning physical quantities, with regard to what takes place in nature, their consequences may be demonstratively deduced, and thus a science may be established, which may be properly called mathematical. The use of algebra in this science, which is sometimes called Theoretical Mechanics, is obvious from the principles already laid down.

In conducting these inquiries, it is to be observed, that, for the sake of brevity, the language of algebraical operation is often used with regard to physical quantities themselves; though it is always to be understood, that, in strict propriety, it can be applied only to the mathematical notations of these quantities.

Before illustrating this application of algebra by examples, it may be proper to explain a method of finding the proportion of variable quantities, and reasoning with regard to it, which is of general use in natural philosophy.

2. Of the Proportion of Variable Quantities.

Mathematical quantities are often so connected, that when the magnitude of one is varied, the magnitudes of the others are varied, according to a determined rule. Thus, if two straight lines, given in position, intersect each other, and, if a straight line, cutting both, moves parallel to itself, the two segments of the given lines between their intersection and the moving line, however varied, will always have the same proportion. Thus also, if an ordinate to the diameter of a parabola move parallel to itself, the absciss will be increased or diminished in proportion as the square of the ordinate is increased or diminished.

In like manner may algebraical quantities be connected. If \( x, y, z, \) &c. represent any variable quantities, while \( a, b, c \), represent such as are constant or invariable, then an equation containing two or more variable quantities, with any number of constant quantities, will exhibit a relation of variable quantities, similar to those already mentioned. Thus, if \( ax = by \), then \( x : y :: b : a \), that is, \( x \) has a constant proportion to \( y \),
EQUATIONS.

In whatever way these two quantities may be varied.

Likewise, if $xy = z$, then $ax = bx$, or $y : x = \frac{b}{a}$; that is, $y$ has a constant proportion to the reciprocal of $x$, or $y$ is increased in the same proportion as $x$ is diminished, and conversely. It is necessary to premise the following definitions.

Definitions.

Let there be any number of variable quantities, $X$, $Y$, $Z$, $V$, &c. connected in such a manner, that when $X$ becomes $x$, $Y$, $Z$, $V$, &c. become respectively $y$, $z$, $v$, &c. Then

1. If two variable quantities $X$ and $Y$ are so connected, that whatever be the values of $x$ and $y$, $X : Y = x : y$, this proportion is expressed thus, $X=YZ$, and $X$ is said to be directly as $Y$, or shortly, $X$ is said to be as $Y$. If, then $X=YZ$, and $X$ is said to be inversely as $Y$, and the conseqents by $z$, then $XZ = YZ$; and directly as $Y$.

2. If two variable quantities $X$ and $Y$ are so connected, that $X : x = y : y$, or $X : x = \frac{1}{y} : \frac{1}{y}$, their relation is thus expressed, $X=\frac{1}{y}$; and $X$ is said to be inversely, or reciprocally as $Y$.

3. If $X$, $Y$, $Z$, are three variable quantities, so connected that $X : x = y : y$, their relation is expressed, $X=YZ$, and $X$ is said to be directly as $Y$ and $Z$, jointly; or $X$ is said to be as $Y$ and $Z$.

4. If any number of variable quantities as $X$, $Y$, $Z$, $V$, &c. are so connected, that $XT : x = YZ : \frac{V}{y}$, then $YT = \frac{YZ}{y}$, and $XY$ is said to be directly as $YZ$.

5. Let the preceding notation of proportion be called a proportional equation ($A$), the equation formerly treated of in this place, for the sake of distinction, called absolute.

Cor. Every absolute equation, containing more than one variable quantity, may be considered as a proportional equation; and in a proportional equation, if at any particular corresponding values of the variable quantities, the equation becomes absolute, it will be universally absolute.

Prop. If one side of a proportional equation be either multiplied or divided by any constant quantity, it will continue to be true. Thus, if $X=\frac{1}{y}$, then $\frac{a}{b}X=\frac{a}{b}\frac{1}{y}$.
Cor. 2. If two proportional equations have a common side, that side will be as the square root of the product of the other two. Thus if \(X=Y\), and \(Z=Z\) by this Prop. \(Y=XY\) and (Cor. 1) \(X=Z \cdot Z\). Hence also, in this case, \(\sqrt{X}=X \cdot Z\); for (Prop. 3) \(Y=X \cdot Z\).

Cor. 3. If one side of a proportional equation be a factor of a side of another proportional equation, the remaining side of the former may be inferred in the latter, in place of that factor. Thus, if \(X=YZ\), and \(Z=Z\), then \(X=Z\) as appears by multiplying the two equations, and dividing by \(Z\).

Prop. 5. Any proportional equation may be made absolute, by multiplying one side by a constant quantity.

Thus, if \(X=Y\), then let two particular corresponding values of these variable quantities be assumed as constant, and let them be \(a\) and \(b\), then \(X:a::Y:b\), and \(X \cdot a = Y \cdot b\), or \(X \cdot Y = a \cdot b\), an absolute equation.

Scholium.

1. If there are two variable physical quantities, either of the same, or of different kinds, which are so connected, that when the one is increased or diminished, the other is increased or diminished in the same proportion; or, if the magnitudes of the one, in any two situations, have the same ratio to each other, as the magnitudes of the other in the corresponding situations, the relation of the mathematical measure of these quantities may be expressed by a proportional equation, according to Def. 1.

2. If two variable physical quantities be so connected, that the one increases in the same proportion as the other is diminished, and conversely; or, if the magnitudes of the one, in any two situations, be reciprocally proportional to the magnitudes of the other, in the corresponding situations, the relation of their measures may be expressed by a proportional equation, according to Def. 2.

3. If three variable physical quantities are so connected, that one of them is increased or diminished, in proportion as both the others are increased or diminished; or, if the magnitudes of one of them, in any two situations, have a ratio which is compounded of the ratios of the magnitudes of the other two, in the corresponding situations; the relation of the measures of these three may be expressed by a proportional equation, according to Def. 3.

4. In like manner may the relations of other combinations of physical quantities be expressed according to Def. 4. And when these proportional equations are obtained, by reasoning with regard to them, according to the preceding propositions, new relations of the physical quantities may be deduced.

2. Examples of Physical Problems.

The use of algebra, in natural philosophy, may be properly illustrated by some examples of physical problems. The solution of such problems must be derived from known physical laws, which, though ultimately founded on experience, are here assumed as principles, and reasoned upon mathematically. The experiments by which the principles are ascertained admit of various degrees of accuracy; and on the degree of physical accuracy in the principles will depend the physical accuracy of the conclusions mathematically deduced from them. If the principles are inaccurate, the conclusions must, in like manner, be inaccurate; and, if the limits of inaccuracy in the principles can be ascertained, the corresponding limits in the conclusions derived from them, may likewise be calculated.

Example 1. Let a glass tube, 30 inches (\(a\)) long, be filled with mercury, excepting 8 inches (\(b\)), and let it be inverted as in the Torricellian experiment, so that the 8 inches of common air may rise to the top. It is required to find at what height the mercury will remain suspended, the mercury in the barometer being at that time 28 inches (\(a\)) high.

The solution of this problem depends upon the following principles:

1. The pressure of the atmosphere is measured by the column of mercury in the barometer; and the elastic force of the air, in its natural state, which resists this pressure, is therefore measured by the same column.

2. In different states, the elastic force of the air is reciprocally as the spaces which it occupies.

3. In this experiment, the mercury which remains suspended in the tube, together with the elastic force of the air in the top of it, being a counterbalance to the pressure of the atmosphere, may therefore be expressed by the column of mercury in the barometer.

Let the mercury in the tube be \(x\) inches, the air in the top of it occupies now the space \(a-x\); it occupied formerly \(b\) inches, and its elastic force was \(a\) inches of mercury: Now, therefore, the force must be \(a-x:b:a\) inches. (2.) Therefore \((x-\frac{b}{a})=d\). This reduced, and putting \(a-x\) the equation is \(x-\frac{b}{a}=d\). This resolved gives \(x=m\sqrt{m^{2}+b-ad}\).

In numbers \(x=44\) or 14.

One of the roots 44 is plainly excluded in this case, and the other, 14, is the true answer. If the column of mercury \(x\), suspended in the tube, were a counterbalance to the pressure of the atmosphere, expressed by the height of the barometer \(d\), together with the measure of the elastic force of \(b\) inches of common air in the space \(a-x\), that is, if \(x+b=d\) or \(x-\frac{b}{a}=d\), the equation will be the same as before, and the root 44 would be the true answer. But the experiment in this question does not admit of such a supposition.

Example 2. The distance of the earth and moon (\(d\)), and their quantities of matter (\(t\), \(f\)), being given, to find the point of equal attraction between them. Let the distance of the point from the earth be \(x\); its distance from the moon will be therefore \(d-x\). But gravitation is as the matter directly, and as the square of the distance inversely; therefore the earth’s attraction is as \(t\); and the moon’s attraction as \(\frac{1}{d-x}\). But these are here equal; therefore,
ALGEBRA.

In the following theorems let \( p \) denote any principal sum of which \( x \) is the unit, \( t \) the time during which it bears interest, of which one year shall be the unit, \( r \) the rate of interest of \( x \) for one year, and let \( s \) be the amount of the principal sum \( p \) with its interest for the time \( t \) at the rate \( r \).

I. Of Simple Interest.

When the simple interest at the end of every year is supposed to be joined to the principal sum, and both to bear interest for the following year, money is said to bear compound interest. The same notation being used, let \( I + p = R \). Then \( I = pRt \).

For the simple interest of \( x \) in a year is \( r \), and the new principal sum therefore which bears interest during the second year is \( (1 + rt)R \); the interest of \( R \) for a year is \( rR \), and the amount of principal and interest at the end of the 2d year, is \( R + rR = Rx(1 + r) \). In like manner, at the end of the 3d year it is \( R^2 \), and for the sum \( p \) it is \( pR^2 \).

Cor. 1. Of these four \( p \), \( R \), \( t \), \( r \), any three being given, the fourth may be found. When \( r \) is not very small, the solution will be obtained most conveniently by logarithms. When \( R \) is known \( r \) may be found, and conversely.

Ex. If \( 500 \) has been at interest for 21 years, the whole arrear due, reckoning \( 4\% \) per cent. compound interest, is \( 1260.12 \) or \( 1260.25 \). In this case \( p = 500 \), \( R = 1.045 \) and \( t = 21 \), and \( R = 1260.12 \), and any one of these may be derived by the theorem from the others being known. Thus, to find \( R \); take \( R = R^2 \)

\[
\text{Sd. 2.} \quad \text{The present worth of a sum \( f \) in reversion, that is payable after a certain time \( t \), is found thus. Let the present worth be \( x \), then this money improved by compound interest during \( t \) produces \( xR \), which must be equal to \( f \), and if \( xR^2 = f \), \( x = \frac{f}{R^2} \).
\]

Cor. 3. The time in which a sum is doubled at compound interest will be found thus. \( pR = 2p \) and \( R = 2 \) and \( t = \frac{2}{7} \); thus, if the rate is 5 per cent. \( R = 2 \), and the time is \( \frac{2}{7} \).

III. Of Interest and Annuities.

The application of algebra to the calculation of interests and annuities, will furnish proper examples of its use in business. Algebra cannot determine the propriety or justice of the common suppositions on which these calculations are founded, but only the necessary conclusions resulting from them.

Note.

Many other suppositions might be made with regard to the improvement of money by compound interest. The interest might be supposed to be joined to the capital, and along with it to bear interest at the end of every
An annuity is a payment made annually for a certain term of years, and the chief problem with regard to it is, to determine its present worth. The supposition on which the solution proceeds is, that the money received by the payer, being improved by him in a certain manner during the continuance of the annuity, amounts to the same sum as the several payments received by the purchaser, improved in the same manner. The suppositions with regard to the improvements may be various. What is called the method of simple interest, in which simple interest only is reckoned upon the purchase-money, and simple interest on each annuity from the time of payment, is so manifestly unsatisfactory, as to be universally rejected; and the supposition which is now generally admitted in practice, is the highest improvement possible on both sides, viz. by compound interest. As the taking compound interest is prohibited by law, the realizing of this duped improvement requires punctual payment of interest, and therefore the interest in such calculations is usually made low. Even with this advantage, it can hardly be rendered effectual in its full extent; it is however universally acquiesced in, as the most proper foundation of general rules; and when peculiar circumstances require any different hypothesis, a suitable calculation may be made.

Let then the annuity be called $a$, and let $p$ be the present worth of it or purchase-money, $t$ the time of its continuance, and let the other letters denote as formerly.

The seller, by improving the price received $p$, at compound interest, at the time the annuity ceases, has $pRt$.

The purchaser is supposed to receive the first annuity $a$ at the end of the first year, which is improved by him for $t-1$ years; it becomes therefore (Th. 2.) $aR^{t-1}$.

He receives the $a$ th annuity at the end of the 2d year, and when improved $t-2$, it becomes $aR^{t-1}$. The third annuity becomes $aR^{t-1}$, &c.

The last annuity is simply $a$, therefore the whole amount of the improved annuities is the geometrical series $a+aR+aR^2$, &c. &c. $aR^{t-1}$. The sum of this series, by Chap. VI. Sect. 2., is $axR^{t-1}-1$.

But, from the nature of the problem, $pRt=axR^{t-1}$, and hence $p=axR^{t-1}$.

The same conclusion results from calculating the present worth of the several annuities, considered as sums payable in reversion.

Cor. 1. Of the four $p$, $a$, $R$, $t$, any three being given, the fourth may be found, by the solution of equations; $t$ is found easily by logarithms, $R$ or $r$ can be found only by resolving an affected equation of the $t$ order.

Cor. 2. If an annuity has been unpaid for the term $t$, the arrear, reckoning compound interest, will be $axR^{t-1}$. 

Cor. 3. The present worth of an annuity in reversion, that is to commence after a certain time ($a$), and then to continue $t$ years, is found by subtracting the present worth for $n$ years from the present worth for $n+t$ years, and then

$$p = a\frac{R^{t-1} - R^t}{Rk + a R^{t-2}}.$$ 

Also of $R$, $t$, $n$, $a$, $p$, any four being given, the fifth may be found.

Cor. 4. If the annuity is to continue for ever, then $R^{t-1}$ and $Rt$ may be considered as the same; and

$$p = a\frac{R^{t-1} - a}{R^t}.$$ 

Cor. 5. A perpetuity in reversion (by Cor. 3.) since $R^{t-1} = R$, is $p = aR^t$.

Prob. When 12 years of a lease of 21 were expired, a renewal for the same term was granted for 1000; 8 years are now expired, and for what sum must a corresponding renewal be made, reckoning 5 per cent, compound interest? From the first transaction the yearly profit must be deduced; and from this the proper fine in the second may be computed.

In the first bargain, an annuity in reversion for 12 years, to commence 9 years hence, was sold for 1000. The annuity will therefore be found by Cor. 3, in which all the quantities are given, but $a = 4\frac{r}{R}$.

and by inserting numbers, viz. $p = 1000$, $t = 12$, $n = 9$, $r = 0.05$, and $R = 1.05$; and working by logarithms $a = 175.029 = 175.117$.

Next, having found $a$, the second renewal is made by finding the present worth of the annuity $a$ in reversion, to commence 13 years hence, and to last 8 years. In the canon (Cor. 5.) infer for $a = 175.029$, and let $t = 12$, $n = 13$, and $r = 0.05$ as before, $p = 599.93 = 599.835$. The fine required.

As these computations often become troublesome, and are of frequent use, all the common cases are calculated in tables, from which the value of any annuity for any time, at any interest, may easily be found.

It is to be observed also, that the preceding rules are computed on the supposition of the annuities being paid yearly; and therefore, if they be supposed to be paid half yearly, or quarterly, the conclusions will be somewhat different, but they may be easily calculated on the preceding principles.

The calculations of life annuities, depend partly on the principles now explained, and partly on physical principles, from the probable duration of human life, as deduced from bills of mortality.
Of the General Properties and Resolutions of \textit{Equations} of all Orders:

\textbf{CHAPTER I}

Of the Origin and Composition of \textit{Equations}; and of the Signs and Coefficients of their Terms.

In order to resolve the higher orders of equations, and to investigate their general affections, it is proper first to consider their origin from the combination of inferior equations.

As it would be impossible to exhibit particular rules for the solution of every order of equations, their number being indefinite; there is a necessity of deducing rules from their general properties, which may be equally applicable to all.

In the application of algebra to certain subjects, and especially to geometry, there may be an opposition in the quantities, analogous to that of addition and subtraction, which may therefore be expressed by the signs + and -. Hence these signs may be understood by subtraction, to denote contrariety in general; and therefore, in this method of treating of equations, negative roots are admitted as well as positive. In many cases the negative will have a proper and determinate meaning; and when the equation relates to magnitude only, where contrariety cannot be supposed to exist, these roots are neglected, as in the case of quadratic equations formerly explained. There is besides this advantage in admitting negative roots, that both the properties of equations from which their resolution is obtained, and also those which are useful in the many extensive applications of algebra, become more simple and general, and are more easily deduced.

In this general method, all the terms of any equation are brought to one side, and the equation is expressed by making them equal to 0. Therefore, if a root of the equation be inferred instead of \((x)\) the unknown quantity, the positive terms will be equal to the negative, and the whole must be equal to 0.

Def. When any equation is put into this form, the term in which \((x)\) the unknown quantity, is of the highest power, is called the \textit{First} that in which the index of \(x\) is less by 1, is the \textit{Second}, and so on, till the last, into which the unknown quantity does not enter, and which is called the \textit{Absolute Term}.

Prop. I. If any number of equations be multiplied together, an equation will be produced, of which the dimension \((a)\) is equal to the sum of the dimensions of the equations multiplied.

If any number of simple equations be multiplied together, as \(x=c_0, x=b+c_0, x=c_0, \&c.\), it is obvious, that the product will be an equation of a dimension, containing as many units as there are simple equations. In like manner, if higher equations are multiplied together, as a cubic and a quadratic, one of the fifth order is produced, and so on.

\textit{Conversely.} An equation of any dimension is considered as compounded either of simple equations, or of others, such that the sum of their dimensions is equal to the dimension of the given one. By the resolution of equations these inferior equations are discovered, and by investigating the component simple equations, the roots of any higher equation are found.

Cor. 1. Any equation admits of as many solutions, or has as many roots as there are simple equations which compose it, that is, as there are units in the dimension of it.

Cor. 2. And conversely, no equation can have more roots than the units in its dimension.

Cor. 3. Imaginary or impossible roots must enter an equation by pairs; for they arise from quadratics, in which both the roots are such.

Hence also, an equation of an even dimension may have all its roots, or any even number of them impossible, but an equation of an odd dimension must at least have one possible root.

Cor. 4. The roots are either positive or negative, according as the roots of the simple equations, from which they are produced, are positive or negative.

Cor. 5. When one root of an equation is discovered, one of the simple equations is found, from which the given one is compounded. The given equation, therefore, being divided by this simple equation, will give an equation of a dimension lower by 1. Thus, any equation may be deprefed as many degrees as there are roots found by any method whatever.

\textit{Prop. II.} To explain the general properties of the signs and coefficients of the terms of an equation.

Let \(x=c_0, x=b+c_0, x=-d+c_0, \&c.\) be simple equations, of which the roots are any positive quantities \(+a, +b, +c, +d, \&c.\) and let \(x=-m+c_0, x=-n+c_0, \&c.\) be simple equations, of which the roots are any negative quantities \(-m, -n, \&c.\) and let any number of these equations be multiplied together, as in the following table:

\[\begin{align*}
x & = c_0 \\
x + b & = c_0 \\
x - d & = c_0 \\
x + m & = c_0, \quad x + n & = c_0, \\
x + a & = c_0 \\
x + bx + ax & = c_0 \\
x + bx + ab & = c_0, \quad \text{a Quadratic.} \\
x + c & = c_0 \\
\end{align*}\]

\(\text{(*) The term \textit{dimension}, in this treatise, is used in senses somewhat different, but so as not to create any ambiguity. In this chapter it means either the order of an equation, or the number denoting that order, which was formerly defined to be the highest exponent of the unknown quantity in any term of the equation.}\)
CHAP. II.

Of the Transformation of Equations.

There are certain transformations of equations necessary towards their solution; and the most useful are contained in the following propositions.

Prop. 1. The affirmative roots of an equation become negative, and the negative become affirmative, by changing the signs of the alternate terms, beginning with the second.

Thus the roots of the equation \( x^4 - x^3 - 7x^2 + 49x = 0 \) are +1, -3, 2, -5, whereas the roots of the equation \( x^4 + x^3 - 19x^2 - 49x - 250 = 0 \), are -1, -3, 2, -5.

The reason of this is derived from the composition of the coefficients of these terms, which consist of combinations of odd numbers of the roots, as explained in the preceding Chapter.

Prop. 2. An equation may be transformed into another that shall have its roots greater or less than the roots of the given equation by some given difference.

Let \( x \) be the unknown quantity of the equation, and \( e \) the given difference; let \( \frac{x + e}{x - e} = \frac{A}{B} \), and if for \( x \) and its power in the given equation, \( y = e \), and its powers be inverted, a new equation will arise, in which the unknown quantity is \( y \), and its value will be \( x - e \); that is, its roots will differ from the roots of the given equation by \( e \).

Let the equation proposed be \( x^3 - px^2 + qx - r = 0 \), of which the roots must be diminished by \( e \). By inverting for \( x \) and its powers \( x + e \) and its powers, the equation required is,

\[
\left( x + e \right)^3 - p\left( x + e \right)^2 + q\left( x + e \right) - r = 0
\]

**Cor. 1.** From this transformation, the second, or any other intermediate term, \( m \) may be taken away; granting the resolution of equations.

Since the coefficients of all the terms of the transformed equation, except the first, involve the powers of \( e \) and known quantities only, by putting the coefficient of any term equal to \( 0 \), and resolving that equation, a value of \( e \) may be determined; which being substituted, will make that term to vanish.

Thus, in this example, to take away the second term, let its coefficient, \( 3x - 50x \), and \( e = 4 \), which being substituted for \( e \), the new equation will want the second term. And universally, the coefficient of the first term of a cubic equation being \( x \), and \( x \) being the unknown quantity, the second term may be taken away by supposing \( x = y - m \), then \( x + m \) being the coefficient of that term.

**Cor. 2.** The second term may be taken away by the solution of a simple equation, the third by the solution of a quadratic, and so on.

**Cor. 3.** If the second term of a quadratic equation, be taken away, it will become a pure equation, and thus a solution of quadratics will be obtained, which coincides with the solution already given in Part I.

**Cor. 4.** The last term of the transformed equation is the same with the given equation, only having \( e \) in place of \( x \).

**Prop. 3.** In like manner may an equation be transformed into another, of which the roots shall be equal to the roots of the given equation, multiplied or divided by a given quantity.

Let \( x \) be the unknown letter in the given equation, and \( y \) that of the equation wanted; also let \( e \) be the given quantity.

To multiply the roots let \( xe = y \) and \( xe = ye \).

To divide the roots let \( \frac{x}{e} = y \) and \( xe = ye \). Then...
Part II.  

**ALGEBRA.**

Of Equations. 

Then substitute for \( x \) and its powers, \( y \) or \( y \) and its powers, and the new equation of which \( y \) is the unknown quantity will have the property required.

Cor. 1. By this proposition an equation, in which the coefficient of the first term is any known quantity, as \( a \), may be transformed into another, in which the coefficient of the first term shall be unit. Thus, let the equation be \( ax^1 + px + qy + r = 0 \). Suppose \( y = ax \), or \( x = \frac{y}{a} \), and for \( x \) and its powers insert \( \frac{y}{a} \) and its powers, and the equation becomes

\[ \frac{y}{a} \left( \frac{y}{a} + p \right) + qy + r = 0 \]

Corollary 1. Let the second term of the given equation be \( ax^1 + px + qy + r = 0 \); and if \( x = \frac{y}{a} \), then \( y = \frac{ax^1}{a} + \frac{px}{a} + qy + r = a^2 \). Also, let the equation be \( ax^1 - 6x + 7x - 30 = 0 \); and if \( x = \frac{y}{a} \), then \( y = \frac{ax^1}{a} - 6y + 7y = a^2 \). Cor. 2. If the two transformations in Prop. 2. and 3. be both required, they may be performed either separately or together.

Thus, if it is required to transform the equation \( ax^1 + px + qy + r = 0 \) into one which shall want the second term, and in which the coefficient of the first term shall be \( x \); let \( x = \frac{y}{a} \) and then \( x = \frac{ax^1}{a} + \frac{px}{a} + \frac{qy}{a} + \frac{r}{a} = a^2 \).

Cor. 3. If there are fractions in an equation, they may be taken away by multiplying the equation by the denominators, and by this proposition the equation may then be transformed into another, without fractions, in which the coefficient of the first term is \( x \). In like manner may a fourth coefficient be taken away in certain cases.

Cor. 4. Hence alfo, if the coefficient of the second term of a cubic equation is not divisible by \( 3 \), the fractions thence arising in the transformed equation, wanting the second term, may be taken away by the preceding corollary. But the second term also may be taken away, so that there shall be no such fractions in the transformed equation, by supposing \( x = \frac{z}{3} \), being the coefficient of the second term of the given equation. And if the equation \( ax^1 + px + qy + r = 0 \) be given, in which \( p \) is not divisible by \( 3 \), by supposing \( x = \frac{z}{3} \), the transformed equation reduced is \( z^1 + \frac{2}{3}z^2 + \frac{4}{9}z^3 + \frac{2}{27}r = 0 \), wanting the second term, having one for the coefficient of the first term, and the coefficients of the other terms being all integers, the coefficients of the given equation being also supposed integers.

**General Corollary to Prop. 1. 2. 3.**

If the roots of any of these transformed equations be found by any method, the roots of the original equation, from which they were derived, will easily be found from the simple equations expressing their relation. Thus, if \( 8 \) is found to be a root of the transformed equation \( z^1 + 3z^2 - 60z = 0 \) (Cor. 2. prop. 3.), since \( x = \frac{z}{3} \), the corresponding root of the given equation \( 5x^1 - 6x^2 + 7x - 30 = 0 \) must be \( \frac{8}{3} + 2 = 2 \). It is to be observed also, that the reasoning in Prop. 2. and 3. and the corollaries, may be extended to any order of equations, though in them it is applied chiefly to cubic.

**CHAPTER III.**

Of the Resolution of Equations.

From the preceding principles and operations, rules may be derived for resolving equations of all orders.

I. **CARDAN'S RULE FOR CUBIC EQUATION.**

The second term of a cubic equation being taken away, and the coefficient of the first term being made \( 1 \), (by Cor. 1. Prop. 2. and Cor. 1. Prop. 3. Chap. II.), it may be generally represented by \( x^1 + 3x^2 + 3x + 1 = 0 \); the index + in all terms denoting the addition of them, with their proper signs. Let \( x = m + n \), and also \( mn = -q \); by the substitution of these values, an equation of the 6th order, but of the quadratic form, is deduced, which gives the values of \( m \) and \( n \); and hence,

\[ (m + n)^2 = x = \sqrt{-r + \sqrt{r^2 + q^3}} + \sqrt{-r - \sqrt{r^2 + q^3}}; \]

or \( x = \sqrt{-r + \sqrt{r^2 + q^3}} + \sqrt{-r - \sqrt{r^2 + q^3}} \).

Cor. 1. In the given equation, if \( 3y \) is negative, and if \( r \) is less than \( q^2 \), this expression of the root involves impossible roots; while, at the same time, all the roots of that equation are possible. The reason is, that in this method of solution it is necessary to suppose that \( x \) the root may be divided into two parts, of which the product is \( q \). But it is easy to show, that in this, which is called the irreducible case, it cannot be done.

For example, the equation (Ex. 3. Sect. 3. of this Chapter), \( x^1 - 1564 + 5600 \), belongs to the irreducible case, and the three roots are \( +4, +10 \), and all of these roots can be divided into two parts \( (m \) and \( n \) \), of which the product can be equal to \( \frac{1564}{3} = 52 \), for the greatest product from the division of the greatest root \(-14 \), is \( -7x = -52 \) less than 52.

If the cubic root of the compound sum can be extracted, the impossible parts balance each other, and the true root is obtained.

The geometrical problem of the trisection of an arch
Rule 1. All the terms of the equation being brought to one side, find all the divisors of the absolute term, and substitute them successively in the equation for the unknown quantity. That divisor which, substituted in this manner, gives the result \( \neq 0 \), shall be a root of the equation. 

\[
Ex. 1. \quad x^3 - 2ax^2 + 2a^2x - 2a^3b = 0.
\]

The simple literal divisors of \(-2ab\) are \(a, b, 2a, 3b\), any of which may be inferred for \(x\). Supposing \(x = a\), the equation becomes 

\[
x^3 - 2ax^2 + 2a^2x - 2a^3b = -3a^3 + 3ab^2
\]

which is obviously \(= 0\).

\[
Ex. 2. \quad x^3 - 2x^2 - 33x + 90 = 0.
\]

The operation is thus:

<table>
<thead>
<tr>
<th>Suppose,</th>
<th>Result</th>
<th>Divisors</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x = 3)</td>
<td>-5</td>
<td>3, 2, 1</td>
</tr>
<tr>
<td>(x = 0)</td>
<td>90</td>
<td>9, 10</td>
</tr>
<tr>
<td>(x = -1)</td>
<td>-262</td>
<td>13, 19, 1</td>
</tr>
</tbody>
</table>

In this example there is only one progression, 4, 5, 2; and therefore 3 is a root, and it is \(-3\), since the series decreases.

It is evident by the rules for transforming equations (Chap. II.), that by inferring for \(x\), \(1\) \((= a)\) the result is the absolute term of an equation of which the roots are less than the roots of the given equation by \(1\) \((= x)\). Cor. 4. Prop. 2. When \(x = 0\) the result is the absolute term of the given equation. When for \(x\) is inferred \(-1\) \((= r)\) the result is the absolute term of an equation whose roots exceed the roots of the given equation by \(1\) \((= x)\). Hence, if the terms, of the series \(1, 0, -1, -2, \&c\), be inferred successively for \(x\), the results will be the absolute terms of so many equations, of which the roots form an increasing arithmetical feries with the difference \(1\). But as the commensurate roots of these equations must be among the divisors of their absolute terms, hence they must be among the arithmetical progressions found by this rule. The roots of the given equation therefore are to be sought for among the terms of these progressions which are divisors of the result, upon the supposition of \(x = 0\), because that result is its absolute term.

It is plain that the progressions must always be increasing, only it is to be observed, that a decreasing series with the sign \(+\) becomes increasing with the sign \(-\). Thus, in the preceding example, \(-4, -3, -2\), is an increasing series, of which \(-3\) is to be tried, and it succeeds.

If, from the substitution of three terms of the progression, \(1, 0, -1, \&c\), there arise a number of arithmetical feries. by substituting more terms of that progression, some of the feries will break off, and, of course, fewer trials will be necessary.

### III. Examples of Questions producing the higher Equations.

**Examp. 1.** It is required to divide 161. between two persons, so that the cube of the one’s share may exceed the cube of the other’s by 386.

Let the greater share be \(x\) pounds, and the less be \(16-x\).

By the question, \(x^3 - 16 - x^3 = 386\)

And by Inv. \(2x^3 - 48x^2 + 768x - 4096 = 386\)

Transp. and divide \(x^3 - 224x^2 + 38x - 2241 = 0\).

<table>
<thead>
<tr>
<th>Suppose,</th>
<th>Result</th>
<th>Divisors</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x = 1)</td>
<td>-1880</td>
<td>1, 2, 5, 8, 10, 20</td>
</tr>
<tr>
<td>(x = 0)</td>
<td>-2241</td>
<td>1, 3, 5, 7, 8, 9</td>
</tr>
<tr>
<td>(x = -1)</td>
<td>-2650</td>
<td>1, 2, 5, 10, 25, 53</td>
</tr>
</tbody>
</table>

Where 8, 9, 10, differ by \(1\); therefore \(x = 9\) to be tried; and being inferred for \(x\), the equation is \(= 0\). The two shares then are 9 and 7 which succeed.

Since
Part II.

ALGEBRA.

Of Equations.

Since \( x = 9 \); \( x = 9 \) is one of the simple equations from which this cubic is produced, therefore

\[
x^3 - 24x^2 + 384x - 2241 = 0.
\]

And the two roots of this quadratic are impossible.

Example 2. What two numbers are those whose product multiplied by the greater will produce 495, and the difference multiplied by the lesser be 20?

Let the greater number be \( x \) and the lesser \( y \).

Then by quest.

\[
\begin{align*}
\frac{(x+y)(x-y)}{x} &= 495 \\
\frac{(x-y)}{x} &= 20
\end{align*}
\]

Therefore

\[
x = \frac{495 + 420y}{y} + 400
\]

Also

\[
x = \frac{405}{y},
\]

Therefore

\[
x^2 + 40y^2 + 400 = 405.
\]

This cubic equation has one positive incommensurate root, viz. \( 11.14 \), &c., which may be found by the rule in the next section, and two incommensurate roots \( y = 11.14 \), &c., which gives \( x = 19.067 \), &c., and these two answer the conditions very nearly.

Example 3. The sum of the squares of two numbers is 208, and the sum of their cubes 2240 being given, to find them.

Let the greater be \( x+y \), and the lesser \( x-y \).

Then

\[
x^2 + y^2 + 2xy = 208
\]

Hence

\[
y = 104 - x
\]

Also

\[
x + y = 2x^2 + 6xy = 2240
\]

Substitute \( y \) its value and \( 2x^2 + 6xy = 2240 \),

This reduces gives

\[
x^2 = 156x + 560 = 0
\]

The roots of this equation are \( + 10 \), \( + 14 \), \( - 14 \). If \( x = 10 \), then \( y = 2 \); and the numbers sought are 12 and 8, which give the only just solution. If \( x = 4 \), then \( y = 38 \) and \( y = \sqrt{88} \). The numbers sought are therefore \( 4 + \sqrt{88} \) and \( 4 - \sqrt{88} \). The last is negative, but they answer the conditions. Lastly, if \( x = -14 \), then \( y = 92 \), hence \( y = \sqrt{92} \), is impossible; but still the two numbers \( -14 + \sqrt{92} \), \( -14 - \sqrt{92} \), being inferred, would answer the conditions. But it has been frequently observed, that such solutions are both useless and without meaning.

IV. Solution of Equations by Approximation.

By the former rules, the roots of equations, when they are incommensurate may be obtained. These, however, more rarely occur; and when they are incommensurate, we can find only an approximate value of them, but to any degree of exactness required. There are various rules for this purpose; one of the most simple is that of Sir Isaac Newton, which shall be now explained.

Volume I.

Lemma. If any two numbers, being inferred for the unknown quantity \( x \) in any equation, give results with opposite signs, an odd number of roots must be between these numbers.

This appears from the property of the absolute term, and from this obvious maxim, that if a number of quantities be multiplied together, and if the signs of an odd number of them be changed, the sign of the product is changed. For, when a positive quantity is inferred for \( x \), the result is the absolute term of an equation whose roots are less than the roots of the given equation by that quantity (Prop. 2. Cor. 3. Chap. II.) If the result has the same sign as the given absolute term, then from the property of the absolute term (Prop. 2. Chap. I.) either none or an even number only of the positive roots, have had their signs changed by the transformation; but if the result has an opposite sign to that of the given absolute term, the signs of an odd number of the positive roots must have been changed. In the first case, then, the quantity substituted must have been either greater than each of an even number of the positive roots of the given equation, or less than any of them; in the second case, it must have been greater than each of an odd number of the positive roots. An odd number of the positive roots, therefore, must lie between them when they give results with opposite signs. The same observation is to be extended to the substitution of negative quantities and the negative roots.

From this lemma, by means of trials, it will not be difficult to find the nearest integer to a root of a given numerical equation. This is the first step towards the approximation; and both the manner of continuing it, and the reason of the operation, will be evident from the following example.

Let the equation be \( x^3 - 2x - 5 = 0 \).

1. Find the nearest integer to the root. In this case a root is between 2 and 3; for these numbers being inferred for \( x \), the one gives a positive, and the other a negative, result. Either the number above the root, or that below it, may be assumed as the first value; only it will be more convenient to take that which appears to be nearest to the root, as will be manifest from the nature of the operation.

2. Suppose \( x = 2 + f \), and substitute this value of \( x \) in the equation.

\[
x^3 - 2x - 5 = 14 + 6f + 4f + \frac{4f}{3} = 0.
\]

As \( f \) is less than unit, its powers \( f^2 \) and \( f^3 \) may be neglected in this first approximation, and \( f = 0.1 \) nearly, therefore \( x = 2.1 \) nearly.

3. As \( f = 0.1 \) nearly, let \( f = 1 + g \), and infer this value of \( f \) in the preceding equation.

\[
f^3 = 0.001 + 0.03g + 0.3g^3 + 6g^3
\]

\[
f^2 = 0.06 + 1.2g + 6g^3
\]

\[
f = 1 + 10g
\]

\[
f + 6f + 10f = 0.061 + 11.2g + 6.3g^3 + g^3 = 0.
\]

and neglecting \( g^3 \) and \( g^3 \) as very small \( 0.01 + 11.2g \)

\( f = 0 \).
In the same manner may the root of a pure equation be found, and this gives an easy method of approximating to the roots of numbers which are not perfect powers.

This rule is applicable to numerical equations of every order; and, by affining a general equation, general rules may be deduced for approximating to the roots of any proposed equation. By a similar method we may approximate to the roots of literal equations, which will be expressed by infinite series.

PART III.

Of the Application of Algebra to Geometry.

CHAP. I.

General Principles.

Geometry has been rendered far more extensive and useful, and algebra itself has received considerable improvements.

I. Of the Algebraical Expression of Geometrical Magnitudes.

A line, whether known or unknown, is represented by a single letter: a rectangle is properly expressed by the product of the two letters representing its sides: and a rectangular parallelopiped by the product of three letters; two of which represent the sides of any of its rectangular bases, and the third the altitude.

These are the most simple expressions of geometrical magnitudes; and any other which has a known proportion to these, may in like manner be expressed algebraically. Conversely, the geometrical magnitudes, represented by such algebraical quantities, may be found, only the algebraical dimensions above the third, not having any corresponding geometrical dimensions, must be expressed by proportionals (a).

The opposite position of straight lines may be expressed by the signs + and — . But, in order to express the various other positions of geometrical figures by algebra from the principles of geometry, some relations of magnitude must be found, which depend upon these positions, and which can be exhibited by equations: And, conversely, by the same principles may the positions of figures be inferred from the equations denoting such relations of their parts.

Though this application of algebra appears to be indirect, yet such is the simplicity of the operations, and the general nature of its theorems, that investigations, especially in the higher parts of geometry, are generally easier and more expeditious by the algebraical method, though less elegant than by what is purely geometrical. The connections also, and analogies of the two sciences established by this application, have given rise to many curious speculations.

Thus, let a point A be given in the line

\[ \overline{PA} \quad \overline{AM} \quad \overline{MP} \quad \overline{PB} \]

AP, any segment AP taken to the right hand being considered as positive, a segment AP to the left is properly

(a) All algebraical dimensions above the third must be expressed by inferior geometrical dimensions; and though any algebraical quantities of two or three dimensions may be immediately expressed by surfaces and solids respectively, yet it is generally necessary to express them, and all superior dimensions, by lines.

If, in any geometrical investigation by algebra, each line is expressed by a single letter, and each surface or solid by an algebraical quantity of two or three dimensions respectively, then whatever legitimate operations are performed with regard to them, the terms in any equation derived will, when properly reduced, be all of the same dimension; and any such equation may be easily expressed geometrically by means or proportionals, as in the following example.

Thus, if the algebraical equation \( a^4 + b^4 = c^4 - d^4 \), is to be expressed geometrically, \( a, b, c, d \), being supposed to represent straight lines; let \( a : b : c : d \), in continued proportion, the \( a^4 : b^4 : c^4 : d^4 \); and \( a^4 + b^4 : a^4 + b^4 : c^4 + d^4 \), etc., etc.: also, let \( a : c : b : d \), etc., etc., etc.; and \( a^4 : b^4 : c^4 : d^4 \), etc., etc., etc.; and \( c : e : p^4 : a : b : c \), and combining the latter with this last found, \( c^4 : d^4 : a^4 + b^4 : e : f : x^2 : c^4 + d^4 \); therefore \( c^4 - d^4 = x^2 : c^2 + d^2 \), and

\( e : c^4 + d^4 : f : x^2 + c^4 + d^4 \), and

\( c : e : p^4 : a : b : c \).
Part III.

Applicable demonstrations of the 11th and 13th propositions of the 2d book of Euclid, require only the 47th of the 1. 11. The 25th and 26th of the 3d book require only the 3. 11. 11 and 47. 11.

From a few simple geometrical principles alone, a number of conclusions, with regard to figures, may be deduced by algebra; and to this in a great measure is owing the extensive use of this science in geometry. If other more remote geometrical principles are occasionally introduced, the algebraical calculations may be much abridged. The same is to be observed in the solution of problems; but such in general are less obvious, and more properly belong to the first geometrical method.

III. Of the Solution of Problems.

Upon the same principles are geometrical problems to be resolved. The problem is supposed to be constructed, and proper algebraical notations of the known and unknown magnitudes are to be sought for, by means of which their connections may be expressed by equations. It may first be remarked, as was done in the case of theorems, that in those problems which relate to the divisions of a line and the proportions of its parts, the expression of the quantities, and the solving their relations by equations, are so easy as not to require any particular directions. But when various positions of geometrical figures and their properties are introduced, the solution requires more attention and skill. No general rules can be given on this subject, but the following observations may be of use.

1. The construction of the problem being supposed, it is often farther necessary to produce some of the lines till they meet; to draw new lines joining remarkable points; to draw lines from such points perpendicular or parallel to other lines, and such other operations as seem conducive to the finding of equations; and for this purpose, those especially are to be employed which divide the scheme into triangles that are given, right angled or similar.

2. It is often convenient to denote by letters, not the quantities particularly sought, but some others from which they can easily be deduced. The same may be observed of given quantities.

3. The proper notation being made, the necessary equations are to be derived by the use of the most simple geometrical principles; such as the addition and subtraction of lines or of figures, the proportionality of lines, particularly of the sides of similar triangles, &c.

4. There must be as many independent equations as there are unknown quantities assumed in the investigation, and from these a final equation may be inferred by the rules of Part I.

If the final equation from the problem be resolved, the roots may often be exhibited geometrically; but the geometrical construction of problems may be effected.
Applying also without resolving the equation, and even without deducing a final equation, by the methods afterwards to be explained.

If the final equation is simple or quadratic, the roots being obtained by the common rules, may be geometrically exhibited by the finding of proportionals, and the addition or substraction of squares.

By inserting numbers for the unknown quantities, a numeral expression of the quantities sought will be obtained by resolving the equation. But in order to determine some particulars of the problem besides finding the unknown quantities of the equation it may be further necessary to make a simple construction; or, if it is required that everything be expressed in numbers, to substitute a new calculation in place of that construction.

**Prop. I. To divide a given straight line AB into two parts, so that the rectangle contained by the whole line and one of the parts may be equal to the square of the other part.**

This is prop. 11th B. of Eucl.

\[ \frac{AC}{BC} = \frac{p}{x} \]

Let C be the point of division, and let \( AB = a \), \( AC = x \), and then \( CB = a-x \). From the problem \( a^2 = px \cdot x^2 \); and this equation being resolved (Chap. V. P. II.) gives \( x = \sqrt{a^2 + a^2} \).

The quantity \( \sqrt{a^2 + a^2} \) is the hypotenuse of a right-angled triangle, of which the two sides are \( a \) and \( a \), and is therefore easily found; \( \frac{a}{2} \) being taken from \( \frac{a}{2} \) this line, gives \( x = AC \), which is the proper solution. But if a line \( AC \) be taken on the opposite side of \( A \), and equal to the abovementioned hypotenuse, together with \( a \), it will represent the negative root \(-\sqrt{a^2 + a^2} \).

\[ -\frac{a}{2} \] and will give another solution; for in this case also \( AB \times BC = AC^2 \). But \( C \) is without the line \( AB \); and therefore, if it is not considered as making a division of \( AB \), this negative root is rejected.

This solution coincides with what is given by Euclid. For \( \sqrt{a^2 + a^2} \) is equal (see the fig. of Prop. 11th Eucl. Simson’s edit.) to \( EB \) or \( EF \), and therefore \( x = \sqrt{a^2 + a^2} \) \( = EF = EA = AF = AH \); and

\[ \frac{4}{2} \] the point \( H \) corresponds to \( C \) in the preceding figure.

Besides, if on \( (EF + EA) = CF \) (instead of \( EF = EA = FA \) a square be described on the opposite side of \( CF \) from \( AG, BA \) produced will meet a side of it in a point; which if it be called \( K \), will give \( KB \times BA = KA \). \( K \) corresponds to \( C \), and this solution will correspond with the algebraical solution by means of the negative root.

If \( CB \) had been called \( x \), and \( AC = a-x \), the equation would be \( ax = a^2 - 2a \cdot x + x^2 \), which gives \( x = \frac{a^2 + a^2}{2} \), in which both roots are positive, and the solutions derived from them coincide with the proceeding. If the solution be confined to a point within the line, then one of these positive roots must be rejected, for one of the roots of the compound square from which it is derived, \( x = \frac{a}{2} \), is a negative quantity which in this strict hypothesis is not admitted. In such a problem, however, both constructions are generally received, and considered even as necessary to a complete solution of it.

If a solution in numbers be required, let \( AB = 10 \), \( AC = 6 \), \( BC \) and \( AD = 7 \), both of which are given because the triangle is given. Let \( AK \) be assumed as the unknown quantity, because from it the square can easily be constructed; and let it be called \( x \). Then \( (KD = EG) = EF = 2 \). On account of the parallels \( EF, BC, AD : BC : AK \times EF \); that is, \( p : a : x ; p-x \), and \( p + px = ax \), which equation being resolved, gives \( x = \frac{p}{x} \).

Therefore \( x \) or \( AK \) is a third proportional to \( p-a \) and \( p \), and may be found by \( 11 \). VI. El. The point \( K \) being found, the construction of the square is sufficiently obvious.

**Prop. III. In the right-angled Triangle ABC, the Base BC, and the Sum of the Perpendicular and Sides BA+AC+AD being given, to find the Triangle.**

Such parts of this triangle are to be found as are necessary for describing it: The perpendicular \( AD \) will be sufficient for this purpose; and let it be called \( x \). Let \( AB + AC + AD = a \), \( BC = b \); therefore \( BA + AC = a - x \). Let

\[ \frac{4}{2} \]
Part III.

Application to Geometry.

Let $BA - AC$ be denoted by $y$, then $BA = \frac{a + y - x}{2}$.

and $AC = \frac{a - x - y}{2}$. But [47. I. El.] $BC = BA + AC + AD = \frac{a + y - x}{2} + \frac{a - x - y}{2} + \frac{a - 2ax + x^2 + y^2}{2}$. Like-wise, from a known property of right-angled triangles, $BC \times AD = BA \times AC$; that is, $BC = \frac{a + y - x}{2}$.

This last equation being multiplied by 2, and added to the former, gives $b^2 + 2bx = a^2 - 2ax - x^2$, which being resolved according to the rules of Part I. Chap. V. gives $x = a + b - \sqrt{2ab + 2b^2}$.

To construct this: $a + b$ is the sum of the perimeter and perpendicular, and is given; $\sqrt{2ab + 2b^2} = \sqrt{a + b + 2b^2}$ is a mean proportional between $a + b$ and $b^2$, and may be found; therefore, from the sum of the perimeter and perpendicular subtract the mean proportional between the said sum and double the base and the remainder will be the perpendicular required.

From the base and perpendicular the right-angled triangle is easily constructed.

In numbers, let $BA + AC + AD = 18.8 = a$; $BC = 10 = b$; then $AD = 4.8 = \sqrt{2ab + 2b^2} = 18.8 - \sqrt{576} = 4.8 = x$, and $BA + AC = 14$. By either of the first equations $y = a^2 + 2ax - a^3 = 4$ and $y = BA - AC = 4$; therefore $BA = 8$, and $AC = 6$.

The geometrical expression of the roots of certain equations arising from problems may be found without resolving them by the intersection of geometrical lines. Thus, the roots of a quadratic are found by the intersections of the circle and straight line, those of a cubic and biquadratic, by the intersections of two conic sections, &c.

The solution of problems may be effected also by the intersections of the loci of two intermediate equations without deducing a final equation. But these two last methods can only be understood by the doctrine of the loci of equations.

CHAP. II.

Of the Definition of Lines by Equations.

Lines which can be mathematically treated of must be produced according to an uniform rule, which determines the position of every point of them. This rule constitutes the definition of any line from which all its other properties are to be derived. A straight line has been considered as so simple as to be incapable of definition. The curve lines here treated of are supposed to be in a plane; and are defined either from the section of a solid by a plane, or more universally by some continued motion in a plane, according to particular rules. Any of the properties apply which are shown to belong peculiarly to such a line, may be assumed also as the definition of it, from which all the others, and even what upon other occasions may have been considered as the primary definition, may be demonstrated. Hence lines may be defined in various methods, of which the most convenient is to be determined by the purpose in view. The simplicity of a definition, and the ease with which the other properties can be derived from it, generally give a preference.

Definitions. 1. When curve lines are defined by equations, they are supposed to be produced by the extremity of one straight line, as PM moving in a given angle along another straight line AB given in position, which is called the base.

2. The straight line PM moving along the other, is called an Ordinate, and is usually denoted by $y$.

3. The segment of the base AP between a given point in it A, and an ordinate PM, is called an Absciss with respect to that ordinate, and is denoted by $x$. The ordinate and absciss together are called Co-ordinates.

4. If the relation of the variable absciss and ordinate AP and PM, be expressed by an equation, which besides $x$ and $y$ contains only known quantities, the curve MO described by the extremity of the ordinate, moving along the base, is called the Locus of that equation.

5. If the equation is finite, the curve is called Algebraical (a). It is this class only which is here considered.

6. The dimensions of such equations are estimated from the highest sum of the exponents of $x$ and $y$ in any term. According to this definition, the terms $x^n$, $x^n y$, $x^m y^r$, $x y^r$, $y^r$ are all of the same dimension.

7. Curve lines are divided into orders from the dimensions of their equations, when bred from fractions and surds.

In these general definitions, the straight line is supposed to be comprehended, as it is the locus of simple equations. The loci of quadratic equations are shown to

(a) The terms Geometrical and Algebraical, as applied to curve lines, are used in different senses, by different writers; there are several other classes of curves besides what is here called algebraical, which can be treated of mathematically, and even by means of algebra. See Scholium at the end.
to be the conic sections, which are hence called lines of the second order, &c.

It is sufficiently plain from the nature of an equation, containing two variable quantities, that it may determine the position of every point of the curve, defined by it in the manner now described: for if any particular known value of one of the variable quantities as t be assumed, the equation will then have one unknown quantity only, and being resolved, will give a precise number of corresponding values of y, which determine so many points of the curve.

As every point of the locus of an equation has the same general property, it must be one curve only, and from this equation all its properties may be derived. It is plain also, that any curve line defined from the motion of a point, according to a fixed rule, must either return into itself, or be extended ad infinitum with a continued curvature.

The equation, however, is supposed to be irreducible; because, if it is not, the locus will be a combination of inferior lines: but the combination will possess the general properties of the lines of the order of the given equation.

It is necessary to be observed all along that the positive values of the ordinate, as PM, being taken upwards, the negative PM will be placed downwards, on the opposite side of the base: and if positive values of the abscissa, as AP, be assumed to the right from its beginning, the negative values, AP will be upon the left, and from these the points of the curve are to be determined.

In the general definition of curves it is usual to suppose the co-ordinates to be at right angles. If the locus of any equation be described, and if the abscissa be assumed on another base, and the ordinate be placed at a different angle, the new equation expressing their relation though of different form, will be of the same order as the original equation; and likewise will have, in common with it, those properties which distinguish the equations of that particular curve.

This method of defining curves by equations may not be the best for a full investigation of the properties of a particular curve; but as their number is without limit, such a minute inquiry concerning all, would be not only useless, but impossible. It has this great advantage, however, that many of the general affects of all curves, and of the different orders, and also some of the most useful properties of particular curves, may be easily derived from it.

1. The Determination of the Figure of a Curve from its Equations.

The general figure of the curve may be found by substituting successively particular values of x the abscissa, and finding by the resolution of these equations the corresponding values of y the ordinate, and of consequence so many points of the curve. If numeral values be substituted for x, and also certain numbers for the known letters, the resolution of the equation gives numerical expressions of the ordinates; and from these, by means of scales, a mechanical description of the curve will be obtained, which may often be useful, both in pointing out the general disposition of the figure, and also in the practical applications of geometry.
The portion between A and E is called a *Nodus*.

If $y$ be put $= 0$, then the values of $x$ are $o$, $o$, $b$.

That is, the curve passes twice through $A$, or $A$ is a punctum duplex, and it passes also through $E$ as before. (r.)

The mechanical description of curves mentioned in the beginning of this section, may be illustrated by the preceding example. For this purpose, let any numerical values of $x$ and $b$ be assumed; and if successive numerical values of $x$ be inferred, corresponding numerical values of $y$ will be obtained, by which so many points in the curve may be constructed. Let $AC = 10$; $AE = b = 12$; and, first let $x = 1$, then

$$y = x \sqrt{\frac{x + b}{a - x}} = \frac{\sqrt{13}}{3} = 1.2$$

nearly, which gives the length of the ordinates when the abscises is 1; and in the same manner the ordinates to be found when $x$ is 2, 3, or any other number. Thus, if $x = 6$,

$$y = 6 \times \frac{\sqrt{13}}{2} = 12.73$$

nearly; and if $AP$ be taken from the scale of equal parts (according to which $A B$ and $A E$ are supposed to be laid down) and equal to 6, then $PM$, $PM$, being taken from the same scale, each equal to 12.73, will give the points of the curve.

In like manner, if $x = y$, then $y = 9 \frac{\sqrt{3}}{19} = 3.58$ nearly; and if $AP = 9$, then $PM$, $PM$ being taken from the same scale equal to 3.58, will give the points $M$, $M$. In the same manner any number of points may be found, and these being joined, will give a representation of the curve, which will be more or less just, according to the number of points found, and the accuracy of the several operations employed.

By the same methods the locus of any other equation is to be traced. Thus, by varying the former equation, the figure of its locus will be varied. If $b = 0$, then the point $A$ and $E$ coincide, the nodus vanishes, and $A$ is called a *root*.

If $b$ is negative, then $E$ is to the right of $A$, which application will now be a punctum conjugation. The rest of the curve will be between $E$ and $C$ and $CD$ becomes an asymptote.

If $x = 0$ then $y = x \sqrt{\frac{x + b}{a - x}}$ or $y = bx - x^2$, which is an equation to the circle of which $b = AE$ is the diameter.

### II. General Properties of Curves from their Equations.

The general properties of equations lead to the general affections of curve lines. For example, A straight line may meet a curve in as many points as there are units in the dimension of its equation; so many roots may that equation have. An asymptote may cut a curve line in as many points, excepting two, as it has dimensions, and no more. The same may be observed of the tangent.

Impossible roots enter an equation by pairs; therefore the intersections of the ordinate and curve must vanish by pairs.

The curves of which the number expressing the order is odd, must have at least two infinite areas; for the abscises may be so assumed, that, for every value of it, either positive or negative, there must be at least one value of $y$, &c.

The properties of the coefficients of the terms of equations, mentioned Part II. Chap. I. furnish a great number of the curious and universal properties of curve lines. For example, the second term of an equation is the sum of the roots with the signs changed, and if the second term is wanting, the positive and negative roots must be equal. From this it is easy to demonstrate, That if each of two parallel straight lines meet a curve line in as many points as it has dimensions, and if a straight line cut these two parallels, so that the sum of the segments of each on one side be equal to the sum of the segments on the other, this straight line will cut any other line parallel to these in the same manner. Analogous properties, with many other consequences from them, may be deduced from the composition of the coefficients of the other terms.

Many properties of a particular order of curves may be inferred from the properties of equations of that order. Thus, If a straight line cut a curve of the third order in three points, and another straight line be drawn, making a given angle with the former, and cutting the curve also in three points, then the parallels by the segments of one of these lines between its intersection with the other, and the points where it meets the curve, will be to the parallels by the like segments of the other line in a given ratio. This depends upon the composition of the absolute term, and may be extended to curves of any order.

### III. *To* Subdivide *Con* of Curves.

As lines are divided into orders from the dimensions of their equations, in like manner, from the varieties of the equations of any order, may different genera and species of that order be distinguished, and from the peculiar properties of these varieties, may the affections of the particular curves be discovered.

For this purpose a complete general equation is assumed of that order, and all the varieties in the terms and coefficients which can affect the figure of the locus are enumerated.
It was formerly observed, that the equations belonging to any one curve, may be of various forms, according to the position of the base, and the angle which the ordinate makes with it, though they be all of the same order, and have also certain properties, which distinguish them from the other equations of that order.

The locus of simple equations is a straight line. There are three species of lines of the second order, which are easily shown to be the conic sections, reckoning the circle and ellipse to be one. Seventy-eight species have been numbered of the third order: And as the superior orders become too numerous to be particularly reckoned, it is usual only to divide them into certain general classes.

A complete arrangement of the curves of any order would furnish canons, by which the species of a curve whose equation is of that order might be found.

IV. Of the place of Curves defined from other principles in the Algebraical System.

If a curve line be defined from the section of a solid, or from any rule different from what has been here supposed, an equation to it may be derived, by which its order and species in the algebraical system may be found. And, for this purpose, any base and any angle of the co-ordinates may be assumed, from which the equation may be most easily derived, or may be of the most simple form.

The three Conic Sections are of the second order, as their equations are universally quadratic; the Circle of the ancients is of the third order, and the 42d species, according to Sir Isaac Newton's enumeration; this is the curve defined by the equation in page 439, col. i. par. ult., when $b=0$. The curve delineated above in the same page, is the 43d species. When $b$ is negative in that equation, the locus is the 43d species. The Conchoid of Nicomedes is of the fourth order; the Caffinian curve is also of the fourth order, &c.

It is to be observed, that not only the first definition of a curve may be expressed by an equation, but likewise any of those theorems called loci, in which some property is demonstrated to belong to every point of that curve. The expression of these propositions by equations, is sometimes difficult; no general rules can be given, and it must be left to the skill and experience of the learner.

Scholium.

This method of treating curve lines by equations, besides the uses already hinted at, has many others, which do not belong to this place; such are, the finding the tangents of curves, their curvature, their areas and lengths, &c. The solution of these problems has been accomplished by means of the equations to curves, though by employing, concerning them, a method of reasoning different from what has been here explained.

CHAP. III.

I. Construction of the Loci of Equations.

The description of a curve, according to the definition of it, is assumed in geometry as a postulate. If the properties of a particular curve are investigated, it will appear that it may be described from a variety of data different from those assumed in the postulate, by demonstrating the dependence of the former upon the latter.

As the definitions of a curve may be various, so also may be the postulates, and a definition is frequently chosen from the mode of description connected with it. The particular object in view, it was formerly remarked, must determine the proper choice of a definition; the simplicity of it, the ease with which the other properties of the figure may be derived from it, and sometimes even the ease with which it can be executed mechanically, may be considered as important circumstances.

In the straight line, the circle, the conic sections, and a few curves of the higher orders, the most convenient definitions, and the postulates connected with them, are generally known and received. An equation to a curve may also be assumed as a definition of it; and the description of it, according to that definition, may be considered as a postulate; but, if the geometrical construction of problems is to be investigated by means of algebra, it is often useful to deduce from the equation to a curve, those data which, from the geometrical theory of the curve, are known to be necessary to its description in the original postulate, or in any problem founded upon it. This is called Constructing the locus of an equation, and from this method are generally derived the most elegant constructions which can be obtained by the use of algebra. In the following section, there is an example of a problem resolved by such constructions.

Sometimes a mechanical description of a curve line defined by an equation is useful; and as the exhibition of it, by such a motion as is suggested in that definition, is rarely practicable, it generally becomes necessary to contrive some more simple motion which may in effect correspond with the other, and may describe the curve with the degree of accuracy which is wanted. Frequently, indeed, the only method which can be conveniently practised, is the finding a number of points in the curve by the resolution of numerical equations, in the manner mentioned in Sect. 1. of this Chapter, and then joining these points by the hand; and though this operation is manifestly imperfect, it is on some occasions useful.

II. Solution of Problems.

The solution of geometrical problems by algebra is much promoted, by describing the loci of the equations arising from these problems.

For this purpose, equations are to be derived according to the methods formerly described, and then to be reduced to two, containing each the same two unknown quantities. The loci of these equations are to be described, the two unknown quantities being considered as the co-ordinates, and placed at the same angle in both. The co-ordinates at the intersection of the loci, will be common to both, and give a solution of the problem.

The simplicity of a construction obtained by this method, will depend upon a proper notation, and the choice of the equations of which the loci are to be described. These will frequently be different from what would be proper in a different method of solution.
Part III.

A L G E B R A.

PROB. IV. To find Point P in the Base of the given Triangle ABC, so that the Sum of the Squares of FE, FD drawn from it perpendicular upon the two Sides, may be equal to a given Space.

Draw BH, CG perpendicular on the two sides, and let $FD = x$, $FE = y$.

Also $\frac{bh}{r} = \frac{z}{a}$, and $x = \frac{y}{b}$.

Therefore $\frac{bh}{a} = \frac{y}{b}$.

That is $y = \frac{bx}{r}$.

An equation to a straight line.

But $x^2 + y^2 = m^2$ of which the locus is a circle, having $m$ for the radius. By constructing these loci, their intersection will give a solution of the problem.

Let $KL = CG = \frac{r}{a}$ be at right angles to $LM = BH = \frac{z}{a}$, join $KM$, to which let $LK$ be parallel; $LN$ is the straight line of the equation $y = \frac{bx}{r}$; for let any line $OPQ$ be drawn parallel to $LM$, if $KP = x$, then $PQ = \frac{bx}{r}$.

And $OQ = LM = \frac{z}{a}$, therefore $OQ = y = \frac{bx}{r}$.

About the centre $K$, with a distance equal to the line $m$, let a circle be described; that circle will be the locus of the equation $m^2 = x^2 + y^2$; for it is plain that if $OP$ be any perpendicular from the circumference upon $KL$, $KP$ being $x$, $OP$ will be $y$. Either of the points, therefore, in which this two loci intersect each other, as $O$, will give $OP$ an ordinate in both equations, $KP$ being the common absciss; therefore $KP$, $OP$ are the two perpendiculars required, from which the point $F$ is easily found.

The construction might have been made on figure 18, with fewer lines. If the circle touches $LN$, there is only one solution which is a minimum; and if the circle does not meet $LN$, the problem becomes impossible.

When the circle touches $LN$, the radius $m$ must be equal to the perpendicular from $K$ on $LN$, or from $L$ Vol. 1.

PROB. V. Between two given Lines to find two mean Proportional.

Let the lines be $a$ and $b$, and let the two means be $x$ and $y$; therefore $ax = yb$, and hence $y = \frac{ax}{b}$, which are both equations to the parabola, and are easily constructed. The co-ordinates at the intersection of these two loci will be the means required.

If one unknown quantity only is assumed, or if it is convenient to deduce a final equation containing only one, the construction of the roots is to be obtained by the method mentioned in the next section.

Scholium.

The constructions of the two preceding problems are geometrical; but it is sometimes convenient to have a practical solution, by the mechanical description either of the algebraical lines employed in the geometrical solution, or of other geometrical lines by which it can be effected. But few of these are tolerably accurate; so that, in general, by means of calculation, the practical operations are all reduced to what may be performed by a ruler and a compas.

III. Construction of Equations.

The roots of an equation, containing only one unknown quantity, may be found by the intersection of lines, the product of whose dimensions is equal to the dimension of that equation. And hence problems are resolved without an algebraical solution of the equation arising from them.

Thus cubic and biquadratic equations may be constructed by the intersections of two conic sections as the circle and parabola, which are generally assumed as being most easily described.

In order to find these constructions, a new equation is to be assumed, containing two variable quantities, one of which is the unknown quantity of the given equation, and the other by substitution is to be inferred also in the given equation; the intersection of the loci of these equations will exhibit the roots required.

Canons may be devised for the construction of particular orders, without adumbrating the new equation.

The final equation from prob. 4, would be $x^3 = ax^2 + b$, which being constructed according to the rules, exhibits the common geometrical solution of that problem by the circle and parabola.

If an equation be assumed, as $ax = y$, the other by substitution becomes $y = ax$; the locus of the former is a parabola, and of the latter an hyperbola, one of its asymptotes being the base, and the co-ordinates at their intersection will represent $x$ and $y$; the first of the two means is $x$, and in this case $y$ is the other.
Equations also might be formed so as to give a solution of this problem by other combinations of two of the conic sections, one of them not being the circle.

As geometrical magnitudes may be represented by algebra, so algebraical quantities and numbers may be represented by lines. Hence this construction of equations has sometimes been used as an easy method of approximation to the roots of numerical equations. For this purpose, the necessary straight lines must be laid down by means of a scale of equal parts, and the curve lines, on whose intersection the construction depends, must be actually described; the linear roots being measured on the scale will give the numbers required. These operations may be performed with sufficient accuracy for certain purposes; but as they depend on mechanical principles, the approximation obtained by them cannot be continued at pleasure; and hence it is seldom used, except in finding the first step of an approximation, which is to be carried on by other methods.

Scholium.

If the relation between the ordinate and abscissa be fixed, but not expressible by a finite equation, the curve is called Mechanical (a) or Transcendental. This class is also sometimes defined by equations, by supposing either \( x \) or \( y \) in a finite equation to be a curve line, of which the relation to a straight line cannot be expressed in finite terms.

If the variable quantities \( x \) or \( y \) enter the exponents of any term of an equation, the locus of that equation is called an Exponential Curve.

Many properties of these two classes of curves may be discovered from their equations.

---

(a) The term Mechanical, in this place, is used merely as the name of a particular class of curves, without implying that they have any more dependence on the principles of Mechanics or Physics than the algebraical curves which have been treated of.
happened about the middle of the seventh century; and the Arabs continued masters of the country, divided into a great number of petty kingdoms or states, under chiefs of their own choosing, till the year 957.

This year, one Abubekeber-ben-Omar, or, as the Spanish authors call him, Abu Texefien, an Arab of the Ziahigian tribe, being provoked at the tyranny of those despots, gathered, by the help of his marabouts or saints, a most powerful army of malcontents, in the southern provinces of Numidia and Libya. His followers were nicknamed Marobites or Morabites; by the Spaniards, Amóravides; probably from their being assembled principally by the saints who were also called Morabites. The Khalif of Káyém's forces were at this time taken up with quelling other revolts in Syria, Mefopotamia, &c. and the Arabs in Spain engaged in the most bloody wars; so that Texefien having nothing to fear from them, had all the succours he could with against the Arabian chekys or petty tyrants, whom he defeated in many battles, and at last drove them not only out of Numidia and Libya, but out of all the western parts, reducing the whole province of Tingi under his dominion.

Texefien was succeeded by his son Yufif, or Joseph, a brave and warlike prince. In the beginning of his reign, he laid the foundation of the city of Morocco, which he designed to make the capital of his empire. While that city was building, he sent some of his marabouts ambassadors to Tremecen (now a province of Algiers), at that time inhabited by a powerful and inoffent sect of Mahometans called Zeneti. The design of this embassy was to bring them back to what he called the true faith; but the Zeneti, defpising his offers, assembled at Amaf, or Amfa, their capital, murdered the ambassadors, and invaded Joseph's dominions with an army of 50,000 men.

The king hearing of their infamous proceedings, speedily mustered his army, and led it by long marches into their country, destroying all with fire and sword; while the Zeneti, instead of opposing his progress, retired as fast as possible towards Fez, in hopes of receiving assistance from thence. In this they were miserably deceived: the Fezzans marched out against them in a hostile manner, and taking up with his unhappy Zeneti, encumbered with their families and baggage, and ready to expire with hunger and weariness, they cut them all to pieces, except a small number who were mostly drowned in attempting to swim across a river, and some others who in their flight perished by falling from the high adjacent rocks. In the mean time Joseph reduced their country to a mere desolation, which was, however, soon peopled by a numerous colony of Fezzans, who settled there under the protection of the reigning kings. In this war it is computed that near a million of the Zenni, men, women, and children, lost their lives.

The reliefs and ambitions temper of Joseph did not let him remain long at peace. He quickly declared war against the Fezzans, reduced them to become his tributaries, and extended his conquests all along the Mediterranean. He next attacked some Arabian chekys who had not yet submitted to his jurisdiction; and pursued them with such fury, that neither the Libyan deserts, nor ridges of the most craggy rocks, could shelter them from his arms. He attacked them in such of their retreats, castles, and fortresses, as were still then deemed impregnable: and at last subdued them, to the great grief of the other African nations, who were greatly annoyed by the ravages committed by his numerous forces.

Thus was founded the empire of the Morabites; which, however, was of no long duration; being in the 12th century driven out by Mohaveds, a marabout. This race of priests was expelled by Abdul-Darr governor of Fez; and he, in the 13th century, stripped of his new conquests by the Sharifs of Hafien, and the descendants of those Arabian princes whom Abu-Texeien had formerly expelled.

The better to secure their new dominions, the Sharifs divided them into several little kingdoms or provinces; and among the rest the present kingdom of Algiers was divided into four, namely, Tremecen, Tenez, Algiers proper, and Bajeyah. The four first monarchs laid so good a foundation for a lasting balance of power between their little kingdoms, that they continued for some centuries in mutual peace and amity; but at length the king of Tremecen having ventured to violate some of their articles, Abul-Fariz, king of Tenez, declared war against him, and obliged him to become his tributary. This king dying soon after, and having divided his kingdom among his three sons, new discord arose; which Spain taking advantage of, a powerful fleet and army was sent against Barybar, under the Count of Navarre, in 1505. This commander soon made himself master of the important cities of Oran, Bajeyah, and some others; which is alarmed from the Algériens, that they put themselves under the protection of Selim Eltemi, a noble and warlike Arabian prince. He came to their assistance with a great number of his bravest subjects, bringing with him his wife Zaphira, and a son then about 12 years old. This however was not sufficient to prevent the Spaniards from landing a number of forces near Algiers that same year, and obliging that metropolis to become tributary to Spain. Nor could Prince Selim hinder them from building a strong fort on a small island opposite to the city, which terrifed their corsairs from sailing either in or out of the harbour.

To this galling yoke the Algeriens were obliged to submit till the year 1516; when, hearing of the death of Ferdinand king of Spain, they sent an embassay to Aruch Barbarofa, who was at this time no less dreaded for his valour than his surpaizing success, and was then sent on a cruize with a squadron of galleys and barks. The purport of the embassay was, that he should come and free them from the Spanish yoke; for which they agreed to pay him a gratuity answerable to so great a service. Upon this Barbarofa immediately dispatched 18 galleys and 30 barks to the assistance of the Algerines; while he himself advanced towards the city with 800 Turks, 3000 Jigelites, and 2000 Moorish volunteers. Instead of taking the nearest road to Algiers, he directed his course towards Sharif-lo, where Hafien, another famed corsair, had settled himself. He surprised him, and obliged to surrender: not without a previous promise of friendship: but no sooner had Barbarofa got him in his power, than the cut off his head; and obliged all Hafien's Turks to follow him in his new expedition.

On Barbarofa's approach to Algiers, he was met by Prince
prince Eutemi, attended by all the people of that metropolis, great and small; who looked for deliverance from this abandoned villager, whom they accounted in- 
vincible. He was conducted into the city amidst the 
acclamations of the people, and lodged in one of the 
nobles apartments of prince Eutemi’s place, where 
he was treated with the greatest marks of distinction. 
Eulogized beyond measure with this kind reception, Bar- 
baroffa formed a design of becoming king of Algiers; 
and fearing some opposition from the inhabitants, on 
account of the excesses he suffered his soldiers to com-
mitted, murdered prince Eutemi, and caused himself to be 
proclaimed king; his Turks and Moors crying out as 
he rode along the streets, “Long live King Archu 
Barbaroffa, the invincible king of Algiers, the chosen 
of God to deliver the people from the oppression of 
the Christians; and destruction to all that shall oppose, or 
refuse to own him as their lawful sovereign.” These 
last threatening words so intimidated the inhabitants, 
already apprehensive of a general massacre, that he was 
immediately acknowledged king. The unhappy prin-
cess Zaphira, it is said, poisoned herself, to avoid the 
brutality of this new king, whom the unsuccessfuilly in-
deavoured to stab with a dagger.

Barbaroffa was no sooner seated on the throne, than 
he treated his subjects with such cruelty, that they used 
to shut up their houses and hide themselves when he ap-
ppeared in public. In consequence of this, a body was 
soon formed against him; but being discovered, he cau-
ted twenty of the principal conspirators to be behead-
ed, their bodies to be buried in a dunghill, and laid a 
heavy fine on those who survived. This terrified the 
Algerines, that they never afterwards durst attempt 
any thing against either Barbaroffa or his successors.

In the mean time, the son of prince Eutemi having 
flown to Oran, and put himself under the protection of 
the marquis of Gomarez, laid before that nobleman a 
plan for putting the city of Algiers into the hands of 
the king of Spain. Upon this, young Selim Eutemi 
was sent to Spain, to lay his plan before cardinal Xi-
menes; who having approved of it, sent a fleet with 
10,000 land forces, under the command of Don Francis-
to, or, as others called him, Don Diego de Vera, to drive 
out the Turks, and restore the young prince. But the 
fleet was no sooner come within sight of land, than 
it was dispersed by a storm, and the greatest part of 
the ships dashed against the rocks. Most of the Spa-
niards were drowned; and the few who escaped to shore 
were either killed by the Turks or made slaves.

Though Barbaroffa had nothing to boast on this oc-
casion, his pride and insolence were now swelled to such 
a degree, that he imagined himself invincible, and that 
the very elements conspired to make him so. The A-
rabians were so much alarmed at his successes, that they 
implored the assistance of Hamidel Abdes king of Te-
nez, to drive the Turks out of Algiers. That prince 
readily undertook to do what was in his power for this 
purpose, provided they agreed to settle the kingdom 
on himself and his descendants. This proposal being 
accepted, he immediately set out at the head of 10,000 
Moors; and, upon his entering the Algerine domin-
oins, was joined by all the inhabitants. Barbaroffa 
engaged him, only with 1000 Turkish muf-
queteers and 500 Granada Moors; totally defeated his 
numerous army; pursued him to the very gates of his 
capital, which he easily made himself master of; and, 
having given it up to be plundered by his Turks, obli-
ged the inhabitants to acknowledge him as their fuse-
reign. This victory, however, was chiefly owing to 
the advantage which his troops had from their fire-
arms; the enemy having no other weapons than ar-
rows and javelins.

No sooner was Barbaroffa become master of the king-
dom of Tenez, than he received an embassy from 
the inhabitants of Treemecen; inviting him to come to 
their assistance against their then reigning prince, with 
whom they were dissatisfied on account of his having dethro-
ned his nephew, and forced him to fly to Oran, offering 
him even the sovereignty, in case he accepted of 
their proposal. The king of Treemecen, not sifts peading 
the treachery of his subjects, met the tyrant with an 
army of 6000 horse and 3000 foot: but Barbaroffa’s 
artillery gave him such an advantage, that the king 
was at length forced to retire into the capital; which 
he had no sooner entered than his head was cut off, and 
fled to Barbaroffa, with a fresh invitation to come and 
take possession of the kingdom. On his approach, he 
was met by the inhabitants, whom he received with great 
complaisance, and many fair promises; but beginning 
to tyrannize as usual, his new subjects soon convinced 
him that they were not so passive as the inhabitants of 
Algiers. Apprehending, therefore, that his reign 
might prove unjust and precarious, he entered into an 
alliance with the king of Fez; after which, he took 
care to secure the reft of the cities in his new kingdom 
by garrisoning them with his own troops. Some 
of these, however, revolted soon after; upon which he 
sent one of his corsairs, named Efsander, a man no les 
cruel than himself, to reduce them. The Tremeceni-
ans now began to repent in good earnest of their 
habitants having invited such a tyrant to their assistance; 
and held conferences on the most proper means of driving him 
away, and bringing back their lawful prince Abuchen 
Men; but their cabals being discovered, a great num-
ber of the conspirators were massacred in the most cruel 
manner. The prince had the good luck to escape to 
Oran, and was taken under the protection of the mar-
quis of Gomarez, who sent immediate advice of it to 
Charles V. then lately arrived in Spain, with a power-
ful fleet and army. That monarch immediately or-
ed the young king a succour of 10,000 men, under the 
command of the governor of Oran; who, under the 
guidance of Abuchen Men, began his march towards 
Treemecen, and in their way they were joined by prince 
Selim, with a great number of Arabs and Moors. The 
first thing they resolved upon was, to attack the im-
portant fortes of Calau, situated between Treemecen 
and Algiers, and commanded by the corsair Efsander 
at the head of about 300 Turks. They invested it 
closely on all sides, in hopes Barbaroffa would come out 
of Treemecen to its relief, which would give the Trem-
ecenians an opportunity of keeping him out. That 
tyrant, however, kept close in his capital, being em-
arrassed by his fears of a revolt, and the polite delays 
of the king of Fez, who had not sent the auxiliaries 
he promised. The garrison of Calau, in the mean 
time, made a brave defence; and, in a gory they made 
at night, cut off near 300 Spaniards. This encouraged 
them to venture a second time; but they were now re-
pelled with great loss, and Efsander himself wounded; 
soon
Barbaroffa being soon informed that Abuchen Men, with his Arabs, accompanied by the Spaniards, were in full march to lay siege to Tremecen, thought proper to come out, at the head of 1500 Turks and 5000 Moorish horse, in order to break his way through the enemy: but he had not proceeded far from the city, before his council advised him to return and fortify himself in it. This advice was now too late; the inhabitants being resolved to keep him out, and open their gates to their own lawful prince as soon as he appeared. In this distress Barbaroffa saw no way left but to retire to the citadel, and there defend himself till he could find an opportunity of fealing out with his men and all his treasure. Here he defended himself vigorously; but his provisions failing him, he took advantage of a subterfum which had served him so well to be digged up for that purpose, and, taking his immense treasure with him, stole away as secretly as he could. His flight, however, was soon discovered: and he was so closely pursued, that to assure, as he hoped, the enemy, he caused a great deal of provilions to be taken with him, and to his comrades, &c. to be scattered all the way, thinking they would not fail to stop his pursuit together it up. This stratagem, however, failed, through the vigilance of the Spanish commander, who being himself at the head of the pursuers, obliged them to march on; till he was come up close to them on the banks of the Hvaeeda, about eight leagues from Tremecen. Barbaroffa had just crossed the river with his vanguard, when the Spaniards came up with his rear on the other side, and cut them all off; and then crossing the water, overthrew him in a small distance from it. Here a bloody engagement ensued, in which the Turks fought like as many lions; but, being at length overpowered by numbers, they were all cut to pieces, and Barbaroffa among the rest, in the 40th year of his age, and four years after he had raised himself to the royal title of feige of the adjacent country, two years after he had taken the preeminence of Algiers, and scarce a twelvemonth after the reduction of Tremecen. His head was carried to Tremecen, on the point of a spear; and Abuchen Men proclaimed king, to the joy of all the inhabitants. A few days after the flight, the king of Fez made his appearance at the head of 20,000 horse, near the field of battle; but hearing of Barbaroffa’s defeat and death, marched off with all possible speed, to avoid being attacked by the enemy.

The news of Barbaroffa’s death spread the utmost consternation among the Turks at Algiers; however, they caused his brother Hayradin to be immediately proclaimed king. The Spanish commander now sent back the emperor’s forces, without making any attempt upon Algiers; by which he lost the opportunity of driving the Turks out of that country; while Hayradin, justly dreading the confquences of the tyranny of his officers, fought the protection of the Grand Signior. This was readily granted, and himself appointed ballaw or viceroy of Algiers; by which means he received such considerable reinforcements, that the unhappy Algerines durst not make the least complaint; and such numbers of Turks reforted to him, that he was not only capable of keeping the Moors and Arabs in subjection at home, but of annoying the Christians at sea. His first step was to take the Spanifh fort abovementioned, which was a great nuisance to his metropolis. The Spaniards held out to the last extremity; but being all slain or wounded, Hayradin easily became master of the place.

Hayradin next set about building a strong mole for the safety of his ships. In this he employed 30,000 Christian slaves, whom he obliged to work without intermission for three years; in which time the work was completed. He then caused the fort he had taken from the Spaniards to be repaired, and placed a strong garrison in it, to prevent any foreign vessels from entering the harbour without giving an account of themselves. By these two important works, Hayradin soon became dreaded not only by the Arabs and Moors, but also by the maritime Christian powers, especially the Spaniards. The viceroy failed not to acquaint the Grand Signior with his success, and obtained from him a fresh supply of money, by which he was enabled to build a stronger fort, and to erect batteries on all places that might favour the landing of an enemy. All these have since received greater improvements from time to time, as often as there was occasion for them.

In the mean time the Sultan, either out of a sense of succeeded the great services Hayradin had done, or perhaps but by Alfant of jealousy left him should make himself independent, Aga raised Hayradin to the dignity of baron of the empire, and appointed Aga Aga, a Sardinian renegade, an intrepid warrior, and an experienced officer, to succeed him as ballaw of Algiers. Hayradin had no sooner taken possession of his new government, than he began to pursue his ravages on the Spanish coast with greater fury than ever; extending them to the ecclesiastical state, and other parts of Italy. But Pope Paul III. being alarmed at this, exerted the emperor Charles V. to send a powerful fleet to stoppeth those frequent and cruel piracies; and, that nothing might be wanting to render the interceptive successful, a bull was published by his holiness, wherein a pious abstinence of fish, and the crown of martyrdom, was promised to all those who either fell in battle or were made slaves; the emperor on his part needed no spur; and therefore set sail at the head of a powerful fleet consisting of 120 ships and 20 galleys, having on board 30,000 chosen troops, an immense quantity of money, arms, ammunition, &c. In this expedition many young nobility and gentry attended as volunteers, and among these many knights of Malta, so remarkable for their valour against the enemies of Christianity. Even ladies of birth and character attended Charles in his expedition, and the wives and daughters of the officers and soldiers followed them with a design to settle in Barbary after the conquest was finished. All these meeting with a favourable wind, soon appeared before Algiers; every ship displaying the Spanish colours on the stern, and another at the head, with a crucifix to serve them for a pilot.

By this prodigious armament, the Algerines were Algiers in thrown into the utmost consternation. The city was great con

Barbaroffa defeated and killed by the Spaniards.

Succeeded by Hayradin.
Soon after this, the prophet Yusuf, who had foretold the destruction of the Spaniards, was not only declared the deliverer of his country, but had a considerable gratuity decreed him, with the liberty of exercising his prophetic function unmolested. It was not long, however, before the marabouts, and some interpreters of the law, made a strong opposition against him; re-monstrating to the baibaw, how ridiculous and scandalous it was to their nation, to acribe the deliverance of it to a poor fortune-teller, which had been obtained by the fervent prayers of an eminent faint of their own profession. But though the bahaw and his douwan deemed, out of policy, to give into his last notion, yet the impression which Yusuf's predictions and their late accomplishments had made upon the minds of the common people, proved too strong to be eradicated; and the spirit of divination and conjuring has since got into such credit among them, that not only their great statesmen, but their priests, marabouts, and fannoos, have applied themselves to that study, and dignified it with the name Mahomet's Revelations.

The unhappy Spaniards had scarce reached their ships, when they were attacked by a fresh storm, in which several more of them perished; one ship in particular, containing 700 soldiers, besides sailors, sunk in the emperor's sight, without a possibility of saving a single man. At length, with much labour, they reached the port of Bujejah, at that time possessed by the Spaniards, whither Haifan king of Tunis soon after repaired, with a supply of provisions for the emperor, who received him graciously, with fresh assurances of his favour and protection. Here he diffimled the few remains of the Maltese knights and their forces, who embarked in three shattered galleys, and with much difficulty and danger reached their own country. Charles himself said no longer than till the 16th of November, when he fell sick of Carthagena, and reached it on the 25th of the same month. In this unfortunate expedition upwards of 280 ships and galleys were lost, above 300 colonels and other land and sea officers, 8000 soldiers and marines, besides those destroyed by the enemy on the reembarkation, or drowned in the last storm. The number of prisoners was so great, that the Algerines sold some of them, by way of contempt, for an onion per head.

Haifan, elated with this victory, in which he had so little share, undertook an expedition against the king of Tremecen, who, being now deprived of the assistance of the Spaniards, was forced to procure a peace by paying a vast sum of money, and becoming tributary to him. The baibaw returned to Algiers, laden with riches; and soon after died of a fever, in the 66th year of his age.

From this time the Spaniards were never able to annoy the Algerines in any considerable degree. It is said, when taken from 1555, they left the city of Bujejah, which was then captured by Saliba Rais, Haifan's successor; who next year set out with a new expedition, which he kept a secret, but was suspected to be intended against Oran: but he was scarcely got four leagues from Algiers, when the plague, which at that time raged violently in the city, broke out in his train, and carried him off in 24 hours.

Immediately after his death the Algerine soldiery chose a Corsican renegade, Haifan Corfo, in his room, baibaw by till they should receive further orders from the Porte, the Janissaries.
He did not accept of the bashawhip without a good deal of difficulty; but immediately prosecuted the intended expedition against Oran, dispatching a messenger to acquaint the Porte with what had happened. They had hardly begun their hostilities against the place, when orders came from the Porte, expressly forbidding Haifan Corfo to begin the siege, or, if he had begun it, enjoining him to raise it immediately. This news was received with great grief by the whole fleet and army, as they thought themselves sure of success, the garrison being at that time very weak. Nevertheless, as they dared not disobey, the siege was immediately raised.

Corfo had hardly enjoyed his dignity four months, before news came, that eight galleys were bringing a new bashaw to succeed him; one Tekelli, a principal Turk of the Grand Signior’s court: upon which the Algerines unanimously resolved not to admit him. By the treachery of the Levantine soldiers, however, he was admitted at first, and the unfortunate Corfo thrown over a wall in which a number of iron hooks were fixed; one of which catching the ribs of his right side, he hung three days in the most exquisite torture before he expired.

Tekelli was no sooner entered upon his new government, than he behaved with such cruelty and rapacity, that he was assassinated even under the dome where they were so shamefully repulsed by an handful of Spaniards by Tekelli, who put him to a cruel death.

Yusef was succeeded by Haifan the son of Hayraddin, who had been formerly recalled from his bashawhip, when he was succeeded by Selha-Reis; and now had the good fortune to get himself reinstituted in his employment. Immediately on his arrival, he engaged in a war with the Arabs, by whom he was defeated with great loss. The next year, the Spaniards undertook an expedition against Moftagan, under the command of the count d’Alcandela; but were utterly defeated, the commander himself killed, and 12,000 taken prisoners. This disaster was owing to the incon siderable rashness, or rather madness, of the commander; which was so great, that, after finding it impossible to rally his scattered forces, he rushed, sword in hand, into the thickest of the enemy’s ranks, at the head of a small number of men, crying out, “St Jago! St Jago! the victory is ours, the enemy is defeated,” soon after which he was thrown from his horse, and trampled to death.

Haifan having had the misfortune to disoblige his subjects by allowing the mountainers of Cuco to buy ammunition at Algiers, was sent in iron to Constan tinople, while the aga of the Janissaries, and general of the land forces, supplicated his place.—Haifan easily found means to clear himself; but a new bashaw was appointed, called Achmet; who was no sooner arrived, than he sent the two deputy-bashaws to Constan tinople, where their heads were struck off.—Achmet was a man of such infatiable avarice, that, upon his arrival at Algiers, all ranks of people came in crowds to make him presents; which he more greedily accepted, as he had bought his dignity by the money he had amassed while head gardener to the Sultan. He enjoyed it, however, only four months; and after his death, the state was governed other four months by his lieutenant; when Haifan was a third time sent viceroy to Algiers, where he was received with the greatest demonstrations of joy.

The shift enterprize in which Haifan engaged, was the siege of Marfaquiwer, situated near the city Oran, Siege of Marfaquiwer. The army employed in this siege consisted of 26,000 foot and 10,000 horse, besides which he had a fleet consisting of 50 galleys and gallions, together with three French vessels laden with biscuit, oil, and other provisions. The city was defended by Don Martin de Cordova, brother of the Count d’Alcandela, who had been taken prisoner in the battle where that nobleman was killed, but had obtained his liberty from the Algerines with immense sums, and now made a most gallant defence against the Turks. The city was attacked with the utmost fury by sea and land, so that several breaches were made in the walls. The Turkish standards were several times planted on the walls, and as often dislodged; but the place must have in the end submitted, had not Haifan been obliged to raise the siege in haste, on the news that the famed Genoese admiral Doria was approaching with considerable forces from Italy. The fleet accordingly arrived soon after; but missing the Algerine gallies, bore away for Penon de Velez, where they were shamefully repulsed by an handful of Turks who garrisoned that place; which, however, was taken the following year.

In 1567, Haifan was again recalled to Constan tinople, where he died three years after. He was suc ceeded by Mahomet, who gained the love of the Algerines by several public spirited actions. He incorporated the Janissaries and Levantine Turks together, and by that means put an end to their dissensions, which laid the foundation of the Algerine independency on the Porte. He likewise added some considerable fortifications to the city and castle, which he designed to render impregnable. But while he was thus studying the interests of Algiers, one John Gascon, a bold Span ish adventurer, formed a design of surprising the whole piratic navy in the bay, and setting them on fire in the night-time, when they lay defenceless, and in their first sleep. For this he had not only the permission of king Philip II. but was furnished by him with proper vessels, mariners, and fire-works, for the execution of his plot. With these he fell on Algiers in the most proper season, viz. the beginning of October, when most, if not all the ships lay at anchor there; and easily sailed near enough, unsuspected, to view their manner of riding, in order to catch them napping, at a time when the greater part of their crew were dispersed in their quarters. He came accordingly, unperceived by any, to the very mole-gate, and dispersed his men with their fire-works; but to their great surprize, they found them so ill mixed, that they could not with all their art make them take fire. In the mean time, Gascon took it into his head, by way of bravado, to go to do at the mole-gate, and give three loud knocks at it with city gate. the pommel of his dagger, and to leave it fixed in the gate by its point, that the Algerines might have cause to remember him. This he had the good fortune to do without meeting with any disturbance or opposition: but it was not so with his men; for no sooner did they find their endeavours unsuccessful, than they made such a battle as quickly alarmed the gendar soldiery on the adja
Algiers, from which the uproar quickly spread itself thro' the whole garrison. Gafcon, now finding himself in the utmost danger, falled away with all possible haste: but he was pursued, overtaken, and brought back a prisoner to Mahomet; who no sooner got him into his power, than he immediately caused a gibbet of considerible height to be erected on the spot where Gafcon had landed, ordering him to be hoisted up, and hung by the feet to a hook, that he might die in exquisite torture; and to shew his resentment and contempt of the king his master, he ordered his commiss on to be tied to his toes. He had not, however, hung long in that state, when the captain who took him, accompanied by a number of other corsairs, interceded so strongly in his behalf, that he was taken down, and put under the care of some Christian surgeons; but two days after, some Moors reporting that it was the common talk and belief in Spain, that the Algerines durst not hurt a hair of Gafcon's head, &c. the unfortunate Spaniard was hoisted up by a pulley to the top of the execution-wall, and let down again upon the hook, which in his fall caught him by the belly, and gave him such a wound, that he expire without a groan. — Thus ended the expedition of John Gafcon, which has procured him a place among the Spanish martyrs; while, on the other hand, the Algerines look upon his disappointment to have been miraculous, and owing to the efficacious protection of the powerful saint Sidi Outededda, whose prayers had before raised such a terrible flood against the Spanish fleet.

Mahomet, being soon after recalled, was succeeded by the famous renegade Ochali, who reduced the kingdom of Tunis; which, however, remained subject to the viceroy of Algiers only till the year 1566, when a bath of Tunis was appointed by the Porte.

The kingdom of Algiers continued to be governed, till the beginning of the seventeenth century, by viceroys or bahaws appointed by the Porte; concerning whom we find nothing very remarkable, further than that their avarice and tyranny was intolerable both to the Algerines and the Turks themselves. At last the Turkish Janizaries and militia becoming powerful enough to support the tyrannic sway of these bahaws, and the people being almost exhausted by the heavy taxes laid upon them, the former resolved to depose these petty tyrants, and set up some officers of their own at the head of the realm. The better to succeed in this attempt, the militia sent a deputation of some of their chief members to the Porte, to complain of the avarice and oppression of these bahaws, who fulk both the revenue of the state, and the money remitted to it from Constantinople, into their own coffers, which should have been employed in keeping up and paying the soldiery; by which means they were in continual danger of being overpowered by the Arubians and Moors, who, if ever so little affiled by any Christian power, would hardly fail of driving all the Turks out of the kingdom. They represented to the Grand Vizir how much more honourable, as well as easier and cheaper, it would be for the grand Signior to permit them to choose their own day, or governor, from among themselves, whose interest it would then be to see that the revenue of the kingdom was rightly applied in keeping up its forces complete, and in supplying all other exigencies of the state, without any further charge or trouble to the Porte than that of allowing them its protection. On their part, they engaged always to acknowledge the Grand Signior as their sovereign, and to pay them their usual allegiance and tribute, to respect their bahaws, and even to lodge and maintain them and their retinue, in a manner suitable to their dignity, at their own charge. The bahaws, however, were, for the future, to be excluded from affairs at any but general downans, unless invited to it; and from having the liberty of voting in them, unless when their advice was asked, or the interest of the Porte was likely to suffer by their silence. All other concerns, which related to the government of Algieries, were to be wholly left under the direction of the day and his downan.

These proposals having been accepted by the Porte, the deputies returned highly satisfied; and having notified their new privileges, the great downans immediately proceeded to the election of a day from among themselves. They decided on a new set of laws, and made several regulations for the better support and maintenance of this new form of government, to the observation of which they obliged all their subjects to swear; and the militia, navy, commerce, &c. were all settled pretty nearly on the footing upon which they now are, and which shall be afterwards described; the subsequent alterations that frequently happened between the bahaws and deys, the one endeavouring to recover their former power, and the other to curtail it, caused such frequent complaints and differences at the Ottoman court, as made them frequently repent their compliance.

In the year 1601, the Spaniards, under the command of Doris the Genoese admiral, made another attempt upon Algiers, in which they were more fortunate than usual, their fleet being only driven back by contrary winds, so that they came off without loss. In 1609, the Moors being expelled from Spain, flocked in great numbers to Algiers; and as many of them were very able sailors, they undoubtedly contributed to make the Algerine fleet so formidable as it became soon after; tho' it is probable the frequent attempts made on their city would also induce them to increase their fleet. In 1616, their fleet consisted of 40 sail of ships between 200 and 400 tons, their admiral sectoins. It was divided into two squadrons, one of 18 sail, before the port of Malaga; and the other at the Cape of Santa Maria, between Lisbon and Seville; both of which fell foul on all Christian ships, both English and French, with whom they pretended to be in friendship, as well as Spaniards and Portuguese, with whom they were at war.

The Algerines were now become very formidable to the European powers. The Spaniards, who were most formidable in danger, and least able to cope with them, solicited to the European powers for the assistance of England, the pope, and other states. The French, however, were the first who dared to shew their resentment of the perfidious behaviour of these miscreants; in 1617, M. Beaulieu was sent against them with a fleet of 50 men of war, who defeated their fleet, took two of their vessels, while their admiral sunk his own ship and crew, rather than fall into his enemies hands.

In 1620, a squadron of English men of war was sent against Algiers, under the conduct of Sir Robert Manley;
of this expedition we have no other account, than that it returned without doing any thing;
and the Algerines, becoming more and more insolent, openly defied all the European powers, the Dutch only excepted; to whom, in 1623, they sent a propofal, directed to the prince of Orange, that in case they would fit out 20 fail of ships the following year, upon any good service against the Spaniards, they would join them with 60 fail of their own.

The next year, the Couloies, or Cellogies (the children of such Turks as had been permitted to marry at Algiers), who were enrolled in the militia, having feized on the citadel, had no high made themselves masters of the city; but were attacked by the Turks and renegades, who defeated them with terrible slaughter. Many scores of them were executed; and their heads thrown in heaps upon the city-walls, without the eastern gate. Part of the citadel was blown up; and the remaining Culiolles were dispersed from the militia, to which they were no again admitted till long after.

In 1623, the Algerines and other states of Barbary threw off their dependence on the Porte, and set up for themselves. What gave occasion to this was the 25 years truce which Sultan Amurath IV. was obliged to make with the emperor Ferdinand II. to prevent his being overmatched by carrying on the war at the same time. As this put a stop to the piratical trade of the Algerines, they proceeded as above-mentioned, and resolved, that whofe defiered to be at peace with them, must, definitively and separately, apply to their government.

No fooner was this resolution taken, than the Algerines began to make prizes of several merchant ships belonging to powers at peace with the Porte. Nay, having feized a Dutch ship and pasture at Scandereroon, they ventured on shore; and finding the town abandoned by the Turkish aga and inhabitants, they plundered all the magazines and warehouses, and set them on fire. About this time Lewis XIII., undertook to build a fort on their coasts, instead of one formerly built by the Marfilians, and which they had demolished. This, after some difficulty, he accomplished; and it was called the Bafion of France; but the situation being afterwards found inconvenient, the French purchased the port of La Calle, and obtained liberty to trade with the Arabs and Moors.

The Alban court, in the mean time, was so much embarrassed with the Perfian war, that there was no leisure to check the Algerine piracies. This gave an opportunity to the vizir and other courtiers to compound matters with the Algerines, and to get a share of their prizes, which were very considerable. However, for form's sake, a severe reprimand, accompanied with threats, was sent them; to which they replied, that "these depredations deferred to be indulged to them, seeing they were the only bulwark against the Christifan powers, especially against the Spaniards, the sworn enemies of the Moslem name." Adding, that "if they should pay a punctual regard to all that would purchase peace, or liberty to trade with the Ottoman empire, they would have nothing to do but set fire to all their shipping, and turn camel-drivers for a livelihood."

In the year 1625, four younger brothers of a good family in France, entered into an undertaking to defend, that perhaps the annals of knight-errantry can

fearful furnish its equal.—This was no less than to red

Algerines, 1

The Algerines profecuted their piracies with incom

punity, to the terror and disgrace of the Europeans, till the year 1652; when a French fleet being accident

ally driven to Algiers, the admiral took it into his head to demand a release of all the captives of his nation, without exception. This being refused, the Frenchman without ceremony carried off the Turkish vice

roy, and his cadi or judge, who were just arrived from the Porte, with all their equipage and retainue. The Algerines, by way of reprisal, surprifed the Bafion of France already men- tioned, and carried off the inhabitants to the number of 600, with all their effects; which provoked the admiral, that he sent them word that he would pay them another visit the next year with his whole fleet.

The Algerines, undismayed by the threats of the French admiral, fitted out a fleet of 16 galleys and gal

fiots, excellently manned and equipped, under the com

mand of Admiral Hall Pinchinin.—The chief design of this armament was against the treasure of Loreto; which, however, they were prevented by contrary winds from obtaining. Upon this they made a descent on Puglia in the kingdom of Naples; where they rava

ged the whole territory of Nocera, carrying off a large number of captives, and amongst them some nuns. From thence steering towards Dalmatia, they foured the Adriatic; and loading themselves with immense plunder, left those coasts in the utmost consternation and re

sentiment.

At last the Venetians, alarmed at such terrible de

predations, equipped a fleet of 28 fail, under the com

mand of admiral Capello, which express orders to burn, sink, or take, all the Barbary corsairs he met with, ei

ter on the open seas, or even in the Grand Signor's harbours, pursuant to a late treaty of peace with the Porte. On the other hand, the captain bailiff, who had been sent out with the Turkish fleet to chase the Florentine and Maltese cruisers out of the Adriatic lagoon, understanding that the Algerine squadron was so near, sent express orders to the admiral to come to his assistance. Pinchinin readily agreed; but having first resolved on a descent upon the island of Livat, or Lif

L,

D"
Algiers, belonging to the Venetians, was overtaken by Capello, from whom he retired to Valona, a sea-port belonging to the Grand Signior, whither the Venetian admiral pursued him; but the Turkish governor returning to eject the pirates according to the articles of the peace between the Ottoman court and Venice, Capello was obliged to content himself with watching them for some time. Pinchinin was soon weary of restraint, and ventured out; when an engagement immediately ensued, in which the Algerines were defeated, and five of their vessels disabled; with the loss of 1500 men, Turks, and Christian slaves; besides 1600 galley-slaves, who regained their liberty. Pinchinin, after this defeat, returned to Valona, where he was again watched by Capello; but the latter had not lain long at his old anchorage before he received a letter from the senate, desiring him to make no further attempt on the pirates at that time, for fear of a rupture with the Porte. This was followed by a letter from the governor of Valona, desiring him to take care lest he incurred the Sultan's displeasure by such infults. The brave Venetian was forced to comply; but, resolving to take such a leave of the Algerines as he thought they deserved, observed how they had reared their tents, and drawn up their lines along the shore. He then kept firing among their tents, while some well-manned galleys and brigantines were ordered among their shipping, who attacked them with such bravery, that, without any great loss, they towed out their 16 galleys, with all their cannon, horses, &c. In this left engagement, a ball from one of the Venetian galleys happening to strike a Turkish mosque, the whole action was considered as an insult upon the Grand Signior. To conceal this, Capello was ordered to sink all the Algerine ships he had taken, except the admiral; which was to be conducted to Venice, and laid up as a trophy. Capello came off with a severe reprimand; but the Venetians were obliged to buy, with 500,000 ducats, a peace from the Porte. The Grand Signior offered to repair the loss of the Algerines by building ten galleys for them, upon condition that they should continue in his service till the end of the ensuing summer; but Pinchinin, who knew how little the Algerines chose to lie under obligation to him, civilly declined the offer.

In the meantime, the news of this defeat and loss filled Algiers with the utmost grief and confusion. The whole city was on the point of a general insurrection, when the bawhaw and dowounif issued a proclamation, forbidding, not only complaints and outcries, under the severest penalties; but all persons whatever to take their thumbs from within their girdles, while they were deliberating on this important point. In the mean time, they applied to the Porte for an order, that the Venetians settled in the Levant should make up their loss. But with this the Grand Signior refused to comply, and left them to repair their losses, as well as build new ships, in the best manner they could. It was not long, however, before they had the satisfaction to see one of their corsairs land, with a fresh supply of 600 slaves, whom he had brought from the coast of Iceland, whither he had been directed by a miscreant native taken on board a Danish ship.

Our pirates did not long continue in their weak and defenceless state; being able, at the end of two years, to appear at sea with a fleet of 65 galleys. The admiral Pinchinin equipped four galleys at his own expense; with which, in conjunction with the Chiajah, or secretary of the bath of Tripoli, he made a second excursion. This small squadron, consisting of five galleys and two brigantines, fell in with an English ship of 40 guns; which, however, Pinchinin's captains refused to engage; but being afterwards reproached by him for their cowardice, they swore to attack the next Christian ship which came in their way. This happened to be a Dutch merchantman, of 25 guns and 40 men, deeply laden, and unable to use her sails by reason of a calm. Pinchinin immediately summoned her to surrender; but receiving an ironical answer, drew up his squadron in form of an half-moon, that they might pour their shot all at once into their adversary. This, however, the Dutchman avoided, by means of a breeze of wind which fortunately sprung up and enabled him to turn his ship; upon which the galleys ran foul of each other. Upon this, Pinchinin ran his own galley along side of the merchantman, the upper deck of which 70 Algerines immediately took possession of, some of them cutting the rigging, and others plying the hatches with hand-grenades: but the Dutchmen, having secured themselves in their close quarters, began to fire at the Algerines on board, from two pieces of cannon loaded with small shot; by which they were all foon killed, or forced to submit. Pinchinin, in the mean time, made several unsuccessful attempts to receive his men, as well as to surround the Dutchman with his other galleys; but that ship lay so deep in the water, that every shot did terrible execution amongst the pirates; so that they were obliged to remove farther off. At last the Dutch captain, having ordered his guns to be loaded with cartouches, gave them such a parting volley as killed 200 of them, and sent the rest back to Algiers in a most dismal plight.

But though Pinchinin thus returned in disgrace, the rest of the fleet quickly came back with vast numbers of slaves, and an immense quantity of rich spoils; incomparable to that of which the English, French, and Dutch, were obliged to crie to the mighty Algerines, who sometimes vouchsafed to be at peace with them, but swore eternal war against Spain, Portugal, and Italy, whom they looked upon as the greatest enemies to the Mahometan name. At last Lewis XIV. provoked by the grievances committed by the Algerines on the coasts of Provence, and Languedoc, ordered, in 1681, a considerable fleet to be fitted out against them, under the Marquis de Queste, vice-admiral of France. His first expedition was against a number of Tripolitan corsairs; who had the good fortune to outrow him, and shelter themselves in the island of Scio belonging to the Turks. This did not, however, prevent him from pursuing them thither, and making such terrible fire upon them as quickly destroyed 14 of their vessels, besides battering the walls of the castle.

This severity seemed only to be designed as a check to the piracies of the Algerines; but, finding they still continued their outrages on the French coast, he sailed to Algiers in August 1682, cannonading and bombarding it to furiously, that the whole town was in flames in a very little time. The great mosque was neither burnt down, and most of the houses laid in ruins, infomuch that the inhabitants were on the point of abandoning the place; when on a sudden the wind turned about, and
 Algiers

45 Algiers commit dreadful ravages in France.

46 The city again bombarded.

and obliged Du Quefne to return to Toulon. The Algerines immediately made reprisals, by sending a number of galleys and galleons to the coasts of Provence, where they committed the most dreadful ravages, and brought away a vast number of captives: upon which a new armament was ordered to be got ready at Toulon and Marseille against the next year; and the Algerines, having received timely notice, put themselves into as good a state of defence as the time would allow.

In May 1685, Du Quefne with his squadron cast anchor before Algiers; where, being joined by the Marquis D’Affranville, at the head of five galleys, the French were brought away. The Algerines, having received timely notice, put themselves into as good a state of defence as the time would allow. The French, finding the Algerines not in a convenient posture to receive battle, gave them no time to consider of the matter, but immediately delivered up, with a promise of sending him a proper commiffary-general and one of his engineers into the town; but with express orders to infift upon the delivery of all the French captives without exception, together with the effects they had taken from the French; and that Mezomorto their then admiral, and Hali Rais one of their captains, should be given as hostages.

This last demand having embarrassed the dey, he assembled his council, and acquainted them with it; upon which Mezomorto fell into a violent passion, and declared that the Algerines were now at the helm that had occasioned the ruin of Algiers; but that, for his part, he would never consent to deliver up any thing that had been taken from the French. He immediately acquainted the foldingy with what had passed; which so exasperated them, that they murdered the dey that very night, and on the morrow chose Mezomorto in his place. This was no sooner done, than he cancelled all the articles of peace which had been made, and hostilities were renewed with greater fury than ever.

The French admiral now kept pouring in such volleys of bombs, that, in less than three days, the great part of the city was reduced to ashes, and the fire burnt with such vehemence, that the seas was enlightened with it for more than two leagues round. Mezomorto, unmoved at all these disasters, and the vast number of the slain, whose blood ran in rivulets along the streets; or rather, grown furious and desperate, fought only how to wreak his revenge on the enemy; and, not content with caufing all the French in the city to be cruelly murdered, ordered their conftal be tied hand and foo, and fastened alive to the mouth of a mortar, from whence he was shot away against their navies—

By this piece of inhumanity Du Quefne was so exag-
Stadholders, have become more powerful, the douwan is principally composed of 30 chiah-bahaws, or colonels, with now and then the mufiif and cadi upon some emergencies; and on the election of a dey, the whole foldiers are allowed to come and give their votes. All the regulations of state ought to be determined by that asembly, before they pass into a law, or the dey hath power to put them in execution: but, for many years back, the douwan is of so little account, that it is only converted out of formality, and to give assent to what the dey and his chief favorites have concerted beforehand. The method of gathering the votes in this august assembly is perfectly agreeable to the character of those who compose it. The aga, or general of the janies, or the president protempore, first proposes the question; which is immediately repeated with a loud voice by the chiah-bahaws, and from them echoed again by four officers called bahalldales, from the idea the question is repeated from one member of the douwan to another, with strange contortions, and the most hideous growlings, if it is not to their liking. From the loudness of this growling noise, the aga is left to determine what the dey and assembly are pleased to give for the question; and from such a prepositional method, it is not surprising that these assemblies should seldom end without some tumult or disorder. As the whole body of the militia is concerned in the election of a new dey, it is seldom carried on without blows and bloodshed: but when once the choice is made, the person elected is saluted with the words Alle barik, "God bless you, and prosper you!" and the new dey usually causes all the officers of the douwan who had opposed his election to be strangled, filling up their places with those who had been most zealous in promoting it. From this account of the election of the deys, it cannot be expected that their government should be all secure; and as they arrive at the throne by tumult, disorder, and bloodshed, they are generally deprived of it by the same means, scarcely one in ten of them having the good fortune to die a natural death.

In this country it is not to be expected that justice will be administered with any degree of impartiality. The Mahometan foldiers, in particular, are so much favoured, that they are seldom put to death for any crime, except rebellion; in which case they are either strangled with a bow-string, or hanged to an iron hook. In lesser offences, they are flogged, or their pay stopped; and if officers, they are reduced to the station of common soldiers, from whence they may gradually raise themselves to their former dignity. Women guilty of adultery, have a halter tied about their necks, with the other end fastened to a pole, by which they are held under water till they are suffocated. The ballinado is likewise inflicted for small offences; and is given either upon the belly, back, or soles of the feet, according to the pleasure of the cadi; who also appoints the number of strokes. These sometimes amount to 200 or 300, according to the indulgence the offender can obtain either by bribery or friends; and hence he often dies under this punishment, for want of powerful enough advocates. But the most terrible punishments are those inflicted upon the Jews or Christians who speak against Mahomet or his religion; in which case, they must either turn Mahometans, or be impaled alive. If they afterwards apostatize, they are burned or roasted alive, or else thrown down from the top of the city-walls upon iron hooks, where they are caught by different parts of their body, according as they happen to fall, and sometimes expire in the greatest torments; though by accident they may be put out of pain at once, as we have already related of the Spanish adventurer John Gafcon. This terrible punishment, however, begins now to be diffused.

The officer next in power to the dey is the aga of the janies, who is one of the oldest officers in the Janies army, and holds his post only for two months. He is then succeeded by the chiah, or next senior officer. During the two months in which the aga enjoys his dignity, the keys of the metropolis are in his hands; all military orders are issu'd out in his name; and the sentence of the dey upon any offending soldier, whether capital or not, can only be executed in the court of his palace. As soon as he is gone through this short office, he is considered as mazouli, or supernannted, receives his pay regularly, like the other janies officers, and has a right to come at all times, but hath no longer a vote in the government. To the next in the aga in dignity, is the secretary of state, who registers all the public acts; and after him are the 30 chiah or colonels, who next to the aga in the douwan, and in the same gallery with him. Out of this class are generally chosen those who go embassadors to foreign courts, or who dispose of the dey's orders throughout the realm. Next to them are 800 bahack-bahaws, or eldest captains, who are promoted to that of chiah-bahaws, according to their seniority. The oldack-bahaws, or lieutenants, are next; who amount to 400, and are regularly raised to the rank of captains in their turn, and to other employments in the state, according to their abilities. These, by way of distinction, wear a leather fap, hanging down to the middle of their back. One rule is strictly observed in the rotation of these troops from one depot to another; viz. the right of seniority; one single infringement of which would cause an insurrection, and probably cost the dey his life. Other military officers of note are the vezir, or purveyors of the army; the peys, who are the four oldest foldiers, and consequently the nearest to preferment; the fouldiers, who are the next in seniority to them, and are part of the dey's body-guard, always marching before him when he takes the field, and distinguished by their carbiners and gilt fcyrmiers, with a brass gun on their caps; the kayts, or Turkish foldiers, each band of whom have the government of one or more adowars, or itinerant villages, and collect their taxes for the dey; and the fagiards, or Turkish lances, 100 of whom always attend the army, and watch over the water appointed for it. To these we may add the beys, or governors of the three great provinces of the realm. All the above-mentioned officers ought to compose the great douwan or council above-mentioned: but only the 30 chiah-bahaws have a right to sit in the gallery next after the dey; the rest are obliged to stand on the floor of the hall, or council-chamber, with their arms acros, and, as much as possible, without motion; neither are they permitted to enter with their swords on, for fear of a tumult. As for those who
The kingdom of Algiers is at present divided into three provinces or districts, viz. the eastern, western, and southern. The eastern, or Levantine government, which is by far the most considerable of the three, and is also called Beylick, contains the towns of Boano, Constantina, Gigeri, Bujeyah, Stella, Tebef, Zamora, Bifara, and Necanz, in all which the Turks have their garrisons: besides which, it includes the two ancient kingdoms of Cuco and Labez, though independent of the Algerine government, to whose forces their country is inaccessible; so that they still live under their own chekys chosen by each of their adowars or hords. To these we may add a French factory at Callo, under the direction of the company of the French Bafion. — The western government hath the towns of Oran, Tremecan, Moflagan, Tenez, and Secrally with its cable and garrison. — The southern government hath neither town, village, nor even a house, all the inhabitants living in tents, which obliges the key and forces to be always encamped.

The most considerable rivers of Algiers are the Zha, or Zina, which runs across the province of Tremecan, and the desert of Anguid, falling into the Mediterranean near the town of Taberica, where it has the name of Sirut. (2.) The Haregol, supposed the Sign of Ptolemy, comes down from the great Atlas, crosses the desert of Anguid, and falls into the sea, about five leagues from Oran. (3.) The Mina, supposed the Chlematis of Ptolemy, a large river, which runs through the plains of Bithala, and falls into the sea near the town of Arzew. This river hath lately received the name of Cena, who rebuilt the town of Bathala after it had been destroyed. (4.) The Shif, Zilef, or Zilif, descending from the mount Gnauezert, runs through some great deserts, the lake Titteri, the frontiers of Tremecan and Tenez, falling into the sea a little above the city of Moflagan. (5.) The Celic, supposed to be the Carchena of the ancients, falls into the sea about three leagues west of Algiers, after a short course of 18 or 20 leagues. (6.) The Hued-alquivir, supposed to be the Natobola, or Naffa, of the ancients, and called by the Europeans Zinganir, runs down with a swift course, through some high mountains of Cuco, and falls into the sea near Bujeyah. Whilst the city of Bujeyah was in the hands of the Christians, the mouth of this river was locked up with sand, that no vessel could come up into it; but in 1558, very soon after it was taken by the Moors, the great rains filled it to such a degree, that all the sand and mud was carried off; so that galleys, and other vessels, have ever since entered it with ease, where they lie safe from storms, and all winds, but that which blows from the north. (7.) Suf-Gemar, or Suf-Gimmar al Kumm, supposed to be the Ayufaga of Ptolemy, hath its source on mount Auras, on the confines of Atlas; and runs through some barren plains, and the fruitless town of Constantina, where its stream is greatly increased by some other rivers that receive; from thence running northward, along the ridges of some high mountains, it falls into the sea a little east of Gigeri, (8.) The Ladag, or Ludeg, runs down from mount Atlas through part of Contantina, and falls into the sea a little eastward of Bona. (9.) Guadi, or Gaudel Barbar, springs from the head of Orbis, or Urbs, in Tripoli, runs through Bujeyah, and falls into the sea near Tabeira.

Besides these there are many others of less note; of Account of which, however, we do not find that the Algerines avail themselves as they might do, their genius leading them too much to the piratical trade to mind any real advantage that might be derived from their own country. The corsairs, or pirates, form each a small republic, of which the rais or captain is the supreme bailaw; who, with the officers under him, form a kind of douwan, in which every matter relating to the vessel is decided in an arbitrary way. These corsairs are chiefly instrumental in importing whatever commodities are brought into the kingdom either by way of merchandise or prizes. These consist chiefly of gold and silver stuffs, damasks, cloths, fables, tin, iron, plated brass, lead, quicksilver, cordage, flail-clubs, bullets, cochineal, linen, tartar, alum, rice, sugar, soap, cotton raw and spun, copperas, aloes, brazil and logwood, vermilion, &c. Very few commodities, however, are exported from this part of the world: the oil, wax, hides, paffe, and corn produced, being but barely sufficient to supply the country; though, before the loss of Oran, the merchants had been known to ship off from one or other of the ports of Barbary several thousand tons of corn. The consumption of oil, though here in great abundance, is likewise considerable in this kingdom, that it is seldom permitted to be shipped off for Europe. The other exports consist chiefly in oriches feathers, copper, rubies, silk fables, embroidered handkerchiefs, dates, and Christian slaves. Some manufactures in silk, cotton, wool, leather, &c. are carried on in this country, but mostly by the Spaniards settled here, especially about the metropolis. Carpets are also a manufacture of the country, which, though much inferior to those of Turkey, both in beauty and fineness, are preferred by the people to lie upon, on account of their being both cheaper and stouter. There were also, at Algiers, looms for velvet, taffets, and other wrought silks; and a coarse sort of linen is likewise made in most parts of the kingdom. The country furnishes no materials for ship-building. They have neither ropes, tar, flails, anchors, nor even iron. When they can procure enough of new wood to form the main timbers of a ship, they supply the rest from the materials of prizes which they have made; and thus find the secret of producing new and swift sailing vessels from the ruins of the old. Of all the states on the coast of Barbary, the Algerines are the strongest at sea.

The inhabitants along the sea-coasts are a mixture of different nations; but chiefly Moors and Morefois, driven out of Catalonia, Aragon, and other parts of Spain. Here are also great numbers of Turks, who come from the Levant to seek their fortune; as well as multitudes of Jews and Christians taken at sea, who are brought hither to be sold for slaves. The Barbers are some of the most ancient inhabitants of the country; and are supposed to be descended from the ancient Sabians, who came hither from Arabia Felix, under the conduct of one of their princes. Others be-
The name of brick, with a square court on iron, believe barbary, and perhaps chiefs: mobiles or portable huts; others in scattered villages: they have, nevertheless, kept themselves for the most part from intermixing with other nations. The Berbers are reckoned the richest of all, go better clothed, and carry on a much larger traffic of the country at a much higher rate than the Canaanites driven out of the land, and live in tents, or portable huts; others in scattered villages: they have, nevertheless, kept themselves for the most part from intermixing with other nations. The Berbers are reckoned the richest, offer a better exchange without ceremony. The women have baths in public; and the Jews do not. They are rich clothes made of silk, embroidered with flowers of gold, and turbans enriched with jewels. The Turks, who compose the military force, have great privileges, pay no taxes, are never publicly punished, and rarely in private. The lowest sildier dominates over the most distinguished Moors at pleasure. If he finds them better mounted than himself, he changes horses without ceremony. The Turks have the privilege of carrying fire-arms. Many good qualities, however, distinguish them in spite of this excess of despotism. They never game for money, not even for trifles; and they never profane the name of the Deity. They soon forget their private quarrels; and after the first paroxysm of resentment is over, it is infamy for a Turk to keep in remembrance the injuries he has received. In this respect certainly they are less barbarous than other nations that boast of their civilization. See Moors.

Algiers, a city, the capital of the above kingdom, is probably the ancient Iofium; or by the Arabians called Alcazar, or rather Al-jezer, or Al-Jezrar, i.e. the island, because there was an island before the city, to which it had been since joined by a mole. It is built on the declivity of a hill by the sea-side, in the form of an amphitheatre: at sea, it looks like the top-ful of a ship. The tops of the houses are quite flat and white; infomuch, that when it was first discovered, one would take it to be a place where they bleach linen. One house rises above another in such a manner that they do not hinder each other's prospect. The streets are fo narrow, that they will fear to admit two persons to walk 'a-breadth, and the middle part is lower than the sides. When any loaded beasts, such as camels, horses, mules, or asses, pass along, you are forced to stand up close to the wall, to let them pass by. There is but one broad street, which runs through the city from east to west, in which are the shops of the principal merchants, and the market for corn and other commodities. The lower part of the walls of the city are of hewn stone, and the upper part of brick: they are 30 feet high on the land side, and 40 towards the sea; the fosses or ditches are twenty feet broad, and seven deep. There is no sweet water in the city; and tho' there is a tank or cistern in every house, yet they often want water, because it rains but seldom: the chief supply is from a spring on a hill, the water of which is conveyed by pipes above a hundred fountains, at which a bowl is fastened for the use of passengers. The common reservoir is at the end of the mole, where the ships take in their water. Every one takes his turn at these places, except the Turks, who are first, and the Jews last. There are five gates, which are open from morn till noon: and seven forts, or castles, without the wall, the greatest of which is on the mole without the gate, all of which are well supplied with great guns. There are ten large mosques, and fifty small ones; three great college schools, and a great number of petty ones for children. The houies are square, and built of stone and brick, with a square court in the middle, and galleries all round. There are said to be about 10,000 inhabitants in the city, comprising 3000 Jewish families, besides Christians. There are four inns, or public inns, such as are in Turkey, and six cazernes, or barracks, for the married Turkish soldiers, which will hold 600 each. There are no inns for Christians to lodge at; but only a few tippling hats kept by slaves, for the accommodation of Greeks and the poorer sort of travellers, where anything may be had for money. Here are bagnios, or public baths, in the same manner as in Turkey, at a very moderate rate. The women have baths of their own, where the men dare not come. Without the city there are a great number of sepulchres, as also cells or chapels, dedicated to matrons, or reputed saints, which the women go to visit every Friday. The Turkish soldiers are great tyrants: for they not only turn others out of the way in the streets, but will go to the farmhouses in the country for twenty days together, living on free quarters, and making use of every thing, not excepting the women. The Algerines seat, as in Turkey, sitting crooks-legged round a table about four inches high, and use neither knives nor fork; before they begin, every one says Bismile Allah, "In the name of God." When they have done, a slave pours water on all their hands as they sit, and then they wash their mouths. Their drink is water, sherbet, and coffee. Wine is not allowed, though drank immoderately by some. The prospect of the country and sea from Algiers is very beautiful, being built on the declivity of a mountain: but the city, though for several ages it has been stormy of the greatest powers in Chrifendom, it is said, could make but a faint defense against a regular siege; and that
that three English fifty-gun ships might batter it about the ears of its inhabitants from the harbour. If so, the Spaniards must have been very deficient either in courage or conduct. They attacked it in the year 1775, by land and by sea, but were repulsed with great loss; though they had near 20,000 foot and 2000 horse, and 47 king's ships of different rates and 346 transports. In the year 1783 and 1784, they also renewed their attacks by sea to destroy the city and galleries; but, after spending a quantity of ammunition, bombs, &c. were forced to retire without either its capture or extinction. The mole of the harbour is 500 paces in length, extending from the continent to a small island where there is a cape and large battery.

E. Long. 3. 30. N. Lat. 36. 40.

ALGOL, a fixed star of the third magnitude, called Nielus's Head, in the constellation Perseus; its longitude is 21° 50' 42" of Taurus, and its latitude 23° 23' 47" north, according to Flamsteed's catalogue. For an account of its changes, period, and other circumstances, see Astronomy (Index.)

ALGONQUINS, a nation in North America, who formerly polluted great tracts of land along the north shore of the river St Lawrence. For a long time they had no rivals as hunters and warriors, and were long in alliance with the Iroquois, among whom they agreed to protect from all invaders, and to let them have a share of their venison. The Iroquois, on the other hand, were to pay a tribute to their allies, out of the culture of the earth; and for them all the menial duties, such as flaying the game, curing the flesh, and dressing the skins. By degrees, however, the Iroquois associated in the hunting matches and warlike expeditions of the Algonquins; so that they soon began to fancy themselves as well qualified, either for war or hunting, as their neighbours. One winter, a large detachment of both nations having gone out a-hunting, and encamped, as they thought, a vast quantity of game, six young Algonquins and as many Iroquois were sent out to begin the slaughter. The Algonquins, probably became a little jealous of their associates, upon seeing a few elk, the Iroquois to return on pretence that they would have sufficient employment in slaying the game they should kill; but after three days hunting, having killed none, the Iroquois exulted, and in a day or two privately set out to hunt for themselves. The Algonquins were so exasperated at seeing their rivals return laden with game, that they murdered all the hunters in the night-time. The Iroquois intimidated their resentment; but in order to be revenged, applied themselves to study the art of war as practiced among those savage nations. Being afraid of engaging with the Algonquins at first, they tried their prowess on other inferior nations, and, when they thought themselves sufficiently expert, attacked the Algonquins with such diabolical fury, as shewed they could be satisfied with nothing less than the extermination of the whole race; which, had it not been for the interposition of the French, they would have accomplished. — The few Algonquin nations that are now to be seen, seem entirely ignorant of agriculture, and infidant by fishing and hunting. They allow themselves a plurality of wives; to withstanding which, they daily decrease in population, few or none of their nations containing above 6000 souls, and many of them not 2000. Their language is one of the three radical ones in North America, being understood from the river St Lawrence to the Multifippi.

ALGOR, with physicians, an unusual coldness in any part of the body.

ALGORITHM, an Arabic word expressive of numerical computation.

ALGUAZIL, in the Spanish polity, an officer who Blacked in the decrees of a judge executed.

ALHAGI, in botany, the trivial name of a species of hedyarum. See HEDYSARUM.

ALHAMBRA, a very pleasant town of the kingdom of Granada, in Spain, situated in the midst of some craggy mountains, about 25 miles S. W. of Granada, on the banks of the Rio Frio, in W. Long. 10. 10. N. Lat. 36. 59. and having the finest warm baths in all Spain. It was taken from the Moors in 1481. — The inhabitants, though surprized, and the town without a garrison, made a gallant defence: but being at length forced to submit, the place was abandoned to the pillage of the Christian soldiers; who, not satisfied with an immense quantity of gold and jewels, made slaves of upwards of 3000 of the inhabitants.

ALHAMBRA, the ancient fortresses and residence of the Moorish monarchs of Granada. It derives its name from the red colour of the materials which it was originally built with, Alhambra signifying a red house. It appears to a traveller a huge heap of as ugly buildings as can well be seen, all huddled together, seemingly without the least intention of forming one habitation out of them. The walls are entirely unornamented, all gravel and pebbles, daubed over with plaster by a very coarse hand; yet this is the palace of the Moorish kings of Granada, indubitably the most curious place within that exists in Spain, perhaps in the world. In many countries may be seen excellent modern as well as ancient architecture, both entire and in ruins; but nothing to be met with anywhere else can convey an idea of this edifice, except the decorations of an opera, or the tales of the genie.

Paving round the corner of the emperor's palace, one is admitted at a plain unornamented door in a corner. On my first visit, says Mr. Swinburne, I confess I was struck with amazement, as I Rept over the Spain, threshold, to find myself on a sudden transported into a species of fairy land. The first place you come to is the court called the communa or del mezquitar, that is the common baths, an oblong square, with a deep basin of clear water in the middle; two flights of marble steps leading down to the bottom; on each side a parterre of flowers, and a row of orange-trees. Round the court runs a peristyle paved with marble; the arches bear upon very flight pillars, in proportions and style different from all the regular orders of architecture. The ceilings and walls are incrusted with fret-work in stucco, so minute and intricate, that the most patient draughtsman would find it difficult to follow it, unless he made himself master of the general plan. This would facilitate the operation exceedingly; for all this work is frequently and regularly repeated at certain distances, and has been executed by means of square moulds applied faceeffectively, and the parts joined together with the utmost nicety. In every division are Arabic sentences of different lengths, most
of them expressive of the following meanings: "There is no conqueror but God," or, "Obedience and honour to our Lord Abouabdoula." The ceilings are gilt or painted, and time has caused no diminution in the freshness of their colours, though constantly exposed to the air. The lower part of the walls is disposed in gilt, finer than any thing else that he had ever seen, must afford a stranger the most agreeable fenthions while he treads this magic ground. The porches at the ends are more like groito-work threatening you of them that they might enter into the court at the two extremities. The squirels painted with coloured tiles; the colonnade with white marble. The walls are covered five feet up from the ground with blue and yellow tiles, disposed chequerwise. Above and below is a border of small effentchoes, enamelled blue and gold, with an Arabic motto on a band; signifying, "No conqueror but God." The columns that support the roof and gallery are of white marble, very slender, and fantastically adorned. They are 9 feet high, including base and capital, and 8 inches diameter. They are very irregularly placed; sometimes singly, at others in groups of three, but more frequently two together. The width of the horse-shoe arches above them is four feet; two inches for the large ones, and three for the smaller. The ceiling of the portico is finished in such manner and more complicated manner than that of the commans, and the two are laid on the walls with inimitable delight. In the ceiling it is so artfully fosled and handled as to exceed belief. The capitals are of various designs, though each design is repeated several times in the circumference of the court, but not the least attention has been paid to placing them regularly or opposite to each other. Not the slightest representation of animal life can be discovered amidst the varieties of foliages, grotesques, and strange ornaments. About each arch is a large square of arabesques, surrounded with a rim of characters, that are generally quotations from the Koran. Over the pillars is another square of delightful filigree work. Higher up is a wooden rim, or kind of cornice, as much enriched with carving as the stucco that covers the part underneath. Over this projects a roof of red tiles, the only thing that disfigures this beautiful square. This ugly covering is modern, put on by order of Mr Wall, the late prime minister, who a few years ago gave the Alhambra a thorough repair. In Moorish times, the building was covered with large painted and glazed tiles, of which some few are still to be seen. In the centre of the court are twelve ill-made lions muzzled, their fore parts smooth, their hind parts rough, which bear upon their backs an enormous bason, out of which a lesser rives. While the pipes were kept in good order, a great volume of water was thrown up, that falling down into the basons, passed through the beasts, and issued out of their mouths into a large reservoir, where it communicated by channels with the jet d’eaus in the apartments. This fountain is of white marble, embelished with many festoons and Arabic detached, thus translated:

"Seest thou not how the water flows copiously like the Nile?"

"This resembles a sea washing over its shores, threatening shipwreck to the mariner."

"This water runs abundantly, to give drink to the lions."

"Terrible as the lion is our king in the day of battle."

"The Nile gives glory to the king, and the lofty mountains proclaim it."

"This garden is fertile in delights: God takes care that no noxious animal shall approach it."

"The fair princes that walk in this garden, covered with pearls, augments its beauty so much, that thou may’st doubt whether it be a fountain that flows, or the tears of her admirers."

Palling along the colonnade, and keeping on the south side, you come to a circular room afbed by the men as a place for drinking coffee and forbes in. A fountain in the middle refreshes the apartment in summer. The form of this hall, the elegance of its copula, the cheerful distribution of light from above, and the exquisite manner in which the stucco is designed, painted, and finished, exceed all powers of description. Every thing in it inspires the most pleasing, voluptuous ideas; yet in this sweet retreat they pretend that Abouabdoula assembled the Abencerrages, and caused their heads to be struck off into the fountain. Continuing your walk round, you are next brought to a couple of rooms at the head of the court, which are supposed to have been tribunals, or audience-chambers.

Opposite to the Sala de los Abencerrajes is the entrance into the Terra de los Cariestones, or the tower of the two siffers; so named from two very beautiful pieces of marble laid as flags in the pavement. This gate exceeds all the rest in profusion of ornaments, and in beauty of prospect which it affords through a range of apartments, where a multitude of arches terminate in a large window open to the country. In a gleam of sunlight, the variety of tints and lights thrown upon this entable are uncommonly rich. The first hall is the concert room, where the women sit; the musicians played above in four balconies. In the middle is a jet d’eau. The marble pavement is equal to the finest existing, for the lizer of the flags and evenness of the colour. The two siffers, which give name to the room, are stobs that measure 15 feet by 71, without flaw or stain. The walls, up to a certain height, are mosaico, and above are divided into very neat compartments of stucco, all of one design, which is also followed in many of the adjacent halls and galleries. The ceiling is a fretted cove. To preserve this vaulted roof, as well as some of the other principal cupolas, the outward walls of the towers are raised 10 feet above the top of the dome, and support another roof over all, by which means no damage can ever be caused by wet weather or excessive heat and cold. From this hall you pass round the little myrtle-garden..."
The description of the Alhambra may be finished by observing how admirably everything was planned and calculated for rendering the place the most voluptuous of all retreats; what plentiful supplies of water were brought to refresh it in the hot months of summer; what a free circulation of air was contrived, by the judicious disposition of doors and windows; what shady gardens of aromatic trees; what noble views over the beautiful hills and fertile plains! No wonder the Moors regretted Granada; no wonder they still offer up prayers to God every Friday for the recovery of this city, which they efeem a terrestrial paradise. See Granada.

All, gives denomination to a seat, or division, among the Mahometans, who adhere to the right of succession of Ali the fourth caliph or successor of Mahomet, and to the return of Mahometanism introduced by him. The seflies of Ali are more particularly called abites; and (and opposed to the Sunnites, or feet of Omar, who adhere to the law as left by Mahomet, Abubeker, and Omar. Ali was cousin of Mahomet, and fon-in-law of that prophet, having married his daughter Fatimah. After Mahomet's death, great disputes arose about the succession. Many foid for Ali; but Abubeker was preferred, and elected the first kalif. Ali took his turn, after the death of Othman. — The Perfians are the chief adherents to the feet of Ali, whom they hold to have been the legitimate successor of Mahomet, and Abubeker, an usurper. On the contrary, the Turks are of the feet of Omar; and hold Ali in estimation, having raised a furious civil war among the Morifkans. The distinguishing badge of the followers of Ali is a red turban, which is worn by the Persians, who are hence called in derision, by the Turks, Albigachi, q. d. red-heads. Ali is reputed the author of several works, particularly a Centiloquium, in great esteem among the Arabs and Persians, part of which has been published in English by Mr. Ockley.

Aljameia is a name which the Morifkans in Spain give to the language of the Spaniards. Among other articles agreed on by the junio, which was appointed by the emperor Charles V. in 1520, in favour of the Morifkans, this was one, That the Morifkans should no longer speak Algareicia, i. e. Moorish or Arabic; but should speak Aljameia, i. e. Spanish, as it was called by the Moors, and all their writings and contradics should be in that language.

Alias, in law, a second or farther writ issued from the courts of Westminster, after a capias, &c. fled out without effect.

Alibi, in law, denotes the absence of the accused from the place where he is charged with having committed a crime; or his being otherwise, as the word imports, at the time specified.

Alcant, a large sea port town in the province of Valencia and territory of Segura. It is feated between the mountains and the sea, and has a wall deemed impregnable. The port is defended by three bastions furnished with artillery. To prevent the visits of the Algerine pirates, watch-towers were built to give notice of the approach of an enemy's ship. It was taken by the English in 1504. The castle was taken by the English in 1706; and held out a siege of two years before it was retaken by the French and Spaniards, and at last surrendered upon honourable terms.
A L I E N A T I O N, in law, denotes the act of making over a man’s property in land, tenements, etc., to another person.

Alienation in mortmain, is making over lands, tenements, etc., to a body-politic, or to a religious house, for which the king’s licence must first be obtained, otherwise the lands, &c. alienated will be forfeited.

Alienation in fee, is the selling the fee-simple of any land, or other incorporeal right. All persons who have a right to lands may generally alienate them to others; but some alienations are prohibited: such as alienations by tenants for life, &c., whereby they incur a forfeiture of their estate. By the statute of Edward I. a bar was put to alienations by which we call entail, which is an expedient for procuring perpetuities in families; but counter expedients were devised to defeat this intent, and a practice was introduced of cutting off entail by fines, and of barring remainders and reversions by recoveries. The statute for alienations in Henry VII’s time had a great effect on the constitution of England; as, among other regulations of that reign, it tended to throw power more into the hands of the people. By the statute 12 Car. II. cap. 24. fines for alienations are taken away. Crown lands are only alienable under a faculty of perpetual redemption. The council of Lateran held in 1123, forbade any clerk to alienate his benefice, prebend, or the like. By the laws of the ancient Jews, lands could only be alienated for the space of 50 years. At each return of the jubilee all returned again to the primitive owners, or their descendants, to whom the lands were originally allotted at the first distribution of Canaan.

Alienation Offices, is an office to which all writs of covenants and entry, upon which fines are levied, and recoveries suffered, are carried, to have fines for alienation set and paid thereon.

Aliment, (from aed to nourish), implies food both solid and liquid: from which, by the process of digestion, is prepared a very mild, sweet, and whitish liquor resembling milk, and distinguished by the name of chyle; which being absorbed by the lacteal veins, by them conveyed into the circulation, and there assimilated into the nature of blood, affords that supply of nutrition which the continual waste of the body is found to require.—Next to air, food is the most necessary thing for the preservation of our bodies: and as on the choice thereof our health greatly depends, it is of great importance to understand in general, what is the proper food for our nourishment; and in particular deviations from health, what is the best adapted to restore us. Our blood and juices naturally incline to become purulent and insipid: fresh chyle, duly received, prevent this destructive tendency, and preserves them in that mild state which alone consides with health. An animal diet affords the most of this bland nutritious viscid: watery fluids dilute the too gros parts, and carry off what is become unfit for use: It is only the small portion of jelly which is separated from the farinaceous parts of vegetables, that, after being much elaborated, is converted into the animal nature; yet the use of vegetables prevents both repletion and a too great tendency to a putrescent acrimony of the

merely very numerous in England, and so called from Alienation their belonging to foreign abbays.
A L I

Aliment. blood. In hot climates, as well as against the constitutional heat of particular poisons, vegetables are deemed in the largest proportions; animal substances afford the highest relish while our appetite continues; but will fatigue the appetite before the stomach is duly filled. Vegetables may be eaten after either fish or fowl: few herbs or fruits fatigue so much as that the stomach may not be filled with them, when it is already satisfied with flesh or fowl; whence it may be observed, that no diet which is very nourishing can be eaten to fullness, because its nutritious parts are oily and fattifying. Health depends almost wholly on a constant supply of the blood; and to preserve this a mixture of vegetables in some degree is always required, for a fast is soon the consequence of animal food alone: hot temperate habits, too, receive from milk and vegetables what is needful for correcting their excess; but in cold, pithy, and nervous habits, who want much nourishment from leaf digestion, and from the smallest quantity of food, animal diet is to be used more freely.

Thus much being offered as general principles with respect to the matter and quality of our aliment, the vaevodinarian may easily regulate his diet with some advantage to himself by an attention to the few ensuing particulars. In winter, eat freely, but drink sparingly: roast meat is to be preferred, and what is drunk should be stronger than at other seasons. In summer, let the thirst determine the quantity to be drunk; cold stomachs never require much; boiled meats and vegetables, if not otherwise contradicted, may now be more freely used. Lax habits require the winter’s diet to be continued all the year, and rigid ones should be confined to that of summer. Fat people should fast at times, but the lean should never do so. Those who are troubled with eructations occasioned by their food, should drink but little, and use some unaccommodated exercise. The thirsty should drink freely, but eat sparingly. In general, let moderation be observed; and the no dinner hath been had, a light supper is at all times to be preferred. After very high-seasoned meats, a glass of water acidulated with the acid elixir of vitriol, or in all weak stomachs the sweet elixir of vitriol, is far more almighty to the work of digestion than the common method of taking brandy. See further Food and Drink.

Obligation of Aliment, in Scots law, the natural obligation on parents to provide their children with the necessaries of life, &c. See Law, Part III. No. clxxiii. 4.

Alimentarii Partis, &c. were certain children maintained and educated by the munificence of the emperors, in a sort of public places, not unlike our hospitals. —Trajan was the first that brought up any of these alimentarii boys. He was imitated by Adrian. Antoninus Pius did the fame for a number of maidens, at the solicitation of Faustina; and hence, in some medals of that empress, we read Pveeliae Favstimiae. —Alexander Severus did the like at the request of Mammea; and the maids thus educated were called Mammceae.

Alimentary Duc or Canal, is a name given by Dr Tyfon and some others to that part of the body thro’ which the food passes, from its reception into the mouth to its exit at the anus; including the gula, stomach, and intestines. See Anatomy.

This duct has been said to be the true characteristic of an animal, or (in the jargon of the schools) in proportion to the size, physiology, and whatever has it being proportioned under the class of animals. Plants receive their nourishment by the numerous fibres of their roots, but have no common receptacle for digesting the food received, or for carrying off the recrement. But in all, even the lowest degree of animal life, we may observe a stomach and intestines, even where we cannot perceive the leaf formation of any organ of the fencles, unless that common one of feeling as in eyeflers. Phil. Trans. No. 269, p. 776, seq.

Dr Wallis brings an argument from the structure of the alimentary tube in man, to prove that he is not naturally carnivorous, to which Dr Tyfon makes some objections. V. Phil. Trans. No. 269, p. 777.

Alimontari, for alimentum, was an old law among the Romans, whereby children were obliged to find sustenance for their parents.

Alimony, in law, implies that allowance which a married woman fues for, and is intituled to, upon any occasional separation from her husband. See Law, Part III. No. clx. 13.

Alipilarius, or Alipillus, in Roman antiquity, a servant belonging to the baths, whose business it was, by means of waxen plasters, and an instrument called rostella, to take off the hairs from the armpits, and even arms, legs, &c. this being deemed a point of cleanliness.

Alipterium, abietius, in antiquity, a place in the ancient Palphare, where the athletes were accustomed before their exercises.

Aliquant Part, in arithmetic, is that number which cannot measure any other exactly without some remainder. Thus 7 is an aliquant part of 16; for twice 7 wants two of 16, and three times 7 exceeds 16 by 5.

Aliquot Part, is that part of a number or quantity which will exactly measure it without any remainder. Thus 2 is an aliquot part of 4; of 9; of 10, &c.

Alisanders, or Alexanders, in botany. See Snyrium.

Alisma, or Water-Plantain: A genus of the polygynia order, belonging to the herzaclia class of plants; and in the natural method ranking under the 5th order, Trapaetaloides. The characters are: The calyx is a three-leafed perianthium: the corolla consists of three roundish, large, flat, expanding petals: The flaminia consists of six subdivided filaments shorter than the corolla; the anthera are roundish: The pistillum consists of more than five germinas; the styli are simple, the stigma obtuse: The perciparium consists of compressed capsule: The seeds are small and follicary. Of this genus there are eight species, viz. The plantago, or great water-plaintain which grows in all the proper parts of Britain; the ranunculoides, or lesser water-plaintain; the ranas, or creeping water-plaintain; the damasamines, or star-headed water-plaintain, and all which are natives of Britain. The others, viz. the flava, cordifolia, subulata, and parafloria, are natives of America, where they are generally found in flagging waters, and other swampy places; so that it would be difficult to preserve them in Britain, for they will not live in the open.
ALKALI.

1. ALKALIS. 1. ALKALI. [460]

Properties common to all the alkaline salts.

1. They require a bog to make them thrive; but as they are plants of no great beauty or use, it is fearful how long they will continue to grow. 2. A river of Belgic Gaul, now Adige; which rising on the borders of Lorraine, and running through the duchy, waters the city of Luxemburg, and, swelled by other rivulets, falls into the Sea. 3. A river of the Alps, called the Aligardar. It is the city of Luxemburg, and, swelled by other rivulets, falls into the Sea. 4. A branch of Motazalites, and the former is now become as ridiculous as the philosopher's stone, the perpetuum mobile, &c.—It is likewise used by some authors for all fixed salts volatilized. 5. The Alkali, in chemistry, one of the general divisions of salts, comprehending that class of chemical elements which, by their union with acids, form perfect neutrals; in opposition to the salts formed of acids with metals or earths, which are volatile and folid masses in the fire, and which, when the salts are very pure, degenerate into absolute causticity, and would entirely destroy the organ of secession if long applied to it. 2. A tendency to diffuse animal substances, and reduce them to a gelatinous substance, which all of them will do when very strong. 3. An attraction for acids, with a power of separating them, and make them less, though previously combined with the same. 4. They change the blue vegetable juices to green; the green to yellow; the yellow to orange; the orange to red; and the red to purple. 5. They unite with oils, and destroy or caustic almost all kinds of colours that can be put upon cloth, whence their use in bleaching, &c.

2. Properties common to the two fixed alkalies.

1. They refulb the action of fire to a great degree, so that they can easily be reduced to a solid form by evaporating any liquid in which they happen to be dissolved. 2. By an intense fire, they flow into a liquid, which concretizes into a hard and solid mass in the cold. 3. When mixed in certain proportions with those earths or stones called vitrifiable, they melt, in a heat still more intense, into glasses. Mixed with ammoniacal salts, with animal substances, or with foot, they extricate a volatile alkali. The volatile alkali differs from the other two in being unable to refract the fire, and being entirely resoluble into an invisible and permanently elastic fluid, called by Dr. Priestley alkaline air. In consequence of this volatility, it always affects the olfactory nerves very perceptibly, and its smell is the general criterion by which its strength may be judged of. Its attraction toward acids, power of changing colours, &c. are also considerably weaker than those of the invariable alkali. Though two sorts of volatile alkali are commonly found under the names of spirits of hartshorn and of sal ammoniac, the one differs from the other only in its degree of purity. The former is called from its being originally made from the horns of deer; but this material has long been laid aside, and the bones of horses, the fints, as they are called, of the horns of cattle, the parings of hoofs, &c. have been substituted in their stead. This kind, however carefully prepared always contains a portion of animal oil, the smell of which is very perceptible; the other, prepared from pure sal ammoniac, is totally free of any empyrean-like smell, and is as pure as it can be obtained by any means whatever.

Effective with acids was formerly supposed to effervescence with acids to be a distinguishing property of alkalis, though it was always known that by a mixture with quicklime they might be deprived of this property. Dr. Black, however, has shown, that the effervescence with acids is no property of pure alkali, but is occasioned only by the escape of fixed air from it: of consequence, when quicklime is added, which attracts the whole or greatest part of the fixed air, no effervescence can be perceived. In the flate in which the fixed alkalis are commonly met with, indeed, effervescence with acids may be said to be an essential property; but this is entirely owing to the caustic just mentioned, viz. a quantity of fixed air, to which they are united during the process by which they were originally formed. The quantity of this air, however, is never so great as to saturate them entirely; on the contrary, their alkaline properties are always very perceptible, and they are commonly said to be in a mild state. But the truth is, that now they are in a kind of intermediate state between what may be called perfectly mild and perfectly caustic. In their perfectly mild state, they are united with such a large quantity of fixed air as entirely overpowers their alkaline properties; but this is entirely owing to the name of alkalis in this state, than when combined with the marine, nitrous, or any other acid; in which case the compounds are called neutral salts. But it is a much more laborious and tedious process to saturate an alkali completely with fixed air than with any other acid; nor does it very easily retain the aerial acid after it has once been combined with it. Hence the caustic taste and properties of the alkali are almost always predominant, and the salt contains a portion of pure and caustic alkali, to which alone its virtues are to be ascribed.

Vegetable alkali is obtained in its greatest purity by preparing deflagrating nitre with charcoal, provided we make use of the strow the nitrous acid. It is, however, a very difficult matter to adjust this proportion with sufficient accuracy; for if we employ too much charcoal, the salt will be considerably phlogisticated; if too little, some part of the nitre will remain undecomposed. Burnt tarr, therefore, purified by solution and filtration, may be looked upon as the best alkali we have. The common alkalis, or alkales as they are called, and said to be obtained from the ashes of vegetables, are always mixed
Alkali.

ed with much phlogiston, and sometimes with lime, salt, or other heterogeneous matters; for which reason they are not to be employed in the nicer chemical experiments, without being purified by solution in water, by filtration, and crystallization. The purity of all these salts is that called the blue pearl, imported from Hungary.

The vegetable alkali when thus purified, and containing near one half its weight of fixed air, is of a white colour when dry, with a very hot and caustic taste; possessing in an eminent degree all those qualities which have been ascribed to the alkaline salts in general. It runs per de liques when exposed to the air; and is usually incapable of being crystallized, though it acquires this property after being employed in the rectification of ardent spirits. It adheres more closely to acids than any substance hitherto discovered; though, from some experiments, Bergman was induced to believe that pure terra pomerana attracted acids still more powerfully. But it has been discovered by a mistake by Dr Withering, who, in a paper published in the 7th volume of the Philosophical Transactions, shows, that unless where the earth is united with vitriolic acid, not only the vegetable, the fossil, but even the volatile alkali in its pure or caustic state, will separate it from any other with which it may be combined. Terra pomerana, therefore, will always decompose vitriolated tartar, Glauber's salt, or vitriolic ammoniac; whence the mistake of this celebrated chemist probably has proceeded. After this alkali has been once united with marine acid, it appears to have undergone some change; for the salt then produced, by combining it with the vitriolic acid, resembles Glauber's salt almost as much as it does vitriolated tartar. It seems therefore to have made some approach towards the nature of fofill alkali; but chemists have not inquired what would be the consequence of repeated combinations of this kind.

The fofill alkali differs from the vegetable in having a smaller attraction for acids, in being more easily fusible by heat, and forming a more soluble compound with the vitriolic acid. It is also easily crystallizable, even without the addition of more fixed air than it naturally contains; and experience has determined it to be more proper for glasses or soap manufactures than the vegetable alkali; for which reason the demand for it is very considerable.

The fofill alkali was anciently called natron or nitre, and is spoken of by Pliny and Tacitus as an ingredient in glafs, &c. and the scriptures inform us that it was used in baths. The knowledge of this salt was lost in the general obfervation of science which took place on the decline of the Roman empire; and do we find it mentioned till the time of the P. B. H. P. G. B. P. H. P. G. B. P. H. P. G. B. P. H. P. G. B.

The vegetable alkali is commonly made use of in the material for the common caustic or bals infirmentis of the shops; for the preparation of which, see CHEMISTRY. Index. Both alkalis attract moisture from the air when reduced to a solid form in their caustic state, though neither the fofill alkali nor its combinations do so in any other; e. g. In their caustic state also they only unite with oils, or dilute in spirit of wine; which last
they have been supposed to purify, though it is more
than probable that they decompose and communicate
disagreeable qualities to it.

The volatile alkali, when procured immediately
by the distillation of any substance capable of yielding it,
is obtained in a state similar to that in which the alkalis
are usually met with, viz. half mild and half caustic.
By exposing the liquid alkali to a great quantity
of fixed air, we may at last have it perfectly mild and
neutralized; in which state it appears as a white salt
extremely volatile, though less so than the pure caustic
alkali. It dissolves very readily in water, but unless
some caustic spirit, or some lye or fixed alkali be added,
in order to abstract part of the fixed air, it will
s scarcely exhibit the characteristic of volatile alkali, viz.
a pungent and urinous smell. The addition of fixed air,
however, makes very little difference with regard to
the chemical combinations of this salt; for as fixed
air has a very slender power of acidity, it is expelled
by every other acid with the greatest ease, and the
same combinations formed as though it had not been
present. The only difference is, that when a mild alkali
is added to an acid, a strong effervescence takes
place by reason of the escape of the fixed air through
the liquid, while with the caustic alkali the mixture is
made quietly and without disturbance.

The various combinations of the alkaline fals with the
different acids, and the neutral compounds thence
resulting, are exhibited in the following table.

1. Vegetable fixed alkali combined with
   Vitriolic acid
   Nitrous acid
   Marine acid
   Acetous acid
   Acid of tartar
   Acid of borax
   Acid of phosphorus
   Saccharine acid, &c.
   Aerial acid

   forms
   Vitriolated tartar.
   Nitre.
   Sal digestivus.
   Terra foliata tartari.
   Soluble tartar.
   Anomalous salts, whose
   properties have not
   been ascertained.
   Mild or aerated alkali.

2. Fossil or mineral fixed alkali combined with
   Vitriolic acid
   Nitrous acid
   Marine acid
   Acetous acid
   Acid of tartar
   Acid of borax
   Acid of phosphorus
   Saccharine acid, &c.
   Aerial acid

   forms
   Glauber's salt.
   Cubicular nitre.
   Common salt.
   A salt resembling terra
   foliata tartari, but which
   does not deliquate.
   Rochelle salt.
   Borax.
   Unknown salts.
   Mild fossil alkali.

3. Volatile alkali combined with
   Vitriolic acid
   Nitrous acid
   Marine acid
   Acetous acid

   forms
   Vitriolic ammoniac, or
   Glauber's secret salt
   ammoniac.
   Nitrous ammoniac, or
   volatile nitre.
   Common salt ammoniac
   Spiritus mindereri.

Volatile alkali combined with
   Acid of tartar
   Acid of borax
   Acid of phosphorus
   Saccharine acid, &c.
   Aerial acid

   forms
   A salt whose properties
   have not been investiga-
   gated; which shoots
   into fine long crystals,
   and does not deliquate
   in the air.
   An anomalous salt.
   Microscopic salt, or ef-
   fential salt of urine.
   Anomalous salts.
   Volatile sal ammoniac, or
   salt of hartshorn.

Besides their attraction for acids, the alkalis have
also an attraction for oils, sulphur, and spirit of wine,
in the most way, when the salts are deprived of their
fixed air; and in this, as well as the dry way, with
several metals, and vitrifiable earths and flones, as has
been already mentioned.

With oil the vegetable fixed alkali forms a soap,
though less perfect than that made with the caustic
mineral alkali. When combined with fixed air they
s scarcely unite with oils. Boiled with sulphur, or melt-
ed in it with their dry state, they unite into a very
fetid compound called hispar sulphuris, which is soluble
in water, but totally and very quickly decomposed by
the contact of air. Vegetable alkali unites with iron,
tin, and zinc; corrodes copper, and runs with it into
a liquor of a deep blue colour, and joins with lead in
fusion. It does not act upon gold in its metallic state;
but if a sufficient quantity be added to a small solution of
gold in aqua regia, the cals of the metal will be first
precipitated and afterwards dissolved.

Vegetable alkalis a principal ingredient in the pow-
ders called fluxes, used for the fusion of metalline ores.
It promotes the fusion of earths, and forms glas with
the crystalline kind. It is soluble in an equal weight of
distilled water; and, when exposed to the air, it soon
attracts moisture from it and flows into a liquid.
In its caustic state it dissolves in spirits of wine, and
forms with it a red tincture called Van Helmont's
tincture of salt of tartar, formerly used both as an
internal and external remedy, but now fallen into dis-
repute.

Fossil alkali in its caustic state unites with oil into
an harder soap than that made with vegetable alkali.
With sulphur it forms a heavier sulphuris in the same
manner as the vegetable alkali, and yields a tincture
with spirit of wine, which dissolves part of the salt
while hot, but lets it fall again in a crystalline form
when cold. Gold, silver, or quicksilver, are not af-
fected by a solution of this salt; but copper and tin
are dissolved by it in the open air. It affects tin, lead,
regulus of antimony, and cobalt, slightly; but acts
powerfully upon zinc, and forms a kermes mineral
with crude antimony. Copper, iron, bismuth, zinc,
antimony, and regulus of cobalt, fused with two parts
of fossil alkali, are almost entirely dissolved in a very
strong heat; but tin, lead, and regulus of antimony,
treated in the same manner, only suffer a partial so-
fusion.

All the alkalis are of considerable use in medicine,
ALK [463] A L K

Though the particular virtues of vegetable and fossil alkali have not hitherto been properly ascertained. It is probable, however, that there must be a considerable diversity in their operations on the human body, as the vegetable alkali flows itself so much more acid and powerful than the fossil. As both of them unite immediately with acids, and change them into mild neutral salts; hence, if any of the strong mineral acids should fall upon any part of the human body, and begin to corrode and give pain, the immediate application of the lixivium turpic, or of a solution of any of those alkaline salts in water, or of the salts themselves in powder, will destroy their causticity, and prevent their doing further mischief: Or if any of these acids should drop on clothes, linen, or other substances, and alkaline salts are immediately applied, they will neutralize the acid, and prevent its further corrosion: Or if a person should, through halfake, swallow any other corroding salt which an alkali will decompose, the taking the lixivium turpic, or a solution of the alkaline salts, or the salts themselves in proper doses, are the most likely means of affording relief, it not given too late (a).

Both the vegetable and fossil alkali applied externally in a caustic state, first irritate and inflame the skin, and afterwards act as fire in mortifying and destroying it; and therefore have been much used by surgeons for opening buboes and other ulcers, and for eating away proud or fungous flesh that sprouts out from sores. Various formulæ of caustic alkalis have been employed for these purposes, of which an account is given under Chemistry and Pharmacy.

The alkaline salts, when much diluted with water, have been used as washes for removing pimples from the face; but if such washes are continued long, they are apt to spoil the skin. The ancient often used to dissolve tar (the fossil alkali) in their baths, and esteemed such baths useful for removing itchings of the skin, the fice, the impetigo, leprosy, and almost all sorts of cutaneous eruptions; and they employed baths of the same kind for promoting sweat, and for curing various disorders. They mixed it likewise with turpentine, with oils, and with fluids of various kinds, and rubbed or applied such compositions to the skin, for removing different complaints, to heal sores, to strengthen weak or relaxed parts, to destroy the poison of the bite of a mad dog, and of serpents; and they esteemed it as an antidote against many other poisons. It has been proved that alkaline salts preserve animal substances from putrefaction; on which account some practitioners have concluded that they act as strong antiseptic remedies when swallowed as medicines, and are taken up by the lachrymal vessels, and by them carried to the subclavian vein to be mixed with the blood. Experience, however, has shown that they have effects directly opposite, and that by dilating the vessels and quickening the circulation, they contribute towards the dissolution of the vital fluid; of which Dr Monro says he has seen several instances.

Alkalis promote the secretions in general particularly by the kidneys; but by the help of warm liquors and bed-clothes, their operation may be directed towards the skin. They have also been used in the cases of heartburn, and others where an acid prevails in the stomach and bowels, or where these organs are loaded with viscid phlegm. They are likewise given with a view to affright the operation of the bile when it is too weak and inert, either by themselves, or mixed with purgative or other medicines. The fossil alkali has been alleged to be a more powerful solvent of the human calculus than the vegetable, though perhaps without any just foundation. It is given from 7 to 20 grains three times a-day; and in some cases even to double that quantity. It may be taken in any common liquor, or in clear broth made of lean meat, from which the fat has been skimmed off; or the powdered salts may be made up in pills or boluses mixed with liqueurice powder, by means of mucilage of gum Arabic or conserve. In the vegetable alkali has been long used as a diuretic. Are of common droppings with great success; and Dr Monro informs us, that he has seen a number of cases of anafarea in which the water was carried off by it. As diuretics, it may be taken from ten grains to half a drachm, or more, two or three times a-day, mixed with some distilled water, syrup, broth, or water-gruel, or with two ounces of white wine, which partly neutralizes the salt. When added to infusions of juniper berries, broom tops, horse-radish, mustard-feed, winter's-bark, &c. in wine and beer, they prove powerful diuretics; and Dr Monro gives the following formula.

"Take bromptops, horse-radish, and juniper-berries, of each an ounce; bruise them in a stone or marble mortar; put them into a large wide-mouthed bottle, and add to them an ounce of salt of tartar, and two quarts of Rhenum wine. Infuse them for four days; decant off the wine, and filter it through paper for use. Two or three ounces may be taken three or four times a-day." Or, "Take an ounce of canella alba, and as much mustard-feed and juniper-berries; bruise them well in an iron mortar, and add an ounce of purified vegetable alkali with two quarts of porter; infuse for four days, and filter the liquor through paper; let the patient take a wine glassfully every four or six hours.

The diuretic powers of these medicines are sometimes increased by opium, and they have been successfully joined with essential oils and oilbams.

The most remarkable property of these salts, however, is that of dissolving the human calculus, for the lent solvent discovery of which, Mrs Stephens, in the year 1740, obtained a parliamentary reward of 5000l. At that time Dr Jurins being afflicted with the stone, tried a number of experiments on these medicines; from which he concluded, that their efficacy depended entirely on the

(a) With regard to the mineral acids, an exception seems to take place if oil of vitriol in its concentrated state should happen to be swallowed: for this contracts such a degree of heat on the contact of any aqueous fluid as would destroy the patient, independent of another cause. An instance we have seen where a person unhappily muflook a bottle of oil of vitriol for water in the night-time. He recovered by swallowing instantly a great quantity of milk. Another recovered by drinking a bottle of Florence oil.
the alkaline falls and lime which they contained and therefore he began to try what effects a soap-leaf would have on himself. At first he took only a few drops, but gradually increased this dose till he came to an ounce and sometimes an ounce and a half, in a proper vehicle, in 24 hours. This produced the discharge of a very small calculus, and relieved him of the symptoms of the stone. Dr. Harley, likewise, intoxicated under this complaint; and believing that the efficacy of Mrs. Stephens's medicines depended on the soap, lime, and alkaline falls which they contained, ordered a paste to be prepared for himself, made of eight ounces of soap, one of oyster-shell lime, a drachm of salt of tartar, and as much water as formed the whole into a soft mass; of which he took large quantities, and found himself greatly relieved, though not cured, as a stone was found in his bladder after his death. These and other instances of success, soon brought the medicines into general use: but though many found relief from them, others, particularly those who were afflicted with the stone, had all the symptoms of their distemper aggravated, by the falls rendering the blood, and other liquors of the body, particularly the urine, sharp and acid, so as to irritate and inflame the bladder, which was already in too irritable a state, from the confluent friction of the calculus lodged within it. The late experiments of Mr. Scheele and Sir Torbern Bergman, however, have made it evident, that the human calculus is composed of a concrete acid joined to a small portion of animal earth. Most people, however, have not been afflicted with the stone or gravel, with this corollary, to try the efficacy of these remedies, rather than submit to the dangerous operation of lithotomy; we shall therefore subjoin, from Dr. Monro, the following directions for making and using the soap-leaf.

**1.** Take of salt of tartar, eight ounces; of fresh quick-lime, four ounces; of distilled water, a quart: mix them all well together in a large bottle, and let them stand for 24 hours; then pour off the ley and filter it through paper, keeping it in well-stoppered vials for use. Of this the dose is from 30 drops to three or four drachms, which is to be repeated two or three times in the day.

**2.** One of the best methods of taking this ley is, to mix the quantity to be used in the day with three pints of plain broth, which has been made with the lean part of veal, with all the fat or oily parts separated from it, by putting it, when made, into a large bowl, and skimming off with a spoon when cold, and to drink, within an hour, a pint of this broth three times in the day—early in the morning—all day; and in the evening; and to continue the use of this medicine for three or four, or more months; and, during this course, to live on such things as least counteract the operation of the medicine: to take for breakfast some plain broth, such as has been described, with dry toasted bread or biscuit: or a dib or two of tea or coffee in place of the broth; for dinner to eat the lean part of plain boiled or roasted meat, or a fowl, with their own gravy or juice for sauce; and to eat only of vegetables which contain but little acid, such as potatoes, &c. and to use for drink toat and water, or water with a very small portion of spirit in it, and to abstain from eating fruit and acid or sweet vegetables, fat meat, butter, or oil; and from drinking wine, beer, cyder, punch, and in short from taking any thing which is likely to confound or depress the effects of the ley.

*With regard to the use of the soap-leaf, our author observes, "that he has seen a number of people who have taken it, both for gravelish complaints and for the stone; that many of those who had gravel were relieved, and some of them seemed to be cured; that some few of those who had the confirmed stone, received considerable relief for a time from its use: but the complaints after wards returned; nor can he say that one complete cure was made; though from the accounts given by the late Dr. Whytt of Edinburgh, and others, it should appear that this had sometimes happened; in many cases of stone the ley occasioned pain and irritation, and increased the violence of the symptoms so much, that the patients were obliged to lay it aside; and that this happened most frequently where the bladder seemed already to be diseased from the irritation of the stone: that at all times it is advisable to lay aside this medicine, at least for a time, whenever it irritates and occasions pain, or where there are appearances of its continued use having broken down the crafts of the blood."

Instead of the soap-leaf, the following solution of vegetable alkali, fully saturated with fixed air, has been lately recommended as a powerful solvent of the stone. *Take two ounces of salt of tartar, and dissolve it in two quarts of distilled water, and then saturate it fully with mixed air; and let the patient take eight ounces of it every eight hours.* If they have been related in which this medicine is said to have been serviceable, our author says he has seen only one gentleman who had taken it, and who had found considerable relief from it. Soap-leaf has likewise been recommended as a solvent of bilious calculi, and has sometimes been of service; but this has probably arisen more from its property of dissolving thick and viscid humours, and aiding the action of the bile, than by acting on the calculi themselves.

The volatile alkali has many of the virtues of the fixed, but affects animal substances, particularly in its virtues of the volatile brisk and strong stimulus to the nerves and fibres of living animals; and is therefore employed in ulcers where the pus boils and the circulation too languid; in low fevers, where the patient is in danger of sinking; in apoplectic and lethargic disorders of elderly people of phlegmatic habits, in paralytic cases, fainting fits, &c. where a brisk and stimulating remedy is wanted. It is often used as diaphoretic and sudorific in cases of rheumatism, in the end of fevers, catarrh, and other diseases, where a plentiful diaphoresis or sweat is required; and, according to our author, it is principally owing to this quality that the alkali have obtained their reputation of being efficacious remedies against the bites of serpents and other venomous animals. It is equally efficacious against mineral acid poisons with the fixed alkali.

It now remains only to give some account of the origin of the alkalis, or that process by which they are naturally produced. This subject, however, is very extensive, much involved in obscurity; nor has the origin of the alkalis, stear, been investigated with such diligence and success as that of the acids. Chemists have been divided in their opinions, whether alkaline falls be natural
Alkali.

tural bodies, or formed by the force of fire, uniting the principles of which they consist in the burning or distilling the substanccs from which they are got. It is generally supposed that they are formed by the force of fire intimately uniting an earth, an acid, and an inflammable matter together, so as to form an alkaline salt, which is supposed to be composed of these principles. In support of this opinion, it has been alleged, 1. That the fixed vegetable alkalii is produced by burning vegetables which contain the principle of fire, and by forming these salts; though no vestige of an alkali can be discovered in these vegetables in their natural state. 2. That the essential salts of vegetables, which contain an acid and an earth, on being calcined in a crucible with charcoal, yield an alkaline salt. 3. That by alternately allowing the vegetable alkali to remain delicium, and drying it again, it precipitates a quantity of earth, every time it is dissolved; so that the whole of the salt is at last reduced to this kind of earth, while the acid, phlogosion, &c. have evaporated, or been destroyed by the repeated application of heat for drying the salt. 4. In like manner the volatile alkali is produced by distilling animal substances, which contain the principles fit for producing it, though no marks of a volatile alkali could be discovered in these substances while they were fresh.

On the other hand, it has been asserted that the alkaline salts obtained by burning vegetables or distilling animal substanccs, existed originally in the materials from which they are produced, that they were generated in the plants by the process of vegetation, and freed by the fire from the other principles which distinguished them. In support of this opinion the following arguments are made use of by Neifira & Cie, Robenflie, Morvieux, &c. 1. That they had not been able to procure an alkaline salt by mixing earths, oil, and acids together, and subjecting them to the most intense fire. 2. The crysHals of tartar, which were formerly believed to be pure acid salts, have been found by late experiments to contain vegetable alkali. 3. The vegetable alkaline salt, when purified is always of the same nature, from whatever substance it is procured; and therefore must have been an original principle or body existing in the vegetables from which it is procured: for had it been produced by art, it would have varied, and we should have had different species of it, according to the principles which the plants contained. And, 4. The neutral salts which have been found mixed with the ashes of plants, as vitriolated tartrar, nirre, and sea-salt, are likewise strong proofs of the original existence of alkali in vegetables.

On this subject Dr. Monro observes, that hitherto we have not sufficient evidence to determine positively whether the vegetable alkali be produced by the force of fire, or if it existed originally in the substances from which it is prepared, though he is inclined to favour the former opinion. With regard to the volatile alkali, however, we have abundant evidence of it being produced from substances which could not possibly be supposed to contain it originally. Dr. Stahl affirms us, that if any dry fixed alkaline salt be well rubbed in a mortar with such a quantity of oil of turpentine, as is sufficient to make it of the consistence of a pulp, and digested for some weeks in a cucurbit or retort, we obtain a volatile alkali. Mr. Geoffrey relates, that having placed a large retort in a furnace, and adapted a
tubulated receiver to it, afterwards heating the bottom of the retort red-hot, he put into it, by means of a long tube rising from the upper part of the neck, a powder composed of equal parts of nirre and charcoal on which there came over into the receiver a liquor highly impregnated with volatile alkali. Cartheuer, in the first volume of his Materia Medica, tells us, that if two parts of salt of tartar be mixed with one of sulfur, and be afterwards distilled, they yield a volatile alkaline salt and spirit. Boerhaave and Macquer have both affirmed, that the vegetative process itself produces a volatile alkali; and that the juices got by bruising mustard-seed and other alkalifcent vegetables, as they are called, contain a volatile alkali which effervesces with acids: but this is denied by Cartheuer and Vogel, who affirm that they could discover no traces of volatile alkali in their juices by any experiments they made.

But whatever may be concluded from the experience of former chemists, the late discoveries of Dr. Priestley and Mr. Cavendish have decisively shown, that the volatile alkali is by no means a simple element or natural principle, but a compound, and which may be artificially prepared. Dr. Priestley informs us, that by the See Acid. See Air. union of nitrous air with iron, a volatile alkali is generated; and Mr. Cavendish, that by the action of the electric fluid, or pure elementary fire, upon phlogifitioned air, the nitrous acid is produced: the volatile alkali therefore, must be supposed to consist ultimately of phlogifitioned air united to a great quantity of elementary fire. In like manner, if we can suppose this subtle element to enter into the substance of any kind of earth in such a manner as to exert its peculiar action when that substance is applied to any other, we may reasonably conclude that the fixed alkalis also are not simple and permanent principles, but capable of artificial composition and decomposition. It is certain that the action of alkaline salts is extremely similar to that of fire; and as we know that this element is combined in a latent state with fluids, there can be no absurdity in supposing it capable of combining with solids.

Alkali, or Salt, in botany. See Salicornia.

Alkanet, in botany. See Anchusa.

Alkekengi, in botany, the trivial name of a species of physalis. See Physalis.

Alkena, in botany. See Lawsonia.

Alkermes, in pharmacy, a compound cordial medicine made in the form of a confection, deriving its name from the kermes-berries used in its composition.

Alkoran. See Alcoran.

All-Hallows. See All-Saints.

All-Cod. See Chenopodium.

All-Heal. See Heracleum and Stachys.

All-Saints, in the calendar, denotes a festival celebrated on the first of November, in commemoration of all the saints in general; which is otherwise called All-hallows. The number of saints being so excessively multiplied, it was found too bare to leave to dedicate a feast-day to each. In reality, there are not days enough, scarce hours enough, in the year, for this purpose. Hence an expedient was had recourse to, by commemorating such in the lump as had not their own days. Boniface IV. in the ninth century, introduced
The feast of All Saints in Italy, which was soon adopted into the other churches. All Saints, in the calendar, denotes a feast-day, held on the second of November, in commemoration of all the faithful deceased.—The feast of All Souls was first introduced in the eleventh century, by Odilo, abbot of Cluny, who enjoined it on his own order: but it was not long before it became adopted by the neighbouring churches.

All-Spice. See Myrtus and Calycanthus. All A, or Allan, the name by which the professors of Mahometanism call the Supreme Being.

The term Allatius Arabic, derived from the verb alab, to adore. It is the same with the Hebrew Eloah, which signifies the Adorable Being.

Allamanda, in botany: a genus of the monogynia order, belonging to the pentandria class of plants. The characters are: The calyx is five-leaf'd perianthus: The corolla consists of one funnel-shaped petal: the tube cylindrical: the border semiquincuncial and ventricose; the divisions expanding and obtuse: The stamens have four filaments: the anthers are five, arrow-shaped, converging, in the throat of the tube: The pistillum has an oval germin: girt at the base with an annular margin: the stylus is filiform, the length exceeding the tube: the stigma is bearded, and constricted in the middle: the pericarpium is an orbicular, compressed, brisht capsule, containing one cell with two valves: The seeds are imbricated, orbicular, flat, with a membraneous wing on the margin, and are very numerous. There is but one species, the cathartic, a native of Surinam.

Alantois, or Alantoides, a gut-shaped vesicle investing the forus of cows, goats, sheep, &c. filled with an urinous liquor conveyed to it from the uracus.—(See Comparative Anatomy). Anatomists are not agreed whether the alantois has any existence in the human species or not.

Allatus (Leo), keeper of the Vatican library, a native of Scio, and a celebrated writer of the 17th century. He was of great service to the gentlemen of Port Royal in the controversy they had with M-Clause touching the belief of the Greeks with regard to the eucharist. No Latin was ever more devoted to the s of Rome, or more inveterate against the Greek schismatics, than Allatus. He never engaged in matrimony, nor was he ever in orders; and pope Alexander VII. having asked him one day, why he did not enter into orders? he answered, “Because I would be free to marry.” The pope rejoined, “If so, who do you not marry?” “Because,” replied Allatus, “I would be at liberty to take orders.” Thus, as Mr Bayly observes, he passed his whole life, wavering between a parish and a wife; for, perhaps at his death, for having chosen neither of them; when, if he had fixed upon one, he might have repented his choice for 30 or 40 years.—If we believe John Patricius, Allatus had a very extraordinary pen, with which and no other, he wrote Greek for 40 years: and we need not be surprised, that, when he left it, he was so grieved, that he could scarce bear the crying. He published several manuscripts; several translations of Greek authors, and several pieces of his own composing. In his compositions he is thought to have more erudition than judgment: he used alla to make frequent digressions from one subject to another. He died at Rome in 1669, aged 83.

Allay. See Alloy.

Allegata, a word anciently subscribed at the bottom of rescripts and constitutions of the emperors; as sigata, or tefiata, was under other instruments.

Allegenis, or Allegias, a stuff manufactured in the East-Indies. There are two sorts of them: some are of cotton, and others of several kinds of herbs, which are spun like flax and hemp. Their lengths and breadth are of eight ells, by five, six, or seven-eighths, and of twelve ells, by three-fourths, or five-eighths.

Allegiance, is the tie, or ligament, which binds the subject to the government, in return for that protection which government affords the subject. The thing itself, or substantial part of it, is founded in reason and the nature of government; the name and the form are derived to us from ancient Gothic usage. Under the feudal system, every owner of land held them in subjection to some superior or lord, from whom or from whomsoever the tenant or vassal had received them: and there was a mutual trust or confidence subsisting between the lord and vassal, that the lord should protect the vassal in the enjoyment of the territory he had granted him, and on the other hand, that the vassal should be faithful to the lord, and defend him against all his enemies.

This obligation on the part of the vassal was called his feidelitas or fealty; and an oath of fealty was required by the feudal law to be taken by all tenants to their lord, which is couched in almost the same terms as the ancient oath of allegiance; except that, in the usual oath of fealty, there was frequently a favor or exception of the faith due to a superior lord by name, under whom the landlord himself was perhaps only a tenant or vassal. But when the acknowledgment was made to the absolute superior himself, who was vassal to no man, it was no longer called the oath of fealty, but the oath of allegiance, and therein the tenant swore to bear faith to his sovereign lord, in opposition to all men, without any favor or exception. Land held by this exalted species of fealty, was called feudum ligatum, a liege fee, the vassals homines ligati, or liege men; and the sovereign dominus ligatus, or liege lord. And when sovereign princes did homage to each other for lands held under their respective sovereignties, a distinction was always made between simple homag, which was only an acknowledgment of tenure, and liege homage, which included the fealty before-mentioned, and the services consequent upon it. In Britain, it becoming a settled principle of tenure, that all lands in the kingdom are held of the king as their sovereign and lord paramount, no oath but that of fealty could ever be taken to inferior lords; and the oath of allegiance was necessarily confined to the person of the king alone. By an easy analogy, the term allegiance was soon brought to signify all other engagements which are due from subjects to their prince, as well as those duties which were simply and merely territorial. And the oath of allegiance, as administered in England for upwards of 600 years, contained a promiss to be true and faith­ful to the king and his heirs, and truth and faith to hear of life and limb and terrane honos, and not to
Allegiance is know or hear of any ill or damage intended him, "without defending him therefrom." But, at the revolution, the terms of this oath being thought perhaps to favour too much the notion of non-resistance, the present form was introduced by the convention parliament, which is more general and indeterminate than the former; the subject only promising "that he will be faithful and bear true allegiance to the king," without mentioning "his heirs," or specifying in the least wherein that allegiance consists. The oath of supremacy is principally calculated as a renunciation of the pope's pretended authority: and the oath of abjuration, introduced in the reign of King William, very amply supplies the loose and general texture of the oath of allegiance; it recognizing the right of his majesty, derived under the act of settlement; engaging to support him to the utmost of the juror's power; promising to disclose all traitorous conspiracies against him; and expressly renouncing any claim of the descendants of the late pretender, in as clear and explicit terms as the English language can furnish. This oath must be taken by all persons in any office, trust, or employment; and may be rendered by two juries of the peace to any person whom they shall suspect of disaffection. And the oath of allegiance may be tendered to all persons above the age of twelve years, whether natives, denizens, or aliens.

But, besides these express engagements, the law also holds that there is an implied, original, and virtual allegiance, owing from every subject to his sovereign, antecedently to any express promisive, and although the subject never swore any faith or allegiance in form. Thus Sir Edward Coke very justly observes, that "all subjects are equally bounden to their allegiance as if they had taken the oath; because it is written by the finger of the law in their hearts, and the taking of the corporal oath is but an outward declaration of the same."

Allegiance, both express and implied, is however distinguished by the law into two sorts or species, the one natural, the other local; the former being also perpetual, the latter temporary.

Natural allegiance is such as is due from all men born within the king's dominions immediately upon their birth. For immediately upon their birth, they are under the king's protection; at a time too, when (during their infancy) they are incapable of protecting themselves. Natural allegiance is, therefore, a debt of gratitude; which cannot be forfeited, cancelled, or altered, by any change of time, place, or circumstance, nor by any thing but the united concurrence of the legislature. A Briton who removes to France, or to China, owes the same allegiance to the king of Britain there as at home, and twenty years hence as well as now. For it is a principle of universal law, that the natural-born subject of one prince cannot by any act of his own, no, not by swearing allegiance to another, put off or discharge his natural allegiance to the former: for this natural allegiance was intrinsic, and primitive, and antecedent to the other; and cannot be divided without the concurrent act of that prince to whom it was first due.

Local allegiance is such as is due from an alien, stranger born, for so long time as he continues within the king's dominion and protection; and it ceases the infant such stranger transfers himself from one kingdom to another. Natural allegiance is therefore perpetual, and local temporary only; and that for this reason, evidently founded upon the nature of government. That allegiance is a debt due from the subject, upon an implied contract with the prince; that so long as the one affords protection, so long the other will demean himself faithfully.

The oath of allegiance, or rather the allegiance itself, is held to be applicable, not only to the political capacity of the king, or regal office, but to his natural person and blood-royal; and for the misapplication of their allegiance, viz. to the regal capacity or crown, exclusive of the person of the king, were the Spencers banished in the reign of Edward II. And from hence arose that principle of personal attachment and affectionate loyalty, which induced Englishmen in former times (and if occasion required, would doubtless induce their sons) to hazard all that was dear to them, life, fortune, and family, in defence and support of their liege lord and sovereign.

It is to be observed, however, in explanation of this allegiance, That it does not preclude resistance to the king, when his misconduct or weakness is such as to make resistance beneficial to the community. It seems fairly provable, that the convention parliament, which introduced the oath of allegiance in its present form, did not intend to exclude all resistance; since the very authority by which the members sat together, was itself the effect of a successful opposition to an acknowledged sovereign.

Again: The allegiance above described can only be understood to signify obedience to lawful commands. If, therefore, the king should issue a proclamation, levying money or imposing any service or restraint upon the subject, beyond what the law authorized, there would exist no sort of obligation to obey such a proclamation, in consequence of having taken the oath of allegiance.

Neither can allegiance be supposed to extend to the king after he is actually and absolutely deposed, driven into exile, or otherwise rendered incapable of exercising the regal office. The promise of allegiance implies, that the person to whom the promise is made continues king: that is, continues to exercise the power, and afford the protection, which belong to the office of king; for it is the possession of these which makes such a particular person the object of the oath.

ALLEGORY, in composition, consists in choosing a secondary subject, having all its properties and circumstances resembling those of the principal subject, and describing the former in such a manner as to represent the latter. The principal subject is thus kept out of view, and we are left to discover it by reflection. In other words, an allegory is, in every respect, similar to an hieroglyphical painting, excepting only that words are used instead of colours. Their effects are precisely the same: At hieroglyphics rises two images in the mind; one, that represents one that is not seen: An allegory does the same; the representative subject is described, and the resemblance leads us to apply the description to the subject represented.

There cannot be a finer or more correct allegory than the following, in which the vineyard is made to represent God's own people the Jews:

"Thus
"Thou hast brought a vine out of Egypt; thou hast cast out the heathen, and plantest it. Thou didst cause it to take deep root, and it filled the land. The hills were covered with its shadow, and the boughs thereof were like the goodly cedars. Why hath thou then broken down her hedges, that all that pass do pluck her? The boar out of the wood doth waste it, and the wild beast doth devour it. Return, we beseech thee, O God of hosts: look down from heaven, and behold, and visit this vine and the vineyard thy right-hand hath planted, and the branch thou madest strong for thyself." Psal. lxxx.

Nothing gives greater pleasure than an allegory, when the representative subject bears a strong analogy, in all its circumstances, to that which is represented. But most writers are unlucky in their choice, the analogy being generally so faint and obscure, as rather to puzzle than to please. Allegories, as well as metaphors and similes, are unnatural in expressing any severe passion which totally occupies the mind. For this reason, the following speech of Macbeth is justly condemned by the learned author of the Elements of Criticism:

"Methought I heard a voice cry, Sleep no more! Macbeth doth murder Sleep; the innocent sleep; Sleep that knits up the ravell'd sleeve of Care, The birth of each day's life, fore labour's bath, Balm of hurt minds, great Nature's second course, Chief nourisher in life's feast."

Aft ii. Sc. 3.

But see this subject more fully treated under the article Metaphor and Allegory.

ALLEGRI. (Antonio), called Correggio from the place of his birth, an eminent historical painter, was born in the year 1494. Being descended of poor parents, and educated in an obscure village, he enjoyed none of those advantages which contributed to form the other great painters of that illustrious age. He saw none of the statues of ancient Greece or Rome; nor any of the works of the established schools of Rome and Venice. But Nature was his guide; and Correggio was one of her favourite pupils. To express the facility with which he painted, he used to say that he always had his thoughts ready at the end of his pencil.

The agreeable smile, and the profusion of grace, which he gave to his maidens, saints, and children, have been taxed with being sometimes unnatural; but still they are amiable and seducing: An easy and flowing pencil, an union and harmony of colours, and a perfect intelligence of light and shade, gave an astonishing relief to all his pictures, and have been the admiration both of his contemporaries and his successors. Annibal Caracci, who flourished 50 years after him, studied and adopted his manner of preference to that of any other master. In a letter to his cousin Louis, he expresses with great warmth the impression which was made on him by the first sight of Corregio's paintings: "Everything which I see here (says he) astonishes me; particularly the colouring and the beauty of the children. They live — they breathe. They smile with so much grace, so much reality, that it is impossible to refrain from smiling and partaking of their enjoyment. My heart is ready to break with grief when I think on the unhappy fate of poor Correggio — that so wonderful a man (if he ought not rather to be called an angel) should finish his days so miserably, in a country where his talents were never known!"

From want of curiosity or of resolution, or from want of patronage, Correggio never visited Rome, but remained his whole life at Parma, where the art of painting was little esteemed, and of condescension poorly rewarded. This concurrence of unfavourable circumstances occasioned at last his premature death at the age of 40. He was employed to paint the cupola of the cathedral at Parma, the subject of which is an allusion of the Virgin; and having executed it in a manner that has long been the admiration of every person of good taste, for the grandeur of design, and especially for the boldness of the fore-shortenings (an art which he first and at once brought to the utmost perfection), he went to receive his payment. The canons of the church, either through ignorance or baseness, found fault with his work; and although the price originally agreed upon had been very moderate, they alleged that it was far above the merit of the artist, and forced him to accept of the paltry sum of 200 livres; which, to add to the indignity, they paid him in copper money. To carry home this unworthy load to his indigent wife and children, poor Correggio had to travel six or eight miles from Parma. The weight of his burden, the heat of the weather, and his chagrin at this villanous treatment, immediately, threw him into a palsy, which in three days put an end to his life and his misfortunes.

For the preservation of this magnificent work the world is indebted to Titian. As he passed through Parma, in the suite of Charles V. he ran instantly to see the chef d'oeuvre of Correggio. While he was attentively viewing it, one of the principal canons of the church told him that such a grotesque performance did not merit his notice, and that they intended soon to have the work defaced. "Have a care of what you do (replied the other), if I were not Titian, I would certainly wish to be Correggio."

Correggio's exclamation upon viewing a picture by Raphael is well known. Having long been accustomed to hear the most unbounded applause bestowed on the works of that divine painter, he by degrees became less desirous than afraid of seeing any of them. One, however, he at last had occasion to see. He examined it attentively for some minutes in profound silence; and then with an air of satisfaction exclaimed, I am still a painter. — Julio Romano, on seeing some of Correggio's pictures at Parma, declared they were superior to any thing in painting he had yet beheld. One of these no doubt would be the famous Virgin and Child, with Mary Magdalene and St Jerome: But whether our readers are to depend upon his opinion, or upon that of Lady Millar, who in her Letters from Italy gives a very unfavourable account of it, we shall not presume to determine. This lady, however, speaks in a very different style of the no less famous Notre or Night of Correggio, of which she saw only a copy in the Duke's palace at Modena, the original having been sold for a great sum of money to the king of Poland. "It surpasses me very much (says she), to see how different the characters are in this picture from that which I already have described to you. The subject is a Nativity; and the extraordinary beauty of this picture proceeds from the clair obscur.
in the Revelation (xix. 1, 3, 4, 6) says, that he heard a great voice of much people in heaven, who said, Alleluia; and the four and twenty elders, and the four beasts, fell down and worshipped God that sat on the throne, saying, Alleluia. This hymn of joy and praise was transferred from the synagogue to the church. St. Jerome tells us, that at the funeral of Fabiola several psalms were sung with loud alleluias; and that the monks of Palestine were awakened, at their midnight watchings, with the singing of alleluias. So much energy has been observed in this term, that the ancient church thought proper to preserve it, without translating it either into Greek or Latin, for fear of impairing the genius and softness of it. The fourth council of Toledo has prohibited the use of it in times of Lent, or other days of fasting, and in the ceremonies of mourning: and, according to the present practice of the Romish church, this word is never repeated in church, nor in the offices of the dead; notwithstanding which, it is used in the crafts for the dead, according to the masarabic ritual, at the intone, when they sing, Tu es pater meus, Domine, Alleluia, in ter- ranam terrenam, Alleluia, Alleluia. The singing alleluia was oftentimes an invitational or call to each other to praise the Lord.

ALLEMAND a sort of grave solemn music, with good measure, and a slow movement. It is also a brisk kind of dance, very common in Germany and Switzerland.

ALLEMANNIC, in a general sense, denotes anything belonging to the ancient Germans. Thus, we meet with Allemannic history, Allemannic language, Allemannic law, &c.

ALLEN (John) archbishop of Dublin in the reign of King Henry VIII. was educated in the universities of Oxford; whence removing to Cambridge, he there took the degree of bachelor of laws. He was sent by Dr. Warden, archbishop of Canterbury, to the pope, about certain matters relating to the church. He continued at Rome nine years, and was created doctor of laws; either there or in some other university of Italy. After his return, he was appointed chaplain to Cardinal Wolsey, and was commissary or judge of his court as legate ad locum; in the execution of which office he was suspected of great dishonesty, and even perjury. He assisted the cardinal in living, and afterwards furnishing 40 of the smaller monasteries, for the erection of his college at Oxford; and that at Ipswich. The cardinal procured for him the living of Dalby in Leicestershire, though it belonged to the matter and brethren of the hospital of Burton Lazars. About the latter end of the year 1529, he was incorporated doctor of laws in the university of Oxford. On the 1st of March 1528 he was consecrated archbishop of Dublin, in the room of Dr. Hugh Inge deceased, and about the same time was made chancellor of Ireland. He wrote, 1. Epistola de Patribus significatione et passione; penned by him at the time when he received the archiepiscopal pall. 2. De confectioribus ac jurisdictione in viris conditores obsessoribus. He wrote also several other pieces relating to the church. His death, which happened in July 1534, was very tragical: for being taken in a time of rebellion by Thomas Fitzgerald, eldest son to the earl of Kilkenny, he was by his command most cruelly murdered, being
ALLEN (Thomas), a famous mathematician of the 16th century, born at Uttoxeter in Staffordshire the 21st of December 1542. He was admitted scholar of Trinity-college Oxford the 4th of June 1561; and in 1567 took his degree of master of arts. In 1570 he quitted his college and fellowship and retired to Gloucester-hall; where he studied very closely, and became famous for his knowledge in antiquity, philosophy, and mathematics. Having received an invitation from Henry earl of Northumberland, a great friend and patron of the mathematicians, he spent some time at the earl's house, where he became acquainted with those celebrated mathematicians Thomas Harriot, John Dee, Walter Warner, and Nathaniel Torporley. Robert earl of Leicester had a particular esteem for Mr Allen, and would have conferred a bishopric upon him, but his love of solitude and retirement made him decline the offer. His great skill in the mathematics made the ignorant and vulgar look upon him as a magician or conjurer: the author of a book intitled *Leicester's Comonwealth*, has accordingly accused him with using the art of figuring, to procure the earl of Leicester's unlawful designs, and endeavouring by the black art to bring about a match betwixt him and Queen Elizabeth. But without pretending to point out the absurdity of the charge, it is certain that the earl placed such confidence in Allen, that nothing material in the state was transacted without his knowledge; and the earl had confiant information, by letter, from Mr Allen, of what passed in the university. Mr Allen was very curious and indefatigable in collecting scattered manuscripts relating to history, antiquity, astronomy, philosophy, and mathematics: these collections have been quoted by several learned authors, &c. and mentioned to have been in the Bibliotheca Alleniana. He published in Latin the second and third books of Claudius Ptolemy of Ptolemais, *Concerning the Judgment of the Stars*, or, as it is commonly called, of the Quaeripartite Confudition: with an exposition. He wrote also notes on many of Lilly's books, and some on John Bale's work *De Scriptoribus & Historiis*. Having lived to a great age, he died at Gloucester-hall on the 30th of September 1622.

ALLENDORF, a small town in the circle of the Upper Rinine, and in the landgrave of Heife-Cassel, remarkable for its fair-works and three stone-bridges. It is seated on the river Werfer, 15 miles east of Cassel: E. Long. 10. 5. N. Lat. 51. 26.

ALLER, a river which runs through the duchy of Lunenburg, and falls into the Weser a little below Verden.

Aller, good, in ancient writers. The word aller serves to make the expression of superlative signification. So, aller-good is the greatest good. Sometimes it is written aller.

ALLERION, or Alleron, in heraldry, a sort of eagle without beak or feet, having nothing perfect but the wings. They differ from martlets by having their wings expanded, whereas those of the martlet are close; and denote imperialisits vanquithed and disfamed; for which reason they are more common in French than in German coats of arms.

ALLESTRY (Richard, D. D.) an eminent divine, born at Uppington in Shropshire in March 1619, was educated in the grammar-school at Coventry, and afterwards at Christ-church in Oxford. His parts, which were extraordinary, were improved by a noble family. He took an arm for King Charles I. and was sometimes seen with his muller in one hand and his book in the other. He was very active in the service of King Charles II. before his restoration, and was employed by the royalists in transacting business with that prince during his exile; but was at last seized at Dover by a party of soldiers, and committed prisoner to Lambeth house, where he was confined fix or eight weeks; but soon after the restoration he was made canon of Christ-church, created doctor of divinity, and appointed chaplain in ordinary to the king, and regius professor of divinity. In 1665 he was appointed provost of Eton college, where he raised the school, which he found in a low condition, to an uncommon pitch of reputation. The west side of the outward quadrangle of that college was built from the ground at his expense. The excellent Dr Hammond, who was his intimate friend, left him his valuable library, which he himself afterwards bequeathed to his successors in the divinity chair. He was eminent for his piety, benevolence, and integrity; for the sincerity of his friendship, and his disinterested temper. He wrote several books; and a collection of his sermons were printed after his decease by Dr Fell bishop of Oxford. He died August 28. 1665.

ALLESTRY (Jacob), an English poet of the last century. He was the son of James Allenstr, a bookseller of London who was ruined by the great fire in 1666. Jacob was educated at Westminster school, entered at Christ-church Oxford, in the 6th term 1671 at the age of 18. and was elected student in 1672. He took the degree in arts; was music-reader in 1679, and terra flius in 1681; both which offices he executed with great applause, being esteemed a good philologist and poet. He had a chief hand in the verses and pastoralcs spoken in the theatre at Oxford May 21. 1681, by Mr. William Savile second son of the Marquis of Halifax, and George Cholmondeley second son of Robert vicount Kells (both of Christ-church), before James duke of York, his duchess, and the lady Anne; which verses and pastoralcs were afterwards printed in the "Examen Poeticum." He died October 15. 1686, and was buried in St Thomas's church-yard.

ALLEUVRE, a small brass Swedisch coin, worth about 1d. English money.

ALLEVIATION, denotes the making a thing lighter, and easier to bear or endure. It stands opposed to aggravation.

ALLEY (William), bishop of Exeter in the reign of queen Elizabeth, was born at Great Wycomb in Buckinghamshire. From Eton school, in the year 1528, he removed to king's-college Cambridge, where he took the degree of bachelor of arts. He also studied some time at Oxford; afterwards he married, was presented to a living, and became a zealous reformer. Upon queen Mary's accession he left his cure and retired into the north of England; where he maintained his wife and himself by teaching a school, and practising physic. Queen Elizabeth ascending the throne, he went to London, where he acquired great reputation by reading the divinity-lecture at St Paul's, and
in July 1560 was consecrated bishop of Exeter. He was created archbishop of Canterbury in 1581. He died on the 10th of April 1570, and was buried at Exeter in the cathedral. He wrote, 1. The
poet's Library, 2 vol. fol. Lond. 1571. These volumes contain twelve volumes on the first edition of
St. Peter's, read at St. Paul's. 2. A letter to Lord Burghley.

Whether it was ever published is uncertain. He translated the Pentateuch, in the version of the Bible which
was undertaken by queen Elizabeth's command.

Alley, in gardening, a straight parallel walk, bounded on both sides with trees, shrubs, &c. and
usually covered with gravel or turf.

Alley, among builders, denotes a narrow passage
leading from one place to another.

Alley, in perspective, that which, in order to have
a greater appearance of length, is made wider at the
entrance than at the termination.

Alley, in the new husbandry, implies the vacant space
between the outermost row of corn on one bed and the nearest row on it to the next parallel bed; and
it is usually about four feet in breadth, exclusive of the
partitions between the rows of corn in the beds.
The first hoeing of wheat is performed in the begin-
ning of winter, and the earth is ploughed away from
the rows into the intervals, which forms small ridges
in the middle between the double rows. The second
hoeing is in the spring, which turns it back to the
rows, leaving a furrow in the middle of the alley. The
third hoeing is from the rows, after the wheat has
blossomed; this turns the earth into the intervals,
forming small ridges there; as at the first hoeing.
The fourth hoeing returns the earth to the ridges, which
is performed a month or more after the third hoeing.

This commonly finishes the hoeing, if the land
is in good heart; otherwise one or two more hoeings
are necessary.

Alley (Edward), a celebrated English actor
in the reigns of queen Elizabeth and king James, and
founder of the college at Dulwich in Surrey, was born
at London, in the parish of St. Gobelin, Sept. 1, 1565, as
appears from a memorandum of his own writing.
Dr Fuller says, that he was bred a player; and
that his father would have given him a liberal
education, but that he was not turned for a serious course
of life. He was, however, a youth of an excellent
capacity, a cheerful temper, a tencious memory, a
sweet eloquence, and in his person of a stately port and
aspect; all which advantages might well induce a young
man to take to the theatrical profession. By several
authorities we find he must have been on the stage some
time before 1592; for at this time he was in high
favour with the town, and greatly applauded by the best
judges, particularly by Ben Johnson.

Haywood, in his prologue to Marlowe's Jew of Mal-
ta, calls him Proteus for shapes, and Roscius for a
tongue. He usually played the capital parts, and was
one of the original actors in Shakespeare's plays; in
some of Ben Jonson's he was also a principal perform-
er: but what characters he perforated in either of
these poets, it is difficult now to determine. This is
owing to the inaccuracy of their editors, who did not
print the names of the players opposite to the charac-
ters they performed, as the modern custom is; but gave
one general list of actors to the whole set of plays, as
in the old folio edition of Shakespeare; or divided one
from the other, letting the dramatic performances before
the plays, and the catalogue of performers after them,
as in Johnson's

It may appear surprising how one of Mr Alley's
production should be able to earn such an edifice as
Dulwich College, and liberally endow it for the main-
tenance of so many persons. But it must be observed
that he had some paternal fortune, which, though
small, might lay a foundation for his future influence;
and it is to be presumed, that the profits he received
from acting, to one of his provident and managing
disposition, and one who by his excellence in playing
drew after him such crowds of spectators, must have
considerably improved his fortune: besides, he was not
only an actor, but master of a playhouse, built at his
own expense, by which he is said to have amassed con-
 siderable wealth. He was also keeper of the king's
wild beasts, or master of the royal beaucharden, which
was frequented by vast crowds of spectators; and the
profits arising from these sports are said to have amount-
ed to 500l. per annum. He was thrice married; and
the portions of his two first wives, they leaving him
no issue to inherit, might probably contribute to this
benefaction. Such kind of donations have been fre-
quently thought to proceed more from vanity and of-
tention than real piety; but this of Mr Alley has
been ascribed to a very singular cause, for the devil has
been said to be the first promoter of it. Mr Aubrey
mentions a tradition, "That Mr Alleyn playing a de-
mon with six others, in one of Shakespeare's plays,
was, in the midst of the play, surprised by an ap-
carition of the devil, which so worked on his fan-
cy, that he made a vow, which he performed by
building Dulwich College." He began the foun-
dation of this college; under the direction of Inigo
Jones, in 1614; and the buildings, gardens, &c. were
finished in 1617, in which he is said to have expended
about 10,000l. After the college was built, he met
with some difficulty in obtaining a charter for settling
his lands in mortmain; for he proposed to endow it
with 8000l. per annum for the maintenance of one
master, one warden, and four fellows, three of whom
were to be clergymen, and the fourth a skilful or-
ganist; also six poor men, and as many women, besides
twelve poor boys to be educated till the age of four-
ten or sixteen, and then put out to some trade or call-
ing. The obfruction he met with arose from the lord
chancellor Bacon, who wished king James to settle part
of those lands for the support of two academical lec-
tures; and he wrote a letter to the Marquis of Buck-
ingham, dated August 18, 1618, intreating him to
use his interest with his Majesty for that purpose. Mr
Alley's solicitation was however at last complied with,
and he obtained the royal licence, giving him full pow-
er to lay his foundation, by his Majesty's letter-patent,
bearing date the 21st of June, 1619, by virtue whereof
he did, in the chapel of the said new hospital at Dul-
wich, called "The College of God's Gift," on the
1st of September following, publicly read and pub-
lished a quadruplicate writing in parchment, whereby
he created and established the said college; he then
subscribed it with his name, and fixed his seal to se-
veral parts thereof, in presence of several honourable
persons, and ordered copies of the writings to four
different
ALLEYNE was himself the first master of his college; so that to make use of the words of Mr. Haywood, one of his contemporaries, "He was so mingled with humility and charity, that he became his own petitioner, humbly submitting himself to that proportion of diet and clothes which he had bestowed on others." We have no reason to think he ever repented of this distribution of his substance; but on the contrary, that he was entirely tained, as appears from the following memorial in his own writing, found amongst his papers: "May 26, 1620—"My wife and I acknowledged the fine at the common plea bar, of all our lands to the college; blefted be God that he has given us life to do it." His wife died in the year 1623; and about two years afterwards he married on lady Kinchoe, who survived him, and received remarkable proofs of his affection, if at least we may judge of it by his will, wherein he left her considerably. He died Nov. 25, 1626, in the 61st year of his age, and was buried in the chapel of his new college, where there is a tomb-stone on his grave, with an inscription. His original Diary is also there preserved.

The following anecdote is entertaining in itself, and shows the high esteem in which Mr. Alleyne was held as an actor: "Edward Alleyne, the Garrick of Shakespeare's time, had been on the most friendly footing with our poet, as well as Ben Johnson. They used frequently to spend their evenings together at the sign of the Globe, somewhere near Black Friars, where the playhouse then was. The word need not be told, that the convivial hours of such a triumvirate must be pleasing as well as profitable, and may truly be said to be such pleasures as might bear the reflections of the morning. In consequence of one of these meetings, the following letter was written by G. Peck, a fellow of Christ-church college, Oxford, and a dramatic poet, who belonged to the Club, to one Marle, and intimate of his:

"Friend Marle,

"I must dey that my fython yr watch, and the cookery book you promysed, may be sente by the man. I never longed for thy company more than last night; we were all very merry at the Globe, when Ned Alleyne did not scruple to affyme pleasurably the friends' will, that he had stolen his speech about the Qualities of an actor's excellence; in Hamlet's Tryadegy, from conversations many fold which had passed between them, and opinions given by Alleyne touching the subject.---Shakespeare did not take this talk in good part; but Johnson put an end to the strife with wittyly re-markinge, This taffert needeth no Contention; you hole it from Ned, no doubt; do not marvel: Have you not seen him all times out of number? Believe me most sincerely, yours, G. Peck."

ALLIA, a river of Italy, which running down a very steep channel from the mountains of Cufiumum, mixes with the Tiber at 40 miles from Rome; famous for the great slaughter of the Romans by the Gauls, under Brennus; hence Alliatis dies, an unlucky day, (Virgil, Ovid, Lucan.) Our ancestors, says Cicero, deemed the day of the flight of Allia more fatal than that of taking the city.

ALLIANCE, in the civil and canon law, the relation contracted between two persons or two families by marriage.

Alliance is also used for a treaty entered into by sovereign princes and states, for their mutual safety and defence. In this sense, alliances may be distinguished into such as are offensive, whereby the contracting parties oblige themselves jointly to attack some other power; and into defensive ones, whereby they bind themselves to stand by and defend each other in case they are attacked by others.---Alliance, with the ancient Romans, though a sort of servitude, was much coveted. Ariarathes, we are told by Polybius, offered a substitute to the gods by way of thanking for having obtained alliance. The reason was, that thence-forwards people were sure not to receive any injuries except from them.---There were different sorts of alliances: some only united to them by a participation of the privileges of Romans, as the Latini and Hernici; others by their very foundation, as the colonies; others by the benefactions they received from them, as Mafimillas, Armenians, and Attalus, who owed their kingdoms to Rome; others by free treaties, which last by a long alliance became subjects, as the kings of Bithynia, Cappadocia, Egypt, and Kings of Greece: lastly, others by compulsory treaties, and the law of subjiction, as Philip and Antiochus. For they never granted peace to an enemy, without making an alliance with him; that is, they never subdued any people without using it as a means of subduing others.

The forms or ceremonies of alliances have been various in different ages and countries. At present, signing and swearing, sometimes at the altar, are the chief; anciently eating and drinking together, chiefly offering sacrifices together, were the customary rite of ratifying an alliance. Among the Jews and Chaldeans, beffers or calves; among the Greeks, bulls or goats; and among the Romans, hogs were sacrificed on this occasion. Among the ancient Arabs, alliances were confirmed by drawing blood out of the palms of the hands of the two contracting princes with a sharp stone, dipping herein a piece of their garments, and therewith smearing seven stones, at the same time invoking the gods Votans and Alliat, i. e. according to Herodotus, Bacchus and Urania. Among the people of Cholchis, the confirmation of alliances is said to be effected by one of the princes offering his wife's breasts to the other to suck, which he was obliged to do till there issued blood.

Alliance, in a figurative sense, is applied to any kind of union or connection; thus we say, there is an alliance between the church and state.

Alliati, in Roman antiquity, the balsam kind of flaves, who were usually kept fettered. The Romans had three degrees, or orders, of slaves or servants; the first employed in the management of their estates; the second in the mediocr or lower functions of the family; the third called alliati, above-mentioned.

Alligation, the name of a method of solving all questions that relate to the mixture of one ingredient with another. Though writers on arithmetic generally make alligation a branch of that science; yet, as it is plainly nothing more than an application of the common properties of numbers, in order to solve a few questions that occur in particular branches of business,
Alligation we choose rather to keep it distinct from the science of arithmetic.

Alligation is generally divided into medial or alternate.

**Alligation Medial.** From the rates and quantities of the simples given, discovers the rate of the mixture.

**Rule.** As the total quantity of the simples, 
To their price or value; 
So any quantity of the mixture, 
To the rate.

**Examp.** A grocer mixes 30 lb. of currants, at 4d. per lb. with 10 lb. of other currants, at 6d. per lb.: What is the value of 11 lb. of the mixture? 

\[ \frac{30 \text{ lb.}}{4 \text{ d.}} : \frac{10 \text{ lb.}}{6 \text{ d.}} = \frac{11 \text{ lb.}}{x \text{ d.}} \]

\[ x = \frac{11 \times 54}{40} = 16.5 \text{ d.} \]

**Note 1.** When the quantity of each simple is the same, the rate of the mixture is readily found by adding the rates of the simples, and dividing their sum by the number of simples. Thus,

Suppose a grocer mixes several sorts of sugar, and of each an equal quantity, viz. at 50s. at 54s. and at 60s. per cwt. the rate of the mixture will be 54s. 8d. per cwt.; for

\[ \frac{50 + 54 + 60}{3} = 54 \text{ s. 8d.} \]

**Note 2.** If it be required to increase or diminish the quantity of the mixture, say, As the sum of the given quantities of the simples, to the several quantities given; fo the quantity of the mixture proportioned, to the quantities of the simples fought.

**Note 3.** If it be required to know how much of each simple is an assigned portion of the mixture, say, As the quantity of the mixture, to the several quantities of the simples given; fo the quantity of the assigned portion, to the quantities of the simples fought.

Thus,

Suppose a grocer mixes 10 lb. of raisins with 30 lb. of almonds and 40 lb. of currants, and it be demanded, how many ounces of each sort are found in every pound or in every 16 ounces of the mixture, say,

\[ \frac{80}{10} : \frac{16}{2} = \text{raisins.} \]

\[ \frac{30}{16} : \frac{6}{2} = \text{almonds.} \]

\[ \frac{40}{16} : \frac{8}{2} = \text{currants.} \]

**Proof 16**

Note 4. If the rates of two simples, with the total value and total quantity of the mixture, be given, the quantity of each simple may be found as follows, viz. 
Multiply the lesser rate into the total quantity, subtract the product from the total value, and the remainder will be equal to the product of the excess of the higher rate above the lower, multiplied into the quantity of the higher-priced simple; and consequently the said remainder, divided by the difference of the rates, will give the said quantity. Thus,

Suppose a grocer has a mixture of 400 lb. weight, that cost him 7l. 10s. consisting of raisins at 4d. per lb.
Alligation. viz. 2 and 1, they are added; and the answer to the question is, that 2 lb. at 5d. 2 lb. at 7d. and 4 lb. at 10d. will make the mixture required.

The truth and reason of the rules will appear by considering, that whatever is lost upon any one branch is gained upon its yokc-fellow. Thus, in the above example, by selling 4 lb. of 10d. sugar at 8d. per lb. there is 8d. lost: but the like sum is gained upon its two yokc-fellows; for by selling 2 lb. of 5d. sugar at 8d. per lb. there is 6d. gained; and by selling 2 lb. of 7d. sugar at 8d. there is 2d. gained; and 6d. and 2d. make 8d.

Hence it follows, that the rate of the mixture must always be mean or middle with respect to the rates of the simples; that is, it must be less than the greatest, and greater than the least; otherwise a solution would be impossible. And the price of the total quantity mixed, computed at the rate of the mixture, will always be equal to the sum of the prices of the several quantities call’d up at the respective rates of the simples.

**Variety II.** When the question is limited to a certain quantity of one or more of the simples, this is called Alligation Partial.

If the quantity of one of the simples may be limited, alligate the branches, and take their differences, as if there had been no such limitation; and then work by the following proportion:

As the difference right against the rate of the simple whose quantity is given,
To the other differences respectively;
So the quantity given,
To the several quantities sought.

**Example.** A distiller would, with 40 gallons of brandy at 12s. per gallon, mix rum at 7s. per gallon, and gin at 4s. per gallon: How much of the rum and gin must he take, to fell the mixture at 8s. per gallon?

\[
\begin{array}{c|c|c|c|c|c}
\text{Gal.} & 30 & 30 & 120 & 144 & \text{total.} \\
\text{of wine.} & 0 & 6 & 24 & 0 & \\
\hline
\text{of water.} & 0 & 0 & 0 & 0 & \\
\hline
\text{Proof} & 144 & 4320 & (30) \\
\text{As} & 36 & : & 30 & : : & 144 & : 120 \\
\text{As} & 36 & : & 6 & : & 144 & : 24 \\
\end{array}
\]

There being here only two simples, and the total of the mixture limited, the question admits but of one answer.

ALLIGATOR, in zoology, a synonyme of the Lacerta crocodilus, See Lacerta.

ALLIOT, a star in the tail of the greater bear, much used for finding the latitude at sea.

Alliteration, an ornament of language chiefly used in poetry, and confisting in the repetition of the same letter at certain intervals. We do not remember to have ever seen any satisfactory account of alliteration in the writings of the critics. They seem to have placed it over in contemptuous silence; either as a false refinement or as a mere trite. It perhaps deserves a better fate. Many chapters have been composed on quantity, on the expression resulting from different arrangements of long and short syllables, and on the powers of pauses as they are variously placed, without a word of alliteration. This is the more extraordinary, as one should think it impossible for any man to examine minutely, and, as it were, dissect a number of verses, without perceiving the vast abundance of this ornament. It is as if an anatomist should publish a complete table of the arteries in the human body, and affect never to have seen a vein nor a nerve; for it may be affirmed, with small danger of mistake, that if you examine any number of verses, remarkable either for sweetness or for energy, you will be found in some degree alliterative. We do not pretend to say, that the sweetnefs and energy of verification depends chiefly on this circumstance, yet we cannot help believing that it may claim some share; for it is a constant appearance, as far as we have ever observed, that the poets whose fame is highest for verification, are most extensive dealers in this article.

The trifling poor appearance of the ornament itself, upon
Alliteration, and the frequent shade of it are circumstances indeed which give no encouragement to a serious inquiry into its nature and operation. How common is it for writers, who would be comic, when least likely for viewing a smile, to use alliteration with success? But, in the fine arts, no beauty nor grace is beyond the power of ridicule. The noblest attitudes in painting have been rendered laughable by caricature. St Paul preaching at Athens, in the design of Raphael, appears elegant, noble, and in some degree awful. The same apostle, represented by Hogarth in nearly the same attitude, pleading before the governor Felix, seems altogether ridiculous. So the language and verification of Milton in the Paradise Lost appear only proper for the most elevated subjects. In the Splendid Shilling of Philips, they appear equally proper for the lowest. So far it also with alliteration. Nor ought we to be morbid at the discovery, that much of the delight afforded by the language and beauty of Milton ill the common works of his verfificatlon; is it tor the ear.

The ear seems equally contemptible.

We apprehend the principal operation of this ornament to be quite mechanical. It is easier for the organs of speech to refraine, at short intervals, one certain conformation, than to throw themselves into a number of different ones, unconnected and discordant. For example, a succession of labials, interspersed at regular distances with dentals and gutturals, will be more easily pronounced than the succession of all the three at random. Sounds of which the articulation is easie, are most completely in the power of the speaker. He can pronounce them slowly or rapidly, softly or with force, at pleasure. In this we imagine the power and advantage of alliteration is founded: for we would not lay any stress on the pleasure which can result to the ear from the repetition of the same letter twice, or often, on the accented parts of a verse; for there are many other causes of pleasure, which, when thus detected and taken to pieces, seem equally contemptible.

These remarks might be confirmed and illustrated by numberless passages from the best poets. Some few lines will suffice, taken from Gray, who seems to have paid particular attention to this grace. He proceeded to have learned his verification from Dryden, as Dryden did from Spencer; and these three abound in alliteration above all the English poets. We choose Gray for another reason, in proof of what we mentioned before, that alliteration contributes not only to the sweetness, but also to the energy, of verification; for he uses it chiefly when his aim is at strength and boldness. In the Sifer Odor (as Dr Johnson styles them), almost every figure of speech commences and concludes with an alliterative line. The poet, we suppose, wished to begin with force, and end with dignity.

"Ruin feiz thee, ruthles king."

"To high-born Hoel's harp, or soft Llewellyn's lay."

"Wave the warp, and weave the woof,"

"Stamp weare vengeance deep, and ratiye his doom."

Alliteration is already in question; we might, however, have proceeded, as many of our ancient metrical poets did, from the simple assertion of the truth, to the demonstration of it. That it has a bearing on the subject is evident from the following passage: "The poet, we suppose, wished to begin with force, and end with dignity."

"Mountains, ye mourn in vain."

"Modest whole magic," — &c.

If alliteration thus contributes to enforce the expression of a poetical sentiment, its advantages in poetry must be considerable. If two words offer of equal propriety, the one alliterative the other not, we think the first ought to be chosen. We would compare this to the practice of fuguing in music. A composer who aims at expression will not hunt after fugues; but if they offer, if they seem to arise spontaneously from the subject, he will not reject them. So a good poet ought not to select an epithet merely for beginning with a certain letter, unless it suits his purpose well in every other respect; for the beauty of alliteration, when happy, is not greater than its deformity when affected. A couplet from Pope will exemplify both; the first line being bad, and the second good:

"Eternal beauties grace the rhining scene,

"Fields ever fresh, and groves for ever green."

Allium (from Latin, "to avoid or flumm," because many flumm the smell of it), Garlic: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking in the 9th order, Spathecaceae. The characters are: The calyx is a common spatha, roundish, withering, and multi-florous: The corolla consists of six oblong petals: The Stamina have six subulate filaments, often the length of the corolla; the antherae are oblong and erect: The Pistilum has a germin above, shorter, nearly three-cornered, with angles engraved with a line; the pistil are simple, the stigmatic acute: The pericarpum is a very short, broad, three-lobed capsule, with three cells and three valves: The seeds are many and roundish. Of this genus no fewer than 40 different species are enumerated by Linnaeus, among which he includes the cepa and porrum, or onions and leeks.

1. The fatum, or garlic, has a bulbous root, of an irregular roundish shape, with several fibres at the bottom; each root is composed of a number of lesser bulbs, called coves of garlic, inclosed in one common membranous
All the parts of this plant, but more especially the roots, have an acrimonious, and almost caustic taste, with a fiery offensive smell, which last has induced those who preferred some of the species in gardens on account of their yellow flowers, to eradicate them.

This pungent root warms and stimulates the solids, and attenuates tenacious juices; for which it is well adapted, on account of its being very penetrating; in so much that, when applied to the feet, its scent is soon discovered in the breath; and, when taken internally, its smell is communicated to the urine, or the matter of an illness, and perspires through the pores of the skin. Hence, in cold leucopneumogatic habits, it proves a powerful expectorant, diuretic, and emmenagogue; and, if the patient is kept warm, fudorific.

It is also of great service in humoral athermas and catarrhal disorders of the breast, and in other disorders proceeding from a laxity of the solids, and cold flagitious indispositions of the fluids. It is also frequently of service in the droopy, in the beginning of which it is particularly recommended by Sydenham, as a warm strengthening medicine; we have even many examples where it acts so powerfully as a diuretic, as to carry off all the water of dropies. It may be taken the length of a dram or two in substance for a dose. — There is a syrup and oxymel made with it, which may be employed for the same purposes as the garlic in substance; but they are mostly used in pulmonary disorders.

— It is applicable, if inflamed and ulcerates the skin, and is sometimes employed for this use in small-pox. It has also been recommended by Sydenham as a most powerful revolvent; for which purpose he was led to make use of it in the confinement small-pox. His method was to cut the root in pieces, and apply it, tied in a linen cloth, to the soles of the feet, about the eighth day of the disease, after the face began to swell; renewing it once a day till the danger was over. — When made into an unguent with oills, and applied externally, garlic is said to resolve and diffus cold tumours, and has been by some greatly celebrated in curaneous disorders.

The acrimonious qualities of this root, however, render it manifestly improper on many occasions. Its liberal use is apt to occasion head-ach's, flats and headaches, thirst, rebele heat, inflammatory distempers, and sometimes discharges of blood from the hemorrhoidal vesicles. In hot bilious constitutions, where there is already a degree of irritation, where the juices are too thin and acrimonious, or the viscera unfoad, it never fails to aggravate the distemper.

In Kamitchaka, the allium uritanum, or wild garlic, is very common and useful in medicine as well as food. Both Ruffians and natives gather it in great quantities for winter service. They steep it in water, then mix it with cabbage, onions, and other ingredients, and form out of them a ragout which they eat cold. It is also the principal remedy for the fourry. As soon as this plant appears above the snow, they seem to put this dreadful disorder at defiance, and find a cure almost in its worst stages.

Garlic is very hardy, and will thrive in almost any soil or situation. It is easily propagated either by the roots or seeds. If from the roots, they ought to be planted in autumn, that they may take good root in the ground before the spring, which is necessary to make them flower through the following summer. If they are propagated by seeds, they may be sown on a border of common earth, either in autumn soon after the seeds are ripe, or in the spring following; and will require no farther care than to keep them clean weeds. In the following autumn, they may be transplanted into the borders where they are to remain.

2. The ascalumnum, or echalot, was found wild in Palestine by Dr. Hafelquet. The root is conglobate, consisting of many oblong roots bound together by thin membranes. Each of these small roots sends forth two or three filiform, long, oval shaped leaves, issuing from a fistach, and are nearly like those of the common onion. The flower-heads spring from a membraneous fistach; is round, almost naked, and terminated by a globular umbel of flowers, which have crest, purplish, lance-shaped petals, of the length of the dimina. — The root of this species is very pungent, has a strong but not unpleasant smell, and therefore is generally preferred to the onion for making high-flavoured soups and gravies. It is also put into pickles, and in the East Indies they use an abundance of it for this purpose.

3. The scorodoprasum, or rokambolo, grows naturally in Denmark and Sweden. It has a heart-shaped solid root, which stands sidewise of the stalk. The leaves are broad, and are a little crenated on their edges. The flowers are of a pale purple colour, and collected into a globular head. The roots are used for the same purpose as the former.

4. The chobroeprasum, or chives, is an inhabitant of Siberia, and is a very small plant compared with the former, the leaves and stems seldom exceeding six inches in length, and the roots never producing any bulbs. The leaves are oval-shaped, hollow, and the stem naked. It was formerly in great request for mixing with salads in the spring, but has been little regarded lately. Its taste, smell, and virtues, are much the same as those of the common onion. It is propagated by parting the roots.

5. The cepa, or common onion, differs from the garlic only in the swelling pipy stalk, which is much larger in the middle than at either end. — From whence this was first brought into Europe is not known; but that it is natural to Africa is beyond a doubt, it being evident that onions were eaten by the Egyptians above 2000 years before Christ; and they make a great part of their constituent food to this day in Egypt. Dr. Hafelquet says it is not to be wondered at that the Israelites should long for them after they had left this place: for whoever had tasted onions in Egypt must allow, that none can be had better in any part of the universe. Here, he observes, they are sweet, in other countries they are nauseous and strong. Here they are soft; whereas in the north and other parts they are hard, and their coats so compact that they are difficult to digest. They eat them roasted, cut into four pieces, with some bits of roasted meat, which the Turks call kebab; and with this dish they are so delighted, that they wish to enjoy it in paradise. They likewise make a loop of them in Egypt, which Hafelquet says is one of the best dishes he ever eat. The many ways of dressing onions in Britain are known to every family: but in regard to wholeomenesses, there is certainly no method equal to boiling; as thus they are rendered mild, of easy digestion, and go off without leaving those heats in the stomach and bowels which
which they are apt to do any other way. Their nature is to attenuate thick, viscid juices; consequently a plentiful use of them in cold phlegmatic constrictions must prove beneficial. Many people, thus on account of the strong, disagreeable taste, they commonly cause to the breath. This may be remedied by eating a few raw parsley leaves immediately after, which will effectually overcome the scent of the onions, and cause them to lie more easy on the stomach.

The varieties are, the Sarburgh, the Spanish, and the Egyptian onion. They are propagated by seeds, which should be sown the latter end of February, or the beginning of March, on good, light, rich ground, well dug and levelled, and cleared from weeds. They should also be sown at a time when the surface of the ground is not moist; and where they are intended for a winter crop, they must not be sown too thick. The common allowance is six pounds of seed to an acre; though some allow more, in order to have a crop to draw out, which they call callings. In about six weeks after, the onions will be up and forward enough to hoe; at which time the weeds should be lightly cut up with a small hoe about two inches and a half broad, and as also the onions themselves where they grow too close. In bunches, leaving them at this first time at least two or three inches apart. This, if properly performed, and in a dry season, will preserve the ground clear of weeds at least a month, when they must be hoed over again, leaving them at this time about four or five inches farther. In six weeks after they must be hoed a third time. The weeds are now to be carefully cut up, and the onions fangled out so as to leave them about six inches square; by which means they will grow much larger than if left too close. This, if well performed, in case the weather proves dry, will keep the onions till they are fit to pull; but if the weather should prove moist, and any of the weeds take root again, the weeds must be pulled out with the hand; for the onions having now begun to bulb, must not be disturbed with a hoe. Towards the middle of August, the onions will have arrived at their full growth, which may be known by their blades falling to the ground, and their heads being formed. At this time, therefore, before their necks or blades are withered off, they should be drawn out of the ground, the extreme part of the blade cut off, and the onions laid upon a dry spot of ground, observing to turn them every other day at least, to prevent them from taking root again; which in moist weather they would be apt to do. At any rate, they are very apt to grow in the lofts where they are kept all winter; the most effectual method of preventing which is, with a hot iron, lightly to touch their heads or roots, which will effectually prevent their sprouting; but in doing this, great caution must be used not to touch the pulp, for that will cause them to perish soon after. In order to fave seeds, you must in the spring make choice of some of the largest, firmest and bell-shaped onions (in quantity proportionable to the seed you intend to fave), and having prepared a piece of good ground, which should be well dug, and laid out in beds about three feet wide, the onions must be planted in the beginning of March, in the following manner: Having stratified a lane of about four inches within the side of the bed, you must with a spade throw out an opening six inches deep, the length of the bed, into which you should place the onions with their roots downward, at about nine inches distance from each other; and with a rake draw the earth into the opening again to cover the bulbs: then proceed to move the line again about a foot farther back, where you must make an opening as before, and so again, till the whole is finished, by which you will have four rows in each bed; between each bed you must allow the space of two feet for an alley to go among them. In a month's time the leaves will appear above ground, and many of the roots will produce three or four flowers each. About the beginning of June, when the flowers begin to appear, the flowers must be tied to stakes to prevent them from being broke by their own weight. About the end of August the seeds will be ripe, which may be known by the opening of the cells which contain it, and its changing to a brown colour. When the heads are cut off, they should be spread abroad upon coarse cloths in the sun, observing to keep it under shelter in the night, as also in wet weather. When the heads are quite dry, the seeds should be beat out from them, and after being cleared from the husks, and exposed one day to the sun to dry, they may be put up in bags for use.

Besides the abovementioned sorts of onions, the scallions or c Babies, and Welsh onions, were formerly in great repute. The former is a root which never forms any bulbs at the roots, and was chiefly used in the spring for green onions; but is now become so scarce as hardly to be known. Some gardeners, instead of the scallion, substitute such onions as decay and rot in the house. These they plant in a bed early in the spring, and in a short time they become large enough for use. The true scallion is easily propagated by parting the roots either in the spring or autumn; but the latter is preferable. The roots should be planted three or four in a hole, and about six inches distance every way. The Welsh onions are propagated only for spring use; they never make any bulbs, and are therefore fit only to be used green for salads. They are sown in the end of July, in beds about three feet, and a half wide. In a fortnight's time they appear above ground; but in October their blades die, and the ground becomes quite naked. In January, however, they will again appear very strong, and in March will be fit to draw for young onions.

6. The porrum, or leek, has been so long cultivated, that its native place of growth cannot be traced. It is undoubtedly the same as that mentioned in the eleventh Chap. of Numbers, where it is said the Israelites longed for leeks in conjunction with onions. The leaves are much of the same nature as those of the latter, and they are yet a constant dish at the tables of the Egyptians, who chop them small and then eat them with their meat. They are in great esteem, too, with the Welsh, and their general use as a pot herb is well known. The culture is the same with that of the onion.

ALLX (Dr Peter), a learned French Protestant divine, born at Alençon in 1641. He became minister of the reformed church at Rouen, where he published many learned and curious pieces; the credit of which induced the reformed to call him to Charenton, about a league from Paris, being the principal church
they had in France. On the revocation of the edict of
Nantes, he retired to England; where he studied the
language with so much success, as to publish a work,
titled Reflections on the Books in the Holy Scriptures,
to establish the Truth of the Christian religion; 2 vols.;
which he dedicated to James II. acknowledging his
obligation to that prince, and his kind behaviour to
the distressed sufferers in general. He wrote several
other treatises relating to ecclesiastical history; which
rendered him as famous in England as in France, for
his ingenious and solid defences of the reformed reli-
gion. He was complimented with the degree of
D. D. and in 1690 was made treasurer of the church
of Salisbury. He died in 1717.

ALLOA, or ALLOWAY, a sea-port town in Scot-
land, situated on the Forth, about 20 miles higher up
the river than Leith, and five miles east of Stirling.
It is a populous place; has two market days in the
week; and is remarkable for its fine castle the seat of
the earl of Mar, and for the coal-mines near it. The
harbour is extremely commodious, with great depth
of water; and vessels are expeditiously loaded with
coals from the pits by an uncommon wagggon-way, on
which one horse draws with ease three waggons at
once, each wagggon containing a ton and a half. An
elegant dry dock has also been lately erected here,
capable of receiving ships of the greatest burden.
There is likewise a large glass-house for blowing bottles,
of which vessels are supplied with any quan-
tity upon the shortest notice.

The tower and lands of Alloa were exchanged by
David II. king of Scots, anno 1365, with Thomas
Lord Erskine, for the lands and estate of Strathgar-
ney in Perthshire; and since that time the castle of
Alloa has been the favourite residence of the family of
Mar. The situation is uncommonly beautiful. The
gardens here were the first that were laid out on a
great scale in Scotland; and, with the advice of Le
Nautre, were indebted to the taste of John the late
Earl of Mar, who began to plant them in the year
1706. They contain about 40 acres; and would have
exhibited to Dr Johnstoun, had he travelled that way,
as fine timber of four-score years growth as his favou-
rite England can produce.

The tower of Alloa is 89 feet in height, with walls
of 11 feet in thickness; and was built in the end of
the 13th century. In this residence of the family of
Erskine, many of the Scottish princes received their
education, having been for more than two centuries
the wards of the Lords Erskine and Earls of Mar;
who held generally the castle of Stirling, and frequent-
ly the three principal fortresses in that kingdom, Edin-
burgh, Stirling, and Dunbarton. The last heir of the
Scottish monarchy who was nurtured there was
Henry Prince of Wales; whose cradle, golf-clubs, and
other infantine and youthful remains, are preserved by
the heirs of the earls of Mar, in remembrance of that
spirited and promising prince; of whom Dr Birch has
preserved several anecdotes connected with the Erskines
and his residence at Alloa.—Among other remains of
antiquity preserved at Alloa, in remembrance of the
confidence and affection which subsisted always between
the Stuarts and the Erskines, is the private fogenet
of the unfortunate Mary, which she gave to the regent
Mar, after she was obliged by the treaty of Edinburgh
to yield from wearing the arms of England in the gift
quarter: the child's-chair of James I. her son; and
the fiddle-chair of Thomas Lord Erskine the 3d
Earl of Mar of the name, with the fashionable grace
carved on it, Salus Dei Honorem et Christo.

ALLOBROGES, in botany: a genus of the
monogynia order, belonging to the octandria clafs
of plants. The characters of which are: the calyx
is a four-leaved perianthium, with orbicular leaflets,
the opposite ones eaves: The corolla consists of four
orbiocular equal petals, less than the calyx; the claws
broader, the length of the smaller leaves of the calyx:
The stamina consist of eight slender filaments, the
length of the corolla; the antheræ are roundish: The
pilillum has a round didymous germain above; the
stylus is filiform, and longer than the stamina; and
the stigma is bised, with revolute divisions.

There is but one species, the zeulanicus, a native of Cey-
on.

ALLOTTING, or ALLENTMENT of Goods,
in matters of commerce, is when a ship's cargo is divided
into severall parts, bought by divers persons, whose names
are written on as many pieces of paper, which are ap-
plied by an indifferent person to the several lots or par-
cels; by which means the goods are divided without
partiality, every man having the parcel which the lot
with his name on is appropriated.

ALLOY, or ALAY, properly signifies a propor-
tion of a bairer metal mixed with a finer one. The
alloy of gold is estimated by carats, that of silver by
penny-weights. (See GOld, &c.) In different na-
tions, different proportions of alloy are used; whence
their moneys are said to be of the same fineness or
baseness, and are valued accordingly in foreign ex-
changes.—The chief reasons alleged for the alloying
of coin are: 1. The mixture of the metals, which, when melted from the mine, are not perfectly pure.
2. The paying the expense it must otherwise cost if they were to be refined. 3. The necessity of rendering them harder, by mixing some parts of other metals with them, to prevent the diminution of weight by wearing in passing from hand to hand. 4. The melting of foreign gold or coin which is alloyed. 5. The charges of coinage, which must be made good by the profit arising from the money coined. 6. And lastly, the duty belonging to the sovereign, on account of the power he has to cause money to be coined in his dominions.

In a more general sense, the word is employed in chemistry to signify the union of different metallic matters. As an infinity of different combinations may be made according to the nature, the number, and the proportions of the metallic matters capable of being alloyed, we shall not here enter into the detail of the particular alloys, all which are not yet nearly known. Those which are used, are brass, tombac, brassy, white copper, &c. may be found under their particular names; and what is known concerning other alloys may be found under the names of the different metals and semi-metals.

ALLUM. See Alum.

ALLUMINOR, from the French alumer, "to lighten," is used for one who coloureth or painteth upon paper or parchment; and the reason is, because he gives light and ornament by his colours to the letters or other figures. Such ornaments are called illuminations. The word is used in lat. R. III. cap. 9. But now such a person is called a limner.

ALLUSH, (anc. geog.) The Israelites being in the wilderness of Shur, departed from Dophkah, and went to Allush, from whence they proceeded to Rephidim; Num. xxxiii. 13, 14. Eusebius and St Jerom fix Alluh in Idumæa, about Gabaala or Petra, the capital of Arabia Petraæ. In the accounts of the empire, it is situated in the third Palestine; and by Ptolemy, among the cities of Idumæa.

Allusion, in rhetoric, a figure by which something is applied to, or understood of, another, on account of some similitude between them.

AlluVion, in law, denotes the gradual increase of land along the sea-shore, or on banks of rivers.

Also, in matters of policy, a sovereign prince or state that has entered into alliance with others. See Alliance.

Almacantars. See Almucantars.

Almacrossen, a sea-port town of Spain, in the province of Murcia, at the mouth of the river Guadalentin. It is about twenty miles west of Cartagena, and is remarkable for the prodigious quantity of alum found in its territory. W. Long. 1. 15. N. Lat. 37.

Almadie, a town of Spain, in the province of La Mancha, in the kingdom of Castile, situated upon the top of a mountain, where are the most ancient as well as the richest silver mines in Europe.

Almadie, a kind of canoe, or small vessel, about four fathoms long, commonly made of bark, and used by the negroes of Africa.

Almadie is also the name of a kind of long-boats, fized out at Calicut, which are eighty feet in length, and fix or seven in breadth. They are exceedingly swift, and are otherwise called catohirs.

Almagest, in matters of literature, is particularly used for a collection or book composed by Ptolemy, containing various problems of the ancients both in geometry and astronony.

Almagest is also the title of other collections of this kind. Thus Ricci-Ali has published a book of astronomy, which he calls the New Almagest; and Plucken, a book which he calls Almagestrum Botanicum.

Almagra, a fine deep red ochre, with some admixture of purple, very heavy, and of a denser yet friable structure, and rough dusty surface. It adheres very firmly to the tongue, melts easily and freely in the mouth, is of an astringent and strongly astringent taste, and stains the skin in touching. It is the sal ammoniac of the ancients; it furnishes very violently with acid menstruums; by which single quality, it is sufficiently distinguished from the sal sylviferum, to which it has in many respects a great similarity. It is found in immense quantities in many parts of Spain; and in Andalusia there are in a manner whole mountains of it. It is used in painting, and in medicine as an astringent.

Almagro, a fortress of Spain, the capital of one of the dioceses of La Mancha. It was built by the archbishop Roderic of Toledo, who finished it in 1214, and put a considerable garrison into it to refrain the incursions of the Moors. This was hardly done, when the fortress was beleaguered by an army of 5000 horse and foot, under the command of a Moorish officer of great reputation; but the prelate, its founder, took care to supply those within with such necessaries, that at length the enemy found themselves obliged to raise the siege and retire with great loss.

Almanack, a book, or table, containing a calendar of days and months, the rising and setting of the sun, the age of the moon, the eclipses of both luminaries, &c.—Authors are divided with regard to the etymology of the word; some deriving it from the Arabic particle al, and manah, to count; some from al-manah, new-year's gifts, because the Arabian astrologers used at the beginning of the year to make presents of their ephemerides; and others, from the Teutonic almanach, observations on all the months. Mr Johnson derives it from the Arabic particle al, and the Greek μή, a month. But the most simple etymology appears from the common spelling; the word being composed of two Arabic ones, Al Manack, which signify the Diary. All the classes of Arabs are commonly much given to the study of astronomy and astrology; both which a pastoral life, and a sort of husbandry, not only incline them but give them time and leisure to apply themselves to them. They never sow, reap, plant, travel, buy or sell, or undertake any expedition or matter, without previously consulting the stars, or, in other words, their almanacks, or some of the masters of them. From these people, by their vicinity to Europe, this art, no less useful in one sense than stupid and ridiculous in another, hath passed over thither; and those astronomical compositions have still everywhere not only retained their old Arabic name; but were, like theirs, for a long while, and still are among many European nations, interpolated with a great number of astrological rules for planting, sowing, bleaching, purging, &c. down to the cutting of the hair and paring of teeth.
Almanack of the nails.—Regiomontanus appears to have been the first in Europe, however, who reduced almanacks into their present form and method, gave the characters of each year and month, foretold the eclipses and other phæses, calculated the motions of the planets, &c. His first almanack was first published in 1474.

Almanacks differ from one another, entirely, in containing some more, others fewer, particulars.

The essential part is the calendar of months and days, with the risings and settings of the sun, age of the moon, &c. To these are added various parerga, astronomical, meteorological, chronological, political, rural, &c. as calculations and accounts of eclipses, solar ingresses, prognostics of the weather, tables of the tides, terms, &c. lists of pigs, offices, dignities, public institutions, with many other articles political as well as local, and differing in different countries.

A great variety are annually published in Britain; some for binding, which may be denominated book-almanacks; others in loose papers, called frezzi-almanacks.

The modern almanack answers to the Faust of the ancient Romans. See FASTI.

Confrontation of Almanacks. The first thing to be done is, to compute the sun's and moon's place for each day of the year, or it may be taken from some ephemerides and entered into the almanack; next, find the domical letter, and, by means therof, distribute the calendar into weeks; then, having computed the time of easter, by it fix the other moveable feasts; adding the immovable ones, with the names of the martyrs, the rising and setting of each luminary, the length of day and night, the aspects of the planets, the phases of the moon, and the sun's entrance into the cardinal points of the ecliptic; i.e. the two equinoxes and solstices. (See Astronomy, paffim.) By the help of good astronomical tables or ephemerides, the construction of almanacks is extremely easy.

In Britain almanacks for one year printed on one side of the paper, pay of the duty 2d.; those for more years pay for three years 1s. 6d.; but perpetual almanacks are to pay only for three years at 3d. Out of the duties by this act there shall be paid to each university L. 500 per annum half-yearly, at Midsummer and Christmas, and the surplus shall be paid into the exchequer to go to the sinking fund. Selling unsteamed almanacks incurs the same penalty as for selling unstamped newspapers. Almanacks in bibles and common prayer books are exempted.

Almanack, among antiquaries, is also the name given to a kind of instrument, usually of wood, inscribed with various figures and Runic characters, and representing the order of the feasts, domical letters, days of the week, and golden number, with other matters necessary to be known throughout the year; used by the ancient northern nations, in their computations of time, both civil and ecclesiastical. Almanacks of this kind are known by various names, among the different nations wherein they have been used; as rimstocks, primataries, runstocks, runtaffs, Seipiones Runic, Baccell Almanacs, clogs, &c. They appear to have been used only by the Swedes, Danes, and Norwegians. From the second of these people, their use was introduced into England, whence divers remains of them in the counties. Dr Plot has given the description and figure of one of these clogs, found in Staffordshire, under the title of The perpetual Staffordshire Almanack. The external figure and manner of these calendars appear to have been various. Sometimes they were cut on one or more wooden leaves, bound together after the manner of books; sometimes on the scabbards of swords, or even on daggers; sometimes on tools and implements, as portable sextoards, hammers, the handles of hatchets, fans, &c. Sometimes they were made of brass or horn; sometimes of the skins of eels, which, being drawn over a fick properly inleribbed, retained the impressions of it. But the most usual form was that of walking sticks, or ficks, which they carried about with them to church, market, &c. Each of these ficks is divided into three regions; whereas the first indicates the signs, the second the days of the week and year, and the third the golden number. The characters engraved on them are, in some, the ancient Runic; in others, the later Gothic characters of Ulfilus. The saints days are expressed in hieroglyphics, significant either of some endowment of the saint, the manner of his martyrdom, or the like. Thus, against the notch for the first of March, or St David's day, is represented a harp; against the 25th of October, or Crispin's day, a pair of shoes; against the 10th of August, or St Lawrence's day, a gridiron; and, lastly, against New-year's day, a horn, the mark of good drinking, which they gave a loose to at that feast.

Almanza, a little town of New-Castile, on the frontiers of the kingdom of Valencia in Spain, situated in W. Long. 1° 19'. N. Lat. 38° 54'. It is remarkable for the defeat of the allies in 1707, under the Marquis de las Minas and the Earl of Galway. In the beginning of this action, the English troops penetrated thro' the center of the Spanish army; but the Portuguese cavalry being broken by the Spaniards, and the French infantry making a dreadful fire on their flanks, the allied army was at last broken, and began their retreat when it was almost dark. Colonel Hill carried off the remains of thirteen battalions towards the river Xucar, which, if they could have passed, they might have been safe: but being very much fatigued, they were obliged to halt; by which means they were surrounded, and forced to surrender prisoners of war. In this battle, the allies lost 120 standards, together with all their artillery and baggage; a great number were killed, and several thousands taken prisoners. The Marquis de las Minas was dangerously wounded; and his miltrels, in the garb of an amazon, killed by his side. The earl of Galway had two cuts cross the face, which, though not dangerous, had prevented him from seeing, or giving orders properly.

Heresy of Almaric, a tenet broached in France by one Almaric, in the year 1200. It consisted in affirming, that every Christian was actually a member of Christ, and that without this faith no one could be saved. His followers went farther, and affirmed, that the power of the Father lapsed only during the continuance of the Mosaic law; that the coming of Christ introduced a new law; that at the end of this began the reign of the Holy Ghost; and that now confession and the sacraments were at an end, and that every one was to be saved by the personal and only Saviour, the Holy Spirit alone, without any external act of religion. Their morals were as infamous as their doctrine was
was absurd. Their tenets were condemned by a public decree of the council of Sens, in the year 1229.

**ALME, or ALMA**, singing and dancing girls in Egypt, who, like the Italian Improvisatori, can occasionally pour fourth "unpremeditated verse." They are called *Almés*, from having received a better education than other women. They form a celebrated society in this country. To be received into it, according to Mr. Savary, it is necessary to have a good voice, to understand the language well, to know the rules of poetry, and be able to compose and sing couplets on the spot, adapted to the circumstances. The Almés know by heart all the new songs. Their memory is furnished with the most beautiful tales. There is no festival without them; no entertainment of which they do not constitute the ornament. They are pantomime ballets, in which they represent the repast. They then descend into reserve, they refer to toxication. They are the Bacchants in a delirium. Their memory is furnished with the tales. They are (alled catarrh than other women. They form a circle of Tralos Montes, on the confines of Leon, where there was a very brisk action between the French and Portuguese in 1663; 17 miles N. W. of Cividal Rodrigo. W. Long. 7. 10. N. Lat. 40. 41.

**ALMEHRAB**, in the Mahometan custom, a rich in their mosquites, pointing towards the kebla or temple of Mecca, to which they are obliged to bow in praying. See KEBLA.

**ALMEISAR**, a celebrated game among the ancient Arabs, performed by a kind of casting of lots with arrows, strictly forbid by the law of Mahomet, on account of the frequent quarrels occasioned by it.

The manner of the game was thus: A young camel being brought and killed, was divided into a number of parts. The adventurers, to the number of seven, being met, 11 arrows were provided without heads or feathers; seven of which were marked, the first with one notch, the second with two, the third with three, &c. the other four had no marks. These arrows were put promiscuously into a bag, and thus drawn by an indifferent person. Tho' to whom the marked arrows fell, won shares in proportion to their lot; the rest to whom the blanks fell, were entitled to no part of the camel, but obliged to pay the whole price of it. Even the winners tailed not of the flesh themselves more than the loafers, but the whole was distributed to the poor.

**ALMENE**, in commerce, a weight of two pounds used to weigh saffron in several parts of the continent of the E. Indies.

**ALMERIA**, a sea-port town in the kingdom of Granada in Spain, pleasantly situated in a fine bay at the mouth of the river Almeria, on the Mediterranean; W. Long. 3. 20. N. Lat. 36. 51. This town is by some thought to have riven upon the ruins of the ancient Abdera, and was formerly a place of great consequence. It was taken from the Moors in 1147, by the emperor Conrad III. in conjunction with the French, Genoese, and Venetians. It was at that time the strongest place in Spain, held by the infidels; from which their privates, which were exceedingly numerous, not only troubled the sea-coasts inhabited by the Christians, but gave equal disturbance to the maritime provinces of France, Italy, and the adjacent islands. The city being well fortified, having a strong castle, a numerous garrison, and being excellently provided with everything necessary, made a vigorous resistance; but was at last taken by storm, when the visitor put to the sword all the inhabitants who were found in arms, distributing the best part of the plunder among his allies,

Vol. I.
lies, whom he sent away thoroughly satisfied. The Genevese, particularly, acquired here that emerald vefel which still remains in their treasury, and is deemed invaluable.

Upon its reduction by the Christians Almeria became a bishopric; but is at present very little better than a village, indiscriminately inhabited, and has nothing to testify so much as the probability of its former greatness, except certain circumstances which cannot be effaced even by the indolence of the Spaniards themselves. What these are, Udal ap Rhys, a Welshman, thus describes, in his tour through Spain and Portugal. "Its climate (says he) is so peculiarly blest, that one really wants words to express its excellence. Its fields and meads are covered with flowers all the year round; they are adorned also with palms, myrtles, plane-trees, oranges, and olives; and the mountains and promontories near it are as noted for their hills thence resorting in that fort of precious stones, infomuch that the next promontory to it is called the Cape of Gates, which is a corruption from the word agares, the hills thenceabounding in that sort of precious stones, as well as in emeralds and amethysts, granites or coarse rubies, and extreme curious alabaster in the mountains of Filanres." ALMISSA, a small but strong town at the mouth of the Cetina, in Dalmatia, famous for its piracies; ten miles east of Spalatro. E. Long. 39. 33. N. Lat. 42. 56.

ALMOND, the fruit of the almond-tree. See AMYGDALUS.

ALMOND, in commerce, a measure by which the Portuguese sell their oil; 26 almonds make a pipe.

ALMONDS, in anatomy, a name sometimes given to the glands, generally cited under the term of fat.

Almonds, among lapidaries, signify pieces of rock-crystal, used in adorning branch-candlesticks, &c. on account of the resemblance they bear to the fruit of that name.

ALMOND-Furnace, among refiners, that in which the flags of lathigre, left in refining silver, are reduced to lead again by the help of charcoal.

ALMONDBURY, a village in England, in the west-riding of Yorkshire, six miles from Halifax.

ALMONER, in its primitive sense, denotes an officer in religious houses, to whom belonged the management and distribution of the alms of the house. By the ancient canons, all monasteries were to spend at least a tenth part of their income in alms to the poor. The almoner of St Paul's is to dispose of the monies left for charity, according to the appointment of the donors, to bury the poor who die in the neighbourhood, and to breed up eight boys to singing, for the use of the choir. By an ancient canon, all bishops are required to keep almoners.

Lord a Loxsom, or Lord High Almoner, of England, is an ecclesiastical officer, generally a bishop, who has the forfeiture of all decodants, and the goods of felos de se, which he is to distribute among the poor. He has also, by virtue of an ancient custom, the power of giving the first dinner from the king's table to whatever poor person he pleases, or, instead of it, an alms in money.

Great Almoner, Grand Almonier, in France, is the highest ecclesiastical dignity in that kingdom. To him belongs the superintendency of all hospitals and houses of lepers. The king receives the sacrament from his hand; and he says mass before the king in all grand ceremonies and solemnities.

Almoner is also a more fashionable title given by some writers to chaplains. In this sense we meet with almoner of a regiment.

ALMONRY, or AUMBRY, the office or lodgings of the almoner; also the place where alms are given. See AUMBRY.

ALMS, a general term for what is given out of charity to the poor.

In the early ages of Christianity, the alms of the charitable were divided into four parts; one of which was allotted to the bishop, another to the priests, and a third to the deacons and subdeacons, which made their whole subsistence; the fourth part was employed in relieving the poor, and in repairing the churches.

No religious system is more frequent or warm in its exhortations to alms-giving than the Mahometans. The Alcoran represents alms as a necessary means to make prayer heard. Hence that laying of one of their khalifs: "Prayer carries us half-way to God, fasting brings us to the door of his palace, and alms introduces us into the presence-chamber." Hence many illustrious examples of this virtue among the Mahometans. Hafan, the son of Ali, and grandson of Mohammed, in particular, is related to have thrice in his life divided his substance equally between himself and the poor, and twice to have given away all he had. And the generality are so addicted to the doing of good, that they extend their charity even to brutes.

Alms, also, denotes lands or other effects left to churches or religious houses, on condition of praying the soul of the donor. Hence, Free Alms was that which is liable to no rent or service.

Reasonable Alms was a certain portion of the estates of intestate persons, allotted to the poor.

ALMS-Box, or Cheff, a small chest, or coffer, called by the Greeks κεφας, wherein anciently the alms were collected, both at church and at private houses.

The alms-cheff in English churches, is a strong box, with a hole in the upper part, having three keys, one to be kept by the parish or curate, the other two by the church-wardens. The erection of such alms-cheff in every church is enjoined by the book of canon, as also the manner of distributing what is thus collected among the poor of the parish.

ALMS-House, a petty kind of hospital, for the maintenance of a certain number of poor, aged, or disabled people.

ALMUCANTARS, in astronomy, an Arabic word denoting circles of the sphere passing through the centre of the sun, or a flat, parallel to the horizon, being the fame as PARALLELS of ALITUDE.

ALMUCANTARS-STAFF, is an instrument usually made of pear-tree or box, having an arch of 15 degrees; used to take observations of the sun, about the time of its rising and setting; in order to find the amplitude, and consequently the variation of the compasses.

ALMUCIUM, denotes a kind of cover for the head, worn chiefly by monks and ecclesiastics: It was of a figure
ALMUGIM, or ALMUG-TREE, a certain kind of wood mentioned in the first book of Kings, (x. 11.) which the vulgate translates ligna thyna, and the Septuagent wrought wood. The Rabbins generally render it coral; others, ebony, brazii, or pine. But it is observed, that the almug-tree can by no means be coral, because that wood is not fit for the purposes that the Scripture tells us the almug-tree was used, such as musical instruments, sthair-cafes, &c. The word thynun is a name for the citron-tree, known to the ancients, and very much esteemed for its sweet odour and great beauty. It came from Mauritania. The almug-tree, or almugim, or simply gummin, taking at for a kind of article, is therefore by the best commentators understood to be an oily and gummy sort of wood; and particularly that sort of tree which produces the gum ammoniac, which is also thought to be the same with the shittim-wood, whereof there is some frequent mention made by Moses.

ALMUNECAR, a sea-port town in the kingdom of Granada, seated on the Mediterranean, with a good harbour, defended by a strong castle, 20 miles south of Alhama. W. Long. 3. 45. N. Lat. 36. 50.

ALNAGE, or ALNAGE, the measuring of woollen manufactures with an ell. It was at first intended as a proof of the goodness of that commodity, and accordingly a feal was invented as a mark that the commodity was made according to the statute; but, being now possible to purchase these feals, they are affixed, whenever the vendor pleases, to all cloths indiscriminately, to the great prejudice of the British woollen manufactures.

ALNAGER, or ALNANGER, q. d. meafurer by the ell; signifies a sworn public officer, who by himself, or deputy, is to look to the affize of woollen cloth made throughout the land, i.e. the length, width, and work thereof; and to the feals for that purpose ordained. The office of king's alnager seems to have been derived from the statute of Richard I. A. D. 1197, which ordained, that there should be only one weight and one meafeure throughout the kingdom; and that the meafeody of the affize, or standard of weights and meafeures, should be committetl to certain persons in every city and borough. His business was, for a certain fee, to meafeure all cloth made for sale, till the office was abolished by the statute 11 and 12 W. III. cap. 20.

ALNUS, the ALDER-TREE, a species of betula. See Betula.

ALNICK, a thoroughfare town in Northumberland, on the road to Scotland. Here Malcolm, king of Scotland, making an inroad into Northumberland, was killed, with Edward his son, and his army defeated by Robert Mowbray, earl of this county, anno 1092. Likewise William, king of Scotland, in 1174, invading England with an army of 80,000 men, was here encountered, his army routed, and himself made prisoner. The town is populous, and in general well built; it has a large town-house, where the quarter-sefions and county-courts are held, and members of parliament elected. It has a spacious square, in which a market is held every Saturday. Alnwick appears to have been formerly fortified, by the vestiges of a wall still visible in many parts, and three gates which remain almost entire. It is governed by four chamberlains, who are chosen once in two years out of a common council, consisting of 24 members. It is ornamented by a stately old Gothic castle, which has been the seat of the noble family of Piercy, earls of Northumberland. As the audits for receipt of rents have ever been in this castle, it has always been kept in tolerable repair; and not many years ago, it was repaired and beautified by the duke of Northumberland, who made very considerable alterations, upon a most elegant plan, with a view to reside in it some part of the summer-seaon. The manner of making freemen is peculiar to this place, and indeed is as ridiculous as singular. The persons who are to be made free, or, as the phrase is, leap the well, assemble in the market-place, very early in the morning, on the 25th of April, being St. Mark's day. They appear on horse-back, with every man his sword by his side, dressed in white, and with white night-caps, attended by the four chamberlains and the castle-bailiff, mounted and armed in the same manner; from hence they proceed, with music playing before them, to a large dirty pool, called Free-man's-well, where they dismount, and draw up in a body, at some distance from the water, and then rush into it all at once, and scramble through the mud as fast as they can. As the water is generally very foul, they come out in a dirty condition; but taking a dram, they put on dry clothes, remount their horses, and ride full gallop round the confines of the district; then re-enter the town, sword in hand, and are met by women dressed in ribbons with bells and garlands, dancing and singing. These are called zimmer-wails. The houses of the new freemen are on this day distinguished by a great holly-bush, as a signal for their friends to assemble and make merry with them after their return. This ceremony was owing to king John, who was mired in this well; and who, as a punishment for not mending the road, made this a part of their charter. Alnwick is 310 miles north by west from London, 33 north of Newcastle, and 29 south of Berwick. W. Long. 1. 10. Lat. 55. 24.

ALOA, in Grecian antiquity, a festival kept in honour of Ceres by the husbandmen, and supposed to resemble our harvest-home.

ALOE, in botany, a genus of the monogynia order, belonging to the hexandria class of plants; and, in the natural method, ranking under the 10th order, Coronaria. The character is: There is no calyx: The corolla is monopetalous, erect, six-cleft, and oblong; the tube gibbous; the border spreading, and small; with a nectar-bearing bottom: The stamens consist of six subulate filaments, rather surpassing the corolla in length, and inserted into the receptacles; the anthers are oblong and incumbent: The pistillum has an ovate germen; the stylus is simple, the length of the stigma; the stigma is obus and trifid: The perianthium is an oblong capsule, three-furrowed, three-valved: The seeds are many and angular. Of this genus, botanical writers enumerate nine species; of which the most remarkable are,

1. The difficha, by some called the soap aloe, by others
ALO

**ALO** [484]

**ALO**

Others *calilin aloe*. This seldom rises above two feet high. The leaves are very broad at the base, where they closely embrace the stalk, and gradually decrease to a point. The edges are fret with sharp spines, and the under leaves spread open horizontally every way. These are of a dark green colour spotted with white, somewhat resembling the colour of soft soap, from whence the plant got the name of *soap-aloe*. The flowers grow in umbels on the tops of the stalks, are of a beautiful red colour, and appear in August and September. 1. The variegated, or partridge-breast aloe, is a low plant, seldom rising above eight inches high. The leaves of this are triangular, and curiously veined and spotted, somewhat like the feathers of a partridge's breast. The flowers grow in very loose spikes, and are of a fine red colour tipped with green. 2. The wicofa, with funnel-shaped flowers, grows near a foot high, with triangular leaves of a dark green colour. The flowers grow thinly upon very slender footstalks, are of an herbaceous colour, and their upper part turns backward. 3. The spiralis, with oval rounded flowers, grows somewhat like the former: only the flowers grow upon taller stalks, which branch out and grow in very long close spikes. 4. The linguiformis, or tongue-aloe, has its leaves about six inches in length, and shaped like a tongue. The flowers grow in fezier loose spikes, each hanging downward, of a red colour below, and green at the top. 5. The margaritifera, or pearl aloe, is a very beautiful plant. It is smaller than most of the aloe kind. The leaves are short, very thick, sharp pointed, and turning down, with a large thick end, appear there triangular. The colour of the leaves is a fine green, striped in an elegant manner with white, and frequently tipped with red at the point. The flower-stalk, which rises in the midst of the leaves, is round, smooth, of a purple colour, and generally about eight inches high. When the plant has been properly cultivated, the flowers are striped with green and white; and sometimes they are entirely white. This aloe is singular in not having the bitter rheumy juices with which the leaves of most others abound; when a leaf of this species is cut, what runs from it is watery, colourless, and perfectly insipid. 7. The perforata, or foctorine aloe, hath long, narrow, fuculent leaves, which come out without any order, and form large heads. The stalk grows three or four feet high; and has two, three, and sometimes four, of these heads branching out from it. The flowers grow in long spikes, each hanging on a pretty long footstalk; they are of a bright red colour tipped with green, and generally appear in the winter season. 8. The retina, or cushion aloe, hath very short, thick, succulent leaves, compressed on the upper side like a cushion. This grows very close to the ground; the flowers grow on slender stalks, and are of an herbaceous colour.

**Culture.** The proper earth for planting these vegetables in, is, one half fresh light earth from a common, and the rest an equal mixture of white sea-fand and sifted lime-rubbish. This mixture should be always made fix or eight months before the plants are to be set in. The common aloe will live in a dry green-house in winter; and may be placed in the open air in summer, in a sheltered situation, but must have very little water. Most of the other aloes are best preferred in an airy glass-cage, in which there is a floe, to make a little fire in very bad weather. The tenderest kinds require a greater share of heat to preserve them in winter, and should be kept in a good floe, in a degree of heat ten degrees above temperate. Many other kinds may also be kept in this heat; but the greater the heat, the more water they always require. About the beginning of June, it is usual in England to set the pots of aloes out of the house: but they should be set under the shelter of hedges or trees, to keep them from the violence of the sun; the rains also, which usually fall in this and the following month, are apt to rot them. It is therefore best to keep them under cover the greatest part of the year. The best time to shift these plants is the middle of July. They are, on this occasion, to be taken out of the pots, the loofe earth to be picked from about their roots, and the decayed or mouldy parts of them cut off; then a few stones are to be put at the bottom of the pot, and it is to be filled with the composition already described, and the plants carefully put in, the roots being so disposed as not to interfere with one another. They are to be carefully watered after this, at times, for three weeks, and set in a shady place. The common kind will bear the open air from May till October, and should be shifted every year. All the aloes are propagated by off-sets, or by planting the leaves. The off-sets should be taken from the mother plant, at the time when it is shifted: they are to be planted in very small pots of the proper mixed earth; and if that part of the plants which joined to the mother-plant be observed to be moist when taken off, it should lie on the ground in a shady place two or three days before it is planted, otherwise it will rot. After planting these, they should remain in a shady place a fortnight; and then be removed to a very moderate hot bed, plunging the pots therein, which will help their striking new roots. Towards the end of August they must be, by degrees, hardened to the open air, by taking off the glases of the hot-bed; and in September they may be removed into the green-house.

**Properties, &c.** The aloe is a kind of symbolic plant to the Mahometants, especially in Egypt, and in some measure dedicated to the offices of religion; for whenever retums from a pilgrimage to Mecca, hangs it over his street-door, as a token of his having performed that holy journey. The superstitious Egyptians believe that this plant hinders evil spirits and apparitions from entering the house; and on this account, whoever walks the streets in Cairo, will find it over the doors both of Christians and Jews. From the same plant the Egyptians distil a water, which is sold in the apothecaries shops at Cairo, and recommended in coughs, hysterics, and asthma. An unexperienced French surgeon, says Haffelquift, gave a Coptite, 40 years old, afflicted with the jaundice, four teacups full of the distilled water of this species of *aloe*, and cured him in four days. This remedy, unknown to our apothecaries, is not difficult to be obtained, as the plant might easily be raised in the warm southern parts of Europe. The Arabsians call it *sabara*.

Of the leaves of the Guinea aloe, mentioned by Mr. Adanfon in his voyage to Senegal, the negroes make very good ropes, not apt to rot in the water.

Dr. Sloane mentions two sorts of *aloe*; one of which
is used for fishing-lines, bow-flings, stockings, and hammocks; the other has leaves which, like those of the wild-pine and bananas, hold rain-water, and thereby afford a very necessary refreshment to travellers in hot countries, where there is generally a scarcity of wells and water.

In Mexico, the maguce, a species of aloe, yields almost every thing necessary to the life of the poor. Besides making excellent hedges for their fields, its trunk served in place of beams for the roofs of their houses, and its leaves instead of tiles. From those leaves they obtained paper, thread, needles, clothing shoes, and stockings; and from its copious juice they made wine, honey, sugar, and vinegar. Of the trunk, and thickest part of the leaves, when well baked, they made a very tolerable diath of food. Lastly, it was a very powerful medicine in several disorders, and particularly in those of the urine. It is also at present one of the plants most valued and most profitable to the Spaniards.

The medical substance known by the name of aloe is the infipid juice of some of the aforesaid species. The ancient distinguished two sorts of aloes: the one was pure and of a yellowish colour, inclining to red, resembling the colour of a liver, and thence named hepatic; the other was full of impurities, and hence supposed to be only the dregs of the better kind. At present, various sorts are met with in the shops; which are distinguished either from the places, from the species of the plants, or from some difference in the juices themselves. These may be all ranged in three classes:

1. Aloe Perfoliata, focotrine aloe, brought from the island Soocotora in the Indian ocean, wrapt in skins; it is obtained from the 5th species aforesaid—

2. Aloe Hepatica, hepatic, Barbadoes, or common aloes (the juice of a variety of the former), is not so clear and bright as the foregoing sort; it is also of a darker colour, more compact texture, and for the most part drier. Its smell is much stronger and more disagreeable. Its taste intensely bitter and nauseous, with little or nothing of the fine aromatic flavour of the focotrine.—The best hepatic aloes come from Barbadoes in large gourd-sheals; an inferior sort of it (which is generally soft and clammy) is brought over in casks.

Of the cultivation and preparation of hepatic aloes in the island of Barbadoes, we have the following account in the London Medical Journal. "The lands in the vicinity of the sea, that is, from two to three miles which are rather subject to drought than otherwise, and are so stony and shallow as not to admit of the planting of sugar canes with any prospect of success, are generally found to answer best for the aloe plant. The flowers, at least the larger ones, are first picked up, and either packed in heaps, upon the most shallow barren spots, or laid round the field as a dry wall. The land is then lightly ploughed, and very carefully cleared of all noxious weeds, lined at one foot distance from row to row, like cabbages, at about five or six inches distance from each other. This regular mode of lining and levelling the plants is practiced only by the most exact planters, in order to facilitate the weeding of them, by hand, very frequently; because, if they are not kept perfectly clean and free from weeds, the produce will be but very small. They will bear being planted in any season of the year, even in the driest, as they will live on the surface of the earth many weeks without a drop of rain. The most general time, however, of planting them, is from April to June.

In the March following, the labourers carry a parcel of tubs and jars into the field, and each takes a dip or breadth of it, and begins by laping hold of a bunch of the blades, as much as he can conveniently grasp in one hand, while with the other he cuts it just above the surface of the earth, as quickly as possible (that the juice may not be wasted), and then places the blades in the tub, bunch by bunch, or handful by handful. When the first tub is thus packed quite full, a second is begun (each labourer having two); and by the time the second is filled, all the juice is generally drained out of the blades in the first tub. The blades are then lightly taken out, and thrown over the land by way of manure; and the juice is poured out into a jar. The tub is then filled again with blades, and so alternately till the labourer has produced his jar full, or about four gallons and a half of juice, which is often done in six or seven hours, and he has then the remainder of the day to himself, in being his employer's interest to get each day's operation as quickly done as possible. It may be observed, that although aloes are often cut in nine, ten, or twelve months after being planted, they are not in perfection till the second and third year; and that they will be productive for a length of time, say ten or twelve years, and even for a much longer time, if good dung, or manure of any kind, is fireewed over the field once in three or four years, or oftener if convenient.

The aloe juice will keep for several weeks without injury. It is therefore not boiled till a sufficient quantity is procured to make it an object for the boiling-house. In the large way, three boilers, either of iron or of copper, are placed to one fire, though some have two, and the small planters only one. The boilers are filled with the juice; and, as it ripens or becomes more impalpable, a confant but regular fire, it is ladied forward from boiler to boiler, and the juice is added to that farthest from the fire, till the juice in that nearest to the fire (by much the smallest of the three, and commonly called by the name of tach, as in the manufactury of sugar) becomes of a proper consistence to be skipp'd or lad'd out into gourds, or other small vessels, used for its final reception. The proper time to skipp or ladle it out of the tach, is when it is arrived at what is termed a refin height, or when it cuts freely, or in thin flakes, from the edges of a small wooden slice, that is dipped from time to time into the tach for that purpose. A little lime-water is used by some aloe-boilers, during the process, when the ebullition is too great."
Aloe

As to the sun-dried aloe (which is most approved for medicinal purposes), very little is made in Barbadoes. The process is, however, very simple, though sometimes brought on troublesome symptoms. As it is a flow working purge, it is generally taken at bedtime, and it operates next day.

With regard to this, as well as to all other resistant purges, it ought to be observed, that when they are given in suffrance without any mixture, they are apt to adhere to the coats of the intestines, and to occasion griping and uneasiness; for these reales aloe is generally mixed with some pungent or refreshment body, to destroy its viscid tenacity, before it is given in suffrance. The substances which are most used for this purpose are, a small quantity of the fixed alkaline salts; soap; the yolk of an egg; and gummy vegetable extracts. Mr. Barton alleges, that by triturating aloe with a small quantity of alkaline salts, its tenacity was more effectually destroyed than by any other thing he tried: that Castile soap and the yolk of an egg answered best, next to it: that mann, sugar, and honey, were far inferior to them; and that gummy, or mucous vegetable extracts, such as the extracts of genian, or of liquorice root, triturated with the aloe, in the proportion of one part of the extract to two of the aloe, and then made up into pills with a sufficient quantity of syrup, destroyed the viscidity of the aloe, and rendered its operation more prompt.

Socororine aloe contains more gummy matter than the hepatic; and hence it is like-wise found to purge more and with greater irritation. The first it is more proper where a stimulus is required, as for promoting or exciting the menstrual flux; whilst the latter is better calculated to act as a common purge. For the aloeic preparations, see Pharmacy. Index. Aloe-Wood. See Xyla-Aloe. American Aloe. See Agave.

ALOGIANS, in church-history, a sect of ancient heretics, who denied that Jesus Christ was the Logos, and consequently rejected the gospel of St. John. The word is compounded to the primitive α and λογος, q. d. without Logos or Word. Some ascribe the origin of the name, as well as of the sect of Alogians, to Theodore of Byzantium, by trade a currier; who having apostatized under the persecution of the emperor Severus, to defend himself against those who reproached him therewith, said, that it was not God he denied, but only man. Whence his followers were called in Greek αλογιον, because they rejected the Word. But others, with more probability, suppose the name to have been first given them by Epiphanius in the way of reproach. They made their appearance toward the close of the second century.

ALOGOTROPHIA, among physicians, a term signifying the unequal growth or nourishment of any part of the body, as in the rickets. ALOOF, has frequently been mentioned as a sea-term; but whether justly or not, we shall not presume to determine. It is known in common discourse to imply at a distance; and the resemblance of the phrase keep a look, and keep a look or keep the look, in all probability gave rise to this conjecture. If it was really a sea-phrase originally, it seems to have referred to the dangers of a lee-shore, in which situation the pilot might naturally apply it in the senate commonly understood, viz. keep all off, or quite off: it is, however, never expressed in that...
Alopeca, ALOPECIA (anc. geog.), an island placed by Ptolemy at the mouth of the Tanais, and called the island Tanais; now l'isle des Renards (Baudrand). Also an island of the Bosphorus Cimmerius (Pliny); and another in the Egean sea, over against Smyrna.

ALOPECA, a term used among physicians to denote a total falling off of the hair from certain parts, occasioned either by the defect of nutritious juice, or by its vicious quality corroding the roots of it, and leaving the skin rough and colours.

The word is formed from alouros, τυλίς, “a fox;” whose urine, it is said, will occasion baldness; or because it is a disease which is common to that creature. It is directed to wash the head every night at going to bed with a ley prepared by boiling the ashes of vine branches in common water, is also recommended for the same purpose.

In cafes where the baldness is total, a quantity of the finest burdock roots are to be bruised in a marble mortar, and then boiled in white wine until there remains only as much as will cover them. This liquor, carefully strained off, is said to cure baldness, by washing the head every night with some of it warm. A ley made by boiling ashes of vine branches in common water, is also recommended with this intention. A fresh cut onion, rubbed on the part until it be red and itch, is likewise said to cure baldness.

A multitude of such remedies are everywhere to be found in the works of Valence de Taranta, Rondeletius, Hollerius, Trincavellius, Celsus, Senertay, and other practical physicians. See also BUXUS.

ALOPECURUS, or FOX-TAIL GRASS, in botany: A genus of the triandria digynia class; and in the natural method ranking under the 4th order, Gramina. The characters are: The calyx is single flowered bivalve glume: The corolla is one-valved: The stamina consist of three capillary filaments; the antherae bifurcated at both ends: The stigmate is a roundish germens; there are two styli; and the stigmate is simple: The perigotrum is a corolla cloathing the feeds; and the feed is single and roundish. There are eight species, viz. the pratensis, or meadow fox-tail grass; the bulbous, or bulbous fox-tail grass; the geniculatus, or flore fox-tail grass; and the mycofoideus, or field fox-tail grass; these four grow wild in Britain: the agrestis, the monopellicus, the panicurus, and the hordeiformis, are all natives of France and the southern parts of Europe, except the lath, which is a native of India. See GRASS.

ALOPEX, in zoology, a species of the canis, with a straight tail and black tip. It is commonly called the field fox.

ALOSA, the fad, or mother of harrings, a species of the clupea. See CLUPEA.

ALOST, a town in Flanders, belonging to the house of Austria, seated on the river Dender, in the midway between Brussels and Ghent. It has but one parish; but the church is collegiate, and has a provost, and a dean, and twelve canons. Here is a convent of Carmelites, another of capuchins, another of bare-footed Carmelites, three nunneries, an hospital, and a convent of Guilemins, in which is the tomb of Theodore Martin, who brought the art of printing out of Germany into the Low Countries. He was a friend of Erasmus, who wrote his epigraph. E. Long. 4. 10. N. Lat. 49. 55.

ALPHA, the name of the first letter of the Greek alphabet, anfwering to our A.—As a numeral, it stands for one, or the first of any thing. It is particularly used, among ancient writers, to denote the chief or first man of his class or rank. In this sense, the word stands contradistinguished from beta, which denotes the second person. Plato was called the Alpha of the wits: Eratosthenes, keeper of the Alexandrian library, whom some called a Second Plato, is frequently named Beta. Alpha is also used to denote the beginning of any thing. In which it signifies opposed to omega, which denotes the end. And these two letters were made the symbol of Christianity; and accordingly were engraved on the tombs of the ancient Christians, to distinguish them from those of idolaters. Moralez, a Spanish writer, imagined that this custom only commenced since the rife of Ariana; and that it was peculiar to the orthodox, who hereby made confession of the eternity of Christ: but there are tombs prior to the age of Constantine whereon the two letters were found, besides that the emperor just mentioned bore them on his labarum before Arianism appeared.

ALPHABET, the natural or customary series of the several letters of a language (see LANGUAGE and WRITING). The word is formed from alpha and beta, the first and second letters of the Greek alphabet. The number of letters is different in the alphabets of different languages. The English alphabet contains 24 letters; to which if we add / and v consonant, the sum will be 26: the French contains 23; the Hebrew, Chaldee, Syriack, and Samaritan, 22 each; the Arabic 28; the Persian 31; the Turkish 23; the Georgiack 36; the Coptic 32; the Muscovite 43; the Greek 24; the Latin 22; the Scalvonic 32; the Chaldee, Syriack, and Samaritan languages. The Greek alphabet contains 24 letters; and accordingly were engraved on the tombs of the ancient Christians, to distinguish them from those of idolaters. Moralez, a Spanish writer, imagined that this custom only commenced since the rife of Ariana; and that it was peculiar to the orthodox, who hereby made confession of the eternity of Christ: but there are tombs prior to the age of Constantine whereon the two letters were found, besides that the emperor just mentioned bore them on his labarum before Arianism appeared.

Arguments for writing being a divine revelation.
2. If alphabetical writing were a mere human invention, it might be expected that different nations would have fallen upon the same expedient independent of each other during the compass of so many ages. But no such thing has taken place; and the writing of every people on earth may be referred to one common original. If this can be proved, the argument from successive derivation, without a single instance of independent discovery, must be allowed to amount to the very highest degree of probability in favour of our hypothesis, which will now rest on the evidence for or against this fact; and which may be summed up in the following manner.

Among the European nations we find none who can pretend any right to the discovery of letters. All of them derived the art from the Romans, excepting only the Turks, who had it from the Arabians. The Romans never laid claim to the discovery; but confessed that they derived their knowledge from the Greeks, and the latter owned that they had it from the Phoenicians, who, as well as their colonists the Carthaginians, spoke a dialect of the Hebrewincarefully varying from the original. The Coptic, or Egyptian, resembles the Greek in most of its characters, and is therefore to be referred to the same original. The Chaldee, Syriac, and later Samaritan, are dialects of the Hebrew, without any considerable deviation, or many additional words. The Ethiopic differs more from the Hebrew, but less than the Arabic; yet these languages have all issued from the same stem, so to speak, as the familiarity of their formation, and the number of words common to them, all sufficiently evince; and the Peric is very nearly allied to the Arabic. Alterations indeed would naturally be produced, in proportion to the civilization of the several nations, and their intercourse with others; which will account for the superior copiousness of some above the rest. It appears then, that all the languages in use among men that have been conveyed in alphabetical characters, have been the languages of people connected ultimately or immediately with the Hebrews, who have handed down the earliest specimens of writing to posterity; and we have therefore the greatest reason to believe, that their method of writing, as well as their language, was derived from the same source.

This proposition will be further confirmed from considering the sameness of the artificial denominations of the letters in the Oriental, Greek, and Latin languages, accompanied also by a similar arrangement, as alpha, beta, etc. It may still be objected, however, that the characters employed by the ancients to discriminate their letters are entirely dissimilar. Why should not one nation, it may be urged, adopt from Alphabet, the other the mode of expressing the art as well as the art itself? To what purpose did they take the trouble of inventing other characters? To this objection it may be replied, 1. From the instance of our own language we know what diversities may be introduced in this respect merely by length of time and an intercourse with neighbouring nations. And such an effect would be more likely to take place before the art of printing had contributed to establish a uniformity of character: For when every work was transcribed by the hand, we may easily imagine how many variations would arise from the fancy of the scribe, and the mode of writing so constantly different in individuals. 2. This diversity might sometimes arise from vanity. When an individual of another community had become acquainted with this wonderful art, he might endeavour to recommend himself as the inventor; and to avoid detection, might invent other characters. 3. The characters of the alphabet might sometimes be accommodated as much as possible to the symbology marks already in use amongst a particular people. These having acquired a high degree offacility by the use of many generations, would not be easily superceded without the aid of some such contrivance. 4. This is supported by the testimony of Herodotus; who informs us, that "tho Phoenicians who came introduced many improvements among the Greeks, and alphabetical writing too, not known among them before that period. At first they used the Phoenician character; but in process of time, as the pronunciation altered, the standard of the letters was also changed. The Ionian Greeks inhabited at that time the parts adjacent to Phoenicia; who having received the art of alphabetical writing from the Phoenicians, used it, with an alteration of some few characters, and confessed ingenuously, that it was called Phoenician from the introducers of it." He tells us that he had himself seen the characters of Cadmus in a temple of Hellenic Apollo at Thebes in Boeotia, engraved upon tripods, and very much resembling the Ionian characters. 5. The old Samaritan is precisely the same as the Hebrew language; and the Samaritan Pentateuch does not vary by a single letter in twenty words from the Hebrew: but the characters are widely different: for the Jews adopted the Chaldaic letters during their captivity at Babylon, instead of the characters of their forefathers.

What we know of those nations who have continued for many centuries unconnected with the rest of the world, strongly militates against the hypothesis of the human invention of alphabetical writing. The experiment has been fairly made upon the ingenuity of mankind for a longer period than that which is supposed to have produced alphabetical writing by regular gradations; and this experiment determines peremptorily in their favour. The Chines, a people famous for their discoveries and mechanical art of genius, have made some advances towards the delineation of their ideas by arbitrary signs; but have nevertheless been unable to accomplish this exquisite device; and after so long a trial to no purpose, we may reasonably infer, that their mode of writing, which is growing more intricate and voluminous every day, would never terminate in so clear, so comparatively simple,
Alphabet. Simple, an expediency as that of alphabetical characters.

The Mexicans, too, had made some rude attempts of the same kind; but with less facility than the Chinese.

We know also, that hieroglyphics were in use among the Egyptians prior to the practice of alphabetical writing by the Jews; but whether the epigraph or, as it is called, of the former people, which was in vogue during the continuance of the hieroglyphics, might not possibly be another name for alphabetical writing, cannot be decided.

4. We shall consider the argument on which the commonly received supposition entirely depends: that is, the natural gradation through the several species of symbols acknowledged to have been in use with various people, terminating at last by an easy transition, in the detection of alphabetical characters. The strength of this argument will be best understood from the following representation.

"1. The first method of embodying ideas would be by drawing a representation of the objects themselves. The impracticability of this method is very obvious, both on account of its tedium-nests and its inability of going beyond external appearances to the abstract ideas of the mind.

"2. The next method would be somewhat more general, and would substitute two or three principal circumstances for the whole transactin. So two kings, for example, engaging each other with military weapons, might serve to convey the idea of a war between the two nations. This abbreviated method would be more expeditious than the former; but what it gained in conciseness would be lost in perplexity. It is a description more compendious and indeed, but still a description of outward objects alone, by drawing their resemblance. To this head may be referred the picture-writing of the Mexicans.

"3. The next advance would be to the use of symbols: the incorporation, as it were, of abstract and complex ideas in figures more or less generalized, in proportion to the improvement of it. Thus, in the earlier stages of this device, a circle might serve to express the sun, a semicircle the moon; which is only a contraction of the foregoing method. This symbol-writing in its advanced state would become more refined, but etymological and mystical in proportion to its refinement. Hence it would become less fit for common use, and therefore more particularly appropriated to the mysteries of philosophy and religion. Thus, two feet standing upon water served to express an impossibility, a serpent denoted the oblique trajectories of the heavenly bodies; and the beetle, on account of some supposed properties of that insect, served to represent the sun. The Egyptian hieroglyphics were of this kind.

"4. This method being still too verbose and complicated for common use, the only plan to be pursued was a reduction of the first stage of the preceding method. Thus a dot, instead of a circle, might stand for the sun: and a similar abbreviation might be extended to all the symbols. On this scheme every object and idea would have its appropriated mark: these marks therefore would have a multiplicity proportional to the works of nature and the operations of the mind. This method was likewise practised by the Egyptians; but has been carried to greater perfection by the Chinese. The vocabulary of the latter is therefore infinite, or at least capable of being extended to any imaginable length. But if we compare this tedious and awkward contrivance with the abridging brevity and perfections of alphabetical writings, we must be persuaded that no two things can be more dissimilar; and that the transition from a form constantly enlarging itself, and growing daily more intricate, to the expression of every possible idea by the modified arrangement of four-and-twenty marks, is not so very easy and perceptible as some have imagined. Indeed this seems still to be rather an expression of things in a manner similar to the second stage of symbol-writing than the notification of ideas by arbitrary signs."

To all this we shall subjoin the following remarks, which seem to give additional force to the foregoing reasoning.

"1. Pliny affirms the use of letters to have been eternal, which shows the antiquity of the practice to extend beyond the era of authentic history.

"2. The cabalistical doctors of the Jews maintain, that alphabetical writing was one of the ten things which God created on the evening of the Sabbath.

"3. Most of the profane authors of antiquity ascribe the first use of alphabetical characters to the Egyptians, who, according to some, received them from Mercury; and, according to others, from their god Teth.

"4. There is very little reason to suppose that even language itself is the effect of human ingenuity and invention."

Thus we have stated the arguments in favour of the alphabetical writing; which are answered, by those who take the contrary side, in the following manner.

1. Moses no where says that the alphabet was a new thing in his time; nor does he give the least hint of his being the inventor of it. The first mention we find of writing is in the 17th chapter of Exodus; where Moses is commanded to write in a book; and which took place before the arrival of the Israelites at Sinai. This shows that writing did not commence with the delivery of the two tables of the law, as some have supposed. Neither are we to conclude that the invention had taken place only a short time before; for the writing in a book, is commanded as a thing commonly understood, and with which Moses was well acquainted. It is plain, from the command to engrave the names of the twelve tribes of Israel upon stones like the engravings of a signet, that writing had been known and practised among them, as well as other nations, long before. We must also remember, that the people were commanded to write the law on their door-posts, &c., so that the art seemed not only to have been known, but universally practised among them. But had writing been a new discovery in the time of Moses, he would probably have commemorated it as well as the other inventions of music, &c.; and there is not an argument against that God was the immediate revealer of the art; for Moses would never have omitted to record a circumstance of such importance, as the memory of it would have been one of the strongest barriers against idolatry.
Alphabet.

Again, though several profane writers attribute the origin of letters to the gods, or to some divine person, yet this is no proof of its being actually revealed; but only that the original inventor was unknown. The learned bishop of Gloucester observes, that the ancients gave nothing to the gods of whose origin they had any records, but where the memory of the invention was lost, as of feed-corn, wine, writing, civil society, &c., the gods seized the property, by that kind of right which gives strays to the lord of the manor.

As neither the sacred nor profane historians, therefore, have determined anything concerning the invention of letters, we are at liberty to form what conjectures we think most plausible concerning the origin of them; and this, it is thought, might have taken place in the following manner.

1. Men in their rude uncultivated state, would have neither leisure, inclination, nor inducement, to cultivate the powers of the mind to a degree sufficient for the formation of an alphabet: but when a people arrived at such a pitch of civilization as required them to represent the conceptions of the mind which have no corporeal forms, necessity would occasion further exertions, and urge them to find out a more expeditious manner of transmitting their thoughts than by picture-writing.

2. These exertions would take place whenever a nation began to improve in arts, manufactures, and commerce; and the greater genius such a nation had, the more improvements would be made in the notation of their language; whilst those people who had made less progress in civilization and science, would have a less perfect system of elementary characters; and perhaps advance no farther for many ages than the marks or characters of the Chinese. Hence we may see, that the benefices of princes, as well as the manufacturers and commerce of each country, would produce the necessity of devising some expeditious manner of communicating information to one another.

The art of writing, however, is of so great antiquity, and the early history of most nations is so full of tales, that it must be extremely difficult to determine what nation or people may justly claim the honour of the invention. But as it is probable that letters were the produce of a certain degree of civilization among mankind, we must therefore have recourse to the history of those nations who seem to have been first civilized.

The Egyptians have an undoubted title to a very early civilization; and many learned men have attributed the invention of letters to them. The late bishop of Gloucester contends, that Egypt was the parent of all the learning of Greece, and was referred to by all the Grecian legislators, naturalists, and philosophers; and endeavours to prove that it was one of the first civilized countries on the globe. Their writing was of four kinds: 1. Hieroglyphic; 2. Symbolic; 3. Epistolical; and, 4. Hierogrammatical. In the most early ages they wrote like all other infant nations, by pictures; of which some traces yet remain amongst the hieroglyphics of Horapollo, who informs us, that they represented a fuller by a man's two feet in water; fire, by smoke ascending, &c. But to render this rude invention less inconvenient, they soon devised the method of putting one thing of similar qualities for another.

The former was called the curiologic, the latter the tropical hieroglyphic; which last was a gradual improvement on the former. These alterations in the manner of delineating hieroglyphic figures produced and perfected another character, called the running-hand of the hieroglyphics, resembling the Chinese writing; which having been first formed by the outlines of each figure, became at length a kind of marks; the natural effects of which were, that the constant use of them would take off the attention from the symbol and fix it on the thing signified. Thus the fluid of symbolic writing would be much abbreviated; because the writer or decipherer would then have little to do but to remember the power of the symbolic mark; whereas before, the properties of the thing or animal delineated were to be learned. This, together with the other marks by institution, to denote mental conceptions, would reduce the characters to a similar state with the present Chinese; and these were properly what the ancients called hieroglyphical. We are informed by Dr Robert Huntington, in his account of the Porphyry pillars, that there are some ancient monuments of this kind yet remaining in Egypt.

The sacred book or ritual of the Egyptians, according to Apuleius, was written partly in symbolic and partly in these hieroglyphical characters, in the following manner: "He (the hierophant) drew out certain books from the secret repositories of the sanctuary, written in unknown characters, which contained the words of the sacred formula compendiously expressed, partly by figures of animals, and partly by certain marks or notes intricately knotted, revolving in the manner of a wheel, crowded together, and curled inward like the tendrils of a vine, so as to hide the meaning from the curiosity of the profane."

But though letters were of great antiquity in Egypt, letters not invented in Egypt.

The Egyptians have an undoubted title to a very early civilization; and many learned men have attributed the invention of letters to them. The late bishop of Gloucester contends, that Egypt was the parent of all the learning of Greece, and was referred to by all the Grecian legislators, naturalists, and philosophers; and endeavours to prove that it was one of the first civilized countries on the globe. Their writing was of four kinds: 1. Hieroglyphic; 2. Symbolic; 3. Epistolical; and, 4. Hierogrammatical. In the most early ages they wrote like all other infant nations, by pictures; of which some traces yet remain amongst the hieroglyphics of Horapollo, who informs us, that they represented a fuller by a man's two feet in water; fire, by smoke ascending, &c. But to render this rude invention less inconvenient, they soon devised the method of putting one thing of similar qualities for another. The former was called the curiologic, the latter the tropical hieroglyphic; which last was a gradual improvement on the former. These alterations in the manner of delineating hieroglyphic figures produced and perfected another character, called the running-hand of the hieroglyphics, resembling the Chinese writing; which having been first formed by the outlines of each figure, became at length a kind of marks; the natural effects of which were, that the constant use of them would take off the attention from the symbol and fix it on the thing signified. Thus the fluid of symbolic writing would be much abbreviated; because the writer or decipherer would then have little to do but to remember the power of the symbolic mark; whereas before, the properties of the thing or animal delineated were to be learned. This, together with the other marks by institution, to denote mental conceptions, would reduce the characters to a similar state with the present Chinese; and these were properly what the ancients called hieroglyphical. We are informed by Dr Robert Huntington, in his account of the Porphyry pillars, that there are some ancient monuments of this kind yet remaining in Egypt.

The sacred book or ritual of the Egyptians, according to Apuleius, was written partly in symbolic and partly in these hieroglyphical characters, in the following manner: "He (the hierophant) drew out certain books from the secret repositories of the sanctuary, written in unknown characters, which contained the words of the sacred formula compendiously expressed, partly by figures of animals, and partly by certain marks or notes intricately knotted, revolving in the manner of a wheel, crowded together, and curled inward like the tendrils of a vine, so as to hide the meaning from the curiosity of the profane."

But though letters were of great antiquity in Egypt, letters not invented in Egypt.
The Greeks, as we have already observed, knew no older Hermes than the second, who lived about 400 years after the Mezric Taaut or Hermes. This second Hermes is called by Plato *Theuth*, and counsellor or sacred scrie to king Thanius; but it is not said that he ever reigned in Egypt: but the former Taaut, or Athothes, as Manetho calls him, was the immediate successor of Menes. The first king of Egypt. His second Mercury, if we may believe Manetho, composed several books of the Egyptian history; and having improved both the language and letters of that nation, the Egyptians attributed the arts and inventions of the former to the latter. The Phoenician language is generally allowed to have been a dialect of the Hebrew; and though their alphabet does not entirely agree with the Samaritan, yet there is a great similarity between them. Astronomy and arithmetic were much cultivated among them in the most early ages: their fine linen, purple, and glafs, were much superior to those of other nations; and their extraordinary skill in architecture and other arts was such, that whatever was great, elegant, or pleasing, whether in buildings, apparel, or toys, was distinguished by the epithet of Tyrian or Sidonian; these being the chief cities of Phoenicia. Their great proficiency in learning and arts of all kinds, together with their engrossing all the commerce of the western world, are likewise thought to give them a just claim to the invention of letters.

The Chaldeans also have laid claim to the invention of the letters; and with regard to this, there is a tradition Chaldean, among the Jews, Indians, and Arabsians, that the Egyptians derived their knowledge from Abraham, who was a Chaldean. This tradition is in some degree confirmed by most of the western writers, who ascribe the inventions of arithmetic and astronomy to the Chaldeans. Josephus positively affirms, that the Egyptians were ignorant of the sciences of arithmetic and astronomy before they were instructed by Abraham; and Sir Isaac Newton admits, that letters were known in the line of that patriarch for many centuries before Moses. The Chaldaic letters appear to have been derived from the Hebrew or Samaritan; which are the same, or nearly so, with the old Phoenician. Ezra is supposed to have exchanged the old Hebrew characters for the more beautiful and commodious Chaldee, which are still in use. Berosus, the most ancient Chaldean historian, who was born in the minority of Alexander the Great, does not say that he believed his countrymen to have been the inventors of letters.

The Syrians have also laid claim to the invention of the Syriac letters. It is certain, indeed, that they yielded to the Syrians no nation in knowledge and skill in the fine arts. Their language is said to have been the vernacular of all the Oriental tongues, and was divided into three dialects. 1. The Aramean, used in Mesopotamia, and by the inhabitants of Roza and Edesa of Harram, and the Outer Syria. 2. The dialect of Palestine, spoken by the inhabitants of Damascus, Mount Libanus, and the Inner Syria. 3. The Chaldee or Nabathean dialect, the most unpolished of the three; and spoken in the mountainous parts of Alaysia, and the villages of

(A) See above, n° 2. where he says that the knowledge of letters was eternal. What dependence can we put in the testimony of such a writer?
words; the fundamental part being being divided into three classes, viz. 1. Dhaut or roots of verbs; 2. Shabd, or original nouns; 3. Eya, or particles. Their alphabet contains 50 letters; viz. 34 consonants and 16 vowels. They assert that they were in possession of letters before any other nation in the world; and Mr Halhed conjectures, that the long-boated original civilization of the Egyptians may still be a matter of dispute. The Rajah of Kishangur affirms, that he has in his possession Shanferit books, where the Egyptians are constantly described as disciples, not as instructors; and as seeking in Hindooslan that liberal education, and those sciences, which none of their own countrymen had sufficient knowledge to impart. Mr Halhed hints also, that the learning of Hindooslan might have been transplanted into Egypt, and thus have become familiar to Mofes. Several authors, however, are of opinion, that the ancient Egyptians possessed themselves of the trade of the East by the Red Sea, and that they carried on a considerable traffic with the Indian nations before the time of Sesostris; whom they suppose to have been contemporaneous with Rehoboam, though Sir Isaac Newton conjectures him to have been the child of Jedidiah who took Jerusalem in the time of Rehoboam.

In the year 1769, one of the sacred books of the Gentoo called Bagaaudam, translated by Meridas Poole, a learned man of Indian origin, and chief interpreter to the supreme council of Pondicherry, was sent by him to M. Bertin in France. In his preface he says, that it was composed by Visifer the son of Brahma, and is of sacred authority among the worshipers of Vishnou. This book claims an antiquity of 5000 years; but M. de Guines has shown, that its pretensions to such extravagant antiquity are entirely inconclusive and unsatisfactory; whence we may conclude, says Mr Adle, that though a farther inquiry into the literature of the Indian nations may be desirable, yet we must by no means give too easy credit to their relations concerning the high antiquity of their manuscripts and early civilization.

It is not pretended that the Persians had any great Letters not learning among them till the time of Herilages the invented in father of Darius. The former, we are told, travelled into India, and was instructed by the Brahins in the sciences for which they were famed at that time. The ancient Persians defied riches and commerce, nor had they any money among them till after the conquest of Lydia. It appears by several inscriptions taken from the ruins of the palace of Persepolis, which was built near 700 years before the Christian era, that the Persians sometimes wrote in perpendicular columns like the Chinees. This mode of writing was first made use of on the stems of trees, pillars, or obelisks. As for those simple characters found on the west side of the Baur-cafe of Persepolis, some have supposed them to be alphabetic, some hieroglyphic, and others antediluvian. Dr Hyde pronounces them to have been mere whimsical ornaments, though the author of Conjectural Observations on Alphabetic Writing supposes them to be fragments of Egyptian antiquity brought by Cambyses from the spoils of Thesbes. The learned are generally agreed, that the Persians were later in civilization than many of their neighbours; and they are not supposed to have any pretensions to the invention of letters.

As the Arabian have been in possession of the coun-
The parents of letters. This circumstance greatly favours their claim to the invention; because Chaldea, and the countries adjacent, are allowed by all authors both sacred and profane, to have been peopled before Egypt; and it is certain that many nations said to be descended from Shem and Japheth, had their letters from the Phenicians, who were descended from Ham.

"It is observable, that the Chaldeans, the Syrians, Phenicians and Egyptians, all bordered upon each other; and as the Phenicians, were the greatest in the most ancient commercial nation, it is very probable that they communicated letters to the Egyptians, the ports of Tyre and Sidon being not far distant from each other.

"Mr Jackson is evidently mistaken when he says, that letters were invented 2190 years before the birth of Christ. The deluge recorded by Moses was 2249 years before that event; and if letters were not invented till 550 years after, as he affirms, we must date their discovery only 1799 years before the Christian era, which is 410 years after the reign of Menes the first king of Egypt, who, according to Syncellus and others, is said to have been the same person with the Mifor of Sanchoniatho, the Mizraim of the Scriptures and the Oliris of the Egyptians; but whether this be true or not, Egypt is frequently called in Scripture the land of Mizraim.

"This Mizraim, the second son of Amyn or Ham seated himself near the entrance of Egypt at Zoan, in the year before Christ 2188, and 160 years after the flood. He afterwards built Thebes, and some say, Memphis. Before the time that he went into Egypt, his son Taant had invented letters in Phenicia; and if this invention took place ten years before the migration of his father into Egypt, as Mr Jackson supposes, we may trace letters as far back as the year 2172 before Christ, or 550 years after the deluge recorded by Moses; and beyond this period, the written annals of mankind, which have been hitherto transmitted to us, will not enable us to trace the knowledge of them; though this want of materials is no proof that letters were not known until a century and an half after the deluge. As for the pretensions of the Indian nations we must be better acquainted with their records before we can admit of their claim to the first use of letters; especially as none of their manuscripts of any great antiquity have as yet appeared in Europe. That the Arabian nations were not the inventors of letters, has appeared by their own confession.—Plato somewhere mentions Hyperborean letters very different from the Greek; and these may have been the characters used by the Tartars or ancient Scythians.

"It may be expected that something should be said concerning those books mentioned by some authors to have been written before the deluge. Amongst others, Dr Parsons, in his Remains of Japhet, p. 346, 350, supposes letters to have been known to Adam; and the Sabaeans produce a book which they pretend was written by Adam. But concerning these we have no guide to direct us any more than concerning the supposed books of Enoch; some of which, Origen tells us, were found in Arabia Felix, in the dominion of the queen of Sheba. Tertullian affirms, that he saw and
Mr. Affle next proceeds to consider what alphabets are derived from the Phoenician. These he proposes to have been immediately the ancient Hebrew or Samaritan; the Chaldaic; the Baftilian (A) or Spanish Phcenicium; the Punic, Carthaginian, or Sicilian; and the Pelagian. From the ancient Hebrew proceeded the Chaldaic or square Hebrew; the round Hebrew; and what is called the running hand of the Rabbins. The Pelagian gave birth to the Etruca, Eugubian, or Umbrian, Ofcan, Samnite, and Ionic Greek, written from the left. From the Chaldaic or square Hebrew are derived the Syrian, and the ancient and modern Arabic. The Syrian is divided into the Esrangelo and Mendezan, and the modern Arabic has given rise to the Persian and Turki. From the ancient Arabic are derived the Kufic or Oriental, the Mauritanic or Occidental; the African or Saracen, and the Moorish. The Ionic Greek gave rise to the Arcadian, Latin, ancient Gaulish, ancient Spanish, ancient Gothic, Coptic, Ethiopick, Russian, Illyrian or Slavonic, Bulgarian and Armenian. From the Roman are derived the Lombardic, Visigothic, Saxoum, Gallican, Franko-Galic or Merovingian, German, Caroline, Capetian, and modern Gothic.

The Punic letters are also called Tyrian, and were much the same with the Carthaginian or Sicilian. The Punic language was at first the same with the Phoenician; it is nearly allied to the Hebrew, and has an affinity with the Chaldeese and Syriac. Some remains of it are to be met with in the Maltefe. To make a complete Punic, Carthaginian, or Sicilian alphabet, we must admit several pure Phoenician letters.

The Pelaѓi were likewise of Phoenician original; and, according to Sanconiotho, the Dioscuri and Cabiri wrote the first annals of the Phoenician history, by order of Taut the inventor of letters. They made ships of barchen, and being cast upon the coast near mount Caicus, about 40 miles from Pelusium, where they built a temple in the second generation after the deluge related by Moses, they were called Pelaѓi from their paling by fire, and wandering from one country to another. Herodotus informs us, that the Pelagi were descendants of the Phcenian Cabiri, and that the Samothracians, received and practised the Cabiric mysteries from them. The Pelagic alphabet prevailed in Greece till the time of Deucalion, when the Pelagi were driven out of Thessaly or Oenotria by the Hellenes; after which some of them settled at the mouth of the Po, and others at Croton, now Cartona in Tuscany. Their alphabet consisted of 16 letters, and the Tyrrenian alphabet, brought into Italy before the reign of that prince, consisted of no more than 13. Deucalion is said to have reigned about 820 years after the deluge, and 1520 before the Christian era.

That the Turrhini, Tysfeni, or Hetrufci, resettled in Italy long before this period, appears from the testimony of Herodotus, who informs us, that a colony went by sea from Lydia into Italy under Turrhenus; and Dionysius of Halicarnassus proves that many authors called them Pelagi. He then cites Hellanicus Lelbicus, an author somewhat more ancient than Herodotus,

(A) The Baftuli are said to have been a Canaanitish or Phcenician people who fled from Joshua, and settled afterwards in Spain.
The Etruscan letters are Pelasgic, and several of the Etruscan inscriptions are written in the Pelasgic language. The Roman letters are Ionic. The Oscan language was a dialect of the Etruscan; their characters are nearer the Ionic or Roman than the Etruscan. There is also very little difference between the Etruscan, Oscan, and most ancient Greek letters, which are placed from right to left. The Arcadians were ancient Greeks, and used the Ionic letters, but at what time they began to write from left to right is not known, as their chronology is very uncertain. The Etruscan, Oscan, and Samnite alphabets are derived from the Pelasgic; they differ from each other more in name than in form, but a far greater number are derived from the Ionic Greek; namely, the Arcadian, the Latin or Roman, and the others already enumerated. The Runic is immediately derived from the Gothic.

According to Dionysius of Halicarnassus, the first Greek colony which came into Italy consisted of Arcadians under the conduct of Oenorbus the son of Lycaon, and fifth in descent from Phoroneus the first king of Argos, who reigned about 566 years before the taking of Troy, and 1730 years before the Christian era. These Arcadians were called Aborigines; and after they had been engaged for many years in a war with the Siculi, entered into an alliance with a colony of the Pelasgii, who came out of Thessaly into Italy, after having been driven from the Ionian country. — About 1476 B.C. another colony of the Pelasgii, who had been driven out of Thessaly by the Curetes and Leleges, arrived in Italy, where they allied themselves with the Aborigines to drive out the Siculi, poising themselves on the highest part of the country between the Tiber and the Liris, and building several cities. Solinus and Pliny tell us, that the Pelasgii first carried letters into Italy; and the latter distinguishing between the Pelasgii and the Arcades: so the letters first carried into Italy were not the Ionic Greek, but those more ancient Pelasgic characters which the Pelasgii carried with them before Dencalius and Cadmus are said to have come into Etruria and Thessaly. The story of Cadmus is much involved in fable; but it is agreed by most of the ancients, that the children of Agenor, viz., Cadmus, Europa, Phoenix, and Cilix, carried with them a colony composed of Phoenicians and Syrians, into Aea Minor, Crete, Greece, and Libya, where they introduced letters, music, poetry, and other arts, sciences, and customs of the Phoenicians. Dionysius enumerates the following Greek colonies which came into Italy: 1. The Aborigines under Oenorbus from Arcadia. 2. The Pelasgic colony which came from Hecatomia or Thessaly. 3. Another Arcadian colony which came with Evander from Pallantium. 4. Those who came from Peloponneseas with Hercules; and, 5. Those who came with Atreus from Troy. It is not easy to discover when the Ionic way of writing from left to right was introduced into Italy; but it is certain, that it did not universally prevail even in Greece till several ages after it was found out. The Athenians did not comply with it till the year of Rome 350; nor was it practiced by the Samnites even in the sixth century of that city, or 230 years before Christ: for M. Cæcilin, Vol. VI. pl. 2, gives us the Samnite alphabet of that century, wherein the letters are placed from right to left, although the Ionic way of writing prevailed in some parts of Italy in the third century of Rome. "In time (says Pliny), the same content of all nations agreed to use the Ionic letters. The Romans consented to this mode about the time of Tarquiniius Priscus their fifth king." The letters brought by Damareus left Asia Minor and Crete, the father of Evander, Mr. Whittaker thinks, must have been the new or Ionic alphabet, and not the same with that brought by Evander 300 years before. After the Romans had established the use of the Ionic letters, they seem not to have acknowledged the Pelasgian and Etruscan to have been Greek alphabets; the most learned of them knew none older than the Ionic, as appears from the Greek Farneuse inscriptions of Herodes Atticus. This learned man, out of a regard to antiquity, cau­fed the oldest orthography to be observed in the writing, and the letters to be delineated after the most antique forms that could be found; and they are plainly no other than the Ionic or right-handed characters.

The ancient Gaulish letters are derived from the Greek, and their writing approaches more nearly to the Gothic than that of the Romans; this appears from the following Latin inscriptions of Gordian, messengers of the Gauls, who suffered martyrdom in the third century with all his family. These ancient Gaullish characters were generally used by that people before the conquest of Gaul by Caesar; but after that time the Roman letters were gradually introduced. The ancient Spaniards used letters nearly Greek before their intercourse with the Romans. The ancient Gothic alphabet was very similar to the Greek, and is attributed to Ulphilas, bishop of the Goths, who lived in Maslia about 370 years after Christ. He translated the Bible into the Gothic tongue. This circumstance might have occasioned the tradition of his having invented these letters; but it is probable that these characters were in use long before this time. The Runic alphabet is derived from the ancient Gothic.

The Coptic letters are derived immediately from the Greek. Some have confounded them with the ancient Egyptian; but there is a very material difference between them. The Ethiopic alphabet is derived from the Coptic.

The alphabet proceeding from that of the Scythians established in Europe, is the same with that St. Cyril calls the Servian. The Russian, Hungarian or Slavonic, and the Bulgarian, are all derived from this alphabet. The Armenian letters differ very much from the Greek, from which they are derived, as well as from the Latin.

With regard to the alphabets derived from the Latin, the Lombardic relates to the manuscripts of Italy; the
Alphabet. The Visigothic to those of Spain; the Saxon to those of England; the Gallican and Franco-Gallic or Merovingian to those of that country; and the Caroline Capetian, and Modern Gothic, to all the countries of Europe who read Latin. The first six of these alphabets are before the age of Charlemagne, the last three posterior to it. They are more distinguished by their names than the forms of their characters, and the former indicate all to have been of Roman extraction. Each nation, in adopting the letters of the Romans, added thereto a style and manner peculiar to itself, which obviously distinguished it from the writings of all other people; whence arose the differences between the writings of the Lombards, Spaniards, French, Saxons, Germans, and Goths, and all the strange terms observable in the writings of the Francs Gauls or Merovingians; and those of the Carolingians their successors may be traced from the same source. From these distinctions the name of national writing was derived.

The writing of Italy was uniform till the irruption of the Goths, who disfigured it by their barbarous taste. In 569, the Lombards, having possessed themselves of all Italy, excepting Rome and Ravenna, introduced that form of writing which goes under their name; and as the Popes used the Lombardic manner in their bulls, the name of Roman was sometimes given to it in the 11th century; and though the dominion of the Lombards continued no longer than 200 years, the name of their writing continued in Italy from the 7th to the 13th century, and then ceased: when learning, having declined in that as well as in other countries, the manner of writing degenerated into the modern Gothic.

The Visigoths introduced their form of writing into Spain, after having overrun that country; but it was abolished in a provincial synod held at Leon in 1091, when the Latin characters were established for all public instruments, though the Visigothic were used in private writings for three centuries afterwards.

The Gauls, on being subjected by the Romans, adopted the manner of writing, but by subsequent additions of their own, their characters were changed into what is called the Gallican or Roman Gallic mode. This was changed by the Franks into the Franco-Gallic or Merovingian mode of writing, being practised under the kings of the Merovingian race. It took place towards the close of the sixth century, and continued till the beginning of the ninth.

The German mode of writing was improved by Charlemagne, and this improvement occasioned another distinction in writing by introducing the alphabet named Caroline, which declined in the 12th century, and was succeeded in the 13th by the modern Gothic. In France it had degenerated by the middle of the 10th century, but was restored in 987 by Hugh Capet, whence it obtained the name of Capetian. It was used in England as well as Germany and France.

The modern Gothic, which spread itself all over Europe in the 12th and 13th centuries, is improperly named, as not deriving its origin from the writing anciently used by the Goths. It is, however, the worst and most barbarous way of writing, and originated among the schoolmen in the decline of the arts; being indeed nothing else than Latin writing degenerated.

It began in the 12th century, and was in general use, especially among monks and theologians, in all parts of Europe, till the restoration of arts in the 14th century, and continued longer in Germany and the northern nations. The late books are still printed in Gothic letters. The most barbarous writing of the seventh, eighth, and ninth centuries, was preferable to the modern Gothic. It is diversified in such a manner as can scarcely admit of description; and the abbreviations used by the writers were so numerous, that it became very difficult to read it; which was one of the great causes of the ignorance of those times. Along with this, however, the Lombardic, Gothic, Roman, Caroline, and Capetian modes of writing, were occasionally used by individuals.

The idea that all the alphabets abovementioned are derived from the Roman, tends to prove the distinctness of national writing, and is of great use in discovering the age of manuscripts: for though we may not be able exactly to determine the time when a manuscript was written, we may be able nearly to ascertain its age. For example, if a writing is Merovingian, it may be declared not to be posterior to the ninth, nor prior to the fifth century. If another be Lombardic, it may be affirmed to be posterior to the middle of the sixth, and prior to the 13th. Should it be Saxon, it cannot be of an earlier date than the 7th, nor later than about the middle of the 12th.

Having considered whence the alphabets now in use throughout the various nations of the world are derived, it remains to say something concerning them as the elements of words, or how far they are capable of expressing those sounds, which, by proper combination and arrangement, constitute articulate language. The number of simple sounds in any language cannot be very numerous; and it is plainly these simple sounds alone that we have occasion to represent by alphabetical characters. Hence the person who first invented letters, must have been capable of analysing language in a manner which seems by no means easy to do, and concerning which even the learned among ourselves are not yet agreed. It is this difficulty which has produced the great diversity in the number of alphabetical characters used by different nations; and where we see a vast number of them used, we may account the writing not the better, but much the worse for it; and whoever the pretended inventor was, it is more reasonable to suppose that he disfigured an alphabet already invented, by unnecessary additions, than been the author of one himself.

When we consider alphabetical characters as thus probably resulting from an analysis of language, it will by no means appear probable that it was derived from a gradual and progressive operation of the human mind through many ages. There is not the least affinity between representing any object by a picture and finding out the sounds which compose the word by which it is expressed; nor, indeed, though a nation had been in use to represent things either in this method, or by any kind of arbitrary marks, for thousands of years, could the one ever have led to the other. Arbitrary marks must always be the same with pictures in this respect, that they must always be fixed to particular objects, and thus increased ad infinitum. Letters, on the other hand, are indifferent to all

**Plate VII**
...other things strongly inspired, ventured, nature. This might furnish an argument for the faculty of articulate sounds, which mankind have invented, we know how; so that if one inclined to suppose this a turn of thought in a divine revelation, he could be at little loss for arguments to support his hypothesis. This was what all the inventions and evolutions of human powers since the creation had never been able to accomplish; yet nobody believes that it required supernatural abilities to be the author of this art, because we see plainly that it might have occurred to the human mind from various sources, and are surprised that it did not occur long before. In like manner, the method of accounting for the celestial motions by the united forces of projection and gravitation, was no refult of the progress that mankind had made in science, but luckily occurred to Mr Horrox, without any thing that we know to direct him, or perhaps from causes almost unknown to himself. Thus also, the steam-engine, aca-40

dimation of a separate mark or letter to represent each articu-}
Mr. Sheridan observes, that our alphabet is ill calculated for the notation of the English tongue, as there are many sounds for which we have no letters or marks, and ought to be nine more characters or letters to make a complete alphabet, in which every simple sound ought to have a mark peculiar to itself. The reason of the deficiency is, that the Roman alphabet was formerly adopted for the notation of the English language, though by no means fitted to the purpose.

It now remains only to take some notice of the forms of the different letters; some knowledge of which is absolutely necessary, for after attending the age and authenticity of inscriptions, manuscripts, charters, and ancient records. Many authors are of opinion that letters derive their forms from the positions of the organs of speech in their pronunciation. Van Helmont has taken great pains to prove, that the Chaldaic characters are the genuine alphabet of Nature; because, according to him, no letter can be rightly founded without disjoining the organs of speech into an uniform position with the figure of each letter; and in support of this system, he has ascertained the organs of articulation.

Mr. Helmont endeavored to show, that all elementary characters, or letters, derive their forms from the line and the circle. His alphabet consists of 13 radical letters, four diminished, and four augmented. The radicals are D, O, S, A, B, C, D, N, U, J, E, M, F. H, according to him, is derived from A; P from U; T from D; and F from U: these are all called diminished letters. The augmented ones are Z from S; G from C; W from U; and Y from I. He proves that his characters are very similar to those of the ancient Etruscans: but all characters are composed either of lines and circles of the former, and of parts of the latter. Mr. Gelbin deduces them from hieroglyphic representations, and has given several delineations of human figures, trees, &c. in confirmation of this hypothesis.

One of the most simple alphabets has been formed, by making two perpendicular and two horizontal lines: a b c d e f g h i j k l; from which may be deduced nine different characters or letters; thus:

Nine more may be made by adding a point to each, Alphanis,

and as many more as n o p may be sufficient q r s t u v w x y z for the notation of any language, by adding two or more points to each character. Though these square characters are not calculated for dispatch; yet they may be made as expeditiously, or more so, than the Tartar, the Bramin, the Cachmirian, or many others. Writing composed of these characters, is at first sight somewhat like the Hebrew. — Mr. Dow, author of the History of New Indo-Indian, lately formed a new language and alphabet, invented by

ALPHENIX, white barley-fugar, to which is given an extraordinary name, to render it more valuable. This fugar, which is thought good for colds, is made of common fugar, which is boiled until it becomes easy to crack, when they pour it upon a marble table, greased with oil of sweet almonds, and mould it into various figures with a brais crotchet. It is easily fattened with flour.

ALPHERY (Mikipher), born in Russia, and of the Imperial line. When that country was torn to pieces by intestine quarrels, in the latter end of the 16th century, and the royal house particularly was so severely persecuted by impostors, this gentleman and his two brothers were sent over to England, and recommended to the care of Mr. Joseph Bidell, a Ruffian merchant. Mr. Bidell, when they were of age fit for the universality, sent them to Oxford, where the small-pox unhappily prevailing, two of them died of it. We know not whether this surviving brother took degrees or not, but it is very probable he did, since he entered into holy orders; and in the year 1618, had the rectory of Woolley in Huntingdonshire, a living of no very considerable value, being rated at under £10 in the king’s books. Here he did his duty with great cheerfulness and alacrity; and although he was twice invited back to his native country by some who would have ventured their utmost to have set him on the throne of his ancestors, he chose rather to remain with his flock, and to serve God in the humble station of a parson’s cot. Yet in 1643, he underwent the severest trials from the rage of the fanatics; who, not satisfied with depriving him of his living, insulted him in the most barbarous manner, for having procured a file of musqueteers to pull him out of his pulpit, as he was preaching on a Sunday, they turned his wife and small children into the street, into which also they threw his goods. The poor man in this distress raised a tent under some trees in the church-yard, over against his house, where he and his family lived for a week. One day having gotten a few eggs, he picked up some rotten wood and dry sticks, and with these made a fire in the church-porch in order to boil them; but some of his adversaries, to show how far they could carry their rage against the church, for this poor man was so harmless they could have none against him, came and kicked about his fire, threw down his skillet, and broke his eggs. After this, having still a little money, he made a small purchase in the neighbourhood, built
him a house, and lived there some years. He was encouraged to this by a Prelatyman minister who came in his room, who honestly paid him the fifth part of the annual income of the living, which was the allowance made by parliament to ejected ministers, treated him with great humanity, and did him all the services in his power. It is a great misfortune that this gentleman's name is not preserved, his conduct in this respect being the more laudable, because it was not a little singular. Afterwards, probably on the territory of Megalopolis, he returned to the town of Arcadia, and by Olympia in Elis, with a fourth part of the proceeds paid him in possession of his living again. He returned on this occasion to Huntingdonshire, where he did not stay long; for being upwards of 80, and withal very infirm, he could not perform the duties of his function. Having, therefore, letted a curate, he retired to his eldest son's house at Hammermith, where shortly after he died, full of years and of honour.

The Alpheus, (Strabo, H. P., (Polyemus); a noted and large river of the Eleonnesos; which, rising in, and after several windings running through, Arcadia, and by Olympia in Elis, with a south-west course, pours into the Sinus Arcadion, about ten miles to the south of Olympia. It has a common spring with the Eurotas, at the foot of mount Parthenius, near the village Arece, (Strabo.) The Alpheus and Eurotas mix and run together for 20 stadia; after which, they enter a subterraneous passage at Mantinea; then again emerge, the Eurotas at Lacocina, and the Alpheus in the territory of Megalopolis. (Pausanias.) The poetics stange things of this river; particularly, that, out of love to the nymph Arethusa, it runs under the sea to Sicily, and bursts out at the fountain of that name in Syracuse, (Virgil.) Its waters are reckoned good in the leprosy, which is called Aegis by the Greeks; and hence the name Alpheus.—Pausanias adds, that the Eleans had a law, which condemned any woman to death that should either appear at the Olympic games, or even cross this river during that solemnity: and the Eleans add, that the only woman who transgressed it, had disguised herself in the habit of a woman, and conducted her son thither; but when the law came off victorious, her joy made her forget her disguise, so that her sex was discovered. She was pardoned, but from that time a law was made that the keepers should appear there naked.

ALPHONSIN, in surgery, an instrument for extracting bullets out of gun-shot wounds. This instrument derives its name from the inventor Alphonse Ferrer, a physician of Naples. It consists of three branches, which are closed by a ring. When closed and introduced into the wound, the operator draws back the ring towards the handle, upon which the branches opening take hold of the ball; and then the ring is pushed out of the haft, by which means the branches grasp the ball so firmly, as to extract it from the wound.

ALPHONSOX. King of Leon and Castile, surnamed the Wise, was author of the astronomical tables called Alphonsias. Reading of Quintus Curtius gave him such delight, that he recovered him out of a dangerous illness. He read the Bible fourteen times, with several comments on it. He is said to have found fault with the structure of the mundane system, and has been charged with impiety on that score; but unjustly, for he only found fault with the involved system of some astronomers. He was detoined by his son Sancho; and died of grief, A. D. 1284.

ALPINI (Propero), a famous physician and botanist, born in the Venetian territory, 1553. He travelled in Egypt to acquire a knowledge of exotic plants, and was the first who explained the fertilization and generation of plants by the sexual fluid. Upon his return to Venice, in 1589, Andrea Doria, prince of Melfi, appointed him his physician: and he distinguished himself so much in this capacity, that he was esteemed the first physician of his age. The republic of Venice began to be uneasy, that a subject of theirs, of so great merit as Alpini, should continue at Genoa, when he might be of so much service and honour to their state: they therefore recalled him in 1593, to fill the professorship of botany at Padua: and he had a salary of 200 florins, which was afterwards raised to 750. He was discharged this office with great reputation; but his health became very precarious, and he had been much broken by the voyages he had made. According to the register of the university of Padua, he died the 5th of April 1617, in the 64th year of his age; and was buried the day after, without any funeral pomp, in the church of St Anthony. Alpini wrote the following works in Latin: 1. Of the physic of the Egyptians, in four books. Printed at Venice, 1591, in 4to. 2. A treatise concerning the plants of Egypt. Printed at Venice, 1592, in 4to. 3. A dialogue concerning balsams. Printed at Venice, 1592, in 4to. 4. Seven books concerning the method of forming a judgment of the life or death of patients. Printed at Venice, 1691, in 4to. 5. Thirteen Books concerning methodical Physic. Padua, 1611; folio; Leyden, 1719, in 4to. 6. A Disputation held in the school at Padua, concerning the Raphonticum. Padua, 1612, and 1624, 4to. 7. Of exotic plants, in two books. Venice, 1699, in 4to. He left several other works, which have never been printed; particularly, 8. The fifth book concerning the physic of the Egyptians. 9. Five books concerning the natural history of things observed in Egypt, adorned with a variety of draughts of plants, flowers, and animals.

ALPINIA, in botany: A genus of the monandria order, belonging to the monandria class of plants; and in the natural method ranking under the 8th order, Scitamineae. The characters are: The calyx is a perianthium above, small, and trifid: The corolla is monopetalous, unequal, and as if doubled: The flaminea consist of one filament, with linear anticlvea, joining to the margin: The pistillum has a roundish stalk, beneath; the stylus simple, and the stigma obtusely trigonous: The pericarpium is a finely ovate trilocular capsule, with three valves: The seeds are ovate, and very numerous; the receptaculum is pulpy and very large. Of this genus there is but one species which is a native of the West Indies, where it grows naturally in moist places. The leaves decay every winter, and are pulled off from the roots in the spring, like the ginger and maranta; fo must be managed in the same manner as directed for these two plants, and may be propagated by parting the roots when the leaves decay.
The prospect from many parts of this enormous range of mountains is extremely romantic, especially towards the north-west. One of the most celebrated is the Grande Chartreuse, where is a monastery founded by St Bruno about the year 1084. From Chartreux, a little village in the mountains of Savoy, to the top of the Chartreuse, the distance is five miles. Along this course the road runs winding up, for the most part not fixed feet broad. On one hand is the rock, with woods of pine trees hanging over head; on the other a prodigious precipice almost perpendicular; at the bottom of which rolls a torrent; that, sometimes tumbling among the fragments of stone which have fallen from on high, and sometimes precipitating itself down vast declivities with a noise like thunder, rendered yet more tremendous by the echo from the mountains on each side, consorts to form one of the most solemn, the most romantic, and most astonishing scenes in nature.

To this description may be added the strange views made by the crags and cliffs, and the numerous cascades which throw themselves from the very summit down into the vale. On the top of the mountain is the convent of St Bruno, which is the superior of the whole order. The inhabitants consist of 100 fathers, with 200 servants, who grind their corn, press their wine, and perform every domestic office, even to the making of their clothes. In the Album of the fathers is admired an alea odes, written by the late ingenious Mr. Gray when he visited the Chartreuse, and which has since been published among his works.

The glaciers of Savoy are also justly reckoned among the most stupendous works of nature. These are immense masses of ice, lodged upon the gentler declivities amidst the Alps, and exhibiting representations beyond conception fantastic and picturesque. In the extraordinary narrative of Mr. Bourri's journey thither, we meet with the following account of the Pierre, in the valley of Champillon. We had, says he, the magnificent prospect of a chain of mountains, equally inaccessible, and covered with ice; and above the rest that of Mount Blanc, whose top seemed to reach, and even pierce, the highest region of the clouds. The chain upon which this mountain looks down like a giant, is composed of masses of rocks, which terminate in pikes or spires, called the Needles, and which are ranged like tus in a camp. Their sides appear lighter and more airy, from the ornament of several hollow breaks and furrows fretted in the rock itself, as well as from the different streaks and lanes of ice and snow, which, without changing the general character of their form, or the majesty of their appearance, give them a picturesque variety. Lower down, the eye survey's with ravishment the hills of ice, and the several glaciers, extending almost into the plain, whilst this appears like an artificial garden, embellished with the mixture of a variety of colours. We have a picturesque opposition to this chain, which is formed by innumerable mountains at the distance of near 50 leagues, between whose tops we have a glimpse of those several plains which they environ. M. de Sainthubert, who had visited those mountains about two months before M. Bourri, felt himself naturally electrified in this place. This extraordinary phenomenon seems not to have been experienced by the latter or his company; but they heard a long-conceived
Alps. tinued rumbling noise, like that of thunder, which was rendered more awful by the silence of the place where they stood. This noise proceeded from the subsequent causes, viz. the avalanches of snow, which separated from the tops of the mountain, and rolled down to the bottom; considerable fragments of the rocks which followed them, overturning others in their fall; and many blocks of ice, which precipitated from the summits.

The valley of Montanvert appears to be peculiarly romantic. Here, says M. Borrut, we beheld a spacious icy plain entirely level. Upon this there reigned a mountain all of ice, with steps ascending to the top, which seemed the throne of some divinity. It likewise took the form of a grand cascade, whose figure was beyond conception beautiful; and the sun, which shone upon it, gave a sparkling brilliance to the whole. The valley on our right hand was ornamented with prodigious glaciers, that, shooting up to an immeasurable height between the mountains, blend their colours with the skies, which they appear to reach. At rs, besides its proper signification, by which it denotes a certain chain of mountains which separate Italy from France and Germany, is frequently used as an appellative to denote any mountains of extraordinary height or extensive range. In this sense, Auvergne and others call the Pyrenean mountains, Alpi; and Gellius the Spanish Alps, Apini Hifpani.

Hence also we say, the British Alps, the Asiatic Alps, the Alps of America.

The Scottish Alps terminate in a most sublime and abrupt manner, at the great promontory the alta Ripa of Ptolemy, the Ord or Ard, i.e. the Height, of Caithness. The upper part is covered with gloomy heaths, the lower is a stupendous precipice, excavated into vast caverns the haunt of cubs and different sea fowl. On the eastern side of the kingdom, this is the striking termination of the vall mountains of Sco land which from its hights, the habitation of the original inhabitants, driven from their ancient seats by the ancestors of the land Scots, descendants of Saxons, French, and Normans; congenial with the English, yet absurdly and invi­diously distinguished from them. Language, as well as striking natural boundaries, mark their place. Their mountains face on the west the Atlantic ocean; wind along the west of Caithness, among which Morvern and Scatraben, Ben-Hop and Ben-Lugal, arise pre-eminent, Sutherland is entirely Alpine, as are Rossberry and Invernesshire. Their Sirmian Alps are, Neal Fourvou­nich, the Coryarich, Benewihand Benevih near Fort­William; the laft of which is reported to be 1450 yards in height. Great part of Aberdeenshire lies in this tract. It boas of another Morvern, soaring far beyond the others. This is the centre of the Grampian hills, and perhaps the highest from the sea of any in Great Britain. They again comprehend the eastern part of Pershire, and finish on the magnificent shores of Lochlomond, on the easter side of which Ben­lomond ripes, distinguished among its fellows. From hence the rest of north Britain forms a chain of hum­bler hills; but in Cumberland, part of Westmorland, Yorkshire, Lancashire, and Derbyshire, the Alps resume their former majesty. A long and tame interval succeeds. The long sublime track of Wales arises, the ancient poſsession of the ancient British race. From the Ord, the great mountains recede inland, and leave a vall flat between their bases and the sea, fronting the waves with a series of lofty rocky precipices, as far as the little creek of Staxico; the whole a bold, but most inhospitable shore for shipping. Wick and Stax­ico have indeed their creeks, or rather chasms, which open between the cliffs, and may accidentally prove a retreat, unless in an eastern wind.

The Asiatic Alps are described under the articles Az­tac Chain and Wetteranian Mountains. The American Alps, are, The Andes of Cordilleras, in South America; and the Appalachian of Alleghany mountains, in North America.

The highest ground in North America is placed by Captain Carver in lat. 57° west long. from Land 90° between a lake from which the Oregon fows, and another called White-bear Lake, from which arises the Missippi.

This excited situation is part of the Shining Mountains, which are branches of the vall chain which pervades the whole continent of America. It may be fairly taken from the southern extremity where Staten Land and Terras del Fuego rise out of the sea as isolated links to an immense height, black, rocky, and marked with rugged fiery tops, frequently covered with snow. New Georgia may be added as another horribly congenial, rising detached farther to the east. The mountains about the Straits of Magellan soar to an amazing height, and infinitely superior to those of the northern hemisphere under the same degree of latitude. From the north side of the Straits of Magellan, they form a continued chain through the kingdoms of Chili and Peru, preferring a course not remote from the Pacific Ocean. The summits, in many places, are the highest in the world. There are not less than 72, which are from 2400 to 3000. Pichincha, wich impends over Quito, is about 35 leagues from the sea; and its summit is 2450 toises above the surface of the water. Cayambe, immediately under the equator, is above 3000; and Chimbo­razo higher than the last by 200. Most of them have been volcanic, and in different ages marked with eruptions far more horrible than have been known in other quarters of the globe. They ex end from the equator through Chili, in which kingdom is a range of volcanoes, from lat. 25. south, to 47. north, and possibly from thence to Terra del Fuego itself, which forming the Straits of Magellan, may have been rent from the continent by some great convulsion, occasioned by their labours; and New Georgia forced up from the same caufe. An unparalleled extent of plain appears on their eastern side. The river of Amazonas runs along a level clothed with forests, after it bursts from its confinement at the Pongo of Borjas, till it reaches its sea-like discharge into the Atlantic Ocean.

In the northern hemisphere, the Andes pass through the narrow Isthmus of Darien into the kingdom of Mexico, and preserve a majestic height and their volcanic disposition. The mountain Popocatepepe made a violent eruption during the expedition of Cortez, which is most beautifully described by his historian An­tonio de Solis. This, probably, is the same volcano observed by the Abbé d'Aulnoy, in his way from Vera Cruz to Mexico; which, from the naked­ness of the lavas, he conjectured to have been but late­
ly extinguished. From the kingdom of Mexico, this branch is continued northward, and tho the east of California, then verges to greatly towards the west, as to leave a very inconceivable space between it and the Pacific Ocean, and frequently detached branches just enter sea, and form promontories; whilst, with parts of the chain itself, were often seen by our navigators in the course of their voyage. Some branches, as we have before observed, extend towards the east, but not to any great distance. A plain, rich in woods and savannas, warm with bison, buffaloes, flags, and Virginian deer, with bears, and great variety of game occupies an amazing track, from the great lakes of Canada, as low as the Gulf of Mexico, and easterly to the other great chain of mountains, the Appalachian, which are the Alps of that side of northern America. Its commencement is supposed to be about Lake Champlain and Lake George, with branches pointing obliquely to the river St Lawrence eastward, and rifting on its opposite coasts; others extending with lowering progress, even into Nova Scotia. The main chain passes through the state of New York, where it is disfigured by the name of the Highlands, and lies within 40 miles of the Atlantic. From thence it recedes from the sea, in proportion as it advances, southward; and near its extremity in southern Carolina is 300 miles distant from the water. It consists of several parallel ridges, divided by most interesting valleys and generally clothed with a variety of woods. These ridges rise gradually from the coast, one above the other, to the central, from which they gradually fall to the west, into the vast plains of the Mississippi. The middle ridge is of an enormous bulk and height. The whole extends in breadth about 70 miles; and in many places leaves great chains for the discharges of the vast and numerous rivers which rise in the bofoms of the mountains, and empty themselves into the Atlantic Ocean, after yielding a matchless navigation to the provinces they water.

Beyond the branch of the Appalachian mountains called the Endless, is another of amazing extent, nearly as high as the mountains themselves. This plain (called the Upper Illinois) is exceedingly rich land; begins at the Mahock’s River; reaches to within a small distance of Lake Ontario; and to the westward forms part of the extensive plains of the Ohio, and reaches to an unknown distance beyond the Mississipi. Vast rivers take their rise, and fall to every point of the compass; into Lake Ontario, into Hudson’s River, and into the Delaware and Susquehanna. The tide of the Hudson’s River flows thro' its deep-worn bed far up, even to within a small distance of the head of the Delaware; which, after a furious course down a long descent, interrupted with rapids, meets the tide not very remote from its discharge into the ocean.

APUXARAS, or ALPAXARES, mountains of Spain, in the Province of Granada, on the Coast of the Mediterranean Sea. They are about 17 leagues in length, and 11 in breadth, reaching from the city of Velez to Almeria. They are inhabited by Moors, who are the remains of the dispersion and ruin of their empire. They embraced the Christian religion; but preserved their own manner of living, and their language, though much corrupted. Here is a rivulet between Pitros and Portugos, which dyes linen that is dipped in it black in an instant. Near this rivulet is a cavern, from which proceeds a malignant fume, that destroys such animals as come near it. The Moors cultivate the soil extremely well, and plant fruit-trees, some of which grow to a prodigious height and thickness, and give the mountains a very agreeable aspect.

ALQUIER, a liquid measure, used in Portugal to measure oil, two of which make an almond. See ALMOND.

ALQUIFON, or ALQUIFOU, is a sort of lead ore, which, when broken, looks like antimony. It is used by the potters to give a green varnish to their works, and thence is called potter’s ore. It is met with in Cornwall, &c. The potters mix a small portion of manganese with the alquifon, and then the varnish of glazing on their ware is of a blackish hue.

ALREDUS, ALBRECHT, or ALBERDUS, of Beverley, one of the most ancient and best English historians. He wrote in the reign of Henry 1. There are no circumstances of his life known with any degree of certainty. It is generally believed that he was educated at Cambridge, and that he afterwards became one of the canons and treasurer of St John’s at Beverley. And we learn in a note of bishop Tanner’s, that, for the sake of improvement, he travelled through France and Italy; and that at Rome, he became canon and titular chaplain to cardinal Othobon. He died in the year 1128 or 1129; leaving behind him the following works: 1. The Annals of Alured of Beverley. Oxford, 1726. Published by Mr Hearne, from a manuscript belonging to Thomas Rawlinson, Esq. It contains an abridgment of the history from Brutus to Henry I. written in good Latin; and with great accuracy. 2. Historiae ecclesiae St Johannis de Beverloro, &c. a manuscript in the Cotton library. It is a collection of records relative to the church at Beverley, translated by our author from the Saxon language. The Biographia Britannica evidently proves these to be all that were written by Alredus.

ALRESFORD, a town of Hampshire, seated on the road from London to Southampton, close by the river Itchen, which feeds a great pond to the left of the town. Part of a Roman highway runs from thence to Alton. It is a rectory, with the rectory of Old Alresford, of L.49:12:8 in the king’s books. It consists of about 200 houses; has one church, two principal streets, which are large and broad; and a small manufacture of linseys.

ALSA, a river of Carniola (Pliny), now the Aupa, running by Aquileia with a short course from north to south, into the Adriatic; where Constanine, the son of Constantine the Great, fighting against Constanis his brother, lost his life.

ALSACE, a province of France, bounded on the east by the Rhine, on the south by Switzerand, on the west by Lorrain, and on the north by the palatinate of the Rhine. It was formerly a part of Germany, but was given to France by the treaty of Munster. It is one of the most fruitful and plentiful provinces of Europe, abounding in corn, wine, wood, flax, tobacco, pulle, fruits, &c. The mountains which divide it from Lorrain are very high, and generally covered with fir, oak, and horn beam. Those on the side of Switzerand are
Alten, Altenh. are lofty high and furnished with all sorts of wood, as well for fuel as building. The country is well diversified with rising hills and fertile vales, besides large forests; but that between the rivers Ill, Main, and the Rhine, as far as Strauburg is inferior to the region about the frequent overflows of the Rhine. In High Alsen there are mines of silver, copper, and lead. They however work none but those of Gromany, from which are annually drawn 1600 marks of silver, each mark being eight ounces; and 24,000 pounds of copper: but the expense of working them is almost equal to the profit. There are iron-works in several parts of Alsen, and particularly at Bedford. There is a mineral spring at Sultibach, near Munster, in High Alsen; which is of great reputation for the bath, weakness of the nerves, and the gravel. The original inhabitants of Alsen are honest and good-natured, but wedded to their own manners and customs. The fruitfulness of their country renders them indolent and inactive; for the Swits make their hay and reap their corn, as well as manage the vintage of High Alsen, which lends a great deal of money out of the province. The common language is the German; however, the better sort of people speak French in the towns, and even in the country, they speak French well enough to be understood.

Alsen, an island of Denmark in the Jæger Bell, or entrance into the Baltic sea, between Slefwick and Sweden, is called the capital of the province. The common language is Danish. It is situated on the river Sæb, now Sfr, and had a well-watered garden for every house; but was ruined by Jenghiz Khan, who took the city, and caused a great number of its inhabitants to be massacred.

Alsheda, a parish of Sweden, in the province of Smaland, where a gold mine was discovered in 1735.

Alsi, in botany, a synonym of the theligonum. See Theligonum.

Alsinastrum, in botany, the trivial name and also a synonym of the clatine. See Clatine.

Alsin, or Chickweed: A genus of the trignia order, belonging to the pentandria class of plants; and, in the natural method, ranking under the 22d order, Caryophylli. The characters are: The calyx is quinquefoilous: The corolla consists of five equal petals, longer than the calyx: The filaments consist of five capillary filaments; the anthers are roundish: The pistilium has an oval germin, three siliform filii, and obtuse stigma: The pericarpium is an ovate unilocular capsule, with three valves: The seeds are roundish and numerous. Of this genus a great number of species are enumerated by some botanical writers; but none of them possess any remarkable properties, except the media, or common chickweed, with white blossoms, which is so well known as to need no particular description. This species affords a notable instance of what is called the sleep of plants: for, every night, the leaves approach in pairs, as to include within their upper surfaces the tender rudiments of the new flowers; and the uppermost pair but one at the end of the stalk are furnished with longer leaf-stalks than the others; so that they can close upon the terminating pair, and protect the end of the branch. The young flowers and leaves, when boiled, can hardly be distinguished from spring spinach. They are deemed refrigerating and nutritious, and an excellent food for persons of a consumptive habit of body. — Swiss are extremely fond of chickweed; cows and horses eat it, sheep are indifferent to it; and goats refuse it.

Alsiniat, in the Mahometan theology, denotes a bridge laid over the middle of hell, finer than a hair, and sharper than the edge of a sword, over which people are to pass, after their trial, on the day of judgement. To add to the difficulty of the passage, Mahomet affuirs, that the alligator, narrow as it is, is beset with briars and thorns; and even in the path of the good, will be an impediment to the good, who shall fly over it like the wind; Mahomet and his muflemen lean the way; whereas the wicked, by the narrowness of the path, the entangling of the thorns, and extinction of the light which directed the former to paradise, will soon mis their footing, and tumble headlong into hell, which is gaping beneath to receive them.

Alsiem, a city of ancient Etruria, occupying (according to Calverius) the spot on which Fiji now stands. We are told by Dionysius Halicarnassenis, that Almus was built by the Aborigines, long before the Tyrrhenians invaded Italy. In this case it must have been founded not long after the dispersion in the days of Teleg. Its founder is said to have been one Alsiem, Aescul, or Alita; whom some conjecture to have been Altith, or Eliina, the son of Javan mentioned in scripture.

Alsons (Anthony), a divine and poet, was educated at Westminster-school, and thence elected to Christ-church, Oxford, where he took the degree of M. A. in March 1665, and of B. D. in Decem. 1706. On his coming to the university, he was very soon distinguished by Dean Aldrich, and published Fabula- rum Euyperianum Letalis, Oxon. 1685, 8vo. with a poetical dedication to lord viscount Sandamore, and a preface in which he took part against Dr Bentley in the famous dispute with Mr Boyle. He passed through the usual offices in his college to that of censor with considerable reputation; and for some years had the principal noblemen and gentlemen belonging to the society committed to his care. In this employment he continued till his merit recommended him to Sir Jonathan Trelawney, bishop of Winchester, who appointed him his chaplain, and soon after gave him a prebend in his own cathedral, together with the rectory of Brightwell in the county of Berks, which afforded him ample provision for a learned retirement, from which he could not be drawn by the repeated solicitations of those who thought him qualified for a more public character and a higher station. In 1717 an action was brought against him by Mrs Elizabeth Alfrey of Oxford, for a breach.
ALS

breach of a marriage contract; and a verdict obtained against him for 2000l. which probably occasioned him to leave the kingdom for some time. His death, which happened June 10, 1726, was occasioned by his falling into a ditch that led to his garden-door. A quarto volume was published in 1752, under the title of Antiquari Aesopi, &c. with English and Latin libri duo. Four English poems of his are in Dodgley’s Collections, one in Pearch’s, several in the early volumes of the Gentleman’s Magazine, and some in “The Student.” Mr Allop is respectfully mentioned by the incautious Dr King of the Commons (vol. I, p. 256), as having enriched the commonwealth of learning, by “Translating IPables from Greek, Hebrew, and Arabic;” and not less detracingly by Dr Bentley, under the name of “Tony Allop, a late editor of the Asiopan Fables.”

Allop (Vincent), an eminent divine, was educated in St John’s College in Cambridge, where he took the degree of Master of Arts. He received deacon’s orders from a bishop, after which he went down to Rutlandshire, and settled at Oakham, where he was an assistant to the master of the free-school. As he was a man of a sprightly turn, he fell there into indifferent company; but was reclaimed by the frequent admonitions of the reverend Mr Benjamin King. He afterwards married that gentleman’s daughter, and becoming a convert to his principles, received ordination in the Presbyterian way, not being satisfied with that which he had from the bishop. He was settled at Willes in the county of Northampton, whence he was ejected in 1662, for nonconformity. After this he ventured to preach sometimes at Oakham, and at Wellingborough where he lived, and was once six months in prison for praying by a sick person. A book he wrote against Dr Sherlock in a humorous style, made him well known to the world, and induced Mr Cawton, an eminent nonconformist in Willemington, to recommend him to his congregation for his successor. On receiving this call, he quitted Northamptonshire and came to London, where he preached constantly, and wrote several pieces which were extremely well received by the public. His living in the neighbourhood of the court exposed him to many inconveniences; but these ended with the reign of Charles II, or at least in the beginning of the next reign, when Mr Allop’s son engaging in treasonable practices was freely pardoned by king James. After this our divine went frequently to court, and is generally supposed to have been the person who drew the Presbyterian’s address to that prince for his general indulgence. After the revolution, Mr Allop gave very public testimonies of his affection for the government; yet upon all occasions he spoke very respectfully of king James, and retained a very high sense of his clemency in sparing his only son. The remainder of his life he spent in the exercise of his ministry, preaching once every Lord’s day; besides which he had a Thursday lecture, and was one of the lecturers at Plincker’s hall. He lived to be a very old man, and preserved his spirits to the last. On grave subjects he wrote with a becoming seriousness; but where wit might properly be shown, he displayed his to great advantage.

His funeral sermon preached by Mr Slater, and his memory will be always preserved by his own learned and elegant writings. Of these the most remarkable, besides his sermons, are, 1. Anti-fozes; in vindication of some great truths opposed by Dr William Sherlock, 8vo, 1675. 2. Reliquiae Anglicanae; in answer to Dr Goodman’s Compendious Enquiry, 8vo, 1679. 3. The Mitchell of Impostures; in answer to Dr Dillingham’s Hitchick of Separation, 1680. 4. A faithful Re-proof to a False Report, with reference to the Differences among the United Dissenters in London, 8vo.

ALSTEDIUS (Joan-Henry), a German Protestant divine, and one of the most indefatigable writers of the 17th century. He was some time professor of philosophy and divinity at Herborn in the county of Nassau: from hence he went into Transylvania, to be professor at Alba Julia; where he continued till his death, which happened in 1638, being then 50 years of age. His Encyclopaedia has been much extolled even by the Roman Catholics; it was printed at Lyons, and sold very well throughout all France. His Theofanae Chronicagineae is by some esteemed one of his best works, and has gone thro’ several editions. He also wrote Triumphus Bibliorum, to show that the principles of all arts and sciences are to be found in the Scriptures; but he gained very few to his opinion. He was a Millenarian; and published, in 1627, a tractate De milie annis, in which he asserted that the reign of the saints on earth was to begin in 1694.

ALSTON-MORE, a town in Cumberland, feared on a hill; at the bottom of which runs the river Tyne, with a stone bridge over it. Near this place is plenty of lead ore. W. Long 2. 4. N. Lat. 34. 45.

ALSTONIA, in botany; a genus of the monogynia order, belonging to the hexandria class of plants. The characters are: The calyx is a perianthium beneath, imbricated: The corolla is monopetalous, and shorter than the calyx; the border expanding, eight or ten parted, with alternate divisions: The stamina consist of numerous short filaments, the exterior ones longer; the anther are orbicular and furrowed: The pistillum has a small ovate germe above; a simple stylus the length of the corolla, filiform and erect; the stigma inverase egg-headed. There is but one species, the theasformis, a native of America.

ALSTROEMERIA, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and, in the natural method, ranking under the 11th order, Sarmentaceae. The characters are: There is no calyx: The corolla is nearly bilabiated; and consists of five petals, the two inferior tubular at the base: The stamina consist of six filabulated filaments, declining and unequal; the anther oblong: The pistillum has an hexangular germe beneath; the stylus declining, filiform, the length of the stamina; and three oblong bifid stigmae: The pericarpm is a roundish hexangular capsule, with three cells and three valves: The seeds are globular and numerous. There are five species, natives of Italy and Peru.

ALT, in music, a term applied to the high notes in the scale.

ALTAIC CHAIN, a range of mountains which bounds Asia on the south. It begins at the vallus mountain Bogdo, passes above the head of the Iriffich, and then takes a course zigzag, precipitous, clothed with snow, and rich in minerals, between the Iriffich and Obj
ALTAR, a very handsome town in Italy, in the kingdom of Naples, and in Calabria Citerior, 15 miles north-west of Bagnigno. E. Long. 16. 22. N. Lat. 30. 40.

ALTAMURA, a town of Naples, in the territory of Bari, with the title of a principality, seated on the foot of the Apennine mountains. E. Long. 16. 54. N. Lat. 41. 0.

ALTAR, a place upon which sacrifices were anciently offered to some deity. The heathens at first made their altars only of turf; afterwards they were made of stone, of marble, of wood, and even of horn, as that of Apollo in Delos.

Altars differed in figure as well as in materials. Some were round, others square, and others triangular. All of them were turned towards the east, and stood lower than the figures of the gods; and were generally adorned with sculptures, representing either the gods to whom they were consecrated, or their symbols. See the PAGAN ALTARS represented on Plate XI. Upon the fides of No. 1. a trident and two dolphins are exhibited, which denote it to have been dedicated to Neptune. No. 2. a four square altar, was dedicated to the nymphs, as the inscription imports. No. 3. exhibits a Bacchus holding a thyrsus in his hand, a mark of the altar's being built to Bacchus: it had two other fides, which made it appear triangular. Of No. 4. which was also triangular, each face or side exhibited a genius, one of whom (on the side represented) carries an ear upon his neck, which seemed to denote it an altar of Neptune. No. 5. an altar of a round shape, is inscribed Arca Neptuni: the god himself is there represented, all naked, giving the pallium upon his shoulder; and holding in his left hand a trident, and in his right a dolphin.

The height of altars also differed; according to the different gods to whom they were consecrated. According to Servius, those altars set apart for the honour of the celestial gods, and gods of the higher class, were placed on some pretty tall pile of building; and for that reason were called altares from the words alta and arae, "a high elevated altar." Those appointed for the terrestrial gods were laid on the surface of the earth, and called arae. And, on the contrary, they dug into the earth and opened a pit for those of the infernal gods, which they called obelica, "serpulicula." But this distinction is not everywhere observed; the best authors frequently use arae as a general word, under which are included the altars of the celestial and infernal, as well as those of the terrestrial, gods. Witsers Virgin, Eccl. 5.

---En quatuor arat.

Where arae plainly includes altaria; for whatever we make of Daphnis, Phoebus was certainly a celestial god. So Cicero, pro Quinct. Arae delibragas Hecules in Grecia victimas. The Greeks also distinguished two sorts of altars; that whereon they sacrificed to the gods was called aedes, and was a real altar, different from the other whereon they sacrificed to the heroes, which was smaller, and called sagittas. Pollock makes this distinction of altars in his Onomasticon: he adds, however, that some poets used the word sagitta for the altar whereon sacrifice was offered to the gods. The Septuagint version does sometimes also use the word aedes for a fort of little low altar, which may be expressed in Latin by easticula; being a hearth rather than an altar.

Before temples were in use, altars were erected sometimes in groves, sometimes in the highways, and sometimes on the tops of mountains; and it was a custom to engrave upon them the name, ensign, or character, of the deity to whom they were consecrated.

In the great temples of ancient Rome there were ordinarily three altars: the first was placed in the sanctuary, at the foot of the statue of the divinity, upon which incense was burnt and libations offered; the second was before the gate of the temple, and upon it they sacrificed the victims; and the third was a portable altar, upon which was placed the offering and the sacrificial vessels.

Besides these uses of altars, the ancients swore upon them, and swore by them, in making alliances, confirming treaties of peace, and other solemn occasions. Altars also served as places of refuge to all those who fled to them, whatever crime they had committed.

Altars are doubtless as ancient as sacrifices themselves; consequently their origin is not much later than that of the world; Gen. ch. iv. Some attribute their origin to the Egyptians; others to the Jews; others to the patriarchs before the flood. Some carry them as far back as Adam, whose altar is much more ancient than by Jewish, and even Christian writers. Others are contented to make the patriarch Enoch the first who consecrated a public altar. Be this as it will, the earliest altars we find any express testimony of are those erected by Abraham.

Altars, in the patriarchal times, were very rude. The altar which Jacob set up at Beth-el was nothing but a stone, which served him instead of a bolder; that of Gideon, a stone before his bones: and the first which

God
God commanded Moses to erect was probably of earth, or unpurified stones, without any iron; for if any thing was made of that metal, the altar was declared impure.

The principal altars of the Jews were, The altar of incense; that of burnt-offering; and the altar, or table, for the show-bread.

The altar of incense was a small table of shittim-wood, covered with plates of gold; of one cubit in length, another in width, and two in height. At the four corners, were four kinds of horns, and all round a little border or crown over it. This was the altar hidden by Jeremiah before the captivity; and upon it the officiating priest offered, every morning and evening, incense of a particular composition. See Plate XI.

The altar of burnt-offerings was made of shittim-wood, and carried upon the shoulders of the priests by staves of the same wood overlaid with brass. In the time of Moses, this altar was five cubits square and three high; but in Solomon's temple it was much larger, being 20 cubits square and 10 in height. It was covered with brass; and at each corner was a horn or spire, wrought out of the same wood with the altar, to which the sacrifices were tied. Within the hollow was a grate of brass, on which the fire was made; through it fell the ashes, and were received in a pan below. At the four corners of the grate were four rings and four chains, which kept it up at the horns. This altar was placed in the open air, that the smoke of the burnt-offerings might not fully the inside of the tabernacle. See Plate XI.

The altar, or table, for the show-bread, was likewise of shittim-wood, covered with plates of gold, having a little border round it, adorned with sculpture. It was two cubits long, one wide, and one and an half in height. Upon this table, which stood in the holy of holies, were put, every sabbath-day, 12 loaves, with salt and incense.

The Jewish altars, after their return from the captivity, and the building of the second temple, were in some respects different from those described above. That of burnt-offerings was a large pile, built of unhewn stone, 32 cubits square at the bottom, and 24 square at the top. The ascent was by a gentle rising, 32 cubits in length, and 16 in breadth.

Altar, or altar, is also used among Christians for the communion-table.

In the primitive church, the altars were only of wood; as being frequently to be removed from place to place. But the council of Paris, in 509, decreed that no altar should be built but of stone.—At first there was but one altar in each church; but the number soon increased; and from the writings of Gregory the Great, who lived in the sixth century, we learn; that there were sometimes in the same church 12 or 13. In the cathedral of Magdeburg there are no less than 49 altars.

The altar is sometimes supported on a single column; as in the subterraneous chapels of St Cecilia, at Rome, &c.; and sometimes by four columns, as the altar of St Sebastian of Crypta Aretinana; but the customary from is, to be a massive of stone-work, sustaining the altar-table. These altars bear a resemblance to tombs: to this purpose, we read in church history, that the primitive Christians chiefly held their meeting at the tombs of the martyrs, and celebrated the mysteries of religion upon them for which reason, it is a standing rule to this day in the church of Rome, never to build an altar, without including the relics of some saint in it.

Altar-thane, or Altarist, in old law-books, an appellation given to the priest or parson of a parish, to whom the altarage belonged. See Altarage.

Altarage, in law, altars erected in virtue of donations before the Reformation, within a parochial church, for the purpose of singing of masses for deceased friends. Altarage likewise signifies the profits arising to the priest on account of the altar.

Altayeff, a town of Huzza, a district of Arabia Felix. It is situated about 60 miles east of Mecca, behind mount Gazwan, where the cold is more intense than in any other part of the district, but the air very wholesome. Its territory abounds in fountains, and produces excellent raisins. The town is surrounded with a wall but is not very large.

Altendorf, a large handsome town in Switzerland, and the chief of the canton of Uri. It is situated below the lake of the four cantons, in a plain, at the foot of a mountain, whose pavilages are difficult, and serve instead of fortifications. It has four churches and two convents: St Martin's and that of the Holy Cross are the finest. The town-house, and the arsenal are also worth seeing. E. Long. 8. 30. N. Lat. 46. 50.

Altea, a sea-port town of Valencia, in Spain. It was taken in 1703, in favour of the archduke Charles; but lost after the battle of Almanza. W. Long. 0. 15. N. Lat. 46. 44.

Altemburg, a town of Transylvania, 17 miles S. W. of Wittenburg, and 35 S. of Claunenburg. E. Long. 23. 5. N. Lat. 46. 25.

Altenburg, a sea-port town of Germany, in the duchy of Holstein, in Lower Saxony. It is a modern town, built by the king of Denmark, and was burnt by the Swedes in 1712; but has since been beautifully rebuilt. The merchants brought from Asia, by the Danish East-India company is sold here. E. Long. 10. 6. N. Lat. 52. 51.

Altenburg, an ancient town in Germany, situated on the river Pleis, with a good castle placed on a rock, in Mifia, in the circle of the Upper Saxony. It was formerly an imperial city, but a present belongs to the house of Saxony. Here is a college which has always been in a flourishing condition. In 1703, there was a nunnery founded for women of high rank, who are Protestants. E. Long. 15. 8. N. Lat. 50. 59.

Altenburg, a small fortified town of Hungary, in the territory of Mofon, near the Danube, about 53 miles from Vienna. E. Long. 35. 30. N. Lat. 48. 15.

Altenburg, or Oswar, a small but strong town of Hungary seated in a marsh, with wide streets. It is near the river Danube, and is surrounded with deep ditches. It is 15 miles from Prague, 40 south-east of Vienna, and 63 south-west of Buda. E. Long. 17. 56. N. Lat. 44. 0.

ALTE
ALTERANTS, or ALTERNATIVE Medicines, such as correct the bad qualities of the blood and other humours, without occasioning any sensible evacuation.

ALTERNATION, in physics, the set of changing the circumstances and manner of a thing; its general nature and appearance remaining the same. Or, it is an accidental and partial change in a body, without proceeding so far as to make the subject quite unknown, or to take a new denomination thereupon. Or, it may be defined, the acquisition or loss of such qualities as are not essential to the form of the body. Thus, a piece of iron, which before was cold, is said to be altered, when it is made hot; since it may still be perceived to be iron, is called by that name, and has all the properties thereof. By this alteration is distinguished from generation and corruption; these terms expressing an acquisition or loss of the essential qualities of thing.

The modern philosophers, after the ancient philosophers, and corporelarians, hold all alteration to be effected by means of local motion. According to them, it always consists either in the emulsion, accession, union, separation, or transposition, of the component particles.

ALTERNATION, a debate or contest between two friends or acquaintance. The word comes from alterari, which anciently signified to converse or hold different opinions. Thus, they say, they never come to an open quarrel, but there is continually some little alteration or other.

ALTERATION, a change or alteration of some thing propounded. This is also called permutation, &c. and is easily found by a continual multiplication of all the numbers, beginning at unity. Thus, if it be required to know how many changes or alterations can be run on six bells, multiply the numbers 1, 2, 3, 4, 5, 6, continually into one another; and the last product gives the number of changes.

ALTERNATIVE, is particularly used for the choice of two things propounded. In this sense, we say, to take the alternative of two propositions.

ALTHEA, MARSHMALLOW: A genus of the polyantha order, belonging to the monadelphia class of plants; and, in the natural method, ranking under the 37th order, Compositae. The characters are: The calyx is a double perianthus, the exterior one nectarifer: The corolla consists of five petals, conflated at the base: The flava of numerous filaments is the anther; and these are hairy. The piliferous has an orbicular generum; a short cylindrical stylus; and numerous brightly stigmatic, the length of the stylus: The pericarpium consists of numerous arillus: The seeds are solitary, and kidney-shaped. There are three

Species. 1. The vulgaris, or common marshmallow, is a native of Britain, and hath a perennial root, and an annual stalk, which perishes every autumn. The stalks grow erect to the height of four or five feet. These are garnished with leaves which are hoary, soft to the touch, and placed alternately on the branches. The flowers come out from under the wings of the seeds, like the willow, and are of a purplish white. 2. The brizula, or hairy marshmallow, is a native of Spain and Portugal. It is a low plant, whose branches trail on the ground, unless they are supported by stalks. The leaves and stalks are beft with strong hairs, the flowers come out like those of the common sort, but are smaller, and have purplish bottoms. 3. The cannabina, or hirsute marshmallow, is a native of Hungary and Italia. It has a woody stem, which rises to the height of four or five feet; and puts out many side-branches. The flowers come out in the same manner as in the others, but are of a deeper red colour. This sort is called the first year, unless the fummer proves warm; but when the plants live through the winter, they will flower early in the following summer, and produce good seeds.

Culture. Though the first sort is found naturally in salt marshes, it will thrive when transplanted into any soil, or in any situation; however, it will always grow larger in moist than in dry soil. It may be propagated either by parting the roots in autumn when the stalks decay, or by fowing the seeds in the spring. If the seeds of the second species are sown in April, the plants will flower in July, and carry ripe seed in September. They ought to be sown in the places where they are to remain, as the roots shoot deep in the ground; so that unless the plants are removed very young, they seldom survive it. The seeds of the cannabina ought also to be sown where the plants are to remain, for the reason just now given. They should have a sheltered situation and dry soil, otherwise they will not live through the winter. Indeed they seldom continue in Britain above two years, with all the care that can be taken of them.

Medicinal Uses. The first is the only species used in medicine. The whole plant, especially the root, is abundant with a mild mucilage. It has the general virtues of an emollient medicine; and proves serviceable in a thin acrimonious state of the juices, and where the natural mucus of the intestines is abraded. It is chiefly recommended in sharp defluxions upon the lungs, hoarseness, dysesthesias; and likewise in nephritie and calculous complaints: not, as some have supposed, that this medicine has any peculiar power of dissolving or expelling the calculi; but as, by lubricating and rendering the vessel, it procures a more free and easy passage. The root is sometimes employed externally for softening and maturating hard tumours; though it is said to give rise in difficult dentition of children.

This root gave name to an official syrup, decoction,
II. the compound, This heights, whether river on foot, but the southern; of it is.

Altitude, or Equal Altitude Instrument, is that used to observe a celestial object when it has the same altitude on the east and west sides of the meridian. See Astronomy, the last section.

Altitude in astronomy, is the distance of a star, or other point, in the mundane sphere, from the horizon.

This altitude may be either true or apparent. — If it be taken from the rational or real horizon, the altitude is said to be true or real; if from the apparent or sensible horizon, the altitude is apparent. — Or, rather, the apparent altitude is such as it appears to our observation; and the true is that from which the refraction has been subtracted.

The true altitudes of the sun, fixed stars, and planets, differ but very little from their apparent altitudes; because of their great distance from the centre of the earth, and the smallness of the earth's semidiameter, when compared thereto. But the difference between the true and apparent altitude of the moon is about 52. This subject is further explained under Astronomy.

Altitude, in geometry, is that of a thing, whether accessible or inaccessible. See Geometry.

The method of taking considerable terrestrial altitudes, of which those of mountains are the greatest, by means of the barometer, is very easy and expeditious. It is done by observing, on the top of the mountain, how much the mercury has fallen below what it was at the foot of the mountain. See Barometer.

Altitude of the Eye, in perspective, is a right line let fall from the eye, perpendicular to the geometrical plane.

Altitude, in geometry, is the distance of a star, or other point, in the mundane sphere, from the horizon.

This altitude may be either true or apparent. — If it be taken from the rational or real horizon, the altitude is said to be true or real; if from the apparent or sensible horizon, the altitude is apparent. — Or, rather, the apparent altitude is such as it appears to our observation; and the true is that from which the refraction has been subtracted.

ed all marks of distress the moment he was removed from his presence, and now thought of nothing but Alvarés. He was therefore recalled; and, being invested with his usual authority, revenged himself severely upon his enemies, by perfuming the king to banish them. Of the 45 years he spent at court, he enjoyed for 30 of them to entire an ascendency over the king, that nothing could be done without his express orders: nay, it is related by Mariana, that the king could not change an officer or servant, or even his clothes or diet, without the approbation of Alvarés. In short, he wanted nothing to complete his grandeur but the name of king: he had all the places in the kingdom at his disposal; he was master of the treasury, and by bounties had gained the hearts of the subjects, that the king, though his eyes now were opened, and his affections sufficiently turned against him, durst not complain. But the day of reckoning was approaching, and at length he was seized: yet not directly, openly, and violently, but with some of that management which upon a similar occasion was formerly employed by Tiberius against Sejanus. During his confinement, however, several attempts to speak to the king in person; but not being able to effect this, he sent the following letter, from which, as well as from the rest of Alvarés’s history, all court favourites may draw abundant matter for edification and instruction. “Sir, it is five and forty years since I was admitted into your service. I do not complain of the rewards I have received; they were greater than my merits or expectation, as I shall not deny. There was but one thing wanting to complete my happiness; and that was to have fixed proper limits in time to this great fortune of mine. While, instead of choosing retirement, after the example of the greatest men, I still continued in the employment, which I thought not only my duty, but necessary for your interest; I fell into this misfortune. It is very hard that I should be deprived of liberty, when I have risked life and fortune more than once to restore it to you. Grief prevents me from saying more. I know that the Delity is provoked against me by my sins; but it will be sufficient for me, if his anger is appeased by the calamities I now suffer. I can no longer bear that prodigious mass of riches, which it was wrong in me to have heaped together. I should willingly resign them, but that every thing I have is in your power; and I am denied the opportunity of showing mankind, that you have raised a person to the height of greatness, who can contain wealth as well as procure it, and give it back to him from whom he received it. But I desire you in the strongest terms, that, as I was obliged by the looseness of the treasury to raise 10,000 or 15,000 crowns by methods I ought not to have taken, you will restore them to the persons from whom they were extorted. If you will not grant this on account of the services I have done, yet I think it necessary to be done from the reason of the thing.”

This letter, however, produced no effect in his favour: Alvarés was tried, and condemned to lose his head. After condemnation, he was removed to Valladolid; and, having confessed himself, and received the sacrament, he was carried, on a mule to the market-place, in
in the middle of which a large scaffold was erected. Mounting the scaffold, he paid reverence to the crofs, and presently gave his hat and lignet to his page, saying, "This is the last gift you will ever receive from me." He then submitted himself to the axe with the utmost intrepidity. Dr. Geddes relates, that he was executed the 4th of June, others the 5th of July, 1453.

ALUDELIS, in chemistry, are earthen pots without bottoms, inferted into each other, and used in sublimations.

ALVEARIUM, in anatomy, the bottom of the conchus, or hollow of the outer ear.

ALVEARIUM also signifies a bee-hive. The word is formed of alveo, a "channel or cavity"; in allusion to the alveoli, or cells in bee-hives.

Some of the ancients use also the word alvearium for a bee-hive, more usually called among others the alvearii, or cells in bee-hives.

In medicine it is of considerable use as an astringent and tonic. It is reckoned particularly serviceable for restraining hemorrhages, and immoderate secretions from the blood; but less proper in intestinal fluxes. In violent hemorrhages, it may be given in doses of 15 or 20 grains, and repeated every hour or half hour till the bleeding abates; in other cases, smaller doses are more advisable; large ones being apt to nauseate the stomach, and occasion violent confluxions of the bowels. It is used also externally, in astringent and repulsive lotions and collyria. Burnt alum taken internally has been highly esteemed in cases of colic. In such instances, when taken to the extent of a scruple for a dose, "it has been found gently to move the belly, and give very great relief from the severe pain. Its official preparations are, for internal use, polius foplicenus, and aqua foplicina externus applications, the aqua aluminis, and quassium aluminis and alumnum aluminis;" which last is no other than the alum dried by fire, or freed from the watery moisture, which, like other alums, it always retains in its crystalline form. By this...
ALUM mines are said to have been first found in Italy in the year 1460; and in 1506 King Henry VII. made a monopolizing grant of this commodity to Angeline Chigi, a merchant of Sienna. In the year 1608 the manufacture of alum was first invented, and successfully practised in England, meeting with great encouragement in Yorkshire, where it was first made, from Lord Sheffield, and other gentlemen of that county. King James I. by advice of his ministry, assumed the monopoly of it to himself, and therefore prohibited the importation of foreign alum; and in 1635 the importation of it was further prohibited by the proclamation of Charles I.

ALUM-works, places where alum is prepared, and manufactured in quantities for sale. They differ from alum-mines, as in the former an artificial alum, and in the latter natural alum, is produced.

ALUNTIIUM, Aluminiolum, (anc. geog.) a town in the north of Sicily, situated on a steep eminence, at the mouth of the Chydas; said to be as old as the war of Troy. Now in ruins; from which arose the hamlet St Filadelfo, in the Val di Demona. The inhabitants were called Haluntinii.

ALVUS, in anatomy, a term used for the belly in general, but more-frequently applied to the bowels.

ALWAIDI! a feft of Mahometans who believe all great crimes to be unpardonable. — The Alvidi stand in opposition to the Morghi. They attribute less efficacy to the true belief in the salvation of men than in the feet of the Muffelmanns.

ALYSSUM, Alyson, or Alysoides, Madwort; (from a reason, to be mad; because it was believed to have the property of curing madness): A genus of the fricculosa order, belonging to the tetradynamia class of plants; and, in the natural method, ranking under the 30th order, Siliquosa. The characters are: The calyx is an oblong four-leaved perianthium: The corolla consists of four cruciform petals; with claws the length of the calyx; the petals shorter; The filamina consist of six filaments, the length of the calyx; two of them rather shorter and denticulated; the anther is crociform and expanding; The pistillum has an ovate germen; the stylus is simple, and the length of the filamina; the stigma is obtuse: The pericarp is a sub-globular emarginated siliqua, furnished with a bilocular stylus, having an elliptic partition; the seeds are few, orbicular, and affixed to filiform receptacles.

Species. Of this genus, Linnaeus enumerates 19 species; but none of them are remarkable either for beauty, or any other property, except the hallifimum; and madwort with whole spear-shaped leaves. This spreads itself upon the ground, and never rises to any height. It produces, at the extremity of its branches, very pretty racemes of small white flowers; of which it is seldom defitute for six or seven months successively; for which reason it well deserves a place in the gardens of the curious.

Culture. Though these plants are natives of the southern parts of Europe; yet, if planted on a dry, lean, or rubbishy soil, they will endure the severest winds in the open air. — The hallifimum is a plant continues about two or three years, and must therefore be often transplanted; or if the seeds are suffered to fall, the plants will rise without any trouble. It may also be propagated by cuttings, which ought to be planted in April or May, and are very apt to take root, if kept shaded in the heat of the day, and gently refreshed with water.

This plant, as already observed, was thought to cure some kinds of madness; but the present practice has entirely rejected it for this or any other purpose.

ALYTARCHA, a priest of Antioch in Syria, who, in the games instituted in honour of the gods, prevailed over the officers who carried rods to clear away the crowd and keep order.

In the Olympic games, the Alytarsha had the same command, and obliged every person to preserve order and decency.

ALZIRA, a town of Spain, in the kingdom of Valencia, seated on the river Xucar, E. Long. 0. 20. N. Lat. 39. 10.

AMA, in ecclesiastical writers, denotes a vessel wherein wine, water, or the like, were held, for the service of the eucharist. In this sense the word is also written amula; sometimes also hama, and hamula.

AMA is sometimes allowed for a wine measure, as a cafe, pipe, or the like.

AMABYR, a barbarous custom which formerly prevailed in several parts of England and Wales, being a sum of money paid to the lord when a maid was married within his lordship. The word is old British, and signifies "the price of virginity."

AMADABAT, a corruption from AHMED ABAD or Ahmed's city; (so called from a king of that name); a large and populous city of Indostan, and the capital of the province of Guzerat. It is situated in E. Long. 72. 12. N. Lat. 23. 0. Amadabat was formerly called Ghurabad, Guzerat; and by Shah Jehan nicknamed Chero-nabad, or "the habitation of dust," because it was much in-commoded therewith. It was the seat of the Guzerat kings, as it is now of the Mogul governor. The city stands in a beautiful plain; and is watered by the little river Schirnetti, which, though not deep, in time of rains overflows the plains prodigiously. The walls are built with stone and brick, shaded at certain distances with great round towers and battlements. It has twelve gates; and, including the suburbs, is about four miles and a half long. The streets are wide. The meydán bâdad, or king's square, is 700 paces long and 400 broad, planted round with trees. On the west side is the castle, well walled with fine stone, and as spacious as a little city; but its inward appearance is not conformable to its external magnificence. The caravansera is on the south of the square, and its chief ornament. Near the meydán also is the king's palace, whose apartments are richly ornamented; and in the midst of the city is the English factory, where they purchase fine chintz, caleecees, and other Indian merchandise. The place is full of gardens flored with fruit-trees, that from an eminence it looks like a wood. The Hindoos have here an hospital for sick beasts, and another for sick birds, which they take great care of. According to some late accounts, this city is little inferior to the best in Europe, and is thought to yield ten times as much revenue as Surat.

AMA, the
AMA

AMADAN, or Hamadan, a town of Persia, between Taurus, and Ipsphan. E. Long. 47° 4'. N. Lat. 41° 30'. It is seated at the foot of a mountain, where there are a great many springs, which water the adjacent country. The extent of the city is very large; and there are a great many waste spots within it, as well as cultivated land. The houses are built of brick hardened in the sun, and have but a very indistinct aspect. There is but one tolerable street; and that is where stuffs, garments, and the like, are exposed to sale: it is straight, long, and wide; and the shops are very well furnished. The adjacent parts are fruitful in corn and rice, in such that the neighbouring provinces are supplied from hence. It is famed to enjoy a very fabulous air, but the cold in winter is intense. The Armenians have a church in this town, but it is a very ill-contrived structure. The Jews have a synagogue near a tomb, where they pretend Esther and Mordecai interred. To this place they come in pilgrimage from several parts of the Levant. About a league from Amadan, there is a mountain called Naithaa, which abounds with all sorts of curious herbs. In the ring, people flock to this mountain from all parts to recover their health, by sucking in the sulphurous effluvia with their breath.

Amadan is a very ancient city. It is said to have been destroyed by Nebuchadnezzar, and rebuilt by Darius, who brought hither all his riches. The kings of Persia frequently retired to this place on account of its delightful situation; for which reason it obtained the name of the Royal city. It was conquered by the khalif Othman, and narrowly escaped being destroyed by Jenghiz Khan in 1220. It had then strong walls and a good castle, which are now in ruins. Its present beauty consists in its gardens and springs.

AMADANAGER, a town in the hither peninsula of India, in the province of Decan. E. Long. 74° 11'. N. Lat. 18° 10'.—It was taken by the Moguls in 1592, after a siege of six months; being at that time defended by a strong castle, situated on an eminence, and surmounted with deep ditches, into which several springs discharged their waters.

AMADIA, a trading town of Aegina, in Curdiistan, belonging to the Turks; seated on a high mountain. E. Long. 43° 1'. N. Lat. 36° 25'.

AMADOV, a kind of black-match, tinder, or touch-wood, which comes from Germany. It is made of a sort of large mushrooms, or spungy excreences, which commonly grow on old trees, especially oaks, ash, and firs. This substance being boiled in common water, and afterwards dried and well beaten, is to be put into a strong lye prepared with salt-petre, after which it is again put to dry in an oven. The druggists sell this match wholesale in France, and several hawkers retail it. Some give to the amado the name of Pyrotechnical Sponge, because of its aptness to take fire.

AMADORY, a kind of cotton which comes from Alexandria, by the way of Marselles.

AMAIN, in the sea-language, a term importing to lower something at once. Thus, to strike amain, is to lower, or let fall, the top-falls; to wave amain, is to make a signal, by waving a drawn sword, or the like, as a demand that the enemy strike their top-falls.

AMAC, a small island in the Baltic sea, near Copenhagen, from which it is separated by a canal, over which there is a draw-bridge. Amak is about four miles long and two broad; and is chiefly peopled by the descendants of a colony from East Friesland, to whom the island was configned by Christian II. at the request of his wife Elizabeth, sister of Charles V., for the purpose of supplying her with vegetables, cheese, and butter. From the intermarriages of these colonies with the Danes, the present inhabitants are chiefly descended; but as they wear their own dress, and enjoy peculiar privileges, they appear a distinct race from the natives. The island contains about six villages, and between 3000 and 4000 souls. It has two churches, in which the ministers preach occasionally in Dutch and Danish. The inhabitants have their own inferior tribunals; but in capital offences are amenable to the king's court of justice at Copenhagen. The old national habit, brought by the original colony when they first migrated to the island, is still in use amongst them. It resembles the habit of the ancient Quakers, as represented in the pictures of the Dutch and Flemish painters. The men wear broad-brimmed hats, black jackets, full glazed breeches of the same colour, loose to the knee, and tied round the waist. The women were drest chiefly in black jackets and petticoats, with a piece of blue glazed cloth bound round their heads. The island is laid out in gardens and pastures; and till, according to the original design, supplies Copenhagen with milk, butter, and vegetables. E. Long. 12° 19'. N. Lat. 55° 20'.

AMAL, a town of Sweden, in the province of Daland, seated on the river Wefer. It has a good harbour; and carries on a great trade, especially in timber, deals, and tar. E. Long. 40° 40'. N. Lat. 58° 50'.

AMALEK, the son of Eliphaz, by Timna his concubine, and the grandson of Eau. Gen. xxxvi. 12. and 1 Chr. i. 36. Amalek succeeded Gatam in the government of Edom. He was the father of the Amalekites; a powerful people who dwelt in Arabia Petraea, between the Dead Sea and the Red sea, or between Havila and Shur (1 Sam. xv. 7.); sometimes in one canton, and sometimes in another. It does not appear that they had cities: for there is no mention of any but one in the Scriptures (id. ib 5.); they living generally in hamlets, caves, or tents.

The Israelits had scarce passed the Red Sea on their way to the wilderness, before the Amalekites came to attack them in the deserts of Raphidin (Ex. xvii. 8.); put to them cruelly to the sword who were obliged, either through fatigue or weakness, to remain behind. Moses, by divine command, directed Joshua to fall upon this people by record the act of humanity which they had committed in a book, in order to have it always before his eyes; and to revenge it in the most remarkable manner. Joshua therefore fell upon the Amalekites, and defeated them while Moses was upon the mountain with Aaron and Hur in company. Moses, during the time of the engagement, held up his hands, to which the success of the battle was owing; for so often as he let them down, Amalek prevailed. But Moses's hands being tired, Aaron and Hur supported his arms, and held them extended, while the battlelasted, which was from morning till the approach of night, when the Amalekites were cut in pieces. This happened in the year of the world 3912, before Chrifi 1491.

A M A

A m a l e k .

The ground of the enmity of the Amalekites against the Israelites is generally supposed to have been an innate hatred from the remembrance of Jacob's depriv- ing their progenitor both of his birthright and bless- ing. Their falling upon them, however, and that without any provocation, when they saw them reduced to so low a condition by the fatigues of their march and the excessive drought they laboured under, was an inhuman action; and justly deserved the defeat which Joshua gave them. Under the Judges (v. 3.), we see the Amalekites united with the Midianites and Moab- ites; in a design to oppress Israel; but Ehud delivered the Israelites from Eglon, king of the Moabites (Judges iii.), and Gideon (chap. vii.) delivered them from the Midianites and Amalekites. About the year of the world 2940, Saul marched against the Amalekites, advanced so far as their capital, and put all the people of the country to the sword; but spared the best of all the cattle and moveables, contrary to a divine command; which act of disobedience was the cause of Saul's future misfortunes.

After this war, the Amalekites scarce appear any more in history. However, about the year of the world 3049, a troop of Amalekites came and pillaged Ziklag, which belonged to David (1 Sam. xxxix.), where he had left his two wives Ahinoam and Abigail; but his returning from an expedition which he had made in the company of Achish into the valley of Jezreel, pursued them, overtook and dispersed them, and recovered all the booty which they had carried off from Zik- lag.

The Arabians maintain Amalek to have been the son of Ham and grandson of Noah; that he was the progenitor both of his nation and his posterity. The Mahometans say that Ad was the father of an ancient tribe called Atit; who were exterminated, as they tell us, for not hearkening to the patriarch Eber, who preached the unity of God to them. Ad had two sons, Schedad and Schedii. Some make him the son of Uz, and grandson of Aram; but the experience of history is against all these traditions.

Amalekites united with the Midianites and Philistines, and never with the Edomites; and when Saul made war upon the Amalekites, and almost utterly destroyed them, we do not find that the Edomites made the least motion towards their assistance, nor to revenge them afterwards. Thence it is thought probable, that the Amalekites who are so often mentioned in Scrip- ture were a free people descended from Canaan, and devoted to the curse as well as the other Amorites, and very different from the descendants of Amalek the grandson of Eglon.

The accounts which the Arabians give us of the Amalekites destroyed by Saul are as follows. Amalek was the father of an ancient tribe in Arabia, exterminated in the reign of Saul. This tribe contained only the Arabians who are called Pure; the remains whereof were mingled with the posterity of Joktan and Adnan, and became Mofarabes or Mofaarabes; that is to say, Arabians blended with foreign nations. They farther believe, that Goliath, who was overcome by David, was king of the Amalekites; and that the giants who inhabited Palestine in Joshua's time were of the same race. That at last part of the Amalekites retired into Africa while Joshua was yet living, and settled upon the coasts of Barbary, along the Mediterranean sea. The sons of Amalek were Ad, a celebrated prince among the Arabians. Some make him the son of Uz, and grandson of Aram; the sons of them. Let this be as it will, the Mahometans say that Ad was the father of an Arabian tribe called Adites; who were exterminated, as they tell us, for not hearkening to the patriarch Eber, who preached the unity of God to them. Ad had two sons, Schedad and Schedii.

AMALFI, an ancient city of Italy, situated in E. Long. 15° 20', Lat. 40° 35'. It is said to have derived its origin from a number of Roman families, who, about the middle of the fourth century, either from private views of emolument, or in consequence of compulsory orders from the emperor, had left Rome and embarked for Constantinople; but meeting with storms on their passage, were cast away on the shores of Salerno, and deprived of the means of pursuing their voyage. In this state of perplexity they long remained, but at last came to the resolution of settling on the present site of Amalfi, where they expected to enjoy security and sufficient plenty of the necessaries of life. The earliest notice of them in this settlement dates no higher than the latter end of the fifth century. Impervious mountains and inaccessible coasts preferred their infant state from the first fury of the Lombards, who seldom attempted the conquest of a maritime people.

In the year 825, when this little republic had, under the patronage of the eastern emperors, attained a degree of wealth and reputation sufficient to excite the ambition of its neighbours, Sico, prince of Salerno, marched a body of troops by night; surprized Amalphi; and, carrying off the greatest part of the inhabitants, compelled them to fix at Salerno, which had lately suffered a great loss of people by an epidemic disorder. But before the fourth year of their captivity was expired, the Amalphins took advantage of the absence of the Salernian chiefs, who were then carrying on a war with the Beneventans; armed themselves; and, after burning and plundering Salerno, marched in triumph back to their own country.

Here they framed a better system of government, and reformed many abuses in their former legislation; adopting various measures that were likely to promote internal concord and defeat the evil intention of foreign enemies. Their first plan was to vest the supreme authority in a temporary prefect; but the experience
of a few years caused them to prefer lodging that
power in the hands of a duke elected for the term of
his natural life. Under these governors Amalfi
attained the summit of her military and commercial glo-
ry. It extended its territory, which reached eastward
from Venice to Cynisca, and westward to the promontory
of Minerva, including likewise the island of Caprea,
and the two islands of the Galli. Towards the north
it comprehended the cities of Lettrea, Gragnanis,
Pimontio, and Capule di Franchi; towards the south,
the of Scala, Ravelli, Minori, Majuri, Atrani, Tra-
monti, Agerula, Citara, Praiano, and Rosiano.
Leo IV. found the Amalians an useful ally in his
wars with the infidels, and honoured the commonwealth
with the title of Defender of the Faith. The Neapol-
tians, with whom, as Greek valets, they were united
in strict bounds of friendship, experienced many sig-
nal favours at their hands; and the Mussulmen them-
theselves found it expedient to court their alliance, and to
enter into treaty with them. Their situation had from
the beginning given them a turn to commerce, and
their attention to naval affairs so much confluence in
the eyes of their protector, the emperor of Constan-
tinople, that by his orders a court was established at
Amalfi for the decision of all controversies arising in
maritime transactions. Its code and reports became the
general rule in those cafes throughout this part of Eu-
rop e; its precedents and decrees were allowed to be
good authority to found judgment upon even in foreign
tribunals. To crown the mercantile and naval glory of
the republic, it was referred to the lot of an Amal-
fi an to make, or at least to perfect, the most impor-
tant discovery ever made for the improvement of navi-
gation. Paifano, a village which stands on the shore
a few miles west of Amalfi, boasted of having given
birth to Flavious Gioia, the inventor of the mariner's
compass.

The merchants of this town engrossed the trade of
the Levant, and transacted the commercial business of
the world in a lucrative and exclusive manner. The
Pisans, Venetians, and Genoese, rose upon their ruin;
and after monopolising the emoluments of trade for
some ages, made way for the more comprehensive and
daring spirit of the present maritime powers.

At present Amalfi is subject to Naples, and is the
see of an archbishop. It is but a shadow of what it
was in its flourishing state, when it extended over the
stupendous rocks that hang on each side, still crowned
with battlemented walls and ruined towers. Its build-
ings, Mr Swinburne says, are not remarkable for elag-
ge or size; and contain at most 4000 inhabitants,
who seem to be in a poor line of life. The cathedral
is an uncoath building. Under the choir is the chas-
pel and tomb of the apostle St Andrew; to whose
honour the edifice was dedicated, when Cardinal
Capuano in 1208 brought his body from Constantin-
ople.

AMALGAM, mercury united with some metal.
AMALGAMATION, the operation of making an
amalgam, or mixing mercury with any metal.

For the combination of one metal with another, it
is generally sufficient that one of them be in a state of
fluidity. Mercury being always fluid, is therefore
capable of amalgamation with other metals without
heat; nevertheless, heat considerably facilitates the
operation.

To amalgamate without heat requires nothing more
than rubbing the two metals together in a mortar 
but the metal to be united with the mercury should be
previously divided into thin plates or grains.

When heat is used (which is always most effectual
and with some metals indispensably necessary), the
mercury should be heated till it begins to fumke, and
the grains of metal made red-hot before they are
thrown into it. If it be gold or silver, it is sufficient to
stir the fluid with an iron rod for a little while, and
then throw it into a vessel filled with water. This
amalgam is used for gilding or silvering on copper,
which is afterwards exposed to a degree of heat suffi-
cient to evaporate the mercury.

Amalgamation with lead or tin is effected by pouring
an equal weight of mercury into either of these
metals in a state of fusion, and stirring with an iron
rod. Copper amalgamates with great difficulty, and
iron not at all.

AMALTHEA, the name of the Cumean Sibyl,
who offered to Tarquin Superbus nine books, con-
taining the Roman defineds, and demanded 300 pieces
of gold for them. He derided her; whereupon
she threw three of them into the fire; and retuming, asked
the same price for the other six; which being denied;
she burnt three more; and returned, still demanding
the same price. Upon which Tarquin consulting the
pontiffs, was advised to buy them. These books were
in such esteem, that two magistrates were created to
consult them upon extraordinary occasions.

AMALTHEA, in pagan mythology, the daughter
of Melitus, king of Crete, and the nurse of Jupiter,
whom she fed with goat's milk and honey. Accord-
ing to others, Amalthea was a goat, which Jupiter,
translated into the sky, with her two kids, and gave
one of her horns to the daughters of Melitus, as a re-
ward for the pains they had taken in attending him.
This horn had the peculiar property of furnishing them
with whatever they wished for; and was thence called
the cornucopia, or horn of plenty.

AMALTHEUS (Jerome, John Baptista, and Cor-
nielle), three celebrated Latin poets of Italy, who flou-
ried in the 16th century. Their compositions were
printed at Amsterdam in 1683. One of the prettiest
pieces in that collection is an epigram on two children,
whose beauty was very extraordinary, though each of
them was deprived of an eye:

- Lumine Acon dextro, capta est-Leonilla sinistro:
  Et poterat forma vincere uterque deos.
- Parve puer, lumen quod habes concede fori;
  Sic tu cæsus Amor, fic erit illa Venus.

AMAMAS (Sixtus), professor of the Hebrew tongue
in the university of Franeker, a man of great learning,
born in Friesland, and had studied under Druñas.
He published a criticism upon the translation of the
Pentateuch; collated the Dutch translation of the Bi-
ble with the original and most accurate translations;
and wrote a commentary on the Vulgate translation of the
historical books of the Old Testament, Job, the Psalms
and Canticles. It is impossible to answer the reasons
whereby he shows the necessity of consulting the origi-

als.
AMAND (Mark-Anthony-Gerard, sieur de St.), a French poet, was born at Roan in Normandy in 1594. In the epistle dedicatory to the third part of his works, he tells us, that his father commanded a squadron of ships in the service of Elizabeth queen of England for two years, and that he was for three years prisoner in the Black Tower at Constantinople. He mentions also, that two brothers of his had been killed in an engagement against the Turks. His own life was spent in a continual succession of travels, which was of no advantage to his fortune. There are miscellaneous poems of this author, the greatest part of which are of thecomic or burlesque, and the amorous kind. Though there are many blemishes in his poems, yet he had the talent of reading them so agreeably a manner, that every one was charmed with them. In 1650, he published "Stances de la grotte de la reine de Pologne," which was printed at Paris in 1656. Mr Broclette says that he wrote also a poem upon the moon, wherein he paid a compliment to the moon it fell into contempt. Amand wrote also a very first-rate piece, intituled "Stances à M. Corneille, fur fon imitation de Jefus Christ," which was printed at Paris in 1653, he printed his "Moife fauve, idyle heroïque." This poem had at first many admirers: Mons. Chapelain called it a speaking picture; but it has since fallen into contempt. Amand wrote also a very devout piece, intituled "Stances à M. Corneille, fur fon imitation de Jefus Christ," which was printed at Paris in 1653. Mr Broclette says that he wrote also a poem upon the moon, wherein he paid a compliment to Lewis XIV. upon his skill in swimming, in which he used often to exercise himself when he was young, in the river Seine; but the king could not bear this poem, and continued from evening till the next morning. — That prince, thinking the name too vulgar, changed it into that of the feast of the gods, in regard each person here represented some deity as it fell to his lot. The queen assumed the name of Amarante; that is, unfading, or immortal. The young nobility, dressed in the habit of nymphs and sibyls, served the gods at the table. At the end of the feast, the queen threw off her habit, which was covered with diamonds, leaving it to be pulled in pieces by the masques; and, in memory of so gallant a feast, founded a military order, called in Sweden Gefchilder, into which all that had been present at the feast were admitted, including 16 lords and as many ladies, besides the queen. Their device was the cypher of Amarante, composed of two A's, the one erect, the other inverted, and interwoven together; the whole inclosed by a laurel crown, with this motto, Dolce nella memoria.

Bulstrode Whitlock, the English ambassador from Cromwell to the court of Sweden, was made a knight of the order of Amarante; on which account it seems to be, that we sometimes find him styled Sir Bulstrode Whitlock.

AMARANTHOIDES, in botany, the trivial name of a species of ilicicenum. See I. LEC. EBRUM.

AMARANTHUS (of a private, and upurative, to wither, because the flower of this plant when cropped does not soon wither), Amarant, of flower: gentle: A genus of the pentandra order, belonging to the monoezia class of plants; and, in the natural method, ranking under the 54th order, Bifclierum. The characters are: The nuc calyx is a five or three leaved perianthium, erec, coloured, and perisepht; There is no corolla: The flavus consist of five or three erec capitil filaments, the length of the calyx: the anther are oblong and verflis: The female calyx the same as the male, and no corolla: The pisfliumus has an ova german; the fllyli are three, short, and stubulated; the filgmina simple and perisepht: The pericarpium is an .
AMARYLLIS, LILY-ASSIMILATE: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 9th order, Spatulaceae. The characters are: The calyx is an oblong obutate spatha, emarginated, and withering. The corolla consists of six petals, lanceolate: the stamens consist of fix filabulate stamens; the androsmes oblong, incumbent, and ascending: the pistillum has an oblong deccussate stamens beneath: a filiform style, nearly the length of the stamens, the stigma trifid and slender: The pericarpium is an ovate trilocular capsule, with three valves: The seeds are many.

Principal Species. I. The lutea, or autumnal narcissus. This is usually fold by gardeners, along with colchicums, for autumnal ornaments to gardens. For this purpose it is very proper, as it will keep flowering from the beginning of September to the middle of November, provided the frost is not too severe as to destroy the flowers. Although there is but one flower in each cover, yet there is a succession of flowers from the same root, especially when they are suffered to remain three or four years removed. The flowers seldom rise above three or four inches high. They are shaped somewhat like the flowers of the yellow crocus; the green leaves come up at the same time, like the saffron; and, after the flowers are past, the leaves increase all the winter. The roots are bulbous, and shaped like those of the narkis: so are proper ornaments for such borders as are planted with cyclamen, saffron, autumnal crocus, colchicums, and such low autumnal flowers. 2. The formosifima, or jacobea lily, produces its flowers two or three times in a year, without being regular to any season. The flowers are of a deep red, the under petals very large, and the whole flower stands nodding on one side of the stalk, making a beautiful appearance. The stamens of the flowers are produced from the sides of the bud; so that when the flowers produced on one side are decayed, another stalk arises from the other side of the bud; but there is no more than one flower produced on the same stalk. When the roots are in vigour, flowers will be produced from March to the beginning of September. 3. The farricius, or Guernsey lily, is supposed to have come originally from Japan, but has been many years cultivated in the gardens of Guernsey and Jersey; in both which places they seem to thrive as well as if it was their native country, and from these islands their roots are sent annually to the curious in most parts of Europe. The flowers of this species are admired for the richness of their colour, which is commonly red, though they have no scent. They appear towards the end of September: and, if properly managed, will continue a month in beauty. The roots of these plants do not flower again the succeeding year, as is the case with many other bulbs; but if their bulbs contain two buds in their centre, which is often the case, they frequently flower twice in three years: after which the same individual root does not flower again in several years, but only the offsets from it. 4. The regina, or belladonna lily, is a native of Portugal, where it was formerly cultivated in great plenty; but of late it has been propagated by the Jacobaea lily, so that the roots which have been taken from that country for some time past for the belladonna, have generally proved the Jacobaea lily. This kind, if properly managed, will sometimes put out two or three stems, growing near three...
three feet high, and produce many flowers in each umbel, which make a fine appearance during the month of October. 5. The zeylanica, or Ceylon lily, is a native of the West Indies, and usually flowers in June. Sometimes the same root will flower again in autumn, but the flowers are of no long duration. 6. The orientalis, or lily siccifolium, with leaves shaped like a tongue. This is a native of the Cape of Good Hope. The bulbs of the root are large and almost round; the leaves long, broad, and rounded at their extremities; these spread two ways on the surface of the ground, and do not come up till after the flower-item appears, which is generally in November. After the flowers are past, the leaves increase till spring, and in May they begin to decay; so that from the middle of June to October the roots are entirely delitiate of leaves.

Cultivation. The first fort is very hardy, and will thrive in almost any foil or situation; but will succeed best in a fresh light dry soil, and not too near the dripping of trees, or too near walls. It increases very fast by offsets, by which all the other species are also to be propagated. These roots may be transplanted any time from May to the end of July; after which it will be too late to remove them. The soil ought to be kept in a moderate state all winter, which case it will send forth plenty of offsets, that will produce vigorous plants. The roots of the Guernsey lily are generally brought over in June and July; but the sooner they are taken out of the ground after the leaves decay, the better: for although the roots which are taken up when their flower-items begin to appear, will flower; yet their flowers will not be so large, nor will their roots be near so good after as those which were removed before they sent forth fresh fibres. When these roots come over, they should be planted in pots filled with fresh, light sandy earth, mixed with a little very rotten dung, and placed in a warm situation, observing now and then to refresh the earth with water: but by no means let them have too much wet, for they will not root their roots, especially before they come up. About the middle of September, such of the roots as are strong enough to flower will begin to show the bud of their flower-item; therefore these pots ought to be removed into a situation where they may have the benefit of the sun, and be sheltered from strong winds. When the flowers begin open, the pots should be removed under shelter, to prevent Injury from too much wet. After the flowers are decayed, the green leaves will begin to show forth in length; and, if sheltered from severe cold, will continue growing all winter: but they must have as much free air as possible in mild weather, and are to be covered only, in great rains or frosts. For this purpose, a common hot-bed frame is the most proper shelter for them: the glasses of which may be taken off every day in dry open weather, which will encourage the leaves to grow strong and broad. The roots should be transplanted every fourth or fifth year, toward the end of June or beginning of July; the offsets also should be taken off and planted in pots, where in three years time they will produce flowers. The other species of the amaryllis may easily be raised by taking care to shelter them in a stove from the winter's cold.

AMARYNTHUS (anc. geog.), a hamlet of Eretrias, in the island of Euboea, about seven stadia distant from its walls. Here Diana was worshipped by an annual solemnity, at which those of Carytyas assisted; hence the title of the goddess was Amalthea, and Amayris.

AMASIA (anc. geog.), now Marpurg, a city in the landgrave of Hesse, on the Lahn. According to others, it is Eubon in Westphalia. AMASIA, an ancient town of Turkey, in Natolia, remarkable for the birth of Strabo the geographer. It is the residence of a bailiff, and gives its name to the province it stands in, where there are the best wines and the best fruits in Natolia. It is seated near the river Iris or Cafalmack; and was anciently the residence of the kings of Cappadocia. E. Long. 36° N. Lat. 39° 33'.

AMASIA, the name of the northern division of Leffer Afia, lying on the south shore of the Euxine sea in Natolia. It takes its name from Amasia the capital, mentioned in the preceding article.

AMASONIA, in botany: A genus of the angio-

AMATHUS, a very ancient town in the south of Cyprus (Strabo, Pтолеmy): so called from Amathus the founder; or, according to others from Amath, a Phoenician town sacred to Venus, with a very ancient temple of Adonis and Venus: and hence Venus is denominated Anathusia (Tacitus). According to Ovid, it was a place rich in copper-ore, and where the inhabitants became Herae, or horned. Now called Limifso.

AMATHUS (anc. geog.), a town of the tribe of Gad, beyond Jordan; but whether at a greater or less distance from it, is not so easy to determine. Eufebius places it in the Lower Persea; Roland, in Ramoth-Gilead. Gabinius, proconsul of Syria, established five judicial conventions in Judea; two of which were on the other side Jordan; one at Gadera, the other at Amathus (Josephus).

AMATORII MUSCULI, in anatomy, a term sometime used for the obliquus superior and obliquus inferior muscles of the eye, as these muscles assist in ogling or drawing the eye sideways.

AMATRICE, a city of the kingdom of Naples, in the farther Abruzzo, upon the confines of the pope's territories, and the marquisate of Ancona.

AMAUROSIS, in medicine, a deprivation of sight, the eye remaining fair, and seeming unaffected. A perfect amaurosis is when the blindness is total; when there is still a power of distinguishing light from darkness, the disease is called by M. de St Ives an imperfect amaurosis. There is a periodical fort which comes on instantaneously, continues for hours, or days, and then disappears. Mr Hay, surgeon at Leeds, mentions several cases of patients affected with the amaurosis who were relieved by being electrified.

AMAZONIA, or the country of the American
Amazonia. Amazons, is situat between 50 and 70 degrees of west latitude; and between the equator and 50 degrees of south latitude; being bounded on the south by La Plata, on the west by Peru, on the north by the province of Terra Firme, and on the east by Brazil.

With respect to the Amazons paid to have given name to this territory, they have been represented as governed and led to war only by their queen. No men were suffered to live among them; though those of some neighbouring nations were suffered to visit them, at a certain season, for the sake of procreation. The females issuing from this commerce were bred up with care, and instructed in what relates to war and government; as to the males, they were sent away into the country of their fathers. But no such nation is at present to be found, any more than the giants and cannibals mentioned by the first adventurers thither.

Amazonia is generally a flat region, abounding in woods, lakes, rivers, bogs, and mosquitoes. The chief river, and one of the largest in the world, is that called the river of Amazons, or the Orelliana, which is formed by two large rivers, the one rising in the province of Quito, a little south of the equator, in 73 degrees of well longitude, and the other, named Xauxa, rising in the lake of Bourbon, near the Andes, in ten degrees of south latitude. These two rivers uniting on the confines of Peru and Amazonia, in three degrees odd minutes of south latitude, assume the name of Amazon; whence running eastward upwards of 300 miles, and afterwards inclining to the north, they fall into the Atlantic ocean by 84 channels, which in the rainy season overflow the adjacent country. Besides the two streams mentioned, a multitude of others, both on the north and south side, contribute to the formation of this extraordinary river. As it runs almost across the broadest part of South America, it is computed to be between four and five thousand miles in length, including all its windings. Its channel from Junta de los Rios, about 60 degrees from its head, to the river Maranon, is from one to two leagues broad; it then widens from three to four, and becomes gradually broader as it approaches the ocean. Between the places last mentioned, its depth is from five to ten fathoms; but from Maranon to Rio Negro it increases to 20 fathoms; after which it is sometimes 30, and some times 50 fathoms, or more, till it comes near to the end of its course. It has no sand-banks, nor does the shore ever lo as to render it dangerous for vessels.

The manatu and tortoise abound both upon the banks of this and the other rivers; and the fishermen must be upon their guard against the crocodiles, alligators, and water serpents, which also swarm here.

The air, as in the countries under the same parallel, is observed to be nearly as cool under the equator as the air in the tropics, on account of the rains continuing longer, and the sky in that season being clouded. Besides, an-easterly wind sets from the Atlantic up the river so strong, that vessels are carried by it against the stream.

The produce of the country is Indian corn and the cassava root, of which they make flour and bread; tobacco, cotton, sugar, farfaparilla, yams, potatoes, and other roots. They have also plenty of venison, fish, and fowl. Among the latter are vast flocks of parrots of all colours, the flesh of which serves for food and the feathers for ornament. All the trees here are evergreens; and fruits, flowers, and herbs, are in perfection all the year round. The principal fruits are cocoa-nuts, ananas or pine-apples, guavas, bananas, and fuch others as are usually found between the tropics. The forest and timber trees are cedar, Brazil wood, oak, ebony, logwood, iron-wood, so called from its weight and hardnefs, and several sorts of dyeing wood.

The natives are of the common stature, with good features, a copper complexion, black eyes and hair. It is computed that there are of them about 150 different tribes or nations, and the villages are so numerous as to be within call of one another. Among these the Homagues, a people near the head of the river, are famous for their cotton manufactures; the Juries, who live between five and ten degrees of latitude, for their joiners' work, and the Wroffaires for their earthware. The Topinambes, who inhabit a large island in the river, are remarkable for their strength. Some of these nations frequently make war upon each other. Their armour consists of darts, javelins, bows and arrows, and they wear targets of cane, or fish-skin. They make shields of their prisoners, whom they otherwise use very well. Every tribe is governed by its respective chief or king, the marks of whose dignity are a crown of parrots' feathers, a chain of lions' teeth or claws hung round his neck, or girt about his waist, and a wooden sword, which he carries in his hand.

Most of these nations, except the Homagues, go naked. The men thrust pieces of cane through their ears and under lips, as well as through the skin of the pudenda. At the gristle of their noses they also hang glass beads, which hang to and fro when they speak. They are such skilful marksmen, that they will shoot five as they swim; and what they catch, they eat without bread or salt. They worship images, which they always carry with them on their expeditions; but they neither have temples nor any order of priests; and permit both polygamy and concubinage.

The country affords neither gold nor silver mines; only a small quantity of the former is found in the rivulets which fall into the Amazon near its sources in Peru. While the Spaniards imagined that it contained those metals, they made great efforts from Peru to reduce this territory to subjection; till being at length undeceived, they abandoned the design. Amazonia, in antiquity, a nation of female warriors, who founded an empire in Asia Minor, upon the river Thermodon, along the coasts of the Black Sea. They are said to have formed a state out of which men were excluded. What commerce they had with that sex, was only with strangers; they killed all their male children; and they cut off the right breast of their females, to make them more fit for the combat. From which last circumstance it is, that they are supposed to take their name, viz., from the primitive, man, mamma, mamma, "breast." But Dr Bryant, in his Analysis of ancient mythology, explains this account as fabulous; and observes, that they were in general Cuthite colonies from Egypt and Syria, who formed settlements in different countries, and that they derived their name from xon, the "fun," which was the national object of worship. Vol. iii. p. 493. — It has indeed
Amazons

Amazons have been controverted even among ancient writers, whether ever there really were such a nation as that of the Amazons. Strabo, Pausanias, and others, deny it. On the contrary, Herodotus, Polybius, Dio- dorus Siculus, Trogus Pompeius, Justin, Pliny, Mela, Plutarch, &c., expressly affirm it.

M. Petit, a French physician, published a Latin dissertation in 1685, to prove that there was really a nation of Amazons; it contains abundance of curious inquiries, relating to their habit, their arms, the cities built by them, &c. Others of the moderns also maintain, that their existence is sufficiently proved by the testimony of such of the historians of antiquity as are most worthy of credit; by the monuments which many of them have mentioned; and by medals, some of which are still remaining; and that there is not the least reason to believe that what is said of them is fabulous.

The Amazons are mentioned by the most ancient of the Greek writers. In the third book of the Iliad, Homer represents Priam speaking of himself as having been young, in the earlier part of his life, in a battle with the Amazons: and some of them afterwards came to the siege of Troy. The Amazons are particularly mentioned by Herodotus. That historian informs us, that the Greeks fought a battle with the Amazons on the river Thermodoon, and defended them. After their victory, they carried off all the Amazons they could take alive, in three ships. But whilst they were out at sea, these Amazons confpired against the men, and killed them all. Having, however, no knowledge of navigation, nor any skill in the use of the rudder, sails, or oars, they were driven by wind and tide till they arrived at the precipices of the lake Mazoia, in the territories of the Scythians. Here the Amazons went ashore, and marching into the country, seized and mounted the first horses they met with, and began to plunder the inhabitants. The Scythians at first conceived them to be men; but after they had had skirmishes with them, and taken some prisoners, they discovered them to be women. They were then unwilling to carry on hostilities against them; and by degrees a number of the young Scythians formed connections with them, and were desirous that these gentle dames should live with them as wives, and be incorporated with the rest of the Scythians. The Amazons agreed to continue their connection with the Scythian husbands, but refused to associate with the rest of the inhabitants of the country, and especially with the women of it. They afterwards prevailed upon their husbands to retire to Sarmatia, where they settled. "Hence," says Herodotus, "the wives of the Sarmatians still continue their ancient way of living. They hunt on horseback in the company of their husbands, and sometimes alone. They march with their armies, and wear the same dress with the men. The Sarmatians use the Scythian language, but corrupted from the begining, because the Amazons never learned to speak correctly. Their marriages are attended with this circumstance: no virgin is permitted to marry till she has killed an enemy in the field; so that some always grow old before they can qualify themselves as the law requires."

Diodorus Siculus says, "There was formerly a nation who dwelt near the river Thermodoon, which was subjected to the government of women, and in which the women, like men, managed all the military affairs. Among these female warriors, it is said, was one who excelled the rest in strength and valour. She assembled together an army of women, whom she trained in military discipline, and subdued some of the neighbouring nations. Afterwards, having by her valour increased their fame, she led her army against the rest; and being successful, she was so exulted, that she flew herself the daughter of Mars, and ordered the men to spin wool, and do the work of the women within doors. She also made laws, by which the women were enjoined to go to the wars, and the men to be kept at home in a servile state, and employed in the meanest offices. They also debilitated the arms and limbs of those male children who were born to them, that they might be thereby rendered unfit for war. They feared the right breasts of their girls, that they might be no hindrance to them in fighting: from whence they derived the name of Amazons. Their queen, having become extremely eminent for skill and knowledge in military affairs, at length built a large city at the mouth of the river Thermodoon, and adorned it with a magnificent palace. In her enterprise she exactly adhered to military discipline and good order; and she added to her empire all the adjoining nations, even to the river Tanais. Having performed these exploits, she at last ended her days like a hero, falling in a battle, in which she had fought courageously. She was succeeded in the kingdom by her daughter, who imitated the valour of her mother, and in some exploits excelled her. She cauited the girls from their very infancy to be exercised in hunting, and to be daily trained in military exercises. She instituted solemn festivals and sacrifices to Mars and Diana, which were named Tauropoli. She afterwards carried her arms beyond the river Tanais, and subdued all the people of those regions even unto Thrace. Returning then with a great quantity of spoil into her own kingdom, she caused magnificent temples to be erected to the deities before mentioned; and she gained the love of her subjects by her mild and gentle government. She afterwards undertook an expedition against those who were on the other side of the river, and subjected to her dominion a great part of Asia, extending her arms as far as Syria."

Diodorus also mentions another race of Amazons who dwelt in Africa; and whom he speaks of as being of greater antiquity than those who lived near the river Thermodoon. "In the western parts of Libya," says he, "upon the borders of those tribes that are habitable, there was an ancient nation under the government of women, and whose manners and mode of living were altogether different from ours. It was the custom for these women to manage all military affairs; and for a certain time, during which they preferred their virginity, they went out as soldiers in the field. After some years employed in this manner, when the time appointed for this purpose was expired, they associated themselves with men, in order to obtain children. But the magistracy, and all public offices, they kept entirely in their own hands. The men, as the women are with us, were employed in household affairs, submitting themselves wholly to the authority of their wives. They were not permitted to take any part in military
military affairs, or to have any command, or any public authority, which might have a tendency to encourage them to cast off the yoke of their wives. As soon as any child was born, it was delivered to the father, to be fed with milk or such other food as was suitable to its age. If females were born, they feared their breasts, that they might not be burdened to them when they grew up; for they considered them as great hindrances in fighting."

Justinian represents the Amazonian republic to have taken its rise in Scythia. The Scythians had a great part of Asia under their dominion upwards of 400 years, till they were conquered by Ninus, the founder of the Assyrian empire. After his death, which happened about 150 years before the Christian era, and that of Semiramis and their son Ninias, Lulus and Scelopites, princes of the royal blood of Scythia, were driven from their country by other princes, who like them aspire to the crown. They departed with their wives, children, and friends, and being followed by a great number of young people of both sexes, they pulled into Asiatic Sarmatia, beyond mount Camalus, where they formed an establishment, supplying themselves with the riches they wanted, by making excursions into the countries bordering on the Euxine Sea. The people of those countries, either from the incursions of their new neighbours, united, surprised, and massacred the men.

The women then resolving to revenge their death, and at the same time to provide for their own security, resolved to form a new kind of government, to choose a queen, enact laws, and maintain themselves, without men, even against the men themselves. This design was not so very surprizing as at first sight appears: for the greatest number of the girls among the Scythians had been injured to the same exercises as the boys; to draw the bow, to throw the javelin, to manage other arms; to riding, hunting, and even the painful labours which they now considered as an infupportable slavery. As soon as the girls permitted, they took away the right breast, that they might draw the bow with the greater force. The common opinion is, that they burnt that breast, by applying to it, at eight years of age, a hot brazen instrument, which indefatigably dried up the fibres and glands: some think that they did not make use of so much ceremony, but that when the part was formed they got rid of it by amputation: some, again, with much greater probability, affert, that they employed no violent measures; but, by a continual compulsion of that part from infancy, prevented its growth, at least so far as to hinder its ever being inconvenient in war.

Plutarch, treating of the Amazons in his life of Theseus, considers the accounts which had been preserved concerning them as partly fabulous and partly true. He gives some account of a battle which had been fought between the Athenians and the Amazons at Athens; and he relates some particulars of this battle, which had been recorded by an ancient writer named Cidemus. He says, "That the left wing of the Amazons moved towards the place which is yet called Amazonium, and the right to a place called Pryxa, near Chrysa; upon which the Athenians, infuing from behind the temple of the muses, fell upon them; and that this is true, the graves of those who were slain, to be seen in the streets that lead to the gate Piraeus, by the temple of the hero Chaleodis, are sufficient proof. And here it was that the Athenians were routed, and shamefully turned their backs to women, as far as to the temple of the Furies. But fresh supplies coming in from Palladium, Ardetus, and Lyceum, charged their right wing, and beat them back into their very tents; in which action a great number of the Amazons were slain." In another place he says, "It appears that the passage of the Amazons through Thessaly was not without opposition; for there are yet to be seen many of their sepulchres nearScotus and Cynephale." And in his life of Pompey, speaking of the
The Amazons, Plutarch says, "They inhabit those parts of mount Caucasus that look towards the Hyrcanian sea (not bordering upon the Albanians, for the territories of the Goths and the Leges lie betwixt): and with these people do they yearly, for two months only, accompany and cohabit, bed and board, near the river Thermodoon. After that they retire to their own habitations, and live alone all the rest of the year."

Quintus Curtius says, "The nation of the Amazons is situated upon the borders of Hyrcania, inhabiting the plains of Hermicyra, near the river 1 thermodoon. Their queen was named Thalestris; and she had under her subjection all the country that lies between mount Caucasus and the river Phasis. This queen came out of her dominions, in conformance of an ardent desire she had conceived to see Alexander; and being advanced near the place where he was, she previously sent messengers to acquaint him, that the queen was come to have the satisfaction of seeing and conversing with him.

Having obtained permission to visit him, she advanced with 300 of her Amazons, leaving the rest of her troops behind. As soon as she came within sight of the king, she leaped from her horse, holding two javelins in her right hand. The apparel of the Amazons does not cover all the body, for their left side is naked down to the stomack, nor does the skirts of their garments, which they tie up in a knot, reach below their knees. They prefer their left breast entire, that they may be able to fuckle their female offspring; and they cut off and fear their right, that they may draw their bows, and cast their darts, with the greater ease. Thalestris looked at the king with an undaunted countenance, and narrowly examined his person; which did not, according to her ideas, come up to the fame of his great exploits: For the barbarians have a great veneration for a majestic person, deeming those only to be capable of performing great actions, on whom nature has conferred a dignified appearance. The king having asked her whether she had any thing to desire of him, she replied, without scruple or hesitation, that she was come with a view to have children by him, the being worthy to bring him heirs to his dominions. Their offspring, if of the female sex, she would retain herself; and if of the male sex, it should be delivered to Alexander. He then asked her, whether she would accompany him in his wars? But this she declined, alleging, that she had left nobody to take care of her kingdom. She continued to solicit Alexander, that he would not send her back without conforming to her wishes; but it was not till after a delay of 13 days that he complied. She then returned to her own kingdom.

Justin also repeatedly mentions this visit of Thalestris to Alexander; and in one place he says, that she made a march of 25 days, in order to obtain this meeting with him. The interview between Alexander and Thalestris is likewise mentioned by Diodorus Siculus. The learned Goropius, as he is quoted by Dr Petit, laments, in very pathetic terms, the hard fate of Thalestris, who was obliged to travel so many miles, and to encounter many hardships, in order to procure this interview with the Macedonian prince, and, from the circumstances, is led to consider her action as incredible. But Dr Petit, with equal erudition, with equal eloquence, and with superior force of reasoning, at length determines, that her journey was not founded upon irrational principles, and that full credit is due to those grave and venerable historians by whom this transaction has been recorded.

The Amazons are represented as being armed with bows and arrows, with javelins, and also with an axe of a particular construction, which was denominated the axe of the Amazons. According to the elder authors, this axe was invented by Penthesilea, one of their queens. On many ancient medals are representations of the Amazons, armed with these axes. They are also said to have had backlers in the shape of a half-moon.

The Amazons are mentioned by many other ancient authors besides those which have been enumerated; and if any credit be due to the accounts concerning them, they subsisted through several ages. They are represented as having rendered themselves extremely formidable; as having founded cities, enlarged the boundaries of their dominions, and conquered several other nations.

That at any period there should have been women, who, without the assistance of men, built cities and governed them and called and administered public affairs, and extended their dominion by arms, is undoubtedly contrary to all that we have seen and known of human affairs, as to appear in a very great degree incredible; but that women may have excelled sufficiently robust and sufficiently courageous to have engaged in warlike enterprises, and even to have been successful in them, is certainly not impossible, however contrary to the usual course of things. In support of this idea of the question, it may be urged, that women who have been early trained to warlike exercises, to hunting, and to an hard and laborious mode of living, may be rendered more strong, and capable of more vigorous exertions, than men who have led indolent, delicate, luxurious lives, and who have seldom been exposed even to the inclemencies of the weather. The limbs of women, as well as of men, are strengthened and rendered more robust by frequent and laborious exercises. A nation of women, therefore, brought up and disciplined as the ancient Amazons are represented to have been, would be superior to an equal number of effeminate men; though they might be much inferior to an equal number of hardy men trained up and disciplined in the same manner.

That much of what is said of the Amazons is fabulous, there can be no reasonable doubt; but it does not therefore follow, that the whole is without foundation. The ancient medals and monuments on which they are represented are very numerous, as are also the testimonies of ancient writers. It seems not rational to suppose that all this originated in fiction, though it may be much blended with it. The Abbe Guyon speaks of the history of the Amazons as having been regarded by many persons as fabulous, "rather from prejudice than from any real and solid examination;" and it must be acknowledged, that the arguments in favor of their existence, from ancient history, and from ancient monuments, are extremely powerful. The fact seems to be, that truth and fiction have been blended in the narrations concerning these ancient heroines. A character of heroism in women have occasionally occurred in modern times, figures resembling that of the ancient Amazons. The times and the manners of chivalry in particular, by bringing great enterprizes,
bold adventures, and extravagant heroism, into fashion, inspired the women with the same taste. The women, in consequence of the prevailing passion, were now seen in the middle of camps and of armies. They quitted the soft and tender inclinations, and the delicate offices of their own sex, for the toils and the toilsome occupation of ours. During the crusades, animated by the double enthusiasm of religion and of valor, they often performed the most romantic exploits; obtained indulgences on the field of battle, and died with arms in their hands, by the side of their lovers or of their husbands.

In Europe, the women attacked and defended fortifications; princesses commanded their armies, and obtained victories. Such was the celebrated Joan de Montfort, disputing for her duchy of Brestagne, and fighting in person. Such was that still more celebrated Margaret of Anjou, active and intrepid general and soldier, whose genius supported a long time a feeble husband; which taught him to conquer; which replaced him upon the throne; which twice relieved him from prison; and, oppressed by fortune and by rebels, which did not bend till after she had decided in person twelve battles.

The warlike spirit among the women, confinset with ages of barbarism, when every thing is impetuous but nothing is fixed, and when all excess is the excess of force, continued in Europe upwards of 400 years, showing itself from time to time, and always in the middle of convulsions or on the eve of great revolutions. But there were eras and countries in which that spirit appeared with particular lustre. Such were the displays it made in the 15th and 16th centuries in Hungary, and in the ilands of the Archipelago and the Mediterranean when they were invaded by the Turks.

Among the striking instances of Amazonian conduct in modern ladies, may be mentioned that of Jane of Belleville, widow of Monf. de Clifton, who was beheaded at Paris in the year 1443, on a suspicion of carrying on a correspondence with England and the Count de Montfort... This lady, filled with grief for him to modern manners, and exhibited among the female inhabitants of that province were spectators more than once, whilst their villages were all in a blaze, of one of the finest women in Europe, with a sword in one hand and a torch in the other, urging the carnage, and saying with pleasure all the horrors of war.

We read in Mazarin, under the article of the Croisade, preached by St Bernard in the year 1147, "That many women did not content themselves with taking the crofs, but that they also took up arms to defend it, and composed squadrons of females, which rendered credible all that has been said of the prowess of the Amazons."

In the year 1509, the League party obtained some troops from the king of Spain. Upon the news of their being disembarked, Barri de St Aunez, Henry IV.'s governor at Leucate, set out to communicate a scheme to the Duke de Montmorency, commander in that province. He was taken on his way by some of the troops of the League, who were also upon a march with the Spaniards towards Leucate. They were persuaded, that by thus having the governor in their hands the gates of that place would be immediately opened to them, or at least would not hold out long. But Contiantina de Ceceli, his wife, after having assembled the garrison, put herself to rout at their head, pike in hand, that she inspired the weakest with courage; and the besiegers were repulsed wherever they presented themselves. Shame and their great loss having rendered them desperate, they sent a message to this courageous woman, acquainting her, that if she continued to defend herself they would hang her husband. She replied with tears in her eyes, "I have riches in abundance: I have offered them, and I do still offer them, for his ransom; but I would not ignominiously purchase a life which he would reproach me with, and which he would be ashamed to enjoy. I will not disillusion him by treason against my king and country." The besiegers having made a fresh attack without success, put her husband to death, and raised the siege. Henry IV. afterwards sent to this lady the bouquet of governess of Leucate, with the reversion for her son.

The famous Maid of Orleans, also is an example known to every reader.

The Abbé Arnaud, in his Memoirs, speaks of a Countess of St Balmont, who used to take the field with her husband and fight by his side. She sent several Spanish prisoners of her taking to Marshal Fenquisers; and what is not a little extraordinary, this Amazon at home was all affability and sweetness, and gave herself up to reading and acts of piety.

Dr Johnson seems to have given some credit to the accounts which have been transmitted down to us concerning the ancient Amazons; and he has endeavoured to shew, that we ought not hastily to reject ancient historical narrations because they contain facts repugnant to modern manners, and exhibit scenes to which nothing now occurring bears a resemblance. "Of what we know not (says he), we can only judge by what we know. Every novelty appears more wonderful as it is more remote from any thing with which experience or testimony have hitherto acquainted us; and if it passes farther, beyond the notions that we have been accustomed to form, it becomes at last incredible. We seldom consider, that human knowledge is very narrow; that national manners are formed by chance; that uncommon conjunctures of causes produce rare effects; or that what is impossible at one time or place may yet happen in another. It is always easier to deny than to enquire. To refuse credit confers for a moment an appearance of superiority which every little mind is tempted to assume, when it may be gained far cheaper as by withdrawing attention from evidence, and declining the fatigue of comparing probabilities. Many relations of travellers have been slighted as fabulous, till more frequent voyages have confirmed their veracity; and it may reasonably be imagined, that many ancient historians are unjustly suspected of falsehood, because our own times afford no instance of the fables which they tell. Yet many narratives will either to men or women appear more incredible than the histories of the Amazons; of female nations, of whose con-
AMBACHT, in topography, denotes a kind of jurisdiction or territory, the polis or of the administration of justice both in alto and bajof; or of what is called in the Scots law a power of pit and gallows, i.e. a power of drowning and hanging. In some ancient writers, ambacht is particularly used for the administration, government, or chief magistracy of a city. The word is very ancient, though used originally in a sense somewhat different. Ennius calls a mercenary, or flave hired for money ambactus; and Cæsar gives the same appellation to a kind of dependents among the Gauls, who, without being slaves, were attached to the service of great lords.

AMBAGES. See Circumlocution.

AMBARVALIA, in antiquity, a ceremony among the Romans, when, in order to procure from the gods an happy harvest, they conducted the victims thrice round the corn fields in procession, before sacrificing them.—Ambarvalia were either of a private or public nature; the private were performed by the master of a family; and the public by the priests who officiated at the solemnity, called fraterseculares. The prayer preferred on this occasion, the formula of which we have in Cat. de Rel. Rustica, cap. xlvii, was called cornem ambarevala. At these feasts they sacrificed to Ceres a sow, a sheep, and a bull or heifer, whom they took the name of foc Jensauridae. The method of celebrating them was, to lead a victim round the fields, while the chief priest accompanied it, and one of their number, crowned with oak, hymned forth the praises of Ceres, in verses composed on purpose. This festival was celebrated twice a year; at the end of January, according to some, or in April, according to others; and for the second time, in the month of July.

AMBASSADOR, or Embassador, a public minister sent from one sovereign prince, as a representative of his person to another.

Ambassadors are either ordinary or extraordinary. Ambassadors in ordinary, is he who constandy resides in the court of another prince, to maintain a good understanding, and look to the interest of his master. Till about two hundred years ago, ambassadors in ordinary were not heard of; all, till then, were ambassadors extraordinary; that is, such as are sent on some extraordinary occasion, and who retire as soon as the affair is dispatched.

By the law of nations, none under the quality of a sovereign prince can send or receive an ambassador. At Athens, ambassadors mounted the pulpit of the public orators,
And where he resides, as long as he shall continue there; and if he refuses, then letters of relieve are to go from the king's or state's leave where he resides, as some conceive; for all actions ought to be far from an ambassador, as well as that which touches his necessaries, as his person; if, therefore, he hath contrived any debt, he is to be called upon kindly; and if he refuses, then letters of request are to go to his master. Nor can any of the ambassador's domicile servants that are registered in the secretaries of state's office be arrested in person or goods; if they are, the process shall be void, and the parties facing out and executing it shall suffer and be liable to such penalties and corporal punishment as the lord chancellor or either of the chief justices shall think fit to inflict. Yet ambassadors cannot be defended when they commit any thing against that state, or the person of the prince, with whom they reside; and if they are guilty of treason, felony, &c. or any other crime against the law of nations, they lose the privilege of an ambassador, and may be subject to punishment as private aliens.

Ambassadors should never attend any public solemnities, as marriages, funerals, &c. unless their masters have some interest therein; nor must they go into mourning on any occasions of their own, because they represent the person of their prince. By the civil law, the movable goods of an ambassador, which are accounted an accession to his person, cannot be seized on, neither as a pledge, nor for payment of a debt, nor by order, or execution of judgment, nor by the king's or state's leave where he resides, as some conceive; for all actions ought to be far from an ambassador, as well as that which touches his necessaries, as his person: if, therefore, he hath contrived any debt, he is to be called upon kindly; and if he refuses, then letters of request are to go to his master. Nor can any of the ambassador's domicile servants that are registered in the secretaries of state's office be arrested in person or goods; if they are, the process shall be void, and the parties facing out and executing it shall suffer and be liable to such penalties and corporal punishment as the lord chancellor or either of the chief justices shall think fit to inflict. Yet ambassadors cannot be defended when they commit any thing against that state, or the person of the prince, with whom they reside; and if they are guilty of treason, felony, &c. or any other crime against the law of nations, they lose the privilege of an ambassador, and may be subject to punishment as private aliens.

AMB in surgery, the name of an instrument for reducing dislocated bones. In entomology, a term for the superficial jutting out of a bone.

AMB (Succedaneum), in natural history, a solid, hard, fennile, bituminous substance of a particular nature, of use in medicine and in several of the arts. It has been called amber by the Arabsians, and amber by the Greeks.

Ambassadors have been of great repute in the world from early times. Many years before Christ, it was in effect as a medicine; and Plato, Aristotle, Herodotus, Archelaus, and others, have commended its virtues. In the times of the Romans it became in high esteem as a gem; and in the luxurious reign of Nero, immense quantities of it were brought to Rome, and used for ornamenting works of various kinds.

The most remarkable property of this substance is, that, when rubbed, it draws or attract other bodies to it: and this, it is observed, does, even to those substances which the ancients thought it had an antipathy to, as oily bodies, drops of water, human sweat, &c. Add, that by the friction is brought to yield light pretty copiously in the dark; whence it is reckoned among the native phosphors.

The property which amber possesses of attracting light bodies, was very anciently observed. Thales of Mileus, 600 years before Christ, concluded from hence that it was animated. But the first person who expressly mentions this substance, is Theophrastus, about the year 300 before Christ. The attractive property of amber is likewise occasionally taken notice of by Pliny, and other later naturalists, particularly by Gaffendor, Kenelm Digby, and Sir Thomas Brown; but it was generally apprehended that this quality was peculiar to amber and jet, and perhaps agate, till Gilbert published his treatise De Magnete, in the year 1600. From amber, the Greek name for amber, is derived the term Electricity, which is now very extensively applied not only to the power of attracting light bodies, inherent in amber, but to other similar powers, and their various effects, in whatever bodies they reside, or to whatever bodies they may be communicated.

Amber assumes all figures in the ground; that of a pear, an almond, a pea, &c. In amber there have been found to be letters found very well formed; and even Hebrew and Arabic characters. Within some pieces, leaves, insects, &c. have likewise been found included; which seems to indicate, either that the amber was originally in a fluid state, or that having been exposed to the sun, it was once softened, and rendered susceptible of the leaves, insects, &c. which came in its way. The latter of these suppositions seems the more agreeable to the phenomenon, because these insects, &c. are never found in the centre of the pieces of amber, but always near the surface. It is observed by the inhabitants of those places where amber is produced, that all animals, whether terrestrial, aerial, or aquatic, are extremely fond of it, and that pieces of it are frequently found in their excrements. The bodies of insects, found buried in amber, are viewed with admiration by all the world; but of the most remarkable of these, many are to be suspected as counterfeit, the great price at which beautiful specimens of this kind fell, having tempted ingenious cheats to introduce artificial bodies in such artful manners into seemingly whole pieces of amber, that it is not easy to detect the fraud.

Of those insects which have been originally included in amber, some are plainly seen to have struggled hard for their liberty, and even to have left their limbs behind them in the attempt; it being no unusual thing to see, in a mass of amber that contains a stout beetle, the animal wanting one, or perhaps two of its legs; and those legs left in different places, nearer that part of the mass from which it has travelled. This also may account for the common accident of finding legs or wings of flies, without the rest of their bodies, in pieces of amber; the insects having, when entangled in the yet soft and viscous mass, escaped, at the expense of leaving those limbs behind them. Drops of clear water are sometimes also preferred in amber. These have doubtless been received into while soft, and preserved by its hardening round them. Beautiful leaves of a pinnated structure, resembling some of the ferns, or maidenhair, have been found in some pieces; but these are rare, and specimens of great value. Mineral substances are also found at times lodged in masses of amber. Some of the pompos collections of the German princes boast of specimens of native gold and silver in masses of amber; but as there are many substances of the marcasite, and other kinds, that have all the glittering appearance of gold and silver, it is not to be too hastily concluded that these metals are really lodged in these beds of amber. Iron is found in various shapes imbedded in amber; and as it is often seen corroded, and sometimes in the state of vireo, it is not improbable but that copper, and the other metals, may be also sometimes imbedded in it in the same state; hence the bluish and greenish colours, frequently found in the recent pieces of amber, may be owing, like the particles.
particles of the gem colours, to those metals; but as the gems, by their dense texture, always retain their colours, this lighter and more lax bitumen usually loses what it gets of this kind, by keeping some time. Small pebbles, grains of sand, and fragments of other stones, are not unfrequently also found immersed in amber.

Naturalists have been greatly divided as to the origin of this sub stance, and what clods of substances it belongs to; some referring it to the vegetable, others to the mineral, and some even to the animal kingdom. Pliny describes it as a "refraneous juice, oozing from aged plumes and firs (others say from poplars, where there are whole forests on the coasts of Sweden), and discharged thence into the sea, where, under going some alteration, it is thrown, in this form, upon the shores of Prussia, which lie very low: he adds, that it was hence the ancients gave it the denomination *fucus maris; from fucus, juice."

Some suppose amber a compound substance. Prussia, they say, and other countries which produce amber, are moistened with a bituminous juice, which mixing with the vitriolic farts abounding in those places, the points of those farts fix its fluidity, whence it commingles; and the refult of that conglutination makes what we call amber; which is more or less pure, transparent, and firm, as thofe parts of falt and bitumen are more or less pure, and are mixed in this or that proportion.

Mr. Brydone, in his tour to Sicily and Malta, says, that the river Gareta, formerly celebrated by the poets under the name of Simetus, throws up near its mouth great quantities of amber. He mentions also a kind of artificial amber, not uncommon there, made, as he was told, from coals, but very different from the natural.

According to Hartman, amber is formed of a bitumen, mixed with vitriol and other farts. But though this were allowed him in regard to the fossil amber, many dispute whether the sea-amber be so produced. It is, however, apparent, that all amber is of the same origin, and probably that which is found in the sea has been wafted thither out of the cliffs; though Hartman thinks it very probable, that fome of it may have been formed in the earth under the sea, and be wafted up thence. The sea-amber is usually finer to the eye than the fossil, but the reafon is, that it is divifed of that coarse coat with which the other is covered while in the earth.

Upon the whole, it seems generally agreed upon, that amber is a true bitumen of fossil origin.—In a late volume of the *Journal de Physique,* however, we find it afferted by Dr. Gitanner to be an animal product, a fort of honey or wax formed by a species of large ant called *Linnæus formica rufa.* These ants, our author informs us, inhabit the old pine forests, where they sometimes form hills about fix feet in diameter; and it is generally in these ancient forests, or in places where they have been, that foille amber is found. This substance is not hard as that which is taken up in the sea at Prussia, and which is well known to naturalists. It has the confistency of honey or of half melted wax, but it is of a yellow colour like common amber; it gives the same product by chemical analysis, and it hardens like the other when it is suffered to remain some time in a solution of common salt. This accounts for the insects that are so often found imbedded in it. Among these insects ants are always the moft prevailing: which tends farther, Mr. Gitanner thinks, to the confirmation of his hypothesis. Amber then, in his opinion, is nothing but a vegetable oil rendered concrete by the acid of ants, just as wax is nothing but an oil hardened by the acid of bees; a fact incontrovertibly proved, we are told, since Mr. Metheric has been able to make artificial wax by mixing oil of olives with the nitrous acid, and which wax is not to be distinguished from the natural.

There are several indications which discover where amber is to be found. The surface of the earth is there covered with a soft gray flene; and vitriol in particular always abounds there, which is sometimes found white, sometimes reduced into a matter, like melted gips, and sometimes figured like petrified wood.

Amber of the finest kind has been found in England. It is frequently thrown on the shores of Yorkshire, and many other places, and found even in the clay-pits; the pits dog for tile-clay, between Tyburn and Kentington gravel-pits, and that behind St. George's Hospital at Hyde park corner, have afforded fine specimens. In Poland, Silezia, and Bohemia, are famous for the amber dug up there at this time. Germany affords great quantities of amber, as well dug up from the bowels of the earth, as taffed about on the shores of the sea and rivers there. Saxony, Mifnia, and Sweden, and many other places in this tract of Europe, abound with it. Denmark has afforded, at different times, several quantities of fossil amber; and the shores of the Baltic abound with it. But the countries lying on the Baltic afford it in the greatest abundance of all; and of these the most plentiful country is Prussia, and the next is Pomerania. Prussia was, as early as the times of Theodoric the Goth, famous for amber. For this substance coming into great repute with that prince, some natives of Prussia, who were about his court, offered their service to go to their own country, where that substance, they said, was produced, and bring back great stores of it. They accordingly did so; and from this time Prussia had the honour to be called the Country of Amber, instead of Italy, which had before undeservedly that title. This article alone brings his Prussian Majesty a revenue of 26,000 dollars annually. The amber of Prussia is not only found on the sea-coast, but in digging; and though that of Pomerania is generally brought from the shores, yet people who dig, on different occasions, in the very heart of the country, at times find amber.

Junker describes, after Neumann, the Prussian amber-mines, which are the richest known.—First, at the surface of the earth, is found a stratum of sand. Immediately under this sand is a bed of clay, filled with small flakes of about an inch diameter each. Under this clay lies a stratum of black earth, or turf, filled with fossil wood, half decomposed, and bituminous; this stratum is extended upon a bank of minerals, containing little metal, except iron, which are conseqently pyrites. Lastly, under this bed the amber is found, scattered about in pieces, or sometimes accumulated in heaps.

Amber has a subacid resinosous taste, and fragrant aromatic smell, especially when dissolved. It differs from the other bituminous substances in this, that it yields by distillation a volatile acid salt, which none of the others do; otherwise it affords the same sort of principles.
AMB

principles as them, viz. an acid phlegm, an oil which gradually becomes thicker as the distillation is con-
tinued: and when the operation is finished, there re-
 mains a black caput mortuum in the retort.—When
boiled in water, it neither softens, nor undergoes any
sensible alteration. Exposed to the fire in an open
vessel, it melts into a black mass very like a bitumen:
It is partly soluble in spirit of wine, and likewise in
every essential oil; but it is with difficulty that the
exuded ones are brought to act upon it; the stronger
forms of fixed alkaline lixivia almost totally dif-
olve it.

This substance is principally of two colours, white
and yellow. The white is the most esteemed for me-
dicinal purposes, as being the most odoriferous, and
containing the greatest quantity of volatile falt; tho'
the yellow is most valued by those who manufacture
beads and other toys with it, by reason of its tran-
parency.

Amber is the basis of all varnishes, 'by solution'
in the ways described under the article VARNISH.

Amber, when it has once been melted, irrecover-
ably loses its beauty and hardnefs. There have been
some, however, who pretend they had an art of melt-
ing some small pieces of amber into a mass, and
constituting large ones of them: but this seems fuch
another undertaking as the making of gold: all the tri-
als that have yet been made by the most curious expe-
rimenterf, proving, that the heat which is neces-
sary to melt amber, is sufficient to destroy it. Phil. Tranf.
N 4 248. p. 25.

Could amber indeed be dissolved without impairing
its transparence, or one large mass be made of it by
uni ting several small ones, it is easy to see what would
be the advantages of a fuch a process. The art of em-
balmimg might possibly be also carried to a great height
by this, if we could preferve the human corpe in a
transparent cafe of amber, as the bodies of flies, spi-
ders, grafthoppers, &c. are to a great perfection.

Something of a substitute of this kind we have in fine
coals: which being dissolved by heat, and the bodies
of small animals several times dipped in it, they are
thus coated with collophiny, that in some degree re-
sembles amber; but this must be kept from dust.

Amber in substance has been much recommended
as a nervous and cordial medicine; and allledged to be
very efficacious in promoting the menifral discharge,
and the exclusion of the fucus and fecundines in la-
bour: but as in its crude flate it is quite insoluble by
our juices, it certainly can have very little effecl on
the animal fystem, and therefore it is now feldom
given in substance. The forms in which amber is pre-
pared are, A incharé, a cell, and an oil; the prepa-
ation and ufe of which are described in the proper
place under the article PHARMACY.

AMBER-TREE, the English name of a species of
ANTHOSPERMUM.

AMBERG, a city of Germany, the capital of the
palatinate of Bavaria, with a good cattle, ramparts,
halfons, and deep ditches. It is feated near the con-
fines of France, on the river Wills. It drives a great
trade in iron and other metals, found in the neigh-
bouring mountains. E. Long. 12. 4. N. Lat. 20. 46.

AMBERGRIZE, AMBERGREASE, or GREY AM-
BER, in natural hifiory, is a solid, opake, ash-coloured,

fatty, inflammable substance, variegated like marble,
remarkably light, rugged and uneven in its surface,
and has a fragrant order when heated. It does not
ceffive with acids; it melts freely over the fire,
into a kind of yellow roth; and is hardly soluble in
spirit of wine.

It is found swimming upon the sea, or the sea-coast,
or in the sand near the sea-coast; especially in the At-
lantic ocean, on the sea-coast of Brazil, and that of Ma-
dagascar; on the coasts of Africa, of the East Indies,
China, Japan, and the Molucca islands; but most of
the ambergrize which is brought to England comes
from the Bahama islands, from Providence, &c. where
it is found on the coast. It is also sometimes found in
the abdomen of whales by the whale-fishermen, always
in lumps of various shapes and sizes, weighing from
half an ounce to an hundred and more pounds. The
piece which the Dutch East India Company bought
from the king of Tydor, weighed 182 pounds. An
American fisherman from Antigua found some years
ago, about 52 leagues south-east from the Windward
islands, a piece of ambergrize in a whale, which weighed
about 150 pounds, and sold for 300 l. Sterling.

There have been many different opinions concerning
the origin of this substance.

It has been supposed to be a fossil bitumen or naph-
tha, exuding out of the bowels of the earth in a fluid
form, and distilling into the sea, where it hardens and
floats on the surface. But having been frequently
found in the belly of whales, it has by others been
considered as entirely an animal production.

Clausius ascribed it to be a phlegmatic recrement, or
indurated indigifible part of the food, collected and
found in the foam of the whale, in the fame man-
ner as the BEZOARS are found in the fomachs of other
animals.

In an account communicated by Paul Dudley, Esq;
in the 23d volume of the Philosophical Transac-
tions, the ambergrize found in whales is represented as a kind
of animal produfct, like mufk, and castoreum, &c.
fercated and collected in a peculiar bag or bladder, which
is furnished with an excretory duct or canal, the spuit
of which runs tapering into and through the length of
the penis; and that this bag, which lies just over the
teficles, is almost full of a deep orange-coloured liquor,
not quite fo thick as oil, of the fame flmell as the balls
of ambergrize, which float and swim loose in it; whose
colour and liquor may also be found in the canal of the
penis; and that therefore ambergrize is never to be
found in any female, but in the male only. But these
circumstances are not only deftrict of truth, but also
contrary to the laws of the animal econony: For, in
the firft place, ambergrize is frequently found in females
as well as males; although that found in females is
never in fuch large pieces, nor of fo good a quality, as
what is found in males. Secondly, No perfon who has
the leafl knowledge in anatomy or phyfology, will e-
ever believe that organifed bodies, fuch as the beams of
the Sepia, which are fo continually found in amber-
grize taken out of the whale, can have been aborbed
from the intestines by the lachets or lymphatics, and
collectcd with the ambergrize in the precluded bag a-
bovementioned.

Kempfer, who has given us fo many other faithful
accounts in natural hifiory, seems to come nearer the
truth
in the spermactei whale; and they are so convinced of this fact, that whenever they hear of a place where ambergris is found, they always conclude that the fea in that part are frequented by this species of whale.

The persons who are employed in the spermactei whale fishery, confine their views to the physeter macrocephalus. They look for ambergris in all the spermactei whales they catch, but it seldom happens that they find any. Whenever they hook a spermactei whale they observe, that it constantly not only vomits up whatever it has in its stomach, but also generally discharges its faeces at the time; and if this latter circumstances takes place, they are generally disappointed in finding ambergris in its belly. But whenever they discover a spermactei whale, male or female, which seems torpid and sickly, they are always pretty sure to find ambergris, as the whale in this state seldom voids its faeces upon being hooked. They likewise generally meet with it in the dead spermactei whales, which they sometimes find floating on the sea. It is observed also, that the whale, in which they find ambergris, often has a morbid protuberance; or, as they express it, a kind of gathering in the lower part of its belly, in which, if cut open, ambergris is found. It is observed, that all those whales, in whose bowels ambergris is found, seem not only torpid and sick, but are also constantly leaner than others; so that, if we may judge from the constant union of these two circumstances, it would seem that a large collection of ambergris in the belly of the whale is a source of disease, and probably sometimes the cause of its death. As soon as they hook a whale of this description, torpid, sickly, emaciated, one that does not dung on being hooked, they immediately either cut up the abovementioned protuberance, if there be any, or they rip open its bowels from the orifice of the anus, and find the ambergris, sometimes in one sometimes in different lumps, of generally from three to twelve and more inches in diameter, and from one pound to twenty or thirty pounds in weight, at the distance of two, but most frequently of about six or seven feet from the anus, and never higher up in the intestinal canal; which, according to their description, is, in all probability, the intestinum caecum, hitherto mistaken for a peculiar bag made by nature for the secretion and collection of this singular substance. That the part they cut open to come at the ambergris is no other than the intestinal canal is certain, because they constantly begin their incision at the anus, and find the cavity every where filled with the faeces of the whale, which from their colour and smell it is impossible for them to mistake. The ambergris found in the intestinal canal is not so hard as that which is found on the fae or sea-coast, but soon grows hard in the air: when first taken out, it has nearly the same colour, and the same disagreeable smell, though not so strong, as the more liquid dung of the whale has; but, on exposing it to the air, it by degrees not only grows greyish, but its surface is covered with a greyish dust like old chocolate, but it also loses its disagreeable smell, and, when kept for a certain length of time, acquires the peculiar odour which is so agreeable to most people.

The gentlemen the Doctor conversed with confessed, that if they knew not from experience that ambergris thus found will in time acquire the abovementioned qua-
qualities, they would be distinguished from hard indurated faces. This is so true, that whenever a whale voids its faces upon being hooked, they look carefully to see if they cannot discover among the more liquid excrements (of which the whale discharges several barrels) some pieces floating on the sea, of a more compact substance than the rest; these they take up and wash, knowing them to be amber-grife.

In considering whether there be any material difference between amber-grife found upon the sea or coast, and that found in the bowels or among the dung of the whale, the Doctor refutes the opinion, that all amber-grife found in whales is of an inferior quality, and therefore much less in price. Amber-grife, he observes, is only valued for its purity, lightness, compactness, colour, and smell. There are pieces of amber-grife found on different coasts, which are of a very inferior quality; whereas there are often found in whales pieces of it of the first value; nay, several pieces found in the same whale, according to the abovementioned qualities, are more or less valuable. All amber-grife found in whales has at first when taken out of the intestines very near the same smell as the liquid excrements of that animal have; it has then also nearly the same blackish colour: they find it in the whale sometimes quite hard, sometimes rather soft, but never so liquid as the natural faces of that animal. And it is a matter of fact, that, after being taken out and kept in the air, all amber-grife grows not only harder and whiter, but also loses by degrees its smell, and attains such an agreeable one, as that in general has with which it is found swimming upon the sea; therefore the goodnes of amber-grife seems rather to depend on its age. By being accumulated after a certain length of time in the intestinal canal, it seems even then to become of a whiter colour, and loses ponderous, and acquires its agreeable smell. The only reason why amber-grife found floating on the sea generally poises the abovementioned qualities in a superior degree, is because it is commonly older, and has been longer exposed to the air. It is more frequently found in males than females; the pieces found in males are in general smaller, and those found in males seem constantly to be larger and of a better quality, and therefore the high price in proportion to the size is not merely imaginary for the rarity-fake, but in some respect well founded, because such large pieces appear to be of a greater age, and possesses the abovementioned qualities in general in a higher degree of perfection than smaller pieces.

It is known, that the Sepia octopoda, or cuttle-fish, is the constant and natural food of the spermacte whale, or Physeter macrocephalus. Of this the filters are so well perfuaded, that whenever they discover any recent relics of it swimming on the sea, they conclude that a whale of this kind is, or has been, in that part. Another circumstance which corroborates the fact is, that the spermacte whale on being hooked generally vomits up some remains of the Sepia. Hence it is easy to account for the many beaks, or pieces of beaks, of the Sepia found in all amber-grife. The beak of the Sepia is a black horny substance, and therefore passes undigested through the stomac into the intestinal canal, where it is mixed with the faces; after which it is either evacuated with them, or if these latter be preter-naturally retained, forms concretions with them, which render the animal sick and torpid, and produce an ob­fipation, which either in an abcefs of the abdomen, as has been frequently observed, or becomes fatal to the animal; whence in both the cases, on the burring of its belly, that inhabitants substance, known under the name of amber-grife, is found swimming on the sea, or thrown upon the coast.

From the preceding account, and his having constantly found the abovementioned beaks of the Sepia in all pieces of amber-grife of any considerable size, Dr. Swediar concludes with great probability, that all amber-grife is generated in the bowels of the Physeter macrocephalus, or spermacte whale; and there mixed with the beaks of the Sepia octopoda, which is the principal food of that whale. He therefore defines amber-grife to be the preternaturally hardened dung or faces of the Physeter macrocephalus, mixed with some indigestible relics of its food.

The use of amber-grife in Europe is now nearly confined to perfumery; tho' it has formerly been recommended in medicine by several eminent physicians. Hence the Eistentia Ambræ Hoffmanni, Tinhuræ Regia Cod. Parisini, Trochici de Ambra Ph. Wurtemberg, &c.

If we wish to try any medicinal effects from this substance, the Doctor observes, we must certainly not expect them from two or three grains, but give rather as many scupetes of it for a dose: though even then, he thinks, there would not be reason to expect much effect from it, as he had himself taken of pure undecorated amber-grife in powder 50 grains at once, without observing the least sensible effect from it. A sailor, however, who had the curiosity to try the effects of recent amber-grife upon himself, took half an ounce of it melted upon the fire; and found it a good purgative; which proves that it is not quite an inert substance.

In Asia and part of Africa amber-grife is not only used as a medicine and as a perfume, but considerable use is also made of it in cookery, by adding it to several dishes as a spice. A great quantity of it is also constantly bought by the pilgrims who travel to Mecca; probably to offer it there, and use make of it in fumulations, in the same manner as frankincense is used in Catholic countries. The Turks make use of it as an aphrodisiac. Our perfumers add it to scented pillars, candles, balls or bottles, gloves, and hair powder; and its essence is mixed with pomatums for the face and hands, either alone or mixed with musk, &c. tho' its smell is to fome persons extremely offensive.

Amber-grife may be known to be genuine by its fragrant scent when a hot needle or pin is thrust into it, and its melting like fat of an uniform consistence; whereas the counterfeit will not yield such a smell, nor prove of such a fat texture.—One thing, however, is very remarkable, that this drug, which is the most sweet of all the perfumes, should be capable of being remelted in fumell by a preparation of one of the most odious of all stinks. Mr. Honberg found, that a vessel in which he had made a long digestion of the human faces, acquired a very strong and perfect smell of amber-grife, insomuch that any one would have thought a great quantity of essence of amber-grife had been made in it. The perfume was strong and offensive, that the vessel was forced to be removed out of the laboratory.
AMBERT, a small town of France, in lower Auvergne, the chief place of a small territory called Liutadour. It is remarkable for its paper manufactury and camblets. E. Long. 3. 35. N. Lat. 45. 28.

AMBETTUWAY, in botany, a barbarous name of a tree, the leaves of which, when boiled in wine, are said to create an appetite, and is used by the people in Guinea with that intention.

AMBIBIANI, or Ambianesis civitas, now Amiens, a city of Picardy. It is called Samaria by Caesar and Cicero; which, according to Valerius, signifies the bridge of the Samara or Sonate. Ambitus is a later name, taken from that of the people, after the usual manner of the lower age.

AMBIDEXTER, a person who can use both hands with the same facility, and for the same purposes, that the generality of people do their right hands. As to the natural cause of this faculty, some, as Hoefer, attribute it to an extraordinary supply of blood and spirits from the heart and brain, which furnish both hands with the necessary strength and agility: others, as Nicholas Maffa, to an exact situation of the heart, inclining neither to the right hand nor left; and others to the right and left subclavian arteries being of the same height and the same distance from the heart, by which the blood is propelled with equal force to both hands. But these are only conjectures, or rather chimeras. Many think, that, were it not for education and habit, all mankind would be ambidexters; and in fact, we frequently find naries obliged to be at a good deal of pains before they can bring children to forego the use of their left hands. How far it may be an advantage to be deprived of half our natural dexterity, may be doubted. It is certain, there are infinite occasions in life, where it would be better to have the equal use of both hands. Surgeons and surgeons are of necessity obliged to be ambidexters; bleeding, &c. in the left-hip or left-ankle, and operations on the left-eye, cannot be well performed but with the left-hand. Various instances occur in history, where the left hand has been excercised preferably to the right. But by the laws of the ancient Scythians, people were enjoined to exercise both hands alike; and Plato enjoins ambidexterity to be observed and encouraged in his republic.

AMBIDexter, among English lawyers, a juror or embrasser, who accepts money of both parties, for giving his verdict; an offence for which he is liable to be imprisoned, for ever excluded from a jury, and to pay ten times the fine he accepted of.

AMBIENT, a term used for such bodies, especially fluids, as encompass others on all sides; thus, the air is frequently called an ambient fluid, because it is diffused round the earth.

AMBIGENÆVES, in the heathen sacrifices, an appellation given to such ewes as, having brought forth twins, were sacrificed together with their two lambs, one on each side. We find them mentioned among other sacrifices to Juno.

AMBIGENÆAL HYPERBOLA, a name given by Sir Isaac Newton to one of the triple hyperbolas of the second order, having one of its infinite legs falling within an angle formed by the asymptotes, and the other without.

VOL. I.
AMBLESIDE, a town in Westmoreland, seated at one end of Winandermeer, W. Long. 0. 49. N. lat. 54. 30.

AMBLYGNON, in geometry, denotes an obtuse-angled triangle, or a triangle one of whose angles consists of more than 90 degrees.

AMBLE, in horsemanship, a peculiar pace by which a horse's two legs of the same side move at the same time. See HORSEMANN.

AMBLE, a kind of pulpit or desk, in the ancient churches, were the priests and deacons stood to read or sing part of the service, and preach to the people; called also AMBULIUM. The term is derived from ambulare, "to mount."—The ambo was mounted upon two abuts; whence some also derive the appellation from the Latin ambo, "both."

The ambo was ascended by steps; which occasioned that part of the office performed there to be called the Gradual. See GRADUAL.

Besides the gospel, which was read at the top of the ambo, and the epistle, which was read at a step lower, they likewise published from this place the acts of the martyrs, the commemoration of departed saints, and the letters of peace and communion sent by one church to another: here, too, converts made a public profession of their faith; and bishops, their defence, when accused: treaties also were sometimes concluded, and the coronations of emperors and kings performed, in the same place.

The modern reading-desks and pulpits have been generally substituted to the ancient Ambos; though, in some churches, remains of the ambos are still seen. In that of St John de Lateran at Rome, there are two moveable ambos.

AMBOITSMEH, or VONITSANGHOMSE, a province of the island of Madagascar, so called from some red mountains of the same name, lying in S. Lat. 20°. These mountains are very high, resembling the

Tafelburg of the Cape of Good Hope. On one side of this ridge the sea extends into the country for fifteen leagues; on the other is a flat country abounding in ponds and marshes. Here is also a lake fifteen leagues in length, and the same in breadth, containing many small islands. The inhabitants of the mountains are called Zafarangoh; and have plenty of gold, iron, cattle, silk, &c.

AMBOISE, a town of France, in Toursafi, seated at the confluence of the rivers Loire and Masse. The town is mean and ill built; but has been rendered famous in history by the conspiracy of the Protéfan, in 1560, which opened the fatal wars of religion in France. The castle is situated on a craggy rock, extremely difficult of access, and the sides of which are almost perpendicular. At its foot flows the Loire, which is divided into two streams by a small island.

To this fortress the duke of Guife, when he expected an insurrection among the Huguenots, removed Francis II. as to a place of perfect security. Only two defended parts of the ancient castle now remain, one of which was constricted by Charles VIII. and the other by Francis I. The former of those princes was born and died at Amboise. The town is situated E. Long. 1. 30. N. Lat. 47. 25.

AMBOULE, a province of Madagascar, somewhat to the northward of S. Lat. 23°. It is a fertile and agreeable country, watered by the river Manampani, whose mouth lies in S. Lat. 23. 30. The country produces plants and fruits in plenty. Iron mines are also found here. The black cattle are extremely fat, and their flesh excellent. In this province stands a large town of the same name; near which is a fountain of hot water, within 20 feet of a small river whose land is also burning. The water of the fountain is said to boil an egg hard in two hours; and the inhabitants affirm it to be a sovereign remedy against the goat. The people here are employed in different preparations of iron and steel, which they have from their own mines, and forge several instruments with tolerable skill. Their governor is honoured with the title of Rabbartau, or Great Lord. He exercises sovereign authority and absolute power; but is frequently, in times of distress, surprised by his subjects, who assemble in great numbers, seize his person, and threaten him with death unless they are relieved. To extricate himself from this dilemma, he is instantly obliged to issue orders for distributing provisins among them; but is usually repaid with interest, a quadruple return being made in a plentiful harvest. The people of Amboise live in great licentiousness with their superiors, and their country is generally a retreat for the roguish and lazy.

AMBOYNA, one of the Molucca islands, in the East Indies. It lies in S. Lat. 3. 36. and E. Long. 126. 20. and is remarkable for being the centre of the commerce for nutmegs and cloves, which is entirely monopolized by the Dutch East-India company. It is about 24 leagues in circumference. Besides cloves, it likewise abounds in most of the tropical fruits and fish; nor is there here any deficiency of good water; but fish is very scarce. This scarcity, however proceeds more from the policy of the Dutch than either the intemperance of the climate or the barrenness of the soil: For, excepting cloves, they have in Amboyna,
Amboyna, as well as the Moluccas, industriously discouraged the cultivation of every sceleant commodity, with the view of with-holding subsistence from those who might be tempted to invade them.

Of the natives, the men wear large whiskers, but leave little hair upon their chin; and have only a light piece of stuff wrapped round their middle. The women tie their hair in knots: the maids are bought of their fathers before they are married; and if the wife proves barren, the marriage is dissolved. Some of the natives are Mahometans, and some Christians: but they are all said to be lazy, deceitful, and treacherous. They make war with small swift vessels, in shape like dragons with regard to the head and tail. Their houses are built of bamboo-canes and fago-trees. They sleep on mats. Their weapons are bows and arrows, javelins, scythes, and targets.

Amboyna was first discovered by the Portuguese, who built a fort upon it, which was taken from them by the Dutch in 1605. They did not, however, become masters of the whole island at once. The English had here five factories, which lived under the protection of the Dutch East India Company, holding the factories of the natives Mahometans, and some Christians: but they are all said to be lazy, deceitful, and treacherous. They make war with small swift vessels, in shape like dragons with regard to the head and tail. Their houses are built of bamboo-canes and fago-trees. They sleep on mats. This was difficult by the quantities of gold-dust that were washed from some mountains by the torrents.

Here also grow several kinds of valuable wood, of which they made tables, chairs, efitotrois, &c. for the principal persons in the government; and the rest is sold all over the Indies at a very extravagant rate.

Ambonua is divided into two parts, viz. a greater and lesser peninsula. The former, called ilius, is 12 leagues in length, and two and a half broad. In this the Dutch have no lesse which principal persons in the government; and the latter to be continually upon their guard, and to redoubts, mounted with cannon. The other is called small defiance from the sea. At government but a small number are Dutch; and this by nature and art, as to be in a manner impregnable; broad, which is the southerm compafs. The compafs. The line being completed, the lines were Dutch; and this by the river, but with communication of their forts, or rather strong redoubts, mounted with cannon. The other is called Lestimer, five leagues in length, and one and a half broad, which is the southern part of the island; on this stands the fort of Victoria, which is the residence of the governor, and his council, composed of 15 gentlemen or merchants. The fortres is a square, the ramparts mounted with 60 pieces of brass cannon, and the garrisons usually composed of 600 men. It is so strong by nature and art, as to be in a manner impregnable; and so effectively does it command the harbour, that no vessel could come in or go out without being fank by the cannon, if the governor chose. The inhabitants of Ambonua are computed at 70 or 80,000, of whom but a small number are Dutch; and this obliges the latter to be continually upon their guard, and to keep a competent number of troops in each of their forts, particularly in that of Middleburgh, which stands upon the island that connects these peninsulas. There are also redoubts and garrisons in all the isles of this government.

AMBRACIA; one of the most considerable cities of ancient Epirus, situated on the river Arazthus, at a small distance from the sea. At first it was a free city; but was afterwards reduced by the Macedonians, and especially by the Romans, who chose it for the place of their residence. In process of time, the Epirots made themselves masters of it, and held it till the year before Christ 189, when it fell into the hands of the Romans. At this time Ambracia was a place of great strength. It was defended on one side by the river Arachthus, and on the other by steep and craggy hills; and surrounded with an high and thick wall, above three miles in compass. The Roman consul Fulvia began the siege by forming two camps, separated by the river, but with a communication between them; the Romans were posted in one, and the Epirots their allies in the other. He then threw up two lines, one of circumvallation, and the other of contravallation; and built a wooden tower, in form of a castle, over against the citadel, which stood on a hill. The Epirots, however, before the lines were quite finished, found means to throw about 1000 men into the place.

The lines being completed, the city was attacked in five different places at once. The battering-rams shook the walls on all sides; and the Romans, from their movable towers, pulled down the battlements with a kind of lyethes which they fastened to long beams. The besieged made a vigorous defence. They were night and day on the wall, and indefatigable in preventing the effects of the rams and lyethes. The strokes of the former they deadened, by letting down beams, large stones, lumps of lead, &c. by means of pulleys, upon them when they were in motion; the others they rendered useless, by pulling the beams which they were fastened into the city with hooks contrived for the purpose.

While Fulvia was carrying on the siege, Nicander the Aetolian pretor found means to throw 500 men into the city, under the command of one Nicodorus, with whom Nicander agreed to attack the Roman camp in the night-time; not doubting, that, if the garrison from within, and the army from without, fell upon them at the same time they would be obliged to raise the siege. Nicodorus narrowly watched the time at which he was ordered to fall; and though Nicander did not appear, marched out at the head of the garrison, armed with fire-brands and torches. The Roman centurions, surprised at this sight, ran to wake the legions, and soon spread a general alarm all over the camp. The legions marched in small bodies as they happened to meet, to repulse the enemy, whom they engaged in three different places. Two parties of the garrison were driven back; but the third, commanded by two Aetolian generals, made a great slaughter of the Romans; and, not finding themselves seconded by Nicander, retired in good order into the city.

Though the besieged were thus abandoned, and had no hopes of assistance, they continued to defend themselves with incredible vigour and resolution. The Romans had no sooner made a breach in the wall, but it was repaired, and a new one built behind it. The conful, therefore, altered his measures; and, instead of making breaches with the ram, began to undermine the wall, in hopes of throwing down great part of it at once, and entering the city before the besieged could have time to rebuild a new wall. The miners being covered, were not observed by the garrison, till the great quantities of earth brought out of the mine gave the alarm. The Aetolians immediately began a countermine; and having dug a trench of the depth they supposed the mine to be, they carried it along the wall, where they heard the strokes of the pick-axes of the Romans. When the two mines met, a battle ensued, first with pick-axes and spades, and then with swords and spears; but this attack did not last long, each party making themselves a kind of rampart with the loose earth. The Aetolians, in order to drive their enemies quite out of the mine, invented a machine, which they brought to the place where the two mines met: this was an hollow vessel with an iron bottom, bored through in many places, and armed with spikes at proper distances to prevent the enemy from approaching it. This vessel they filled with feathers, which they set on fire, and with bellows driving the smoke on the beligerents, obliged them to leave the mine, half-suffocated. This interval the Aetolians made use of in repairing the foundations of the wall.

The vigorous resistance made by the Ambracians, however, did not raise the courage of the nation in general, who were determined on a peace with Rome at all events. Fulvia, in the mean time, being defirous of getting possession of Ambracia before the conclusion of the peace, employed Amyntander, king of the Athenians, to persuade the inhabitants to surrender. As Amyntander had great interest in Ambracia, having long reided there, he easily persuaded them to capitulate on the following terms, viz. That the Aetolian garrison should have leave to march out of the city; that the inhabitants
AMBREADA, thus they call the false or facitious amber, which the Europeans use in their trade with the negroes on the coast of Africa, and particularly on the river Senegal. There are some large and red pearls in it, a thousand of which making twenty ropes or strings, weigh three pounds. There are others small, and also red, which weigh but two pounds and an half.

AMBRESBERRY, a market-town in Wiltshire, about six miles north of Salisbury, and situated in W. Long. 1°. 40' and N. Lat. 51° 20'.

AMBROINES, a Gaulish people who lived near the foot of the Alps, between Switzerland and Provence. They invaded the Roman territories in conjunction with the Cimbri and Teutones; but were defeated with great slaughter by Marius, about 107 years before Christ. Their women, who had flayed the enemy during the engagement in a kind of fortification made with their carts, on seeing their husbands lying, and the Romans at their heels, armed themselves with axes, and gnashing with their teeth, fell with fury on the pursuers and the pursued. Their first rage being spent, they desired to surrender themselves, upon the single condition, that their chastity should not be violated; but this equitable request being denied, they first killed their children, and then themselves, not one remaining alive out of the whole multitude.

AMBROSIA, a small island laid down in some of the most approved charts, and particularly mentioned in Mr. Robertson's Elements of Navigation, as lying in S. Lat. 25° 30'. W. Long. 82° 20'. It was searched for, however, in 1767, by Captain Carteret, with such diligence, that he concludes it to have no existence, as he could not discover land any where near that place.

AMBROSE (St.), bishop of Milan, one of the most eminent fathers of the fourth century, born in Gaul in the year 334, according to Dr. Cave, or in 340, as Mr. Du Pin affirms. His father was at this time prefidentes, in Gaul; and retired at Arles, the capital of Gallia Narbonensis. The birth of Ambrose is said to have been followed with a remarkable preface of his future eloquence; for we are told, that a swarm of bees came and settled upon his mouth as he lay in his cradle. He soon made himself master of the several parts of secular learning; and pleased caues before Probus with so much eloquence, that he was appointed his afeiller, and soon after governor of the provinces of Liguria and Æmilia. He settled at Milan; where, in the year 374, upon the death of Auxentius bishop of that city, there being a great contest between the Catholics and Arians concerning the choice of a new bishop, Ambrose thought it his duty, as governor, to go to the church, in order to compose the tumult. He accordingly addressed himself to the people in a gentle pathetic speech, to exhort them to return to their choice in a calm and friendly manner: while he was speaking to them, the whole assembly cried out with one voice, "Let Ambrose be bishop!" Such a sudden and unexpected incident surprized him extremely; so that he retired immediately, and used every method to divert them from their resolution of choosing him; but at last he was obliged to comply; and was baptiz'd (being but a catechumcn before), and ordained bishop, towards the latter end of the yeare 374, or beginning of 375. About the year 377, the barbarous nations making an incursion into the Roman empire, he fled to Illyricum, and afterwards to Rome. In the year 384, he was sent to the tyrant Maximus, who had usurped the empire, and prevailed upon him not to pass over into Italy. The heathens being encouraged by these intemperate commotions in the empire, attempted to restore their religion, and employed Q. Aurelianus Symmachus, preëxct of Rome, a man of great eloquence, to plead their cause. This gave rise to the famous contéll between St. Ambrose and him, about repairing the altar of Victory. But Symmachus having lost his cause, was expelled the city, and commanded not to approach within an hundred miles of it. The petition which he presented to the emperor Valentinian the younger, is still extant; we find in it the strongest figures of rhetoric and the greatest force of eloquence. St. Ambrose wrote a refutation of this petition; but he has been thought guilty of many paradoxes; and yet he protests, "that he endeavoured only after the solidity of reasoning, leaving Symmachus all the glory of eloquence and politeness; it being (says he) the peculiar privilege of the pagan philosophers to amuse the mind with colours as false as their idols; and to say great things, not being capable of saying true ones." Ambrose met with a good deal of opposition from the Arians, against whom he acted with great spirit and intrepidity. Julian the emperor and mother of Valentinian, who was an Arian, resolving to restore Arianism at Milan, began with demanding of St. Ambrose one of the churches, which was called the Portian church: but he refused it; and the people surrounding the palace in a body, he was obliged to leave him in possession of his church, and even desire him to pacify the people.

Ambrose was a second time sent to the tyrant Maximus, for Valentinian found no person so proper to negotiate with him. He spoke to him with great courage and boldness, but could obtain nothing; for Maximus soon after marched into Italy, and made himself master of the western empire: so that Valentinian was obliged to retire, with his mother Julianus and his sister Gala, to Thessalonica in Illyricum, in order to depose Theodosius his successor; who defeated Maximus, and restored Valentinian to the empire.

While Theodosius continued in Italy, after the defeat of Maximus, an insurrection happened at Thessalonica, in which several of the magistrates were yeoned, and their bodies dragged along the streets. Theodolus being informed of this, hastily commanded a certain number of the inhabitants to be put to death promiscuously. Ambrose thought it his duty, as governor, to go to the church, in order to compose the tumult. He accordingly addressed himself to the people in a gentle pathetic speech, to exhort them to return to their choice in a calm and friendly manner: while he was speaking to them, the whole assembly cried out with one voice, "Let Ambrose be bishop!" Such a sudden and unexpected incident surprized him extremely; so that he retired immediately, and used every method to divert them from their resolution of choosing him; but at last he was obliged to comply; and was baptiz'd (being but a catechumcn before), and ordained bishop, towards the latter end of the yeare 374, or beginning of 375. About the year 377, the barbarous nations making an incursion into the Roman empire, he fled to Illyricum, and afterwards to Rome. In the year 384, he was sent to the tyrant Maximus, who had usurped the empire, and prevailed upon him not to pass over into Italy. The heathens being encouraged by these intemperate commotions in the empire, attempted to restore their religion, and employed Q. Aurelianus Symmachus, preëxct of Rome, a man of great eloquence, to plead their cause. This gave rise to the famous contéll between St. Ambrose and him, about repairing the altar of Victory. But Symmachus having lost his cause, was expelled the city, and commanded not to approach within an hundred miles of it. The petition which he presented to the emperor Valentinian the younger, is still extant; we find in it the strongest figures of rhetoric and the greatest force of eloquence. St. Ambrose wrote a refutation of this petition; but he has been thought guilty of many paradoxes; and yet he protests, "that he endeavoured only after the solidity of reasoning, leaving Symmachus all the glory of eloquence and politeness; it being (says he) the peculiar privilege of the pagan philosophers to amuse the mind with colours as false as their idols; and to say great things, not being capable of saying true ones." Ambrose met with a good deal of opposition from the Arians, against whom he acted with great spirit and intrepidity. Julian the emperor and mother of Valentinian, who was an Arian, resolving to restore Arianism at Milan, began with demanding of St. Ambrose one of the churches, which was called the Portian church: but he refused it; and the people surrounding the palace in a body, he was obliged to leave him in possession of his church, and even desire him to pacify the people.

Ambrose was a second time sent to the tyrant Maximus, for Valentinian found no person so proper to negotiate with him. He spoke to him with great courage and boldness, but could obtain nothing; for Maximus soon after marched into Italy, and made himself master of the western empire: so that Valentinian was obliged to retire, with his mother Julianus and his sister Gala, to Thessalonica in Illyricum, in order to depose Theodosius his successor; who defeated Maximus, and restored Valentinian to the empire. While Theodosius continued in Italy, after the defeat of Maximus, an insurrection happened at Thessalonica, in which several of the magistrates were yeoned, and their bodies dragged along the streets. Theodolus being informed of this, hastily commanded a certain number of the inhabitants to be put to death promiscuously.
AMBROSE, by which means the city was filled with the blood of many innocent persons, and amongst the rest several strangers who had but just come there: no regard was had to any distinction of persons, no form of trial was observed; but they were cut down like corn in the harvest, as Theodoret expresses it, to the number of 7000. At this time an assembly of bishops was held at Milan, who all expressed an abhorrence of such cruelty in the emperor. Ambrose wrote a letter to him, in which he represented the enormity of his crime, and exhorted him to make satisfaction by a sincere submission and repentance. Some time after, Theodosius coming to Milan, went to receive the sacrament at the great church; where Ambrose meeting him at the door, denied him entrance, and represented to him, in which he represented the enormity of Theodorus year after, Ambrose, being convinced of the sincerity of his repentance, admitted him into the church.

In 392, Valentinian the emperor being assassinated by the contrivance of Argobaltes, and Eugenius usurping the empire, Ambrose was obliged to leave Milan; but about a year after, Ambrose, being convinced of the sincerity of his repentance, admitted him into the church.

AMBROSE, in heathen antiquity, denotes the solid food of the gods, in contradistinction from the drink, which was called mel, or ambrosia. It had the appellation ambrosia (compounded of the particle an, and eperios, immortal) as being supposed to render those immortal who fed on it.

AMBROSE is also a splendid kind of title, given by some physicians to certain alexipharmic compositions, of extraordinary virtue. The name was particularly given to a famous antidote of Philip of Macedonia, against all poisons, bites, and stings of venomous creatures as well as many internal diseases.

AMBROSID, a genus of the pentandria order, belonging to the monoeia class of plants; and, in the natural method, ranking under the 49th order, Compositae-nucamentaceae. The characters are:—The male flowers are compound: The common calyx is a single-leaved perianthium, the length of the florets: The compound corolla is uniform, tubular, flat, and hemispherical; the proper is monopetalous, funnel-shaped, and quinquefert: The stamina consist of five very small filaments; the anther is erect, parallel, and pointed: The pistillum has a filiform style, the length of the stamina; the stigma orbicular and membranous: The receptacle is naked. Female flowers below the male ones, on the same plant, double: The calyx is a single-leaved perianthium, entire (with the belly quinquetented), one floreted, and persistent: There is no corolla: The pistillum has an ovate germ in the bottom of the calyx: a filiform style, the length of the calyx; and two long brizly stigmaae: The pericarpium is an ovate unilocular nut: The seed is singular and roundish. Of this genus five species are enumerated; but having no properties worthy of notice, we omit any further account of them.

AMBROSIAN Office, or Rite, in church-history, a particular formula of worship in the church of Milan, which takes its name from St Ambrose, who instituted that office in the fourth century. Each church originally had its particular office; and when the Pope, in after-times, took upon him to impose the Roman office upon all the western churches, that of Milan sheltered itself under the name and authority of St Ambrose; from which time the Ambrosian ritual has prevailed.

AMBROSIN, in middle-aged writers, denotes a coin struck by the lords or dukes of Milan, wherein was represented St Ambrose on horseback with a whip in his right hand. The occasion of this coinage is said to have been a vision of that saint, who appeared to the Milanese general in 339, during the time of a battle.

AMBROSIA, in botany, a genus of the polyandria order, belonging to the gynandria class of plants; the characters of which are: The calyx is a single-leaved latha, divided by a partition into two cells: There is no corolla: The stamina consist of a single filament in the interior cell; the anther are numerous,
The Amhrolius, numerous, with two roundish concave nectaries at their base; the pellifium is in the interior cell; the german roundish; the stylus cylintrical, and shorter than the spatha: the stigma oblate: The periampium (a capsule?) roundish and unilocular. There is but one species, a native of Turkey.

AMBROSIUS APRELIANUS, or Aurelius Ambrosi, a famous general of the ancient Britons, of Roman extraction. He was educated at the court of Aldroan of America; who, at the request of the Britons, sent him over with ten thousand men, to assist them against the Saxons, whom Vortigern had invited into Britain. Ambrosius had such success against the Saxons that the Britons chose him for their king, and compelled Vortigern to give up to him all the western part of the kingdom divided by the Roman highway called Watling-street. Some time after, the Britons being discontented with Vortigern, and having withdrawn their allegiance from him, he retired to a battle in Wales, where being besieged by Ambrosius, and the cattle taking fire, he perished in the flames, and left his rival sole monarch of Britain; who now took upon him the imperial purple, after the manner of the Roman emperors. Geoffrey of Monmouth tells us, that Ambrosius built Stonehenge near Salisbury in Wilts. Ambrosius, according to this historian, coming to a monastery near Caerarodac, now Salisbury, where three hundred British lords, massacred by Hengist, lay buried, and resolving to perpetuate the memory of this action, he ordered his workmen to prepare a large quantity of stones and other materials. But having, at the instigation of Tremonus archbishop of Caereleon, consulted the famous Merlin, this magician advised him to send over to Ireland for certain great stones, called chora gigantium, the giant's dance, placed in a circle on a hill called Kilair, having been brought thither by giants from the farthest borders of Africa. A body of forces were accordingly sent into Ireland, under Pendragon, Ambrosius's brother, to fetch these stones; but were opposed in their attempt by the Saxons, and vanquished this prince in battle, brought away the stones; and by the direction and assistance of Merlin, who had accompanied them, these wonderful stones, by order of Ambrosius, were placed over the graves of the British lords, and are now what is called Stonehenge. Alexander Mechan celebrates this fable in his poem De divina sapientia laudibus. Polydore Virgil affirms another origin of Stonehenge: he tells us it was erected by the Britons as a monument to their general Ambrosius, on the place where he fell in battle, to perpetuate the memory of his glorious actions and services done to his country. Both these stories are rejected by the best antiquaries; who, however, are by no means agreed as to the true origin of this famous piece of antiquity. See Stonehenge.

After the Britons had defeated the Saxons, and obliged them to retire northward, Ambrosius is said to have convened the princes and great men at York, where he gave orders for repairing the churches destroyed by the Saxons, and restoring the exercise of religion to its former lustre. This is confirmed by Matthew of Wellsminster; who highly applauds the great zeal of Ambrosius in repairing the churches, encouraging the clergy, and reaforning the honour of religion. The Monmouth historian gives this prince a very high character. "He was a man (says he) of such bravery and courage, that when he was in Gaul, no one durst enter the lists with him; for he was sure to unhorse his antagonist, or to break his spear into shivers. He was, moreover, generous in bestowing, careful in performing religious duties, moderate in all things, and more especially abhorred a lie. He was strong on foot, stronger on horseback, and perfectly qualified to command an army." The same author tells us he was poisoned at Winchester by one Eoga Saxon, disguised as a physician, and hired for that purpose by Palentius one of the sons of Vortigern: but the generally received opinion is, that he was killed in a battle which he lost in the year 509, against Cedric, one of the Saxon generals.

AMBRBY, a place in which are deposited all the utensils necessary for house-keeping. In the ancient abbeys and priories, there was an office under this denomination, wherein were laid up all charities for the poor.

AMBULAJÆ, in Roman antiquity, were immodest women, who came from Syria to Rome, where they lived by prostitution and by playing on the flute: the word is derived from the Syriac abah, which signifies a flute; altho' others make it to come from an and Bata, because these prostitutes often retired to Bata. According to Cruquius, these women used likewise to fell paint for ornamenting the face, &c.

AMBULANT, or ambulatory. They give in France the name of ambulant commiffiores to those commissioners, or clerks of the king's farms, who have not settled office; but visit all the offices within a certain distinc, to see that nothing be done in them against the king's right, and interest of the farm.

AMBULANT is also used to denote those brokers at Amsterdam or exchange agents, who have not been sworn before the magistrates. They transact brokerage business, but their testimony is not received in the courts of justice.

AMBULATORY, a term anciently applied to such courts, &c., as were not fixed to any certain place; but held sometimes in one place, and sometimes in another. In opposition to stationary courts.—The court of parliament was anciently ambulatory; so also were the court of king's bench, &c.

AMBURBIUM, in Roman antiquity, a procession made by the Romans round the city and pomerium, in which they led a victim, and afterwards sacrificed it, in order to avert some calamity that threatened the city.

AMBURY, or Ambur, among farriers, denotes a tumor, wart or swelling, which commonly happens in about eight days, growing very high on horsehair very hard about its root; and, when it has fallen off, which commonly happens in about eight days, strewing some powder of verdigris upon the part, to prevent the return of the complaint. If the tumor be so low that nothing can be tied about it, they cut it out with a knife, or else burn it off with a sharp hot iron; and, in fine parts, where a hot iron is improper, they eat it away with oil of vitriol, or white sublimate.

Many
Ambuscade Many of our forriers boast of a secret which infallibly cure all kinds of protuberances of this kind; the preparation of which is this: Take three ounces of green vitriol and one ounce of white arsenic; beat them to a coarse powder, and put them into a crucible; place the crucible in the midst of a charcoal fire, stirring the sublimate, but carefully avoiding the poisonous steam; when the whole grows red, take the crucible out of the fire, and when cool, break it and take out the matter at the bottom; beat this to powder in a mortar, and add to four ounces of this powder five ounces of whitewash; make the whole into an ointment, and let it be applied cold to warts; rubbing them with it every day. They will by means of this fall off gently and easily, without leaving any swellings. It is best to keep the horse quiet, and without working, during the cure. What fores remain on the parts which the swellings fall off from, may be cured with the common application called the counterfoot's ointment.

AMBUSCADE, or AMBUSHE, in the military art, properly denotes a place where folders may lie concealed till they find an opportunity to surprize the enemy.

In the language of Scripture, these terms are not always taken in their proper significance, for laying ambuscades for any one, attacking him in secret, laying snares for him. They sometimes signify no more than attacking a man who has no right to such a thing; attacking one behind, concealing one's self in some green particular place in order to surprize any one. See the book of Judges, ch. ix. 25. 32. 34. 35. Abimelech, who lay lurking with his people in the heights of Sichem, fo, however, as to rob and treat those who passed that way very ill, came and attacked the city of Sichem with his troops divided into three bodies: Tendeit infidias juxta Sichinam in quatuor locis. Literally, according to the Hebrew, "They prepared ambuscades against Sichem in four heads or companies." And a little farther, verse 45. Abimelech being informed that the Sichemites were marched, took his army and divided it into three bodies, and laid wait for them in the field. It seems certain that in these passages, ambuscades, properly so called, were not the things in question. In the first book of Samuel, Saul complains that David laid ambuscades for him: Invidiator nefque bodie permanens. Now nothing could be worse grounded than this accusation, if we understand the word indignari in its proper signification; but he might say, though unjustly, that David was his secret enemy. And in the Chronicles it is said, that God turned the ambuscades laid by the enemies of Israel upon themselves; that is to say, their endeavours, their malice, their arms, he turned against themselves: for the enemies there mentioned came not in private or by surprizam; they marched openly in arms against Israel.

AMBY, a town of the Austrian Netherlands, in the province of Limburg, situated opposite to Maerfricht, on the east side of the river Maas, in E. Long. 5° 45. N. Lat. 50° 57'.

AMEDIANS, in church-history, a congregation of religious in Italy, so called from their professing themselves amantes Deum, "lovers of God;" or rather amati Deus, "beloved of God." They wore a grey habit and wooden shoes, had no breeches, and girt themselves with a cord. They had 26 convents; and were united by Pope Pius V, partly with the Cistercian order, and partly with that of the Scolopi, or wooden-shoe wavers.

AMELIA, an episcopal city of Italy, in the state of the church, seated on a mountain, 50 miles N. E. of Rome, and 25 miles S. W. of Spoleto. E. Long. 13° 20'. N. Lat. 42° 33'.

AMELLUS, STARWORT: A genus of the polyg- mania superflus order, belonging to the syngeneia classei plants; and in the natural method ranking under the 42th order, Composite- opposiffilia. The characters are: The common calyx is imbricated and roundish: The compound corollia is radiated; the hermaphrodite corollas numerous in the disk; the female numerous in the ray: Proper corolla of the hermaphrodites are tubular and quinquefid; of the females, tongued, loose, and two or three toothed: The flamina in the hermaphrodites consist of five short capillary filaments; the antherae cylindric and tubular: The pistillum has an ovate germen; a filiform stylus the length of the flamina; and two filiform stigmas: There is no pericarpium, but the calyx unchanged: The seeds are ovate and foliary: the pappus is hairy; the receptaculum chaffy. Of this there are two.

Species. 1. The lychnitis, with one flower on each footstalk. This is a native of the Cape of Good Hope. It is a perennial plant, rising about three feet high, sending out many branches on each side, so as to form a bushy plant; the branches are garnished with oblong spear-shaped leaves placed opposite, and are terminated by single naked flower-stalks, each supporting one violet-coloured flower, having a yellow disk, which is succeeded by oblong seeds. 2. The umbellatus, with flowers growing in umbels, is a native of Jamaica; and rises from two to three feet high, sending out many branches cloathed with opposite leaves, which are terminated by small flowers in umbels.

Culture. The first is easily propagated, either by cuttings planted in the summer-months, or by seeds sown on a moderate hot-bed in the spring, but the plants require a flight shelter in winter. The second is much more tender, and therefore requires to be preserved in a stove during the winter season.

AMELOT DE LA HOUSSET (Nicholas), born at Orleans in 1634, was much esteemed at the court of France, and appointed secretory of an embassy which court sent to the commonwealth of Venice, as appears by the title of his translation of Father Paul's History of the Council of Trent; but he afterwards published writings which gave such offence that he was imprisomed in the Bastile. The fifth works he printed were the History of the Government of Venice, and that of the Ufcocks, a people of Croatia. In 1668 he published his translation into French of Machiavel's Prince, and Father Paul's History of the Council of Trent, and Political Discourses of his own upon Tacitus. These performances were well received by the public. He did not prefix his own name to the two last mentioned works, but concealed himself under that of La Mothe Joffeval. His translation of Father Paul was attacked by the partisans of the pope's unbounded power and authority. In France, however, it met with great success; all the advocates for the liberty of the Gallican church poreading the success of the to the tumult of their power; though at the same time there were these memorials presented
AMELEOT, attended by AMELEOT, presented to have it suppressed. When the second edition of this translation was published, it was violently attacked by the Abbé St Real, in a letter he wrote to Mr Bayle, dated October 17, 1685. Amelot defended himself, in a letter to St Real, entitled a letter to St Real, entitled

He printed at Paris a French translation of Baltafar Gracian's Oraculo manual, with the title of l'Honneur de Cour. In 1686, he printed La Morale de Tacite de la fraternité, in which he collected several particular facts and maxims, which represent in a strong light the artifices of court-flatterers, and the mischievous effect of their poisonous discourses. Frederick Leonard, a bookseller at Paris, having proposed, in the year 1692, to print a collection of all the treaties of peace between the kings of France and all the other princes of Europe, since the reign of Charles VII. to the year 1690, Amelot published a small volume in duodecimo, containing a preliminary discourse upon these treaties; wherein he endeavours to show, that most princes, when they enter into a treaty, think more how to evade than how to perform the terms they subscribe to. He published also an edition of Cardinal d'Offet's Letters in 1697, with several observations of his own; which, as he tells us in his advertisement, may serve as a supplement to the history of the reigns of Henry III. and Henry IV. kings of France. He wrote several other works; and died at Paris in 1706, being then almost 72 years of age.

AMELOT (Denis), a celebrated French writer, was born at Saintonge in 1606. He maintained a close correspondence with the fathers of the Oratory, a congregation of priests founded by Philip Neri. He wrote the life of Charles de Condren, second superior of this congregation, and published it at Paris in 1643. In this piece he said something of the famous Abbé of St Cyran, which greatly displeased the gentlemen of Port Royal, who, to be revenged of him, published a libel against him, intitled Idées générales de l'esprit et de l'ame en France. He was so much provoked by this satire, that he did all in his power to injure them.

They had finished a translation of the New Testament, and were zealous to have it published; for which purpose they endeavoured to procure an approbation from the doctors of the Sorbonne, and a privilege from the chancellor, preventing them from succeeding. In this he had also a view to his own interest; for he was about to publish a translation of his own of the New Testament. Amelot's translation with annotations, in 4 vols. octavo, was printed in the years 1666, 1667, and 1668. It is not very exact, according to P. Simon, who tells us that it contains some very gross blunders. Amelot wrote also an Abridgment of Divinity, a Catechism for the Jubilee, and a kind of Christiana Manual for every Day. Towards the end of his life, he entered into the congregation of the Oratory in 1690; and continued amongst them till his death, which happened in 1678.

AMENN, Amen., signifies true, faithful, certain. It is made use of likewise to affirm anything, and was a sort of affirmation used often by our Saviour: Amen. Amen. I say unto you. Lastly, it is understood as expressing a wish; as Amen, Amen.

So be it, Numb. v. 22. or an affirmation, Amen, yes, I believe it, 1 Cor. xiv. 16. The Hebrews end the five books of Psalms, according to their way of distributing them, with the words amen, amen; which the Sepulchritans have translated amen, amen; and the Latin, fiat, fiat. The Greek and Latin churches have preserved this word in their prayers, as well as alleluia and istanna; because they observed more energy in them than in any terms which they could use in their own languages. At the conclusion of the public prayers, the people answered with a loud voice, Amen; and St Jerom says, that at Rome when the people answered Amen, the sound of their voices was like a clap of thunder: In simulitationem caelestis tonitru Amen reboat. The Jews affirm that the gates of Heaven are opened to him who answers Amen with all his might.

AMENDE, or AMENDMENT, in the French случions, a pecuniary punishment imposed by a judge for any crime, false accusation, or groundless appeal.

AMENDE Honourable, an infamous kind of punishment inflicted in France upon traitors, parricides, or sacrilegious persons, in the following manner: The offender being delivered into the hands of the hangman, his shirt is stripped off, a rope put about his neck, and a taper in his hand; then he is led into court, where he must beg pardon of God, the king, the court, and his country. Sometimes the punishment ends here; but sometimes it is only a prelude to death, or banishment to the galleys.

AMENDMENT Honourable, is a term also used for making recantation in open court, or in presence of the person injured.

AMENDMENT, in a general sense, denotes some alteration or change made in a thing for the better.

AMENDMENT, in law, the correction of an error committed in the process, which may be amended after judgment, unless the error lies in giving judgment; for in that case it is not amendable, but the party must bring a writ of error. A bill may be amended on the file at any time before the plea is pleaded; but not afterwards, without motion and leave of the court.

AMENDMENT of a Bill, is some alteration made in the first draught of it.

AMENTUM, in botany, the name of a species of calyx, consisting of valves, and hanging down in different directions from the calyx. Common oats afford a good example of the amentum.

AMENEM, in Roman antiquity, a thong tied about the middle of a javelin or dart, and fastened to the forefinger, in order to recover the weapon as soon as it was discharged. The ancients made great use of the amentum, thinking it helped to enforce the blow. It also denotes a latchet that bound their sandals.

AMERADE, a kind of officers among the Saracens, answering to the governors of provinces among the Europeans. The name is originally the name with that of emir.

AMERCEMENT, or AMERCIAMENT, in law, a pecuniary punishment imposed on offenders at the mercy of the court. It differs from a fine in being imposed arbitrarily in proportion to the fault; whereas a fine is a certain punishment settled expressly by some statute.
America is not of equal breadth throughout its whole extent; but is divided into two great continents, called "North," and "South America," by an isthmus 1500 miles long, and which, at Durinc, about Lat. 9° S. is only 50 miles over. This isthmus forms, with the northern and southern continents, a vast gulf, in which lie a great number of islands, called the "West-Indies," in contradistinction to the eastern parts of Asia, which are called the "East-Indies."

"Next to the extent of the New-World, the grandeur of the objects which it presents to view, is most apt to strike the eye of an observer. Nature seems here to have carried on her operations upon a larger scale, and with a bolder hand, and to have displayed the features of this country by a peculiar magnificence. The mountains of America are much superior in height to those in the other divisions of the globe. Even the plain of Quito, which may be considered as the base of the Andes, is elevated farther above the sea than the top of the Pyrenees." The most elevated point of the Andes, according to Don Ulloa, is twenty thousand, two hundred, and eighty feet, which is, at least, seven thousand, one hundred, and two feet above the Peak of Teneriffe, which is the highest known mountain in the ancient continent. (See the article Andes.)

From the lofty and extensive mountains of America descend rivers with which the streams of Europe, of Asia, or of Africa, are not to be compared, either for length of course, or for the vast volumes of water which they pour into the oceans. The Danube, the Indus, the Ganges, or the Nile, in the ancient Hemisphere, are not of equal magnitude with the St. Laurence, the Missouri, or the Mississippi, in North-America; or with the Maraguan, the Orinoco, or the Plata, in South-America. The rivers in the latter of these American continents are like vall arms of the sea. (See the articles St. Laurence, Missouri, & c.)

"The lakes of the New-World are no less conspicuous for grandeur than its mountains and rivers. There is nothing in other parts of the globe which resembles the prodigious chain of lakes in North-America. They may be properly termed inland seas of fresh water; and even those of the second or third class of magnitude, are of a larger circuit (the Capeian sea excepted) than the greatest lake of the ancient continent." (See the articles Superior, Huron, Erie, &c.)

The luxuriance of the vegetable creation in the New-World is extremely great. In the southern provinces, where the moisture of the climate is aided by the warmth of the sun, the woods are almost impervious, and the surface of the ground is hid from the eye, under a thick covering of shrubs, of herbs, and weeds of vegetation. In the northern provinces although the forests are not so encumbered with the same mild luxuriance of vegetation, the trees of various species are generally more lofty, and often much larger, than are to be seen in any other parts of the world.

One of the most remarkable circumstances, or features, of the New-World, is the general predominance of cold, throughout the whole extent of this great continent. Though we cannot, in any country, determine the precise degree of heat merely by the distance of the equator, because the elevation above the sea, the nature of the soil, &c. all affect the climate; yet, in the Ancient Continent, the heat is much more in proportion to the vicinity to the equator than in any part of America. Here the rigour of the frigid zone extends over half that which should be temperate by its position. Even in those latitudes where the winter is scarcely felt in the Old-Continant, it reigns with great severity in America, though during a short period. Nor does this cold, prevalent in the New-World, confine itself to the temperate zones; but extends with the west wind over the western part of the continent, and with the east wind, along the eastern coast, to the torrid zone also, considerably mitigating the excess of its heat.—Along the eastern coast, the climate, tho' more similar to that of the torrid zone in other parts of the earth, is nevertheless considerably milder than in the countries of Asia and Africa which lie in the same latitude. From the southern tropic to the extremity of the American continent, the cold is said to be much greater than in parallel northern latitudes even of America itself.

For this remarkable difference between the climate of the New-Continant and the old, various causes have been assigned by different authors. The following is the opinion of the celebrated Dr. Robertson on this subject. "Though the utmost extent of America towards the north is yet not discovered, we know that it advances nearer to the pole than either Europe or Asia. The latter have large seas to the north, which are open during part of the year; and even when covered with ice, the wind that blows over them is less intensely cold than that which blows over land in the same latitude. But, in America, the land stretches from the river St Laurence towards the pole, and spreads out immenely to the west. A chain of enormous mountains, covered with snow and ice, runs thro' all this dreary region. The wind passing over such an extent of high and frozen land, becomes so impregnated with cold, that it acquires a piercing keenness, which it retains in its progress through warmer climates; and is not entirely mitigated until it reach the gulf of Mexico. Over all the continent of North-America, a north-westerly wind and excursive cold are synonymous terms. Even in the most sultry weather, the moment that the wind veers to that quarter, its penetrating influence is felt in a transition from heat to cold no less violent than sudden. To this powerful cause we may ascribe the extraordinary dominion of cold, and its violent inroads into the southern provinces in that part of the globe. "Other causes, no less remarkable, diminish the active
The climate of America is its extreme moisture in general. In some places, indeed, moisture of the western coast, rain is not known; but, in all other parts, the moistness of the climate is as remarkable as the cold. — The forests wherever it is it is every where covered, no doubt, partly, occasion the moistness of its climate; but the most prevalent and obvious cause is the vast quantity of water in the Atlantic and Pacific Oceans, with which America is environed on all sides. Hence, those places where the continent is narrowest are deluged with almost perpetual rains, accompanied with violent thunder and lightning, by which some of them, particularly Porto-Bello, are rendered in a manner uninhabitable.

From the coldness and the moisture of America, an Malignity extreme malignity of climate has been inferred, and at- ferred by M. de Pauw in his Recherches Philosophiques unjustly a- par les Américains. Hence, according to the hypothesis of this author, the smallness and irregularity of the nobler animals, and the size and enormous multiplication of reptiles and insects.

But the supposed smallness and ferocity of the American animals, the Abbé Clavigero observes, instead of the malignity, demonstrates the mildness and vol. II. bounty of the climate, if we give credit to Buffon, at p. 253: whose fountain M. de Pauw has drank, and of whose testimony he has availed himself against Don Pernetty. Buffon, who in many places of his Natural History produces the smallness of the American animals as a certain
certain argument of the malignity of the climate of America; in treating afterwards of savage animals, in Tom. II. speaks thus: "As all things, even the most free creatures, are subject to natural laws, and animals as well as men are subjected to the influence of climate and soil, it appears that the same causes which have civilized and polished the human species in our climates, may have likewise produced similar effects upon other species. The wolf, which is perhaps the fiercest of all the quadrupeds of the temperate zone, is, however incomparably less terrible things which are temperate; the wolf, the lion, and the panther of the torrid zone; and the white bear and hyena of the frigid zone. In America, where the air and the earth are more mild than those of Africa, the tyger, the lion, and the panther, are not terrible but in the name. They have degenerated, if fierce, joined to cruelty, made their nature; or, to speak more properly, they have only suffered the influence of the climate: under a milder sky their nature also has become more mild. From climes which are immediate in their temperature are obtained drugs, perfumes, poisons, and plants whose qualities are strong. The temperate earth, on the contrary, produces only things which are temperate; the mildest herbs; the most wholesome pulse, the sweetest fruits, the most quiet animals, and the most humane men, are the natives of this happy clime. As the earth makes the plants, the earth and plants make animals; the earth, the plants, and the animals make man. The physical qualities of man, and the animals which feed on other animals, depend, though more remotely, on the same causes which influence their dispositions and customs. This is the greatest proof and demonstration, that in temperate climates everything becomes temperate, and that in the same temperate climates, the effects are more striking and determinate qualities, depend notwithstanding, like the relative qualities, on the influence of climate. The size of our quadrupeds cannot be compared with that of an elephant, the rhinoceros, or sea-horse. The largest of our birds are but small if compared with the ostrich, the condore, and caynare." So far M. Buffon, whose text we have copied, because it is contrary to what M. de Pauw writes against the climate of America, and to Buffon himself in many other places.

"If the large and fierce animals, says Clavigero, are natives of temperate climates, and small and tranquil animals of other climes, as M. Buffon has here established; if mildness of climate influences the disposition and customs of animals, M. de Pauw does not well deduce the malignity of the climate of America from the smaller size and less fierceness of its animals; he ought rather to have deduced the gentleness and sweetness of its climate from this antecedent. If, on the contrary, the smaller size and less fierceness of the American animals, with respect to those of the old continent, are a proof of their degeneracy, arising from the malignity of the clime, as M. de Pauw would have it, we ought in like manner to argue the malignity of the climate of Europe from the smaller size and less fierceness of its animals, compared with those of Africa. If a philosopher of the country of Guinea should undertake to work in imitation of M. de Pauw, with this title, "Recherches Philosophiques sur les Europeens," he might avail himself of the same argument which M. de Pauw uses, to demonstrate the malignity of the climate of Europe, and the advantages of that of Africa. The climate of Europe he would say, is very unfavourable to the production of quadrupeds, which are found incomparably smaller, and more cowardly than ours. What are the horse and the ox, the largest of its animals, compared with our elephants, our rhinoceroses, our serpents, and our camels? What are its lizards, either in size or irrepidity, compared with our crocodiles? Its wolves, its bears, the most dreadful of its wild beasts, when beside our lions and tigers? Its eagles, its vultures, and cranes, if compared with our ostriches, appear only like hens.

As to the enormous size and prodigious multiplication of the insects and other noxious animals, "The not more infested than other countries with insects and noxious animals." America, the surface of the earth (says M. de Pauw), infected by putrefaction, was over-run with lizards, serpents, reptiles, and insects monstros for size, and the activity of their poison, which they drew from the copious juices of this uncultivated soil, that was corrupted and abandoned to itself, where the nutritive juice became sharpe, the milk in the breast of animals which do not exercise the virtue of propagation. Caterpillars, ants, butterflies, beetles, spiders, frogs, and toads, were for the most part of an enormous corpulence in their species, and multiplied beyond what can be imagined.

Panama is infested with serpents, Carthagena with clouds of enormous bats, Porto-bello with toads, Surinam with kakerlucks or earwachsen, Gaudaloupe, and the other colonies of these islands, with beetles, Quito with niguas or chegoes, and Lima with lice and bugs. The ancient kings of Mexico, and the emperors of Peru, found no other means of ridding their subjects of those insects which fed upon them, than the imposition of an annual tribute of a certain quantity of lice. Ferdinand Cortes found bags full of them in the palace of Montezena." But this argument, exaggerated as it is, proves nothing against the climate of America in general, much less against that of Mexico. There being some lands in America, in which, on account of their heat, their humidity, or want of inhabitants, large insects are found, and excessively multiplied, will prove at most, that in some places the surface of the earth is infested, as he says, with putrefaction; but not that the soil of Mexico, or that of all America, is flinking, uncultivated, vitiated, and abandoned to itself. If such a deduction were just, M. de Pauw might also say, that the foil of the old continent is barren and fettled; as in many countries of it there are prodigious multitudes of monstrous insects, noxious reptiles, and vile animals, as in the Philippine Isles, in many of those of the Indian archipelago, in several countries of the south of Asia, in many of Africa, and even in some of Europe. The Philippine Isles are infested with enormous ants and monstrous butterflies; Japan with scorpions; South of Asia and Africa with serpents; Egypt with asps; Guinea and Ethiopia with armies of ants; Holland with field-rats; Ukraine with toads, as M. de Pauw himself affirms. In Italy, the Campania di Roma (although peopleed for many ages), is infested with vipers; Calabria with tarantulas; the shores of the Adriatic sea with clouds of gnats; and even in France, the population of which is so great and so ancient, whose lands are so well cultivated, and whose climate is so celebrated by the French, there appeared,
America. a new species of field-mice, larger than the common kind, called by him *Sarmatus*, which have multiplied exceedingly, to the great damage of the fields. M. Bazin, in his Compendium of the History of Insects, numbers 77 species of bugs, which are all found in Paris and in its neighbourhood. That large capital, as Mr. Bomare says, swarms with these delightful insects. It is true that there are places in America, where the multitude of insects, and filthy vermin, make life irksome; but we do not know that they have arrived to such excess of multiplication as to depopulate any place, at least there cannot be so many examples produced of this cause of depopulation in the new as in the old; but we are attested by Theophrastus, Varro, Pliny, and other authors. The frogs depopulated one place in Gaul, and the locusts another in Africa. One of the Cyclades was depopulated by mice; Amiclas, near to Taracina, by serpents; another in which they made with their teeth, in eating the fruits of the woods, was heard at the distance of two miles. M. de Pauw says, in talking of serpents, "it cannot be affirmed that the new world has shown any serpents larger than those which Mr. Adanson has found in the defects of Africa." The greatest serpent found in Mexico, after a diligent search made by Hernandez, was 18 feet long: but this is not to be compared with that of the Moluccas, which Bomare says is 33 feet in length; nor with the Anaconda of Ceylon, which the same author says is more than 33 feet long; nor with others of Asia and Africa, mentioned by the same author.

With respect to the size of the insects, reptiles, and such animals, M. de Pauw makes use of the testimony of M. Dumont, who, in his Memoirs on Lothiana, says, that the frogs are so large there that they weigh 37 French pounds, and that their horrid croaking imitates the bellowing of cows. But M. de Pauw himself says (in his an answer to Don Fernetty, cap. 17), that all those who have written about Lothiana from Henepin, Le Clerc, and Toni, to Dumont, have contradicted each other, sometimes on one and sometimes on another subject. In fact, neither in the old nor the new continent are there frogs of 37 pounds in weight (see the article *Rana*); but there are in Asia and in Africa serpents, butterflies, ants, and other animals of such monstrous size, that they exceed all those which have been discovered in the New-World. We know very well, that an American historian says, that a certain gigantic species of serpent is to be found in the woods, which attracts men with their breath, and swallows them up; but we know also that several historians, both ancient and modern, report the same extravagant and incredible thing of the serpents of Asia, and even something more. Megadethes, cited by Pliny, said, that there were serpents found in Asia, so large, that they swallowed entire flags and bulls. Metrodorus, cited by the same author, affirms, that in Asia there were serpents which, by their breath, attracted birds, however high they were or quick their flight. Among the moderns, Gemelli, in Vol. V. of his *Giro del Mundo*, when he treats of the animals of the Philippine isles, speaks thus: "There are serpents in these islands of immense size; there is one called *Bato*, very long, which suspends itself by the tail from the trunk of a tree, waits till flags, bears, and also men pass by, in order to attract them with its breath, and devour them at once entirely." From whence it is evident, that this very ancient fable has been common to both continents. Further, it may be asked, in what country of America could M. de Pauw find ants to equal those of the Philippine isles called *Sthlaum*, respecting which Her-
three other quarters of the world. In their physical
history, however, the greatest peculiarity in the Am-
ericans is their complexion, and the little difference
which is observed, in this respect, throughout the
whole extent of the American continent. In Europe,
and in Asia, the people who inhabit the northern con-
tries are of a fairer complexion than those who dwell
more to the southward. In the torrid zone, both in
Africa and Asia, the natives are entirely black, or the
next thing to it. This, however, must be understood
with some limitation. The people of Lapland, who
inhabit the most northerly part of Europe, are by no
means so fair as the inhabitants of Britain; nor are the
Tartars so fair as the inhabitants of Europe, who lie
under the same parallels of latitude. Nevertheless, a
Laplander is fair when compared with an Abyssinian,
and a Tartar if compared with a native of the Moluc-
sas. — In America, this distinction of colour was
not so distinctly, and so prominently, marked. In the
torrid zone there were no negroes, and in the tempe-
rate and frigid zones there were no white people. Most
of them were of a kind of red copper-colour, which Mr
Forster observed, in the Peferales of Tierra del Fuego,
to have something of a gloss resembling that metal.
It does not appear, however, that this matter has, hither-
to been inquired into with sufficient accuracy. The
inhabitants of the inland parts of South America, in which
that continent is widest, and consequently the in-
fluence of the sun most powerful, have never been
accurately compared with those of Canada, or more
northerly parts, at least as far as we know. Yet this
ought to have been done, and that in many instances
too, before it could be asserted so positively as most
authors do, that there is not the least difference of com-
plexion among the natives of America. Indeed, so many
systems have been formed concerning these singular peo-
ple, that it is very difficult to obtain a true know-
ledge of the most simple facts, even from the best
and most unprejudiced writers. — If we may believe
the Abbé Raynal the Californians are swarthy rather than the
Mexicans; and so positive is he in this opinion, that he
gives a reason for it. — 'This difference of colour,' says
he, 'proves, that the civilized life of society subverts,
or totally changes, the order and laws of nature, since
we find, under the same temperature, savage people that
are blacker than the civilized nations of the torrid
zone.' — On the other hand, Dr Robertson classes all
the inhabitants of Spanish America together with re-
gard to colour, whether they are civilized or uncivil-
ized; and when he speaks of California, takes no notice
of any peculiarity in their colour more than others. —
The general appearance of the indigenous Americans
in various districts is thus described by the chevalier
Pinto: — 'They are all of a copper colour, with some di-
versity of shade, not in proportion to their distance from the
Equator, but according to the degree of elevation of
the territory in which they reside. Those who live in a
high country are fairer than those in the lower low
lands on the coast. Their face is round; farther re-
moved, perhaps, than that of any people, from an oval
shape. Their fore-head is small; the extremity of their
ears far from the face; their lips thick; their nose flat;
their eyes black, or of a chestnut colour, small, but ca-
}
the vast regions extending to the north, as the ornaments of dress among the most polished nations. The buisiness itself they call Matather, and they do not fail to apply all their talents and industry to accomplish it in the most finished manner. No lady of the greatest fashion ever confined her mirror with more anxiety, than the Indians do while painting their bodies. The colours are applied with the utmost accuracy and dexterity. Upon the eye-lids, precisely at the root of the eye-lashes, they draw two lines as fine as the smallest thread; the same upon the lips, the openings of the nostrils, the eye-brows, and the ears; of which last they even follow all the inflexions and irregularities. As to the rest of the face, they distribute various figures, in all which the red predominates, and the other colours are allotted so as to throw it out to the best advantage. The neck also receives its proper ornaments; a thick coat of vermilion commonly distinguishes the cheeks. Five or six hours are requisite for accomplishing all this with the nicety which they affect. As their first attempts do not always succeed to their wish, they efface them, and begin anew upon a better plan. Neither is more faithfulness in her choice of ornament, none more vain when the important adjutment is finished. Their delight and self-satisfaction are then so great, that the mirror is hardly ever laid down. An Indian, Matather, to his mind, is the vainest of all the human species. The other parts of the body are left in their natural state, and, excepting what is called cachecul, they go entirely naked.

Such of them as have made themselves eminent for bravery, or other qualifications, are distinguished by figures painted on their bodies. They introduce the colours by making punctures on their skin, and the extent of surface which this ornament covers is proportioned to the exploits they have performed. Some paint only their arms, others both their arms and legs; others again their thighs, while those who have attained the summit of warlike renown, have their bodies painted from the waist upwards. This is the heraldry of the Indians; the devices of which are probably more exactly adjusted to the merits of the persons who bear them, than those of more civilized countries.

Besides these ornaments, the warriors also carry plumes of feathers on their heads, their arms, and ancles. These likewise are tokens of valour, and none but such as have been thus distinguished may wear them.

The propensity to indolence is equal among all the tribes of Indians, civilized or savage. The only employment of those who have preferred their independence is hunting and fishing. In some districts the women exercise a little agriculture, in raising Indian corn and potatoes, of which they form a species of aliment, by bruiting them together; they also prepare the ordinary beverage in use among them, taking care, at the same time, of the children, of whom the fathers take no charge.

The female Indians of all the conquered regions of South America practice what is called the ara or (a word which among them signifies elevation). It consists in throwing forward the hair from the crown of the head upon the brow, and cutting it round from the ears to above the eye; so that the forehead and eye-brows are entirely covered. The same custom takes place in the Northern countries. The female inhabitants of both regions tie the rest of their hair behind, so exactly in the same fashion, that it might be supposed the effect of mutual imitation. This however being impossible, from the vast distance that separates them, is thought to counteract the supposition of the whole of America being originally planted with one race of people.

This custom does not take place among the males. Those of the higher parts of Peru wear long and flowing hair, which they reckon a great ornament. In the lower parts of the same country they cut it short, on account of the heat of the climate; a circumstance in which they imitate the Spaniards. The inhabitants of Louisiana pluck out their hair by the root, from the crown of the head forwards, in order to obtain a large forehead, otherwise denied them by nature. The rest of their hair they cut as short as possible, to prevent their enemies from seizing them by it in battle, and also to prevent them from easily getting their scalp, should they fall into their hands as prisoners.

According to Don Ulloa, the whole race of the American Indians is distinguished by an uncommon thickness of skin, and by an hardness of their fibres; circumstances which, in the opinion of this learned Spanish writer, contribute to that insensibility to bodily pain for which these singular people are so remarkable. Our author adds an instance in support of this insensibility, in the Americans, in the case of an Indian who was under the necessity of submitting to be cut for the stone. This operation, it is well known, seldom lasts above four or five minutes. Unfavourable circumstances, in his cafe, prolonged it to the uncommon period of 27 minutes. Yet, all this time, the patient gave no tokens of the extreme pain, commonly attended to such operations. He complained only as a person does who feels some slight uneasiness. At last the stone was extracted. Two days after he expressed a desire for food, and on the eighth day from the operation he quitted his bed, free from pain, although the wound was not yet thoroughly closed. The fame want of sensibility, he says, is observed in cases of fractures, wounds, and other accidents of a similar nature. In all these cases their cure is easily effected, and they seem to suffer less pain than any other race of men. The skulls which have been taken up in their ancient burying-grounds are of a greater thickness than that of any bones which is commonly found to be; being from six to seven lines from the outer to the inner peripheries.

It is natural to infer from hence, says Ulloa, that their comparative insensibility to pain is owing to a coufer and stonger organization, than that of other nations. The cave with which they endure the severities of climate is, he thinks, another proof of this. The inhabitants of the higher parts of Peru live amidst perpetual frost and snow. Although their clothing is very light, they support this inclement temperature, without the least inconvenience. Habit, it is to be confessed, may contribute a good deal to this, but much also is to be ascribed to the compact texture of their skin, which defends them from the impression of cold through their pores. We must confess, however, notwithstanding the affections and conjectures of an author so respectable as Don Ulloa, that we are not very confident that either the skins, or the skulls of the Americans are thicker than the skins and skulls of many other nations of mankind. But we do not wish, in this place,
to expatiate on this subject, which can only be reduced to certainty by the investigations of the anatomists, or naturalists.

The northern Indians resemble them in this respect.

The utmost rigours of the winter season do not prevent them from following the chase almost naked. It is true, they wear a kind of woolen cloak, or sometimes the skin of a wild beast, upon their shoulders; but besides that it covers only a small part of their body, it would appear that they use it rather for ornament than warmth. In fact, they wear it indifferently, in the severities of winter and in the full treets of summer, when neither Europeans nor Negroes can suffer any but the lightest clothing. They even frequently throw aside this cloak when they go a-hunting, that it may not embarrass them in traversing their forests, where they say the thorns and undergrowth would take hold of it; while, on the contrary, they slide smoothly over the surface of their naked bodies. At all times they go with their heads uncovered, without suffering the least inconvenience, either from the cold, or from those coups de soleil, which in Louisiana are so often fatal to the inhabitants of other climates.

The Indians of South America distinguish themselves by modern dress, in which they affect various tawes. Those of the high country, and of the valleys in Peru, dress partly in the Spanish fashion. Instead of hats they wear bonnets of coarse double cloth, the weight of which neither seems to inconvenience them when they go to warmer climates nor does the accidental want of them seem to be felt in situations where the most piercing cold reigns. Their legs and feet are always bare, if we except a sort of sandals made of the skins of oxen. The inhabitants of South America, compared with those of North America, are described as generally more feele in their frame; less vigorous in the efforts of their mind; of gentler dispositions more addicted to pleasure, and funk in idleness. This, however, is not universally the case. Many of their nations are, as intrepid and enterprising as any in the world. Among the tribes on the banks of the Oronooko, if a warrior aspires to the post of captain, his probation begins with a long fall, more rigid than any ever observed by the most abstemious hermit. At the close of this the chiefs assemble; and each gives him three lashes with a large whip, applied so vigorously, that his body is almost fayed. If he betrays the least symptom of impatience, or even of sensibility, he is disgraced forever, and is rejected as unworthy of the honour. After some interval, his constancy is proved by a more exhausting trial. He is laid in his hammock with his hands bound fast; and an innumerable multitude of venomous ants, whose bite occasions a violent pain and inflammation, are thrown upon him. The judges of his merit stand around the hammock; and whilst these cruel insects fasten upon the most sensible parts of his body, a figh, a groan, or an involuntary motion expressive of what he suffers, would exclude him from the dignity of which he is ambitious. Even after this evidence, his fortitude is not deemed to be sufficiently ascertained, till he has food another trial more severe, if possible, than the former. He is again suspended in his hammock; and covered with the leaves of the palmetto. A fire of flinking herbs is kindled underneath, so as he may feel its heat, and be involved in smoke. Though scorched and almost suffocated, he must continue to endure this with the same patient incontinence. Many perils in this essay of their firmness and courage; but such as go through it with applause, receive the insignia of their new dignity with much solemnity, and are ever after regarded as leaders of approved resolution, whose behaviour, in the most trying situations, will do honour to their country. In North America the previous trial of a warrior is neither so formal nor so severe: Though, even there, before a youth is permitted to bear arms, his patience and fortitude are proved by blows, by fire, and by insulfs, more intolerable to a haughty spirit than either.

Of the manners and customs of the North Americans more particularly, the following is the most consistent account that can be collected from the best informed and most impartial writers.

When the Europeans first arrived in America, they found the Indians quite naked, except those parts which even the most uncivilized people usually conceal. Since that time, however, they generally use a coarse blanket, which they buy of the neighbouring planters.

Their huts or cabins are made of stakes of wood driven into the ground, and covered with branches of trees or reeds. They lay on the floor either on mats or the skins of wild-beasts. Their dishes are of timber, but their spoons are made of the skulls of wild oxen, and their knives of flint. A kettle and a large plate constitute almost the whole utensils of the family. Their diet consists chiefly in what they procure by hunting; and sagamite, or potage, is likewise one of their most common kinds of food. The most honourable furniture amongst them is a collection of the scalps of their enemies; with those they ornament their huts, which are esteemed in proportion to the number of this sort of spoils.

The character of the Indians is altogether founded upon their circumstances and way of life. A people who are constantly employed in procuring the means of a precarious subsistence, who live by hunting the wild animals, and who are generally engaged in war with their neighbours, cannot be supposed to enjoy much gaiety of temper, or a high flow of spirits. The Indians therefore are in general grave even to fadness; they have nothing of that giddy vivacity peculiar to markable fome nations of Europe, and they despise it. Their behaviour to those about them is regular, modest, and respectful. Ignorant of the arts of amusement, of which that of saying tribes agreeably is one of the most considerabfe, they seldom speak but when they have something important to observe; and all their actions, words, and even looks, are attended with some meaning. This is extremely natural to men who are almost continually engaged in pursuits, which to them are of the highest importance. Their sublimate depends entirely on what they procure with their hands; and their lives, their honour, and every thing dear to them, may be lost by the smallest inattention to the designs of their enemies. As they have no particular object to attach them to one place rather than another, they go wherever they expect to find the necessaries of life in greatest abundance. Cities, which are the effect of agriculture and arts, they have none. The different tribes
tribles or nations, are, for the same reason, extremely small, when compared with civilized societies, in which industry, arts, agriculture, and commerce, have united a vast number of individuals, whom a complicated luxury renders useful to one another. These small tribes live at an immense distance; they are separated by a desert frontier, and hid in the bosom of impenetrable and almost boundless forests.

There is established in each society a certain species of government, which prevails over the whole continent of America, with exceeding little variation; because over the whole of this continent the manners and way of life are nearly similar and uniform. Without arts, riches, or luxury, the great instruments of subjection in polished societies, an American has no method by which he can render himself considerate among his companions, but by inferiority in personal qualities of body or mind. But, as nature has not been very lavish in her personal distinctions, where all enjoy the same education, all are pretty much upon an equality, and will desire to remain so. Liberty, therefore, is the prevalent passion of the Americans; and their government, under the influence of this sentiment, is, perhaps, better secured than by the wisest political regulations. They are very far, however, from desiring all sorts of authority; they are attentive to the voice of wisdom, which experience has conferred on the aged, and they enlist under the banners of the chief in whose valour and military address they have learned to repose a just and merited confidence. In every society, therefore, there is to be considered the power of the chiefs and of the elders. Among these tribes which are most engaged in war, the power of the chief is, naturally, predominant; because the idea of having a military leader was the first source of his superiority, and the continual exigencies of the state requiring such a leader, will continue to support, and even to enhance it. His power, however, is rather persuasive than coercive; he is reverenced as a father, rather than feared as a monarch. He has no guards, no prisons, no officers of justice, and one act of ill-judged violence would pull him from his humble throne. The elders in the other form of government which may be considered as a mild and nominal arbitrariness, have no more power. In most countries, therefore, age alone is sufficient for acquiring respect, influence, and authority. It is age which teaches experience, and experience is the only source of knowledge among a barbarous people. Among those persons business is conducted with the utmost simplicity, and which may recall to those who are acquainted with antiquity, a picture of the most early ages. The heads of families meet together in a house, or cabin appointed for the purpose. Here the business is discussed; and here those of the nation, distinguished for their eloquence or wisdom, have an opportunity of displaying their talents. Their orators, like those of Homer, express themselves in a bold figurative style, stronger than refined, or rather softened, nations can well bear, and with gestures equally violent, but often extremely natural and expressive. When the business is over, and they happen to be well provided with food, they appoint a feast upon the occasion, of which almost the whole nation partakes. The feast is accompanied with a song, in which the real or fabulous exploits of their forefathers are celebrated. They have dances too, though, like those of the Greeks and Romans, they are chiefly of the military kind; and their music and dancing accompany every feast.

To assist their memory, they have belts of small Wampum shells, or beads, of different colours, each representing a particular object, which is marked by their colour and arrangement. At the conclusion of every subject on which they discourse, when they treat with a foreign state, they deliver one of those belts; for if this ceremony should be omitted, all that they have paid passes for nothing. Those belts are carefully deposited in each town, as the public records of the nation; and to them they occasionally have recourse, when any public contest happens with a neighbouring tribe. Of late, as the materials of which those belts are made, have become scarce, they often give some skin in place of the wampum (the name of the beads), and receive in return presents of a more valuable kind from the commissioners; for they never consider a treaty as of any weight, unless every article in it be ratified by such a gratification.

It often happens, that those different tribes or nations, scattered as they are, at an immense distance from one another, meet in their excursions after prey. If there subsists no animosity between them, which seldom is the case, they behave in the most friendly and courteous manner; but if they happen to be in a state of war, or if there has been no previous intercourse between them, all who are not friends are deemed enemies, and they fight with the most savage fury.

If we except hunting and fishing, war is the principal employment of the Indian men: almost every other concern, but in particular the little agriculture which they enjoy, is configned to the women. The most common motive of the Americans for entering into war, when it does not arise from an accidental rencontre, or interference, is either to revenge themselves for the death of some lost friends, or to acquire prisoners, who may assist them in their hunting, and whom they adopt into their society. These wars are either undertaken by some private adventurers, or at the instance of the whole community. In the latter case, all the young men who are disposed to go out to battle (for no one is compelled contrary to his inclination), give a bit of wood to the chief, as a token of their design to accompany him; for every thing among these people is transacted with great deal of ceremony and with many forms. The chief who is to conduct them seeks several solemn days, during which he converses with no one, and sits before his fires and obeys the dreams which he desires to observe his dreams; which the foresight natural to savages generally renders as favourable as he could desire. A variety of other superstitious and ceremonies are observed. One of the most hideous is setting the war-kettle on the fire, as an emblem that they are going out to devour their enemies; which, among these nations, is probable, was formerly the case, since they still continue to express it in clear terms, and use an emblem significant of the ancient usage. Then they dispatch a porcelain, or large shell, to their allies, inviting them to come along, and drink the blood of their enemies. For with the Americans, as with the Greeks of old, "A generous friendship no cold medium knows; But with one love, with one repentment, glows."
They think that those in their alliance must not only adopt their enmities, but that they must also have their resentment wound up to the same pitch with themselves. And, indeed, no people carry their friendships or their resentments so far as they do; and this is what should be expected from their peculiar circumstances: that principle in human nature which is the spring of the social affections, acts with so much the greater force the more it is restrained. The Americans, who live in small societies, who see few objects and few persons, become wonderfully attached to those objects and persons, and cannot be deprived of them without feeling themselves miserable. Their ideas are too confined to enable them to entertain just sentiments of humanity, or universal benevolence. But this very circumstance, while it makes them cruel and savage to an incredible degree, towards those with whom they are at war, adds a new force to their particular friendships, and to the common tie which unites the members of the same tribe, or of those different tribes which are in alliance with one another. Without attending to this reflection, some facts we are going to relate will excite our wonder without informing our reason, and we would be bewildered in a number of particulars, seemingly opposite to one another, without being sensible of the general cause from which they proceed.

Having finished all the ceremonies previous to the war, and the day appointed for their setting out on the expedition being arrived, they take leave of their friends, and exchange their clothes, or whatever war, and the day appointed for their setting out on their fine apparel and vegetables they have, in token of mutual friendship; after they deliver them all their finery, and putting on their worst clothes, proceed on their expedition. When they come up to their women, who lead, bear, otter, wolf, tortoise, and eagle; and by having their perceptions sharpened by keen necessity, and living, in every respect, according to nature, their external senses have a degree of acuteness which, at first view, appears incredible. They can trace out their enemies, at an immense distance, by the smoke of their fires, which they smelt, and by the tracks of their feet upon the ground, imperceptible to an European eye, but which they can count and distinguish with the utmost facility. It is said, they can even distinguish the different nations with whom they are acquainted, and can determine the precise time when they passed, where an European could not, with all his glances, distinguishing footsteps at all. These circumstances, however, are of less importance, because their savage enemies are equally well acquainted with them. When they go out, therefore, they take care to avoid making use of anything by which they might run the danger of a discovery. They light no fire to warm themselves, or to prepare their victuals: they lie close to the ground all day, and travel only in the night; and marching along in files, he that closes the rear diligently covers with leaves the tracks of the ground among the withered herbs and leaves, which their faces are painted to resemble. They paint off or pull out all their hair, except a spot about the breadth of two English crown-pieces, near the top of their heads, and entirely destroy their eye-brows. The lock left upon their heads is divided into several parcels, each of which is stiffened and adorned with wampum, heads, and feathers of various kinds, the whole being twisted into a form much resembling the modern pompon. Their heads are painted red down to the eye-brows, and sprinkled over with white down. The gristles of their ears are split almost quite round, and diffused with wires or splinters, so as to meet and tie together on the nape of the neck. These are, also, hung with ornaments, and, generally, bear the representation of some bird, or beast. Their noses are likewise bored and hung with trinkets of beads, and their faces painted, with various colours, so as to make an awful appearance. Their breasts are adorned with a gorget, or medal, of brass, copper, or some other metal; and that dreadful weapon the scalping-knife hangs by a string from the neck.

The great qualities of an Indian war are vigilance and attention, to give and avoid a surpriz; and, indeed, in these they are superior to all nations in the world. Accustomed to continual wandering in the forests; having their perceptions sharpened by keen necessity, and living, in every respect, according to nature, their external senses have a degree of acuteness which, at first view, appears incredible. They can trace out their enemies, at an immense distance, by the smoke of their fires, which they smelt, and by the tracks of their feet upon the ground, imperceptible to an European eye, but which they can count and distinguishing footsteps at all. These circumstances, however, are of less importance, because their savage enemies are equally well acquainted with them. When they go out, therefore, they take care to avoid making use of anything by which they might run the danger of a discovery. They light no fire to warm themselves, or to prepare their victuals: they lie close to the ground all day, and travel only in the night; and marching along in files, he that closes the rear diligently covers with leaves the tracks of the ground among the withered herbs and leaves, which their faces are painted to resemble. They paint off or pull out all their hair, except a spot about the breadth of two English crown-pieces, near the top of their heads, and entirely destroy their eye-brows. The lock left upon their heads is divided into several parcels, each of which is stiffened and adorned with wampum, heads, and feathers of various kinds, the whole being twisted into a form much resembling the modern pompon. Their heads are painted red down to the eye-brows, and sprinkled over with white down. The gristles of their ears are split almost quite round, and diffused with wires or splinters, so as to meet and tie together on the nape of the neck. These are, also, hung with ornaments, and, generally, bear the representation of some bird, or beast. Their noses are likewise bored and hung with trinkets of beads, and their faces painted, with various colours, so as to make an awful appearance. Their breasts are adorned with a gorget, or medal, of brass, copper, or some other metal; and that dreadful weapon the scalping-knife hangs by a string from the neck.

The great qualities of an Indian war are vigilance and attention, to give and avoid a surpriz; and, indeed, in these they are superior to all nations in the world. Accustomed to continual wandering in the forests; having their perceptions sharpened by keen necessity, and living, in every respect, according to nature, their external senses have a degree of acuteness which, at first view, appears incredible. They can trace out their enemies, at an immense distance, by the smoke of their fires, which they smelt, and by the tracks of their feet upon the ground, imperceptible to an European eye, but which they can count and distinguishing footsteps at all. These circumstances, however, are of less importance, because their savage enemies are equally well acquainted with them. When they go out, therefore, they take care to avoid making use of anything by which they might run the danger of a discovery. They light no fire to warm themselves, or to prepare their victuals: they lie close to the ground all day, and travel only in the night; and marching along in files, he that closes the rear diligently covers with leaves the tracks of the ground among the withered herbs and leaves, which their faces are painted to resemble. They paint off or pull out all their hair, except a spot about the breadth of two English crown-pieces, near the top of their heads, and entirely destroy their eye-brows. The lock left upon their heads is divided into several parcels, each of which is stiffened and adorned with wampum, heads, and feathers of various kinds, the whole being twisted into a form much resembling the modern pompon. Their heads are painted red down to the eye-brows, and sprinkled over with white down. The gristles of their ears are split almost quite round, and diffused with wires or splinters, so as to meet and tie together on the nape of the neck. These are, also, hung with ornaments, and, generally, bear the representation of some bird, or beast. Their noses are likewise bored and hung with trinkets of beads, and their faces painted, with various colours, so as to make an awful appearance. Their breasts are adorned with a gorget, or medal, of brass, copper, or some other metal; and that dreadful weapon the scalping-knife hangs by a string from the neck.

the cottage, were, accord-

ing to the elders, a circum-
stantial account of the

mourn their own village; a

men, who have fallen, the

happiness of the survivors,

shrieks come out to

to the people; and as he

mentions the names of those

who have fallen, the

men, too, join in these cries,

as according as each is

most connected with the
deceased by blood or friend-

ship. The last ceremony is the

proclamation of the victory; each in-

dividual then forgets his private misfortunes, and joins

in the triumph of his nation; all tears are wiped from

their eyes, and, by an unaccountable transition,

pafs, in a moment, from the bitterness of sorrow to an

extravagance of joy. But the treatment of the prizon-

ers, whose fate remains all this time undecided, is

what chiefly characterizes the savage.

We have already mentioned the strength of their af-

cections, or resentments. United, as they are, in small

societies, connected, within them selves, by the firmest

ties, their friendly affections, which glow with the

most intense warmth within the walls of their own vil-

lage, seldom extend beyond them. They feel nothing

for the enemies of their nation; and their resentment

easily extended, from the individual who has injured

them, to all others of the same tribe. The prizon-

ers, who have themselves the same feelings, know the

intentions of their conquerors, and are prepared for them.

The person who has taken the captive attends him to

the cottage, where, according to the distribution made

by the elders, he is to be delivered to supply the loss of a

citizen. If those who receive him have no affection for

him, he is weakened by war or other accidents, they at-}

tend the captive into the family, of which he becomes a

member. But if they have no occasion for him, or their

resentment for the loss of their friends is too high to

endure the sight of any connected with those who

were concerned in it, they sentence him to death.

All those who have met with the same severe sentence

being collected, the whole nation is assembled at the

execution, as for some great solemnity. A scaffold is

erected, and the prisioners are tied to the stake, where

they commence their death-song, and prepare for the

enjoying scene of cruelty with the most unfortified
courage. Their enemies, on the other side, are deter-

mined to put it to the proof, by the most refined and ex-

quisite tortures. They begin at the extremity of his

body, and, gradually, approach the more vital parts.

One plucks out his nails by the roots, one by one;

another takes a finger into his mouth, and tears off the

flesh with his teeth; a third thrusts the finger, mangled

as it is, into the bowl of a pipe made red-hot, which he

smokes like tobacco; then they pound his toes and

fingers to pieces between two stones; they cut circles about

his joints, and gashes in the fleshy parts of his limbs, which

they fear immediately with red-hot irons, cut-
ting, burning, and pinching them, alternately; they

pull off his flesh, thus mangled and roasted, bit by bit,

devouring it with greediness, and smearing their faces

with the blood, in an enthusiasm of horror and fury.

When they have thus torn off the flesh, they twist the

bare nerves and tendons about an iron, tearing and

snapping them, whilst others are employed in pulling

and extending his limbs in every way that can in-
crease the torment. This continues, often, five or six

hours; and sometimes, such is the strength of the sa-

vages, days together. Then they frequently unbind

him, to give a breathing to their fury, to think what

new torments they shall inflict, and to renew the

strength of the sufferer, who, wearied out with such a

variety of unheard-of torments, often falls into a pro-

found a sleep, that they are obliged to apply the fire

to awake him, and renew his sufferings. He is again

fartened to the stake, and again they renew their cru-

ality; they flick him all over with small matches of

wood that easily takes fire, but burns slowly; they con-

tinually run sharp reeds into every part of his body;

they drag out his teeth with pincers, and thrust out his

eyes; and, lastly, after having burned his flesh from

the bones with slow fires; after having so mangled the

body that it is all but one wound; after having mutila-
ted his face in such a manner as to carry nothing hu-

man in it; after having peeled the skin from the head,

and poured a heap of red hot coals or boiling water

over the same skull—thence more mangled the wretch;

who, blind, and staggered with pain and weakness,

assaulted and pelted on every side with clubs and ftones,

now up, now down, falling into their fires at every

step, runs hither and thither, until one of the chiefs,

whether out of compassion, or weary of cruelty, puts an

end to his life with a club or dagger. The body is then

put into a kettle, and this barbarous employment is

successed by a feast as barbarous.

The women, forgetting the human as well as the

female nature, and transformed into something worse

than furies, are falted to furpafs even the men in this scene

of horror; while the principal perffons of the country

round the stake, smoking and looking on, without

the least emotion. What is most extraordinary, the

sufferer himfelf, in the little intervals of his torment,

smokes too, appears unconcerned, and converses with

his torturers about indifferent matters. Indeed, during

the whole time of his execution, there seems a contest

of confcioufness of the faint of the fex, which fhall exceed,

them in inflicting the moft horrid pains, or in enduring them with a firmnefs and confcioufness above human: not a groan, not a figh,

not a diftortion of countenance, escapes him: he pol-

ffeis his mind entirely in the midft of his torments:

he recounts his own exploits: he informs them what
cruelties he has inflicted upon their countrymen; and

threatens them with the vengeance that will attend his
death; and, though his reproaches exasperate them to a

perfect madness of rage and fury, he continues his

infults even of their ignorance of the art of torment-
ing, pointing out himself more exquisite methods, and

more fenfible parts of the body to be afflicted. The

women have this part of courage as well as the men;

and it is as rare for an Indian to behave otherwise as

it would be for any European to suffer as an Indian.

Such is the wonderful power of an early infitution,

and a ferocious thirt of glory! "I am brave and in-

trepid.
journey which he is supposed to take. \textit{This solemnity, like every other, is attended with feasting. The funeral being ended, the relations of the deceased confine themselves to their huts, for a considerable time, to indulge their grief. After an interval of some weeks, they visit the grave, repeat their sorrow, new-clothe the remains of the body, and act over again all the formalities of the funeral.}

Among the various tokens of their regard for their deceased friends, the most remarkable is the ceremony which they call the \textit{feast of the dead}, or the \textit{feast of souls}. The day for the ceremony is appointed in the council of their chiefs, who give orders for every thing which may enable them to celebrate it with pomp and magnificence; and the neighbouring nations are invited to partake of the entertainment. At this time, all who have died since the preceding feast of the kind are taken out of their graves. Even those who have been interred at the greatest distance from the villages, are diligently sought for, and conducted to this rendezvous of the dead, which exhibits a scene of horror beyond the power of description. When the feast is concluded, the bodies are dried in the finest skins which can be procured, and after being exposed for some time in this pomp, are again committed to the earth, with great solemnity, which is succeeded by funeral games.

Their taste for war, which forms the chief ingredient in their character, gives a strong bias to their religion. \textit{Arekouo}, or the god of battle, is revered as the great god of the Indians. Him they invoke before they go into the field; and according as his disposition is more or less favourable to them, they conclude they will be more or less successful. Some nations seem to do a kind of homage to the sun, as a symbol, or minister of the beneficence and power of the \textit{Great Spirit}; others pay a similar homage to the moon and planets; among others, there is a number of traditions, relative to the creation of the world and the history of the gods: traditions which resemble the Grecian fables, but which are still more absurd and inconsistent. But religion is not the prevailing character of the Indians; and except when they have some immediate occasion for the affluence of their gods, they pay them no sort of worship. Like all rude nations, however, they are strongly addicted to superstition. They believe in the existence of a number of good and bad genii, or \\textit{spirits}, who interfere in the affairs of mortals, and produce all our happiness, or misery. It is from the evil genii, in particular, that our diseases, they imagine, proceed; and it is to the good genii we are indebted for a cure. The ministers of the genii are the jugglers, who are also the chief physicians among the savages. These jugglers are supposed to be inspired by the good genii, most commonly in their dreams, with the knowledge of future events: they are called in to the affluence of the sick, and are supposed to be informed by the genii whether they will get over the disease, and in what way they must be treated. But these spirits are extremely simple in their system of physic, and, in almost every case, direct the juggler to the same remedy. The patient is included in a narrow cabin, in the midst of which is a stone red-hot; on this they throw water, until he is well soaked with the warm vapour and his own sweat. Then they hurry him from this bagnio, and plunge him suddenly,
AMERICA

Polygamy is practised by some nations, but it is not general. In most, they content themselves with one wife; but a divorce is admitted of in case of adultery. No nation of the Americans is without a regular marriage, in which there are many ceremonies; the principal of which is, the bride’s presenting the bridegroom with a plate of their corn. The women, though before inexperienced, are remarkable for chastity after marriage.

Liberty, in its full extent, being the darling passion of the Indians, their education is directed in such a manner as to cherish this disposition to the utmost. Hence children are never upon any account chastised with blows, and they are seldom even reprimanded. Reason, they say, will guide their children when they come to the use of it, and before that time their faults cannot be very great: but blows might damp their free and martial spirits, by the habit of a servile motive to aotion. When grown up, they experience nothing like command, dependence, or subordination; even strong provocation is indignantly withheld by those who have influence among them. — No man is held in great esteem, unless he has increased the strength of his country with a captive, or adorned his hut with a scalp of one of his enemies.

Controversies among the Indians are few, and quickly decided. When any criminal matter is so flagrant as to become a national concern, it is brought under the jurisdiction of the great council; but in ordinary cases, the crime is either revenged or compromised by the parties concerned. If a murder be committed, the family which has lost a relation prepares to retaliate on that of the offender. They often kill the murderer; and when this happens, the kindred of the last person slain look upon themselves to be as much injured, and to have the same right to vengeance, as the other party. In general, however, the offender absents himself; the friends send compliments of condolence to those of the person who has been murdered. The head of the family, at length, appears with a number of presents, the delivery of which he accompanies with a formal speech. The whole ends, as usual, in mutual feastings, in songs, and in dances. If the murder is committed by one of the same family, or cabin, that cabin has the full right of judgment within itself, either to punish the guilty with death, or to pardon him, or to oblige him to give some recompense to the wife or children of the slain. Instances of such a crime, however, very seldom happen, for their attachment to those of the same family is remarkably strong, and is said to produce such friendships as may vie with the most celebrated in fabulous antiquity.

Such, in general, are the manners and customs of the peculiar Indian nations; but almost every tribe has something peculiar to itself. Among the Hurons, and the Natchez, the dignity of the chief is said to be hereditary, and the right of succession in the female line. When this happens to be extinct, the most respectable matron of the tribe, we are informed, makes choice of whom she pleases to succeed.

The Cheesake are governed by several factions, or chiefs, elected by the different villages; as are also the Creeks, and the Cherokees. The two latter punish adultery in a woman by cutting off her hair, which they will not suffer to grow till the corn is ripe, the next
The Indians on the Lakes are formed into a sort of empire; and the emperor is elected from the chief tribe, which is that of the Ottowaws. This authority is very considerable. A few years ago, the person who held this rank formed a design of uniting all the Indian nations, under his sovereignty; but he miscarried in the bold attempt.

In general, the American Indians live to a great age, although it is not easy to know from themselves the exact number of their years. It was asked of an Indian, who appeared to be extremely old, what age he was? I am above twenty was his reply. Upon asking the question in a different form, by reminding him of certain circumstances, in former times, my macho, said he, spoke to me, when I was young, of the Incas; and he had seen those princes. According to this reply, there must have elapsed, from the date of his macho's (his grandfather's) remembrance to that time, a period of, at least, 232 years. The man who made this reply, appeared to be 120 years of age: for, besides the whiteness of his hair and beard, his body was almost bent to the ground; without, however, showing any other marks of debility, or suffering. This happened in 1764. This longevity, attended in general with uninterrupted health, is thought, by some writers, to be the consequence, in part, of their vacancy from all pursuits of industry, and employment, joined also with the robust texture and constitution of their bodily organs. If the Indians did not destroy one another, in their almost perpetual wars, and if their habits of intoxication were not so universal and irremediable, they would be, of all the races of men who inhabit the globe, the most likely to extend, not only the bounds, but the enjoyments, of animal life to their utmost duration.

Let us now attend to other pictures which have been given of the aboriginal inhabitants of the New-World. The vices and defects of the American Indians have been, by several writers, not only accounted a disgrace, and one of the principal, but also of the evil, and the cause of all the cruelty, they have been accused of, and accounted for. The following anecdote of an Algonquin woman we find adduced as a remarkable proof of their innate thirst of blood. That nation being at war with the Iroquois, she happened to be taken prisoner, and was carried to one of the villages belonging to them. Here she was stripped naked, and her hands and feet bound, with ropes, in one of their cabins. In this condition she remained ten days, the savages sleeping round her every night. The eleventh night, while they were asleep, she found means to disengage one of her hands, with which she immediately freed herself from the ropes, and went to the door. Though she had now an opportunity of escaping unperceived, her revengeful temper could not let her fly to a favourable opportunity of killing one of her enemies. The attempt was manifestly at the hazard of her own life; yet, snatching up a hatchet, she killed the savage that lay next her: and, quitting the cabin, concealed herself in a hollow tree, where she had observed the day before. The groans of the dying person soon alarmed the other savages, and the young ones immediately set out in pursuit of her. Perceiving, from her tree, that they all directed their course one way, and that no savage was near her, she left her sanctuary, and flying by an opposite direction, ran into a forest without being perceived. The second day after this happened, her footsteps were discovered; and they pursued her with such expedition, that the third day she discovered her enemies at her heels. Upon this, she threw herself into a pond of water; and diving among some weeds and bulrushes, she could just breathe above water without being perceived. Her pursuers, after making the most diligent search, were forced to return.—For 35 days this woman held on her course through woods and deserts, without any other sustenance than that which roots and wild berries afforded her. When she came to the river St Lawrence, she made, with her own hands, a kind of wicker raft, on which she crossed it. As she went by the French fort Trois-Rivières, without well knowing where she was, she perceived a canoe full of savages; and fearing they might be Iroquois, ran again into the woods, where she remained till sunset. Continuing her course soon after, the saw Trois-Rivières; and was then discovered by a party whom she knew to be Hurons, a nation in alliance with the Algonquins. She then squatted down, behind a bush, calling out to them that she was not in a condition to be seen, because she was naked. They immediately threw her a blanket, and then conducted her to a fort, where she recounted her story. Personal courage has been her title. In proof of Repoch their plianility, the following incidents are quoted from Charlevoix by lord Kames, in his Sketches of the History of Man. “The fort de Vercheres, in Canada, belonging to the French, was, in the year 1690, attacked by the Iroquois. They approached silently, preparing to scale the palisade, when some musket-shot made them retire. Advancing a second time, they were again repulsed, wondering that they could discover none but a woman, who was seen every where. This was Madame de Vercheres, who appeared as resolute as if supported by a numerous garrison. The hopes of forming a storming-place without delay, occasioned reiterated attacks. After two days they fled they retired, fearing to be intercepted in their retreat. Two years after a party of the same nation appeared before the fort unexpectedly, that a girl of fourteen, daughter of the proprietor, had but time to shut the gate. With the young woman there was not a soul but one raw soldier. She showed herself, with her affiant, sometimes in one place, and sometimes in another; changing her dress frequently, in order to give some appearance of a garrison; and always firing opportunist. The faint-hearted Iroquois desisted without success.

There is no instance, it is said, either of a single Indian facing an individual, of any other nation, in fair and open combat, or of their jointly venturing to try the fate of battle with an equal number of any foes. Even with the greatest superiority of numbers, they dare not meet an open attack. Yet, notwithstanding this want of courage, they are still formidable; nay, it has been known, that a small party of them has routed a much superior body of regular troops: but this can only happen when they have surprized them in the fastnesses of their forrests, where the covert of the wood may conceal them until they take their aim with the utmost certainty. After one such discharge they immediately retreat.
Nor can this odious cruelty and treachery, it is said, be justly ascribed to their submission to a foreign yoke, seeing the same character belongs equally to all the original inhabitants of this vast continent, even to those who have preferred their independence most completely. Certain it is, continues Ulloa, that these people, with the most limited capacities for every thing else, display an astonishing degree of penetration and subtility, with respect to every object that involves treachery, bloodshed, and rapine. As to these, they seem to have been all educated at one school; and a secret, referring to any such plan, no consideration on earth can extort from them.

Their understandings also have been represented as not less contemptible than their manners are gross and brutal. Many nations, it has been said, are neither capable of forming an arrangement for futurity, nor does their solicitude or foresight extend so far. They set no value upon those things of which they are not in some immediate want. In the evening, says father Labrador, when a Carib is going to rest, no consideration will tempt him to sell his hammock; but in the morning he will part with it for the lightest trifle. At the close of winter, a North-American, mindful of what he has suffered from the cold, sets himself with vigour to prepare materials for erecting a comfortable hut, to protect him against the inclemency of the succeeding season; but as soon as the weather becomes mild, he abandons his work, and never thinks of it more till the return of the cold compels him to resume it. In Alleged ingenuity and obedience, and in supposed stupidity.

The fame gross stupidity is alluded to in those Indians who have retained their original liberty. They are never known to fix the dates of any events in their minds, or to trace the succession of circumstances that have arisen from such events. Their imagination takes in only the present, and in that only what intimately concerns themselves. Nor can discipline or instruction overcome this natural defect of apprehension. In fact, the subject to whom the Spanish, who are furnished with curates perpetually occupied in giving them leons of religion and morality, and to whom are related the exploits of the civilized society established among them, are almost as stupid and barbarous as their countrymen who have had no such advantages. The Peruvians, while they lived under the government...
Their vanity and conceit.

Vanity and conceit are said to be blended with their ignorance, and treachery. Notwithstanding all they suffer from Europeans, they still, in fact, confider themselves as a race more superior to their conquerors. This proud belief, arising from a perverted idea of excellence, is universal over the whole known continent of America. They do not think it possible that any people can be so intelligent as themselves. When they are detected in any of their plots, it is their common observation, that the Spaniards, or Viriobusce, want to be as knowing as they are. Those of Louisiana and the countries adjacent, are equally vain of their superior underhanding; confounding that quality with the cunning which they themselves constantly practice. The whole object of their transactions is to over-reach those with whom they deal. Yet though these last themselves, they never forgive the breach of promise on the part of others. While the Europeans seek their amity by presents, they give themselves no concern to secure a reciprocal friendship. Hence, probably, arises their idea, that they must be a superior race of men, in ability and intelligence, to those who are at such pains to court their alliance, and avert their enmity.

Their eloquence despised.

Their natural eloquence has also been decreed. The free tribes of savages who enter into conventions with the Europeans, it is observed, are accustomed to make long, pompous, and, according to their own notions, sublime harangues, but without any method, or connection. The whole is a collection of disjointed metaphors and comparisons. The light, heat, and course of the sun, form the principal topic of their discourse; and these unintelligible reasonings are always accompanied with violent and ridiculous gestures. Numbers, repetitions prolong the oration, which, if not interrupted, would last whole days: at the same time, they meditate very deep for what they are to say, and the whole is but a vain effort to obtain. This prominent faculty of making speeches is also one of the grounds on which they conceive themselves to be superior to the nations of Europe: they imagine that it is their eloquence that procures them the favours they ask. The subject being their language, to reflect in this respect, is diftinguished a civilized Peruvian from an inhabitant of the most savage districts to the northward.

Concerning the stature of the Americans, M. de Stature, says, that although, in general, it is not equal to the stature of the Caftilians, there is but little difference between them. But the Abbé Clavigero evincem, that the Indians who inhabit those countries lying between 9 and 40 degrees of north latitude, which are the limits of the discoveries of the Spaniards, are more than five Parilin feet in height, and that those who do not reach that stature, are as few in number among the Indians as they are among the Spaniards. It besides certain, that many of the American nations, such as the Apachis, the Hiaques, the Pincuses, and Cochis, are at least as tall as the tallest Europeans; and that, in all the vast extent of the New-World, no race of people has been found, except the Equimaux, in the north, and west, and the Yacana-cunines, and Znulais, &c. in the south, so diminutive in stature as the Laplanders, the Samojeds, and Tartars, in the north of the Old-Continente. In this respect, therefore, the inhabitants of the two continents are upon an equality.

Of the shape and character of the Mexican Indians, the Abbé gives a most advantageous description; which he afferts, no one, who reads it, in America, will contradict, unless he views them with the eye of a prejudiced mind. It is true, that Ulloa, in speaking of the Indians of Quito, he had observed that "imperfect people abounded among them that they were either irregularly.
A M E

regularly diminutive, or monstrous in some other respect; that they became either insensible, dumb, or blind; or wanted some limb of their body."

Having, therefore, made some inquiry respecting this singularity of the Quittans, the Abbé found, that such defects were neither caused by what he calls bad humours, nor by the climate, but by the mistaken and blind humanity of their parents, who, in order to free their children from the hardships and toils to which the healthy Indians are subjected by the Spaniards, fix some deformity or weakness upon them, that they may become useless: a circumstance of misery which does not happen in other countries of America, nor in those places of the same kingdom of Quito, where the Indians are under no such oppression. M. de Pauw, and in agreement with him, Dr Robertson, says, that no deformed persons are to be found among the savages of America; because, like the ancient Lacedæmonians, they put to death those children which are born hunch-backed, blind, or defective in any limb; but that in those countries where they are formed into societies, and where the vigilance of their rulers prevents the murder of such infants, the number of their deformed individuals is greater than it is in any country of Europe. This would make an exceedingly good solution of the difficulty if it were true: but if, possibly, there has been in America a tribe of savages who have imitated the barbarous example of the celebrated Lacedæmonians, it is certain that those authors have no grounds to imagine more contrary to the idea we have of beauty, and the perfection of the human frame, than a man, whose skin is black as ink, whose head and face are covered with black wool, instead of hair, whose eyes are yellow and bloody, whose lips are thick and blackish, and whose nose is flat! Such are the inhabitants of a very large portion of Africa, and of many islands of Asia. What men can be more imperfect than those who preceded no more than four feet in stature, whose faces are long and flat, the nose compressed, the irides yellowish black, the eye-lids turned back towards the temples, the cheeks extraordinarily elevated, their mouths monstrously large, their lips thick and prominent, and the lower part of their visages extremely narrow? Such, according to Count de Buffon, are the Laplanders, the Zemblans, the Borandines, the Sancjeds, and the Tartars, in the East. What objects more deformed than men whose faces are too long and wrinkled even in their youth, their noses thick and compressed, their eyes small and sunk, their cheeks very much raised, the upper jaw low, their teeth long and disfigured, eye-brows so thick that they shade their eyes, the eye-lids thick, some bristles on their faces instead of beard, large thighs and small legs? Such is the picture Count de Buffon gives of the Tartars; that is, of those people who, as he says, inhabit a tract of land in Asia 1200 leagues long and upwards, and more than 750 broad. Amongst these, the Calmucks are the most remarkable for their deformity: which is so great, that according to TavNIer, they are the most brutal men of all the universe. Their faces are so broad that there is a space of five or six inches between their eyes, as Count de Buffon himself affirms. In Cali- cut, in Ceylon, and in other countries of India, there is, says Pyrard, and other writers, on those regions, a race of men who have one, or both, of their legs as thick as the body of a man; and that this deformity among them is almost hereditary.

If we were, in like manner, to go through the nations of Asia and Africa, we should hardly find any extensive country where the colour of men is not darker, where there are not greater irregularities observed, and groffer defects to be found in them, than even the penetrating eye of de Pauw could discover in the Americans. The colour of the latter is a good deal clearer than that of almost all the Africans and the inhabitants of South Asia. Even their alleged scantiness of beard is common to the inhabitants of the Philippine-Islands, and of all the Indian-Archipelago, the Mala- nefe, Japanese, Tartars, and many other nations of the Old-Continent. The imperfections of the Americans, however great they may be represented to be,
Their constitution and corporeal abilities.

55. Their constitution and corporeal abilities.

...are, certainly, not comparable with the defects of that immense people, whose character we have sketched, and others whom we omit.

M. de Pauw represents the Americans to be a flexible and defeated set of nations; and, in order to demonstrate the weakness and disorder of their physical constitution, adduces several proofs equally ridiculous and ill-founded, and which it will not be expected we should enumerate. He alleges, among other particulars, that they were overcome in wrestling by all the Europeans, and that they fink under a moderate burden; that by a computation made, 200,000 Americans were found to have perished, in one year, from carrying of baggage. With respect to the first point, the Abbé Clavigero observes, it would be necessary that the experiment of wrestling was made between many individuals of each continent, and that the victory should be attributed by the Americans, as well as by the Europeans. It is not, however, meant to infift, that the Americans are stronger than the Europeans. They may be less strong, without the human species have degenerated in them. The Swifs are stronger than the Italians; and still we do not believe the Italians are degenerated nor do we think, to have perished, from the weight of baggage, were it true, would not convince, so much of the weakness of the Americans, as of the inhumanity of the Europeans. In the same manner that these 200,000 Americans perished, 200,000 Prufians would also have perished, had they been obliged to make a journey of between 300 and 400 miles, with 100 pounds of burden upon their backs: if they had collars of iron about their necks, and were obliged to carry that load over rocks and mountains; if those who became exhausted with fatigue, or wounded their feet so as to impede their progress, had their heads cut off that they might not retard the pace of the rest; and if they were not allowed but a small morsel of bread to enable them to support so severe a toil. Las Casas, from whom M. de Pauw got the account of the 200,000 Americans, who died under the weight of carrying baggage, relates, also, all the abovementioned circumstances. If that author, therefore, is to be credited in the last, he is also to be credited in the first. But, a philosopher who wants to become witness of the several constitutions and corporeal qualities of Europeans, over those of the Americans, would have done better, we think, to suppress facts so opprobrious to the Europeans themselves.

Nothing, in fact, demonstrates so clearly the robustness of the Americans as those various, and lasting, fatigues in which they were continually engaged. M. de Pauw says, that when the New-World was discovered, nothing was to be seen but thick woods; that, at present, there are some lands cultivated, not by the Americans, however, but by the Africans, and Europeans; and that the soil in cultivation is to the soil which is uncultivated as 2000 to 2,000,000. These three assertions the Abbé Clavigero demonstrates to be precisely so many errors. Since the conquest, the Americans alone have been the people who have supported all the fatigues of agriculture in all the vast countries of the continent of South America, and in the greater part of those of North America subject to the crown of Spain. No European is ever to be seen employed in the labours of the field. The Moors, who, in comparison of the Americans, are very few in number in the kingdom of New-Spain, are charged with the culture of the sugarcane, and tobacco, and the making of sugar; but the soil destined for the cultivation of those plants is not, with respect to all the cultivated land of that country, in the proportion of one to two thousand. The Americans are the people who labour on the soil. They are the tillers, the plowers, the weeder, and the reapers of the wheat, of the maize, of the rice, of the beans, and other kinds of grain or pulse, of the cocoa, of the vanilla, of the cotton, of the indigo, and all other plants useful to the subsistence, the clothing, and commerce of those provinces; and without them so little can be done, that in the year 1762, the harvest of wheat was abandoned, in many places, on account of a sickness which prevailed, and prevented the Indians from reaping it. But this is not all; the Americans are they who cut and transport all the necessary timber from the woods, who cut, transport, and work the fomes: who make lime, plaster, and tiles: who construct all the buildings of that kingdom, except a few places where none of them inhabit; who open and repair all the roads, who make the canals and sluices, and clean the cities. They work in many mines of gold, of silver, of copper, &c.: they are the shepherds, herdmen, weavers, potters, basket-makers, bakers, carriers, day-labourers; &c.: in a word, they are the persons who bear all the burden of public labours. These, says our judicious and indignant author, are the employments of the weak, dastardly, and useless Americans; while the vigorous M. de Pauw, and other indefatigable Europeans, are occupied in writing invectives against them.

These labours, which the Indians are continually employed, certainly, attest their healthiness and strength, for if they are able to undergo such fatigues, they can not be diseased, nor have an exhausted flame of blood in their veins, as M. de Pauw infinuates. In order to make it believed that their constitutions are vitiated, he copies whatever he finds written by historians of America, whether true or false, respecting the diseases which reign in some particular countries of that great continent. It is not to be denied, that in some countries in the wide compass of America, men are exposed, more than elsewhere, to the distempers which are occasioned by the tempestuous climate that is peculiar to the continent; but it is certain, according to the assertion of many respectable authors, acquainted with the New-World, that the American countries, for the most part, are healthy; and if the Americans were disposed to retaliate on M. de Pauw, and other European authors, who write as he does, they would have abundant subject of materials to throw discredit on the climate of the Old-Continent, and the constitution of its inhabitants in the endemic distempers which prevail there.

Lastly, the supposed feebleness and unprofitable habit of the Americans do not correspond with the length of their lives. Among those Americans whose great fatigue and excessive toils do not anticipate their death, there are not a few who reach the age of 80, 90, and 100, or more years, as formerly mentioned; and, what is more, without there being observed in them that decay which time commonly produces in the hair, in the teeth, in the skin, and in the mufcles of the human body. This phenomenon, so much admired by the
The Spaniards who reside in Mexico, cannot be ascribed to any other cause than the vigour of their constitutions, the temperance of their diet, and the slowness of their climate. Historians, and other persons who have resided there for many years, report the same thing of other countries of the New-World.

As to the mental qualities of the Americans, M. de Pauw has not been able to discover any other characters than a memory so feeble, that to-day they do not remember what they did yesterday; a capacity so blunt, that they are incapable of thinking or putting their ideas in order; a disposition so cold, that they feel no excitement of love; a daftardly spirit, and a genius that is torpid, and indolent. Many other Europeans, indeed, and what is still more wonderful, many of those children or descendants of Europeans who are born in America, think as M. de Pauw does; some from ignorance, some from want of reflection, and others from hereditary prejudice and prepossession. But all this, and much more, would not be sufficient to invalidate the testimonies of other Europeans, whose authority has a great deal more weight, both because they were men of great judgment, learning and knowledge, of those countries, and because they give their testimony in favour of strangers, against their own countrymen. In particular, Acosta, whose Natural and Moral History even de Pauw commends as an excellent work, employs the whole sixth book in demonstrating the good fate of the Americans, by an explanation of their ancient government, their laws, their histories in paintings and knots, calendars, &c. M. de Pauw thinks the Americans are bestial; Acosta, on the other hand, reprove those persons weak and presumptuous who think them so.

M. de Pauw says, that the most acute Americans were inferior in industry and sagacity to the rudest nations of the Old-Continent; Acosta extols the civil government of the Mexicans above many republics of Europe. M. de Pauw finds, in the moral and political conduct of the Americans, nothing but barbarity, extravagance, and brutality; and Acosta finds there, laws which are admirable, and worthy of being preferred for ever.

M. de Pauw denies them courage, and alleges the conquest of Mexico as a proof of their cowardice. "Cortes (says he) conquered the empire of Mexico with 450 vagabonds, and 15 horses, badly armed; his miserable artillery consisted of six falconets, which would not at the present day be capable of exciting the fears of a forlorned defended by invalids. During his absence, the capital was held in awe by the half of his troops. What men! what events!—It is confirmed by the depositions of all historians, that the Spaniards entered, the first time, into Mexico without making one single discharge of their artillery. If the title of hero is applicable to him who has the disgrace to occasion the death of a great number of rational animals, Ferdinand Cortes might pretend to it; otherwise I do not see what true glory he has acquired by the overthrow of a tottering monarchy, which might have been destroyed, in the same manner, by any other assassin of our continent."

These passages indicate either M. de Pauw's ignorance of the history of the conquest of Mexico, or a wilful fabrication of what would openly contradict his system; since all who have read that history know well, that the conquest of Mexico was not made with 450 men, but with more than 200,000. Cortes himself, to whom it was of more importance than to M. de Pauw to make his bravery conspicuous, and his conquest appear glorious, confesses the excessive number of the allies who were under his command, at the siege of the capital, and combated with more fury against the Mexicans than the Spaniards themselves. According to the account which Cortes gave to the emperor Charles V. the siege of Mexico began with 87 horses, 848 Spanish infantry, armed with guns, cross-bows, swords, and lances, and upwards of 75,000 allies, of Tlacalca, Hueztonico, Cholula, and Chalco, equipped with various sorts of arms; with three large pieces of cannon of iron, 15 small of copper, and 17 brigantines. In the course of the siege were assembled the numerous nations of the Otomies, the Cehouxicas, and Matlazinikas, and the troops of the populous cities of the lakes; so that the army of the bejegiers not only exceeded 200,000, but amounted to 400,000 according to the letter from Cortes; and besides these, 3000 boats and canoes came to their assistance. Did it betray cowardice to have sustained, for full 75 days, the siege of an open city, engaging, daily, with an army so large, and in part provided with arms so superior, and at the same time having to withstand the ravages of famine? Can they merit the charge of cowardice, who, after having lost seven of the eight parts of their city, and about 50,000 citizens, part cut off by the sword, part by famine and sickness, continued to defend themselves until they were furiously assailed in the last hold which was left them? See the article Mexico.

According to M. de Pauw, "the Americans at first Remarks were not believed to be men, but rather fayrens, or blefionate large apes, which might be murdered, without reparation, or reproach. At last, in order to add insult in M. de Pauw.

To the opprobrium of these times, a pope made an original bull, in which he declared, that being dehorous of founding bithoprics in the richest countries in America, it pleased him and the Holy-Spirit, to acknowledge the Americans to be true men; in so far, that without this decision of an Italian, the inhabitants of the New-World would have appeared, even at this day, to the eyes of the faithful, a race of equivocal men. There is no example of such a decision since this globe has been inhabited by men and apes." Upon this passage the Abbé Clavigero animadverts, as being a singular infatation of calumnies and misrepresentation, and gives the following history of the decision alluded to.

"Some of the first Europeans who established themselves in America, not less powerful than avaricious, the famous idlers of enriching themselves to the detriment of the Indians, kept them continually employed, and made use of them as slaves; and, in order to avoid the reproaches, which were made them, by the bishops and misionaries, who inculcated humanity, and the giving liberty to those people to get themselves instructed in religion, that they might do their duties towards the church, and their families, alleged, that the Indians were by nature slaves and incapable of being instructed; and many other falsehoods of which the Chronicler Herrera makes mention against them. Theze vealous ecclesiastics being unable, either by their authority, or preaching, to free those unhappy converts from the tyranny of such masters, had recourse to the Catholic kings, and,
AME [ 556 ]

America. at last, obtained from their justice and clemency, those laws, as favourable to the Americans as honourable to the court of Spain, that compose the Indian code, which were chiefly due to the indefatigable zeal of the bishop de las Casas. On another side, Garces, bishop of Tlaxcala, knowing that those Spaniards were, notwithstanding their perversity, a great respect to the decision of the vicar of Jefus Christ, made application, in the year 1586, to Pope Paul III. by that famous letter, of which we have made mention; representing to him the evils which the Indians suffered from the wicked Chriflians, and praying him to interpose his authority in their behalf. The pope, moved by such heavy remonstrances, dispatched, the next year, the original bull, a faithful copy of which we have here subjoined (a), which was not made, as is manifest, to declare the Americans true men; for such a piece of weakness was very distant from that or any other pope: but solely to support the natural rights of the Americans, against the attempts of their oppressors, and to condemn the injustice and inhumanity of those, who, under the pretence of flapping those people idolatrous, or incapable of being instructed, took from them their property and their liberty, and treated them as slaves and beasts.

But if, at first, the Americans were esteemed savages, nobody can better prove it than Christopher Columbus, their discoverer. Let us hear, there fore, how that celebrated admiral speaks, in his account to Ferdinand and Isabella, of the first savages he saw in the island of Haiti, or Hispaniola. "I swear," he says, "to your majesties, that there is not a better people in the world than theirs, more affectionate, affable, or mild. They love their neighbours as themselves; their language is the sweetest, the softest, and the most cheerful; for they always speak smiling; and although they go naked, let your majesties believe me, their customs are very becoming; and their king, who is served with great majesty, has such engaging manners, that it gives great pleasure to see him, and also to consider the great retentive faculty of that people, and their degree of knowledge, which incites them to ask the causes and the effects of things."

(a) Paulus papa III. univerilis Chrifti Fidelibus prefentes Literas inspeditus Salutem & Apostolicam Benedictionem— "Veritas ipsa, qua nec fallaci, nec fallacere potest, cum Praedicatorum Fidei ad officium praedicationis dedicarit, dixisse dignitatur: Eiusque doni omnibus gentes: omnes, dixit, abique omni decetius, cum omnibus Fidei disciplina capaces exsitan. Quod videns & invicens iiusus humani generis semulius, qui bonos operibus, ut peram, temperat adverfarum, modum excogitavit haecenus inaudita, quo impediret, ne Verbum Dei Gentibus, ut salve fierent, praediceretur: ut quodam eius felicibus commovit, qui fuerit cupiditatem admirabilem cupientes. Occidentales & Meridionales Indos, & alias Gentes, quae temporibus litis ad nostrum notitiam pervenerunt, ut praetextu quod Fidei Catholicae expertes existet, ut bruta animalia, ad nostrae obedientia redigendos esse, paullum afferrere praebunt, & eos in favitum redigent tantis adelphonis illis urgentes, quantis vix bruta animalia illis fervientia urgent. Nosigitur, qui quidem Domini nobis viciss, licet indigni, generalis in terris, & Omnes gregis sui nobis committis, quae extra ejus Ordines sunt, non habeas cognitio ritum & ius, iisque post naves, & laudes, & laudem homines, non solum Christianae Fidei capaces existere, sed, ut nobis innotuet, ad Fidelam Ipsam praeconem securitatem, ac velentem fupers eius congrus remedius provivere, praedictos Indos & omnes alius gentes ad nostram Christi nostrum inter numquem, licet extra fidem Christi existant, suas libertatem & dominium hujusmodi uti, & positi, & gaudere libere, & licetore potest, nec in favitum redigi debe, ac quosque tovs dominium inter se referri integrum & inane, iusque ipsose, & alias Gentes Verbi Dei praedicatione, & exemplum bonae vitae ad diemad fidem Christi invitandos fore. Autoritate Apostolica per praebentes literas decretum, & declarata, non obstatis proemilliis, eeterque contrariis quibuscumque." Datam Romae anno 1537. IV. Non. Ian. Pontificatus nostrorum anno III. Quae, a non alia est quae famosa bolla, per la quale s'è fatto un fi grande fechiamazzo.

"We have had intimate commerce with the Americans (continues the Abbé) have lived, for some years, in a seminary defined for their instruction; saw the erection and progress of the royal college of Guadaloupe founded, in Mexico, by a Mexican Jefuit, for the education of Indian children; had, afterwards, some Indians among our pupils; had particular knowledge of many American rectors, many nobles, and numerous artists; attentively, observed their character, their genius, their disposition, and manner of thinking; and have examined, besides, with the utmost diligence, their ancient history, their religion, their government, their laws, and their customs. After such long experience and study of them, from which we imagine ourselves, enabled to decide, without danger of erring, we declare to M. de Paw, and to all Europe, that the mental qualities of the Americans are not in the least inferior to those of the Europeans; that they are capable of all, even the most abstruse, sciences; and that if equal care was taken of their education, if they were brought up from childhood in seminaries, under good masters, were protected and stimulated by rewards, we should see rise among the Americans, philosophers, mathematicians, and divines, who would rival the first in Europe."

But, although we should suppose, that, in the torrid climates of the New-World, as well as in those of the Old, especially under the additional depression of slavery, there was an inferiority of the mental powers; that they were inferior in the Chilie, and the North-Americans, have discovered higher rudiments of human excellence and ingenuity than have, perhaps, ever been known among tribes in a similar state of society, in any part of the world. M. de Paw affirms, that the Americans were unacquainted with the use of money, and quotes the following well-known passage from Montefquieu: "Imaginate a yourself that, by some accident, you are placed in an unknown country; if you find money there, do not doubt that you are arrived among a polished people." But, if by money we are to understand a piece of metal with the stamp of the prince, or of the public, the want of it in a nation is no token of barbarism. The American employed oxen for money, as the Romans did sheep. The Romans had no coined money till the time of...
Of Servius Titianus, nor had the Persians until the reign of Darius Hystaspes. But, if by money is understood a sign representing the value of merchandise, the Mexicans, and other nations of Anhuac, employed money in their commerce. The cacao, of which they made constant use in the market to purchase whatever they wanted, was employed for this purpose, as falt is in Abyfniain.

It has been affirmed, that stone bridges were unknown in America, when it was first discovered; and that the natives did not know how to form arches. But, these assertions are erroneous. The remains of the ancient palaces of Tezcucco, and, still more, their vapour baths, show the ancient use of arches and of vaults among the Mexicans. But the ignorance of this art would have been no proof of barbarity. Neither the Egyptians nor Babylonians understood the construction of arches.

M. de Pauw affirms, that the palace of Montezuma was nothing else than a hut. But, it is certain, from the affirmation of all the historians of Mexico, that the army under Cortes, consisting of 6,400 men, were all lodged in the palace; and there remained still sufficient room for Montezuma and his attendants.

The advances which the Mexicans had made in the noble science of astronomy, is, perhaps, the most surprising proof of their attention and sagacity: for it appears, from Abbe Clavigero's History, that they not only counted 365 days to the year, but also knew of the excess of about six hours in the solar over the civil year, and remedied the difference, by means of intercalary days. See Astronomy, n° 5.

Of American morality, the following exhortation of a Mexican to his son may serve as a specimen. "My son, who art come into the light from the womb of thy mother like a chicken from the egg, and, like it, are preparing to fly through the world, we know not how long Heaven will grant to us the enjoyment of that precious gem which we possess in thee; but however short the period, endeavour to live exactly, praying God continually to assist thee. He created thee; thou art his property. He is thy father, and loves thee still more than I do; repose in him thy thoughts, and day and night direct thy thoughts to him. Reverence and subdue thy elders, and hold noone in contempt. To the poor and distressed be not dumb, but rather use words of comfort. Honour all persons, particularly thy parents, to whom thou oweliest obedience, respect and service. Guard against imitating the example of those wicked sons, who, like brutes that are deprived of reason, neither reverence their parents, listen to their instruction, nor submit to their correction; because whoever follows their steps will have an unhappy end, will die in a desperate or sullen manner, or will be killed, and devoured by wild beasts."

"Mock not, my son, the aged or the imperfect. Scorn not him whom you see fall into some folly, or transgression, nor make him reproaches; but refrain thyself, and beware lest thou fall into the same error which offends thee in another. Go not where thou art not called, nor interfere in that which does not concern thee. Endeavour to manifest thy good breeding, in all thy words, and actions. In conversation, do not lay thy hands upon another, nor speak too much, nor interrupt or disturb another's discourse. When any one discourses with thee, hear him attentively, and hold thyself in an easy attitude, neither playing with thy feet, nor putting thy mantle to thy mouth, nor spitting too often, nor looking about you here and there, nor rising up frequently if thou art sitting; for such actions are indications of levity and low-breeding."—The father proceeds to mention several particulars which are to be avoided, and concludes—"Steal not, nor give thyself to gaming; otherwise thou wilt be a disgrace to thy parents, whom thou oughtest rather to honour for the education they have given thee. If thou wilt be virtuous, thy example will put the wicked to shame. No more my son; enough hath been said in discharge of the duties of a father. With these counsels I wish to fortify thy mind. Refuse them not, nor act in contradiction to them; for on them thy life, and all thy happiness depend."

As ranging on the same side with the Abbe Clavigero, our countryman Mr. Jefferson deferves particular attention. This gentleman, in his Notes on the State of Virginia, &c. has taken occasion to combat the opinions of Buffon; and seems, in many instances, to have fully refuted them, both by argument and by facts. The French philosopher affirms, "That living nature is active, lively, energetic, in the New-World than in the Old." He affirms, 1. That the animals common to both continents are smaller in America. 2. That those peculiar to the New are on an inferior scale. 3. That those which have been domesticated in both have degenerated in America; and, 4. That it exhibits fewer species of living creatures. The cause of this he attributes to the diminution of heat in America, and to the prevalence of humidity from the extent of its lakes and waters over a prodigious surface. In other words, he affirms that heat is friendly, and moisture adverse, to the production and development of the larger quadrupeds.

The hypothesis that moisture is unfriendly to animal growth, Mr. Jefferson flows to be contradicted by observation, and by experience. It is by the assistance of heat and moisture that vegetables are elaborated from the elements. Accordingly, we find that the more humid climates produce plants in greater perfection than the dry. Vegetables are immediately, or remotely, the food of every animal; and, from the uniform operation of nature's laws, we discern, that, in proportion to the quantity of food, animals are not only multiplied in their numbers, but improved in their size. Of this last opinion is the Count de Buffon himself; in another part of his work: "En general, il parait que les pays un peu froids conviennent mieux à nos beaux que les pays chauds, et qu'ils font d'autant plus gros et plus grands que le climat est plus humide et plus abondant en purures. Les beaux de Danemark, de la Polonie, de l'Ukraine, et de la Tartarie, qui habitent les Cimounes, font les plus grands et c. t. i."

"Here, then, a race of animals, and one of the largest too, has been increased in its dimensions by cold and moisture, in direct opposition to the hypothesis, which supposes that these two circumstances diminish animal bulk, and that it is theircontraries, heat and dryness, which enlarge it. But, to try the question on more general ground, let us take two portions of the earth, Europe and America for instance, sufficiently extensive to give operation to general causes: let us consider the circumstances peculiar to each, and observe their effects.
America, running through the torrid, as well as temperate, zone, has more heat collectively taken, than Europe. But Europe, according to our hypothesis, is the chief. They are equally adapted, then, to animal productions; each being endowed with one of those causes which befriend animal growth, and with one which opposes it. Let us, then, take a comparative view of the quadrupeds of Europe and of America, prefixing them to the eye in three different tables; in one of which shall be enumerated those found in both countries; in a second, those found in one only; in a third, those which have been domesticated in both. To facilitate the comparison, let those of each table be arranged in gradation, according to their sizes, from the greatest to the smallest, so far as their sizes can be conjectured. The weights of the large animal shall be expressed in the English avoirdupois pound and its decimals; those of the smaller in the ounce and its decimals. Those which are marked thus*, are actual weights of particular subjects, deemed among the largest of their species. Those marked thus†, are furnished with judicious persons, well acquainted with the species, and saying, from conjecture only, what the largest individual they had seen would probably have weighed. The other weights are taken from Mefris Buffon and D'Aubenton, and are of such subjects as came casually to their hands for dissection.

(a) The bones of the Mammoth, or, as it has been called, by Dr Hunter, and by other writers, *Epsoda-Elephant*, appear to be nearly of the same size, and weight, whether they are found in Europe, in Asia, or in America. In these three portions of the earth, the animal, to which these exuviae belonged, was, no doubt, specifically the same. See the article MAMMOUTH.
The result of this view is, that of 26 quadrupeds common to both countries, seven are said to be larger in America, seven of equal size, and 12 not sufficiently examined. So that the first table impeaches the first member of the assumption, that of the animals common to both countries the American are smaller, "Et cela est auense exception." It shows it not juit, in all the latitude in which its author has advanced it, and probably not to such a degree as to found a distinction between the two countries.

Proceeding to the second table, which arranges the animals found in one of the two countries only, M. de Buffon observes, that the tapir, the elephant of America, is but the size of a small cow. To preserve the comparison, Mr. Jefferson states the wild boar; the elephant of Europe, as little more than half that size. He has made an elk, with round or cylindrical horns, an animal of America, and peculiar to it; because he has seen many of them himself, and more of their horns; and because, from the best information, it is certain that, in Virginia, this kind of elk has abounded much, and stil exists, in smaller numbers. He makes the American hare, or rabbit, peculiar, because he believes it to be different from both the European animals of the same denomination, and calls it, therefore, by its Algonquin name, Whabst, to keep it distinct from thefe. Kalm is of the same opinion. The squirrels are denominated from a knowledge derived from daily fight of them, because with that the European appellations and descriptions from irreconcileable. There are the only instances in which Mr. Jefferson departs from the authority of M. de Buffon, in the construction of this table; whom he takes for his ground-work, because he thinks him the best informed of any naturalist who has ever written. The refult is, that there are 18 quadrupeds peculiar to Europe; more than four times as many, to wit, 74, peculiar to America; that the first of these 74, the tapir, the largest of the animals peculiar to America, weights more than the whole column of Europeans; and consequently this second table disproves the second member of the assertion, that the animals peculiar to the New World are on a smaller scale, so far as that assertion relied on European animals for support: and it is in full opposition to the theory which makes the animal volume to depend on the circumstances of heat and moisture.

The third table comprehends those quadrupeds only which are domestic in both countries. That some of these, in some parts of America, have become less than their original flock, is doubtless true: and the reason is very obvious. In a thinly-peopled country, the spontaneous productions of the forest and waste fields are sufficient to support indifferently the domestic animals of the farmer, with a very little aid from him in the feverest and scantient season. He, therefore, finds it more convenient to receive them from the hand of nature in that indifferent state, that to keep up their fize by a care and nourishment which would cost him much labour. If on this low fare, these animals dwindle, it is no more than they do in those parts of Europe where the poverty of the soil, or poverty of the owner, reduces them to the same scanty subsistence. It is the uniform effect of one and the same cause, whether acting on this or that side of the globe. It would be erring therefore against that principle of philosophy, which teaches us to acribe like effects to like causes, should we impute this diminution of size in America to any imbecility or want of uniformity in the operations of nature. It may be affirmed, with truth, that in those countries, and with those individuals, of America, where necessity or curiosity has produced equal care and nourishment in Europe to the nourishment of animals, the horses, cattle, sheep, and hogs of the one continent are as large as those of the other. There are particular instances, well attested, where individuals of America have imported good breeders from England, and have improved their size by care, in the course of some years. And the weights actually known and stated in the third table, will suffice to show, that we may conclude, on probable grounds, that with equal food and care, the climate of America will preserve the races of domestic animals as large as the European flock from which they are derived; and, consequently, that the domestic animals are subject to degeneration from the climate of America, as is probably wrong as the first and second are certainly so.

That the last part of it is erroneous, which affirms, that the species of American quadrupeds are comparatively few, is evident from the tables taken altogether; to which may be added the proofs advanced by the Abbé Clavigero. According to Buffon's latest calculation, in his Époques de la Nature, there are 300 species of quadrupeds;
AME

America.

Draped; and America, though it does not make them live in a third part of the globe, contains, according to Clavigero, not one half of the different species of these animals.

Of the human inhabitants of America, to whom the fame hypothesis of degeneracy is extended, M. Buffon gives the following description: "Though the American savages be nearly of the same stature with men in polished societies; yet this is not a sufficient exception to the general contraction of animated nature throughout the whole continent. In the savage, the organs of generation are small and feeble. He has no hair, no beard, no arbour for the female. Though nimble than the European, because more accustomed to running, his strength is not so great. His sensations are less acute; and yet he is more timid and cowardly. He has no vivacity, no activity of mind. The activity of his body is not so much an exercise or spontaneous motion, as a necessary action produced by want. Destroy his appetite for viands and drink, and you will, at once, annihilate the active principle of all his movements: he remains in stupid repose, on his limbs, or couch, for whole days. It is easy to discover the cause of the scattered life of savages, and of their estrangement from society. They have been refuted the most precise spark of Nature's fire: they have no arbour for women, and of course, no love to mankind. Unacquainted with the most lively and the most tender of all attachments, they areográfous to the same species of his nature cold and languid. Their love to parents and children is extremely weak. The bonds of the most intimate of all societies, that of the family, are feeble; and one family has no attachment to another. Hence no union, no republic, no federal state can take place among them. The physical caufe of love gives rise to the morality of their manners. Their heart is frozen, their society cold, and their empire cruel. They regard their families as servants destined to labour, or at least burden, whom they load unmercifully with the produce of their hunting, and oblige,without pity or gratitude, to perform labours which often exceed their strength. They have few children, and pay little attention to them. Every thing must be referred to the first cause; they are indifferent because they are weak; and this indifference to the sex is the original flaw which disgraces Nature; prevents her from expanding, and by destroying the germs of life, cuts the root of society. Hence, man makes no exception to what has been advanced. Nature, by denying him the faculty of love, has shufled and contracted him more than any other animal."

An humiliating picture, indeed! but which, Mr Jefferson affures us, never was one more unlike the original. M. Buffon grants, that their stature is the same as that of the men of Europe, and he might have admitted, that the Iroquois were larger, and the Le- cupni, or Delawares, taller, than people in Europe generally are. But, he says, their organs of generation are smaller and weaker than those of Europeans: which is not known, at least, to be a fact. And as to their want of heard, this error has been already noticed (n52: fopra).

"They have no arbour for their females." - It is true, they do not indulge those excesses, nor discover that fondness which is customary in Europe; but this is not owing to a defect in nature, but to manners. The soul of the Indian is wholly bent upon war. This is what procures him glory among the men, and makes him the admiration of the women. To this he is educated, from his earliest youth. When he pursues game with ardour, when he bears the fatigue of the chase, when he sustains and suffers patiently hunger and cold; it is not so much for the sake of the game he pursues, as to convince his parents and the council of the nation, that he is fit to be enrolled in the number of the warriors. The songs of the women, the dance of the warriors, the sage counsel of the chiefs, the tales of the old, the triumphal entry of the warriors returning, with success, from battle, and the respect paid to those who distinguish themselves in battle, and in fabricating their enemies; in short, every thing he fears or hears tends to inspire the Indian with an ardent desire for military fame. If a young man were to discover a fondness for women before he has been to war, he would become the contempt of the men, and the scorn and ridicule of the women; or were he to indulge himself with a captive taken in war, and much more were he to offer violence in order to gratify his lust, he would incur indelible disgrace. The seeming frugality of the American, therefore, is the effect of manners, and not a defect of nature. He is neither more defective in ar­ dour, nor impotent with the female, than a white man reduced to the same diet and exercise.

"They raise few children." - They, indeed, raise fewer children than we do; the causes of which are to be found not in a difference of nature, but of circumstance. The women very frequently attending the men in their parties of war and of hunting, child-bearing becomes extremely inconvenient to them. It is said, therefore, that they have learned the practice of procuring abortion by the use of certain vegetables; and that they even tend to prevent conception for a considerable time after. During these parties they are exposed to numerous hazards, to excessive exertions, to the greatest extremities of hunger. Even at their homes, the nation depends for food, through a certain part of every year, on the gleanings of the forest; that is, they experience a famine once in every year. With all animals, if the female be badly fed, or not fed at all, her young perish; and if both male and female be reduced to like want, generation becomes less active; less productive. To the obstacles, then, of want and hazard, which nature has opposed to the multiplication of wild animals, for the purpose of restraining their numbers within certain bounds, those of labour and voluntary abortion are added with the Indian. No wonder, then, if they multiply less than we do. Where food is regularly supplied, a single farm will yield more of cattle than a whole country of forests can of buffa­loes. The same Indian women, when married to white traders, who feed them and their children plentifully and regularly, who exempt them from excessive drudgery, who keep them stationary and unexposed to accident, produce, and raise, as many children as the white women. Influences are known, under these circumstances, of their rearing a dozen children.

Neither do they seem to be "deficient in natural affection." On the contrary their sensibility is keen, sensibility even the warriors weeping most bitterly on the loss of &c. their
Their friendships are strong, and faithful, to the utmost extremity. A remarkable instance of this appeared in the case of the late Col. Byrd, of Virginia, who was sent to the Cheerek nation to transact some business with them. It happened that some of our disorderly people had just killed one or two of that nation. It was therefore proposed in the council of the Cheerek, that Col. Byrd should be put to death in revenge for the loss of their countrymen. Among them was a chief called Sliouee, who on some former occasion, had contracted an acquaintance and friendship with Col. Byrd. He came to him every night, in his tent, and told him not to be afraid, they should not kill him. After many days deliberation, however, the determination was, contrary to Silouee's expectation, that Byrd should be put to death, and some warriors were dispatched as executioners. Silouee attended them; and when they entered the tent, he threw himself between them and Byrd, and said to the warriors, "This man is my friend, before you get at him, you must kill me." On which they returned; and the council repeated the principle so much as to recede from their determination.

That "they are timorous and cowardly" is a character with which there is little reason to charge them, when we recollect the manner in which the Iroquois met Mon.——, who marched into their country; in which the old men, who scorned to fly, or to sur vive the capture of their town, braved death, like the old Romans, in the time of the Gauls, and in which they soon after revenged themselves by facking and destroying Montreal. In short, the Indian is brave, when an enterprise depends on bravery; education with him making the point of honour to confit in the destruction of an enemy by stratagem; and in the preservation of his own person free from injury; or, perhaps this is nature, while it is education which teaches us to honour force more than finesse. He will defend himself against an host of enemies, always choosing to be killed rather than to surrender, though it be to the whites, who, he knows, will treat him well. In other situations also, he meets death with more deliberation; and endures tortures with a firmness unknown almost to religious enthusiasm among us.

Much less are they to be characterized as a people of no vivacity, and who are excited to action or motion only by the calls of hunger and thirst. Their dances, in which they so much delight, and which to a European would be the most severe exercise, fully contradict this; not to mention their fatigue Marches, and the toil they voluntarily and cheerfully undergo in their military expeditions. It is true, that when at home they do not employ themselves in labour or the culture of the soil: but this again, is the effect of customs and manners which have alligned that to the province of the women. But it is said, "they are averse to society and a social life." Can any thing be more inapplicable than this, to a people who always live in towns, or in clans? Or can they be said to have no republicans, who conduct all their affairs in national councils; who pride themselves in their national character; who consider an insult or injury, done to an individual by a stranger, as done to the whole, and resent it accordingly?

To form a just estimate of their genius and mental powers, Mr. Jelfier observes, more talents are wanting, and great allowance is to be made for those circumstances of their situation which call for a display of particular talents only. This done, we shall probably find that the Americans are formed, in mind as well as in body, on the same model with the Homo Faber Europaeus. The principles of their society forbidding all compulsion, they are to be led to duty and to enterprise, personal motives and passions. Hence eloquence in council, bravery and address in war, become the foundations of all confluence with them. To these acquisitions all their faculties are directed. Of their bravery and address in war we have multiplied proofs, because we have been the subjects on which they were exercised. Of their eminence in oratory we have fewer examples, because it is displayed chiefly in their own councils. Some, however, we have of very superior luftre. We may challenge the whole orations of Demosthenes and Cicero, and of any more eminent orator; if Europe has furnished more eminent, to produce a single passage superior to the speech of Logan, a Mingon chief, to Lord Dunmore, when governor of Virginia. The oratory is as follows; of which the authenticity is unquestionable. Hence eloquence in council, bravery and address in war.

In the spring of the year 1774, a robbery and murder were committed on an inhabitant of the frontiers of Virginia by two Indians of the Shawanac tribe. The neighboring whites, according to their custom, undertook to punish this outrage, in a summary way. Colonel Cresap, a man infamous for the many murders he had committed on those much-injured people, collected a party, and proceeded down the Kanawhaw, in quest of vengeance. Unfortunately a canoe of women and children, with one man only, was seen coming from the opposite shore, unarmed, and unsuspecting any hostile attack from the whites. Cresap and his party concealed themselves on the bank of the river; and the moment the canoe reached the shore, fenced out their objects, and, at one fire, killed every person in it. This happened to be the family of Logan, who had long been distinguished as a friend of the whites. This unworthy return provoked his vengeance. He accordingly signaled himself in the war which ensued. In the autumn of the same year, a decisive battle was fought at the mouth of the Great-Kanawhah, between the collected forces of the Shawanees, Mingoes, and Delawares, and a detachment of the Virginia militia. The Indians were defeated, and fled for safety. Logan, however, determined to be seen among the suppliants; but, left the sincerity of a treaty should be distrusted from which so distinguished a chief abstained himself, he went, by a messenger, the following speech, to be delivered to Lord Dunmore:——"I appeal to any white man to say if ever he entered Logan's cabin hungry, and he gave him not meat; if ever he came cold and naked, and he clothed him not. During the course of the last long and bloody war, Logan remained idle in his cabin, an advocate for peace. Such was my love for the whites, that my countrymen pointed as such to the province of the women. But it is said, "they are averse to society and a social life." Can any thing be more inapplicable than this, to a people who always live in towns, or in clans? Or can they be said to have no republicans, who conduct all their affairs in national councils; who pride themselves in their national character; who consider an insult or injury, done to an individual by a stranger, as done to the whole, and resent it accordingly?
The anecdote.

Other anecdotes.

Dilcrlcan and politeness.

... "the veins of any living creature. This called upon us to rejoice at the beams of peace; but do not harbour a thought that mine is the joy of fear. Logan never felt fear. He will not turn on his heel to save his life. We shall mourn for Logan! Not one."

To the preceding anecdotes, in favour of the American character, may be added the following, by Dr Benjamin Franklin.—The Indian men, when young, are hunters and warriors; when old, counsellors; for all their government is by the counsel or advice of the sages. Hence, they generally study oratory; the best speakers having the most influence. The Indian women till the ground, dress the food, nurse and bring up the children, and preferve and hand down to posterity the memory of public transactions. These employments of men and women are accounted natural and honourable. Having few artificial wants, they have abundance of leisure for improvement by conversation and laborious manner of life, compared with theirs, they often visit and trade; and the learning which we value ourselves, they regard as frivolous and useless.

Having frequent occasions to hold public councils, they have acquired great order and decency in conducting them. The old men sit in the foremost rank, the warriors in the next, and the women and children in the hindmost. The business of the women is to take exact notice of what passes; imprint it in their memories, for they have no writing, and communicate it to their children. They are the records of the council, and they preserve tradition of the stipulations in treaties a hundred years back; which, when we compare with our writings, we always find exact. He that would speak, rise. The rest observe a profound silence. When he has finished, and sits down, they leave him five or six minutes to recollect, if he has omitted anything he intended to say, or has anything to add, he may rise again and deliver it. To interrupt another, even in common conversation, is reckoned highly indecent.

The politefns of these favages in conversation is, indeed, carried to excess; since it does not permit them to contradict, or deny, the truth of what is asserted in their presence. By these means, they avoid disputes; but then it becomes difficult to know their minds, or what impression you make upon them. The missionaries, who have attempted to convert them to Christianity, all complain of this, as one of the great difficulties of their mission. The Indians, hear, with patience, the truths of the gospel explained to them, and give their usual tokens of assent and approbation; but this by no means implies conviction: it is mere civility. When any of them come into our towns, our people are apt to crowd round them, gaze upon them, and incommode them when they desire to be private; this they esteem great rudeness, and the effect of the want of instruction in the rules of civility and good manners.

"We have," they say, "as much trouble as you and I, and when we come into your towns, we will for opportunities of looking at you; but for this purpose we hide ourselves behind bushes where you are to a pass, and never intrude ourselves into your company."
The next question which offers itself to our notice, is, Whether the peculiarities of the aboriginal Americans, or the disparity between them and the inhabitants of the Old-World, afford sufficient grounds for determining them, as many eminent writers have done, to be a race of men radically different from all others? In this question, to avoid being tedious, we shall confine ourselves to what has been advanced by Lord Kames; who is of opinion, that there are many different species of men, as well as of other animals; and gives an hypothesis, whereby he pretends his opinion may be maintained in a consistency with Revelation.

"If (says he) the only rule afforded by nature for classing animals can be depended on, there are different races of men as well as of dogs: a mastiff differs not more from a spaniel, than a white man from a negro, or a Laplander from a Dane. And, if we have any faith in Providence, it ought to be so. Plants were created of different kinds, to fit them for different climates; and so were brute animals. Certain it is, that all men are not fitted equally for every climate. There is scarce a climate but what is natural to some men, where they prosper and flourish: and there is not a climate, but where some men degenerate. Doth not then analogy lead us to conclude, that, as there are different climates on the face of this globe, so there are different races of men fitted for these different climates?"

"M. Buffon, from the rule, That animals which can procreate together, and whose progeny can also procreate, are of one species; concludes, that all men are of one race or species; and endeavours to support that favourite opinion, by ascribing to the climate, to food, or to other accidental causes, all the varieties that are found among men. But he is seriously of opinion, that any operation of climate, or of other accidental cause, can account for the copper colour and smooth chin universal among the Americans; the prominence of the pudenda universal among the Hottentot women, or the black nipple no less universal among the female Samoiedes? It is in vain to ascribe to the climate, the low stature of the Equinoctial, the smallness of their feet, the overgrown size of their heads. It is equally in vain to ascribe to climate the low stature of the Laplanders, or their ugly visage. The black colour of negroes, thick lips, flat nose, erifed woolly hair, and rank smell, distinguish them from every other race of men. The Abyssinians, on the contrary, are tall and well made, their complexion a brown olive, features well-proportioned, eyes large and of a sparkling black, thin lips, a nose rather high than flat. There is no such difference of climate between Abyssinia and Negro-land as to produce these striking differences.

"Nor shall our author's ingenious hypothesis concerning the extremities of heat and cold, purchase him impunity with respect to the fallow complexion of the Samoiedes, Laplanders, and Greenlanders. The Finlanders, and northern Norwegians, live in a climate not less cold than that of the people mentioned; and yet are far beyond other Europeans. I say, more, there are many instances of races of people preferring their original colour, in climates very different from their own; but not a single instance of the contrary, as far as I can learn. There have been four complete generations of negroes in Pennsylvania, without any visible change of colour; they continue jet black, as originally. Those who ascribe all to the sun: ought to consider how little probable it is, that the colour it imparts to the parents should be communicated to their infant children who never saw the sun: I should be as soon induced to believe, with a German naturalist, whose name has escaped me, that the negro colour is owing to an ancient custom in Africa, of dyeing the skin black. Let a European, for years, expose himself to the sun, in a hot climate, till he be quite brown; the children will, nevertheless, have the same complexion with those in Europe. From the action of the sun, is it possible to explain, why a negro, like a European, is born with a ruddy skin, which turns jet black, the eighth, or ninth, day?"

Our author next proceeds to draw some arguments for the existence of different races of men, from the various tempers and dispositions of different nations; which he reckons to be specific differences, as well as of colour, stature, &c. Having summed up his evidence, he concludes thus: "Upon summing up the whole particulars, mentioned above, would one hesitate a moment, to adopt the following opinion, were there no counterbalancing evidence, viz. 'That God created many pairs of the human race, differing from each other, both externally and internally; that he fitted those pairs for different climates, and placed each pair in its proper climate; that the peculiarities of the original pairs were preferred entire in their descendants; who, having no affliction but their natural talents, were left to gather knowledge from experience; and, in particular, was left (each tribe) to form a language for itself; that signs were sufficient..."
America. 

sufficient for the original pairs, without any language 
but what nature suggests; and that a language was 
formed gradually, as a tribe increased in numbers, 
and in different occupations, to make speech neces-
sary? But this opinion, however plausible, we are 
not permitted to adopt, being taught a different lesson 
by Scripture, viz., that God created but a single 
pair of the human species. Though we cannot doubt 
the authority of Moses, yet his account of the crea-
tion of man is not a little puzzling, as it seems to 
contradict every one of the facts mentioned above. 
According to that account, different races of men were 
not formed, nor were men formed originally for 
different climates. All men must have spoken the same 
language, viz. That of our first parents. And what of 
all the most contradictory to that account, is the 
savage state: Adam, as Moses informs us, was endued 
by his Maker with an eminent degree of knowledge; 
and he certainly was an excellent preceptor to his chil-
dren and their progeny, among whom he lived many 
generations. Whence then the degeneracy of 
man race to have been divided into different fpecies, at 
the close of each species. That God 

86 His hypo-
theses con-
cerning the 
origin of the 
different 
species.

87 Incom-
plete.

the difficulty will vanish: but if this is his Lordship’s 
interpretation, it is certainly a very singular one.

Before entering upon the consideration of the partic-
ular arguments used by our author for proving the di-
versity of species in the human race, it will be proper 
to lay down the following general principles, which 
may serve as axioms. (1) When we affirm a multi-
plicity of species in the human race, and bring in a 
supernatural cause to solve a natural phenomenon; for 
these species are supposed to be the immediate work of the Deity. (2) No person has a right to call any 
thing the immediate effect of omnipotence, unless by 
express revelation from the Deity, or from a certainty 
that no natural cause is sufficient to produce the effect. The reason is plain. The Deity is invisible, and there 
are many natural causes; when we see an effect, therefore, 
of which the cause does not manifest itself, we 
cannot know whether the immediate cause is the Deity, 
or an invisible natural power. An example of this we 
have in the phenomena of thunder and earthquakes, 
which were often acried immediately to the Deity, 
but were now discovered to be the effects of electricity. 
(3) No person can assert natural causes to be in-
sufficient to produce such and such effects, unless he perfectly 
knows all these causes, and the limits of their power in all possible cases; and this no man has ever 
known, or can know.

By keeping in view these principles, which we hope 
are self-evident, we will easily see Lord Kames’s ar-
guments to consist entirely in a petitio principii. —In 
substance, they are all reduced to this single sentence: 
“Natural philosophers have been, hitherto, unsuccessful 
in their endeavours to account for the differences 
observed among mankind, therefore these differences 
cannot be accounted for from natural causes.”

Lord Kames, however, tells us in the passages al-
ready quoted, that “a mastiff differs not more from a spaniel, than a Laplander from a Dane”: that “it is 
vain to ascribe to climate the low stature of the Lap-
landers, or their ugly visage.” Yet, in a note on the 
word Laplanders, he subjoins, that, “by late accounts 
it appears, that the Laplanders are only degenerated 
Tartars, and that they and the Hungarians originally 
prung from the same breed of men, and from the same 
country.” —The Hungarians are generally handsome 
and well-made, like Danes, or like other people. The 
Laplanders, he tells us, differ as much from them as a 
maiiff from a spaniel. Natural causes, therefore, ac-
cording to Lord Kames himself, may cause two individ-
uals of the same species of mankind differ from each 
other as much as a mastiff does from a spaniel.

While we are treating this subject of colour, it may 
not be amiss to observe, that a very remarkable dif-
ference of colour may accidentally happen to individuals 
of the same species. In the isthmus of Darien, a singu-
lar race of men have been discovered. —They are of 
low stature, of a feeble make, and incapable of endur-
ing fatigue. Their colour is a dead milk white; not 
resembling that of fair people among Europeans, but 
without any blush or sanguine complexion. Their skin 
is covered with a fine hairy down of a chalky white; 
the hair of their heads, their eye-brows, and beard, are of the same hue. Their eyes are of a singular 
form, and so weak, that they can hardly bear the light 

of
of the sun; but they see clearly by moon-light, and are most active and gay in the night. Among the negroes of Africa, as well as the natives of the Indian islands, a small number of those people are produced. They are called Albinos by the Portuguese, and Kackerlakes by the Dutch.

91 Colour no char. specific of diff. spec.

This race of men is not indeed permanent; but it is sufficient to show, that mere colour is by no means the characteristic of a certain species of mankind. The difference of colour in these individuals is undoubtedly owing to a natural cause. To constitute, then, a race of men of this colour, it would only be necessary that this cause, which at present is merely accidental, should become permanent, and we cannot know but it may be so in some parts of the world.

92 Nor nature.

If a difference of colour is no characteristic of a different species of mankind, much less can a difference in nature be thought so. In the southern parts of America, there are said to be a race of men exceeding the common size in height and strength*. This account, however, is doubted by some; but be that as it will, it is certain that the Equinoxes are as much under the common size, as the Patagonians are said to be above it. Nevertheless, we are not to imagine, that either of these are specific differences; seeing the Laplanders and Hungarians are both of the same species, and yet the former are generally almost a foot shorter than the latter; and if a difference of climate, or other accidental causes, can make the people of one country a foot shorter than the common size of mankind, undoubtedly accidental causes of a contrary nature may make those of another country a foot taller than other men.

93 Different causes contr. towards an alteration in colour.

Though the fun has, most undoubtedly, a share in the production of the swarty colour of those nations which are exposed to its influence; yet the manner of living to which people are accustomed; their food, their employment, and many other circumstances, must also contribute a little to a difference of complexion. The more full examination, however, of these several circumstances we refer to for another article. See the article Complexion.

94 Habit capable of affecting the infancy of animals.

It is allowed on all hands, that it is more easy to work a change upon the body of a man, or any other animal, than upon his mind. A man who is naturally choleric, may, indeed, learn to prevent the bad effects of his passion by reason, but the passion itself will remain as immutable as his character—But, to reason in a manner similar to Lord Kames; though a man should be naturally choleric, or subject to any other passion, why should his children be so?—This way of reasoning, however plausible, is by no means conclusive, as will appear from the following passage in Mr Forster's Voyage.

June 9th. "The officers who could not yet relish their last provisions after the refreshments of New Zealand, had ordered their black dog, mentioned p. 135, to be killed: this day, therefore, we dined, for the first time, on a leg of it roasted; which tasted so exactly like mutton, that it was absolutely undistinguishable. In our cold countries, where animal food is so much used, and where to be carnivorous, perhaps, lies in the nature of men, or is indifferably necessary to the preservation of their health and strength, it is strange that there should exist a Jewish aversion to dogs' flesh, when dogs, the most uncleanly of all animals, are eaten without scruple. Nature seems expressly to have intended them for this use, by making their offspring so very numerous, and their increase so quick, and frequent. It may be objected, that the exalted degree of instinct which we observe in our dogs, inspires us with great unwillingness to kill and eat them. But it is owing to the time we spend on the education of dogs, that they acquire those eminent qualities, which attract us so much to them. The natural instincts of our dogs may receive a wonderful improvement; but education must give its assistance, without which the human mind itself, though capable of an immense expansion, remains in a very contracted state. In New-Zealand, and (according to former accounts of voyages) in the tropical isles of the South-Sea, the dogs are the most stupid, dull animals imaginable, and do not seem to have the least advantage in point of sagacity over our sheep, which are commonly made the emblems of fillinets. In the former country they are fed upon fish, in the latter on vegetables, and both these diets may have served to alter their disposition. Education may, perhaps, likewise, grant new instincts: the New-Zealand dogs are fed on the remains of their masters, and that of the bones of other dogs; and the puppies become true cannibals from their birth. We had a young New-Zealand puppy on board, which had certainly had no opportunity of tasting any thing but the mother's milk before we purchased it; however, it eagerly devoured a portion of the flesh and bones of the dog on which we dined to-day; while several others of the European breed, taken on board at the Cape, turned from it without touching it.

"On the 4th of August, a young bitch, of the terrier breed, taken on board at the Cape of Good-Hope, and covered by a Spaniel, brought ten young ones, one of which was dead. The New-Zealand dog mentioned above, which devoured the bones of the roasted dog, now fell upon the dead puppy, and eat of it with a ravenous appetite. This is a proof how far education may go in producing, and propagating, new instincts in animals. European dogs are never fed on the meat of their own species, but rather seem to abhor it. The New-Zealand dogs, in all likelihood, are trained up from their earliest age, to eat the remains of their master's meals: they are, therefore, used to feed upon fish; their own species; and, perhaps, human flesh; and what was only owing to a habit, at first, may have become instinct, by length of time. This was remarkable in our canni­bal dog; for he came on board so young, that he could not have been weaned long enough to have acquired a habit of devouring his own species, and much less of eating human flesh; however, one of our men having cut his finger, held it out to the dog, who fell to greedily, licked it, and then began to bite it."

From this account it appears, that even the instincts of animals are not unchangeable by natural causes; and if these causes are powerful enough to change the dispositions of succeeding generations, much more may we suppose them capable of making any possible alteration in the external appearance.

We are not here necessitated to confine ourseffes to examples of the production of one general character, taken from a mixture of many different
different nations — They were a motley multitude, consisting of various German nations dwelling beyond the Rhine; who, uniting in defence of their common liberty, took thence the name of Frank; the word Frank signifying in their language, as it still does in ours, free. Amongst them the following nations were mentioned, viz. the Achazii, Chamavi, Bructeri, Salii, Frifii, Chauzi, Amfunviri, and Catti. We cannot suppose one character to belong to so many different nations; yet is it certain that the Franks were, nationally, characterized as treacherous. It is in vain, then, to talk of different races of men, either from their colour, size, or prevailing dispositions, seeing we have undeniable proofs that all these may be changed, in the most remarkable manner, by natural causes, without any miraculous interpolation of the Deity.

Of the peopling of America.

The questions which now present themselves to our notice are, From what part of the Old-World America has, most probably, been peopled? — And how was this peopling accomplished? — Few speculations in the history of mankind have been more agitated than these. — Philosophers, and men of learning and ingenuity, have been speculating upon them, ever since the discovery of the American-Islands, by Christopher Columbus. — But notwithstanding all the labours of Acofa, of Grotius, and of many other writers of eminence, the subject still affords an ample field for the researches of the man of science, and for the fancies of the theorist.

Discoveries, long ago made, inform us, that an intercourse between the Old-Continent and America might be carried on, with facility, from the north-west extremities of Europe and the north-east boundaries of Asia. In the ninth century the Norwegians discovered Greenland, and planted a colony there. The communication with that country, was renewed in the last century by Moravian missionaries, in order to propagate their doctrine in that bleak and uncultivated region. By them we are informed that the north-west coast of Greenland is separated from America by a very narrow strait; that at the bottom of the bay it is highly probable that they are united; that the Equinoum of America perfectly resemble the Greenlanders, in their aspect, dress, and mode of living; and that a Moravian vessel, sent to search for Greenland, having visited the country of the Equinoum, found, to his astonishment, that they spoke the same language with the Greenlanders, and were, in every respect, the same people. The tame species of animals, too, are found in the contiguous regions. The bear, the wolf, the fox, the hare, the deer, the roe-buck, the elk, frequent the forests of North-America, as well as those in the north of Europe.

Other discoveries have proved, that if the two continents of Asia and America be separated at all, it is only by a narrow strait. From this part of the Old-Continent, also, inhabitants may have passed into the New; and the resemblance between the Indians of America and the eastern inhabitants of Asia, would induce us to conjecture that they have a common origin.

This is the opinion adopted by Dr Roberton, in his History of America*, where we find it accompanied with the following narrative.

"While those immense regions which fretched easternward from the river Obi to the fca of Kamtchata were unknown, or imperfectly explored, the north-east extremities of our hemisphere were supposed to be so far distant from any part of the New-world, that it was not easy to conceive how any communication should have been carried on between them. But the Ruffians, having subjected the western part of Siberia to their empire, gradually extended their knowledge of that vast country, by advancing towards the east into unknown provinces. These were discovered by hunters in their excursions after game, or by soldiers employed in levying the taxes; and the court of Muscovy estimated the importance of those countries only by the small addition which they made to its revenue. At length, Peter the Great, ascended the Ruffian throne: His enlightened, comprehensive mind, intent upon every circumstance that could aggrandize his empire, or render his reign illustrious, discerned consequences of those discoveries, which had escaped the observation of his ignorant predecessors. He perceived, that, in proportion as the regions of Asia extended towards the east, they must approach nearer to America; that the communication between the two continents, which had long been searched for in vain, would probably be found in this quarter; and that, by opening this intercourse, some part of the wealth and commerce of the western world might be made to flow into his dominions by a new channel. Such an object suited a genius that enlightened in grand schemes. Peter drew up instructions with his own hand for prosecuting this design, and gave orders for carrying it into execution.

"His successors adopted his ideas, and pursued his plan. The officers whom the Ruffian court employed in this service, had to struggle with so many difficulties, that their progress was extremely slow. Encouraged by some faint traditions among the people of Siberia concerning a successful voyage in the year 1648 round the north-east promontory of Asia, they attempted to follow the same course. Vessels were fitted out, with this view, at different times, from the rivers Lena and Kolyma; but in a frozen ocean, which nature seems not to have defined for navigation, they were exposed to many disasters, without being able to accomplish their purpose. No vessel fitted out by the Ruffian court ever doubled this formidable cape; we are indebted for what is known of those eastern provinces of Asia, to the discoveries made in excursions by land. In all those provinces, an opinion prevails, that countries of great extent and fertility lie at no considerable distance from their own coasts. These the Ruffians imagined to be part of America; and several circumstances occurred not only in confirming them in this belief, but in persuading them that some portion of that continent could not be very remote. Trees of various kinds, unknown in those naked regions of Asia, are driven upon the coast by an easterly wind. By the same wind floating ice is brought thither in a few days; flights of birds arrive annually from the same quarter; and a tradition obtains among the inhabitants, of an intercourse formerly carried on with some countries situated to the east.

"After weighing all these particulars, and comparing the position of the countries in Asia which they had discovered, with such parts in the north-west of America as were already known; the Ruffian court formed
At present, they plough those lands, over which ships formerly on foot, and now they fail over lands which were, formerly, cultivated: earthquakes have swallowed some lands, and subterraneous fires have thrown up others: the rivers have formed new foil with their mud: the sea, retiring from the shores, has lengthened the land in some places, and advancing in others has diminished it; it has separated some territories which were formerly united, and formed new straits and gulfs. We have examples of all these revolutions in the past century. Sicily was united to the continent of Naples, as Eubea, now the Black-Sea, was to Bessia. Diodorus, Strabo, and other ancient authors, say the same thing of Spain, and of Africa, and affirm, that by a violent eruption of the ocean upon the land between the mountains Abyla and Calpe, that communication was broken, and the Mediterranean-Sea was formed. Among the people of Ceylon there is a tradition that a similar eruption of the sea separated their island from the peninsula of India. The fame thing is believed by those of Malabar with respect to the isles of Maldives, and with the Malayans with respect to Sumatra. It is certain, says the count de Buffon, that on Ceylon the earth has lost 30 or 40 leagues, which the sea has taken from it; on the contrary, Tongres, a place of the Low-Countries, has gained 30 leagues of land from the sea. The northern part of Egypt owes its existence to inundations of the Nile. The earth which this river has brought from the inland countries of Africa, and deposited in its inundations, has formed a foil of more than 25 cubits of depth. In like manner, adds the above author, the province of the Yellow-River in China, and that of Louisiana, have only been formed by the mud of rivers. Pliny, Seneca, Diodorus, and Strabo, report innumerable examples of similar revolutions, which we omit, that our difference may not become too prolix, as also many modern revolutions, which are related in the history of the earth of the Count de Buffon and other authors. In South-America, all those who have observed with philosophic eyes the peninsula of Yucatan, do not doubt that that country has once been the bed of the sea; and, on the contrary, in the channel of Bahama, many indications show the island of Cuba to have been once united to the continent of Florida. In the strait which separates America from Asia many islets are found, which probably were the mountains belonging to that tract of land which we suppose to have been swallowed up by earthquakes; which is made more probable by the multitude of volcanoes which we know of in the peninsula of Kamchatka. It is imagined, however, that the sinking of that land, and the separation of the sea from those continents, has been occasioned by those great and extraordinary earthquakes mentioned in the histories of the Americans, which formed an era almost as memorable as that of the deluge. The histories of the Toltecas fix such earthquakes in the year I Tecpatl; but as we know not to what century that belonged, we can form no conjecture of the time that great calamity happened. If a great earthquake should overwhelm the isle of Senuz, and there should be at the same time as great a scarcity of historians as there were in the first ages after
after the deluge, it would be doubted, in 300 or 400 years after, whether Asia had ever been united by that part to Africa; and many would firmly deny it.

Whether that great event, the separation of the continents, took place before or after the population discovery by the Savages, or not, we are indebted to the abovementioned navigators for a description of the inhabitants: the Scythians, and other nations, at several periods, arrived there, and inhabited that country, a needle, in various shapes, being the usual arms of the ancient Britons. As the natives of New-Zealand do at present, and as the ancient Britons did with the herb glaftum, or woad, and the Virginians, on the first discovery of that country by the English.

The Scythians were said, for a certain time, annually to transform themselves into wolves, and again to resume the human shape. The new discovered Americans about Nootka-Sound, at this time, disguise themselves in drefses made of the skins of wolves, and other wild beasts, and wear even the heads fitted to their own. These habits they use in the chase, to circumvent the animals of the field, but would not be ascribed to ignorance or superstition ascribe to a supernatural metamorphosis their temporary expedients to deceive the brute creation.

In their marches, the Kamtschatkans never went barefoot, but followed one another in the same track, and dress common to the eastern Indians & the Americans.

The Scythians, the most numerous nation resident in Siberia, prick their faces with small punctures, with a needle, in various shapes; then rub them into charcoal, so that the marks become indelible. This custom is still observed in several parts of America. The Indians on the back of Hudson's Bay, to this day, perform the operation exactly in the same manner, and puncture the skin into various figures; as the natives of New-Zealand do at present, and as the ancient Britons did with the herb glaftum, or woad, and the Virginians, on the first discovery of that country by the English.

The Tungufi use canoes made of birch-bark, distilled over ribs of wood, and nicely fowed together. The Canadian, and many other American nations, use no other fort of boats. The paddles of the Tungufi are broad at each end: those of the people near Cook's river, and of Oonalasa, are of the same form.

In burying the dead, many of the American nations place the corpse at full length, after preparing it according to their customs; others place it in a sitting posture, and lay by it the most valuable clothing, wampum, and other matters. The Tartars did the same: and both people agree in covering the whole with earth, so as to form a tumulus, barrow, or cairned.

Some of the American nations hang their dead in trees. Certain of the Tungufi observe a similar custom.

We can draw some analogy from dreses; convenience in that article must have been confulted on both continents, and originally the materials must have been the same, the skins of birds and beasts. It is singular, that the conic bonnet of the Chines who should be found among the people of Nootka. I cannot give into the notion
The brute creation migrated by the same route.

The continent which flocked America with the human race, is, suppos'd, by Mr Pennant, to have pour'd in the brute creation, through the same passage. Very few quadrupeds continued in the peninsula of Kamtschatka; Mr Pennant enumerates only 25 which are inhabitants of land: all the rest perished in their migration, and fixed their residence in the New-World. Seventeen of the Kamtschatkan quadrupeds are found in America: others are common only to Siberia, or Tartary, having, for unknown causes, entirely evacuated Kamtschatka, and divided themselves between America and the parts of Asia above cited. Multitudes, again, have deferted the Old-World, even to an individual, and fixed their seats at distances most remote from the spot from which they took their departure; from mount Ararat, the resting-place of the ark, in a central part of the Old-World, and excellently adapted for the diffusion of the animal creation, to all its parts. "We need not be startled (says Mr Pennant) at the vast journeys of the quadrupeds to arrive at their present seats. Might not numbers of species have found a convenient abode in the vast alps of Asia, instead of wandering to the Cordilleris of Chili? or might not others have been contented with the boundless plains of Tartary, instead of travelling thousands of miles to the extensive flats of Pampas? — To endeavour to elucidate common difficulties is certainly a trouble worthy of the philosopher, and of the divine; not to attempt it would be a criminal indolence, a neglect to

Vindicate the ways of God to man. But there are multitudes of points beyond the human ability to explain, and yet are truths undeniable: the facts are indubitable, notwithstanding the causers are concealed. In such cases, faith must be called in to our relief. It would, certainly, be the height of folly to deny to that Being who broke open the great fountain of the deep to effect the deluge—and afterwards, to compel the dispersion of mankind to people the globe, directed the confusion of languages—powers inferior in their nature to those. After these wondrous proofs of omnipotency, it will be absurd to deny the possibility of infusing instinct into the brute creation. Deus eft anima brutorum; "God himself is the soul of brutes:" his pleasure must have determined their will, and directed several species, and even whole genera, by impulsive irresistible, to move by flow progression to their destined place. But for that, the Ima and the paco might still have inhabited the heights of Armenia, and some more neighbouring Alps, instead of labouring to gain the distant Peruvian Andes; the whole genus of armadillos, flow of foot, would never have quitted the torrid-zone of the Old-World for that of the New; and the whole tribe of monkeys would have gamboled together in the forests of Indie, instead of dividing their residence between the shades of Indofian, and the deep forests of the Brazils. Lions and tigers might have infested the hot parts of the New-World, as the first do the desarts of Africa, and the half the provinces of Asia; or the pantherine animals of South-America might have remained additional scourges with the savage beasts of those ancient continents. The Old-World would have been overflown with animals; the New remained an unanimated waste! or both have contained an equal portion of every beast of the earth. Let it not be objected, that animals bred in a southern climate, after the descent of their parents from the ark, would be unable to bear the frost and snow of the rigorous north, before they reached South-America, the place of their final destination. It must be considered, that the migration must have been the work of ages; that in the course of their progress each generation grew hardened to the climate it had reached; and that, after their arrival in America, they would again be gradually accustomed to warmer and warmer climates, in their removal from north to south, as they had in the reverse, or from south to north. Part of the tigers still inhabit the eternal snows of Ararat, and multitudes of the very same species live, but with exalted rage, beneath the line, in the burning soil of Borneo, or Sumatra; but neither lions or
A ME

America—tigers ever migrated into the New-World. A few of
the first are found in India and Perhia, but they are
found in numbers only in Africa. The tiger extends
as far north as the north, and never has reached
America."

In fine, the conjectures of the learned respecting the
vicinity of the Old and New-World are now, by the
discoveries of late great navigators, lost in conviction;
and, in the place of imaginary hypotheses, the real
place of migration is almost incontrovertibly pointed out.
Some (from a passage in Plato) have extended over the
Atlantic, from the shores of Gibraltar to the coast of
North and South-America, an island equal in size to the
continents of Asia and Africa; over which has passed,
as over a bridge, from the latter, men and animals;
wool-headed negroes, and lions and tigers, none of
which ever existed in the New-World. A mighty sea
arose, and, in one day and night, engulfed this stupen-
dous tract, and with it every being which had not
completed its migration into America. The whole
egro race, and almost every quadraped, now inhabi-
tants of Africa, perished in this critical day. Five only
are to be found, at present, in America; and of these
only one, the bear, in South-America: Not a single
custom, common to the natives of Africa and America,
to evince a common origin. Of the quadrupeds, the
bear, fox, wolf, fox, and weefel, are the only ani-
mals which we can pronounce, with certainty, to be
found on each continent. The bear, fox, and the
weefel, have made, alfo, no farther progress in Africa
than the north; but on the fame continent the wolf is
spread over every part, yet is unknown in South-Ame-
rica, as are the fox and weefel. In Africa and in South-
America the bear is very local, being met with only
in the north of the firth, and on the Andes in the lat.
Some cause unknown arrested its progress in Africa,
and impelled the migration of a few into the Chilian-
Alps, and induced them to leave unoccupied the vull
tract from North-America to the lofty Cordilleras.

Allusions have often been made by travellers and
others, to some remains in America which appeared to
force the qualified people to abandon them, and were
familiar with the arts of life than the savage tribes which
inhabited this continent on its firft discovery by the
Europeans, or that those which are, at present, scattered
through various parts of its extent. In a small work,
published in London, in 1787, entitled Observations on
some parts of natural history; to which is prefixed, an
account of several remarkable vestiges of an ancient
date, which have been discovered in different parts of
America. Part I. the author has collected the scattered
hints of Kalm, of Carver, of Filfon, and some other
travellers, and writers; and has added a plan and
description of a regular work, which he supposes to
have been a fortification, that has been discovered near
the confluence of the rivers Ohio and Muskingum.
The remains described, or alluded to, in this publica-
tion, are characters, or singular marks, which were
fupposed by some Jesuits, who examined them, to be
Tartarian; furrows, as if the land had been ploughed;
a stone wall; mounds of earth, of different forms and
sizes; earthen walls, and ditches, &c.

The mounds of earth are fupposed, by the author, to
have been designed for different purpofes: the smaller
ones are, evidently, tumufl, or repositories of the dead;
and, he thinks, the larger ones, as that at Grave-Creek
(a branch of the Ohio); many which are to be seen in
Mexico, and in other parts of America, were intended
to serve as the bases of temples.

The most curious part of this little work is the de-
scription, together with the plan, of the supposed for-
tification, above alluded to. It is situated on the east
side of the river Muskingum, about half a mile above its
junction with the river Ohio, nearly in the latitude of
39. 21. and about 170 miles below Fort-Pitt, at the
confluence of the rivers Alleghany and Monangahela.
The town, as it has been sometimes called, is a large
level, encompassed by walls of a tetragon form;
occupying a piece of ground about one quarter of a
mile square. These walls are from six to ten feet in
height, and from twenty to forty feet in thickness.
They are, at present, overgrown with vegetables, of
different kinds, and, among others, with trees, some of
which are of a very considerable diameter. Each side
of the walls is divided, by three openings, into four, nearly equal, parts: these openings are directly
opposite to each other. Within the walls there are
tree elevations; the largest of these is of an oblong
form, 74 yards long, 44 yards broad, and 6 feet in
height: the second is nearly of a similar form, 50
yards long, and 40 broad: the third is, also, an oblong
mount, but much smaller. Besides these three eleva-
tions, there is a small circular mount, placed nearly in
the centre of the small cavels; and a semi-circular
parapet," which, it is not improbable, may have been
designed to guard one of the chafms, or openings: this
parapet has a small mount. The author observes,
that the three elevations "considerably resemble some
of the eminences which have been discovered near the
river Mississipp, of which he has given an ac-
count in his publication.

The fortifications (for a distinction has been made
between them and the town, but we cannot see with
what great propriety) are nearly of the fame form as the
town. The walls have here, also, openings: and at
each of these openings there is one, or more of the fine
circular mounts.

The pyramid is one of the most conspicuous parts of
these singular remains. It is of a circular form; 50
feet in height; 90 feet in circumference; and is sur-
ronded with a ditch, 5 feet deep, and 15 feet wide:
externally to the ditch there is a parapet, which is 759
feet in circumference. "The pyramid, as well as
the eminences and walls, is now covered with graves,
and other kinds of vegetables." Besides these, there
are several other eminences, of which we do not think
it necessary to take any notice, in this place.

The author's opinion concerning these remains is
this; that they owe their original to "the Toltecas, or
some other Mexican nation," and that these people
were, probably, the descendants of the Danes. The
first member of this conjecture appears not improbable,
if we consider the similarity of the Mexican mounts and
fortifications, described by Torquemada, by the Abbe
Clavigero, and by other authors, to those of which our
author has published an account; and, also, if we con-
der the tradition of the Mexicans, that they came from
the north-west, in which tract great numbers of these
remains have been discovered. As to the second mem-
ber of this conjecture, we think it but feebly supported;
although
The ancients supposed that the ancients had some imperfect notion of the New-World; and several ancient authors are quoted in confirmation of this opinion. In a book, ascribed to the philosopher Aristotle, we are told that the Carthaginians discovered an island, beyond the pillars of Hercules, large, fertile, and finely watered, with navigable rivers, but uninhabited. This island was distant a few days' sailing from the continent; its beauty induced the discoverers to settle there; but the policy of Carthage dissuaded the colony, and laid strict prohibition on all the subjects of the state not to attempt any future establishment. This account is also confirmed by an historian of no mean credit, who asserts, with all the extravagant marks of joy and admiration, that he returned home, and, especially if the meaning has been evidently added, he retains the Tyrians would have settled a colony and left the name of Skælinges, or dwarfish people, from their small stature. They were armed with bows and arrows, and had leathern canoes, such as they have at present. All this is probable; nor should the tale of the German, called Tukel, one of the crew, invalidate the account.

He was, one day, musing; but soon returned, leaping and singing, with all the extravagant marks of joy he bore; and, on discovering the inebriating fruit of his country, the grape: Torfæus even says, that he returned in a state of intoxication. To convince his commander, he brought several bunches; and the country, from that circumstance, was named Vineland. There appears no reason to doubt of the discovery; it is thought probable, however, that these people reached no farther than the barren country of Labrador. In short, it is from a much later period that we must date the unquestionable discovery of America.

Towards the close of the 15th century, Venice and Genoa being rivals in commerce, in which the former had greatly the superiority, Christopher Colon, or Columbus, a native of Genoa, conceived a project of failing to the East-Indies by directing his course westward. This design was founded upon a mistake of the geographers, of those days, who placed the eastern parts of Asia immensely too far to the eastward; so that they had been in the right, the shortest way would have been to sail directly westward. Columbus applied, first, to his own countrymen; but being rejected by them, he applied to Portugal, where he met with no better success. Spain was his next resource; here, after eight years' attendance, he obtained, in 1492, by the aid of ships. The largest, a ship of no considerable burthen, was commanded by Columbus, as admiral, who gave it the name of Santa Maria, out of respect for the blessed Virgin, whom he honoured with singular devotion. Of the second, called the Pinta, Martin Pinzon was captain, and his brother Francis pilot. The third, named the Niña, was under the command of Vincent Yanez Pinzon. These two were light vessels, hardly superior in burden, or force, to large boats. This squadron, if it merits that name, was victualled for 12 months, and had on board 90 men, mostly sailors, together with a few adventurers, who followed the fortune of Columbus, and some gentleman of Isabel's court, whom she appointed to accompany him. Though the expense of the undertaking was one of the circumstances which chiefly alarmed the court of Spain, and retarded, so long, the negotiation with Columbus, the sum employed in fitting out this squadron did not exceed 4000L.

As Columbus was deeply impressed with sentiments of religion, he would not set out upon an expedition so arduous, and of which one great object was to extend the knowledge of the Christian faith, without imploping, publicly, the guidance...
dance and protection of Heaven. With this view, he, together with all the persons under his command, marched, in solemn procession, to the monastery of Râbida. After confessing their sins, and obtaining absolution, they received the holy sacrament from the hands of the guardian, who joined his prayers to theirs for the success of an enterprise which he had so zealously patronized.

Next morning, being Friday, the third day of August, in the year 1492, Columbus set sail, a little before sun-rise, in presence of a vast crowd of spectators, who sent up their supplications to Heaven for the prosperous issue of the voyage, which they wished, rather than expected. Columbus steered, directly, for the Canary-Islands, and arrived there without any occurrence that would have deferred notice on any other occasion: but, in a voyage of such expectation and importance, every circumstance was the object of attention. The rudder of the Pinta broke loose, the day after the left the harbour, and that accident alarmed the crew, no less superstitiously than unfeelingly, as a certain omen of the unfortunate destiny of the expedition. Even in the short run to the Canaries, the ships were found to be so crazy, and ill appointed, as to be very improper for a navigation which was expected to be both long and dangerous. Columbus refitted them, however, to the best of his power; and having supplied himself with fresh provisoes, he took his departure from Gomera, one of the most westerly of the Canary-Islands, on the sixth day of September.

Here the voyage of discovery may properly be said to begin; for Columbus, holding his course due west, left, immediately, the usual track of navigation, and stretched into unfrequented and unknown seas. The first day, as it was very calm, he made but little way; but on the second he lost sight of the Canaries; and many of the sailors, already dejected and dismayed, when they contemplated the boldness of the undertaking, began to beat their breasts, and to shed tears, as if they were never more to behold land. Columbus comforted them with assurances of success, and the prospect of vast wealth, in those opulent regions which he was conducting them. He regulated every thing by his sole authority; he superintended the execution of every order; and, allowing himself only a few hours for sleep, he was at all other times upon deck. As his course lay through seas which had not, formerly, been visited, the founding-line, or instruments for observation were continually in his hands. After the example of the Portuguese discoverers, he attended to the motion of tides and currents, watched the flight of birds, the appearance of fishes, of sea-weeds, and of every thing that floated on the waves, and entered every occurrence, with a minute exactness, in the journal which he kept. As the length of the voyage could not fail of alarming sailors inustituated only to short excursions, Columbus endeavoured to conceal from them the real progress which they made. With this view, though they ran 18 leagues the second day, after they left Gomera, he gave out that they had advanced only 15, and he, uniformly, employed the same artifice of reckoning short, during the whole voyage. By the 14th of September, the fleet was above 200 leagues to the west of the Canary-Islands. There they were struck with an appearance, no less astonishing than new. They observed that the magnetic needle, in their compasses, did not point exactly to the polar star, but varied towards the west; and, as they proceeded, this variation increased. This appearance, which is now most observed by the mariners, though it still remains one of the mysteries of nature, into the cause of which the ingenuity of man hath not been able to penetrate, filled the companions of Columbus with terror. They were now in a boundless, unknown, ocean, far from the usual course of navigation; nature itself seemed to be altered, and the only guide which they had left was about to fail them. Columbus, with no less quickness than ingenuity, invented a reason for this appearance, which, though it did not satisfy himself, seemed so plausible to them, that it dispelled their fears, or silenced their murmurs.

He still continued to steer due west, nearly in the same latitude with the Canary-Islands. In this course, he came within the sphere of the trade-wind, which blows, invariably, from east to west, between the tropics, and a few degrees beyond them. He advanced before this steady gale with such uniform rapidity, that it was seldom necessary to shift a sail. When about 400 leagues to the west of the Canaries, he found the sea covered with weeds, that it resembled a meadow of vast extent; and in some places they were so thick, as to retard the motion of the vessels. This strange appearance occasioned new alarm and disquiet. The sailors imagined that they were now arrived at the utmost boundary of the navigable ocean; that these floating weeds would obstruct their farther progress, and conceal dangerous rocks, or some large tract of land, which had sunk, they knew not how, in that place. Columbus endeavoured to persuade them, that what had alarmed, ought rather to have encouraged them, and was to be considered a sign of approaching land. At the same time, a brisk gale arose, and carried them forward. Several birds were seen hovering about the ship, and directed their flight towards the west. The despairing crew resumed some degree of spirits, and began to entertain fresh hopes.

Upon the first of October they were, according to the admiral's reckoning, 770 leagues to the west of the Canaries: but, left his men should be intimidated by the prodigious length of the navigation, he gave out that they had proceeded only 584 leagues; and, fortunately for Columbus, neither his own pilot, nor those of the other ships, had skill sufficient to correct this error, and to discover the deceit. They had, now, been above three weeks at sea: they had proceeded far beyond what former navigators had attempted, or deemed possible; all their prognostics of discovery, drawn from the flight of birds, and other circumstances, had proved fallacious; the appearances of land, with which their own credulity, or the artifice of their commander, had, from time to time, flattered and amused them, had been altogether illusive, and their prospect of success seemed now to be as distant as ever. These reflections occurred often to men, who had no other object, or occupation, than to reason and to discourse concerning the intention and circumstances of their expedition. They made impression, at first, upon the ignorant and timid, and extending, by degrees, to such as were better informed, or more resolute, the contagion spread, at length, from ship to ship. From secret whispers and murmurs, they proceeded to open cabals and public complaints.
They taxed their sovereign with inconsiderate credulity, in paying such regard to the vain promises and rash conjectures of an indigent foreigner, as to hazard the lives of so many of her own subjects, in prosecuting a chimerical scheme. They affirmed that they had fully performed their duty, by venturing so far in an unknown and hopeless course, and could incur no blame, for refusing to follow, any longer, a desperate adventurer to certain destruction. They contended, that it was necessary to think of returning to Spain, while their crazy vessels were still in a condition to keep the sea, but expressed their fears that the attempt would prove vain, as the wind, which had hitherto been favourable to their course, melt render it impossible to fall in the opposite direction. All agreed that Columbus should be compelled by force to adopt a measure on which their common safety depended. Some of the more audacious proposed, as the most expedient and certain method for getting rid, at once, of his remonstrances, to throw him into the sea; being persuaded that, upon their return to Spain, the death of an unsuccessful projector would excite little concern, and be inquired into with no curiosity.

Columbus was fully sensible of his perilous situation. He had observed, with great uneasiness, the fatal operation of ignorance, and of fear, in producing disaffection, among his crew, and feared that it was now ready to burst out into open mutiny. He retained, however, perfect presence of mind. He affected to seem ignorant of their machinations. Notwithstanding the agitatation and solicitude of his own mind, he appeared with a cheerful countenance; like a man satisfied with the progress which he had made, and confident of success. Sometimes he employed all the arts of insinuation to soothe his men. Sometimes he endeavoured to work upon their ambition, or avarice, by magnificent descriptions of the fame and wealth which they were about to acquire. On other occasions, he assumed a tone of authority, and threatened them with vengeance from their sovereign, if, by their dastardly behaviour, they should defeat this noble effort to promote the glory of God, and to exalt the Spanish name, above that of every other nation. Even with seditions sailors, the words of a man, whom they had been accustomed to reverence, were weighty and persuasive; and not only restrained them from those violent excesses which they meditated, but prevailed with them to accompany his admiral for some time longer.

As they proceeded, the indications of approaching land seemed to be more certain, and excited hope in proportion. The birds began to appear in flocks making towards the south-west. Columbus, in imitation of the Portuguese navigators, who had been guided in several of their discoveries by the motion of birds, altered his course from due west towards that quarter, whither they pointed their flight. But after holding on for several days in this new direction without any better success than formerly, having seen no object during 30 days but the sea and the sky, the hopes of his companions subsided faster than they had risen; their fears revived with additional force: impatience, rage, and despair, appeared in every countenance. All sense of subordination was lost. The officers, who had hitherto concurred with Columbus in opinion, and supported his authority, now took part with the private men: they assembled, tumultuously, on the deck, expostulated with their commander, mingled threats with their expostulations, and required him instantly to tack about, and to return to Europe. Columbus perceived that it would be of no avail to have recourse to any of his former arts, which having been tried so often had lost their effect; and that it was impossible to rekindle any zeal for the success of the expedition among men whose breasts fear had extinguished every generous sentiment. He saw that it was no less vain to think of employing either gentle or severe measures, to quell a mutiny so general and so violent. It was necessary, on all these accounts, to foother the passions which he could no longer command, and to give way to a torrent too impetuous to be checked. He promised, solemnly, to his men, that he would comply with their request, provided they would accompany him, and obey his commands for three days longer, and if, during that time, land were not discovered, he would then abandon the enterprise and direct his course towards Spain.

Enraged as the sailors were, and impatient to turn their faces again towards their native country, this proposition did not appear to them unreasonable. Nor did Columbus hazard much in confining himself to a term so short. The prefiges of discovering land were far from the number and promising, that he deemed them infallible. For some days the sounding line had reached the bottom, and the spoil which it brought up indicated land to be at no great distance. The flocks of birds increased; and were composed not only of sea fowl, but of such land-birds as could not be supposed to fly far from the shore. The crew of the Pinta observed a cane floating which seemed to be newly cut, and likewise a piece of timber artificially carved. The sailors aboard the Niagra took up the branch of a tree, with red berries, perfectly fresh. The clouds around the setting sun assumed a new appearance; the air was more mild and warm; and, during night, the wind became unequal and variable. From all these symptoms, Columbus was so confident of being near land, that, on the evening of the 11th of October, after public prayers for success, he ordered the sails to be furlled and the ships to lie by, keeping strict watch, lest they should be driven ashore in the night. During this interval of suspense and expectation, no man shut his eyes, all kept upon deck, gazing intently towards that quarter where they expected to discover the land, which had been so long the object of their wishes.

About two hours before midnight, Columbus standing on the forecastle, observed a light at a distance. Their joy and privately pointed it out to Pedro Gutierrez, a page and calling to Salcedo, commander of the fleet, all three saw it in motion, as if it were carried from place to place. A little after midnight, the joyful sound of Land! land! was heard from the Pinta, which kept always a-head of the other ships. But having been so often deceived by fallacious appearances, every man was now become low of belief; and waited, in all the anguish of uncertainty and impatience, for the return of day. As soon as morning dawned, all doubts and fears were dispelled. From each ship, an island was seen about two leagues to the north, while flat and verdant fields, well flored with wood, and watered with many rivulets, presented the aspect of a delightful country.
The crew of the Pinta instantly began the Te Deum, as a hymn of thanksgiving to God; and were joined by those of the other ships, with tears of joy and transports of congratulation. This office of gratitude to Heaven was followed by an act of justice to their commander. They threw themselves at the feet of Columbus, with feelings of self-condemnation mingled with reverence. They imploréd him to pardon their ignorance, incredulity, and insolence, which had created him so much unnecessary disquiet, and had so often obstructed the prosecution of his well-concerted plan; and palling, in the warmth of their admiration, from one extreme to another, they now pronounced the man whom they had so lately reviled, and threatened, to be a person inspired by Heaven, with sagacity and fortitude more than human, in order to accomplish a design so far beyond the ideas and conception of all former ages.

As soon as the sun arose, all their boats were manned and armed. They rowed towards the island with their colours displayed, with warlike music, and other martial pomp. As they approached the shore, they saw it covered with a multitude of people, whose novelty of the scene had drawn together, whose attitudes and gestures expressed wonder and astonishment, at the strange objects which presented themselves to their view. Columbus was the first European who set foot in the New-World, which he had discovered. He landed in a rich dress, and with a naked sword in his hand. His men followed; and, kneeling down, they all knelt down the ground which they had so long desired to see. They, next, erected a crucifix; and, prostrating themselves before it, returned thanks to God for conducing their voyage to such an happy issue.

The above was one of the Bahama-Islands; to which he gave the name of San Salvador; and took possession of it, in the name of their Catholic majesties. In this first voyage he discovered several other of the Lucayo, or Bahama-Islands, with those of Cuba and Hispaniola. The natives considered the Spaniards as divinities, and the discharge of the artillery their thunder: they fell prostrate at the sound. The women, however, offered their favours, and courted the embraces of their new guest as men. Their husbands were not jealous of them; and in the arms of those wantons the companions of Columbus are said, by some authors, to have caught that malady which directs its poison to the springs of life. In a second voyage, many new islands were discovered. In a third, he attained the great object of his ambition, by discovering the continent of America, near the mouth of the river Oronoko, on the first day of August 1498. His succés produced a crowd of adventurers, from all nations; but the year before this, the northern continent had been discovered by Sebasbían Cabot, in the service of Henry VII. of England.

Notwithstanding the many settlements of the Europeans in this continent, great part of America remains still unknown. The northern continent contains the British colonies of Hudson's-Bay, Canada, and Nova Scotia; the New-England states, New-York, New-Jersey, Pennsylvania, Maryland, Virginia, North and South, Carolina, and Georgia. It contains, also, the Spanish territories of East, and West, Florida, Louisiana, New-Mexico, California, and Mexico. Besides these, there are immense regions to the west, and north, the boundaries of which have never yet been discovered. In America, such assurance in any degree known, dwell the Algonqui, the Hurons, the Iroquois, the Cheerkas, the Chickaaws, and many other tribes of Indians. In the southern continent lie the Spanish provinces of Tiera-Firme, Guiana, Peru, Paraguay, and Chili; together with that of Brazil, belonging to the Portuguese; and the country of Surinam, belonging to the Dutch.

Vast tracts, however, in the inland parts, are unknown, being comprehended under the general name of America. A large district, also, laid to be the residence of a gigantic race of men, lies on the east side of the continent, between the straits of Magellan and the province of Paraguay. See the article Patagonia.

This vast country produces many of the metals, minerals, plants, fruits, trees, and wood, to be met with in the other parts of the world, and many of them in greater quantities, and in high perfection. The gold and silver of America have supplied Europe with such immense quantities of those valuable metals, that they are become vastly more common; so that the gold and silver of Europe now bear little proportion to the high price set upon them before the discovery of America.

It also produces diamonds, pearls, emeralds, amethysts, and other valuable stones, which, by being brought into Europe, have contributed, likewise, to lower their value. To these, which are the chief productions of Spanish America, may be added a great number of other commodities, which, though of less price, are of much greater use. Of these are the plentiful supplies of cochineal, indigo, anatto, logwood, balsa, jute, pimento, lignum vitæ, rice, ginger, cocoa, or the chocolate-nut, sugar, cotton, tobacco, bananas, red-wood, the balsams of Tolo, Peru, and Chili, that valuable article, in medicine, the jefuit's bark, mechoacan, saffrañas, farfparilla, cañas, tamarinds, hides, furs, ambergris, and a great variety of woods, roots, and plants; to which, before the discovery of America, the Europeans were entirely strangers, or which they were forced to buy at an extravagant rate from Asia and Africa, through the hands of the Venetians and Genoese, who then engrossed the trade of the Eastern-World.

On this continent there grows also a variety of excellent native fruits; as pine-apples, citrons, lemons, oranges, malictons, figs, grapes, great numbers of culinary, medicinal, and other herbs, roots, and plants, with many exotic productions, which are nourished in as great perfection as in their native soil.

Although the Indians still live in the quiet possession of many large tracts, America, so far as known, is chiefly claimed, and divided into colonies, by three European nations, the Spaniards, English, and Portuguese. The Spaniards, as they first discovered it, have the largest and richest portion, extending from New-Mexico and Louisiana, in North-America, to the straits of Magellan, in the South-Sea, excepting the large province of Brazil, which belongs to Portugal; for though the French and Dutch have some forts upon Surinam and Guiana, they fearfully deferve to be considered as proprietors of any part of the southern continent.

Next to Spain, the most considerable proprietor of America was Great Britain, who derived her claim to North-America from the first discovery of that continent by Sebasbían Cabot, in the name of Henry VII.
America. anno 1497, about six years after the the discovery of South-America by Columbus, in the name of the king of Spain. This country was in general called Newfoundland; a name which is now appropriated solely to an island upon its coast. It was a long time before the English made any attempt to settle in this country. Sir Walter Raleigh, an uncommon genius and a brave commander, first showed the way, by planting a colony in the southern part, which he called Virginia, in honour of his virgin mistress Queen Elizabeth.

The French indeed, from this period until the conclusion of the war before last, laid a claim to, and notions were adequately high in their own favour. They deemed themselves, not without reason, entitled to every kindreds and indulgence which the mother-country could bestow.

Although their pretensions did not amount to a perfect equality of advantages and privileges in matters of commerce, yet in those of government they thought themselves sufficiently competent to the task of conducting their domestic concerns, with little or no interference from abroad. Through willing to admit the supremacy of Great Britain, they viewed it with a vigilant eye, and with a marked desire to restrain it within its strict constitutional boundaries.

Their improvements in all the necessary and useful arts did honor to their industry and ingenuity. Though they did not live in the luxury of Europe, they had all the solid and substantial enjoyments of life, and were not unequipped with many of its elegancies and refinements.

A circumstance much to their praise is, that notwithstanding their peculiar addiction to those occupations of which luxury is the sole object, they were duly attentive to cultivate the field of learning; and they have, ever since their first foundation, been particularly careful to provide for the education of the rising progeny.

Their vast augmentation of internal trade and external commerce, was not merely owing to their position and facility of communication with other parts; it arose also from their natural turn and temper, full of schemes and projects; ever aiming at new discoveries, and continually employed in the search of the means of improving their condition.

Their condition carried them into every quarter from whence profit could be derived. There was scarcely any part of the American hemisphere to which they had not extended their navigation. They were continually exploring new fields of trade, and were found in every spot where business could be transacted.

To this extensive and incessant application to commerce, they added an equal vigilance in the administration of their affairs at home. Whatever could conduct to the amelioration of the soil they prosecuted, to the progress of agriculture, or to the improvement of their domestic circumstances, was attended to with so much labour and care, that it may be strictly said that Nature had given them nothing of which they did not make the most.

In the midst of this solicitude and toil in matters of business, the affairs of government were conducted with readiness, prudence, and lenity, seldom experienced, and never exceeded, in the best regulated countries of Europe.

Such was the situation of the British colonies in general throughout North America, and of the New-England provinces in particular, when the pacification above-
above-mentioned opened one of the most remarkable scenes that ever commanded the attention of the world.

In treating of the American revolution, it has become a fashion with the English writers to ascribe that event to the successful intrigues of the French government. Instead of contemplating it, with the characteristic philosophy of their country, as the result of a conflict between the desire of power, and the abhorrence of oppression, they have sought the origin of the evil in any source rather than their own miscon duct; and have endeavoured at once, to hush the rep roaches of their political conscience, and to gratify the cravings of their national animosity, in wild conj ections of a scheme formed by their neighbours to divide the British Empire, and in declamatory invective against the Gallic faith and honour. Thus it has been repeatedly asserted, that the French having long view ed, with equal envy and apprehension, the flourishing state of the colonies which Britain had founded in America, began immediately after the peace of Paris to carry into execution their project for separating them from the mother country. Several such emil­eraries, it is said were employed in spreading disat taction among the colonists; and the effects produced by these macabre spirits are described to have been a rapid diminution of that peculiar warmth of attach ment, which the inhabitants of North-America had hitherto demonstrated for the mother country; the ex citement of a jealousy which led them to view her rather in the light of a sovereign than of a parent; and the introduction of a hostile policy which taught them to examine, with a scrupulous nicety, the nature of the theses which rendered them parts of her empire. That such emilaries, it is said, were in fact supported by any document which the purity of historical truth can admit; and although the effects here de scribed, have certainly appeared, it must be remembered that their appearance followed, but did not precede, the attempts of Britain upon the rights and liberties of America. By mere artifice and address to have alienated the affections of the colonists from their mother country, at the close of a war in which their interests and feelings had been intertwined with more than usual strength and energy, was a task of infinite difficulty; not purely to be accomplished in the short period be tween the declaration of peace in 1763, and the pro mulgation of the first obnoxious acts of the British par liament in 1765. Before, if we refer these effects to an other cause, to a love of liberty, and a quick sense of injury, their appearance will be natural and just; con­fident with the American character, and correspon ding with the conduct which was displayed in all the vicissitudes that attended the revolt.

In March, 1764, a bill was passed, by which heavy duties were laid on goods imported into the colonies, from such West-India Islands as did not belong to Great Britain; at the same time that these duties were to be paid into the exchequer in specie; and in the same session, another bill was framed to restrain the currency of paper-money in the colonies themselves. Not only the principle of taxation, but the mode of collection was considered as an unconstitutional and oppressive innovation; for the penalties incurred by an infraction of the acts of parliament, might be recovered in the courts of admiralty, before a single judge (whose salary was the fruit of the forfeitures he decreed) without trial by jury, or any of the other benefits of common law juris prudence. These acts coming so close to each other threw the whole continent into the utmost ferment. Though remonstrances were made to the ministry, and every argument made use of that reason or ingenuity could suggest, but no effect resulted. Their reasoning, however, convinced a great number of people in Britain; and thus the American cause came to be con sidered as the cause of liberty.

The Americans, finding all argumentation vain, at last united in an agreement to import no more of the manufactures of Great Britain, but to encourage to the utmost of their power every thing of that kind among themselves. Thus the British manufacturers also became a party against the ministry, and did not fail to express their resentment in the strongest terms; but the ministry were not so easily daunted, and therefore proceeded to the last step of their intended plan, which was to lay on stamp duties throughout the continent. Previous to this, indeed, several regulations were passed in favour of the commerce of the colonies; but they had now imbibed such unfavourable sentiments of the British ministry, that they paid very little regard to any thing pretended to be done in their favour; or if these acts made any favourable impression, it was quickly obliterated by the news of the stamp act. The reasons given for this act, so exceedingly obnoxious, was, that a sum might be raised sufficient for the defence of the colonies against a foreign enemy; but this pretence was so far from giving any satisfaction to the Americans, that it excited their indignation to the utmost degree. They not only affirmed that they were abundantly able to defend themselves against any foreign enemy, but denied that the British parliament had any right to tax them at all.

It would be superfluous to enter into any arguments used by the contending parties on this important occasion. It was evident that the matter was not to be decided by argument, but by force of arms; and the British ministry, too confident of the authority and power of that country, determined to carry on matters with an high hand, to terrify the colonists into an implicit submission, or, if that would not do, to compel them to it by force. The stamp act, after a violent opposition in parliament, was passed, and its reception in America was such as had been expected. The news, and the act itself, first arrived at Boston, where the bells were muffled and rung a funeral peal. The act was first hawked about the streets with a Death's head, affixed to it, and flayed the folly of England, and the Ruin of America;" and afterwards publicly burnt by the enraged populace: The flamps themselves were feized and destroyed, unless brought by men of war, or kept in fortified places; those who were to receive the stamp duties were compelled to resign their offices; and such of the Americans as fled with government on this occasion, had their houses plundered and destroyed.

Though these outrages were committed by the multitude, they were first connived at by those of superior rank, and the principles on which they were founded afterwards openly patronized by them; and the doctrine
It was now found absolutely necessary either to yield to the Americans, by repealing the obnoxious statutes, or to enforce them by arms. The ferment had diffused itself universally throughout the colonies. Virginia first, and after that all the rest of the provinces, declared against the right of Britain to lay taxes in America; and that every attempt tovelt others with this power besides the king, or the governor of the province and his general assembly, was illegal, unconstitutional, and unjust. Non-importation agreements were every where entered into; and it was even resolved to prevent the sale of any more British goods after the present year. American manufactures, though dearer, as well as inferior in quality to the British, were universally preferred. An association was entered into against eating of lamb, in order to promote the growth of wool; and the ladies with cheerfulness agreed to renounce the use of every species of ornament manufactured in Britain. Such a general and alarming con­ fer­ ency determined the ministry to repeal some of the most obnoxious statutes; and to this they were the more inclined by a petition from the first American congress, held at New York in the beginning of October 1765.

The stamp-act was therefore repealed, to the universal joy of the Americans, and indeed to the general satisfaction of the English, whole manufactures had begun to suffer very severely in consequence of the American association against them. The disputes on the subject without doors, however, were by no means silenced, but each party continued to argue the cause as violently asever. The celebrated Dr Benjamin Franklin was, on this occasion examined before the House of Commons; and his opinion was in substance as follows:

"That the tax in question was impracticable and ruinous. The very attempt had so far alienated the affection of the colonies, that they behaved in a less friendly manner towards the natives of England than before; considering the whole nation as conspiring against their liberty, and the parliament as willing rather to oppress than to support and aflift them. America, in fact, did not stand in any need of British ma­ nufactures, having already begun to construct such as might be deemed absolutely necessary, and that with such success, as left no doubt of their arriving in a short time at perfection. The elegancies of dress had already been renounced for manufactures of the American kind, though much inferior; and the bulk of the people, consisting of farmers, were such as could in no way be affected by the want of British commodities, as having every necessity within themselves. Materials of all kinds were to be had in plenty: the wool was fine; flax grew in great abundance; and iron was every where to be met with."

The Doctor also infisted, That "the Americans had been greatly misrepresented; that they had been traduced as void of gratitude and affection for the parent state; than which nothing could be more contrary to truth. In the war of 1755 they had, at their own expense, raised an army of 2500 men; and in that of 1759, they assisted the British expeditions against South America with several thousand men, and had made many brave exertions against the French in North America. It was said that the war of 1755 had been undertaken in defence of the colonies; but the truth was, that it originated from a contest about the limits between Canada and Nova-Scotia, and in defence of the English rights to trade on the Ohio. The Americans, however, would still continue to act with the colonies in a friendly manner towards the natives of England than to oppress them; though compo­ sed of those who had been active against the stamp-act, less favourable to the measures than in all probability they would otherwise have been. An unlucky circumstance at the same time occurred, which threw every thing once more into confusion. One of the new ministry, Mr Charles Townshend, having declared that he could find a way of taxing the friendship of the Americans without giving them offence, was called upon to propose his plan. This was by imposing a duty upon tea, paper, painters colours, and glass imported into America. The conduct of the New York assembly, repealing the troops, and that of Boston, which had proceeded in a similar manner, caused this bill to meet with less opposition than otherwise it might have done. As a punishment to the refractory assemblies, the legislative power was taken from that of New York, until it should fully comply with the terms of the act. That of Boston at last submitted with reluctance. The bill for the new taxes was quickly passed, and sent to America in 1768.

A ferment much greater than that occasioned by the stamp-act now took place throughout the continent. The populace renewed their outrages, and those of inferior fiction entered into regular associations against it.
The convention, however, had not been allowed to deliver their intending to excite a rebellion which the governor now hurried up to the king's ships out of the harbour.

While the disposition of the Bostonians was thus more more and more irritate news arrived that the agent behaved as for the colony had not been allowed to deliver their increase; petition to the king; it having been objected, that the assembly without the governor was not sufficient authority. This did not contribute to allay the ferment; and it was further augmented by the news that a number of troops had been ordered to repair to Boston, to keep the inhabitants in awe.

A dreadful alarm now took place. The people called on the governor to convene a general assembly, in order to remove their fears of the military; who, they said, were to be assembled overthrow their liberties, and force obedience to laws to which they were entirely averse. The governor replied, it was no longer in his power to call an assembly; having, in his last instructions from England, been required to wait the king's orders, the matter being then under consideration at home. Being thus refused, the people took upon themselves the formation of an assembly, which they called a convention. The proceedings and resolutions of this body could naturally partake of the temper and disposition of the late assembly; but they were more violent, and having voted "that there is apprehension in the minds of many of an approaching rupture with France," requested the inhabitants to put themselves in a posture of defence against any sudden attack of an enemy; and circular letters were directed to all the towns in the province, acquainting them with the resolutions that had been taken in the capital, and exhorting them to proceed in the same manner. The town of Hatfield alone refused its concurrence. The convention, however, thought proper to afford the governor of their pacific intentions, and reafured their request that an assembly might be called; but being refused any audience, and threatened with being treated as rebels, they at last thought proper to disolve of themselves, and having been over to Britain a circumstantial account of their proceedings, with the reason of their having assembled in the manner already mentioned.

The expected troops arrived on the very day on which the convention broke up, and had some houses in the town fitted up for their reception. Their arrival had a considerable influence on the people, and for some time seemed to put a stop to the disturbances; but the spirit of the people was now so much routed, that it was
was impossible to quench the flame. The late outrageous behaviour in Boston had given the greatest offence in England; and, notwithstanding all the efforts of opposition, an address from both houses of parliament was presented to the king, in which the colonists of Massachusetts-Bay were fet forth in the most amiable manner, and the most vigorous measures recommended for reducing them to obedience. The Americans, however, continued steadfast in the ideas they had adopted. Though the troops had for some time quieted the disturbances, yet the calm continued no longer than they appeared respectable on account of their number; but as soon as this was diminished by the departure of a large detachment, the remainder were treated with contempt, and it was even resolved to expel them altogether. The country people took up arms for this purpose, and were to have alligned their friends in Boston; but before this design could be put in execution, an event happened which put an end to every idea of reconciliation between the contending parties.

On the 5th of March 1770, a fracas happened between the soldiers and a party of the town's people. The inhabitants poured in from all quarters to the af- fistance of opposition, an address of protest being presented to the king, requesting the viour of the colony of Massachusetts-Bay was killed; the officers and soldiers were immediately arrested, and were to have been tried for murder. The事件 Rhew & Co., and the tea-merchant, were brought before the superior court at Boston, but they were acquitted, two men being found guilty of manslaughter. The officers and soldiers were immediately arrested, and were to have been tried for murder. The event shewed that their conduct was declared groundsless and scandalous. Matters were now ripe for the utmost extremities on the part of the Americans; and they were brought on in the following manner. Though the colonies had entered into a non-importation agreement against tea as well as all other commodities from Britain, it had nevertheless found its way into America, though in smaller quantities than before. This was largely felt by the East-India Company, who had now agreed to pay a large sum annually to the government for which compliance, and to make up their losses in other respects, they were empowered to export their tea free from any duty payable in Britain; and in consequence of this premilion, several ships freighted with the commodity were sent to North-America, and proper agents appointed for disposing of it. The Americans now perceiving that the tax was thus likely to be enforced whether they would or not, determined to take every possible method to prevent the tea from being landed, as well knowing that it would be impossible to hinder the sale, should the commodity once be brought on shore. For this purpose the people assembled in great numbers, forcing those to whom the tea was confined to resign their offices, and to promise solemnly never to refuse them; and committees were appointed to examine the accounts of merchants, and make public tests, declaring such as would not take them enemies to their country. Nor was this behaviour confined to the colony of Massachusetts-Bay; the rest of the provinces entered into the contest with the same warmth, and manifested the same resolution to oppose this invasion of their rights. 

In the midst of this confusion, three ships laden with tea arrived in Boston; but so much were the captains alarmed at the disposition which seemed to prevail among the people, that they offered, providing they could obtain the proper discharges from the tea-con- signees, custom-house, and governor, to return to Britain without landing their cargoes. The parties concerned, however, though they durst not order the tea to be landed, refused to grant the discharges required. The ships, therefore, would have been obliged to main in the harbour; but the people apprehensive
that if they remained there, the tea would be landed in small quantities and disposed of in spite of every endeavours to prevent it, resolved to destroy it at once.

This resolution was executed with equal speed and effect. The very evening after the above mentioned discharges had been refused, a number of people dressed like Mohawk Indians boarded the ships and threw into the sea their whole cargo, consisting of 342 chests of tea; after which they retired without making any further disturbance, or doing any other damage. No tea was destroyed in other places, though the same spirit was everywhere manifested. At Philadelphia the pilots were enjoined not to conduct the vessels up the river; and at New-York, though the governor caused some tea to be landed under the protection of a man of war, he was obliged to deliver it up to the custody of the people to prevent its being sold.

The destruction of the tea at Boston, which happened in November 1773, was the immediate prologue to the disasters attending civil discord. Government finding themselves everywhere insulted and defied, resolved to enforce their authority by all possible means; and as Boston had been the principal scene of the riots and outrages, it was determined to punish that city in an exemplary manner. Parliament was acquainted by a message from his majesty with the undutiful behaviour of the city of Boston, as well as of all the colonies, recommending to the latter the most vigorous and spirited exertions to reduce them to obedience. The parliament in its address promised a ready compliance; and indeed, the Americans seemed now to have lost many of their partisans. It was proposed to lay a fine on the town of Boston equal to the price of the tea which had been destroyed, and to shut up its port by armed vessels until the refractory spirit of the inhabitants should be subdued; which, it was thought, must quickly yield, as a total stop would thus be put to their trade. The bill was strongly opposed on the ground that the other had been; and it was predicted, that, instead of having any tendency to reconcile or subdue the Americans, it would infallibly exasperate them beyond any possibility of a reconciliation. The petitions against it, presented by the colony's agent, pointed out the same consequences in the strongest terms, and in the most positive manner declared that the Americans never would submit to it; but such was the infatuation attending every rank and degree of men, that it never was imagined the Americans would dare to revile the parent state openly, but would in the end yield implicitly to her commands. In this confidence, a third bill was proposed for the impertinent administration of justice on such persons as might be employed in the suppression of riots and tumults in the province of Massachusetts-Bay. By this act it was provided, that should any persons acting in that capacity be indicted for murder, and not able to obtain a fair trial in the province, they might be sent by the governor to England, or to some other colony, if necessary, to be tried for the supposed crime. These three bills having passed so easily, the ministry proposed a fourth, relative to the government of Canada; which, it was said, had not yet been settled on any proper plan. By this bill the extent of that province was greatly enlarged; its affairs were put under the direction of a council in which Roman Catho-

lics were to be admitted; the Roman Catholic clergy were secured in their possessions and the usual perquisites from those of their own profession. The council abovementioned were to be appointed by the crown; to be removable at its pleasure; and to be invested with every legislative power, excepting that of taxation.

No sooner were these laws made known in America, than they cemented the union of the colonies almost beyond any possibility of dissolving it. The assembly of Massachusetts-Bay had passed a vote against the judges accepting salaries from the crown, and put the question, Whether they would accept them as usual from the general assembly? Four answered in the affirmative; but Peter Oliver, the chief-justice, refused. A petition against him, and an accusation, were brought before the governor; but the latter refused the accusation, and declined to interfere in the matter; but as they still intimated for justice against Mr Oliver, the governor thought proper to put an end to the matter by dissolving the assembly.

In this situation of affairs, a new alarm was occasioned by the news of the port-bill. This had been totally unexpected, and was received with the most extravagant expressions of displeasure among the populace, and while these continued, the new governor, General Gage, arrived from England. He had been chosen to this office on account of his being well acquainted in America, and generally agreed to by the people; but human wisdom could not now point out a method by which the flame could be allayed. The first act of his office as governor was to remove the assembly to Salem, a town 17 miles distant, in consequence of the late act. When this was intimated to the assembly, they replied by requesting him to appoint a day for public humiliation for depriving the wrath of heaven, but met with a refusal. When met at Salem, they passed a resolution, declaring the necessity of a general congress composed of delegates from all the provinces, in order to take the affairs of the colonies at large into consideration; and five gentlemen remarkable for their opposition to the British measures, were chosen to represent that of Massachusetts-Bay. They then proceeded with all expedition to draw up a declaration, containing a detail of the grievances they laboured under; and the necessity of exerting themselves against unlawful power; they set forth the disregard shown to their petitions, and the attempts of Great Britain to destroy their ancient constitution; and concluded with exhorting the inhabitants of the colony, to obstruct, by every method in their power, such evil designs, beginning at the same time a total renunciation of every thing imported from Great-Britain, till a redress of grievances could be procured.

Intelligence of this declaration was carried to the governor on the very day that it was completed; on which he dissolved the assembly. This was followed by an address from the inhabitants of Salem in favour of the crown; to which the latter replied, some imagine that the course of trade might be turned hither, and to our benefit; but nature, in the formation of our harbour, forbids our becoming rivals in commerce with that convenient mart; and were it otherwise,
otherwise, we must be dead to every idea of justice, lost to all feelings of humanity, could we indulge one thought to seize on wealth, and raise our fortunes on the ruin of our suffering neighbours.

It had been fondly hoped by the ministerial party at home that the advantages which other towns of the colony might derive from the annihilation of the trade of Boston, would make them readily acquiesce in the measure of shutting up that port, and rather rejoice in it than otherwise; but the words of the address above mentioned seemed to preclude all hope of this kind; and subsequent transactions only manifested it to be totally vain. No sooner did intelligence arrive of the remaining bills passed in the session of 1774, than the cause of Boston became the cause of all the colonies. The port-bill had already occasioned violent commotions throughout them all. It had been repealed in provincial meetings, and resistance even the last had been recommended against such oppression.

In Virginia, the first of June, the day on which the port of Boston was to be shut up, was held as a day of humiliation, and a public intercession in favour of America was enjoined. The style of the prayer enjoined at this time was, that "God would give the people one heart and one mind, firmly to oppose every invasion of the American rights." The Virginians, however, did not content themselves with acts of religion. They recommended in the strongest manner a general congress of all the colonies, as fully persuading that an attempt to tax any colony in an arbitrary manner was in reality an attack upon them all, and must ultimately end in the ruin of them all.

The provinces of New-York and Pennsylvania, however, were less sanguine than the rest, being to closely connected in the way of trade with Great Britain, that the giving it up entirely appeared a matter of the most serious magnitude, and not to be thought of but after every other method had failed. The intelligence of the remaining bills respecting Boston, however, spread a fresh alarm throughout the continent, and fixed those who had seemed to be the most wavering. The proposal of giving up all commercial intercourse with Britain was again proposed; contributions for the inhabitants of Boston were raised in every quarter; and they every day received addresses commending them for the heroism with which they sustained their calamity.

The Bostonians on their part were not wanting in their endeavours to promote the general cause. An agreement was framed, which in imitation of former times, they called a Solemn League and Covenant. By this the subscribers most religiously bound themselves to break off all communication with Britain after the expiration of the month of August ensuing, until the obnoxious acts were repealed; at the same time they engaged neither to purchase nor use any goods imported after that time, and to renounce all connection with those who did, or refused to subscribe to this covenant; threatening to publish the names of the refractory; which at this time was a punishment by no means to be despised. Agreements of a similar kind were almost instantaneously entered into throughout all America. General Gage indeed attempted to counteract the covenant by a proclamation, wherein it was declared an illegal and traiterous combination, threatening with the pains of law such as subscribed or countenanced it. But matters were too far gone for his proclamations to have any effect.

The Americans retorted the charge of illegality on his own proclamation, and insulted that the law allowed subjects to meet in order to consider of their grievances, and associate for relief from oppression.

Preparations were now made for holding the general congress so often proposed. Philadelphia, as being the most central and considerable town, was pitched upon for the place of its meeting. The delegates, of whom it was to be composed, were chosen by the representatives of each province, and were in number from two to seven for each colony, though no province had more than one vote. The first congress, which met at Philadelphia, in the beginning of September 1774, consisted of 51 delegates. The novelty and importance of the meeting excited and universal attention; and their transactions were such as could not but tend to render them respectable.

The first act of congress was an approbation of the conduct of Massachusets-Bay, and an exhortation to continue in the same spirit with which they had begun. Supplies for the suffering inhabitants (whom the operation of the port-bill had reduced to great distress) were strongly recommended; and it was declared, that in case of attempts to enforce the obnoxious acts by arms, all America should join to afflict the town of Boston; and, should the inhabitants be obliged, during the course of hostilities, to remove further up the country, the losses they might sustain should be repaired at the public expense.

They next addressed General Gage by letter; in which, having stated the grievances of the people of Massachusets colony, they informed him of the fixed and unalterable determination of all the other provinces to support their brethren and to oppose the British acts of parliament; that they themselves were appointed to watch over the liberties of America; and intreated him to desist from military operations, lest such hostilities might be brought on as would frustrate all hopes of reconciliation with the parent state.

The next step was to publish a declaration of their rights. Thence they summed up the rights belonging to Englishmen; and particularly insisted, that as their distance rendered it impossible for them to be represented in the British parliament, their provincial assemblies, with the governor appointed by the king, constituted the only legislative power within each province. They would, however, consent to such acts of parliament as were evidently calculated merely for the regulation of commerce, and securing to the parent state the benefits of the American trade; but would never allow that they could impose any tax on the colonies, for the purpose of raising a revenue, without their consent. They proceeded to reprobate the intention of each of the new acts of parliament; and insisted on all the rights they had enumerated as being unalienable, and what none could deprive them of. The Canada act they particularly pointed out as being extremely inimical to the colonies, by whose allience it had been conquered; and they termed it "An Act for establishing the Roman Catholic religion in Canada, abolishing the equitable system of English laws, and establishing a tyranny there."
declared in favour of a non-importation and non-consumption of British goods, until the acts were repealed by which duties were imposed upon tea, coffee, wine, sugar, and molasses, imported into America, as well as the Boston port-act, and the three others passed in the preceding session of parliament. The new regulations against the importation and consumption of British commodities were then drawn up with great solemnity; and they concluded with returning the warmest thanks to those members of parliament who had, with so much zeal, though without any succour, opposed the obnoxious acts of parliament.

Their next proceedings were, to frame a petition to the king, an address to the British nation, and another to the colonies; all of which were so much in the usual spirited strain of American language for some time past, that it is needless to enter into any particular account of them. It is sufficient to say, that they were all drawn up in a matterly manner, and ought to have impressed the people of England with a more favourable idea of the Americans than they could at that time be induced to entertain.

All this time the disposition of the people had corresponded with the warmest wishes of congress. The first of June had been kept as a fast, not only throughout Virginia, where it was first proposed, but through the whole continent. Contributions for the diftresses of Boston had been raised throughout America, and people of all ranks seemed to be particularly touched with them. Even those who seemed to be most likely to derive advantage from them, took no opportunity, as has been already intimated in the case of Salem. The inhabitants of Marblehead also showed a noble example of magnanimity in the present case. Though situated in the neighbourhood of Boston, and most likely to derive benefit from their diftresses, they did not attempt to take any advantage, but generously offered the use of their harbour to the Bostonians, as well as their wharfs and warehouses, free of all expense. In the mean time the British forces at Boston were continually increasing in number, which greatly augmented the general jealousy and dissatisfaction; the country were ready to take at a moment's warning; and the experiment was made by giving a false alarm that the communication between the town and country was to be cut off, in order to reduce the former by famine to a compliance with the acts of parliament. On this intelligence, the country people assembled in great numbers, and could not be satisfied until they had sent messengers into the city to enquire into the truth of the report. These messengers were enjoined to inform the town's people, that if they should be so pusillanimous as to make a surrender of their liberties, the province would not think itself bound by such examples; and that Britain, by breaking their original charter, had annulled the contract subsisting between them, and left them to act as they thought proper.

The people in every other respect manifested their inflexible determination to adhere to the plan they had so long followed. The new councillors and judges were obliged to resign their offices, in order to preserve their lives and properties from the fury of the multitude. In some places they shut up the avenues to the courts houses; and, when required to make way for the judges, replied, that they knew of none but such as
This disposition, known to be almost universal throughout the continent, was in the highest degree satisfactory to congress. Every one saw that the ensuing spring was to be the season of commencing hostilities, and the most indefatigable diligence was used by the colonies to be well provided against such a formidable enemy. A lift of all the sensible men in each colony was made out, and especially of those who had served in the former war; of whom they had the satisfaction to find that two-thirds were still alive and fit to bear arms. Magazines of arms were collected, and money was provided for the payment of troops. The governors in vain attempted to put a stop to these proceedings by proclamations; the fatal period was now arrived: and the more the servants of government attempted to repress the spirit of the Americans, the more determined it appeared.

The difficulties of the inhabitants of Boston were reduced to great difficulties. The British troops, now distinguished by the name of the enemy, were absolutely in possession of it: the inhabitants were kept as prisoners, and might be made accountable for the conduct of the whole colonies; and various measures were contrived to relieve the latter from such a disagreeable situation. Sometimes it was thought expedient to remove the inhabitants altogether; but this was impracticable without the governor's content. It was then proposed to set fire to the town at once, after valuing the houses and indemnifying the proprietors; but this being found equally impracticable, it was resolved to wait some other opportunity, as the garrison were not very numerous, and not being supplied with necessaries by the inhabitants, might soon be obliged to leave the place. The friends of British government indeed attempted to do something in opposition to the general voice of the people; but after a few ineffectual meetings and resolutions, they were utterly silenced, and obliged to yield to the superior number of the patriots.

Matters had now proceeded so far that the prospect of reconciliation or friendship with Britain became daily more evident, that arms must ultimately decide the contest, experts in military discipline was recommended in the strongest manner, and several military institutions enacted; among which that of the minute-men was one of the most remarkable. There were chosen from the most active and expert among the militia; and their business was to keep themselves in constant readiness at the call of their officers; from which perpetual vigilance they derived their title. It was now easily seen that a flight occasion would bring on hostilities, which could not but be attended with the most violent and certain destruction to the vanquished party; for both were so much exasperated by a long course of reproaches and literary warfare, that they seemed to be filled with the utmost invertebrity against each other.

On the 26th of February General Gage having been informed that a number of field-pieces had been brought to Salem, dispatched a party to seize them. Their road was obstructed by a river, over which was a draw-bridge. This the people had pulled up, and refused to let it down: upon which the soldiers seized a boat to ferry them over; but the people cut out her bottom. hostilities would immediately have commenced, had it not been for the interpolation of a clergyman, who represented to the military, on the one hand, the folly of opposing such numbers; and to the people, on the other, that as the day was far spent the military could not execute their design, so that they might without any fear leave them the quiet possession of the draw-bridge. This was complied with; and the soldiers, after having remained for some time at the bridge, returned without executing their orders.

The next attempt, however, was attended with more serious consequences. General Gage having been informed that a large quantity of ammunition and military stores had been collected at Concord, about 20 miles from Boston, and where the provincial congresses was sitting, sent a detachment, under the command of Colonel Smith and Major Pitcairn, to destroy the stores, and, as was reported, to seize Messrs. Hancock and Adams, the leading men of the congresses. They set out before day-break, on the 19th of April, marching with the utmost silence, and securing every one they met on the road, that they might not be discovered. But notwithstanding all their care, the continual ringing of bells and firing of guns as they went along, soon gave them notice that the country was alarmed.

About
About five in the morning they had reached Lexington 15 miles from Boston, where the militia of the place were exercising. Major Pitcairn called out to them, "dispers, ye rebels; throw down your arms and disperse;" but, as they still continued in a body, he advanced, drove them off, and ordered his soldiers, who instantly obeyed, and killed and wounded several of the militia: a dispersion of the militia was the consequence. The detachment then proceeded to Concord, where, having destroyed the stores, they fired upon the Americans; and a feuille en face, in which several fell on both sides. The purpose of their expedition being thus accomplished, it was necessary for the king's troops to retreat, which they did through a continual fire kept up on them from Concord to Lexington. Here their ammunition was totally expended; and they would have been unavoidably cut off, had not a considerable reinforcement commanded by Lord Percy met them. The Americans, however, continued their attack with great spirit; and the British would still have been in the utmost danger had it not been for two field-pieces which Lord Percy had brought with him. By these the impetuosity of the Americans was checked, and the British made good their retreat to Boston, with the loss of 273 killed wounded and made prisoners: that of the Americans was about 50 killed, 38 wounded and missing.

From the commencement of hostilities, the dispute between Great Britain and the colonies took a new direction. By this engagement the spirits of the Americans were raised; a considerable army was assembled, who formed a line of entrenchment from Roxbury to Mystic, through a space of about 30 miles; and here they were soon after joined by a large body of Connecticut troops, under General Putnam, an old officer of great bravery and experience. By this formidable force was the town of Boston now kept blocked up. General Gage, however, had so strongly fortified it, that the army powerful as they were, durst not make an attack; while on the other hand, his force was too insignificant to meet such an army in the field. But towards the end of May, a considerable reinforcement having arrived, with Generals Howe, Burgoyne, and Clinton, he was soon enabled to attempt something of consequence. Some skirmishes in the mean time happened in the islands lying off Boston harbour, in which the Americans had the advantage, and burnt an armed schooner, which her people had been obliged to abandon after she was left aground by the tide. Nothing decisive, however, took place, till the 17th of June.

In the neighbourhood of Charlestown, a place on the northern shore of the peninsula on which Boston stands, is an high ground called Bunker's Hill, which overlooks and commands the whole town of Boston. In the night of the 6th the provincials took possession of this place: and worked with such indefatigable diligence, that, to the astonishment of their enemies, they had before day-light, almost completed a redoubt, with a strong entrenchment reaching half a mile eastward, as far as the river Mystic. After this they were obliged to detain a heavy and incessant fire from the ships and floating batteries with which Charlestown neck was surrounded, as well as the cannon that could reach the place from Boston; in spite of which, however, they continued their work, and finished it before mid-day. A considerable body of foot was then landed at the foot of Bunker's Hill, under the command of Generals Howe and Pigot; the former being appointed to attack the lines, and the latter the redoubt. The Americans, however, having the advantages of ground, as well as of their intrenchments, continued down such incessant fire, that it threatened the whole body with destruction; and General Howe was for a little time left almost alone, all his officers being killed or wounded. The provincials in the mean time had taken possession of Charlestown, so that General Pigot was obliged to contend with them in that place as well as in the redoubt. The consequence was, that he was overmatched; his troops were thrown into disorder; and he would have been defeated, had not General Clinton advanced to his relief: upon which the attack was renewed with such fury, that the provincials were driven beyond the neck that leads to Charlestown. In the heat of the engagement the British troops, in order to deprive the Americans of a cover, set fire to Charlestown, which was totally consumed; and, eventually, the Americans were obliged to retreat over Charlestown neck, and was raked by an incessant fire from the Glasgow man of war, and several floating batteries. The losses on the British side amounted to about 1000, among whom were 19 officers killed and 70 wounded; that of the Americans did not exceed 139 killed, and 314 wounded.

The British troops claimed the victory of this engagement; but it must be allowed that it was dearly bought; and the Americans boasted that the real advantages were on their side, as they had so much weakened the enemy that they durst not afterwards venture out of their entrenchments. Although this was the first time the provincials had been in actual service, they behaved themselves with the spirit of veterans, and by no means merited the appellation of cowards, with which they were so often branded in Britain. In other places the fame determined spirit of resistance appeared on the part of the Americans. Lord North's conciliatory scheme was utterly rejected by the assemblies of Pennsylvania and New-Jersey, and afterwards in every other colony. The commencement of hostilities at Lexington determined the colony of New-York, which had hitherto continued to waver, to unite with the rest; and as the situation of New-York renders it unable to resist an attack from the sea, it was resolved, before the arrival of a British fleet, to secure the military stores, put off the women and children, and set fire to the city if it was still found incapable of defence. The exportation of provisions was everywhere prohibited, particularly to the British seafery on the Banks of Newfoundland, or to such colonies of America as should adhere to the British interest. Congress resolved on the establishment of an army, and of a large paper currency in order to support it. In the inland northern colonies, Colonel Easton and Ethan Allen, without receiving any orders from Congress, or communicating their designs to any party in the colony, formed the army of Crown-Point, Ticonderago, and the rest that form a communication between the colonies and Canada. On this occasion 200 pieces of cannon fell into their hands, besides mortars, and a large quantity of military stores, together with two armed vessels, and materials for the construction of others.

After
After the battle of Bunker's Hill, the provincials erected fortifications on the heights which commanded Charlestown, and strengthened the def in such a manner that there was no hope of driving them from thence; at the same time that their activity and boldness astonished the British officers, who had been accustomed to entertain a mean and unjust opinion of their courage.

The troops, thus shut up in Boston, were soon reduced to distress. Their necessities obliged them to attempt the carrying off the American cattle on the islands before Boston, which produced frequent skirmishes; but the provincials, better acquainted with the navigation of those shores, landed on the islands, destroyed or carried off whatever was of any use, burned the light-house at the entrance of the harbour, and took prisonors the workmen sent to repair it, as well as a party of marines who guarded them. Thus the garrison were reduced to the necessity of lending out armed vessels to make prizes indiscriminately of all that came in their way, and of landing in different places to plunder for subsistence as well as they could.

The congress in the mean time continued to act with all the vigour which its constituents had expected. Articles of confederacy and perpetual union were drawn up and solemnly agreed upon; by which they bound themselves and their posterity for ever. These were in substance as follows. 

1. Each colony was to be independent within itself, and to retain an absolute sovereignty in all domestic affairs.

2. Delegates to be annually elected to meet in congress, at such time and place as should be enacted in the preceding congresses.

3. This assembly should have the power of determining war or peace, making alliances; and in short all that power which sovereigns of states usually claim as their own.

4. The expenses of war to be paid out of the common treasury, and raised by a poll-tax on miles between 16 and 60; the proportions to be determined by the laws of the colony.

5. An executive council to be appointed to act in place of the congress during its recess.

6. No colony to make war with the Indians without consent of congress.

7. The boundaries of all the Indian lands to be secured and ascertained to them; and no purchasers of lands were to be made by individuals, or even by a colony, without consent of congress.

8. Agents appointed by congress should reside among the Indians, to prevent frauds in trading with them, and to relieve, at the public expense, their wants and difficulties.

9. This confederation to last until there should be a reconciliation with Britain; or, if that event should not take place, it was to be perpetual.

After the action of Bunker's Hill, however, when the power of Great Britain appeared less formidable in the eyes of America than before, congress proceeded formally to justify their proceedings in a declaration drawn up in terms more expressive, and well calculated to excite attention.

"Were it possible (said they) for men who exercised their reason, to believe that the divine Author of our existence intended a part of the human race to hold an absolute property in and unbounded power over others, marked out by his infinite goodness and wisdom as the objects of a legal domination, never rightfully retaliated, however severe and oppressive: the inhabitants of these colonies might at least require from the parliament of Great Britain some evidence that this dreadful authority over them had been granted to that body: but a reverence for our Great Creator, principles of humanity, and the dictates of common sense, must convince all those who reflect upon the subject, that government was instituted to promote the welfare of mankind, and ought to be administered for the attainment of that end.

"The legislature of Great-Britain, however, stimulated by an inordinate passion for power, not only unjustifiable, but which they know to be peculiarly reproved by the very constitution of that kingdom; and despairing of success in any mode of contest where regard should be had to law, truth, or right; have, at length, deferting thence, attempted to effect their cruel and impolitic purpose of enslaving these colonies by violence, and have thereby rendered it necessary for us to close with their last appeal from reason to arms. Yet, however blinded that assembly may be, by their inimical rage for unlimited domination, to flight justice in the opinion of mankind, we esteem ourselves bound by obligations to the rest of the world to make known the justice of our cause."

After taking notice of the manner in which their ancestors left Britain, the happiness attending the mutual friendly commerce between that country and her colonies, and the remarkable success of the late war, they proceed as follows: "The new ministry, finding the brave foes of Britain, though frequently defeated, yet still contending, took up the unfortunate idea of granting them a haftv peace, and of then subduing her faithful friends.

"These devoted colonies were judged to be in such a state as to prevent victories without bloodshed, and all the easy emoluments of stable plunder. The uninterrupted terror of their peaceable and respectful behaviour from the beginning of their colonization; their dutiful, zealous, and useful services during the war, though so frequently and amply acknowledged in the most honourable manner by his majesty's late king, and by parliament, could not save them from the intended innovations. Parliament was influenced to adopt the pernicious project; and assuming a new power over them, has in the course of eleven years given such decisive specimens of the spirit and consequences attending this power, as to leave no doubt of the effects of acquiescence under it.

"They have undertaken to give and grant our money without our consent, though we have ever exercised an exclusive right to dispose of our own property. Statutes have been passed for extending the jurisdiction of the courts of admiralty and vice-admiralty beyond their ancient limits; for depriving us of the acquiescent and incontestable rights of trial by jury, in cases affecting both life and property; for suspending the legislature of one of our colonies; for interdicting all commerce to the capital of another; and for altering fundamentally the form of government established by charter, and secured by acts of its own legislature; and
and solemnly confirmed by the crown; for exempting the murderers of colonists from legal trial, and in effect from punishment; for erecting in a neighbouring province, acquired by the joint arms of Great-Britain and America, a despotism dangerous to our very existence; and for quartering soldiers upon the colonists in time of a profound peace. It has also been resolved in parliament, that colonists, charged with committing certain offences, shall be transported to England to be tried.

"But why should we enumerate our injuries in detail?—By one statute it was declared, that parliament can of right make laws to bind us in all cases whatever. What is to defend us against so enormous, so unlimited a power? Not a single person who assumes it is chosen by us, or is subject to our control or influence; but, on the contrary, they are all of them exempt from the operation of such laws; and an American revenue, if not diverted from the ostensible purposes for which it is raised, would actually lighten their own burdens in proportion as it increases ours.

"We saw the misery to which such despotism would reduce us. We for ten years incessantly and ineffectually besieged the throne as suppliants; we reazoned, we remonstrated with parliament in the most mild and decent language; but administration, felonible that we should regard these measures as freemen ought to do, sent over fleets and armies to enforce them.

"We have pursued every temperate, every respectful measure; we have even proceeded to break off all commercial intercourse with our fellow-subjects, as our last peaceable admonition, that our attachment to no nation on earth would supplant our attachment to liberty: this we startled ourselves was the ultimate step of the controversy; but subsequent events have shown how vain was this hope of finding moderation in our enemies!

"The Lords and Commons, in their address in the month of February, said, that a rebellion at that time actually existed in the province of Massachusetts-Bay; and that those concerned in it had been countenanced and encouraged by unlawful combinations and engagements entered into by his majesty’s subjects in several of the colonies; and therefore they besought his majesty that he would take the most effectual measures to enforce due obedience to the laws and authority of the supreme legislature. Soon after the commercial intercourse of whole colonies with foreign countries was cut off by an act of parliament; by another, several of them were entirely prohibited from the fisheries in the seas near their coasts, on which they always depended for their subsistence; and large reinforcements of ships and troops were immediately sent over to General Gage.

"Fruitless were all the intrigues, arguments, and eloquence of an illustrious band of the most distinguished peers and commoners, who nobly and firenently ascertained the justice of our cause, to play, or even to mitigate, the headless fury with which these accumulated outrages were hurried on. Equally fruitless was the interference of the city of London, of Bristol, and of many other respectable towns in our favour." After having reproached parliament, General Gage, and the British government in general, they proceeded thus: "We are reduced to the alternative of choosing an unconditional submission to tyranny, or resistance by force. The latter is our choice. We have counted the cost of this contest, and find nothing so dreadful as voluntary slavery? Honour, justice, and humanity, forbid us tamely to surrender that freedom which we received from our gallant ancestors, and which our innocent posterity have a right to receive from us. Our cause is just; our union is perfect, our internal resources are great; and, if necessary, foreign assistance is undoubtedly attainable. We fight not for glory or conquest; we exhibit to mankind the remarkable spectacle of a people attacked by unprovoked enemies. They boast of their privileges and civilization, and yet proffer no milder conditions than servitude or death. In our native land, in defence of the freedom that is our birthright, for the protection of our property acquired by the honest industry of our forefathers and our own, against violence actually offered, we have taken up arms; we shall lay them down when hostilities shall cease on the part of our aggressors, and all danger of their being renewed shall be removed— and not before."

These are some of the most striking passages in the declaration of congress on taking up arms against Great-Britain, and dated July 6th, 1775. The determined spirit which it shows, ought to have convinced the people of Britain, that the conquest of America was an event scarce ever to be expected. In every other respect an equal spirit was shown; and the rulers of the British nation had the mortification to see those to whom they flewed edelei and trivules, succeed in negotiations in which they themselves were utterly foiled. In the passing of the Quebec bill, ministry had flattered themselves that the Canadians would be so much attached to them on account of restoring the French laws, that they would very readily join in any attempt against the colonists who had reproached that bill in such strong terms: but in this, as in every thing else indeed, they found themselves mistaken. The Canadians having been subject to Britain for a period of 15 years, and being thus rendered sensible of the advantage of British government, received the bill itself with evident disapprobation; nay, reproved it as tyrannical and oppressive. A scheme had been formed for General Carleton, governor of the province, to raise an army of Canadians wherewith to act against the Americans; and so sanguine were the hopes of administration in this respect, that they had sent 20,000 stand of arms, and a great quantity of military stores, to Quebec for the purpose. But the people, though they did not join the Americans, yet were found immovable in their purpose to stand neutral. Application was made to the bishop; but he declined to interpose his influence, as contrary to the rules of the Popish clergy: so that the utmost efforts of government in this province were found to answer little or no purpose.

The British administration next tried to engage the ministry in their cause. But though agents were dis­ pered among them with large presents to the chief, they universally replied, that they did not understand the nature of the quarrel, nor could they distinguish whether those who dwelt in America or on the other side of the ocean were in fault: but they were for­ prised
Albany, where we may hear each other speak, and not to think of shedding the blood of our brethren.

To the representatives of congress they paid more respect. They felt that, as the English on the other side of the ocean, had taken up arms to enslave, not only their countrymen in America, but the Indians also; and if the latter should enable them to overcome the colonists, they themselves would soon be reduced to a state of servitude also. By arguments of this kind these savages were engaged to remain neutral; and thus the colonists were freed from a most dangerous enemy. On this occasion the congress thought proper to hold a solemn conference with the different tribes of Indians. The speech made by them on the occasion is curious, but too long to be fully inserted. The following is a specimen of the European mode of addressing these people.

"Brothers, Sachems, and Warriors!

"We the delegates from the Twelve United Provinces, now sitting in general congress at Philadelphia, send their talk to our brothers.

"Brothers and Friends, now attend!

"When our fathers crossed the great water, and came over to this land, the king of England gave them a strong chain, and enjoy peace; and it was covenanted, that the fields, houses, goods, and possessions, which our fathers should acquire, should remain to them as their own, and be their children for ever, and at their sole disposal.

"Brothers and Friends, open an ear!

"We will now tell you of the quarrel betwixt the counsellors of King George and the inhabitants and colonies of America.

"Many of his counsellors have persuaded him to break the covenant-chain, and not to fend us any more good talks. They have prevailed upon him to enter into a covenant against us, and have torn asunder, and cast behind their backs, the good old covenant which their apecceors and ours entered into, and took strong hold of. They now tell us they will put their hands into our pockets without asking, as though it were their own, and at their pleasure they will take from us our charters, or written civil constitution, which we love as our lives; also our plantations, our houses, and our goods, whenever they please, without asking our leave. They tell us that our vessels may go to that or this island in the sea, but to this or that particular island we shall not trade any more; and in case of our non-compliance with these new orders, they shut up our harbours.

"Brothers, we live on the same ground with you; the same island is our common birth-place. We desire to sit down under the same tree of peace with you; let us water its roots, and cherish the growth, till the large leaves and flourishing branches shall extend to the setting sun, and reach the skies. If any thing disagreeable should ever fall out between us, the Twelve United Colonies, and you, the Six Nations, to wound our peace, let us immediately seek measures for healing the breach. From the present situation of our affairs, we judge it expedient to kindle up a small fire at Albany, where we may hear each other’s voice, and discompose our minds fully to one another."

The other remarkable transactions of this congress were the ultimate refusals of the conciliatory proposals made by Lord North, of which such fantastic expectations had been formed by the English ministry; and appointing a general-in-chief to command their armies, which were now very numerous. The person chosen for this purpose was George Washington; a man so universally beloved, that he was raised to such a high station by the unanimous voice of congress; and his subsequent conduct showed him every way worthy of it. Horatio Gates and Charles Lee, two English officers of considerable reputation, were chosen; the former an adjutant-general, the second a major-general. Artemus Ward, Philip Schuyler, and Israel Putnam, were likewise nominated major-generals. Seth Pomeroy, Richard Montgomery, David Wooster, William Heath, Joseph Spencer, John Thomas, John Sullivan, and Nathanael Green, were chosen brigadier generals at the same time.

Congress had now also the satisfaction to receive deputies from the colony of Georgia, extending a desire to join the confederacy. The reasons they gave for renouncing their allegiance to Britain was, that the conduct of parliament towards the other colonies had been oppressive; that though the obnoxious acts had not been extended to them, they could view this only as an omission, because of the seeming little conformance of their colony; and therefore looked upon it rather to be a slight than a favour. At the same time they framed a petition to the king, similar to that sent by the other colonies, and which met with a similar reception.

The succours which had hitherto attended the Americans in all their measures, now emboldened them to think not only of defending themselves, but likewise of acting offensively against Great-Britain. The conquest of Canada appeared an object within their reach, and one that would be attended with many advantages; and as an invasion of that province was already facilitated by the taking of Crown-Point and Ticonderoga, it was resolved if possible to penetrate that way into Canada, and reduce Quebec during the winter, before the fleets and armies which they were well assured would fail thither from Britain should arrive. By order of congress, therefore, 3000 men were put under the command of Generals Montgomery and Schuyler, with orders to proceed to Lake Champlain, from whence they were to be conveyed in flat-bottomed boats to the mouth of the river Sorel, a branch of the great river St. Lawrence, and on which is situated a fort of the same name with the river. On the other hand, they were opposed by General Carleton, governor of Canada, a man of great activity and experience in war; who, with a very few troops, had hitherto been able to keep in awe the disaffected people of Canada, notwithstanding all the representations of the colonists. He had now augmented his army by a considerable number of Indians, and promised, even in his present situation, to make a very formidable resistance.

As soon as General Montgomery arrived at Crown-Point, he received information that several armed vessels were stationed at St. John’s, a strong fort on the river Sorel,
Sorel, with a view to prevent his crossing the lake; on which he took possession of an island which commands the mouth of the Sorel, and by which he could prevent them from entering the lake. In conjunction with General Schuyler, he next proceeded to St John's; but finding that place too strong, it was agreed in a council of war, to retire to Isle aux Noix, where General Schuyler being taken ill, Montgomery was left to command alone. His first step was to gain over the Indians whom Gen. Carleton had employed, and this he in a great measure accomplished; after which, on receiving the full number of troops appointed for his expedition, he determined to lay siege to St John's. In this he was facilitated by the reduction of Chamblee, a small fort in the neighbourhood, where he found a large supply of powder. An attempt was made by General Carleton to relieve the place; for which purpose he with great pains collected about 1000 Canadians, while Colonel Maclean proposed to raise a regiment of the Highlanders who had emigrated from their own country to America.

But while Gen. Carleton was on his march with these new levies, he was attacked by the provincials, and utterly defeated; which being made known to another body of Canadians who had joined Colonel Maclean, they abandoned him without striking a blow, and he was obliged to retreat to Quebec.

The defeat of General Carleton was a sufficient recompence to the Americans for that of Colonel Ethan Allen, which had happened some time before. The success which had attended this gentleman against Crown-Point and Titondego had emboldened him to make a similar attack on Montreal; but being attacked by the militia of the place, supported by a detachment of regulars, he was entirely defeated and taken prisoner.

As the defeat of General Carleton and the defection of Maclean's forces left no room for the garrison of St John's to hope for any relief, they now contented to surrender themselves prisoners of war; but were in another respect treated with great humanity. They were in number 500 regulars and 200 Canadians, among whom were many of the French nobility, who had been very active in promoting the cause of Britain among their countrymen.

General Montgomery next took measures to prevent the British shipping from falling down the river from Montreal to Quebec. He accomplished this effectually, that the whole were taken. The town itself was obliged to surrender at discretion; and it was with the utmost difficulty that General Carleton escaped in an open boat by the favour of a dark night.

No further obstacle now remained in the way of the Americans to the capital, except what arose from the nature of the country; and these indeed were very considerable. Nothing, however, could damp the ardour of the provincials. Norwithstanding it was now the middle of November, and the depth of winter was at hand, Colonel Arnold formed a design of penetrating through woods, morasses, and the most frightful solitudes from New-England to Canada by a nearer way than that which Montgomery had chosen; and this he accomplished in spite of every difficulty, to the admonishment of all who saw or heard of the attempt. A third part of his men under another colonel had been obliged to leave him by the way, for want of provisions; the total want of artillery rendered his prospects insignificant before a place strongly fortified; and the smallness of his army rendered it even doubtful whether he could have taken the town by surprise. The Canadians indeed were amazed at the exploit, and their inclination to revolt from Britain was somewhat augmented; but none of them as yet took up arms in behalf of America. The confederation into which the town of Quebec was thrown proved detrimental rather than otherwise to the expedition; as it doubled the vigilance and activity of the inhabitants to prevent any surprise; and the appearance of common danger united all parties, who, before the arrival of Arnold, were contending most violently with one another. He was therefore obliged to content himself with blocking up the avenues to the town, in order to distress the garrison for want of provisions; and even this he was unable to do effectually, by reason of the small number of his men.

The matter was not much mended by the arrival of General Montgomery. The force he had with him, even when united to that of Arnold, was too insignificant to attempt the reduction of a place so strongly fortified, especially with the assistance only of a few mortars and field-pieces. After the siege had continued through the month of December, General Montgomery, conscious that he could accomplish his end no other way than by surprise, resolved to make an attempt on the left day of the year 1775. The method he took at this time was perhaps the best that human wisdom could devise. He advanced by break of day, in the midst of an heavy fall of snow, which covered his men from the sight of the enemy. Two real attacks were made by himself and Colonel Arnold, at the same time that two feigned attacks were made on two other places, thus to distract the garrison, and make them divide their forces. One of the real attacks was made by the people of New-York, and the other by those of New-England under Arnold. Their hopes of surprising the place, however, were defeated by the signal for the attack being through some mistake given too soon. General Montgomery himself had the most dangerous place, being obliged to pass between the river and some high rocks on which the Upper Town stands; so that he was forced to make what haste he could to close with the enemy. His fate, however, was now decided. Having forced the first barrier, a general violent discharge of musketry and grape-shot from the Montgomery killed, and the Americans defeated.

In this action, it must be confessed that the valor of the provincial troops could not be exceeded. They had
In this state of confusion the governor thought it necessary to fortify his palace with artillery, and procure a party of marines to guard it. Lord North’s conciliatory proposal arriving also about the same time, he used his utmost endeavours to cause the people comply with it. The arguments he used were plausible, and had not matters already gone to such a pitch of dissatification, it is highly probable that some attention would have been paid to them. “The view [he said] in which the colonies ought to behold this conciliatory proposal, was no more than an earnest admonition from Great-Britain to relieve their wants: that the utmost confedence had been used in the mode of application; no determinate sum having been fixed, as it was thought most worthy of British generosity to take what they thought could be conveniently spared, and likewise to leave the mode of raising it to themselves,” &c.

But the clamour and dissatisfaction were now universal, that nothing else could be attended to. The governor had called an assembly for the purpose of laying this conciliatory proposal before them; but it had been little attended to. The assembly began their febion by inquiries into the state of the magazine. It had been broken into by some of the townsmen; for which reason spring-guns had been placed there by the governor, which discharged themselves upon the offenders at their entrance: these circumstances with others of a similar kind, raised such a violent uproar, that, as soon as the preliminary balances of the febion was over, the governor retired on board a man of war, informing the assembly that he durst no longer trust himself on shore, nor retire on board a man of war.

This produced a long course of disputations, which ended in a positive refusal of the government to trust himself again in Williamsburg, even to give his assent to the bills, which could not be paffed without it, and though the assembly offered to bind themselves for his personal safety. In his turn he requested them to meet him on board the man of war, where he then was; but his proposal was rejected, and all further correspondence containing the least appearance of friendship was discontinued.

Lord Dunmore, having thus abandoned his government attempts, attempted to reduce by force those whom he could no longer govern. Some of the most fierce and adherents to the British cause, whom their zeal had rendered obnoxious at home, now turned to them. He was also joined by numbers of black slaves. With these, and the affiatice of the British shipping, he was for some time enabled to carry on a kind of predatory war sufficient to hurt and exasperate, but not to subdue. After some inconsiderable attempts on land, proclaiming liberty to the slaves, and setting up the royal standard, he took up his residence at Norfolk, a maritime town of some consequence, where the people were better affected to Britain than in most other places. A considerable force, however, was collected against him; and the natural impetuosity of his temper prompt- ing him to act against them with more courage than caution, he was entirely defeated, and obliged to retire to his shipping, which was now crowded by the number of those who had incurred the resentment of the provincials.

In the mean time a scheme of the utmost magnitude and importance was formed by one Mr Conolly, a Pennsylvanian, attached to the cause of Britain. The first object he aimed at was to raise Virginia,
He discovered and taken prisoner.

The town of Norfolk destroyed.

The governors of South and North Carolina expelled.

Miserable situation of Boston.

Boston severely cannonaded by the provincials.

The step of this plan was to enter into a league with the Ohio Indians. This he communicated to Lord Dunmore, and it received his approbation: Upon which Conolly set out, and actually succeeded in his design. On the 6th of October he was dispatched to General Dunmore, from whom he received a colonel's commission, and set out in order to accomplish the remainder of his scheme. The plan in general was, that he should return to the Ohio, where, by the affliction of the British and Indians in those parts, he was to penetrate through the back settlements into Virginia, and join Lord Dunmore at Alexandria. But by an accident very naturally to be expected, he was discovered, taken prisoner, and confined.

After the retreat of Lord Dunmore from Norfolk, that place was taken possession of by the provincials, who greatly diffused those on board Lord Dunmore's fleet, by refusing to supply them with any necessaries. This proceeding drew a remonstrance from his Lordship; in which he insisted that the fleet should be furnished with necessaries; but his request being denied, a resolution was taken to set fire to the town. After giving the inhabitants proper warning, a party landed, under cover of a man of war, and set fire to that part which lay nearest the shore; but the flames were observed at the same time to break forth in every other quarter, and the whole town was reduced to ashes. This universal destruction, occasioned a loss of more than L. 300,000.

In the southern colonies of Carolina, the governors were expelled, and obliged to take refuge on board of men of war, as Lord Dunmore had been; Mr Martin, governor of North Carolina, on a charge of attempting to raise the back-fellers, confining chiefly of Scots Highlanders, against the colony. Having secured themselves against any attempts from these enemies, however, they proceeded to regulate their internal concerns in the same manner as the rest of the colonies; and by the end of the year 1775, Britain beheld the whole of America united against her in the most determined opposition. Her vast possessions of that tract of land (since known by the name of the Thirteen United States) were now reduced to the single town of Boston; in which her forces were besieged by an army with whom they were apparently not able to cope, and by whom they must of course expire in a very short time to be expelled. The situation of the inhabitants of Boston, indeed, was peculiarly unhappy.

After having failed in their attempts to leave the town, General Gage had contented to allow them to retire with their effects; but afterwards, treacherously refused to fulfi his promise. When he resigned his place to General Howe in October 1775, the latter, apprehensive that they might give intelligence of the situation of the British troops, strictly prohibited any person from leaving the place under pain of military execution. Thus matters continued till the month of March 1776, when the town was evacuated.

On the 2d of that month, General Washington opened a battery on the west side of the town, from whence it was bombarded, with a heavy fire of cannon at the same time; and three days after, it was attacked by another battery from the eastern shore. This terrible attack continued for 14 days without intermission; when General Howe, finding the place no longer tenable, determined if possible to drive the enemy from their works. Preparations were therefore made for a most vigorous attack, on a hill called Dorchester Neck, which the Americans had fortified in such a manner as would in all probability have rendered the enterprise next to impossible. No difficulties, however, were sufficient to daunt the spirit of the general: and every thing was in readiness, when a sudden storm pre-vented an execution which must have been productive of a dreadful waste of blood. Next day, upon a more close inspection of the works they were to attack, it was thought advisable to desist from the enterprise altogether. The fortifications were very strong, and extremely well provided with artillery; and, besides other implements of destruction, upwards of 1000 hog’s heads of fowls were provided to roll down upon the enemy as they came up; which, as the ascent was extremely steep, must have done prodigious execution.

Nothing therefore now remained but to think of a place of retreat; and even this was attended with the utmost difficulty and danger. The Americans, however, knowing that it was in the power of the British general to reduce the town to ashes, which could not have been repaired in many years, did not think proper to give the least molestation; and for the space of a fortnight the troops were employed in the evacuation of the place, from whence they carried along with them 2000 of the inhabitants, who durst not stay on account of their attachment to the British cause. From Boston they failed to Halifax; but all their vigilance could not prevent a number of valuable ships from falling into the hands of the Americans. A considerable quantity of cannon and ammunition had also been left at Bunker’s Hill and Boston Neck; and in the town, an immense variety of goods, principally woolen and linen of which the provincials need very much in need. The effects of those who fled to Halifax were confiscated; as also those who were attached to government, and had remained in the town. As an attack was expected as soon as the British forces should arrive, every method was employed to render the fortifications already very strong, impregnable. For this purpose some foreign engineers were employed, who had before arrived at Boston; and every, eager were people of all ranks to accomplish this business, that every able-bodied man in the place, without distinction of rank, set apart two days in the week, to complete it the sooner.

The Americans exasperated to the utmost by the Congress proceedings of parliament, which placed them out of the royal protection, and engaged foreign mercenaries in the plan for subduing them, now formally renounced all connection with Britain, and declared themselves independent. This celebrated declaration was published on the 4th of July 1776. Previous to this circular letter had been sent through each colony, flattering the reasons for it; and such was the animosity now pervading everywhere prevailing against Great Britain, that it met with universal approbation, except in the province of Maryland alone. It was not long, however, before the people of that colony, finding themselves left in a very dangerous minority, thought proper to accede to the measures of the rest. The manifesto itself was in the usual nervous style, flattering a long list of grievances, for which redress had been often applied
America. in vain; and for these reasons they determined on a final separation; to hold the people of Britain as the rest of mankind, "enemies in war, in peace friends."

After thus publicly throwing off all allegiance and hope of reconciliation, the colonists soon found that an exertion of all their strength was required in order to support their pretensions. Their arms, indeed, had not, during this season, being attended with successes in Canada. Reinforcements had been promised to Colonel Arnold, who still continued the blockade of Quebec; but they did not arrive in time to second his operations. Being sensible, however, that he must either desert from the enterprise, or finish it successfully, he recommenced in form; attempting to burn the shipping, and even to form the town itself. They were unsuccessful, however, by reason of the smallness of their number, though they succeeded so far as to burn a number of houses in the suburbs; and the garrison were obliged to pull down the remainder, in order to prevent the fire from spreading.

As the provincials, though unable to reduce the town, kept the garrison in continual alarms, and in a very disadvantageous situation, some of the nobility collected themselves into a body under the command of one Mr. Brouene, in order to relieve their capital; but they were met on their march by the provincials, and so entirely defeated, that they were never afterwards able to attempt anything. Their want of artillery at last convinced them, that it was impracticable in their situation to reduce a place so strongly fortified; the small-pox, at the same time made its appearance in their camp, and carried off great numbers; intimidating the reft to such a degree, that they deferted in crowds. To add to their misfortunes, the British reinforcements unexpectedly appeared, and the ships made their way through the ice with such celerity, that the one part of their army was separated from the other; and General Carleton falling out as soon as the reinforcement was landed, obliged them to fly with the utmost precipitation, leaving behind them all their cannon and military stores; at the same time that their shipping was entirely captured by vessels sent up the river for that purpose. On this occasion the provincials fled with such precipitation that they could not be overtaken; so that none fell into the hands of the British, excepting the sick and wounded. General Carleton now gave a signal instance of his humanity: Being well apprized that many of the provincials had not been able to accompany the reft in their retreat, and that they were concealed in woods, &c. in a very deplorable situation, he generously issued a proclamation, ordering proper persons to seek them out, and give them relief at the public expense; at the same time lost, through fear of being made prisoners, they should refuse these offers of humanity, he promised that, as soon as their situation enabled them, they should be at liberty to depart to their respective homes.

The British general, now freed from any danger of an attack, was soon enabled to act offensively against the provincials, by the arrival of the forces destined for that purpose from Britain. By these he was put at the head of 12,000 regular troops, among whom were those of Brunswick. With this force he instantly set out to the Three Rivers, where he expected that Ar-

nold would have made a stand; but he had retired to Sorel, a place 80 miles distant from Quebec, where he was at last met by the reinforcement ordered by congress. Here, though the preceding events were by no means calculated to inspire much military ardour, a very daring enterprise was undertaken; and this was, to surprife the British troops posted here under Generals Fraer and Neibit; of whom the former commanded those on land, the latter, such as were on board of transports and were but a little way distant. The enterprize was undoubtedly very hazardous, both on account of the strength of the parties against whom they were to act, and as the main body of the British forces were advanced within 50 miles of the place; besides that a number of armed vessels and transports with troops lay between them and the Three Rivers. Two thousand chozen men, however, under General Thomasfon, engaged in this enterprise. Their success was by no means answerable to their spirit and valour. Though they palled the shipping without being observed, General Fraer had notice of their landing; and thus being prepared to receive them, they were soon thrown into disorder, at the same time that General Neibit, having landed his forces, prepared to attack them in the rear. On this occasion some field-pieces were brought in, for a digestious execution, and a retreat was found to be unavoidable, General Neibit, however, had got between them and their boats, so that they were obliged to take a circuit through a deep swamp, while they were hotly pursued by both parties at the same time, who marched for some miles on each side the swamp, till at last the unfortunate provincials were sheltered from farther danger by a wood at the end of the swamp. Their general, however, was taken with 200 of his men.

By this disaster the provincials lost all hopes of accomplishing anything more in Canada. They demolished their works, and carried off their artillery with the utmost expedition. They were pursued, however, by General Burgoyne; who on the 16th of June arrived at Fort St John's, which he found abandoned and burnt. Chambly had shared the fame fate, as well as all the vessels that were not capable of being dragged up against the current of the river; and the provincial troops had retreated across the lake to Crown-Point, whether they could not be immediately followed. Thus was the province of Canada entirely evacuated by the Americans, who had thus secured the frontiers of the adjacent states from invasion on the part of the British; the object of a campaign in which 13000 men were employed, and near a million of money expended, was rendered in a great measure abortive. General Sullivan, who conducted this retreat after the affair of General Thompson, had great merit in what he did, and received the thanks of congress accordingly.

This was followed by some transactions in the southern colonies, which farther evinced their resolution, and raised the spirits of the Americans—we have formerly taken notice that Mr Martin, governor of North-Carolinas, had been obliged to leave his province and take refuge on board a man of war. Notwithstanding this he did not despair of reducing it again to obedience. For this purpose he applied to the regulators, a daring set of banditti, who lived in a kind
An insurrection in North-Carolina in favour of Britain; 277
kind of independent state; and though considered by
government as rebels, yet had never been molested,
on account of their numbers and known skill in
the use of fire-arms. To the chiefs of these people
commissions were sent, in order to raise some regiments;
and a Colonel Macdonald was appointed to command
them. In the month of February he erected the king's
standard, flung proclamations, &c. and collected some
forces, expecting to be soon joined by a body of regu-
lar troops, who were known to be shipped from Britain
to act against the southern colonies. The Americans,
sensible of their danger, dispatched immediately what
forces they had to act against the royalists, at the same
time that they diligently exerted themselves to support
these with suitable reinforcements. Their present force
was commanded by General Moore, whose numbers
were inferior to Macdonald; for which reason the lat-
ter summoned him to join the king's standard under
pain of being treated as a rebel. But Moore, being
well provided with cannon, and conscious that nothing
could be attempted against him, returned the compli-
tations, by appointing Colonel Macdonald, that if he
and his party would lay down their arms, and subscribe
an oath of fidelity to congress, they should be treated
as friends; but if they persisted in an undertaking for
which it was evident they had not sufficient strength,
they could not but expect the severest treatment. In
a few days General Moore found himself at the head
of 8000 men, by reason of the continual supplies which
daily arrived from all parts. The royal party amount-
ed only to 2000, and they were destitute of artillery,
which prevented them from attacking the enemy while
they had the advantage of numbers. They were now
therefore obliged to have recourse to a desperate exer-
cition of personal valour; by dint of which they effected
a retreat for near 80 miles to Moore's Creek, within 16
miles of Wilmington. Could they have gained this
place, they expected to have been joined by governor
Martin and General Clinton, who had lately arrived
with a considerable detachment. But general Moore
with his army pursuied them so close, that they were
obliged to attempt the passage of the creek itself, tho'
not a considerable body of the Americans, under the com-
mand of Colonel Caswell, with fortifications well plan-
ted with cannon, was posted on the other. On attempt-
ing the creek, however, it was found not to be forda-
able. They were obliged therefore to cross over a wood-
en bridge, which the provincials had not time
to destroy entirely. They had, however, by pulling
up part of the planks, and greasing the remainder in or-
der to render them slippery, made the passage so dif-
ficult, that the royalists could not attempt it. In this situa-
tion they were, on the 27th of February, attacked by
general Moore with his superior army, and totally de-
feated with the loss of their general and most of their
leaders, as well as the best and bravest of their men.
Thus was the power of the Americans established in
North-Carolina. Nor were they left successful in the
province of Virginia; where Lord Dunmore having
long continued an useless predatory war, was at last driv-
en from every creek and road in the province. The
people he had on board were dirstressed to the highest
degree by confinement in small vessels. The heat of
the season, and the numbers crowded together, pro-
duced a pestilential fever, which made great havoc,
especially among the blacks. At last, finding them-
welves in the utmost hazard of perishing by famine as
well as disease, they set fire to the least valuable of
their vessels, referring only about 50 for themselves,
in which they bid a final adieu to Virginia, some sail-
ing to Florida, some to Bermuda, and the rest to the
West-Indies.
In South-Carolina the Americans had a more for-
midable enemy to deal with. At Cape Fear a junc-
tion was formed between Sir Henry Clinton, and
Sir Peter Parker, the latter of whom had failed with
his squadron directly from Europe. They concluded
to attempt the reduction of Charleston as being, of
all places within the line of their instructions, the
object at which they could strife with the greatest
prospect of advantage. They had 2,800 land forces,
which they hoped, with the co-operation of their ship-
ning, would be fully sufficient.
For some months past every exertion had been made
British arm-
to put the colony of South-Carolina, and especially its
permanent capital Charleston, in a respectable posture of defence.
In subervency to this view, works had been erected
on Sullivan's island, which is situated for near the chan-
nel leading up to the town, as to be a convenient post
for annoying vessels approaching it.
Sir Peter Parker attacked the fort on that island with
two fifty gun ships, the Biflot and Experiment, four
frigates, the Aricle, Acteon, Solebay and Syren, each
of 28 guns. The Sphinx of 20 guns, the Frienship
armed vessel of 22 guns, Ranger sloop, and Thunder
bomb, each of 8 guns. On the fort were mounted 26
cannon, 26, 18 and 9 pounders. The attack commenced
between ten and eleven in the forenoon, and was
continued upwards of ten hours. The garrison
consisting of 275 regulars and a few militia, under the
command of Colonel Moultrie, made a most gallant de-
ference. They fired deliberately, for the most part took
aim and seldom missed their object. The ships were torn
almost to pieces, and the killed and wounded on board
exceeded 200 men. The loss of the garrison was only
ten men killed and 22 wounded. The fort being built
of palmetto was little damaged. The shot which struck
it were ineffectually buried in its soft wood. General
Clinton had some time before the engagement, landed
with a number of troops on Long island, and it was ex-
pected that he would have co-operated with Sir Peter
Parker, by crossing over the narrow passage, which di-
vides the two islands, and attacking the fort in its un-
shipped rear; but the extreme danger to which he must
unavoidably have exposed his men, induced him to de-
cline the perilous attempt. Colonel Thomson with 7
or 800 men was stationed at the east-end of Sullivan's
island to oppose their crossing. No serious attempt
was made to land either from the fleet or the detachment
commanded by Sir Henry Clinton. The firing ceased
in the evening, and soon after the ships slipped their
anchor. Before morning they had retired about two
miles from the island. Within a few days more the
troupes re-embarked and sailed from New-York. The
thanks of congress were given to General Lee, who
had been sent on by congress to take the command in
Carolina, and also to Colonels Moultrie and Thomson,
for their good conduct on this memorable day. In
compliment to the commanding officer the fort from
that time was called Fort Moultrie.
This year also, the Americans, having to frequently
made trial of their valour by land, became desirous of
trying
The time, however, was now come when the fortitude and patience of the Americans were to undergo a severe trial. Hitherto they had been on the whole successful in their operations: but now they were doomed to experience misfortune, misery, and disappointment; the enemy over-running their country, and their own armies not able to face them in the field. The province of New-York, as being the most colony, and most accessible by sea, was selected upon for the object of his expedition. The force sent against it consisted of 6 ships of the line, 30 frigates, besides other armed vessels, and a vast number of transports. The fleet was commanded by Lord Howe, and the land forces by his brother General Howe, who was now at Halifax. The latter, however, a considerable time before his brother arrived, had set sail from Halifax, and lay before New-York, but without attempting to commence hostilities until he should be joined by his brother. The Americans had, according to custom, fortified New-York and the adjacent islands in an extraordinary manner. However, General Howe was suffered to land his troops on Staten Island, where he was soon joined by a number of the inhabitants. About the middle of July, Lord Howe arrived with the grand armament; and being one of the commissioners appointed to receive the submission of the colonists, he published a circular letter to this purpose to the several governors who had lately been expelled from their provinces, directing them to make the best of their escape, and that the powers they had exercised in the shape of civil government, were to be exercised by parliament, as public as possible. Here, however, congresses saved him trouble, by ordering his letter and declaration to be published in all the newspapers, "That every one might see the invidiousness of the British ministry, and that they had nothing to trifle with besides the exertion of their own valor."  

Lord Howe next sent a letter to General Washington; but as it was directed "To George Washington, Esq." the General refused to accept of it, as not being directed in the style fitful to his station. To obviate this objection, Adjutant-general Parker was sent with another letter, directed "To General Washington, &c. &c." But though a very polite reception was given to the bearer, General Washington utterly refused the letter; nor could any explanation of the adjutant induce him to accept of it. The only interesting part of the conversation was that relating to the powers of the commissioners, of whom Lord Howe was one. The adjutant told him, that these powers were very extensive; that the commissioners were determined to exert themselves to the utmost, in order to bring about a reconciliation; and that he hoped the General would consider this visit as a step towards it. General Washington replied, that it did not appear that these powers consisted in any thing else than granting pardons; and as America had committed no offence, she asked no forgiveness, and was only defending her unquestionable rights.

The decision of every thing being now by consent of both parties left to the sword, no one was left to commence hostilities. However, Lord Howe next sent a letter to General Washington, who had lately been expelled from their provinces, ordering his letter and declaration to be published in all the newspapers. The adjutant told him, that these powers had ordered the papers to be secured by large detachments, which was executed as if to make a show; but one of the utmost importance, that lay at a distance, was entirely neglected. This gave an opportunity to a large body of troops under Lord Percy and Clinton to pass the mountains and attack the Americans in the rear, while they were engaged with the Hessians in front. Through this piece of negligence their defeat became inevitable. Those who were engaged with the Hessians first perceived their mistake, and began a retreat towards their camp; but the passage was intercepted by the British troops, who drove them back into the woods. Here they were met by the Hessians; and thus they were for many hours slaughtered between the two parties, no way of escape remaining but by breaking through the British troops, and thus regaining their camp. In this attempt many perished; and the right wing, engaged with General Grant, shared the same fate. The victory was complete; and the Americans lost on this fatal day (August 27th) upwards of 1000 men, and two generals; several officers of distinction were made prisoners, with a number of private. Among the slain, a regiment consisting of young gentlemen of fortune in Maryland, was almost entirely cut in pieces, and of the survivors not one escaped without a wound.

The ardour of the British troops was now so great, that they could scarce be restrained from attacking the lines of the provincials; but for this there was no occasion, as it was certain the Indians could not be defended. The British and Hessians about 450 were lost in this engagement. As none of the American commanders thought it proper to risk another attack, it was resolved to abandon their camp as soon as possible. Accordingly, on camp in the night of the 20th of August, the whole of the continental troops were ferried over with the utmost secrecy and silence; so that in the morning the Briti had nothing to do but take possession of the camp and what artillery they had abandoned.

This victory, though complete, was very far from being so decisive as the conquerors imagined. Lord Howe, supposing that it would be sufficient to intimidate the congress into some terms, sent General Sullivan, with a view to have been taken prisoner, in the letter, to concur, &c.
America, congress, with a message, importing, that though he could not consistently treat with them as a legal assembly, yet he would be very glad to confer with any of the members in their private capacity; setting forth at the same time the nature and extent of his powers as commissioner. But the congress were not so humbled as to derogate in the least from the dignity of character they had assumed. They replied, that the congress of the free and independent states of America could not consistently fend any of its members in another capacity, than that which they had publicly assumed; but as they were extremely devout of restoring peace to their country upon equitable conditions, they would appoint a committee of their body to wait upon him, and learn what proposals he had to make. This produced a new conference. The committee appointed by congress was composed of Dr. Franklin, Mr. Adams, and Mr. Rutledge. They were very politely received by his Lordship; but the conference proved as fruitless as before independency had been declared; and the last answer of the deputies was, that they were extremely willing to enter into any treaty with Great Britain that might conduce to the good of both nations, but that they would not treat in any other character than that of independent states. This positive declaration instantly put an end to all hopes of reconciliation; and it was resolved to prosecute the war with the utmost vigour. Lord Howe, after publishing a manifesto, in which he declared the refusal of congress, and that he himself was willing to confer with all well disposed persons about the means of restoring public tranquillity, set about the most proper methods for reducing the city of New-York. Here the provincial troops were posted, and from a great number of batteries kept continually annoying the British shipping. The East River lay between them, of about 1200 yards in breadth, which the British troops were extremely diligent of passing. At last, the ships having, after an incessant cannonade of several days, silenced the most troublesome batteries, a body of troops was sent up the river to a bay, about three miles distant, where the fortifications were less strong than in other places. Here, having driven off the provincials by the cannon of the fleet, they marched directly towards the city; but the Americans finding that they should now be attacked on all sides, abandoned the city, and retired to the north of the island, where their principal force was collected. In their passage thither they skirmished with the British, but carefully avoided a general engagement; and it was observed that they did not behave with that ardour and impetuous violence which had hitherto marked their character. The British and provincial armies were not now above two miles distant from each other. The former lay encamped from shore to shore for an extent of two miles, being the breadth of the island, which, though 15 miles long, exceeds not two in any part in breadth. The provincials, who lay directly opposite, had strengthened their camp with many fortifications; at the same time being masters of all the passes and defiles between the two camps, they were enabled to defend themselves against an army much more numerous than their own, and they had also strongly fortified King's-Bridge, whence they could secure a passage to the continent in case of any misfortune. Here General Wash-
with this further advantage, that the American fleet under commodore Hopkins was obliged to fail as far as possible up the river Providence, and thus remained entirely useless.

The same ill success continued to attend the Americans in other parts. After their expulsion from Canada, they had crossed the Lake Champlain, and taken up their quarters at Crown-Point, as we have already mentioned. Here they remained for some time in safety, as the British had no vessels on the lake, and consequently general Burgoyne could not pursue them. To remedy this deficiency, there was no possible method, but either to construct vessels on the spot, or take to pieces some vessels already constructed, and drag them up the river into the lake. This, however, was effected in no longer a space than three months; and the British general, after incredible toil and difficulty, saw himself in possession of a greater number of vessels, by which means he was enabled to pursue his enemies, and invade them in his turn. The labour undergone at this time by the sea and land forces must indeed have been prodigious; since there were conveyed over land, and dragged up the rapids of St Lawrence, no fewer than thirty large long-boats, 400 bateaux, besides a vast number of flat-bottomed boats, and a gondola of 30 tons. The intent of the expedition was to push forward, before winter, to Albany, where the army would take up its winter-quarters, and next spring effect a junction with that under general Howe, when it was not doubted that the united force and skill of these two commanders would speedily put a period to the war.

By reason of the difficulties with which the equipment of this fleet had been attended, it was the beginning of October before the expedition could be undertaken. It was now, however, by every judge, allowed to be completely able to answer the purpose for which it was intended. It consisted of one large vessel with three masts, carrying 18 twelve-pounders; two schooners, the one carrying 14, the other 12 fix pounders; a large flat-bottomed radeau with fix twenty-four and twelve-pounders, and a gondola with 8 nine-pounders. Besides these, were 20 vessels of a smaller size, called gun-boats, carrying each a piece of brafs ordnance from nine to twenty-four pounders, or howitzers. Several long-boats were fitted out in the same manner; and besides all these, there was a vast number of boats and tenders of various sizes to be used as transports for the troops and baggage. It was manned by a number of feld officers, and the guns were to be served by a detachment from the corps of artillery; the officers and soldiers appointed for this expedition were also chosen out of the whole army.

To oppose this formidable armament, the Americans had only a very inconsiderable force, commanded by general Arnold; who, after engaging part of the British fleet for a whole day, took advantage of the darkness of the night to fer with being perceived, and the next morning was out of sight; but he was so hotly pursued by the British, that on the second day after, he was overtaken, and forced to a second engagement. In this he behaved with great gallantry; but his force being very inferior to that of the enemy, he was obliged to run his ships ashore and set them on fire. A few only escaped to lake George; and the garrison of Crown-Point having destroyed or carried off everything of value, retired to Ticonderoga. Thither general Carleton intended to have pursued them; but the difficulties he had to encounter appeared so many and so great, that it was thought proper to march back to Canada, and defer from any further operations till next spring.

Thus the affairs of the Americans seemed every where going to wreck; even those who had been most rieux alangue in their cause began to waver. The time, most ec- also, for which the soldiers had enlisted themselves was now expired; and the bad success of the pre- pered campaign had been so very discouraging, that no person was willing to engage himself during the continuance of a war of which the event seemed to be so doubtful. In consequence of this, therefore, general Washington found his army daily decreasing in strength; so that, from 50,000, of which it consisted when general Howe landed on Staten Island, a tenth part could now be mustered. To satisfy the chief commander as much as possible, general Lee had collected a body of forces in the north; but on his way southward, having imprudently taken up his lodgings at some distance from his troops, information was given to colonel Harcourt, who happened at that time to be in the neighbourhood, and Lee was made prisoner. General The lots of this general was much regretted, the more Lee was taken especially as he was of superior quality to any prisoner in the possession of the colonists, and could not therefore be exchanged. Six field-officers were offered in exchange for him, and refused; and the congress was highly irritated at its being reported that he was to be treated as a deserter, having been a half-pay officer in the British service at the commencement of the war. In consequence of this they issued a proclamation, threatening to retaliate on the prisoners in their possession whatever punishment would be inflicted on any of those taken by the British, and especially that their conduct should be regulated by the treatment of general Lee.

In the mean time they proceeded with the most in- Continences, engaged diligence to recruit their army, and bound their soldiers to serve for a term of three years, or for 1777 during the continuance of the war. The army was divided for the ensuing campaign, was to consist of 80 battalions; of which each province was to contribute its quota; and 20 dollars were offered as a bounty to each soldier, besides an allotment of lands at the end of the war. No lands were promised to those who enlisted only for three years. All officers or soldiers disabled through wounds received in the service were to enjoy half-pay during life. To defray the expence, congresses borrowed five millions of dollars at five per cent., for the payment of which the United States became surety. At the same time, in order to animate the people to vigorous exertions, a declaration was published, in which they set forth the necessity there was for taking proper methods to infure success in their cause: they endeavoured to palliate as much as possible the misfortunes which had already happened; and represented the true cause of the present difficulties to be the short term of enlistment.

This declaration, together with the imminent dan- of Philadelphia, determined the Americans to ex- general to the utmost in order to reinforce ge-
troops, consisting of three regiments under the com-
mand of Col. Mawhood, who were on their march to Princeton; Trenton. With the centre the enemy en-
gaged, and after killing 60, wounding many, and tak-
ing 300 prisoners, obliged the rest to make a precipi-
tate escape, some towards Trenton, and others in a re-
trograde route to Brunswick. The losses of the Americans was inconsiderable in point of numbers; but the fall of the amiable General Mercer rendered it important. And tre-
The British astonished and discouraged at the success treat
and spirit of these repeated enterprizes, abandoning Brunswick,
both Trenton and Princeton, retreated to Brunswick;
while the triumphant Americans retired to Morris-
town. General Washington, however, omitted no op-
portunity of recovering what had been lost; and by
dividing his army into small parties, which could be
reunited on a few hours warning, he in a manner en-
tirely covered the country with it, and repulsed him-
sfelf of all the important places.

Thus ended the campaign of 1776, with scarce any other real advantage than the acquisition of the city of New York, and of a few fortresses in its neighbour-
hood; where the troops were constrained to act with as much circumspection as if they had been be-
fieged by a victorious army, instead of being them-
selves the conquerors.

The army at New-York began in 1777 to exert Excursions
a kind of predatory war, by sending our parties to de-
froy magazines, make incursions, and take or destroy tith from
such forts as lay on the banks of rivers, to which their great command of shipping gave them access. In this
they were generally successful: the provincial maga-
azines at Peck's Hill, a place about 50 miles distant from New-York, were destroyed, the town of Dan-
bury in Connecticut burnt, and that of Ridgefield in the same province was taken possession of. In returning
from the last expedition, however, the British were

Greatly harassed by the Americans under Generals Ar-
old, Wooster, and Sullivan; but they made good their retreat, though with the loss of above 200 killed and
wounded. On the American side the loss was con-

iderable: General Wooster was killed, and Arnold
in the most imminent danger. On the other hand,
the Americans destroyed the fires at Stagg-harbour,
in Long-Island, and made prisoners of all who defend-
d the place.

As this method of making war, however, could an-
swer but little purpose, and favoured more of the bar-
barous incursions of savages than of a war carried on by
a civilized people, it was resolved to make an attempt
on Philadelphia. At first it was thought that this
could be done through the Jerseys; but the cruelties exer-
cised by the British plundering parties had excited no

general an abhorrence, and General Washington had
The army had received such large reinforcements, and polled himself so strongly, that it was found to be impracticable. Many sharps were used to draw him from his strong situation, but without success; so that it was found necessary to make the attempt on Philadelphia by sea. While the preparations necessary for this expedition were going forward, the Americans found means to make amends for the capture of General Lee by that of General Prefcot, who was feized in his quarters with his aid de camp, in much the same manner as General Lee had been. This was exceedingly mortifying to the General himself, as he had not long before set a prize upon General Arnold, by offering a sum of money to any one that apprehended him; which the latter answered by setting a lower price upon General Prefcot.

The month of July was far advanced before the preparations for the expedition against Philadelphia were completed; and it was the 23d before the fleet was able to sail from Sandy-Hook. The force employed in this expedition consisted of 56 battalions of British and Hessian, a regiment of light horse, and a body of loyalists sallied at New-York. The remainder of these, with 17 battalions, and another body of light horse, were sallioned at New-York under Sir Henry Clinton. Seven battalions were sallioned at Rhode-Island. After a week's falling they arrived at the mouth of the Delaware; but there having received certain intelligence, that the navigation of the river was so effectually obstructed, that no possibility of forcing a passage remained; or more probably that Gen. Washington had marched within a short distance of Philadelphia; it was resolved to proceed further southward to Chesapeake Bay in Maryland, from whence the distance to Philadelphia was not very great, and where the provincial army would find less advantage from the nature of the country than in the Jerseys.

The navigation from Delaware to Chesapeake took up the best part of the month of August, and that up the bay itself was extremely difficult and tedious. At last, having failed up the river Elk, as far as was practicable, the troops were landed without opposition, and set forward on their intended expedition. On the news of their arrival at Chesapeake, General Washington left the Jerseys, and hastened to the relief of Philadelphia; and in the beginning of September met the royal army at Brandywine Creek about mid-way, between the head of the Elk and Philadelphia. Here he adhered to his former method of skirmishing and harrying the royal army on its march; but as this proved insufficient to stop its progress, he retired to that side of the creek next to Philadelphia, with an intent to dispute the passage. This brought on a general engagement on the 11th September. The royal army advanced at day break in two columns, commanded by lieutenant general Knyphausen, and by lord Cornwallis. The first took the direct road to Chafford's Ford, and made a show of paling it, in front of the main body of the Americans. At the same time the other column moved up on the west side of the Brandywine to its fork, and crossed both its branches about 2 o'clock in the afternoon, and then marched down on the east side thereof, with the view of turning the right wing of their adversaries.

This they effected and compelled them to retreat with great loss. General Knyphausen amused the Americans with the appearance of crossing the ford, but did not attempt it until lord Cornwallis having crossed above and moved down on the opposite side, had commenced his attack. Knyphausen then crossed the ford, and attacked the troops posted for its defence. These, after a severe conflict, were compelled to give way. The retreat of the Americans soon became general, and was continued to Chester, under cover of General Weedon's brigade, which came off in good order. The final issue of battles often depends on small circumstances, which human prudence cannot control—one of these occurred here, and prevented General Washington from executing a bold design, to effect which, his troops were actually in motion. This was to have crossed the Brandywine, and attacked Knyphausen, while general Sullivan and Lord Stirling, should keep earl Cornwallis in check. In the most critical moment, general Washington received intelligence which he was obliged to credit, that the column of lord Cornwallis had been only making a feint, and was returning to join Knyphausen. This prevented the execution of a plan, which, if carried into effect, would probably have given a different turn to the events of the day. The killed and wounded in the royal army, were near six hundred. The loss of the Americans was twice that number. The celebrated Marquis de la Fayette here first blazed in the cause of liberty, which he had espoused with enthusiasm. His wound was slight, but it endeared him to the Americans.

The loss of this battle proved also the loss of Philadelphia. General Washington retired towards Lancaster, to save the stores which had been deposited at Reading. But though he could not prevent the loss of Philadelphia, he still adhered to his original plan of dispersing the royal party, by laying ambuscades and cutting off detached parties; but in this he was less successful than formerly; and one of his one detachments which lay in ambush in a wood were themselves surprised and entirely defeated, with the loss of 500 killed and wounded, besides 70 or 80 taken, and all their arms and baggage.

General Howe now perceiving that the Americans would not venture another battle even for the sake of their capital, took peaceable possession of it on the 26th of September. His first care was then to cut it off, by means of strong batteries, the communication between the upper and lower parts of the river; which was executed, notwithstanding the opposition of one American armed vessels; one of which, carrying 36 guns, was taken. His next task was to open a communication with it by sea; and this was a work of no small difficulty. A vast number of batteries and forts had been erected, and immense machines formed like chevaux de frise, from whence they took their name, sunk in the river to prevent its navigation. As the fleet was sent round to the mouth of the river in order to co-operate with the army, this work, however difficult, was accomplished; nor did the provincials give much opposition, as well knowing that all places of this kind were now untenable. General Washington, however, took the advantage of the royal army being divided to attack the camp of the principal division of that lay at German town, in the neighborhood of Philadelphia. In this he met with very little success; for though he reached the place of de-
The British ships of war burnt.

Through this passage, the Vigilant, a large ship, cut down so as to draw but little water, mounted with 4 pounders, made her way to a position from which she might enfilade the works on Mud-Island. This gave the British such an advantage, that the post was no longer tenable. Colonel Smith, who had with great gallantry defended the fort from the latter end of September, to the 11th of November, being wounded, was removed to the main. Within five days after his removal, major Thayer, who as a volunteer had nobly offered to take charge of this dangerous post, was obliged to evacuate it.

This event did not take place till the works were entirely beat down—every piece of cannon dismounted, and one of the British ships so near that she threw grenades into the fort, and killed the men uncovered on the platform. The troops who had so bravely defended fort Millin, made a safe retreat to Red-Bank. Congress voted swords to be given to lieutenant colonel Smith and Commodore Hazlewood, for their gallant defence of the Delaware. Within three days after Mud-Island was evacuated, the garrison was also withdrawn from Red-Bank, on the approach of lord Cornwallis, at the head of a large force prepared to assault it. Some of the American galleys and armed vessels escaped by keeping close in with the Jersey shore, to places not then occupied by Philadelphians, but 17 of them were abandoned by their crews, and fired. Thus the British gained a free communication between their army and shipping. This event was to them very desirable. They had been previously obliged to draw their provisions from Chester, a distance of sixteen miles, at some risque, and a certain great expence. The long protracted defence of the Delaware, deranged the plans of the British, for the remainder of the campaign, and consequentlv favored the adjacent country.

Thus the campaign of 1777, in Pennsylvania, concluded, upon the whole, successfully on the part of the British. In the north, however, matters wore a different aspect. The expedition in that quarter had been projected by the British ministry as the most effectual method that could be taken to crush the colonies at once. The four provinces of New-England had originally begun the confederacy against Britain, and were still considered as the most active in the continuation of it; and it was thought, that any impression made upon them, would contribute to an effectual manner to the reduction of all the rest. For this purpose, an army of 4000 chosen British troops and 3000 Germans were put under the command of General Burgoyne; General Carleton was directed to use his interest with the Indians to persuade them to join in this expedition; and the province of Quebec was to furnish large parties to join in the same. The officers who commanded under General Burgoyne were, General Philips of the artillery, Generals Fraer, Powell, and Hamilton, with the German officers General Reidefel and Speechelt. The soldiers, as has already been observed, were all excellently disciplined, and had been kept in their winter-quarters with all imaginable care, in order to prepare them for the expedition on which they were going. To aid the principal expedition, another was projected on the Mohawk River under Colonel St Leger, who was to be assisted by Sir John Johnson, son to the
the famous Sir William Johnson who had so greatly distinguished himself in the war of 1755.

On the 21st of June 1777, the army encamped on the western side of the Lake Champlain; where, being joined by a consider able body of Indians, General Burgoyne made a speech, in which it is said he exhorted these new allies, but ineffectually, to lay aside their fer rocious and barbarous manner of making war; to kill only such as opposed them in arms; and to spare prisoners, with such women and children as should fall into their hands. After issuing a proclamation, in which the force of Britain, and that which he commanded, was set forth in very ostentatious terms, the campaign opened with the siege of Ticonderoga. The place was very strong, and garrisoned by 6000 men under General St Clair; nevertheless, the works were so extensive, that even this number was scarce sufficient to de fend them properly. They had therefore omitted to fortify a rugged eminence called Sugar-Hill, the top of which overlooked and effectually commanded the whole works; imagining, perhaps, that the difficulty of the ascent would be sufficient to prevent the enemy from taking possession of it. On the approach of the first division of the army, the provincials abandoned and set fire to their outworks; and so expeditious were the British troops, that by the 5th of July every post was secured which was judged necessary for invuling it completely. A road was soon after made to the very summit of that eminence which the Americans had supposed could not be ascended; and so much were they now disheartened, that they instantly abandoned the fort entirely, taking the road to Skeneborough, a place to the south of Lake George; while their baggage, with what artillery and military stores they could carry off, were sent to the same place by water. But the British generals were determined not to let them pass so easily. Both were pursued and both overtaken. Their armed vessels consisted only of five galleys; two of which were taken, and three blown up; on which they set fire to their boats and fortifications at Skeneborough. On this occasion the provincials lost 200 boats, 130 pieces of cannon, with all their provisions and baggage. Their land-forces under Colonel Francis made a brave defence against General Fraser; and superior in number, had almost overpowered him, when General Reidel, with a large body of Germans came to his assistance. The provincials were now overpowered in their turn; and their commander being killed, they fled on all sides with great precipitation. In this action 200 Americans were killed, as many taken prisoners, and above 600 wounded, many of whom perished in the woods for want of assistance.

During the engagement General St Clair was at Cafileton, about six miles from the place; but instead of going forward to Fort Anne, the next place of strength, he repaired to the woods which lie between that fortres and New-England. General Burgoyne, however, detached Colonel Jull with the ninth regiment in order to intercept such as should attempt to retreat towards Fort Anne. On his way he met with a body of the Americans more numerous than his own; but after an engagement of three hours, they were obliged to retire with great loss. After so many disasters, despairing of being able to make any stand at Fort Anne, they set fire to it and retired to Fort Edward. In all these engagements the loss of killed and wounded in the royal army did not exceed 200 men.

General Burgoyne was now obliged to suspend his operations for some time, and wait at Skeneborough for the arrival of his tents, provisions, &c. He employed this interval in making roads through the country about St Anne, and in clearing a path for his troops to proceed against the Americans. This was attended with incredible toil, but all obstructions were surmounted with equal patience and resolution by the army. In the course of this exertion, he arrived with his army before Fort Edward about the end of July. Here General Schuyler had been for some time endeavoring to recruit the scattered American forces, and had been joined by General St Clair with the remains of his army; the garrison of Fort George also, situated on the lake of that name, had evacuated the place and retired to Fort Edward.

But on the approach of the royal army, they received from thence also, and formed their head-quarter to return to Saratoga. Notwithstanding the great successes of the British general, they showed not the least disposition to yield, but seemed only to encourage the New-Englanders, and they might make the most effectual resistance. For this purpose, the militia was every where raised and draughted to join the army at Saratoga; and such numbers of volunteers were daily added, that they soon began to recover from the alarm into which they had been thrown. That they might have a commander whose abilities could be relied on, General Arnold was appointed, who repaired to Saratoga with a considerable train of artillery; but receiving intelligence that Colonel St Leger was proceeding with great rapidity in his expedition on the Mohawk River, he removed to Stillwater, a place about half way between Saratoga and the junction of the Mohawk and Hudson's River.

The Colonel, in the mean time, had advanced as far as Fort Stanwix, the siege of which he pressed with vigour. On the 6th of August, understanding that a supply of provisions, escorted by 800 or 900 men, was on the way to the fort, he dispatched Sir John Johnson with a strong detachment to intercept it. This he did so effectually, that, besides intercepting the provisions, 400 of its guard were slain, 200 taken, and the rest escaped with great difficulty. The garrison, however, were not to be intimidated by the threats or representations of the Colonel; on the contrary, they made several successful sallies under Colonel Willert, the second in command; and this gentleman, in company with another, even ventured out of the fort, and, eluding the vigilance of the enemy, passed through them in order to hasten the march of General Arnold to their assistance.

Thus the affairs of Colonel St Leger seemed to be in no very favourable situation notwithstanding his late and great success, and they were soon totally ruined by the defection of the Indians. They had been alarmed by the report of General Arnold's advancing with 2000 men to the relief of the fort; and while the Colonel was attempting to give them encouragement, another report was spread, that General Burgoyne had been defeated with great slaughter, and was now flying before the provincials. On this he was obliged to do as they thought proper; and the retreat could not be effectuated without
General Burgoyne, in the mean time, notwithstanding all the difficulties he had already sustained, found that he must fill encounter more. The roads he had made with so much labour and pains were destroyed, either by the wetness of the season or by the Americans; so that the provisions he brought from Fort George could not arrive at his camp without the most prodigal toil. On hearing of the siege of Fort Stanwix by Colonel St Leger, he determined to move forward, in hopes of inclining the enemy betwixt his own army and that of St Leger, or of obtaining the command of all the country between Fort Stanwix and Albany; or, at any rate, a junction with Colonel St Leger would be effected, which could not but be attended with the most happy consequences. The only difficulty was the want of provisions; and this it was proposed to remedy by reducing the provincial magazines at Bennington. For this purpose, Colonel Baum, a German officer of great bravery, was chosen with a body of 500 men. The place was about 20 miles from Hudson's River; and no sooner Colonel Baum's party, the whole army marched up the river's bank, and encamped almost opposite to Saratoga, with the river betwixt it and that place. An advanced party was posted at Batten Kill, between the camp and Bennington, in order to support Colonel Baum. In their way the British seized a large supply of cattle and provisions, which were immediately sent to the camp; but the badness of the roads retarded their march so much, that intelligence of their design was sent to Bennington. Understanding now that the American force was greatly superior to his own, the Colonel acquainted the General, who immediately dispatched Colonel Breyman with a party to his assistance; but through the same causes that had retarded the march of Colonel Baum, this assistance could not arrive in time. General Stark who commanded the American militia at Bennington, engaged with them before the junction of the two royal detachments could be effected. On this occasion about 800 undisciplined militia, without bayonets, or a single piece of artillery, attacked and routed 500 regular troops advantageously posted behind entrenchments — furnished with the belt arms, and defended with two pieces of artillery. The field pieces were taken from the party commanded by Col. Baum, and the greatest part of his detachment was either killed or captured. Colonel Breyman arrived on the same ground and on the same day, but not till the action was over. Instead of meeting his friends, as he expected, he found himself briskly attacked. This was begun by colonel Warner, (who with his continental regiment, which having been sent for from Mancheater, came opportunely at this time) and was well supported by Stark's militia, which had just defeated the party commanded by colonel Baum. Breyman's troops, though fatigued with their preceding march, behaved with great resolution, but were at length compelled to abandon their artillery and retreat. In these two actions the Americans took four brass field pieces, twelve brass drums, 250 dragoon swords, 4 ammunition wagons, and about 700 prisoners. The loss of the Americans, inclusive of their wounded, was about 100 men.
ed with great slaughter, and the loss of all their artillery and baggage.

This was by far the heaviest loss the British army had sustained since the action at Bunker's Hill. The lift of killed and wounded amounted to near 200, exclusive of the Germans; but the greatest misfortune was the Americans had now an opening on the right and rear of the British forces, so that the army was threatened with entire destruction. This obliged General Burgoyne once more to shift his position, that the Americans might also be obliged to alter theirs. This was accomplished on the night of the 7th, without any loss, and all the next day he continued to offer the Americans battle; but they were now too well assured of obtaining a complete victory, by cutting off all supplies from the British, to risk a pitched battle. Wherefore they advanced on the right side, in order to enclose him entirely; which obliged the General to direct a retreat towards Saratoga. But the Americans had now flattened a great force on the ford at Hudson's river, so that the only possibility of retreat was by securing a passage to Lake George; and to effect this, a body of workmen were detached, with a strong guard, to repair the roads and bridges that led to Fort Edward. As soon as they were gone, however, the Americans seemed to prepare for an attack; which rendered it necessary to recall the guard, and the workmen being of course left exposed, could not proceed.

In the mean time, the boats which conveyed provisions down Hudson's river were exposed to the continual fire of the American marksmen, who took many of them; so that it became necessary to convey the provisions over land. In this extreme danger, it was resolved to march by night to Fort Edward, forcing the paffles at the fords either above or below the place; and, in order to effect this the more easily, it was resolved that the soldiers should carry their provisions on their backs, leaving behind their baggage and every other incumbrance. But before this could be executed, intelligence was received that the Americans had raised strong entrenchments opposite to the fords, well provided with cannon, and that they had likewise taken possession of the rising ground between Fort George and Fort Edward, which in like manner was provided with cannon.

All this time the American army was increasing by the continual arrival of militia and volunteers from all parts. Their parties extended all along the opposite bank of Hudson's River, and some had even passed it in order to observe the left movement of the British army. Every part of the British camp was reached by the grape and rifle-shot of the Americans, besides a discharge from their artillery, which was almost incessant. In this state of extreme distress and danger, the army continued with the greatest constancy and perseverance till the evening of the 13th of October, when an inventory of provisions being taken, it was found that no more remained than what were sufficient to serve for three days; and a council of war being called, it was unanimously determined that there was no method now remaining but to treat with the Americans. In consequence of this, a negotiation was opened next day, which speedily terminated in a capitulation of the whole British army; the articles of which were 1. The troops under lieut. gen. Burgoyne, to march out of their camp with the honours of war, and the artillery of the intrenchments to the verge of the river where the old fort stood, where the arms and artillery are to be left. The arms to be piled by word of march, and the officers, &c. 2. A free passage to be granted to the army under lieut. gen. Burgoyne to Great-Britain, upon condition of not serving again in North-America during the present contest; and the port of Boston to be signed for the entry of transports, to receive the troops whenever gen. Howe shall order:—3. Should any cartel take place, by which the army under lieut. gen. Burgoyne, or any part of it, may be exchanged, the foregoing article to be void, as far as such exchange shall be made:—4. The army under lieut. gen. Burgoyne to march to Massachusetts-Bay, by the safest, and most expedient and convenient route; and to be quartered in, near, or as convenient as possible to Boston, that the march of the troops may not be delayed when transports arrive to receive them:—The troops to be supplied on the march, and during their being in quarters, with provisions, by major general Gates's orders, at the same rate of rations as the troops of his own army; and, if possible, the officers horses and cattle are to be supplied with forage at the usual rates:—6. All the officers to retain their carriages, bat-horses and other cattle, and no baggage to be modelled or searched; lieut. gen. Burgoyne giving his honour, that there are no public stores contained therein. Major gen. Gates will of course take the necessary measures for the due performance of this article: should any carriages be wanted during the march, for the transportation of officers baggage, they are, if possible, to be supplied by the country at the usual rates:—7. Upon the march, and during the time the army shall remain in quarters, in the Massachusetts-Bay, the officers are not, as far as circumstances will admit, to be separated from their men.—The officers are to be quartered according to their rank, and are not to be hindered from their assembling their men for roll-callings, and other necessary purposes of regularity:—8. All corps whatever of lieut. gen. Burgoyne's army, whether composed of sailors, bateau-men, artificers, drivers, independent companies, and officers of the army, of whatever country, shall be included in the fullest sense and utmost extent of the above articles, and comprehended in every respect as British subjects:—9. All Canadians, and persons belonging to the Canadian establishment, consisting of sailors, bateau-men, artificers, drivers, independent companies, and many other followers of the army, who come under no particular description, are to be permitted to return there: they are to be conducted immediately, by the shortest route, to the first British port on Lake George, are to be supplied with provisions in the same manner as the other troops, and to be bound by the same condition of not serving during the present contest in North-America:—10. Passports to be immediately granted for three officers, not exceeding the rank of captains, who shall be appointed by lieut. gen. Burgoyne, to carry dispatches to Sir Wm. Howe, Sir Guy Carleton, and to Great-Britain by the way of New-York; and major general Gates engages the public faith, that these dispatches shall not be opened. These officers are to set out immedi-

A M E [ 601 ] A M E.
During the stay of the troops in the Maffachufetts-Bay, the officers are to be admitted on parole, and are to be permitted to wear their side arms:—12. Should the army under lieut. gen. Burgoyne, find it necessary to fend for their clothing and other baggage from Canada, they are to be permitted to do it in the most convenient manner, and necessary parallel or supports to be granted for that purpose:—12. These articles are to be mutually signed and exchanged to-morrow morning at nine o'clock; and the troops under lieut. gen. Burgoyne, are to march out of their intrenchments at three o'clock in the afternoon. Camp at Saratoga, October 16, 1777.

HORATIO GATES, Major-General.

To prevent any doubts that might arise from lieut. gen. Burgoyne's name not being mentioned in the above treaty, major general Gates hereby declares, that he is underfoot to be comprehended in it, as fully as if his name had been specifically mentioned.

Such was the impatience of some of the militia to return home before the royal army had been brought to surrender, and to little their concern to be spectators of the event, that one of the Northampton regiments went off the day before the flag came out from Burgoyne. Another regiment took itself away while the town itself was wantonly reduced to ashes, as that called Continent Village had been before. Thus the British armament spent their time in wasting the adjacent country, when by pushing forward 136 miles in six days they might have effectually relieved Burgoyne.

But these successess, of whatever importance they might be, were now disregarded by both parties. They jealously vowed to irritate the Americans, flushed with their successes; and they were utterly insufficient to raise the spirits of the British, who were now thrown into the utmost dismay.

On the 16th of March 1778, Lord North intimated to the house of commons, that a paper had been laid before the king by the French ambassadoir, intimating the conclusion of an alliance between the court of France and the United States of America. The preliminaries of this treaty had been concluded in the end of the year 1777, and a copy of them sent to congress, in order to counteract any proposals that might be made in the mean time by the British ministry. On the 6th of February 1778, the articles were formally signed, to the great satisfaction of the French nation. They were in substance as follows:

1. If Great-Britain should, in consequence of this treaty, proceed to hostilities against France, the two nations should mutually affit one another.

2. The main end of the treaty was, in an effectual manner to maintain the independency of America.

3. Should those places of North-America still subject to Britain be reduced by the colonies, they should be confederated with them, or subjected to their jurisdiction.

4. Should any of the West Indies be reduced by France, they should be deemed its property.

5. No formal treaty with Great Britain should be concluded either by France or America without the consent of each other; and it was mutually engaged that
that they should not lay down their arms till the inde-
pendency of the States had been formally acknow-
ledged.
6. The contracting parties mutually agreed to invite
those powers that had received injuries from Great
Britain to join the common cause.
7. The United States guaranteed to France all the
possessions in the West Indies which the should con-
quer; and France in her turn guaranteed the absolute
independency of the States, and their supreme author-
ity over every country they poiffessed, or might ac-
quire during the war.

The notification of such a treaty as this could not
be looked upon as a declaration of war. On its
being announced to the house, every one agreed in its
adress to his majesty, promising to stand by him to
the utmost in the present emergency; but it was warm-
ly contended by the members in opposition, that the
present ministry ought to be removed on account of
their numberless blunders and miscarriages in every
instance. Many were of opinion, that the only way
to extricate the nation from its trouble was to
legislate the independency of America at once; and thus
the present was now offered them be

The Americans in the mean time affidiously em-
ployed their agents at the courts of Spain, Vienna,
Prufiia, and Tufcany, in order, if possible, to conclude
alliances with them, or at least to procure an acknow-
ledgment of their independency. As it had been report-
ed that Britain intended to apply for afliance to Rus-
sea, the American commissioners were enjoined to use
their utmost influence with the German princes to
prevent such auxiliaries from marching through their
territories, and to endeavour to procure the recall of
the German troops already sent to America. To
France they offered a cession of such West India is-
lands as should be taken by the united strength of France
and America; and should Britain by their joint en-
deavours be dispossessed of Newfoundland, Cape Breton,
and Nova Scotia, those territories should be divided
between the two nations, and Great Britain be totally
excluded from the fishery. The proposals to the Span-
ish court were, in case they should think pro-
per to espouse their quarrel, the American States
should assist in reducing Penfacaola under the domin-
ion of Spain, provided their subjects were allowed the
free navigation of the river Missilippi and the ufe of the
harbour of Penfacaola; and they further offered, that,
if agreeable to Spain, they would declare war against Portugal, should that power expel the Ameri-
can ships from its ports.

In the mean time the troops under General Bur-
goyne were preparing to embark for Britain accord-
ing to the convention at Saratoga; but congresses having
received information, that many articles of negotia-
tion and accointments had not been forrendered agreeably to the stipulated terms, and finding some
cause to apprehend, that sinister designs were har-
boured on the part of Great Britain to convey these
troops to join the army at Philadelphia or New-York,
positively refused to let them embark, until an expli-
cit ratification of the convention should be properly
notified by the British court.

The season for action was now approaching; and
congresses was indefatigable in its preparations for a
new campaign, which it was confidently said would be the
first. Among other methods taken for this purpose, it
was recommended to all the young gentlemen of the
colonies to form themselves into bodies of cavalry to
serve at their own expense during the war. General
Washington at the same time, to remove all incum-
brances from his army, lightened the baggage as much
as possible, by substituting packs and portmanteaus in
place of cheifs and boxes, and using pack-horses in
stead of waggonis. On the other hand, the British ar-
my, expecting to be reinforced by 20,000 men, thought
of nothing but concluding the war according to their
wishes before the end of the campaign. It was with

The utmost concern, as well as indignation, therefore,
that they received the news of Lord North's conciliatory
bill. It was universally looked upon as a national
dishonor; and some even tore the cockades from their
hats, and trampled them under their feet as a token of
their indignation. By the colonists it was received
with infinence. The British commissioners endeav-
oured to make it as public as possible; and the con-
gress, as formerly, ordered it to be printed in all the
newspapers. On this occasion Governor Tryon in-
closed several copies of the bill to General Washington
in a letter, intreating that he would allow them to be
circulated; to which the General returned for answer
a copy of a newspaper in which the bill was printed,
with the resolutions of congress upon it. Thefe were,
That whoever presumed to make a separate agree-
ment with Britain should be deemed a publif enemy;
that the United States could not with any propriety
keep correspondence with the commissioners until
their independence was acknowledged, and the Brit-
ish fleets and armies removed from America. At the
same time, the colonies were warned not to suffer
themselves to be deceived into security by any offers
that might be made; but to use their utmost endeav-
ours to fend their quotas with all diligence into the
field. The individuals with whom the commissioners
conversed on the subject of the conciliatory bill, gene-
 rally returned for answer, that the day of reconcilia-
tion was past; and that the haughtiness of Britain had
extinguished all filial regard in the breasts of Ame-
cans.

About this time also Mr Silas Dean arrived from
France with two copies of the treaty of commerce
and alliance to be signed by congress. Advices of the
most agreeable nature were also received from various
parts, repreffing in the most favourable light the
dispositions of the European powers; all of whom, it
was said, wished to fee the independency of America
settled upon the most permanent basis. Considering
the situation of matters with the colonists at this time,
therefore, it was no wonder the commissioners found
themselves unable to accomplish the errand on which
they came. Their proposals were utterly rejected,
themselves treated as spies; and, after a vain attempt
by
by governor Johnstone, one of the commissioners, to bribe several members of congress, all intercourse with them was interdicted.

But before any final answer could be obtained from congress, Sir Henry Clinton had taken the resolution of evacuating Philadelphia. Accordingly, on the 10th of June, after having made all necessary preparations, the army marched out of the city and crossed the Delaware before noon with all its baggage and other incumbrances. General Washington, apprised of this design, had dispatched express to the Jerseys with orders to collect all the forces that could be assembled in order to obstruct the march of the enemy. After various movements on both sides, Sir Henry Clinton, with the royal army, arrived on the 27th of June at a place called Freehold; where, judging that the enemy would attack him, he encamped in a very strong situation. Here General Washington determined to make an attack as soon as the army had again begun its march. The night was spent in making the necessary preparations, and General Lee with his division was ordered to be ready by day-break. But Sir Henry Clinton, apprehending that the chief object of the Americans was the baggage, committed it to the care of General Knaphaufen, whom he ordered to set out early in the morning, while he followed with the rear of the army. The attack was accordingly made; but the British general had taken such care to arrange his troops properly, and to effectually support his forces when engaged with the Americans, that the latter not only made no impression, but were with difficulty preferred from a total defeat by the advance of General Washington with the whole army. The British troops effected their retreat in the night with the loss of 300 men, of whom many died through mere fatigue, without any wound. In this action General Lee was charged by General Washington with disobedience and misconduct in retreating before the British army. He was tried by a court-martial, and sentenced to a temporary suspension from his command.

After they had arrived at Sandy-Hook, a bridge of boats was by Lord Howe's directions thrown from thence over the channel which separated the Island from the main land, and the troops were conveyed aboard the fleet; after which they failed to New-York. After finding some light detachments to watch the enemy's motions, General Washington marched towards the North-River, where a great force had been collected to join him, and where it was now expected that some very capital operations would take place.

In the mean time France had sent about her preparations for the assistance of the Americans. On the 14th of April Count d'Eslaign had failed from Toulon, with a strong squadron of ships of the line and frigates, and arrived on the coast of Virginia in the beginning of July, with the British fleet was employed in conveying the forces from Sandy-hook to New-York. It consisted of one ship of 90 guns, one of 80, five of 74, and four of 64, besides several large frigates; and, exclusive of its complement of sailors, had 5000 marines and soldiers on board. To oppose this the British had only six ships of 64 guns, three of 50, and two of 40, with some frigates and sloops. Notwithstanding this inferiority, however, the British admiral posted himself to advantageously, and showed such superior skill, that d'Eslaign did not think proper to attack him; particularly, as the pilots informed him that it was impracticable to carry his large ships over the bar into the hook, and General Washington prefigured him to fail for Newport. He therefore remained at anchor four miles off Sandy-hook till the 22d of July, without effecting anything more than the capture of some vessels, which, through ignorance of his arrival, fell into his hands.

The next attempt of the French admiral was, in conjunction with the Americans, on Rhode-Island. It Rhose was proposed that d'Eslaign, with the 6000 troops he had with him, should make an descent on the southern part of the island, while a body of the Americans should take possession of the north; at the same time the French squadron was to enter the harbour of Newport, and take and destroy all the British shipping. On the 8th of August the French admiral entered the harbour as was proposed, but found himself unable to do any material damage. Lord Howe, however, instantly set sail for Rhode-Island; and d'Eslaign, confiding in his superiority, immediately came out of the harbour to attack him. A violent storm parted the two fleets, and did so much damage that they were rendered totally unfit for action. The French, however, suffered a mort; and several of their ships being afterwards attacked singly by the British, very narrowly escaped being taken. On the 20th of August he returned to Newport in a very shattered condition; and, not thinking himself safe there, failed two days after for Boston. General Sullivan had landed in the mean time on the northern part of Rhode-Island with 10,000 men. On the 17th of August they began their operations by erecting batteries, and making their approaches to the British lines. But General Pigot, who commanded in Newport, had taken such effectual care to secure himself on the land-side, that without the assistance of a marine force it was altogether impossible to attack him with any probability of success. The conduct of d'Eslaign, therefore, who had abandoned them when master of the harbour, gave the greatest disgust to the people of New-England, and Sullivan began to think of a retreat. On perceiving his intentions, the garrison fallied out upon him with so much vigour, that it was not without difficulty that he effected his retreat. He had not been long gone when Sir Henry Clinton arrived with a body of 4000 men; which, had it arrived sooner, would have enabled the British commander to have gained a decisive advantage over him, as well as to have destroyed the town of Providence, which, by its vicinity to Rhode-Island, and the enterprises which were continually projected and carried on in that place, kept the inhabitants of Rhode-Island in continual alarms.

The first British expedition was to Buzzard's-Bay, The coast on the coast of New-England and neighbourhood of America. Here they destroyed a great number of vessels by privateers and merchantmen, magazines, with forresses, &c.; whence proceeding to a fertile and populous island, called Martha's-Vineyard, they carried off 2000 sheep and 300 black cattle. Another expedition took place up the North-River, under Lord Cornwallis and General Knaphaufen; the principal event of which was, the destruction of a regiment of American cavalry known by the name of Washington.
York; while General Lin-coin's Light Horse. A third expedition was directed to Little Egg-Harbour in New-Jersey, a place noted for privaters, the destruction of which was its principal intention. It was conducted by Captains Ferguson and Collins, and ended in the destruction of the American vessels, as well as of the place itself. At the same time part of another body of American troops, called Pulaski's legion, was surprized, and a great number of them put to the sword.

The Americans had in the beginning of the year projected the conquest of West-Florida; and one Captain Willing, with a party of resolute men, had made a successful incursion into the country. This awakened the attention of the British to the southern colonies, and an expedition against them was resolved on. Georgia was the place of definition; and the more efficient force, under convoy of some ships of war, commanded by Commodore Hyde Parker, embarked at New-York; while General Prevost, who commanded in East-Florida, was directed to set out with all the force he could spare. The armament from New-York arrived off the coast of Georgia in the month of December; and though the Americans were very strongly posted in an advantageous situation on the shore, the British troops made good their landing, and advanced towards Savannah the capital of the province. That very day they defeated the force of the provincials which opposed them; and took possession of the town with such celerity, that the Americans had not time to execute a resolution they had taken of setting fire on it. In ten days the whole province of Georgia was reduced, Sunbury alone excepted; and this was also brought under subjection by General Prevost in his march northward. Every proper method was taken to secure the tranquillity of the country; and rewards were offered for apprehending committee of Grievances. The provincial assembly, which was assembled, was dismissed, and a chosen body of infantry, mounted on horseback, the command of the troops naturally devolved on him as the senior officer; and the conquest of Carolina was next projected.

In this attempt there was no small probability of success. The country contained a great number of friends to government, who now eagerly embraced the opportunity of declaring themselves; many of the inhabitants of Georgia had joined the royal standard; and there was not in the province any considerable body of provincial forces capable of opposing the efforts of regular and well-disciplined troops. On the 1st of June, General Prevost's approach, the loyalists assembled in a body, imagining themselves able to stand their ground until their allies should arrive; but in this they were disappointed. The Americans attacked and defeated them with the loss of half their number. The remainder retreated into Georgia; and after undergoing many difficulties, at last effected a junction with the British forces.

The town of Charleston, taken by the British, was opened; the American general Prevost therefore determined to dislodge the party at Briar's Creek; and the latter, trudging to their strong situation, and being remiss in their guard, suffered themselves to be surprized on the 30th of March 1779; when they were utterly vanquished; the loss of more than 300 killed and taken, besides a great number drowned in the river or the swamps. The whole artillery, stores, baggage, and almost all the arms of this unfortunate party were taken, so that they could no more make any stand; and thus the province of Georgia was once more freed from the Americans, and a communication opened with those places in Carolina where the loyalists chiefly resided.

The victory at Briar's Creek proved of considerable service to the British cause. Great numbers of the loyalists joined the army, and considerably increased its force. Hence he was enabled to stretch his policy further up the river, and to guard all the principal passes: so that General Lincoln was reduced to a state of inaction; and at last moved off towards Augusta, in order to protect the provincial assembly, which was obliged to sit in that place, the capital being now in the hands of the British.

Lincoln had no sooner quitted his post, than it was judged a proper time by the British general to put in execution the grand scheme which had been meditated against Carolina. Many difficulties indeed lay in his way. The river Savannah was fo swollen by the ex- ceedingly rains of the season, that it seemed impassable; the opposite shore, for a great way, was so full of swamps and marshes, that no army could march over it without the greatest difficulty; and, to render the passage still more difficult, General Moultrie was left with a considerable body of troops in order to oppose the enemy's attempts. But in spite of every opposition, the con- stancy, perseverance, and perseverance of the British troops at last prevailed. General Moultrie was obliged to retire to- wards Charleston; and the pursuing army, after hav- ing passed through the marshes for some time, at last arrived in an open country, through which they pur- sued their march with great rapidity, towards the capital; while General Lincoln made preparations to march to its relief.

Certain intelligence of the danger to which Charles- ton was exposed, animated the American general Prevost to an advance to its relief. The British general Lincoln was exposed, animated the American general Prevost to an advance to its relief. The General of General Prevost's approach, the loyalists assembled in a body, imagining themselves able to stand their ground until their allies should arrive; but in this they were disappointed. The Americans attacked and defeated them with the loss of half their number. The remainder retreated into Georgia; and after undergoing many difficulties, at last effected a junction with the British forces.

In the mean time, General Lincoln, with a considerable body of American troops, had encamped within 20 miles of the town of Savannah; and another strong party had posted themselves at a place called Briar's Creek, farther up the river of the same name. Thus the extent of the British government was likely to be circumscribed within very narrow bounds. General Lincoln therefore determined to dislodge the party at Briar's Creek; and the latter, trudging to their strong situation, and being remiss in their guard, suffered themselves to be surprized on the 30th of March 1779; when they were utterly vanquished; the loss of more than 300 killed and taken, besides a great number drowned in the river or the swamps. The whole artillery, stores, baggage, and almost all the arms of this unfortunate party were taken, so that they could no more make any stand; and thus the province of Georgia was once more freed from the Americans, and a communication opened with those places in Carolina where the loyalists chiefly resided.

The victory at Briar's Creek proved of considerable service to the British cause. Great numbers of the loyalists joined the army, and considerably increased its force. Hence he was enabled to stretch his policy further up the river, and to guard all the principal passes: so that General Lincoln was reduced to a state of inaction; and at last moved off towards Augusta, in order to protect the provincial assembly, which was obliged to sit in that place, the capital being now in the hands of the British.

Lincoln had no sooner quitted his post, than it was judged a proper time by the British general to put in execution the grand scheme which had been meditated against Carolina. Many difficulties indeed lay in his way. The river Savannah was so swollen by the ex- ceedingly rains of the season, that it seemed impassable; the opposite shore, for a great way, was so full of swamps and marshes, that no army could march over it without the greatest difficulty; and, to render the passage still more difficult, General Moultrie was left with a considerable body of troops in order to oppose the enemy's attempts. But in spite of every opposition, the con- stancy, perseverance, and perseverance of the British troops at last prevailed. General Moultrie was obliged to retire to- wards Charleston; and the pursuing army, after hav- ing passed through the marshes for some time, at last arrived in an open country, through which they pur- sued their march with great rapidity, towards the capital; while General Lincoln made preparations to march to its relief.

Certain intelligence of the danger to which Charles- ton was exposed, animated the American general Prevost to an advance to its relief. The General of General Prevost's approach, the loyalists assembled in a body, imagining themselves able to stand their ground until their allies should arrive; but in this they were disappointed. The Americans attacked and defeated them with the loss of half their number. The remainder retreated into Georgia; and after undergoing many difficulties, at last effected a junction with the British forces.

In the mean time, General Lincoln, with a considerable body of American troops, had encamped within 20 miles of the town of Savannah; and another strong party had posted themselves at a place called Briar's Creek, farther up the river of the same name. Thus the extent of the British government was likely to be circumscribed within very narrow bounds. General Lincoln therefore determined to dislodge the party at Briar's Creek; and the latter, trudging to their strong situation, and being remiss in their guard, suffered themselves to be surprized on the 30th of March 1779; when they were utterly vanquished; the loss of more than 300 killed and taken, besides a great number drowned in the river or the swamps. The whole artiller
port his attack by land; and General Lincoln advancing rapidly with a superior army, threatened to include him between his own force and the town; so that should he fail in his first attempt, certain destruction would be the consequence. For these reasons he withdrew his forces from before the town, and took possession of two islands, called St. James's and St. John's, lying to the southward; where having waited some time, his force was augmented by the arrival of two frigates. With these he determined to make himself master of Port-Royal, another island possessed of an excellent harbour, and many other natural advantages, from its situation also commanding all the sea-coast from Charleston to Savannah River. The American general, however, did not allow this to be accomplished without opposition. Perceiving that his opponent had occupied an advantageous post on St. John's island preparatory to his enterprise against Port-Royal, he attempted, on the 20th of June, to dilodge them from it, but, after an obstinate attack, the provincials were obliged to retire with considerable loss. On this occasion the success of the British arms was in a great measure owing to an armed flote, which galled the right flank of the enemy so effectually, that they could direct their efforts only against the strongest part of the lines, which proved impregnable to their attacks. This disappointment was infantly followed by the loss of Port-Royal, which General Prevost took possession of, and put his troops into proper situations, waiting for the arrival of such reinforcements as were necessary for the intended attack on Charleston.

The profligate conduct of the refugees, and the officers and soldiers of the British, in plundering the houses of individuals, during their incursion, is incredible. Negroes were seduced or forced from their masts; furniture and plate were feized without decency or authority; and the most infamous violations of every law of honour and honesty were openly perpetrated. Individuals thus accumulated wealth, but at the expense of the British arms, which proved impregnable to their attacks. This disappointment was instantly followed by the loss of Port-Royal, which General Prevost took possession of, and put his troops into proper situations, waiting for the arrival of such reinforcements as were necessary for the intended attack on Charleston.

D'Estaing's proclamation.

In the mean time Count D'Estaing, who, as we have already observed, had put into Boston harbour to refit, had used his utmost efforts to ingratiate himself with the inhabitants of that city. Zealous also in the cause of his master, he had published a proclamation to be diffused through Canada, inviting the people to return to their original friendship with France, and declaring that all who renounced their allegiance to Great Britain should certainly find a protector in the king of France. All his endeavours, however, proved insufficient at this time to produce any revolution, or ever to form a party of any consequence among the Canadians.

As soon as the French admiral had refitted his fleet, he took the opportunity, while that of Admiral Byron had been shaken off by a storm, of falling to the West Indies. During his operations there, the Americans having represented his conduct as totally unfeivable to them, he received orders from Europe to assist the colonies with all possible speed.

In compliance with these orders, he directed his course towards Georgia, with a design to recover that province out of the hands of the enemy, and to put it, as well as South Carolina, in such a posture of defence as would effectually secure them from any future attack. This seemed to be an easy matter, from the little force with which he knew he should be opposed; and the next object in contemplation was no less than the destruction of the British fleet and army at New York, and their total expulsion from the continent of America. Full of these hopes, the French commander arrived off the coast of Georgia with a fleet of 22 full of the line and 10 large frigates. His arrival was so little expected, that several vessels laden with provisions and military stores fell into his hands; the experiment also, a vessel of 50 guns, commanded by Sir James Wallace, was taken after a stout resistance. On the continent, the British troops were divided. General Prevost, with an incon siderable part, remained at Savannah; but the main force was under Colonel Maitland at Port Royal. On the first appearance of the French fleet, an express was dispatched to Colonel Maitland: but it was intercepted by the Americans; so that before he could set out in order to join the commander in chief, the Americans had secured most of the passes by land, while the French fleet effectually blocked up the passage by sea. But, by taking advantage of creeks and inlets, and marching over land, he arrived just in time to relieve Savannah.

D'Estaing had allowed General Prevost 24 hours to conduct of deliberate whether he should capitulate or not. This the French time the general employed in making the best preparations he could for a defence; and during this time it was that Colonel Maitland arrived. D'Estaing's famous exploit was now rejected. The garrison now consisted of 3000 men, all of approved valour and experience, while the united force of the French and Americans did not amount to 10,000. The event was anfwerable to the expediencies of the British general. Having the advantage of a strong fortification and excellent engineers, the fire of the allies made so little impression that D'Estaing resolved to bombard the town, and a battery of nine mortars was erected for the purpose. This produced a request from General Prevost, that the women and children might be allowed to remove to a place of safety. But the allied commanders, from motives of policy, refused compliance; and they resolved to give a general assault. This was accordingly attempted on the 9th of October: but the assailants were everywhere repulsed with such slaughter, that 1200 were killed and wounded; among the former were Count Pallas, the celebrated conspirator against the reigning king of Poland, and among the latter was D'Estaing himself.

This disaster entirely overthrew the fanguine hopes of the Americans and French; but so far from reenloothing or animosity arising between them, their common misfortune seemed to increase their confidence and esteem for each other; a circumstance fairly to be ascribed to the conciliatory conduct of General Lincoln upon every occasion. After waiting eight days longer, both parties prepared for a retreat; the French to their shipping, and the Americans into Carolina.

While the allies were thus unsuccessfully employed in the southern colonies, their antagonists were no less affiduous in directing them in the northern parts. Sir George Colliet was sent with a fleet, carrying on board General Matthews, with a body of land forces, into the

Successful expeditions against the northern provinces.
the province of Virginia. Their first attempt was on the town of Portsmouth; where though the Americans had destroyed some ships of great value, the British troops arrived in time to save a great number of others.

On this occasion about 150 vessels of different sizes were burnt, and 20 carried off; and an immense quantity of provisions designed for the use of General Washington's army was either destroyed or carried off, together with a great variety of naval and military stores. The fleet and army returned with little or no loss to New-York.

The succcess with which this expedition was attended, soon gave encouragement to attempt another. The Americans had for some time been employed in the erection of two strong forts on the river; one at Verplanks Neck on the east, and the other at Stoney Point on the west side. These when completed would have been of the utmost service to the Americans, as commanding the principal passage called the King's Ferry, between the northern and southern colonies. At present, however, they were not in a condition to make any effectual defence; and it was therefore determined to attack them before the works should be completed.

The force employed on this occasion was divided into two bodies; one of which directed its course against Verplanks, and the other against Stoney Point. The former was commanded by general Vaughan, the latter by General Patterson, while the sailing was under the direction of Sir George Collier. General Vaughan met with no resistance, the Americans abandoning their works, and setting fire to every thing combustible that they could not carry off. At Stoney Point, however, a vigorous defence was made, though the garrison was at last obliged to capitulate upon honourable conditions.

The possession of this last, which was the more important of the two, General Clinton removed from his former situation, and encamped in such a manner that General Washington could not give any assistance. The Americans, however revengeful themselves by différent expedients with their numerous privateers, the trade to New-York.

This occasioned a third expedition to Connecticut, where these privateers were chiefly built and harboured. The command was given to Governor Tryon and to General Garth, an officer of known valour and experience. Under convoy of a considerable number of armed vessels they landed at Newhaven, where they demolished the batteries that had been erected to oppose them, and destroyed the shipping and naval stores but they spared the town itself, as the inhabitants had abdained from firing out of their houses upon the troops. From Newhaven they marched to Fairfield, where they proceeded as before, reducing the town also to ashes. Norwalk was next attacked, which in like manner was reduced to ashes; as was also Greenfield, a small seaport in the neighbourhood. Such repeated confaginations, wantonly and cruelly spread, served only to incite the diligent which was felt by every friend to the American cause.

These successes proved very alarming as well as detrimental to the Americans; so that General Washington determined at all events to drive the enemy from Stoney Point. For this purpose he sent Gen. Wayne with a detachment of chosen men, directing him to attempt the recovery of it by surprisal. On this occasion the Americans showed a spirit and resolution exceeding any thing either party had performed during the course of the war. Though after the capture of it by the British the fortifications of this place had been completed, and were very strong, they attacked the enemy with bayonets, after failing through a heavy fire of musketry and grape shot; and, in spite of all opposition, obliged the surviving part of the garrison, amounting to 500 men, to surrender themselves prisoners of war.

Though the Americans did not at present attempt to retain possession of Stoney Point, the successes they had met with in the enterprise emboldened them to make a similar attempt on Paulus Hook, a fortified post on the Jersey side, opposite to New-York; but, although the heroism of the interprize and the spirit with which it was executed deserves applause, after having completely surprized the posts, the American commander, Major Lee, finding it impossible to retain them, made an orderly retreat, with about 161 prisoners, among whom were seven officers.

Another expedition of greater importance was now undertaken against the post on the river Penobscot, on the borders of Nova Scotia, of which the British had lately taken possession, and where they had begun to erect a fort which threatened to be a very great inconvenience to the colonists. The armament designed against it was so soon got in readiness, that Colonel Macclay, the commanding officer at Penobscot, found himself obliged to drop the execution of part of his scheme; and instead of a regular fort, to content himself with putting the works already constructed in as good a posture of defence as possible.

The Americans could not effect a landing without a great deal of difficulty, and bringing the guns of their largest vessels to bear upon the shore. As soon as this was done, however, they erected several batteries, and kept up a brisk fire for the space of a fortnight; after which they proposed to give a general assault; but before this could be effected, they perceived Sir George Collier with a British fleet sailing up the river to attack them. On this they instantly embarked their artilleri and military stores, sailing up the river as far as possible in order to avoid them. They were so closely pursued, however, that not a single vessel could escape, so that the whole fleet, consisting of 19 armed vessels and 24 transports, was destroyed; most of them indeed being blown up by themselves. The soldiers and sailors were obliged to wander through immense deserts, where they suffered much for want of provisions; and to add to their calamities, a quarrel broke out between the soldiers and seamen concerning the cause of their disaster, which ended in a violent fray, where a great number were killed.

To add to the distress of the Americans, the Indians, accompanied by a number of refugees, attacked the back settlements of Pennsylvania. No effectual measures being taken to repress the hostile spirit of the Indians, numbers joined the tory refugees, and with these commenced their horrid depredations and hostilities upon the back settlers, being headed by Col. Butler and Brandt, an half blooded Indian, of desperate courage, furious and cruel beyond example. Their expeditions were carried on to great advantage, by the exact knowledge which the refugees possessed of
of every object of their enterprise, and the immediate intelligence they received from their friends on the spot. The weight of their hostilities fell upon the fine, new and flourishing settlement of Wyoming, situated on the eastern branch of the Susquehanna, in a most beautiful country and delightful climate. It was settled and cultivated with great ardor by a number of people from Connecticut, which claimed the territory as included in its original grant from Charles II. The settlement consisted of eight townships, each five miles square, beautifully placed on each side of the river. It had increased so by a rapid population, that they sent a thousand men to serve in the continental army. To provide against the dangers of their remote situation. Four forts were constructed to cover them from the irreptations of the Indians. But it was their unhappiness, to have a considerable mixture of loyalists among them; and the two parties were actuated by sentiments of the most violent animosity which was not confined to particular families or places: but creeping within the roofs and to the hearts and floors where it was least to be expected, forever banished the sources of domestic security and happiness, and to cancel the laws of nature and humanity.

They had frequent and timely warnings of the danger to which they were exposed by sending their best men to go a great distance. Their quiet had been interrupted by the Indians, joined by marauding parties of their own countrymen, in the preceding year; and it was only by a vigorous opposition, in a course of successful skirmishes, that they had been driven off. Several tories, and others not before suspected, had then and since abandoned the settlement; and besides a perfect knowledge of all their particular circumstances, carried along with them such a stock of private resentment, as could not fail of directing the fury, and even giving an edge to the cruelty of their Indian and other inveterate enemies. An unusual number of strangers had come among them under various pretences, whose behaviour became so sanguine, that upon being taken up and examined, such evidence appeared against several of them, of their acting in concert with the enemy, on a scheme for the destruction of the settlements, that about twenty were sent off to Connecticut to be there imprisoned and tried for their lives, while the remainder were expelled. These measures excited the rage of the tories in general to the most extreme degree; and the threats formerly denounced against the settlers, were now renewed with aggravated vengeance.

As the time approached for the final catastrophe, the Indians practiced unusual treachery. For several weeks previous to the intended attack, they repeatedly sent small parties to the settlement, charged with the strongest professions of friendship. These parties, beseeching attempts to lull the people into security, answered the purposes of communicating with their friends, and of observing the present state of affairs. The settlers, however, were not infensible to the danger. They had taken the alarm, and Col. Zebulon Butler had several times written letters to congress and gen. Washington, acquainting them with the danger the settlement was in, and requesting assistance; but the letters were never received, having been intercepted by the Pennsylvania tories. A little before the main attack, some small parties made sudden irruptions, and committed several robberies and murders; and from ignorance or a contempt of all ties whatever, massacred the wife and five children of one of the persons sent for trial to Connecticut in their own cause.

At length, in the beginning of July, the enemy suddenly appeared in full force on the Susquehanna, headed by Col. John Butler, a Connecticut Tory, and cousin to Col. Zeb. Butler, the second in command in the settlement. He was assisted by most of the leaders, who had rendered themselves terrible in the present frontier war. Their force was about 1600 men, near a fourth Indians, led by their own chiefs; the others were so disguised and painted as not to be distinguished from the Indians, excepting their officers, who being dressed in regiments, carried the appearance of regulars. One of the smaller forts, garrisoned chiefly by tories, was given up or rather betrayed. Another was taken by storm, and all but the women and children massacred in the most inhuman manner.

Col. Zeb. Butler, leaving a small number to guard fort Wilkesborough, crossed the river with about 400 men, and marched into Kingston fort, whither the women, children and defenseless of all forts crowded for protection. He suffered himself to be enticed by his cousin to abandon the forts. He agreed to march out, and hold a conference with the enemy in the open field (at so great a distance from the fort, as to shut out all possibility of protection from it) upon their withdrawing according to their own proposal, in order to the holding of a parley for the conclusion of a treaty. He at the same time marched out about 400 men well armed, being nearly the whole strength of the garrison, to guard his persons to the place of parley, such was his distrust of the enemy's designs. On his arrival he found no body to treat with him, and yet advanced toward the foot of the mountain, where at a distance he saw a flag, the holders of which, seemingly afraid of treachery on his side, retired as he advanced: whilst he, endeavoring to remove this pretended ill-impression, purified the flag, till his party was thoroughly enclosed, when he was suddenly freed from his delusion, by finding it attacked at once on every side. He and his men, notwithstanding the surpise and danger, fought with resolution and bravery, and kept up so continual and heavy a fire for three quarters of an hour, that they seemed to gain a marked superiority. In this critical moment, a soldier, through a sudden impulse of fear or premeditated treachery, cried out aloud, "the colonel has ordered a retreat." The fate of the party was now at once determined. In the state of confusion that ensued, an unresisted slaughter commenced, while the enemy broke in on all sides without obstruction. Col. Zeb. Butler, and about seventy of his men escaped; the latter got across the river to fort Wilkesborough, the colonel made his way to fort Kingston; which was invested the next day on the land side. Fort Kingston was invested the next day on the land side. Fort Kingston was invested the next day on the land side. Fort Kingst...
Spain made them fcrupulous of fire, they enjoyed the favage pleasure of beholdings the whole continued in one general blaze.

They then croffed the river to the only remaining fort, Wilkesborough, which in hopes of mercy for- rendered without demanding any conditions. They found about forty continental soldiers, who had been engaged merely for the defence of the frontier, whom they butchered with every circumstance of horrid cruelty. The remainder of the men, with the women and children, were shut up as before in the houfes, which being fet on fire, they perifhed altogether in the flames.

A general fcnce of devastation was now spread through all the towns. Fire, fword, and the other different instruments of deftitution alternately triumphed. The fettlements of the towns alone generally escaped, and appeared as islands in the midft of the surrounding ruin. The mercenaries having destroyed the main objets of their cruelty, directed their animofity to every part of living nature belonging to them; Shot and destroyed none of their cattle, and cut out the tongues of others, leaving them still alive to prolong their agonies.

Thus the arms of America and France being atmoft every where unfruitful, the independence of the former fanned yet to be in danger, notwithstanding the affiftance of fo powerful an ally, when further encouragement was given by the aecceffion of Spain to the confederacy againft Britain in the month of June 1779. The firft effect of this appeared in an invasion of West Florida by the Spaniards in September 1779. As the country was in no fate of defence, the enemy easily made themselves masters of the whole, withoat much opposition. Their next enterprife, was againft the Bay of Honduras, where the British logwood-cutter were fettled. These finding themselves too weak to reft, applied to the governor of Jamaica for relief, who fent them a supply of men, ammunition, and military stores, under Captain Dalrymple. Before the arrival of this detachment, the principal fettlement in that parts, called St George’s Key, had been taken by the Spaniards and retaken by the Britifh. In his way Captain Dalrymple fell in with a squadron from Admiral Parker in fearch of fome refifter ships richly laden; but which, retreatting into the harbour of Omoa, were too flrongly proceeded by the fort to be attacked with safety. A project was then formed, in conjunction with the people of Honduras, to reduce this fort.

The design was to surprife it; but the Spaniards having discovered them, they were too well prepared for the Britifh; but the for- tifications were fo strong, that the artillery they had brought along with them were found too light to make any impression. It was then determined to try the fuccefs of an encalade, and this was executed with fo much spirit, that the Spaniards ftood affonnified without making any refiftance, and, in fpite of all the ef- forts of the officers, threw down their arms and for- rendered. The fpoil was immense, being valued at three millions of dollars. The Spaniards chiefly la- mented the los of 250 quintals of quickfiver; a com- modity indifpenfably neceffary in the working of their gold and silver mines, fo that they offered to ranfom it for any price; but this was refused, as well as the ranfom of the fort, though the governor offered 300,000 dollars for it. A small garrison was left for but are the defence of the place; but it was quickly attacked obliged by a fuperior force, and obliged to evacuates it, though not without destroying every thing that could be of ufe to the enemy; fpiking the guns, and even locking the gates of the fort and carrying off the keys. All this was done in fight of the beholders; after which the garrison embarked without the los of a man.

As no operations of any confequence took place this year in the province of New-York, the congrafs made use of the opportunity to difpatch General Sullivan with a confiderable force, in order to take vengeance on the Indians for their ravages and depredations. Of this the Indians were apprife; and collecting all their flrength, refolved to come to a decisive engage- ment. Accordingly they took a ftrong poft in the moft woody and mountainous part of the country; erecting a breast-work in their front, of large logs of wood extending half a mile in length, while their right flank was covered by a river, and the left by a hill of difficult access. This advantageous pofition they had taken by the advice of the refugees who were among them, and of whom 200 or 300 were prefent in the battle.

Thus pofted, the Indians waited the approach of the American army; but the latter having brought some artillery along with them, played it againſt the breast-work of the enemy with fuch fuccefs, that in two hours it was almost destroyed; and at the fame time a party having reached the top of the hill, they became apprehensive of being furredoned, on which they infantly fled with precipitation, leaving a great number of killed and wounded behind them. The Americans after this battle met with no further reffiance of any confequence. They were fuffered to proce without interruption. On entering the country of the Indians, it appeared that they had been acquainted with agriculture and the arts of peace far be- yond what had been fuppofed. From General Sulli- van’s account it was learned, that the Indian houfes were large, convenient, and even elegant; their grounds were excellently cultivated, and their gardens abounded in fruit-trees and vegetables of all kinds fit for food. The whole of this fine country would now have been converted into a defart, had it not been for the humane forbearance of General Hand
and Colonel Durbin. The devastation, however, was extensive, and only to be justified by the savage character and example of their enemy.

We must now take a view of the transactions in the southern colonies; to which the war was, in the year 1779, principally transferred, that the reader may form some idea of the disasters which occurred there before it came to a last decisive. The successes of General Prevost in advancing to the very capital of South-Carolina have already been related, together with the obstacles which prevented him from becoming master of it at that time. Towards the end of the year 1779, however, Sir Henry Clinton set sail from New-York with a considerable body of troops, intended for the attack of Charleston, South-Carolina, in a fleet of ships of war and transports under the command of Vice-admiral Arbuthnot. They had a very tedious voyage; the weather was uncommonly bad; several of the transports were lost, as were also the greater part of the horses which they carried with them, intended for cavalry or other public uses; and an ordnance-ship likewise foundered at sea. Having arrived at Savannah, where they endeavoured to repair the damages sustained on their voyage, they proceeded from thence on the 10th of February, 1780, to North Edisto, the place of debarkation which had been previously appointed. They had a favourable and speedy passage thither; and though it required time to have the bar explored and the channel marked, the transports all entered the harbour the next day; and the army took possession of St. John’s Island, about 30 miles from Charleston, without opposition. Preparations were then made for paffing the squadron over Charleston bar, where the high-water spring-tides were only 19 feet deep: but no opportunity offered of going into the harbour till the 20th of March, when it was effected without any accident, though the American galleys continually attempted to prevent the English boats from founding the channel. The British troops had previously removed from John’s to James’s Island, and on the 29th of the same month they effected operations on Charleston neck. On the 14th of April they broke ground within 800 yards of the American works; and by the 9th the besiegers guns were mounted in battery. As soon as the army began to erect their batteries against the town, Admiral Arbuthnot embraced the first favourable opportunity of paffing Sullivan’s Island, upon which there was a strong fort of batteries, the chief defence of the harbour. He weighed on the 9th, with the Roebuck, Richmond, and Romulus, Blonde, Virginia, Raleigh, and Sandwich armed ships, the Renown bringing up the rear; and, paffing thro’ a severe fire, anchored in about two hours under James’s Island, with the loss of 27 seamen killed and wounded. The Rich mond’s fore-top-mast was shot away, and the ships in general sustained damage in their masts and rigging, though not materially in their hulls. But the Acesus transported, having on board some naval stores, grounded within gun-shot of Sullivan’s Island, and received so much damage that she was obliged to be abandoned and burnt.

On the 10th, Sir Henry Clinton (having received a reinforcement of 5000 men from New York) and Admiral Arbuthnot summoned the town to surrender to his majesty’s arms: but Major-general Lincoln, who commanded in Charleston, returned them an answer, declaring it to be his intention to defend the place. The batteries were now opened against the town; and from their effect the fire of the American advanced works considerably abated. It appears that the number of troops under the command of Lincoln were by far too few for defending works of such extent as those of Charleston; and that many of these were men little accustomed to military service, and very ill provided with clothes and other necessaries. Lincoln had been for some time expecting reinforcements and supplies from Virginia and other places: but they came in very slowly. Earl Cornwallis, and Lieutenant-colonel Tarleton under him, were also extremely active in intercepting such reinforcements and supplies as were sent to the American general. They totally defeated a considerable body of cavalry and militia which was proceeding to the relief of the town; and also made themselves masters of some posts which gave them in a great degree the command of the country, by which means great supplies of provisions fell into their hands. Tarleton was himself, however, defeated in a rencontre, with Lieutenant Colonel Washington, at the head of a regular corps of horse.

Such was the state of things, and Fort Sullivan had also been taken by the king’s troops, when on the 18th of May General Clinton again summoned the town to surrender; an offer being made, as had been done before, that if they surrendered, the lives and property of the inhabitants should be preferred to them. Articles of capitulation were then proposed by General Lincoln; but the terms were not agreed to by General Clinton. At length, however, the town being closely invested on all sides, and the preparations to storm it in every part being in great forwardness, and the ships ready to move to the assault, General Lin­coln, who had been applied to for that purpose by the inhabitants, surrendered it on such articles of capitulation as General Clinton had before agreed to. This was on the 4th of May, which was one month and two days after the town had been first summoned to surrender.

A large quantity of ordnance, arms, and ammunition, was found in Charleston; and, according to Sir Henry Clinton’s account, the number of prisoners taken in Charleston amounted to 5618 men, exclusive of near a thousand failors in arms; but according to General Lincoln’s account transmitted to the congress, the whole number of continental troops taken prisoners amounted to no more than 197. The remainder, therefore, included in General Clinton’s account, consisted of militia and inhabitants of the town. Several American frigates were also taken or destroyed in the harbour of Charleston.

The loss of Charleston evident itself excited a considerable alarm in America; and their popular writers, particularly the author of the celebrated performance entitled Common Sense, in some other pieces made use of it as a powerful argument to lead them to more vigorous exertions against Great Britain; that they might the more effectually and certainly secure their independence.

While Sir Henry Clinton was employed in his voy­age to Charleston, and in the siege of that place fions at the New York.
The garrison at New-York seem not to have been wholly free from apprehensions for their own safety. An intense frost, accompanied with great falls of snow, began about the middle of December 1779, and shut up the navigation of the port of New-York from the sea, within a few days after the departure of Admiral Arbuthnot and General Clinton. The severity of the weather increased to so great a degree, that towards the middle of January all communications with New-York by water were entirely cut off, and as many new ones opened by the ice. The inhabitants could fearfully be said to be in an inurable state. Horses with heavy carriages could go over the ice into the Jersey from one island to another. The passage on the North River, even in the widest part from New-York to Paulus Hook, which was 2000 yards, was about the 19th of January practicable for the heaviest cannon; an event which had been unknown in the memory of man. Provisions were soon after transported upon sledges, and a detachment of cavalry marched upon the ice from New-York to Staten Island, which was a distance of 11 miles.

The city of New-York being thus circumstanced, was considered as much exposed to the attacks from the continental troops: and it was strongly reported that General Washington was meditating a great stroke upon New-York with his whole force, by different attacks. Some time before this, Major-general Paullson, commandant at New-York, having received an address from many of the inhabitants, offering to put themselves in military array, he thought the present a favourable opportunity of trying the sincerity of their professions. Accordingly he issued a proclamation, calling upon all the male inhabitants from 16 to 60 to take up arms. The requisition was so readily complied with, that in a few days 40 companies from the fix wards of the city were enrolled, officered, and under arms, to the number of 2500, many substantial citizens serving in the ranks of each company. Other volunteer companies were formed, and the city was put into a very strong posture of defence.

No attack, however, was made upon New-York, whatever design might originally have been meditated; but an attempt was made upon Staten Island, where there were about 1800 men, under the command of Brigadier-general Sterling, who were well intrenched. General Washington, whose army was halted at Morris-Town, sent a detachment of 2700 men, with six pieces of cannon, two mortars, and some horses, commanded by Lord Sterling, who arrived at Staten Island early in the morning of the 15th of January. The advanced posts of the British troops retired upon the approach of the Americans, who formed the line, and made some movements in the course of the day; but they withdrew in the night after having burnt one house, pillaged some others, and carried off with them about 200 head of cattle.

Immediately on the arrival of the Americans on Staten Island, Lieutenat-general Knox had embarked 600 men to attempt a passage, and to support General Sterling; but the floating ice compelled them to return. It is, however, imagined, that the appearance of these transports, with the British troops on board, which the Americans could see towards the close of the day, induced the latter to make so precipitate a retreat.

After Charleston had surrendered to the King's troops, General Clinton issued two proclamations, and also circulated a hand-bill among the inhabitants of South-Carolina, in order to induce them to return to their allegiance, and to be ready to join the King's troops. It was said, that the helping hand of every man was wanted to re-establish peace and governement; and that as the commander in chief wished not to draw the kings friends into danger, while any doubt could remain of their success; fo, now, that this was certain, he trusted that one and all would heartily join, and by a general concurrence give effect to such necessary measures for that purpose as from time to time might be pointed out. Those who had families were to form a militia to remain at home, and occasionally to assemble in their own districts, when required, under officers of their own choosing, for the maintenance of peace and order. Those who had no families, and who could conveniently be spared for a time, it was presumed, would cheerfully assist his majesty's troops in driving their oppressors, acting under the authority of Congress, and all the miseries of war, far from that colony. For this purpose it was said to be necessary that the young men should be ready to serve whenever required, and to serve with the king's troops for any six months of the ensuing twelve that might be found requisite, under proper regulations. They might choose officers to each company to command them; and were to be allowed, when on service, pay, ammunition, and provisions, in the same manner as the king's troops. When they joined the army, each man was furnished with a certificate, declaring that he was only engaged to serve as a militia-man for the time specified; that he was not to be marched beyond North-Carolina and Georgia; and that, when the time was out, he was freed from all claims whatsoever of military service, excepting the common and usual militia-duty where he lived. He would then, it was said, have paid his debt to his country, and be intitled to enjoy undisturbed that peace, liberty, and property, at home, which he had contributed to secure. The proclamations and publications of General Clinton appear to have produced some effect in South Carolina; though they probably operated chiefly upon those who were before not much inclined to the cause of American independence. Two hundred and ten of the inhabitants of Charleston signed an address to General Clinton and Admiral Arbuthnot, soliciting to be readmitted to the character and condition of British subjects, the inhabitants of that city having been hitherto considered as prisoners on parole; declaring their disapprobation of the doctrine of American independence; and expressing their regret, that after the repeal of those statutes which gave rise to the troubles in America, the overtures made by his majesty's commissioners had not been regarded by the Congress. Sir Henry Clinton, in one of the proclamations issued at this time, declared, that if any persons should henceforward appear in arms in order to prevent the establishment of his majesty's government in that country, or should, under any pretence or authority whatsoever, attempt to compel any other per-
Some doubts having arisen in the congress, towards the close of the preceding year, about the propriety of their assembling in the city of Philadelphia, it was now resolved that they should continue to meet there: and a committee of three members was appointed, to report a proper place where buildings might be provided for the reception of the congress, together with an estimate of the expense of providing such buildings, and the necessary offices for the several boards. It was also resolved by the congress, that a monument should be erected to the memory of their late general Richard Montgomery, who fell at Quebec, in testimony of his signal and important services to the United States of America, with an inscription expressive of his amiable character and heroic achievements; and that the continental treasurers should be directed to advance a sum not exceeding L.300 to Dr Franklin to defray the expense; that gentleman being desired to cause the monument to be executed at Paris, or in some other part of France. It was likewise resolved by the congress, that a court should be established for the trial of all appeals from the court of admiralty of the United States of America, in cases of capture; to consist of three judges, appointed and commissioned by congress, and who were to take an oath of office; and that the trials in this court should be determined by the usage of nations.

The difficulties of the congress and of the people of America had been greatly increased by the depreciation of their paper currency. At the time when the colonies engaged in a war with Great Britain, they had no regular civil governments established among them of sufficient energy to enforce the collection of taxes, or to provide funds for the redemption of such bills of credit as their necessities obliged them to issue. In consequence of this state of things, their bills increased in quantity far beyond the sum necessary for the purpose of a circulating medium: and as they wanted at the same time of specific funds to rest upon for their redemption, they saw their paper-currency daily sink in value. The depreciation continued, by a kind of gradual progression, from the year 1777 to 1780: so that, at the latter period, the continental dollars were passed, by common consent, in most parts of America, at the rate of at least theirs below their nominal value. The imposibility of keeping up the credit of the currency to any fixed standard, occasioned great and almost insurmountable embarrassments in ascertaining the value of property, or carrying on trade with any sufficient certainty. Those who sold, and those who bought, were left without a rule wherein to form a judgment of their profit or their loss; and every species of commerce or exchange, whether foreign or domestic, was exposed to numberless and increasing difficulties. The consequences of the depreciation of the paper-currency were also felt with peculiar severity by such of the Americans as were engaged in their military services, and greatly augmented the other hardships. The requisitions made by the congress to the several colonies for supplies, were also far from being always regularly complied with; and their troops were not frequently in want of the most common necessaries; which naturally occasioned complaints and discontent among them. Such difficulties, resulted from their circumstances and situation, as perhaps no wisdom could have prevented. The cause of the Americans appears also to have suffered somewhat by their depending too much on temporary enlistments. But the congress endeavoured, towards the close of the year 1780, to put their army upon a more permanent footing, and to give all the satisfaction to their officers and soldiers which their circumstances would permit. They appointed a committee for arranging their finances, and made some new regulations respecting the war-office and treasury-board, and other public departments.

Notwithstanding the disadvantages under which they laboured, the Americans seemed to entertain no doubts but that they should be able to maintain their independence. The 4th of July was celebrated this year at Philadelphia with some pomp, as the anniversary of American independence. A commencement for conferring degrees in the arts was held the same day, in the hall of the university there; at which the president and members of the congress attended, and other persons in public offices. The Chevalier de la Luzerne, minister plenipotentiary from the French king to the United States, was also present on the occasion. A charge was publicly addressed by the provost of the university to the students; in which he said, that he could not but congratulate them on that auspicious day, which, according to the confessions and declarations of war, behold learning beginning to revive; and animated them with the pleasing prospect of seeing the sacred lamp of science burning with a still brighter flame, and scattering its invigorating rays over the unexplored declivities of this extensive continent; until the whole world should be involved in the united blaze of knowledge, liberty, and religion. When he stretched his views forward (he said), and surveyed the rising glories of America, the enriching consequences of their determined struggle for liberty, the extensive fields of intellectual improvement and useful inventions, in science and arts, in religion and government, through which the unsteady mind would range, with increasing delight, in quest of the undiscovered treasure which yet lay concealed in the animal, vegetable, and mineral kingdoms of the new world; or in the other fertile sources of knowledge with which it abounded,—his heart swelled with the pleasing prospect, that the sons of that initiation would distinguish themselves, in the different walks of life, by their literary contributions to the embellishments and increase of human happiness."

On the 10th of July, M. Ternay, with a fleet consisting...

A large body of French troops landed at Rhode Island. A committing of seven ships of the line, besides frigates, and a large body of French troops, commanded by the Count de Rochambeau, arrived at Rhode Island, and the following day 6000 men were landed there. A committee from the general assembly of Rhode Island was appointed to converse with the French general upon his arrival: whereupon he returned an answer, in which he informed them, that the king his master had sent him to the assistance of his good and faithful allies the United States of America. At present, he said, he only brought over a number of greater force defined for their aid; and the king had ordered him to affure them, that his whole power should be exerted for their support. He added, that the French troops were under the strictest discipline; and, acting under the orders of General Washington, would live with the Americans as their brethren.

A scheme was soon after formed, of making a combined attack with English ships and troops, under the command of Sir Henry Clinton and Admiral Arbuthnot, against the French fleet and troops at Rhode Island. Accordingly a considerable part of the troops at New-York were embarked for that purpose. General Washington having received information of this, passed the North River, by a very rapid movement, and, with an army increased to 12,000 men, proceeded with celerity towards King's Bridge, in order to attack New-York; but learning that the British general had changed his intentions, and disembarked his troops on the 3d of the month, General Washington recrossed the river and returned to his former station. Sir Henry Clinton and the Admiral had agreed to relinquish their design of attacking the French and Americans at Rhode-Island as impracticable for the present.

An unsuccessful attempt was also made about this time in the Jerseys by General Knoxhausen, with about 7000 British troops under his command, to surprize the advanced posts of General Washington's army. They proceeded very rapidly towards Springfield, meeting little opposition till they came to the bridge there, which was very gallantly defended by 170 of the continental troops, for 15 minutes, against the British army; but they were at length obliged to give up this unequal contest, with the loss of 37 men. After securing this pafs, the British troops marched into the place, and set fire to most of the houses. They also committed some other depredations in the Jerseys; but gained no laurels there, being obliged to return about the beginning of July without effecting any thing material.

But in South-Carolina the royal arms were attended with more success. Earl Cornwallis, who commanded the British troops there, obtained a signal victory over General Gates on the 16th of August. The Action began at break of day, in a situation very advantageous for the British troops, but very unfavourable to the Americans. The latter were much more numerous; but the ground on which both armies was flooded was narrowing to the small river. The attack was made by the British troops with great vigour, and in a few minutes the action was general along the whole line. It was at this time a dead calm with a little haziness in the air, which prevented the smoke from rising, occasioned so thick a darkness, that it was difficult to see the effects of a very heavy and well supported fire on both sides. The British troops either kept up a continuous fire, or desisted, as opportunities offered; and after an obstinate resistance during three quarters of an hour, threw the Americans into total confusion, and forced them to give way in all quarters. The continental troops behaved remarkably well, but the militia were soon broken, and left the former to oppose the whole force of the British troops. General Gates did all in his power to rally the militia, but without effect; the continental retreated in some order, but the rout of the militia was so great, that the British cavalry are said to have continued the pursuit of them to the distance of 22 miles from the place where the action happened. The losses of the Americans was very considerable; about 1000 prisoners were taken, and more are said to have been killed and wounded, but the number is not very accurately ascertained. Seven pieces of brass cannon, a number of colours, and all the ammunition-waggons of the Americans, were also taken. Of the British troops, the killed and wounded amounted to 213.

Among the prisoners taken was Major-general Baron de Kalb, a Prussian officer in the American service, who was mortally wounded, having exhibited great gallantry in the course of the action, and received 11 wounds. The British troops by which this victory was achieved, did not much exceed 2000, while the American army is said to have amounted to 6000; of which, however, the greatest part was militia.

Lieutenant-colonel Tarleton, who had greatly distinguished himself in this action, was detached the Lieut. Co. following day, with some cavalry and light infantry, amounting to about 350 men, to attack a corps of Americans under General Sumpter. He executed this service with great activity and military address. He procured good information of Sumpter's movements; and by force and concealed marches came up with and surprised him in the middle of the day on the 18th, near the Catawba fords. He totally destroyed or dispersed his detachment, which consisted of 700 men, killing 150 on the spot, and taking two pieces of brass cannon, 300 prisoners, and 44 waggons.

Not long after these events, means were found to detach Major-general Arnold, who had engaged for a considerable time in the cause of America, and who had exhibited much bravery in the support of it, from the interests of the congress. Major Andre, adjutant-general to the British army, was a principal agent in this transaction: or, if the overtaking of joining the king's troops came first from Arnold, this gentleman was the person employed to concert the affair with him. More must have been originally comprehended in the scheme than the mere deportation of the American cause by Arnold: The surrender of West-Point into the hands of the royal army, was the probable object; but whatever designs had been formed for promoting the views of the British government, they were frustrated by the apprehending of Major Andre. He was taken in disguise, after having assumed a false name, on the 23d of September, by three American soldiers, to whom he offered considerable rewards if they would have suffered him to escape, but without effect. Several papers written by Arnold were found upon him; and when Arnold had learnt that Major Andre was seized,
feized, he found means to get on board a barge, and to escape to one of the king's ships. General Washington referred the case of Major Andre to the examination and decision of a board of general officers, consisting of Major-general Green, Major-general Lord Sterling, Major-general the Marquis de la Fayette, Major-general the Baron de Steuben, two other major-generals, and eight brigadier-generals. Major Andre was examined before them, and the particulars of his case inquired into; and they reported to the American commander in chief, that Mr. Andre came on shore from the Vulture sloop of war in the night, on an interview with General Arnold, in a private and secret manner; that he changed his drefs within the American lines; and, under a feigned name, and in a disguised habit, passed the American works at Stony and Verplank's points, on the evening of the 22d of September; that he was taken on the morning of the 23d at Tarry-town, he being then on his way for New York: and that, when taken, he had in his possession several papers which contained intelligence for the enemy. They therefore determined, that he ought to be considered as a spy from the enemy; and that, according to the law and usage of nations, he ought to suffer death. Sir Henry Clinton, Lieutenant-general Robertson, and the late American general Arnold, all wrote pressing letters to General Washington on the occasion, in order to prevent the decision of the board of general officers from being put in force: But their applications were ineffectual. Major Andre was hanged at Tappan, in the province of New-York, on the 2d of October. He met his fate with great firmness; but appeared somewhat hurt that he was not allowed a more military death, for which he had solicited. He was a gentleman of very amiable qualities, had a taste for literature and the fine arts, and possessed many accomplishments. His death, therefore, was regretted even by his enemies; and the seeming severity of the determination concerning him was much exclaimed against in Great Britain. It was, however, generally acknowledged by impartial persons, that there was nothing in the execution of this unfortunate gentleman but what was perfectly consonant to the rules of war.

Arnold was made a brigadier-general in the king's service, and published an address to the inhabitants of America, dated from New-York, October 7, in which he endeavoured to justify his desertion of his cause. He said, that when he first engaged in it, he conceived the rights of his country to be in danger, and that duty and honour called him to his defence. A redress of grievances was his only aim and object; and therefore he acquiesced unwillingly in the declaration of independence, because he thought it precipitate. But what now induced him to desert their cause was the dishonour he had conceived at the French alliance, and at the refusal of Congress to comply with the last terms offered by Great Britain, which he thought equal to all their expectations and all to their wishes.

The Americans, however, accounted for the conduct of Arnold in a different and in a more probable and satisfactory manner. They alleged that he had so involved himself in debts and difficulties by his extravagant manner of living in America, that he had rendered it very inconvenient for him to continue there; that after the evacuation of Philadelphia by the British troops, Arnold, being invested with the command in that city, had made the house of Mr. Penn, which was the belt in the city, his head-quarters. This he had furnished in an elegant and expensive manner, and lived in a style far beyond his income. It was manifest, they said, that he could at first have no great aversion to the French alliance, because that when M. Gerard, minister plenipotentiary from the court of France, arrived at Philadelphia in July 1778, General Arnold early and earnestly solicited that minister, with his whole fortune, to take apartments and bed and board at his house, until a proper house could be provided by the order of the congress. This offer M. Gerard accepted, and continued with him some weeks. The French minister resided upwards of 14 months in Philadelphia; during which time General Arnold kept up the most friendly and intimate acquaintance with him, and their was a continued interchange of dinners, balls, routes, and concerts; so that M. Gerard must have believed, that in General Arnold he had found and left one of the warmest friends the court of France had in America. He was also one of the first in congratulating the Chevalier de la Luzerne, the second French minister. About this time complaints and accusations were exhibited against him by the government of Philadelphia for divers mal-practices; among which charges were, the appropriation of goods and merchandise to his own use, which he had feized as British property in Philadelphia in July 1778. It was determined by a court-martial that his conduct was highly reprehensible; but he was indulgently treated, and was therefore only reprimanded by the commander in chief General Washington. It was in these circumstances, the Americans said, bankrupted in reputation and fortune, loaded with debts, and having a growing and expensive family, that General Arnold first turned his thoughts towards joining the royal arms.

After the defeat of General Gates by Earl Cornwallis, that nobleman exerted himself to the utmost in South-Carolina extending the progress of the British arms, and with considerable effect. But one enterprise, which was conducted by Major Ferguson, proved unsuccessful. That officer had taken abundant pains to discipline some of the Tory militia, as they were termed; and with a party of these, and some British troops, amounting in the whole to about 1400 men, made incursions into the country. But on the 7th of October he was attacked by a superior body of Americans, at a place called King's mountain, and totally defeated. One hundred and fifty were killed in the action, and 810 made prisoners, of which 150 were wounded. Fifteen hundred stands of arms also fell into the hands of the Americans, whose loss was inconsiderable. But the following month Lieutenant-Colonel Stiles, with a party of 170, chiefly cavalry, attacked General Sampson, who is said to have had 1000 men, at a place called Black-Stocks, and obliged him to retire. Sampson was wounded, and about 120 of the Americans killed, wounded, or taken. Of the British troops about 50 were killed or wounded.

On the 3d of September, the Mercury, a congress Capture of packet, was taken by the Vessal, Captain Keppel, near Mr. Lau-

Newfoundland. On board this packet was Mr. Lau-

America.

Unhappy fate of Major Andre.

His amiable qualities.

Motives assigned by Arnold for his conduct.
At the beginning of the year 1781, an affair happened in America, from which expectations were formed by Sir Henry Clinton, that some considerable advance might be derived to the royal cause. The long continuance of the war, and the difficulties under which the congress laboured, had prevented their troops from being properly supplied with necessaries and conveniences. In consequence of this, on the first of January, the American troops that were hitted at Morris-town, and who formed what was called the Pennsylvania line, turned out, being in number 1,500, and declared, that they would serve no longer, unless their grievances were redressed, as they had not received their pay or been furnished with the necessary clothing or provisions. It is said that they were somewhat inflamed with liquor, in consequence of rum having been distributed to them more liberally than usual, the preceding day being considered as a kind of festival. A riot ensued, in which an officer was killed, and four wounded; five or six of the insurgents were also wounded. They then collected the artillery, stores, provisions, and wagons, and marched out of the camp. They pulled by the quarters of General Wayne, who sent a message to them, requesting them to desist, or the consequences would prove fatal. They refused, and proceeded on their march till the evening, when they took post on an advantageous piece of ground, and elected officers from among themselves. On the second day they marched to Middlebrook, and on the third to Princeton, where they fixed their quarters. On that day a flag of truce was sent to them from the officers of the American camp, with a message, desiring to know what were their intentions. Some of them answered, that they had already served longer than the time for which they were enlisted, and would serve no longer; and others, that they would not return, unless their grievances were redressed. But at the same time they repeatedly, and in the strongest terms, denied being influenced by the least dissatisfaction to the American cause, or having any intentions of defecting to the enemy.

Intelligence of this transactin was soon conveyed to New-York. A large body of British troops were immediately ordered to hold themselves in readiness to move on the shortest notice, it being hoped that the American provincials might be induced to join the royal army. Messengers were also sent to them from General Clinton, acquainting them that they should directly be taken under the protection of the British government; that they should have a free pardon for all former offences; and that the pay due to them from the congress should be faithfully paid them without any expectation of military service, unless it should be voluntary, upon condition of their laying down their arms, and returning to their allegiance. It was also recommended to them to move beyond the South River; and when they were assured, that a body of British troops should be ready to protect them whenever they defined it. These propositions were rejected with disdain; and they even delivered up two of Sir Henry Clinton's messengers to the congress. Joseph Reid, Esq; president of the state of Pennsylvania, afterwards repaired to them at Princeton, and an accommodation took place: such of them as had served out their full terms were permitted to return to their own homes, and others again joined the American army, upon receiving satisfactory assurances that their grievances should be redressed.

On the 11th of January Lord Cornwallis advanced Exactions towards North Carolina. He wished to drive Gen. Lord Morgan from his station, and to deter the inhabitants from joining him. The execution of this business was intrusted to Lieut. Col. Tarleton; who was detached with the light and legion infantry, the furlers, the first battalion of the 71st regiment, about 390 cavalry, two field pieces, and an adequate proportion of men from the royal artillery, numbered of 1,500 in the whole. This detachment, after a progress of some days, by fatiguing marches, at about ten o'clock on the evening of the 16th of January, reached the ground on which Morgan had quitted, but a few hours before. The pursuit recommenced by two o'clock the next morning, and was rapidly continued through marshes and broken grounds till day light, when the Americans were discovered in front. Two of their videttes were taken soon after, who gave information that Morgan had halted and prepared for action, at a place called the Cowpen, near Pacolet river. The British, beside their field pieces, had the superiority in infantry, in the proportion of five to four, and in cavalry of more than three to one. Beside, nearly two thirds of the troops under Morgan were militia. Morgan had obtained early intelligence of Tarleton's force and advances; and had drawn up his men in two lines. The whole of the North and South Carolina militia present was put under the command of Col. Pickens, and formed the first line; which was advanced a few hundred yards before the second, with orders to form on the right of the second when forced to retire. The second line consisted of the light infantry under Lieut. Col. Howard, and the Virginia riflemen. Lieut. Col. Washington, with his cavalry, and about forty-five militia men, mounted and equipped with swords, under Lieut. Col. M'Call, were drawn up at some distance in the rear of the whole. The open woods in which they were formed, was neither secured in front, flank or rear. Without the delay of a single moment, and in spite of extreme fatigue, the light legion infantry and furlers were ordered to form in line. Before the order was executed, and while Major Newmarth, who commanded the latter corps, was posting his officers, the line, though far from complete, was led to the attack by Tarleton himself. The British advanced with a howl, and poured in an incessant fire of musketry. Col. Pickens directed the militia not to fire till the British were within forty or fifty yards. This order, though executed with great firmness and success, was not sufficiently
sufficient to repel the enemy. The American militia gave way on all quarters. The British advanced rapidly, and engaged the second line. The Continentals, after an obstinate conflict, were compelled to retreat to the cavalry. Col. Ogilive, with his troop of forty men, had been ordered to charge the right flank of the Americans, and was engaged in cutting down the militia; but being exposed to a heavy fire, and charged at the same time by Washington's dragoons, was forced to retreat in confusion. A great number of the British infantry officers had already fallen, and nearly a proportionable number of privates. The remainder being too few and too much fatigued, could not improve the advantage gained over the Continentals; and Tarleton's Legion cavalry standing aloof instead of advancing, Lieut. Col. Howard seized the favourable opportunity, rallied the Continentals, and charged with fixed bayonets, nearly at the same moment when Washington made his successful attack. The example was instantly followed by the militia. Nothing could exceed the abandonment of Tarleton's Legion occasioned by their unexpected charges. Their advance fell back, and communicated panic to others, which soon became general. Two hundred and fifty horses which had not been engaged, fled through the woods with the utmost precipitation, bearing down such officers as opposed their flight; and the cannon were soon feized by the Americans, the detachment from the train either killed or wounded in their defence. The greatest confusion now followed among the infantry. In the moment of it Lieut. Col. Howard called to them to lay down their arms, and promised them good quarters. Some hundreds accepted the offer, and surrendered. The first battalion of the 71st regiment, and two British light infantry companies laid down their arms to the American militia. The only body of infantry that escaped, was a detachment left at some distance to guard the baggage. Early intelligence of their defeat was conveyed to the officer commanding that corps by some loyalists. What part of the baggage could not be carried off immediately destroyed; and with his men mounted on the waggon and spare horses, he retreated to Lord Cornwallis. The British had 70 commissioned officers, and upward of 100 rank and file killed. Two hundred wounded, 29 commissioned officers, and above 500 privates prifoners, fell into the hands of the Americans, besides two pieces of artillery (first taken from the British at Saratoga, then retaken by them at Camden, and now recovered by the Americans) two standards, 800 muskets, 35 baggage waggons, and upward of 100 dragoon horses. Washington pursued Tarleton's cavalry for several miles; but the far greater part of them escaped. They joined their army in two separate divisions. One arrived in the neighbourhood of the British encampment upon the evening of the same day; the other under Tarleton appeared the next morning. Although Tarleton's corps had waged a most cruel warfare, and their progess had been marked with burnings and devastations, not a man of them was killed, wounded, or even insulted after he had surrendered. The Americans had only twelve men killed and sixty wounded.

This defeat of the troops under Tarleton, while it reanimated the despairing friends of America, and brightened their hopes, was a severe stroke to Lord Cornwallis, as the loss of his light infantry was a great disadvantage to him. The day after the event he employed in collecting the remains of Tarleton's corps, and in endeavouring to form a junction with General Leflie, who had been ordered to march towards him with a body of British troops from Wyneborough. Considerable exertions were then made by part of the army, without baggage, to retake the prifoners in the hands of the Americans, and to intercept General Morgan's corps on its retreat to the Catawba. But that American officer, after his defeat of Tarleton, had made forced marches up into the country, and crossed the Catawba the evening before a great rain, which swelled the river to such a degree, as to prevent the royal army from crossing for several days; during which time the British prifoners were got over the Yadkin; whence they proceeded to Dan River, which they also passed, and on the 14th of February had reached Court-House, in the province of Virginia.

Lord Cornwallis employed a halt of two days in collecting some flour, and in destroying numerous baggage and all his waggons, excepting those laden with hospital stores, salt, and ammunition, and four regiments empty in readiness for sick or wounded. Being thus freed from all unnecessary incumbrance, he marches marched through North-Carolina with great rapidity, through and penetrated to the remotest extremities of that province on the banks of the Dan. His progess was sometimes impeded by parties of the militia, and some skirmishes ensued, but he met with no very considerable opposition. On the 1st of February the king's troops crossed the Catawba at M'Cowan's Ford, where General Davison, with a party of American militia, was posted, in order to oppose their passage; but being falling by the first discharge, the royal troops made good their landing, and the militia retreated. When Lord Cornwallis arrived at Hillsborough, he erected the king's standard, and invited, by proclamation, all loyal subjects to repair to it, and to stand forth and take an active part in assisting his Lordship to restore order and government. He had been taught to believe that the king's friends were numerous in that part of the country: but the event did not confirm the truth of the representations that had been given. The Royalists were but few in number, and some of them too timid to join the king's standard. There were, indeed, about 200 who were proceeding to Hillsborough, under Colonel Pyle, in order to avow their attachment to the royal cause; but they were met accidentally, and surrounded by a detachment from the American army, by whom most of them were cut in pieces. Meanwhile General Greene was marching with great expedition with the troops under his command, in order to form a junction with other corps of American troops, that he might thereby be enabled to put some effectual stop to the progess of Lord Cornwallis.

In other places some considerable advantages were obtained by the royal arms. On the 4th of January, Large some ships of war with a number of transports, on quantities board which was a large body of troops under the command of Brigadier-general Arnold, arrived at W°Creford over, about 140 miles from the Capes of Virginia, by Arnold, where the troops immediately landed and marched to Richmond, which they reached without opposition, the
the militia that was collected having retreated on their approach. Lieutenant-colonel Simcoe marched from hence with a detachment of the British troops to Wil­lington, where they destroyed one of the finest found­eries for cannon in America, and a large quantity of stores and cannon. General Arnold, on his arrival at Rich­mond, found there large quantities of salt, rum, fail-­cloth, and tobacco, the last of which he destroyed to a very great amount. The British troops afterwards attacked and dispersed some small parties of the Americans, took some stores and a few pieces of cannon, and on the 20th of the same month marched into Pow­mouth. On the 25th, Captain Barclay, with several ships of war, and a body of troops under the command of Major Craig, arrived in Cape-Fear River. The troops landed about nine miles from Wilmington, and on the 28th entered that town. It was understood that their having possession of that town, and being masters of Cape-Fear River, would be productive of very ben­eficial effects to Lord Cornwallis's army.

General Greene having effected a junction about the 10th of March with a continental regiment of what were called eighteen months men, and two large bodies of militia belonging to Virginia and North-Carolina, formed a resolution to attack the British troops under the command of Lord Cornwallis. The American army marched from the High Rock Ford on the 12th of the month, and on the 14th arrived at Guildford. Lord Cornwallis, from the information he had received of the motions of the American general, concluded what were his designs. As they approached more nearly to each other, a few skirmishes ensued between some advanced parties, in which the advantage was sometimes gained by the Americans and sometimes by the British. On the morning of the 15th, Lord Corn­wallis marched with his troops at day-break in order to meet the Americans or to attack them in their encamp­ment. About four miles from Guildford, the advanced guard of the British army, commanded by Lieutenant-colonel Stuart, fell in with a corps of American rifemen, consisting of Lieutenant-colonel Lee's legion, some Back-Mountain men and Virginia militiamen, with whom he had a severe skirmish, and was, at length, obliged to retreat.

The greater part of the country in which the action happened is a wilderness, with a few cleared fields inter­spersed. The American army was posted on a rising ground about a mile and a half from Guildford court house. It was drawn up in three lines: the front line was composed of the North-Carolina militia, under the command of the generals Butler and Eaton; the second line, of Virginia militia, commanded by the generals Stephens and Lawson, forming two bri­gades; the third line, consisting of two brigades, one of Virginia and one of Maryland continental troops, commanded by General Huger and Colonel Williams. Lieutenant-colonel Washington, with the dragoons of the first and second regiments, a detachment of light infantry composed of continental troops, and a regiment of rifemen under Colonel Lynch, formed a corps of obser­vation for the security of their right flank. Lieu­tenant-colonel Lee, with his legion, a detachment of light infantry, and a corps of rifemen under Colonel Campbell, formed a corps of observation for the security of their left flank. The attack of the American army was directed to be made by Lord Cornwallis in the following order: On the right, the regiment of Bofe and the 71st regiment, led by Major-general Leffie, and supported by the first battalion of guards; on the left, the 23d and 33d regiments, led by Lieu­tenant-colonel Webster, and supported by the gren­adiers and second battalion of guards commanded by Bri­gadier-general O'Hara; the Yagers and light infantry of the guards remained in a wood on the left of the guns, and the cavalry in the road, ready to act as circumstances might require.

About half an hour after the action commenced by a cannonade, which lasted about twenty minutes; when the British troops advanced in three columns and attacked the North-Carolina bri­gades with great vigour, and soon obliged part of these troops to quit the field: but the Virginia militia gave them a warm reception, and kept up a heavy fire for a long time, till, being beaten back, the action became general almost everywhere. The American corps under the lieutenant-colonels Washington and Lee were also warmly engaged, and did considerable ex­ecution. Lieutenant-colonel Tarleton had directions to keep his cavalry compact, and not to charge with­out positive orders, excepting to protect any of the corps from the most evident danger of being defeated. The excessive thickets of the woods rendered the Bri­tish bayonets of little use, and enabled the broken corps of Americans to make frequent stands with an irregular fire. The second battalion of the guards first gained the clear ground near Guildford court-house, and found a corps of continental infantry, superior in number, formed in an open field on the left of the road. Desirous of signallizing themselves, they immediately attacked and soon defeated them, taking two fix pounders: but as they pursued the Americans into the wood with too much ardour, they were thrown into confusion by a heavy fire, and instantly charged and driven back into the field by Lieutenant-colonel Washington's dra­goons, with the loss of the two fix pounders they had taken. But the American cavalry were at first re­pulsed, and the two six pounders again fell into the hands of the British troops. The British troops having at length broken the second Maryland regiment, and turned the left flank of the Americans, got into the The American rear of the Virginia brigade, and appeared to be gaining­i them their right, which would have encircled the whole of the continental troops, when Gen. Greene thought it prudent to order a retreat. Many of the American militia dispersed in the woods; but the continental troops retreated in good order to Reedy-Fork River, and crossed at the ford about three miles from the field of action, and there halted. When they had collected their foragers, they retreated to the iron-works, ten miles distant from Guildford, where they garrisoned. They lost their artillery and two wagons laden with ammunition. It was a hard fought action, and lasted an hour and a half. Of the British troops, the losses, as stated by Lord Cornwallis, was 532 killed, wounded, and missing. General Greene in his ac­count of the action transmitted to the Congress, stated the losses of the continental troops to amount to 29 killed, wounded, and missing; but he made no estimate of the losses of the militia, which was some what more than 100. Lieutenant-colonel Stuart was killed in the ac­tion;
The British troops underwent great hardships in the course of this campaign; and in a letter of Lord Cornwallis's to Lord George Germain, dated March 17th, he observed, that "the soldiers had been two days without bread." His lordship quitted Guilford three days after the battle which was fought in that place; and on the 7th of April, after a retreat marked with proofs of great alarm and precipitation, arrived in the neighbourhood of Wilmington. Soon after, General Greene, notwithstanding his late defeat, endeavoured to make some vigorous attempts against the king's forces in South-Carolina. Lord Rawdon had been appointed to defend the post of Camden, with about 800 British and provincials; and on the 19th of April General Greene appeared before that place with a large body of continental and militia. He found it, however, impossible to attempt to form the town with any prospect of success; and therefore endeavoured to take such a position as should induce the British troops to fall back on their works. He posted the Americans about a mile from the town, on an eminence which was covered with woods, and flanked on the left by an impassable swamp. But on the morning of the 25th, Lord Rawdon marched out of Camden, and attacked General Greene in his camp. The Americans made a vigorous resistance, but were at length compelled to give way; and the pursuit is said to have been continued three miles. For some time after the action commenced, General Greene entertained great hopes of defeating the British troops; in which, as the Americans were superior in point of numbers, he would probably have succeeded, had not some capital military errors been committed by one or two of the officers who served under him. On the American side Colonel Washington had behaved extremely well in this action, having made upwards of 200 of the English prisoners, with 10 or 12 officers, before he perceived that the Americans were abandoning the field of battle. The loss of the English was about 400 killed and wounded. Upwards of 100 of the Americans were taken prisoners; and, according to the account published by General Greene, they had 126 killed and wounded. After this action, Greene retreated to Rugeley's, 12 miles from Camden, in order to collect his troops and wait for reinforcements.

Notwithstanding the advantage which Lord Rawdon had obtained over General Greene at Camden, that nobleman soon after found it necessary, having burned the goal, mills, many private houses, and a part of his own baggage, to quit that post; and the Americans made themselves masters of several other posts that were occupied by the king's troops, and the garrisons of which were obliged to surrender themselves prisoners of war. These troops were afterwards exchanged under a cartel which took place between Lord Cornwallis and General Greene for the release of all prisoners of war in the southern district. After these events, General Greene laid close siege to Ninety-six, which was considered as the most commanding and important of all the posts in the back country; but on the 19th of June he attempted to storm the garrison, but was repulsed by the gallantry of the British troops, with the loss of about 150 killed, wounded, and missing.

General Greene then raised the siege, and retired with his army behind the Saluda, to a strong situation, within 16 miles of Ninety-six.

On the 18th of April a large body of British troops, under the command of Major-general Phillips and Brigadier-general Arnold, embarked at Portfinoath in Virginia, in order to proceed on an expedition for the purpose of destroying some of the American stores. A party of light-infantery were sent 10 or 12 miles up the Chickahominy; where they destroyed several armed ships, sundry ware-houses, and the American state ships. At Petersburg, the English destroyed 4000 hogheads of tobacco, one ship, and a number of small vessels on the banks and in the river. At Chesterfield court-house, they burnt a range of barracks for 2000 men and 300 barrels of flour. At a place called O'born's, they made themselves masters of several vessels loaded with cordage and flour, and destroyed about 2000 hogheads of tobacco, and sundry vessels were sunk and burnt. At Warwick, they burnt a magazine of 500 barrels of flour, five fine mills belonging to Colonel Carey, a large range of public rope-walks and store-houses, tan and bark houses full of hides and bark, and great quantities of tobacco. A like destruction of stores and goods was made in other parts of Virginia.

From the account already given of some of the principal military operations of the present year in America, it appears, that though advantages had been gained by the royal troops, yet no event had taken place from which it could rationally be expected that the final termination of the war would be favourable to Great-Britain. It was also a disadvantageous circumstance, that there was a misunderstanding between Admiral Arbuthnot and Sir Henry Clinton, and a mutual disapprobation of each other's conduct. This was manifested from their dispatches to government, and especially from those of General Clinton, whose expressions respecting the conduct of the admiral were by no means equivocal.

On the 16th of March 1781, a partial action happened off the Cape of Virginia, between the British and one fifty-gun ship, and a French squadron consisting of the same number of ships of the line, and one forty-gun ship. Some of the ships in both fleets received considerable damage in the action, and the loss of the English was 30 killed and 73 wounded; but no ship was taken on either side. The British fleet, however, claimed the advantage; as the French were obliged to retire, and were supposed to be prevented by this action from carrying troops upon the Chickapeak, in order to attack General Arnold and impede the progress of Lord Cornwallis. But it was thought an unfortunate circumstance, that some time before this engagement the Romulus, a ship of 44 guns, was captured by the French off the Cape of Virginia.

Lord Cornwallis, after his victory over General Greene at Guildford, proceeded, as we have seen, to
Wilmington, where he arrived on the 7th of April. But before he reached that place, he published a proclamation, calling upon all loyal subjects to stand forth and take an active part in restoring good order and government; and declaring to all persons who had engaged in the present rebellion against his majesty's authority, but who were now convinced of their error, and defirous of returning to their duty and allegiance, that if they would surrender themselves with their arms and ammunition at head quarters, or to the officer commanding in the districts contiguous to their respective places of residence, on or before the 20th of that month, they should be permitted to return to their homes upon giving a military parole; they would be protected, in their persons and properties, from all forts of violence from the British troops; and would be restored, as soon as possible, to all the privileges of legal and constitutional government. But it does not appear that any considerable number of the Americans were allure by the promises to give any evidences of their attachment to the royal cause.

On the 20th of May, his Lordship arrived at Petersburg in Virginia, where he joined a body of British troops that had been under the command of Major-general Philips; but the command of which, in consequence of the death of that officer, had devolved upon Brigadier-general Arnold. Before this junction he had encountered considerable inconveniences from the difficulty of procuring provisions and forage; so that in a letter to Sir Henry Clinton, he informed him, that his cavalry wanted everything, and his infantry everything but shoes. He added, that he had experienced the difficulties of marching hundreds of miles in a country chiefly hostile, without one active or useful friend, without intelligence, and without communication with any part of the country.

On the 26th of June, about six miles from Williamsburg, Lieutenant-colonel Simcoe, and 350 of the queen's rangers, with 80 mounted yeagers, were attacked by a much superior body of the Americans; but whom they repulsed with great gallantry and with equal success, making four officers and twenty private men prisoners. The loss of the Americans in this action is said to have been upwards of 120, and that of the British troops not more than 40.

On the 6th of July an action happened near the Green Springs in Virginia, between a reconnoitring party of the Americans under General Wayne, amounting to about 800, and a large part of the British army under Lord Cornwallis; in which the Americans had 127 killed and wounded, and the loss of the royal troops is suppos'd to have been considerably greater. It was an action in which no small degree of military skill and courage was exhibited by the Americans. In a variety of skirmishes, the Marquis de la Fayette very much distinguished himself, and displayed the utmost ardour in the American cause.

In South-Carolina, an action happened on the 9th of September near the Eutaw Springs, between a large body of British troops under the command of Lieutenant-colonel Stuart and an equal body of Americans, under the command of General Greene. It was an obstinate engagement and lasted near two hours. The British, with a considerable loss, were in the first part of the battle routed in all quarters, but some having taken

polt in a piquett garden, and others thrown themselves into a brick house, the eagerness of the American pursuit was considerably checked, and gave Colonel Stuart an opportunity on the evening of the next day, to abandon the Eutaw, and march towards Charles- ton, taking a number of his wounded, and about one thousand stand of arms.

In the course of the same month, General Arnold was sent on an expedition against New-London, in Connecticut, where he destroyed a great part of the shipping, and an immense quantity of naval stores, European manufactures, and East and West India commodities. The town itself was also burnt, which is said, but untruly, to have been unavoidable, on account of the expoliations of great quantities of gun-powder which happened to be in the store-houses that were set on fire. A fort, of which it was thought necessary to gain possession in this expedition, was not taken without considerable loss. This was Fort Grifwold, which was defended by the Americans with great gallantry, and the assault was made by the English with equal bravery. The British troops entered the works with fixed bayonets, and were opposed with great vigour by the garrison with long pears. After a most obstinate defence of near forty minutes, the assailants gained possession of the fort, in which 85 Americans were found dead, and 60 wounded, most of them mortally; but of the killed, it is painful to observe, that the greater number fell after the British entered the fort, and when resistance had ceased. Of the British troops Major Montgomery was killed by a pear in entering the American works; and 192 men were also killed and wounded in this expedition.

Notwithstanding the advantages that Lord Cornwallis had obtained over the Americans, his situation in Virginia began by degrees to be very critical; and the rather because he did not receive those reinforcements and supplies from Sir Henry Clinton, of which he had formed expectations, and which he conceived to be necessary to the success of his operations. Indeed, the commander in chief was prevented from sending those reinforcements to Lord Cornwallis which he otherwise might have done, by his fears respecting New-York, against which he entertained great apprehensions that General Washington intended to make a very formidable attack. In fact, no able American general had this object in view; and while the attack was in ferment, a letter from him detailing the particulars of the intended operations of the campaign, being intercepted, fell into the hands of Sir Henry Clinton. After the plan was changed, the royal commander was so much under the impression of the intelligence contained in the intercepted letter, that he believed every movement towards Virginia to be a feint, calculated to draw off his attention from the defence of New-York. Under the influence of this opinion he bent his whole force to strengthen that post, and suffer the French and American armies to pass without any molestation. When the first opportunity of striking at them was elapsed, then for the first time he was brought to believe that the allies had fixed on Virginia, for the theatre of their combined operations. As truth may be made to answer the purposes of deception, so no feint of attacking New-York, could have been more successful than the real inten-
Number of forces.

378

All the American and French troops formed a junction at Williamsburg. The Marquis de la Fayette had been joined by 3000 under St. Simon some days before the 25th of September. The whole regular force thus collected amounted to between 11 and 12,000 men. The militia of Virginia were also called out to service, and were commanded by Gen. Nelson. On the 27th Gen. Washington gave out in general orders—"If the enemy should be tempted to meet the army on its march, the general particularly enjoins the troops to place their principal reliance on the bayonet, that they may prove the vanity of the boast which the British make of their peculiar prowess in deciding battles with that weapon." The next morning the army marched, and halted about two miles from York Town just before fun set. The officers and soldiers were ordered to lie on their arms the whole night. On the 28th, Col. Scammel (being officer of the day) in approaching the enemy's outer works, to see if they had really left them, was mortally wounded and taken prisoner by a party of the enemy's horse, which lay secreted. This day Lord Cornwallis was closely invested in York Town. The French extended from the river above the town to a morass in the centre, where they were met by the Americans, who occupied the opposite side from the river to that spot. The post at Gloucester Point was, at the same time, invested by the Duke de Lauzun with his legion, and a number of Virginia militia under General Weedon.

Before the troops left Williamsburg, Gen. Washington received a letter from the Count de Graaff, informing him that in case of the enemy's putting the fleet as well as the army in a state of marching, the count conceived it to be his duty to go out and meet them at sea, instead of fighting in a confined situation. This information exceedingly alarmed the general, who instantly saw the probability of the British fleet manoeuvring in such manner, as to reinforce or withdraw Lord Cornwallis. To prevent a measure pregnant with so much evil, his excellency wrote to the count on the 26th: "I am unable to describe the painful anxiety under which I have laboured since the reception of your letter of the 23d instant. It obliges me warmly to urge a perverence in the plan agreed upon. The attempt upon York, under the protection of your fleet, is as certain of success as a superior force and a superiority of measures can render any military operation. The capture of the British army is a matter so important in itself and in its consequences, that it must greatly tend to bring an end to the war. If your excellency quits the Bay, an acces is open to relieve York, of which the enemy will instantly avail themselves. The consequence of this will be, not only the disgrace, but the probable disbanded of the whole army; for the present feat of war being such, as absolutely precludes the use of waggons, from the great number of large rivers which intersect the country, there will be a total want of provisions. This province has been..."
Lord Cornwallis was sufficiently strong for fighting the Marquis de la Fayette, even after he had been joined by St Simou and is thought to have been mistaken in not engaging them either separately or together. The moment he heard that the allied troops arrived, he ordered his forces to retreat through North Carolina to Charleston, from thence in time, as would be done under Admiral Digby, to be true, their whole force united could be such as to give them any hope of success in the attacking your fleet. I am to press your excellency to peruse in the scheme so happily concerted between us. Permit me to add, that the absence of your fleet from the Bay may frustrate our design upon the garrison at York. For, in the present situation, Lord Cornwallis might evacuate the place with the loss of his artillery, baggage, and a few men—faecacies, which would be highly justifiable, from the desire of saving the body of the army.—The Marquis de la Fayette carries this. He is not to pass the Cape for fear of accident, in case you should be at sea. This letter, with the Marquis's persuasions, had the desired effect; and the same hour when the combined army appeared before York-Town, the French fleet was brought to the mouth of York river, and by their position effectually covered all subsequent military operations, and prevented either the retreat or succour of Lord Cornwallis's army by water. The posts of York and Gloucester were the most favourable of any in the country for besieging the British, and preventing their escape, when the siege was supported by a superior land and naval force.

Lord Cornwallis was sufficiently strong for fighting the Marquis de la Fayette, even after he had been joined by St Simou; and is thought to have been mistaken in not engaging them either separately or together. The moment he heard that the allied troops were at the Head of Elk, and that de Graffé was arrived with so powerful a fleet at the Cheapeaks, his lordship should have pushed off for Charleston. Therefore it was that General Greene wrote to Baron Steuben on the 17th—"Nothing can save Cornwallis but a rapid retreat through North Carolina to Charleston." His lordship's conduct was influenced by an expectation of a reinforcement from Sir Henry Clinton, and a full persuasion that those exertions would be made at New-York, and such a naval strength would arrive from hence in time, as would effectually relieve him. This may be gathered from his writing on the 16th: "If I had no hopes of relief, I would rather risk an action than defend my half-finished works. But as you say, Admiral Digby's hourly expected, and have promised exertions to assist me, I do not think myself justifiable in putting the fate of the war upon so desperate an attempt." He must have meant that of fighting Fayette and St Simou, for the troops of Generals Washington and Rochambeau did not arrive till afterward. Fayette had taken a strong position; but the attempt would not have appeared so desperate to his lordship, had he known the real number of the enemy covered.

The trenches were opened by the enemy's batteries on the 6th of October, at 600 yards distance from Cornwallis's works. The night being dark and rainy was well adapted to the service, in which there was not a man hurt. In the afternoon of the 9th, the redoubts and batteries being completed, a general discharge of 24 and 18 pounders and of 10 inch mortars commenced by the Americans on the right, and continued all night without intermission. The next morning, the French opened their batteries on the left, and a tremendous roar of cannon and mortars was continued for six or seven hours without ceasing. There was an incessant fire through the succeeding night. By one of the French shells, the Charon of 44 guns and a transport ship were set on fire and burnt. The following morning, the enemy's other guard ship was fired by one of the American shells and consumed. At night, the besiegers opened their second parallel, 200 yards from the works of the besieged. The Americans had 3 men killed and 1 wounded by a French cannon, which fired too low. On the 14th in the evening, an American battalion was ordered into the second parallel, and to begin a large battery in advance on the right. A few minutes before they began to break ground, the enemy kept a constant fire upon them: one of their shells burst in centre of the battalion, and killed a captain and one private, and wounded a second. The fire of the besieged was very great through the night; and it was thought that the besiegers lost as many men within 24 hours at this period, as they had done nearly the whole siege before.

Two redoubts, which were advanced about 200 yards on the left of the British, greatly impeded the progress of the combined armies. An attack on these was therefore proposed.—To excite a spirit of emulation the redoubt of the one was committed to the French, of the other to the Americans. The light infantry of the latter were commanded by the Marquis de la Fayette; and the service was allotted to a fleet corps. The Marquis said to General Washington—"The troops should retaliate on the British, for the cruelties they have practiced." The general answered—"You have full command, and may order as you please." The marquis ordered the party to remember New London, and to retaliate, by putting the men in the redoubt to the word after having carried it. The men marched to the assault with unloaded arms, at dark on the night of the 14th, passed the abatis and palisades, and attacking on all sides carried the redoubt in a few minutes, with the loss of 8 killed and 23 wounded. Lieut. Col. Laurens personally took the commanding officer. The colonel's humanity and that of the Americans fo overcame their sentiments, that they spared the British. When bringing them off as prisoners, they said among themselves—"Why! how is this! We were ordered to put them to death." Being asked by others why they had not done it, they answered—"We could not, when they begged and cried to upon their knees for their lives." About five of the British were killed, and 1 major, 1 captain, and 1 ensign, and 20 privates captured. Col. Hamilton, who conducted the enterprise with much address and intrepidity, in his report to the marquis, mentioned, to the honor of his regiment—"that, incapable of imitating examples of barbarity, and forgetting recent provocations, they spared every man that ceased to resist." The French were equally successful on their side. They carried the
the redoubt committed to them with rapidity, but left a considerable number of men. These two works being taken into the second parallel facilitated the subsequent operations.

The British were fo weakened by the fire of the combined armies, but chiefly by sickness, that Lord Cornwallis could not venture any considerable number in the making of fallies. The present emergency however was such, that a little before day break of the morning of the 16th he ordered a fortie of about 400 men, under Lieut. Col. Abercromby, to attack two batteries which appeared to be in the greatest forwardness, and to spike the guns. Two detachments were appointed to the service; and both attacks were made with such impetuosity, that the redoubts which covered the batteries, were forced, and eleven pieces of cannon spiked. The French troops, who had the guard of that part of the intrenchment, suffered considerably. This successful action did honor to the officers and troops engaged, but produced no essential benefit. The cannon, being hastily spiked, were soon rendered again serviceable; and the combined forces were fo industrious, that they finished their batteries, opened them about 4 o'clock in the afternoon, and fired briskly. Their several batteries were now covered with near 100 pieces of heavy ordnance; and the British works were fo destroyed, that they could not show a single gun.

Thus was Lord Cornwallis reduced to the necessity of preparing for a surrender, or of attempting an escape. He determined upon the latter. Boats were prepared under different pretenses, for the reception of the troops by ten at night, in order to pass them over to Gloucester Point. The arrangements were made with the utmost secrecy. The intention was to abandon the baggage, and to leave a detachment behind to capitulate for the towns near York, and for the sick and wounded, his lordship having already prepared a letter on the subject, to be delivered to Gen. Washington after his departure. The first embarkation was from Gloucester Point, and the greater part of the troops were already landed, when the weather, which was before moderate and calm, infinitely changed to a most violent storm of wind and rain. The boats with the remaining troops were all driven down the river, and the design of passing was not only entirely frustrated, but the absence of the boats rendered it impossible to bring back the troops from Gloucester. Thus weakened and divided, the army was in the most imminent danger. The boats however returned; and the troops were brought back without much loss in the course of the forenoon.

Masters were now hastening to a crisis, which could not be longer averted. The British works were sinking under the weight of the American and French artillery. The continuance of the allied fire, only for a few more hours, would reduce them to such a condition that it would be rashness to attempt their defence.—The time for expecting relief from New York was elapsed. The strength and spirit of the royal troops were worn down by constant watching, and unremitting fatigue. Lord Cornwallis therefore sent out a flag at 10 o'clock in the morning of the 17th with a letter to General Washington, requesting a capitulation of arms for twenty-four hours, and that commissioners might be appointed for digesting the terms of capitulation. An answer was given; and a reply forwarded in the afternoon; to which Gen. Washington rejoined the next day, declaring the general basis on which the capitulation might take place. Commissioners were appointed—on the side of the allies Vifcount de Noailles, and Lieut. Col. Laurens, whose father was in close confinement at the tower, while the son was drawing up articles by which an English nobleman and a British army became prisoners. While settling the terms, the vifcount wished his lordship to state, upon his honor, the value of the military chief. His lordship declared it to be about 1800l. sterling. The vifcount observed that the sum was fo trifling, that it was not worth bringing into the account, and therefore was for leaving it entirely at Cornwallis's disposal. Laurens interfered, and observed to his colleague, that though it was natural for a subject of one of the greatest monarchs in the world to think 1800l. an inconconsiderable sum, yet, for his part, being a subject of an infant state, struggling with infinite inconveniences, and where money was very rare, he must deem it a very considerable sum; and therefore he insisted that it should be accounted for. This was accordingly done; and afterward it was paid into the hands of Timothy Pickering, Esq, American quarter master general, to the amount of 2173l. 6s. sterling, estimating the dollar at 4s. 8d.—There being a manifest impropriety in the Americans fluctuating for the return of the negroes, while they themselves were avowedly fighting for their own liberties, they covered their intention of repolishing them, under the general terms with which the fourth article closed—"It is understood, that any property obviously belonging to the inhabitants of these states, in the possession of the garrison, shall be subject to be reclaimed."

The posts of York and Gloucester were surrendered on the 19th. The honor of marching out with colours of York flying, which had been denied Gen. Lincoln, was now refused to Lord Cornwallis; and Lincoln was appointed to receive the submission of the royal army at York Town, precisely in the same way his own had been conducted about 18 months before. The troops of every kind that surrendered prisoners of war, exceeded 7000 men; but such was the number of sick and wounded, that there were only 3800 capable of bearing arms. The officers and soldiers retained their baggage and effects. Fifteen hundred seamen partook of the fate of the garrison. The Guadaloupe frigate of 24 guns, and a number of transports were surrendered to the conquerors: about 20 transports had been sunk or burned during the siege. The land forces became prisoners to the congress: but the seamen and ships were assigned to the French admiral. The Americans obtained a numerous artillery, 75 brass ordnance and 69 iron cannon, howitzers and mortars.

Lord Cornwallis endeavoured to obtain permission for the British and German troops to return to their respective countries, under engagements not to serve against France or America; and also an indemnity for those who had joined him: but he was obliged to confent, that the former should be retained in the governments of Virginia, Pennsylvania and Maryland; and that the latter, whose cafe lay with the civil authority of the states, should be given up to the unconditional
The British fleet and army, defined for the relief of Lord Cornwallis, arrived off the Chesapeake on the 24th; but on receiving authentic accounts of his surrender, they returned to New York. A few days after their first return, the fleet was increased by four ships of the line; but such was the superiority of the French by de Barras’s junction with the Count Grasse, that nothing short of desperate circumstances could justify attempting a fresh engagement. These circumstances however existing, the British naval commanders used all possible expedition in refitting the ships, with the design of extirpating Cornwallis and his army. The delay occasioned by this business seemed to be compensated by the arrival of the Prince William and Torbay men of war from Jamaica. It was determined that every exertion should be used both by the fleet and army, to form a junction with the British force in Virginia. Sir Henry Clinton embarked with about 7000 of his fleet forces. It was nevertheless the 19th of October before the fleet could fall down to the Hook. They amounted to 25 ships of the line, 25 frigates, and 8 brigates. When they appeared off the Chesapeake, the French made no manner of movement, though they had 36 ships of the line, being satisfied with their present success. The main error, which paved the way to the capture of the British army, appears to be the omission of sending a larger force from the West Indies than that which was dispatched under Sir Samuel Hood. A few more ships in the first instance might have prevented that most woful disappointment with which both Sir Henry Clinton and Lord Cornwallis have been painfully exercised.

Every argument and persuasion was used with the Count de Grasse to induce him to aid the combined arms in an operation against Charleston; but the advanced season, the orders of his court, and his own engagements to be punctual to a certain time fixed for his superior operations, prevented his compliance. His instructions had fixed his departure even to the 15th of October; he however early engaged to stay longer. Could he have extended his co-operation two months more, there would most probably have been a total extirpation of the British force in the Carolinas and Georgia. On the 27th, the troops under the Marquis St Simon began to embark for the West Indies; and about the 5th of November the Count de Grasse failed from the Chesapeake.

The Marquis de la Fayette being about to leave America, the following expressions made a part of the orders included by him previous to his departure from York Town—“Orders for the first brigade of light infantry, filled by Major-General the marquis de la Fayette, Oct. 31, 1781. In the moment the major general leaves this place, he wishes once more to express his gratitude to the brave corps of light infantry, who for nine months past have been the companions of his fortunes. He will never forget, that with them alone of regular troops, he had the good fortune to manœuvre before an army, which after all its reductions, is still six times superior to the regular force he had at the time.” Four days after, this brigade embarked for the Head of Elk; the invalids of the American troops defined for the northward having previously done it. The New Jersey and part of the New York lines marched by land, and were to join the troops which went by water, at the Head of Elk. Such cavalry as were wanted by General Greene marched several days before; and on the 5th of November a reinforcement marched under Gen. St Clair, in order to strengthen him for further offensive operations in South Carolina. The season of the year was unfavorable for the return of the troops to the North river, so that they suffered much in doing it. But they and their comrades had been blest with a series of the most delightful weather from the beginning of their march toward York Town, until the reduction of the place.

No sooner had Congress received and read General Washington’s letter, giving information of the reduction of the British army, than they resolved, on the day of thanks, to Almighty God, for crowning the allied arms of the United States and France, with successes by the surrender of the whole British army under the command of Earl Cornwallis. This army had spread wails and ruin over the face of Virginia for 400 miles on the sea-coast, and for 200 to the westward. Their numbers enabled them to go where they pleased; and their rage for plunder disposed them to take whatever they esteemed most valuable. The reduction of
such an army occasioned transports of joy in the breast of every American. But that joy was increased and maintained, by the further consideration of the influence it would have in procuring such a peace as was desired. Two days after, the congress issued a proclamation for religiously observing throughout the United States, the 13th of December, as a day of thanksgiving and prayer. On the 29th of October they resolved, that thanks should be prefixed to Gen. Washington, Count de Rochambeau, Count de Graffe, and the officers of the different corps, and the men under their command, for their services in the reduction of Lord Cornwallis. They also resolved to erect in York Town a marble column, adorned with emblems of the alliance between the United States and his Most Christian Majesty; and inscribed with a succinct narrative of the surrender of the British army. Two stands of colours taken from the royal troops, under the capitulation, were prefixed to Gen. Washington in the name of the United States in Congress assembled; and two pieces of field ordnance so taken, were by a resolve of Congress, to be prefixed by Gen. Washington to Count de Rochambeau, with a short memorandum engraved thereon, “that Congress were induced to prefix them from considerations of the illustrious part which he bore in effectuating the surrender.” It was further resolved to request the Chevalier de Luzerne, to inform his most Christian Majesty, that it was the wish of Congress, that Count de Graffe might be permitted to accept a testimony of their approbation, similar to that which was to be prefixed to Count de Rochambeau. Legislative bodies, executive councils, city corporations, and many private societies, presented congratulatory propositions which were by a resolve of Congress, to be prefixed to Gen. Washington, accompanied with the warmest acknowledgments to Count de Rochambeau, Count de Graffe and the other officers in the service of his Most Christian Majesty. Places of public worship refounded with grateful praises to the Lord of Hosts, the God of battles, before, at, and after the day of thanksgiving. The singularly interesting event of captivating a second royal army, produced such strong emotions in numbers, both of ministers and people, that they could not wait the arrival of the day.

As no rational expectation now remained of a subjugation of the colonies, the military operations that succeeded in America were of little consequence. Some inconceivable actions and skirmishes did indeed take place after that event; in which the refugees chiefly distinguished themselves, and discovered an inveterate animosity against the Americans. On the 4th of May 1782, Sir Guy Carleton arrived at New-York, being appointed to the command of the British troops in America in the room of Sir Henry Clinton. Two days after his arrival, he wrote a letter to General Washington, acquainting him, that Admiral Digby was joined with himself in a commission to treat of peace with the people of America; transmitting to him, at the same time, some papers tending to manifest the pacific disposition of the government and people of Britain towards those of America. He also desir'd a passport for Mr Morgan, who was appointed to transmit a similar letter of compliment to the congress. General Washington declined signing any passport till he had taken the opinion of congress upon that measure; and by them he was directed to refuse any passport for such a purpose. However, another letter was sent to General Washington, dated the 2d of August, signed by Sir Guy Carleton and Rear-admiral Digby, in which they informed him, that they were acquainted by authority that negotiations for a general peace had already commenced at Paris; that Mr Grenville was invested with full powers to treat with all the parties at war; and was then at Paris in the execution of his commission. They farther informed him, that his Britannic Majesty, in order to remove all objections to that peace which he ardently wished to restore, had commanded his ministers to direct Mr Grenville, that the independency of the thirteen provinces should be propounded by him, in the first instance, instead of making it the condition of a general treaty. But some jealousies were entertained by the Americans, that it was the design of the British court either to divide them, or to bring them to treat of a peace separately from their ally the king of France: they therefore resolved, that any man, or body of men, who should presume to make any separate or partial convention or agreement with the king of Great-Britain, or with any commissioner or commissioners under the crown of Great-Britain, ought to be considered and treated as open and avowed enemies of the United States of America; and also that those states could not with propriety hold any conference or treaty with any commissioners on the part of Great Britain, unless they should, as a preliminary thereto, either withdraw their fleets and armies, or else, in positive or express terms, acknowledge the independence of the said states. They likewise resolved, that any propositations which might be made by the court of Great Britain, in any manner tending to violate the treaty subsisting between them and the king of France, ought to be treated with every mark of indignity and contempt.

In the month of June, the town of Savannah, and different places in Georgia, were evacuated by the British troops; as was also Charleston, South-Carolina, about the close of the year. In the mean time, the negotiations for peace being continued, provisional articles of peace were signed at Paris on the 30th of November by the commissioner of his Britannic Majesty and the American commissioners, in which his Majesty acknowledged the united colonies of New-Hampshire, Massachusetts-Bay, Rhode-Island, and Providence Plantations, Connecticut, New-York, New-Jersey, Pennsylvania, Delaware, Maryland, Virginia, North-Carolina, South-Carolina, and Georgia, to be free, sovereign, and independent states. They had constituted themselves such on the 4th of July 1776; they had been acknowledged such by the French king on the 30th of January 1778, when he concluded with them a treaty of amity and commerce; Holland had acknowledged them as such April 19th 1782; Sweden acknowledged them as such February 5th 1783; Denmark the 25th February, Spain in March, and Russia in July, the same year.

The Definitive Treaty was signed on the 3d of September 1783, and in Aug. Sir Guy Carleton had received his final orders for the evacuation of New-York. Tuesday, November the 25th, was the day agreed upon for this evacuation. To prevent every disorder which might arise,
America. [625] America.

which might otherwise enue from such an event, the American troops under the command of Gen. Knox marched from Haerlem to the Bowery in the morning. They remained there till about one o'clock, when the British forces left the posts in the Bowery, and the Americans marched forward and took possession of the city. This being effected, Gen. Knox and a number of citizens on horseback rode to the Bowery to receive their Excellencies, Gen. Washington and Gen. Clinton, who, with their suites, made their public entry into the city on horseback; followed by the lieutenant-governor and the members of council, for the temporary government of the southern district, four abreast—Gen. Knox and the officers of the army eight abreast—citizens on horseback, eight abreast—the speaker of the assembly and citizens on foot, eight abreast. The procession ceased at Cape's tavern. The governor gave a public dinner at Frances's tavern; at which the commander in chief and other general officers were present. The arrangements for the whole business were so well made and executed, that the most admirable tranquility succeeded through the day and night. Soon after this event, the soldiers of the American army, cheerfully renouncing the character of citizens, returned peaceably to their respective homes; while their beloved and ever-honoured commander, having taken a pathetic leave of his officers, repaired to Annapolis, and, on the 23d of December, at an audience with Congress (perhaps the most munificent and interesting that ever occurred) rising with great dignity, he delivered this address.

"—Mr. President, The great events on which my resignation depended having at length taken place, I now have the honour of offering my sincere Congratulations to Congress, and of presenting myself before them, to surrender into their hands the trust committed to me, and to claim the indulgence of retiring from the service of my country.

"Happy in the confirmation of our independence and sovereignty, and pleased with the opportunity afforded the United States, of becoming a respectable nation, I resign with satisfaction the appointment I accepted with diffidence—a diffidence in my abilities to accomplish so arduous a task; which however was superseded by a confidence in the gratitude of our enemies, the support of the supreme power of the union, and the patronage of Heaven.

"The successful termination of the war has verified the most sanguine expectations; and my gratitude for the interposition of Providence, and the assistance I have received from my countrymen, increases with every review of the momentous contest.

"While I repeat my obligations to the army in general, I should do injustice to my own feelings not to acknowledge in this place, the peculiar services and distinguished merits of the gentlemen who have been attached to my person during the war. It was impossible the choice of confidential officers to compose my family should have been more fortunate. Permit me, Sir, to recommend in particular those who have continued in the service to the present moment, as worthy of the favorable notice and patronage of Congress.

"I consider it as an indispensable duty to close this last act of my official life by commending the interests of our dearest country to the protection of Almighty God, and those who have the superintendence of them to his holy keeping.

"Having now finished the work assigned me, I retire from the great theatre of action, and bidding an affective farewell to this august body, under whose orders I have so long acted, I here offer my commission, and take my leave of all the employments of public life."

"The general was so powerfully impressed, with the great and interesting scenes that crowded in upon his imagination while speaking, that he would have been scarce able to have uttered more than the closing period. He advanced and delivered to the president his commission, with a copy of his address. Having resumed his place, he received in a solemn posture the following answer of Congress; which the president delivered with elegance; but not without such a sensibility as changed, and spread a degree of palesness over his countenance.

"Sir, The United States in Congress assembled receive, with emotions too affecting for utterance, the solemn resignation of the authorities under which you have led their troops with success through a perilous and a doubtful war. Called upon by your country to defend its invaded rights, you accepted the sacred charge, before it had formed alliances, and whilst it was without funds or a government to support you. You have conducted the great military contest with wisdom and fortitude, invariably regarding the rights of the civil power through all difficulties and changes. You have by the love and confidence of your fellow-citizens, enabled them to display their martial genius, and transmit their fame to posterity. You have persevered, till these United States, aided by a magnificent king and nation, have been enabled under a just Providence, to close the war in freedom, safety, and independence; on which happy event we sincerely join you in congratulations.

"Having defended the standard of liberty in this new world; having taught a lesson useful to those who inflat and to those who feel oppression, you retire from the great theatre of action, with the blessings of your fellow-citizens—but the glory of your virtues will not terminate with your military command, it will continue to animate remotest ages.

"We feel with you our obligations to the army in general, and will particularly charge ourselves with the interests of those confidential officers, who have attended your person to this affecting moment.

"We join you in commending the interests of our dearest country to the protection of Almighty God, beseeching him to diffuse the hearts and minds of its citizens, to improve the opportunity afforded them, of becoming a happy and respectable nation. And for we address to him our earnest prayers, that a life so beloved, may be fostered with all his care; that your days may be happy as they have been illustrious; and that he will finally give you that reward which this world cannot give."

Having thus resigned his commission into the hands of the president of that honourable body, he retired from public life amid the acclamations of his grateful and admiring countrymen.

According to the report of the committee appointed for that purpose, the Foreign Debt of the United men and States incurred by the war, amounted to 7,885,083 dollars, the war.
America dollars, and the *Domestic Debt* to $34,115,290, total at 45. 6d. each, equal to 9,450,084. Sterling, the interest of which at 6 per., cent. is $57,003. But the cost to Great Britain is moderately computed at $115,654,914, and the additional annual burden by it $4,557,771. since January 1775. As to the losses of men during the war, the States of America, it is suspected, lost by the sword and in prison near 80,000 men, and by the British returns at New-York, the number of soldiers killed in the service amounted to 42,633.

Of the extent of territory, population, commerce, revenues and wealth of this growing empire; and, also, of the rise, progress, and establishment of the present happy form of government, a particular account shall be given, under the article United States.

**AMERICAN NIGHT-SHADE.** See Phytolacca. **AMERICAN GROUND-NUT.** See Arrachis. **AMERICUS VESPUCIUS,** a Florentine gentleman, from whom America derived its name.—The merchants of Seville having obtained permission to attempt discoveries as private adventurers, sent out four ships in 1499, in the command of the noble Ojeda de Ojeda (who had accompanied Columbus on his second voyage), assisted by Americus Vespucius, who was known to be deeply skilled in the science of navigation. This fleet touched on part of that western continent already discovered by Columbus, whose track Ojeda followed; and Americans, who was a man of much address, as well as possessed of considerable literary talents, by publishing the first voyages on the subject, and other artful means, gave his name to the New-World, in prejudice to the illustrious Genoese. The improviso, though long detected, has been falsified by time; and the fourth division of the globe, so long unknown to the inhabitants of Europe, Asia, and Africa, still continues to be distinguished by the name of America.

**AMERSFORT,** a city in the Netherlands, in the province of Utrecht, seated on the river Ems, E. Long. 5° 20'. N. Lat. 52° 14'. The most remarkable things are, the town-house; the grand palace, which is triangular; the public walk, planted with trees; and the great church, dedicated to St. George. The land to the east and fourth of this city is very fruitful; on the north there is nothing but pasture-ground, and on the west it is woody. Not far from hence is a mountain called Anversfortberg, on which they have planted a villa of trees, which reaches to Utrecht.

**AMERSHAM,** or ACHMENDESCHAM, a market-town in Buckinghamshire, consisting of about 200 houses, with a free-school, and four alm-houses. It sends two members to parliament, and has a market on Tuesday. It is a rectory rated at 481. 16s. 8d. in the king's books. The market-house is a very handsome structure. W. Long. 0° 15'. N. Lat. 51° 47'.

**AMES (William, D. D.)** a learned independent divine, famous for his controvertial writings, was born in 1576, and educated at Chelth's college, in Cambridge. In the reign of King James I. he left the university, and soon after the kingdom, on account of his being unwilling to conform to the rules of the church; and retired to the Hague, where he had not been long before he was invited to the command of Alphonso divinity-chair in the university of Franeker, in Friesland, which he filled with admirable abilities for above twelve years; during which his fame was so great, that many came from remote nations to be educated under him. He from the first removed to Rotterdam for a change of air, which his health demanded; and here he continued during the remainder of his life. His controversial writings, which compose the greatest part of his works, are chiefly against Bellarmine and the Armenians. He also wrote, 1. A Fresh Suit against the Ceremonies. 2. *Lections Históricas Davidis.* 3. *Lectores Theologie,* and several pieces relative to the sciences. He died of an asthma, at Rotterdam, in Nov. 1632.

**AMESTRATA,** a town of Sicily, (Cicero); Amestrats, (Stephanus); Amestra (Silius Italicus); Multistrats, (Polybius): Now Mistretta, in the Val di Demona, on the river Halefus. It was a very strong fort of the Carthaginians, besieged in vain by the Romans for seven months with considerable losses; at length, after another siege taken and razed (Diodor. Siculus).

**AMETHYST,** a transparent gem of a purple colour, which seems composed of a strong blue and a deep red, and, according as either of these prevails, affording different tinges of purple, sometimes approaching to violet, and sometimes even fading to a pale-rose colour. Though the amethyst is generally of a triple colour, it is nevertheless sometimes found naturally coloured, and may at any time be easily made by putting it into the fire; in which pellucid or colourless state, it so resembles the diamond, that its want of hardneff seems the only way of distinguishing it. Some derive the name amethyst from its colour, which resembles wine mixed with water; whilst others, with more probability, think it got its name from its supposed virtue of preventing drunkenness; an opinion which, however imaginary, prevailed to that degree among the ancients, that it was usual for great drinkers to wear it about their necks. Be this as it will, the amethyst is (scarce inferior to any of the gems in the beauty of its colour; and in its purest state is of the same hardnefs, and at least of equal value, with the ruby and sapphire.

It is found of various sizes, from the bigness of a small vetch, to an inch and an half in diameter, and often to much more than that in length. Its shape is extremely various, sometimes roundish, sometimes oblong, and at others flattened, at least on one side; but its most common appearance is in a cryttalliform figure, consisting of a thick column, composed of four plants, and terminated by a flat and short pyramid, of the same number of sides; or else, of a thinner and longer hexagonal column; and sometimes of a long pyramid, without any column. It makes the gayest figure in the last of these flates, but is harder and most valuable in the roundish and pebble-like form. The amethyst is found in the East and West-Indies, and in several parts of Europe; the oriental ones, at least some of the finer specimins, being so hard and bright as to equal any of the coloured gems in value. However, by far the greater number of amethyfts fall infinitely short of these; as all the European ones, and not a few of those brought from the East and West-Indies, are very little harder than common crytals.

**Counterfeit or Falsities Amethyst.** Spars and crystals tinged red and yellow, &c. are sold for amethyfts. The false ones come from Germany, and can be purified by vapours in the mines, and contain some lead. Amethyfts may be counterfeited by glass, to which

Amethyst Ambar.

\[\text{Amethyst}\]

\[\text{Ambar.}\]

the proper colour or stain is given. There were fine ones made in France about the year 1690, which may even impose on connoisseurs, unless the stone be taken out of the collet.—The method of giving this colour to glafs is directed as follows: Take chrysyal-frit, made with the most perfect and fine tarde: Then prepare a mixture of manganese in powder, one pound; and zaffer prepared, one ounce and a half: Mix these powders well together; and add to every pound of the frit an ounce of this powder. Let it be put into the pots with the frit, not into the already made metal. When the whole has stood enough in fusion to be perfectly pure, work it into vessels, and then will reftemble the colour of the amethyst.

Amethy M

Amethyst in heraldry, a term for the purple colour in the coat of a nobleman, in use with those who blazon with precious plants; and, in the 42d order, Verticillata. The characters are: The calyx consists of a single-leaved perianthium, bell-shaped, angular, semiflammulat, and peltifer: The corolla is monopetalous; the border quinquenartic, the lowest division more expanding: The flamina consists of two slender filaments approximated; the antherae are simple and roundish: The pellifimum has a four-cleft germin; fylbus, the size of the flamina; fligmat, two, acute: no corolla: the feeds, four, gibbous, and shorter than the calyx:—there is only one known species.

This plant is a native of Siberia, from whence the seeds were sent to the imperial garden at Petersburg, and thence carried to Britain. It is an annual plant, with an upright stalk, which rises above a foot high. Towards the top it puts forth two or three small lateral branches, garnished with small trifid leaves, sawed on their edges, of a very dark green colour. The flowers appear in June or July, and are produced in small umbels at the extremities of the branches. They are of a fine blue colour, as are also the upper part of the branches, and the leaves immediately under the umbels, so that they make a fine appearance.

Calamagrostis. The feeds of the amethystea should be sown in autumn, as they are apt to remain a whole year in the ground, if kept till the spring. When the plants come up, nothing else is necessary than to keep them clear of weeds, and to thin them where they are too close. They ought to be sown where they are apt to remain, as they do not thrive when transplanted.

Amethystine is applied, in antiquity, to a kind of purple garment dyed of the hue of amethyst. In this sense amethystine differed from Tyrant as well as from hyacinthe purple, being a kind of medium between both.

Amhar, or Amhara, a province of Abyssinia, in the year 1690, which may even impose on connoisseurs, unless the stone be taken out of the collet.—The method of giving this colour to glasses is directed as follows: Take chrysyal-frit, made with the most perfect and fine tarze: Then prepare a mixture of manganese in powder, one pound; and zaffer prepared, one ounce and a half: Mix these powders well together; and add to every pound of the frit an ounce of this powder. Amhar, or Amhara, a province of Abyssinia, said to extend 40 leagues from east to west. It is considered as the most noble in the whole empire, both on account of its being the usual residence of the Abyssinian monarchs, and having a particular dialect different from all the rest, which, by reason of the emperors being brought up in this province, has become the language of the court and of the politer people. Here is the famed rock Amba-arishen, where the young monarchs were formerly confined. See Amha.

Amhurst (Nicholas), an English poet and political writer, was born at Marden in Kent, and entered St John's college Oxford, from whence he was expelled for irregularity of conduct and libertine principles. Retaining great resentment against the university on this account, he abated its learning and discipline, and some of the most respectable characters in it, in a poem published in 1724. called Oczias Britannica, and in a book intituled Terra Fitis. He published a Niffelany of Poems, sacred and profane; and, The Convocation, a poem in five cantos, which was a satire on the Bishop of Bangor's antagonists. But he is best known for the satire he had in the political paper called The Crafism: though, after having been the drudge of his party for near 20 years, he was as much forgotten in the famous compromise of 1742 as if he had never been born; and, when he died in that year of a broken heart, was indebted to the charity of his bookkeeper for a grave.

Amianthus, or Earth-flax, in natural history, a fibrous, flexible, elastic, mineral substance, consisting of short, abrupt, and interwoven filaments. It is found in Germany, in the strata of iron ore, sometimes forming veins of an inch in diameter. Its fibres are so flexible that cloth has been made of them, and the shorter filaments that separate in the washing of the flax may be made into paper in the common manner. For the method of its preparation for manufacture into cloth, see ASBESTOS.

Amianthus is classed by Mr Kirwan in the marianic genus of earths, because it contains a fifth part of magnesia. Its other constituents, are, flint, mild calcareous earth, barytes, clay, and a very small proportion of iron. It is fusible per se in a strong heat, and also with the common fluxus. It differs from asbestos in containing some ponderous earth. 

Amicable, in a general sense, denotes any thing done in a friendly manner, or to promote peace.

Amicable. In Roman antiquity, were, according to Piticus, lower and lesser honourable seats allotted for the judices pedantes, or inferior judges, who, upon being admitted of the emperor's council, were dignified by him with the title amicus.

Amicable Numbers, such as are mutually equal to the sum of one another, and another part. Thus the numbers 284 and 220 are amicable numbers: for the aliquot parts, 1, 2, 4, 5, 10, 11, 22, 20, 44, 55, 110, of 220, are together equal to the other number 284; and the aliquot parts 1, 2, 4, 7, 14, of 284, are together equal to 220.

Amicus, in Roman antiquity, was any upper garment worn over the tunica.

Amicus, among ecclesiatical writers, the uppermost garment anciently worn by the clergy; the other being the alba, singulum, flola, manipulus, and planeta. The amicus was a linen garment, of a square figure, covering the head, neck, and shoulders, and buckled or clasped before the breast. It is still worn by the religious abroad.

Amiculum, in Roman antiquity, a woman's upper garment, which differed from the pala. It was worn both by matrons and courtesans.

Amicus curie, a law-term, to denote a bystander who informs the court of a matter in law that is doubtful or mistaken.

Amida, a god worshipped by the Japanese, who

Amiens, a large handomc city of France, the capital of Picardy. It is agreeably situated on the river Somme, and said to have received its Latin name Ambiaium from being every where encompassed with water. It is a place of great antiquity; being mentioned by Caesar as a town that had made a vigorous resistance against the Romans, and where he convened a general assembly of the Gauls after having made himself master of it. The emperors Antoninus and Marcus Aurelius enlarged it; and Constantine, Conflans, Julian, and several others, refided here a considerable time. The town is enclosed with a wall and other fortifications; and the ramparts are planted with trees, which from a delightful walk. The river Somme enters Amiens by three different channels, under as many bridges; and these channels, after washing the town in several places, where they are of use in its different manufactures, unite at the other end by the bridge of S. Michael. Here is a quay for the boats that come from Abbeville with goods brought by sea. At the gate of Noyon there is a faburb remarkable for the abbey of S. Achen. Next to this gate you come to that of Paris, where they have a long mall between two rows of trees. The houses are well built; the streets spacious, embellished with handomc squares and good buildings; and the number of inhabitants between 40,000 and 50,000. The cathedral, dedicated to our Lady, is one of the largest and most magnificent churches in France; adorned with handomc paintings, fine pillars, chapels, and tombs; particularly the nave is greatly admired. The other places worth seeing are the palace of the bailiwic, the town-hou...
AMMODYTES, a name given to a spacious hall in the palace of the Great Mogul, where he gives audience to his subjects, and where he appears on solemn festivals with extraordinary magnificence. His throne is supported by six large steps of maffy gold, set with rubies, emeralds, and diamonds, estimated at 60,000,000,000.

AMMA, among ecclesiastical writers, a term used to denote an abbess, or spiritual mother.

AMMANT, or AMMANT, in the German or Belgian policy, a judge who has the cognizance of civil causes. — It is also used among the French for a public notary, or officer who draws up instruments and deeds.

AMMANIA: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 17th order, Calycanthema. The characters are: The calyx is an oblong, erect, bell-shaped perianthium, with eight stam, quinquangular, ocoladentated, and persistent: The corolla is either wanting, or it consists of four ovate expanding petals inserted in the calyx: The flaminia consists of four bristly filaments the length of the calyx; the anthers are didymous: The pistillata is a roundish four-celled capsule, covered by the calyx: The seeds are numerous and small. — Of this genus there are three species enumerated: all of them natives of warm climates. They have no beauty or other remarkable property.

AMMI, BISHOP'S-WEED: A genus of the diphylia order, belonging to the pentalandia class of plants; and ranking, in the natural method, under the 45th order, Umbellata. The characters are: Of the calyx the universal umbel is manifold; the partial one short and crowded; the involucra are pinnatifid, with numerous leaflets: The corolla are radiated, and all hermaphrodite: The flaminia consists of five capillary filaments; the anthers are oblong: There is no pericarpium: The fruit is roundish, polished, frigidated, small, and papyraceous. The seeds are two, plano-convex, and frigidated. Of this there are three species.

1. The major, or common bishop's-weed, the seeds of which are used in medicine. The glaucifolium, with all its leaves cut in the shape of a spear.
2. The coticum, or Egyptian bishop's-weed.

Culture, &c. The first is an annual plant; and therefore is to be propagated by seeds sown in the autumn, in the place where the plants are to remain. They will flower in June, and the seeds will ripen in August. This plant will grow in any open situation, but thrives best in a light sandy soil. The second is perennial, and very hardy. It thrives best in a moist soil, and may be propagated by seeds in the same manner as the former.

The third species is now no other wise known than by the figure of its seeds, which were formerly used in medicine, but have long since given place to theof the common kind. The seeds of the ammi-coticum are small, frigidated, of a reddish brown colour, and have a warm pungent taste, and a plesant smell approaching to that of origanum. They are recommended as fomentific, carminative, and diuretic; but have long been strangers to the shops. The seeds of the ammi-majus, which are used in their place, are much weaker both in taste and smell, and without the origanum flavour of the other.

AMMIANUS (Marcellinus), a Grecian and a soldier as he calls himself, was born at Antioch, and flourished under Constantius and the preceding emperors as late as Theodosius. He served under Julian in the East; and wrote in Latin an interesting history, from the reign of Nerva to the death of Valens, in 31 books of which only 18 remain. Though a Pagan, he speaks with candour and moderation of the Christian religion, and even praises it: his hero is the emperor Julian. He died about the year 390. The best edition of his history is that of Gronovius, in 1693.

AMMIRATO (Scipio), an eminent Italian historian, born at Lecco in Naples in 1531. After travelling over great part of Italy, without settling to his satisfaction, he was engaged by the great duke of Tuscany to write The History of Florence; for which he was pretented to a canonry in the cathedral there. He wrote other works while in this station; and died in 1600.

AMMOCHRYSOS, from ammos, sand, and χρυσός, gold, a name given by authors to a stone very common in Germany, and seeming to be composed of a golden sand. It is of a yellow gold-like colour, and its particles are very glossy, being all fragments of a coloured tale. It is usually so soft as to be easily rubbed to a powder in the hand; sometimes it requires grinding to powder in a mortar or other wise. It is used only as sand to fire over writing. The Germans call it katez-gold. There is another kind of it, less common, but much more beautiful, consisting of the same fort of gjoy fangles, but those not of a gold colour, but of a bright red, like vermillion.

AMMODYTES, or SAND-EEL, in ichthyology, a genus of fishes belonging to the order of apodes. This fish resembles an eel, and seldom exceeds a foot in length. The head of the ammodytes is compressed and narrower than the body; the upper jaw is larger than the under; the body is cylindrical, with scales hardly perceptible. There is but one species of the ammodytes, viz. the tobiasian, or lance, a native of Europe. This fish gathers itself into a circle, and where the water is left, at the depth of about a foot; and is in some places dug out, in others drawn up by means of a hook contrived for that purpose. They are commonly used as baits for other fish, but they are also very delicate eating. These fish are found in the stomach of the Porpois; an argument that the last roots up the sand with its nose, as the dogs do the ground.

AMMON, anciently a city of Mamraica (Ptolemy). Ammon calls it a place, not a city, in which stood the temple of Jupiter Ammon, which there was nothing but sandy wastes. Pliny says, That the oracle of Ammon was 12 days journey from Memphis, and among the Nomis of Egypt he reckons the Nomis Ammoniacus: Diodorus Siculus, That the district where the temple stood, though surrounded with desarts, was watered by dews which fell nowhere else in all that country. It was agreeably adorned with fruitful trees and springs.
Ammon. springs, and full of villages. In the middle of the Acropolis stood a citadel, encompassed with a triple wall; the first an inclosure of which contained the palace; the others the apartments of the women, the relations and children, as also the temple of the god, and the sacred fountain for lustrations. Without the acropolis stood, at no great distance, another temple of Ammon, shaded by a number of tall trees: near which was a fountain, called that of the fan, or Solis Fons, because subject to extraordinary changes according to the time of the day; morning and evening, was very cold, at midnight extremely hot. A kind of foif felt was said to be produced here. It was dug out of the earth in large oblong pieces, sometimes three fingers in length, and transparent as crystal. It was thought to be a present worthy of kings, and used by the Egyptians in their sacrifices. From this our sal ammoniac has taken its name.

Ammon, or Hammon, in heathen mythology, the name of the Egyptian Jupiter, worshipped under the figure of a ram.

Bacchus having subdued Asia, and passing with his army through the deserts of Africa, was in great want of water; but Jupiter, his father, assuming the shape of a ram, led him to a fountain, where he refreshed himself and his army; in gratitude for which favour, Bacchus built there a temple to Jupiter, under the title of Ammon from the Greek, αμωμον, which signifies sand, alluding to the sandy desert where it was built. In this temple was an oracle of great note, which Alexander the Great consulted, and which lafted till the time of Theodosius.

Hammon the god of the Egyptians, was the same with the Jupiter of the Greeks; for which reason these latter denote the city which the Egyptians call No-Hammon, or the habitation of Ammon, Diospolis, or the city of Jupiter. He is thought to be the same with Ham, who peopled Africa, and was the father of Mizraim, the founder of the Egyptians.

Ammon, or Ben-Ammi, the son of Lot, begot by that patriarch upon his youngest daughter (Gen. xix. 38.) He was the father of the Ammonites, and dwelt to the coast of the Dead Sea, in the mountains of Gilgal, Ammon, Moab, and Ammonites.

Ammon (Andreas), an excellent Latin poet, born at Luca in Italy, was sent by Pope Leo X. to England, in the characters of prothoneo of the Apostolick See, and collector-general of the kingdom. Being a man of singular genius and learning, he soon became acquainted with the principal literati of those times; particularly with Erasmus, Colet, Grocyn, and others, for the sake of whose company he resided some time at Oxford. The advice which Erasmus gives him, in regard to pursuing his fortune, has a good deal of humour in it, and was certainly intended as a satire on the artful methods generally practised by the selfish and ambitious part of mankind: “In the first place (says he), throw off all sense of shame; thrust yourself into every one’s business, and elbow out whomsoever you can; neither love nor hate anyone; measure every thing by your own advantage; let this be the scope and drift of all your actions. Give nothing but what is to be returned with surry, and be complacent to every body. Have always two strings to your bow. Feign that you are solicited by many from abroad, and get every thing ready for your departure. Show letters inviting you Ammonites elsewhere, with great promises.” Ammon was Latin secretary to Henry VIII. but at what time he was appointed does not appear. In 1512 he was made canon and prebendary of the collegiate chapel of St Stephen, in the palace of Westminister. He was likewise prebendary of Wells; and in 1514 was presented to the rectory of Dychial in that diocese. About the same time, by the king’s special recommendation, he was also made prebendary of Salibury. He died in the year 1517, and was buried in St Stephen’s chapel in the palace of Westminister. He was esteemed an elegant Latin writer, and an admirable poet. The epistles of Erasmus to Ammon abound with encomiums on his genius and learning. His works are, 1. Epistole ad Eranimus, lib. 1. 2. Scotici confititus historia, lib. 1. 3. Buottte vel solane, lib. 1. Brasii 1546. 4. De rebus nihil, lib. 1. 5. Panegyricus guidan, lib. 1. 6. Variorum epigrammata, lib. 1. 7. Perspecta diversa, lib. 1.

Ammoniac, a concrete gummy resinous juice, brought from the East-Indies, usually in large masses, composed of little lumps or tears, of a milky colour, but soon changing, upon being exposed to the air, of a yellowish hue. We have no certain account of the plant which affords this juice; the seeds usually found among the tears, resemble those of the umbelliferous clafs. It has been, however, alleged, and not without some degree of probability, that it is an exudation from a species of the Peucedanum, another species of which produces the affafoidea. The plant producing it is said to grow in Nubia, Abyssinia, and the interior parts of Egypt. It is brought to the western part of Europe from Egypt, and to England from the Red-Sea, by some of the ships belonging to the East-India Company trading to those parts. Such tears as are large, dry, free from little stones, seeds, or other impurities, should be picked out, and preferred for internal use: the coarser kind is purified by solution and colature, and then carefully precipitating it; unless this be artfully managed, the gum will lose a considerable deal of its more volatile parts. There is often vended in the shops, under the name of gum-ammoniacum, a composition of ingredients of much effect. Ammoniac has a nauseous sweet taste, followed by a bitter one; and a peculiar smell, somewhat like that of galbanum, but more grateful: it softens in the mouth, and grows of a whiter colour upon being chewed. Thrown upon live coals, it burns away in flame: it is in some measure soluble in water and in vinegar, with which it assumes the appearance of milk; but the resinous part, amounting to about one half, subides on standing. Ammoniac is an useful deobstruent, and frequently prescribed for opening obstructions of the abdominal visceria, and in hysterial disorders occasioned by a deficiency of the menstrual evacuations. It is likewise supposed to deterge the pulmonary vessels; and proves of considerable service in some kinds of athesmas, where the lungs are oppressed by vitid plhlegm: in this intention, a solution of gum-ammoniac in vinegar affords a medicine of great efficacy, though not a little unpleasant. In long and obstinate cholics proceeding from vitid matter lodged in the intestines, this gummy retin has produced happy effects, after the purges and
Ammoniac, the common carminatives had been used in vain. Ammoniac is most commodiously taken in the form of pills; about a scruple may be given every night, or oftener. Externally, it softens and ripens hard tumours; a solution of it in vinegar stands recommended by some for resolving even obnoxious swellings. A plaster made of it and fquill-vinegar is recommended by some in white swellings. A dilute mixture of the same is likewise rubbed on the parts, which are also fumigated with the smoke of juniper-berries. In the shops is prepared a solution of it in pennyroyal water called from its milky colour fquill-ammoniac. It is an ingredient also in the squill pills.

Salt-Ammoniac, a volatile salt, of which there are two kinds, ancient and modern. The ancient fort, described by Pliny and Dioscorides, was a native salt, generated in those large innumerable caravanserai where the crowd of pilgrims, coming from the temple of Jupiter Ammon, used to lodge; who, in those parts, traveling on camels, and those creatures when in Cyrene, a province of Egypt, where that celebrated temple stood, urinating in the flables, or (lay fome) in the parched sands, out of this urine, which is remarkably strong, arose a kind of salt, denominated sometimes (from the temple) Ammoniac, and sometimes (from the country) Cyreniac. Since the ceffation of these pilgrimages, no more of this salt is produced there; and, from this deficiency, some fuppect there never was any fuch thing: But this fuppicion is removed, by the large quantities of a salt, nearly of the fame nature, thrown ont by the modern sal-ammoniac is entirely different.

Ammonian philosophy. See Ammonius.

Ammonite, in natural history. See Cornu Ammonis.

AMMONITES, a people descended from Ammon the son of Lot. The Ammonites destroyed those giants which they called Zamzummims (Deut. ii. 19—21.), and feized upon their country. God forbade Moses, and by him the children of Israel (id. 19.), to attack the Ammonites; because he did not intend to give their lands unto the Hebrews. Before the Israelites entered the land of Canaan, the Amorites had by conquest got great part of the countries belonging to the Ammonites and Moabites. This Moses retook from the Amorites, and divided between the tribes of Gad and Reuben. In the time of Jephtha, the Ammonites declared war against the Israelites (Judges xii.) under pretence that they detained a great part of the country which had formerly been theirs before the Amorites possessed it. Jephtha declared, that as this was an acquisition which the Israelites had made in a just war, and what they had taken from the Amorites, who had long enjoyed it by right of conquest, he was under no obligation to restore it. The Ammonites were not satisfied with this reason; wherefore Jephtha gave them battle and defeated them. The Ammonites and Moabites generally united whenever there was any design set a-foot of attacking the Israelites. After the death of Othnel (id. iii.), the Ammonites and Moabites joined with Eglon king of Moab to oppress the Hebrews; whom they subdued and governed, for the space of 18 years, till they were delivered by Ehud the Son of Gera, who slew Eglon king of Moab. Some time after this, the Ammonites made war against the Israelites, and greatly distressed them. But these were at last delivered by the hands of Jephtha; who having attacked the Ammonites, made a very great slaughter among them (chap. xi.). In the beginning of Saul's reign (1 Sam. xi.), Naash king of the Ammonites having fallen down before Jabeel-gilead, reduced the inhabitants to the extremity of demanding a capitulation. Naash answered, that he would capitulate on this condition, that every one who submitted to him should have his right eye plucked out, that so they might be made a reproach to Israel; but Saul coming feanonly to the relief of Jabeel, delivered the city and people from the barbarity of the king of the Ammonites. David had been the king of Ammon's friend; and, after the death of this prince, he sent ambassadors to make his compliments of condolence to Hanun his son and successor; who, imagining that David's ambassadors were come as spies to observe his strength, and the condition of his kingdom, treated them in a very injurious manner (2 Sam. x. 4.). David revenged this indignity thrown upon his ambassadors, by lading the Ammonites, the Moabites, and the Syrians, and their allies. Ammon and Moab continued under the obedience of the kings David and Solomon; and, after the separation of the ten tribes, were subject to the kings of Israel till the death of Ahab in the year of the world 3107. Two years after the death of Ahab, Jehoram his son, and successor of Ahaziah, defeated the Moabites (2 Kings iii.) but it does not appear that this victory was so complete as to reduce them to his obedience. At the same time, the Ammonites, Moabites, and other people, made an irruption upon the lands belonging to Judah; but were forced back and routed by Jehoahaz (2 Chr. xx. 1, 2). After the tribes of Reuben, Gad, and the half-tribe of Manasseh, were carried into captivity by Tiglath-pileter in the year 3344, the Ammonites and Moabites took possession of the cities belonging to these tribes. Jeremiah (xlvi. 1.) reproaches them for it. The ambassadors of the Ammonites were some of those to whom this prophet (chap. xxvii. 2—4.) presented the cup of the Lord's fury, and directed to make bonds and yokes for themselves; exhorting them to submit themselves to Nebuchadnezzar, and threatening them, if they did not, with captivity and slavery. Ezekiel (xxv. 4—10.) denounces their entire destruction; and tells them that God would give them up to the people of the eait, who should-fet their palaces in their country, so that there should be no more mention of the Ammonites among the nations. It is believed that these misfortunes happened to the Ammonites in the fifth year after the taking of Jarusalem, when Nebuchadnezzar made war against all the people that dwelt upon the confines of Judea, in the year of the world 3420.

It is also thought probable, that Cyrus gave the Ammonites and Moabites the liberty of returning into their own country, from whence they had been removed by Nebuchadnezzar; for we see them, in the place of their former settlement, exposed to those revolutions which were common to the people of Syria and Palestine; subjects sometimes to the kings of Egypt, and at other times to the kings of Syria. We are told by Polybius, that Antiochus the Great took Rabbah,
AMMONITIS (anc. geo.), a country of Arabia Petraea, occupied by the children of Ammon, whence the appellation. It limits, partly to the west, and partly to the north, where the river Jabbok, whose course is nowhere determined; though Josephus says, that it runs between Rabbath-Ammon, or Philadelphia, and Gerafæ, and falls into the Jordan.

AMMONIUS, surnamed Saccas, was born in Alexandria, and flourished about the beginning of the third century. He was one of the most celebrated philosophers of his age; and, adopting with alterations the Ecclesiastic philosophy, laid the foundations of that sect which was distinguished by the name of New Platonism. See ECCLEOTICS and PLATONISM.

This learned man was born of Christian parents and educated in their religion; the outward profession of which, it is said, he never entirely deserted. As his genius was vast and comprehensive, so were his projects bold and singular: For he attempted a general coalition of all sects, whether philosophical or religious, by framing a system of doctrines which he imagined calculated to unite them all, the Christians not excepted, in the most perfect harmony. In pursuance of this design, he maintained, that the great principles of all philosophical and religious truth were to be found equally in all sects; that they differed from each other only in the method of expressing them, and in some opinions of little or no importance; and that, by a proper interpretation of their respective sentiments, they might easily be united into one body. Accordingly, all the Gentile religions, and even the Christian, were to be illustrated and explained by the principles of this universal philosophy; and the fables of the priests were to be removed from Paganism, and the comments and interpretations of the disciples of Jesus from Christianity. In conformity to this plan, he insisted, that all the religious systems of all nations should be restored to their original purity, and reduced to their primitive standard, viz. the ancient philosophy of the East, preserved uncorrupted by Plato: and he affirmed, that this project was agreeable to the intentions of Jesus Christ; whose sole view in descending upon earth was to set bounds to the reigning superstition, to remove the errors that had blended themselves with the religion of all nations, but not to abolish the ancient theology from which they were derived. He therefore adopted the doctrines which were received in Egypt concerning the universe and the Deity, considered as constituting one great whole; concerning the eternity of the world, the nature of souls, the empire of Providence, and the government of the world by demons. He also established a system of moral discipline; which allowed the people in general to live according to the laws of their country and the dictates of nature; but required the wise to exalt their minds by contemplation, and to mortify the body, so that they might be capable of enjoying the presence and assistance of the Deity, and of attending, after death to the presence of the Supreme Parent. In order to reconcile the popular religions, and particularly the Christian, with this new system, he made the whole history of the Heathen gods an allegory; maintaining that they were only celestial ministrers, intituled to an inferior kind of worship. And he acknowledged that Jesus Christ was an excellent man, and the friend of God; but alleged that it was not his design entirely to abolish the worship of demons, and that his only intention was to purify the ancient religion. This system, so plausible in its first rise, but so comprehensive and complying in its progress, has been the source of innumerable errors and corruptions in the Christian church. At its first establishment it is said to have had the approbation of Athenagoras, Panegyricus, and Clemens the Alexandrian, and of all who had the care of the public school belonging to the Christians at Alexandria. It was afterwards adopted by Longinus the celebrated author of the treatise on the Sublime, Plotinus, Herennius, Origen, Porphyry, Jamblichus, the disciple of Porphyry, Sophater, Eudius, Eustathius, Maximus of Ephesus, Pricius, Chrysantheus the master of Julian, Julian the Apologist, Hierocles, Proclus, and many others, both Pagans and Christians.

The above opinions of Ammonius are collected from the writings and disputations of his disciples, the modern Platonists; for he himself left nothing in writing behind him; nay, he imposed a law upon his disciples not to divulge his doctrines among the multitude; which injunction, however, they made no scruple to neglect and violate.

AMMONIUS, surnamed Lithotome, a celebrated surgeon of Alexandria; so called from his inventing the operation of extracting the stone from the bladder.

AMMCTION, a general name for all warlike provisions; but more particularly powder, ball, &c.

Ammunition, arms, utensils of war, gun-powder, imported without licence from his Majesty, are, by the laws of England, forfeited, and triple the value. And again, such licence obtained, except for furnishing his Majesty's public store, is void, and the offender to incur a premunire, and to be disabled to hold any office from the crown.

AMMUTION Bread, Shoes, &c. such as are served out to the soldiers of an army or garrison.

AMNERY, in matters of policy, denotes a pardon granted by a prince to his rebellious subjects, usually with some exceptions: such was that granted by Charles II. at his restoration.—The word is formed from the Greek αμνεία, the name of an edict of this kind published by Thrasibulus, on his expulsion of the tyrants out of Athens.

ANNIS, in anatomy, a thin pellucid membrane which surrounds the fœtus in the womb. See Fortis.

AMOEBAEUM, in ancient poetry, a kind of poem repre-
AMO

rep resenting a dispute between two persons, who are made to answer each other alternately; such are the third and seventh of Virgil's eclogues.

AMOL, a town of Asia, in the country of the Ubes, seated on the river Gihon. E. Long. 64° 30'. N. Lat. 39° 20'.

AMOMUM, GINGER: A genus of the monogynia order, belonging to the monadrica clas of plants. The characters are: The calyx is an obscure three-toothed perianthium, above: The corolla is monopetalous, the tubus short, the limbus tripartite: The stamina is an oblong filament, with the anthera adjoining: The pistillum has a roundish germen, beneath; the stylus is filiform, the stigma obtuse: The pericarpium is leathery, subovate, trigonous, trilocular, and three-valved: The seeds are numerous.—Of this genus there are four

Species. 1. The zingiber, or common ginger, is a native of the East, and also of some parts of the West Indies; where it grows naturally without culture. The roots are jointed, and spread in the ground: they put out many green reed-like stalks in the spring, which arise to the height of two feet and an half, with narrow leaves. The flower-stems arise by the side of these, immediately from the root: these are naked; ending with an oblong scaly spike. From each of these scales is produced a single blue flower, whose petals are but little lower than the squamous covering. 2. The zingiber, or wild ginger, is a native of India. The roots are larger than those of the first, but are jointed in the same manner. The stalks grow from three to near four feet high, with oblong leaves placed alternately. The flower-stems arise immediately from the root: these are terminated by oblong, blunt, scaly heads; out of each scale is produced a single white flower, whose petals extend a considerable length beyond the scaly covering. 3. The cardamomum, or cardamom, is likewise a native of India; but is little known in Europe except by its seeds, which are used in medicine. Of this there is a variety, with smaller fruit, which makes the distinction into cardamomum major and minor. The first, when it comes to us, is a dried fruit or pod about an inch long, containing, under a thick skin, two rows of small triangular seeds of a warm aromatic flavour. The cardamomum minus is a fruit scarce half the length of the foregoing, but considerably stronger both in smell and taste. 4. The granada paradisi species is likewise a native of the East Indies. The fruit containing the grains of paradise is about the size of a fig, divided into three cells, in each of which are contained two roots of small seeds like cardamoms. They are somewhat more grateful, and considerably more pungent, than cardamoms.

Culture. The first two species are tender, and require a warm stove to preserve them. They are easily propagated by planting the roots in the spring. These should be planted in pots filled with light rich earth, and plunged into a hot-bed of tanner's-bark, where they must constantly remain. If we may believe the Abbé Raynal, cardamoms propagate themselves, in those countries where they are natives, when either sowing or planting. Nothing more is required than, as soon as the rainy season is over, to set fire to the herb which has produced the fruit.

U/21. The dried roots of the first species are of great use in the kitchen, as well as in medicine. They furnish a considerable export from some of the American islands. The green roots, preserved as a sweet-meat, are preferable to every other kind. The Indians mix them with their rice, which is their common food, to correct its natural impurity. This spice, mixed with others, gives the dishes seasoned with it a strong taste, which is extremely disagreeable to strangers. The Europeans, however, who come into Asia without fortune, are obliged to conform to it. The others adopt it out of complaisance to their wives, who are generally natives of the country.—Ginger is a very useful spice, in cold flatulent colics, and in laxity and debility of the intestines; it does not heat so much as those of the pepper kind, but its effects are much more durable. The cardamoms and grains of paradise have the same medicinal qualities with ginger.—In Jamaica, the common people employ it in baths and fomentations with good success, in complaints of the visceras, in pleurisies, and in obstathe and continued fevers.

AMOMUM VERUM, or True Amomum, is a round fruit, about the size of a middling grape, encircled under a membranous cover, a number of small round angular seeds, of a blackish brown colour on the outside, and whitish within: the seeds are lodged in three distinct cells; those in each cell are joined closely together, so that the fruit, upon being opened, appears to contain only three seeds. Ten or twelve of these fruits grow together in a cluster; and adhere without any pedicle, to a woody stalk about an inch long; each single fruit is surrounded by five leaves, in form of a cup; and the part of the stalk void of fruit is clothed with leafy scales.—The husks, leaves, and stems, have a light grateful smell, and a moderately warm aromatic taste: the seeds, freed from the husks, are in both respects much stronger; their smell is quick and penetrating, their taste pungent, approaching to that of camphor. Notwithstanding amomum is an elegant aromatic, it has long been a stranger to the shops.

AMOMUM VULGARE. See SISO.

AMONTONS (William), an ingenious experimental philosopher, was born at Paris in 1663. While he was at the grammar-school, he by sickness contracted a deafness that almost excluded him from conversation. In this situation, he applied himself to mechanics and geometry; and, it is said, refused to try any remedy for his disorder, either because he deemed it incurable, or because it increased his attention. He studied the nature of barometers and thermometers with great care; and wrote Observations and Experiments concerning a new Hour-glass, and concerning Barometers, Thermometers, and Hygroscopes; which, with some pieces in the Journal des Sçavans, are all his literary works. When the Royal academy was new-regulated in 1699 he was admitted a member; and read his new Theory of Friction, in which he happily cleared up an important object in mechanics. He died in 1705.

AMORES, a sort or order of gromatic doctors, or commentators on the Jerusalem Talmud. The Amoreans succeeded the Mithnian doctors. They subsisted 250 years; and were succeeded by the Sebuanians.

VOL. I.

AMORGOS,
AMORGOS, or AMORGUS (anc. geog.), now Morgo, not far from Naxus to the east, one of the European Sporades; the country of Simonides the Iambic poet. To this island criminals were banished. It was famous for a fine flax called Emorgus.

AMORITES, a people descended from Amor, according to the Septuagint and Vulgate; Emarœus, according to other expositors; Æmar, according to the Hebrew; or Emorite, according to our version of the Bible; who was the fourth son of Canaan, Gen. x. 16.

The Amorites first of all peoples the mountains lying to the west of the Dead Sea. They had likewise establishments to the east of the same sea, between the brooks of Jabock and Arnon, from whence they forced the Ammonites and Moabites. Num. xiii. 30. xxi. 29. Josh. v. 1, and Judges xi. 19, 20. Moses made a conquest of this country from their kings Sihon and Og, in the year of the world 2553.

The prophet Amos (i. 6.), speaking of the gigantic flavour of the Amorites, compares their height with that of cedars, and their strength with that of an oak. The name Amorite is often taken in Scripture for all Canaanites in general. The lands which the Amorites possessed on this side Jordan were given to the tribe of Judah, and those which they had enjoyed beyond this river were distributed between the tribes of Reuben and Gad.

AMORIUM, a town of Phrygia Major, near the river Sangarius, on the borders of Galatia. It was taken from the Romans by the Saracens in 668; but soon after retaken by the Romans. A war breaking out again between these two nations in 827, the Roman emperor Theophilus destroyed Sozopetra the birth-place of the khalif Al' Motafem, notwithstanding his earnest intreaties to him to spare it. This so enraged the khalif, that he ordered every one to engrave upon his shield the word Amorium, the birthplace of Theophilus, which he resolved at all events to destroy. Accordingly he laid siege to the place, but met with a vigorous resistance. At length, after a siege of 55 days, it was betrayed by one of the inhabitants who had abjured the Christian religion. The khalif, exasperated at the loss he had sustained during the siege, put most of the men to the sword, carried the women and children into captivity, and levelled the city with the ground. His forces being dilater for want of water on their return home, the Christian prisoners rose upon some of them, and murdered them; upon which the khalif put 6000 of the prisoners to death. According to the eastern historians, 30,000 of the inhabitants of Amorium were slain, and as many carried into captivity.

AMORPHA, FALSE INDIGO: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 22d order, Papilionacæ. The characters are: The calyx is a single-leaved perianthium, tubular and persistent; the corolla consists of an ovate, concave, erect petal, scarcely larger than, and placed on the upper side of the calyx; the flower consists of ten erect and equal stamens, longer than the corolla; the anthers are simple; the pistillum has a roundish germ; the style subulate, and the length of the stigma simple: The pericarpium is a lunula unilocular legumen, reflected, larger than the calyx, and tuberculaté: The seeds are two, and kidney-shaped. By the corolla alone this genus may be distinguished from all the known plants in the universe.

The petals are the banner; the wings and keel are wanting, which is very singular in a papilionaceous corolla.

Of this there is only one known species, a native of Carolina, where the inhabitants formerly made from it a coarse kind of indigo, whence the plant took its name. It rises, with many irregular stems, to the height of 12 or 14 feet. The leaves are late in the spring before their foliage is fully displayed. The ends of their branches are generally destroyed by the frost; or, if they recover it, they have the appearance of being dead; whilst other plants testify the effects of the reviving months. But notwithstanding these defects, this tree has some other good properties that in part make amends for the losses. Its leaves, when out, are admired by all. They are of a pleasant green colour; are very large, beautifully pinnated, the foliages being arranged along the stalk by pairs, and terminate by an odd one. The flowers are of a purple colour; they grow in spikes, seven or eight inches long, at the ends of the branches, and are of a singular structure. In order to make this tree have its best effect, it should be planted among others of its own growth, in a well-sheltered situation; by which means the ends will not be so liable to be destroyed by the winter's frosts; the branches will not suffer by the violence of the winds; and, as it is subject to put out many branches near the root, these indelicacies and imperfections will be concealed; whilst the tree will show itself to the utmost advantage when in blow, by elevating its purple-spiked flowers amongst the others in a pleasing view.

Culture. The amorpha is most readily propagated by seeds. It may also be propagated by laying down the young branches, which in one year will make good roots; and may then be taken off, and planted either in the nursery, or in the places where they are destined to remain. If they are put into a nursery, they should not remain there more than one year; for as the plants make large shoots, they do not remove well when they have remained long in a place.

AMORTIZATION, in law, the alienation of lands or tenements to a corporation or fraternity, and their successors. See Mortmain.

AMOS, the fourth of the small prophets, who in his youth had been a herdman in Tekoa, a small town about four leagues southward of Jerusalem, was sent to the kine of Bethan, that is, to the people of Samaria, or the the kingdom of Israel, to bring them back to repentance, and an amendment of their lives; whence it is thought probable that he was born within the territories of Israel, and only retired to Tekoa on his being driven from Bethel, by Amaziah the priest of the golden calves at Bethel.

The prophet being thus retired to Tekoa, in the kingdom of Judah, continued to prophesy. He complains in many places of the violence offered him, and endeavours to oblige him to silence. He boldly reproaches against the crying sins that prevailed among the Israelites, as idolatry, oppression, wantonness, and obstinacy.
The burning. It is capable of a very high and sublime in the cause Jotham, the son of Joah, king of Israel, two years before the earthquake (Amos i. 1.), which happened in the 24th or 25th year of Uzziah, according to the rabbi- and moss of the modern commentators; or the year of the world 3219. when this prince usurped the glory and their number and great quality in the town of Tekoa, whither he retired. He fore-portions of the tabernacle of David, and erecting the king- are those of the 7th chapter: the finest is in Lancashire and Cheshire; it lies usually at considerable depths. It makes a very brisk fire, flaming violently for a short time, and after that continuing red and glowing hot a long while; and finally is reduced into a small proportion of grey ashes, the greater part of its substance having flown off in the burning. — It is capable of a very high and elegant polish; and, in the countries where it is produced, is turned into a vast number of toys, as full-boxes and the like, which bear all the nicety of turning, and are made to pass for jet. — Husbandmen smear their vines with it, as it kills the vermin which infests them. It is likewise used for the dyeing of hair black. In medicine it is reputed good in colics, against worms, and of being in general an emollient and diffusent; but the present practice takes no notice of it.

**AMPELIANUS** (anc. geog.) a promontory of Mauritania Tingitana, called Cottes by the natives, which is of the same signification with a town of the same name not far from the River Lixus, near the straits of Gibraltar: now Cape-Spartel. W. Long. 6o. N. Lat. 36°. 0.

**AMPHERNES**, in antiquity, a kind of vessels where- in the rowsers plied two oars at the same time, one with the right hand and the other with the left.

**AMPHIATHROSI S**, in anatomy, a term for such junctures of bones as have an evident motion, but different from the diarthros, &c. See **DIARTHROSIS**.

**AMPHIARAUS**, in pagan mythology, a celebrated prophet, who possessed part of the kingdom of Argos.
AMP [ 636 ]

AMP

Amphibia. He was believed to excel in divining by dreams, and is said to be the first who divined by fire. Amphiarus, knowing, by the spirit of prophecy, that he would lose his life in the war against Thebes, hid himself in order to avoid engaging in the expedition; but his wife Erphyle, being prevailed upon by a present, discovered the place in which he had concealed himself; so that he was obliged to accompany the other princes who marched against Thebes. This proved fatal to him; for the earth being split asunder by a thunder-bolt, both he and his chariot were swallowed up in the opening. Amphiarus, after his death, was ranked among the gods; temples were dedicated to him; and his oracle, as well as the sports instituted to his honour, were very famous.

AMPHIBIA, in zoology, the name of Linnaeus's third class of animals; including all those which live partly in water and partly on land. This class he subdivides into four orders, viz. The amphibia reptiles; the amphibia ferpentes; the amphibia nantes; and the amphibia manentes. See ZOOLOGY.

It has been a question whether the animals commonly called amphibia, live most in the water or on land. If we consider the words amsbibs (astringe, both ways), and amphis (viva life), from whence the term amphibia is derived; we should understand, that animals, having this title, should be capable of living as well by land, or in the air, as by water; or of dwelling in either constantly at will: but it will be difficult to find any animal that can fulfill this definition, as being equally qualified for either. An ingenious naturalist, therefore, from considering their economy respectively, divides them into two orders, viz. 1. Such as enjoy their chief functions by land, but occasionally go into the water. 2. Such as chiefly inhabit the water, but occasionally go ashore. What he advances on this subject is curious, and well illustrates the nature of this class.

1. Of the first order, he particularly considers the phocae; and endeavours to shew, that none of them can live chiefly in the water, but that their chief enjoyment of the functions of life is on shore.

These animals (he observes) are really quadrupeds; but as their chief food is fish, they are under a necessity of going out to sea to hunt their prey, and to great distances from shore; taking care that, however great the distance, rocks or small islands are at hand, as resting-places when they are tired, or when their bodies become too much macerated in the water; and they return to the places of their usual resort to sleep, copulate, and bring forth their young, for the following reasons, viz. It is well known, that the only essential difference (as to the general structure of the heart) between amphibia and mere land animals, or such as never go into the water, is, that in the former, the oval hole remains always open. Now, in such as are without this hole, if they were to be immersed in water for but a little time, respiration would cease, and the animal must die; because a great part of the mafs of blood passes from the heart by the pulmonary artery through the lungs, and by the pulmonary veins returns to the heart, while the rest is carrying the greater part of the mafs to the head and extremities, &c.

Now, the blood passes through the lungs in a continual uninterrupted stream, while respiration is gentle and moderate: but when it is violent, then the circulation is interrupted, for inspiration and expiration are only between these two violent actions that the blood can pass: and hence it is, that the lives of animals are shortened and their health impaired, when they are subjected to frequent violent respiration; and thus it is, that when animals have once breathed, they must continue to respire ever after, for life is at an end when that ceases.

There are three necessary and principal uses of respiration in all land-animals, and in those kinds that are counted amphibious.—The first is that of promoting the circulation of the blood through the whole body and extremities. In real fishes, the force of the heart is not capable of sending the blood to every part, as they are not furnished with limbs or extremities; but in the others mentioned, being all furnished with extremities, respiration is an affiitant force to the arteries in sending blood to the extremities; which, being so remote from the heart, have need of such assistance, otherwise the circulation would be very languid in these parts; thus we see, that in persons subject to asthmatic complaints, the circulation grows languid, the legs grow cold and oedematous, and other parts suffer by the defect in respiration.—A second use of breathing is, that, in inspiration, the variety of particles, of different qualities, which float always in the air, might be drawn into the lungs, to be inhaled into the mafs of blood, being highly necessary to temperament and cool the agitated mafs, and to contribute refined pabulum to the finer parts of it, which, meeting with the daily supply of chyle, serves to assimilate and more intimately mix the mafs, and render its constitution the fitter for supporting the life of the animal. Therefore it is, that valetudinarians, by changing foul, or unwholesome air, for a free, good, open air, often recover from lingering diseases.—A third principal use of respiration is, to promote the exhibition of voice in animals; which all those that live on the land do according to their specific nature.

From these considerations it appears, that the phoca of every kind, or are under an absolute necessity of making the land their principal residence. But there is another very convincing argument why they reside on shore the greatest part of their time; namely, that the flesh of these creatures is analogous to that of other land animals: and therefore, by over-long maceration, added to the fatigue of their chafing their prey, they would suffer such a relaxation as would destroy them. It is well known, that animals which have lain long under water, are reduced to a very lax and even putrid state; and the phoca must bark in the air on shore: for while the solids are at rest, they acquire their former degree of tension, and the vigour of the animal is restored; and while he has an uninterrupted placid respiration, his blood is refreshed by the new supply of air, as explained above, and he is rendered fit for his next cruise: for action wastes the most exalted fluids of the body, more or less, according to its duration and violence; and the restorative rest must continue a longer...
Let us now examine by what power these animals are capable of remaining longer under water than land-animals.

All these have the oval hole open between the right and left arteries of the heart; and, in many, the carinalis arteriosus silfo; and while the phoca remains under water, which he may continue an hour or two more or less, his respiration is stopped; and the blood, not finding the passage through the pulmonary artery free, rushes through the hole from the right to the left artery, and partly through the arterial canal, being a short passage to the aorta, and thence to every part of the body, maintaining the circulation; but, upon rising to come ashore, the blood finds its passage again through the lungs the moment he respires.

Thus the fetus in utero, during its confinement, having the lungs compressed, and consequently the pulmonary arteries and veins impeded, has the circulation of the blood carried on through the oval hole and the carinalis silfo. Now, if the phoca be thrown into the water, and the fetus in utero, are analogous; but they differ in other material circumstances. One is, that the fetus having never respired, remains sufficiently nourished by the maternal blood circulating through him, and continues to grow till the time of his birth, without any want of respiration during nine months confinement: the phoca, having respired the moment of his birth, cannot live very long without it, for the reasons given before; and this hole and canal would be closed in them, as it is in land-animals, if the dam did not, soon after the birth of the cub, carry him so very frequently into the water, to teach him; by which practice these passages are kept open during life, otherwise they would not be capable of attaining the food designed for them by Providence.

Another difference is, that the phoca, as was said before, would be relaxed by maceration in remaining too long in the water; whereas the fetus in utero suffers no injury from continuing its full number of months in the fluid it swims in: the reason is, that water is a powerful solvent, and penetrates the pores of the skins of land-animals, and in time can dissolve them; whereas the liquor amnii is an infudial fluid, impregnated with particles more or less mucilaginous, and utterly incapable of making the least alteration in the cutis of the fetus.

Otters, beavers, and some kinds of rats, go occasionally into the water for their prey, but cannot remain very long under water. "I have often gone to shoot otters (says our author), and watched all their motions: I have seen one of them go softly from a bank into the river, and dive down; and in about two minutes rise, at 10 or 15 yards from the place he went in, with a mudding salmon in his mouth, which he brought on shore. I shot him, and faved the fish whole." Now, as all fetuses have these passages open, if a whelp of a true water-animals was immediately after its birth, served as the phoca does her cubs, and immersed in water, to stop respiration for a little time every day, it is probable that the hole and canal would be kept open, and the dog be made capable of remaining as long under water as the phoca.

Frogs, how capable of remaining in the water, yet cannot avoid living on land, for they respire; Amphibia, or short time, according to the quantity of the previous fatigue.

The lizard kind, such as may be called water-lizards (see Lacerta), are all obliged to come to land, in order to deposite their eggs, to feed, and to sleep. Even the crocodiles, who dwell much in rivers, sleep and lay their eggs on shore; and, while in the water, are compelled to rise to the surface to breathe; yet, from the texture of his scaly covering, he is capable of remaining in the water longer by far than any species of the phoca, whose skin is analogous to that of a horse or cow.

The hippopotamus (See Hippopotamus), who wades into the lakes or rivers, is a quadruped, and remains under the water a considerable time; yet his chief residence is upon land, and he must come on shore for respiration.

The teftudo, or sea-tortoise (see Testudo), though he goes out to sea, and is often found far from land; yet, being a respiring animal, cannot remain long under water. He has indeed a power of rendering himself specifically heavier or lighter than the water, and therefore can let himself down to avoid an enemy or a storm: yet he is under a necessity of rising frequently to breathe, for reasons given before; and his most usual situation, while at sea, is upon the surface of the water, feeding upon the various substances that float in great abundance every where about him; these animals sleep securely upon the surface, but not under water; and can remain longer at sea than any other of this class, except the crocodile, because, as it is with the latter, the covering is not in danger of being too much macerated; yet they must go on shore to copulate and lay their eggs.

2. The consideration of these is sufficient to inform us of the nature of the first order of the class of amphibious animals; let us now see what is to be said of the second in our division of them, which are such as chiefly inhabit the waters, but occasionally go on shore.

These are but of two kinds: the eels, and water serpents or snakes of every kind. It is their form that qualifies them for loco-motion on land, and they know their way back to the water at will; but by their structure they have a strong perisaltic motion, by which they can go forward at a pretty good rate: whereas all other kinds of fish, whether vertical or horizontal, are incapable of a voluntary loco-motion on shore; and therefore, as soon as such fishes are brought out of the water, after having flounced a while, they lie motionless, and soon die.

Let us now examine into the reason why these various kinds of fish, the eel and serpent kinds, can live a considerable time on land, and the vertical and horizontal kinds die almost immediately when taken out of the water: and, in this research, we shall come to know what analogy there is between land animals and those of the waters. All land-animals have lungs, and can live no longer than while these are inflated by the ambient air, and alternately compressed for its expulsion; that is, while respiration is duly carried on, by a regular inspiration and expiration of air.

In like manner, the fish in general have, instead of lungs, gills or branchiae; and as in land-animals the lungs have a large portion of the mafs of blood circulating through them, which must be flopped if the air has...
Amphibia. has not a free ingress and egress into and from them; so, in fish, there is a great number of blood-vessels that pass through the branchiae, and a great portion of their blood circulates through them, which must in like manner be totally dried up, if the branchiae are not perpetually wet with water. So that, as the air is to the lungs in land-animals a constant affinit to the circulation; so is the water to the branchiae of those of the rivers and seas: for when these are out of the water, the branchiae very soon grow crisp and dry, the blood-vessels are shrunk, and the blood is obstructed in its passage; so when the former are immered in water, or otherwise prevented from having respiration, the circulation ceases and the animal dies.

Again, as land-animals would be destroyed by too much maceration in water; so fishes would, on the other hand, be ruined by too much excitation; the latter being from their general structure and constitution, made fit to bear, and live in, the water; the former, by their constitution and form, to breathe and dwell in the air.

But it may be asked, why eels and water-snakes are capable of living longer in the air than the other kinds of fish? This is answered, by considering the providential care of the great Creator for these and every one of his creatures: for since they were capable of locomotion by their form, which they need not be if they were never to goon shore, it seemed necessary that they should be rendered capable of living a considerable time on shore, otherwise their locomotion would be in vain. How is this provided for? Why, in a most convenient manner; for this order of fishes have their branchiae well covered from the external drying air; they are also furnished with a slimy mucous, which hinders their becoming crisp and dry for many hours; and their very skins always emit a mucous liquor, which keeps them supple and moist for a long time: whereas the branchiae of other kinds of fish are much exposed to the air, and want the slimy matter to keep them moist. Now, if any of these, when brought out of the water, were laid in a vessel without water, they might be preserved alive a considerable time, by only keeping the gills and surface of the skin constantly wet, even without any water to swim in.

It has been advanced, that man may, by art, be rendered amphibious, and able to live under water as well as frogs. As the focus lives in upero without air, and the circulation is there continued by means of the foramen ovale; by preferring the passage open, and the other parts in status quo, after the birth, the same faculty would still continue. Now, the foramen, it is alleged, would be preferred in its open state, were people accustomed, from their infancy, to hold their breath a considerable time once a-day, that the blood might be forced to resume its pristine passage, and prevent its drying up as it usually does. This conjecture feems, in some measure, supported by the practice of divers, who are taught from their childhood to hold their breath, and keep long under water, by which means the ancient channel is kept open. A Calabrian monk at Madrid laid claim to this amphibious capacity, making an offer to the king of Spain, to continue twice twenty-four hours under Water, without ever coming up to take breath. Kircher gives an account of a Sicilian, named the ffish Cola, who, by a long habitude from his youth, had so accustomed himself to live in water, that his nature seemed to be quite altered; so that he lived rather after the manner of a fish than a man.

AMPHIBIOLOGY, in grammar and rhetoric, a term used to denote a phrase susceptible of two different interpretations. Amphibiology arises from the order of the phrase, rather than from the ambiguous meaning of a word.

Of this kind was that answer which Pyrrhus received from the oracle: Aio te, Macedonas vincerem poefis; where the amphibiology consists in this, that the words te and Macedonas, may either of them precede, or either of them follow, the words vincerem, indefinitely. See ORACLE.

The English language usually speaks in a more natural manner, and is not capable of any amphibologies of this kind: nor is it so liable to amphibologies in the articles, as the French and most other modern tongues. AMPHIBRACHYS, in ancient poetry, the name of a foot consisting of three syllables, whereof that in the middle is long, and the other two short; such is the word [âbârè].

AMPHICOME, in natural history, a kind of figured stone, of a round shape, but rugged, and beset with eminences, celebrated on account of its use in divination. The word is originally Greek ἀμφίκομε, q. d. utrique comenta, or "hairy on all sides." This stone is also called Eretylos, ἐρετύλος, Amatoria, probably on account of its supposed power of creating love. The amphibome is mentioned by Democritus and Pliny, though little known among the moderns. Mercatius takes it for the same with the lapis lumbricatus, of which he gives a figure.

AMPHICTYONS, in Grecian antiquity, an assembly composed of deputies from the different states of Greece: and resembling, in some measure, the diet of the German empire. Some suppose the word ἀμφιττυόν to be formed of ἀμφίως, "about," and ττυόν or φτως, in regard the inhabitants of the country about met here in council: others, with more probability, from ἀμφιττύων, of Deucalion, whom they suppose to have been the founder of this assembly: though others, will have Acronis, king of the Argives, to have been the first who gave a form and laws to it.

Authors give different accounts of the number of the Amphictyons, as well as of the states who were entitled to have their representatives in this council. According to Strabo, Harpocrates, and Suidas, they were twelve from their first institution, sent by the following cities and states; the Ionians, Dorians, Per- rhaebians, Boeotians, Magnesians, Achaæans, Phthians, Melians, Dolopians, Ælianians, Delphians, and Phocians. Æschines reckons no more than eleven; instead of the Achaæans, Ælianians, Delphians, and Dolopians, he only gives the Thessalians, Oetians, and Loerians. Last, Panatanas's list contains only ten, viz. the Ionians, Dolopians, Thessalians, Ælianians, Magnesians, Melians, Phthians, Dorians, Phle- ians, and Loerians.

In the time of Philip of Macedon, the Phocians were excluded the alliance, for having plundered the Delphian temple, and the Lacedemonians were admitted in their place; but the Phocians, 60 years after, having behaved gallantly against Brennus and his Gauls, were restored to their seat in the Amphictyonic council.
admitted into the body; and to make room for it, the Magnesians, Melians, Phthians, and Amniadians, who till then had distinct voices, were ordered to be numbered with the Thessalians, and to have only one common voice. Strabo speaks as if this council were extinct in the times of Augustus and Tiberius: but Pausanias, who lived many years after, under Antoninus Pius, affures us it remained entire in his time, and that the number of Amphictyons was then 30.

The members were of two kinds. Each city sent two deputies, under different denominations; one called Amphidromon, whose business seems to have been more immediately to inspect what related to sacrifices and ceremonies of religion; the other Pleomono, charged with hearing and deciding of causes and differences between private persons. Both had an equal right to deliberate and vote, in all that related to the common interests of Greece. The hieromnemon was elected by lot; the pygerys by plurality of voices.

Though the Amphictyons were first instituted at Thermopylae, M. de Valois maintains, that their first place of residence was at Delphi; where, for some ages, the tranquillity of the times found them no other employment than that of being, if we may so call it, church-wardens of the temple of Apollo. In aftertimes, the approach of armies frequently drove them to Thermopylae, where they took their station, to be nearer at hand to oppose the enemies progress and order timely succour to the cities in danger. Their ordinary residence, however, was at Delphi.

Here they decided all public disputes and differences between any of the cities of Greece; but before they entered upon business, they jointly sacrificed an ox cut into small pieces, as a symbol of their union. Their determinations were received with the greatest veneration, and even held sacred and inviolable.

The Amphictyons, at their admission, took a solemn oath never to divest any city of the right of deputation; never to avert its power to bequeath the temple of Apollo; never to avert its worship on two sides by the Strymon; which city was founded by him and Mopsus. The answers of this oracle were given by dreams; the party inquiring used to pass a night in the temple, and that night's dream was the answer. Dion Callus mentions a picture done by order of Sextus Conciatus, representing the answer he received of the oracle, in the reign of the emperor Commodus.

Amphimacer, in ancient poetry, a foot consisting of three syllables, whereof the first and last are long, and that in the middle short; such is the word [Cafétis.]

Amphion, son of Jupiter and Antiope; who, according to the poets, made the rocks follow his music; and at his harp the stones of Thebes danced into walls and a regular city.

Amphipolis, in antiquity, the principal magistrates of Syracuse. They were established by Timoleon in the 100th Olympiad, after the expulsion of the tyrant Dionysus. They governed Syracuse for the space of 300 years: and Diodorus Siculus affirms us, that they subsisted in his time.

Amphipolis, a city of Macedonia, an Athenian colony, on the Strymon, but on which side is not certain; Pliny places it in Macedonia, on this side; but Scylax, in Thrace, on the other. The name of the town, Amphipolis, however, seems to reconcile their difference; because, as Thucydides observes, it was washed on two sides by the Strymon, which dividing itself into two channels, the city stood in the middle, and on the side towards the sea there was a wall built from channel to channel. Its ancient name was Enas, the Nine Ways, (Thucydides, Herodotus.) The citizens were called Amphipoleotes, (Livy.) It was afterwards called Chrismopolia; now Chrysopolis, or Chersopolis, (Holtenius.)

Amphipolis, a town of Syria, on the Euphrates, built by Seleucus, called by the Syrians Turmeda, (Stephanus): the name with Thapsacus, (Pliny); and supposed to be only renewed and adorned by Seleucus, because long famous before his time, (Xenophon.)

Amphipolis, in Grecian antiquity, soldiery who, in war, used two horses without saddles, and were dextrous enough to leap from one to the other.

Amphiprosphorer, in the naval affairs of the ancients, vellets with a prow at each end. They were used chiefly in rapid rivers and narrow channels, where it was not easy to tack about.

Amphi prostyle, in the architecture of the ancients, a temple which had four columns in the front, and as many in the side behind.

Amphisbaena, in zoology, a genus of serpents belonging...
belonging to the order of amphibia serpents, so called from the fable notion of its having two heads, because it moves with either end foremost.

The head of the amphithea is small, smooth, and blunt; the nostrils are very small; the eyes are minute and blackish; and the mouth is furnished with a great number of small teeth. The body is cylindrical, about a foot long, and divided into about 200 annular convex segments like those of a worm; and it has about 40 longitudinal stipes, of which 12 on each side are in the form of small croisses like the Roman X; the anus is a transverse slit; and the tail ring or segment of the belly has eight small papillae, forming a transverse line before the anus; the tail, i.e. all the space below the anus, is short, consisting of 30 annular segments, without being marked with the cross-lines, and is thick and blunt at the point. The colour of the whole animal is black, variegated with white; but the black prevails most on the back, and the white on the belly. It has a great resemblance to a worm, living in the earth, and moving equally well a foot and divided into about the form of small papillae, forming a transverse line before the anus; the tail, i.e. all the space below the anus, is short, consisting of 30 annular segments, without being marked with the cross-lines, and is thick and blunt at the point. The colour of the whole animal is black, variegated with white; but the black prevails most on the back, and the white on the belly. It has a great resemblance to a worm, living in the earth, and moving equally well with either end foremost. There are but two species, viz. 1. The fuliginosa, which answers exactly to the above description, and is found in Libya and in different parts of America. 2. The alba, which is totally white, is a native of both the Indies, and is generally found in ant-hills. The bite of the amphithea is reckoned to be mortal by many authors; but as it is not furnished with poison of serpents, later writers, particularly the latter. See Plate XVIII.

AMPHIBIANA Aquatic, a name given by Bertratus, Albertus, and several other authors, to that long and slender insect, called by others the seta aquatic, and vermis fistarius. It has the name amphibia, from its going backwards or forwards with equal ease and facility. The usual size is four or five inches long, and the thickness of a large hair.

Dr Lieter accidentally found out the origin of this worm, in his researches into the history of a very different sort of insect. Distinguishing one of the common black beetles dug up in a garden, he found in its belly two of these hair worms, or amphibia; and renewing the experiment on other beetles of the same species, he found that they had already swallowed one, two, or three of these worms. As soon as the body of the beetle is opened, they always crawl out. When put into water they will live a considerable time, and swim nimbly about; but often put up their heads above water, as if endeavouring to make their escape, and sometimes fastening themselves by the mouth to the sides of the vessel, and drawing their whole bodies after them. These creatures are not only found in the waters, but buried in earth, and sometimes on the leaves of trees, in gardens and hedges. Phil. Trans. No 83.

AMPHISC1, among geographers, a name applied to the people who inhabit the torrid zone. The Amphisci, as the word imports, have their shadows one part of the year towards the north, and the other towards the south, according to the sun's place in the ecliptic. They are also called Aëschi. See Aesci.

AMPHISSA, (anc. geog.), the capital of the Locri Oxoae, 120 stadia (or 15 miles) to the west of Delphi, (Pausanias.) So called, because surrounded on all hands by mountains, (Stephanus.) Hence Amphissae, the in- Amphitheatres.

Hence Amphitheatre, the in- Amphitheatres.—Also a town of Magna Graecia, at the mouth of the Sagro, on the coast of the Farther Calabria, situated between Locri and Caulonia, now called Rocellla. Amphitus the epithet, (Ovid.)

AMPHITANE, among ancient naturalists, a stone said to attract gold as the lodestone does iron. Pliny says it was found in that part of the Indies where the native gold lay so near the surface of the earth as to be turned up in small masses among the earth of ant-hills; and describes it to have been of a square figure, and of the colour and brightness of gold. The description plainly points out a well-known foil, called, by Dr Hill, prunicium: this is common in the mines of most parts of the world; but neither this nor any other stone was ever suppressed, in our times, to have the power of attracting gold.

AMPHITHEATRE, in antiquity, a spacious edifice, built either round or oval, with a number of rising seats, upon which the people used to behold the combats of gladiators, of wild beasts, and other sports.

Amphitheatres were at first only of wood; and it was not till the reign of Augustus, that Statilius Taurus built one, for the first time, of stone. The lower part was an oval figure, and called arena, because, for the convenience of the combatsants, it was usually strewed with sand; and round the arena were vaults fluted cavea, in which were confined the wild beasts appointed for the shows.

Above the cavea was erected a large circular peristyle, or podium, adorned with columns. This was the place of the emperors, senators, and other persons of distinction.

The rows of benches were above the podium. Their figure was circular; and they were entered by avenues, at the end of which were gates called vomitoria.

This theatre was built in form of a semicircle, only exceeding a juft semicircle by one fourth part of the diameter; and the amphitheatre was nothing else but a double theatre, or two theatres joined together: so that the longest diameter of the amphitheatre was to the shortest as 1 ½ to 1.

There are amphitheatres still standing at Rome, at Pola, at Nimes, &c. The amphitheatre of Vespasian, called the Colisseum, and that at Verona in Italy, are the most celebrated now remaining of all antiquity. Remains of amphitheatres are shown also at Arles, Bourdeaux, &c. The amphitheatre at Pola, an ancient republic of Istria, is very entire: it consists of two orders of Tuscan pillars, one over the other. The lower have pedestals, which is extraordinary; this order having scarce ever more than bases to support them. The amphitheatre of Vespasian is computed to have been capable of holding 87,000 spectators. That of Verona is the best preserved: for though most of the great and belted stones of the outside are picked out, yet the great vault, on which the rows of the seats are laid, is entire; the rows also (which are 44 in number) are entire. Every row is a foot and a half high, and as much in breadth; so that a man sits conveniently in them; and allowing for a seat a foot and a half, the whole will hold 23,000 persons. Pliny mentions an amphitheatre built by Curio, which turned on large iron pivots; so that of the same amphitheatre...
Amphitheatre two several theatres were occasionally made, wherein different entertainments were sometimes presented at the same time. Mr Brydone (vol. i. 295), mentions an amphitheatre at Syracuse, the theatre of which is so entire, that the gradini for seats still remain; but it is a small theatre, he says, in comparison of the others. See Plate XVI.

Amphitheatre, in gardening, certain dispositions of trees and shrubs on the sides of hilly places, which, if the hill or rising be naturally of a circular figure, always have the best effect. They are to be formed of evergreens, such as hollies, philleries, laurulines, bays, and such plants, observing to plant the shortest growing trees in the front, and those which will be the tallest behind, such as pines, firs, cedars of Lebanon, &c.

Amphitheatres are also sometimes formed of slopes on the sides of hills, covered only with turf; and when well kept, they are a great ornament to large gardens. See Plate X.

The Romans had a method of keeping wine in wells. The Romans had a method of keeping wine, by an enumeration of circumstances; so as to excite the proper emotions in the souls of the auditors. Such is the passage in Virgil, where, instead of saying merely that Turnus died, he amplifies the circumstances of his death.

—Aft illi soluntur frigores membra, Vitaque cum gemini fugit indignata sub umbras.

The masters of eloquence made amplification to be the soul of discourse. See Oratory, n. 39.

Amphora, in antiquity, a liquid measure among the Greeks and Romans. The Roman amphora contained 48 sextaries, equal to about seven gallons one pint English wine-measure; and the Grecian or Attic amphora contained one-third more.

Amphora was also a dry measure used by the Romans, and contained about three bushels.

Amphora, among the Venetians, is the largest measure used for liquids, containing about 16 quarts.

Amphorarium vinum, in antiquity, denotes that which is drawn or poured into amphora or pitchers; by way of distinction from vinum doliare, or cask wine. The Romans had a method of keeping wine in amphora for many years to ripen, by fastening the lids tight down with pitch or gypsum, and placing them either in a situation where the smoke came, or under ground.

Amphorides, in antiquity, a kind of armour or covering for the ears, worn by the ancient pugiles, to prevent their adversaries from laying hold of that part.

Amphi-rus, or Amphrysus, (anc. geog.) a river of Phthiotis, a district of Thessaly, running by the foot of mount Othrys, from south to north, into the Enipeus at Thebes of Thessaly; where Apollo fed the herds of king Admetus (Virgil, Lucan). Another Amphrysus in Phrygia, rendering women barren, according to Pliny; Hence the epithet Amphrysius (Statius). Also a town of Phocias, at the foot of mount Parnassus, encompassed with a double wall by the Thbeans in the war with Philip (Pausanias); Amphrysi Vates, in Virgil, denotes the Sibyl.

Amphthill, a town in Bedfordshire, seated pleasantly between two hills, but in a barren soil. W. Long. 0. 29. N. Lat. 52. 2.

Ampliation, in a general sense, denotes the act of enlarging or extending the compass of a thing.

On a medal of the emperor Antoninus Pius, we find the title Ampliator civium given him, on account of his having extended the jus civilis, or right of citizenship, to many states and people before excluded from that privilege. In effect, it is generally supposed to have been this prince that made the famous confutation, whereby all the subjects of the empire were made citizens of Rome.

Ampliation, in Roman antiquity, was the deferring to pass sentence in certain causes. This the judge did, by pronouncing the word amplius; or by writing the letters N. L. for non liquet; thereby signifying, that, as the cause was not clear, it would be necessary to bring further evidence.

Amplification, in rhetoric, part of a discourse or speech, wherein a crime is aggravated, a praife or commendation heightened, or a narration enlarged; or by an enumeration of circumstances; so as to excite the proper emotions in the souls of the auditors.

Amphux, in antiquity, denotes the clay at the edges is white, and the clay in the middle is red. Of the latter, the ancients imagined that this gulph led to hell. The Moffetta is a narrow valley, extending a considerable way to the south-west, and pressed thickly covered with coppices of oak. The bottom of the valley is inclined to a barren soil, the wind, and to keep clear of it, to avoid suffocation. The bottom of the ditch is bare and arid; in the lowest part, and close under one of the hills, is an oval pond of muddy yellow-coloured water, not above 50 feet in diameter; it boils up in several places with great force in irregular fits, which are always preceded by a hissing sound.

The water was several times spouted up as high as our heads in a diagonal direction, a whirlpool being formed round the tube, like a bason, to receive it as it fell. A large body of vapour is continually thrown out with a loud rumbling noise. The fumes on the rising ground that hangs over the pool are quite yellow, being stained with the fumes of sulphur and sal-ammoniac. A most nauseous smell rising with the steam obliged us to watch the wind, and to keep clear of it, to avoid suffocation.

The water is quite insipid both as to taste and smell; the clay at the edges is white, and carried into Puglia to rub upon scabby sheep, on which account the lake is famed out at 100 ducats a-year. On a hill above this lake stood formerly a temple dedicated to the goddess Mephitis; but I perceived no remains of it.

Amphulla, in antiquity, a round big-bellied vessel,
Ampulla

Ampulla, among ecclesiastical writers, denotes one of the sacred vessels used at the altars. Ampullae were also used for holding the oil used in chrismation, consecration, coronation, &c. Among the ornaments of churches we find frequent mention made of ampuls or vials. In the inventory of the cathedral of Lincoln we meet with ampuls of chrysolite, variously enriched with silver feet and covers; one containing a tooth of St Christopher, another a tooth of St Cecily, another a bone of the head of St John Baptist.

Knights of St Ampulla, belong to an order instituted by Clovis I, king of France; at the coronation they bear up the canopy, under which the ampulla is carried in procession.

Ampura, a province of the kingdom of Peru, before its conquest by the Spaniards. Here the inhabitants worshipped two lofty mountains from a principle of gratitude, because of the descent of the water from them by which their lands were fertilized. It is said to have been conquered by Virachoca, the eighth Inca.

Ampurias, the capital of the territory of Ampurdan, in Catalonia, seated at the mouth of the river Fluvia, in E. Long. 2° 56'. N. Lat. 42° 5'. The land about it is barren, full of briars and thorns; but it was recovered from the incursions of the inhabitants of Utrecth, with whom the Hollanders were often quarrelling; but some months afterwards it was almost reduced to ashes. In 1512, it was besieged by the people of Guelderland; who, not being able to take it, set fire to the ships in the harbour. In 1525, an Ambrasian leader, with 600 of his followers, got into the town-house, where at last he died. But the enemy, being pressed, attacked the town-house, and defeated those that made any resistance. At length they barricaded, with wool and hop-facks, the avenues to the market-place, where these enthusiasts were posted; and so put a stop to their fury till day appeared, so that the whole of them were cut to pieces. About ten years after, there was another tumult raised by a parcel of fanatics, consisting of men and women, who ran about the streets stark naked, and had a design of making themselves masters of the town-house. Their shrieks and cries, which were dreadful enough, soon alarmed the inhabitants, who seized the greatest part of them, and gave them the chastisement they deserved.

Amsterdam was one of the last cities that embraced the reformed religion. It was besieged by the Hollanders in 1578, and submitted after a siege of ten months. One article of the capitulation was, a free exercise of the Roman-catholic religion; but this was not observed by the Protestants; for they soon drove the ecclesiastics, monks, and nuns, out of the city, broke the images, and demolished the altars. From this time it became the general rendezvous of all nations and of every
and broad, full of rounded rum. The principal canal is formed by the dikes and lined with which cross the city in many parts, and the streets of the city, port, and sea. The port is a large square of houses Amsterdam for their beguines (a kind of nuns) to live in; who are not shut up in cloysters as other nuns in Roman-Catholic countries, but have liberty to walk abroad, and may even marry when they are tired of this kind of life. These chapels of the Roman-Catholics have no bells allowed them, being looked upon as conventicles, and may be shut up and opened according as the government pleases. The other third part of the city is made up of Jews, Lutherans, Armenians, Anabaptists, &c. none of whom, as was said of the Roman-Catholics, are allowed to have bells in their churches. Those who marry, and are not of the established religion, are obliged to be joined first by the magistrates, and then they may perform the ceremony in their own assemblies. The Jews, who are very considerate in this place, have two synagogues; one of which, namely, the Portuguese, is the largest in Europe. Within the court-yard, where their synagogue stands, they have several rooms or schools, where their children are taught Hebrew, and very carefully instructed in the Jewish religion.

The most remarkable of the religious buildings is the New Church, dedicated to St Catherine. It was begun in the year 1408, others say 1414; and was 100 years a-building. It had the misfortune of being burnt in the year 1643, but was in a short time after built in a more magnificent manner. The foundation of a steeple is laid before this church, which was designed to be very high. The plan on which it was to be erected is not above 100 feet square, and yet they are 62344 in number, and those very large. Nevertheless it was thought that these vast piles, or rather the ground, were not able to support the pro- digious weight they intended to lay upon it; for which reason the steeple remains unfinished. The pulpit is a masterpiece of the kind, wherefore the four evangelists and many other curious pieces of sculpture are reprefented. The glafs-windows are adorned with paintings, among which the emperor Maximilian is described, presenting an imperial crown to the burgomasters of Amsterdam for the creft of the arms of this city. The organ is very large, and reckoned one of the best in the world. It has a set of pipes that counterfeit a chorus of voices, and has 52 whole flops, besides half flops, with two rows of keys for the feet, and three rows of keys for the hands. Those who hear it play for the first time, imagine they hear a human voice. The grate dividing the chancel from the body of the church is all of Corinthian brafs. The branches of candleflares are the richest in the Seven Provinces. There is a very fine marble monument erected to Admiral Ruyter, who was killed at Medura.

The public buildings of a civil nature are very magnificent. The fleet-house was founded in 1628. It is built upon 14,000 wooden piles; and its front is 282 feet long, its sides 255 feet, and its height to the roof 116. There is a marble pedestal in the front, whereon a woman is carved in relievo, holding the arms of the city; she is seated in a chair, supported by two lions, with an olive branch in her right hand; on each side are four Naiads, who present her with a crown of palm and laurel, and two other marine deities present her with different forms of fruit; besides, there is Neptune with his trident, accompanied with Tritons, a sea-unii...
Amsterdam corn, and a sea-horse. On the top stand three statues in bronze, representing Justice, Strength, and Plenty. On the top of the first is a round tower, 50 feet above the roof, adorned with statues, and a harmonious chime of bells, the biggest of which weighs about 7000 pounds, and the next 6000. They are made to play different tunes every month. It has not one handsome gate, but only seven doors to answer to the number of the United Provinces. On the floor of the great hall are two globes, the celestial and terrestrial, which are made of white and black marble, and are inlaid with Jasper and copper. In general all the chambers are enriched with paintings, carvings, and gildings. While this fladt-houfe was building, the old zens, wherein the keys of the city are locked every night. At the end of the great hall is the schepens or aldermen's chamber, where civil caufes are tried. Besides these, there are the chambers of the senate and council, the burgomasters chamber, the chambers of accounts, &c. The in the second floor is a large magazine of arms; and on the top of the building are six large cisterns of water, which may be conveyed to any room in the house in cafe of fire; to prevent which the chimneys are lined with copper.

The bourfe, or exchange, where the merchants assemble, is all of free-stone, and built upon 2000 wooden piles. Its length is about 250 feet and its breadth 140. The galleries are supported by 26 marble columns, upon each of which are the names of the people that are to meet there. They are all numbered; and there is a place affixed for every merchant under these numbers. On the right hand of the gate is a superb flair-cafe which leads to the galleries; on one side of which there are several shops, and on the other a place to sell clothes. It is not unlike the royal exchange in London.

The admiralty-office, is in a house which belonged formerly to the princes of Orange. The arsenal for their men of war is in the harbour. This is a very handsome building, 200 feet long and 22 broad. The ground floor is filled with bullets; the second floor contains the arms and ordnance; the third their falls, pulleys, flags, &c. This arsenal contains a great many curiosities; among the ref; an Indian canoe brought from the straits of Davies, and a conservatory of water on the top of the house that holds 1600 tons of water, which may be distributed in cafe of fire into 16 different parts by leaden pipes. Hard by this edifice you see the dock or yard where they build their men of war. This dock is 588 feet long, and contiguous to it are houses for lodging the ship-carpenters. The dock is plentifully supplied with every thing necessary for the construction of ships.

The East-India company occupy a large building divided into several offices or apartments. In some Amsterdams of those they have great stores of packed goods, and likewise a room with all sorts of drugs, tea, wax, ambergris, and mace. Here they have a magazine full of medicaments for surgeons chefs, to furnish the company's ships and garrisons in the Indies; as also large magazines of nutmegs, cloves, mace, and cinnamon. In the court-yard there is a guard-chamber, where every night the house-keeper has a watch; and on the other side of the gate, there is a chemist, who with his men prepares medicines for the Indies; and adjoining to this court-yard is their warehouse and powder house for pepper and gros goods. In the new part of the city they have a magazine or palace, which may properly be called an arsenal. The ground on which the building stands is 2000 feet, and square every way, reckoning the moats or burgwall about it. The two rope-alleys are 1800 feet long, on the backside of which is a flore of 500 large anchors besides small ones. In this arsenal they build the ships belonging to the India chamber of Amsterdam; for which reason they have all forts of workhouses here for the artificers that serve the company.

The academy, called the Illustrious School, is likewise a very fine building. It was formerly a convent belonging to the nuns of St Agnes. Here they teach Latin, the oriental languages, theology, philosophy, history, &c. The lawyers and physicians have likewise their schools.

Besides these, there are several hospitails, or houses for orphans, for poor widows, for fick persons, and for mad people; all which are regulated with much prudence. The Rasphoufe, which was formerly a nunnery, is now a fort of a work-house for men that behave ill. They are commonly fed at jaw or rasph Brafal wood; and if they will not perform their task, they are put into a cell which the water runs into, where if they do not almost constantly ply the pump, they run the risk of being drowned. There is likewise a spin-house for debauched women, where they are obliged to spin wool, flax, and hemp, and do other work. All the hospitails are extremely neat, and richly adorned with pictures. They are maintained partly by voluntary contributions, which are raised by putting money into the poor's boxes fixed up all over the city; and partly by taxing all public diversions, as well as fairs, &c. Likewise every person that passes through any of the gates at candle-light pays a penny for the fame uses. These charities are taken care of by certain officers called deacons. The governors are nominated by the magistrates out of the most considerable men in the city.

The common fort have places of diversion called Spill-houfe, where there are music and dancing. They are much of the fame kind as the hops which were so frequent about London. If strangers go there, they must take care not to make their address to a woman that is engaged to any other man.

There are two suburbs to this city; one at the gate of the regulars; and the other goes as far as Overtoon, a village a little way from Amsterdam, where boats which come from Leyden are rolled over land upon wooden rollers. There is likewise in this city an hospital for those that are infected with the plague; which was built in the year 1630, and has 360 windows.
The city is governed by a senate or council, which consists of 56 persons called a Vroedhuis, who enjoy their places for life; and when any of them dies, the remainder choose another in his stead. This senate elects deputies to be sent to the States of Holland, and appoints the chief magistrates of the city, called Burgomasters or Exchequers, who are like our aldermen. The number is twelve; out of which four are chosen every year to execute the office, and are called Burgomaster-regent. Three of those are discharged every year, to make room for three others. One of the four is kept in to inform the new ones of the state of affairs, and also presides the three first months in the year, and the others, three months each; so that, when they are in this office, they may be compared to the lord-mayor of the city of London. These alterations and appointments are made by their own body. They dispose of all inferior offices which become vacant during their regency. They have likewise the direction of all public works, which regard the safety, tranquillity, and embellishment of the city. The keys of the famous bank of this city are in the hands of these magistrates.

The college consists of new burgomasters or exchequers, who are judges in all criminal affairs, without appeal; but in civil causes they may appeal to the council of the province. There are two treasurers, a bailiff, and a penionary. The bailiff continues in his office three years; and searches after criminals, takes care to secure them, and sees their sentence executed. The penionary is the minister of the magistracy, is well versed in the laws, makes public harangues, and is the defender of the interests of the city. The city of Amsterdam contributes to the public income above 50,000 livres per day, besides the excise of beer, flesh, and corn; which, in all, amounts to above 1,600,000 a-year. This is more than is paid by all the rest of the provinces put together; and yet Amsterdam bears the fifth rank in the assembly of the States of Holland, with this distinction, that whereas other cities in two years, this lends four.

The mint of Amsterdam is of considerable. They have 60 companies, each of which has from 200 to 300 men. Jews and Anabaptists are excluded from this service, not being admitted to bear arms; but they are obliged to contribute to the maintenance of the city-guard, which consists of 1400 soldiers; as also to the night-watch, who patrol about the streets and proclaim the hour. Besides these, there are trumpeters on every church steeple, who found every half hour; and if there happens a fire, they ring the fire-bell, and show where it is. The inhabitants have excellent contrivances to extinguish it speedily.

The trade of Amsterdam is prodigious: for almost the whole trade of the East India company centres in this city, which besides carries on a commerce with all the rest of the world, innumerable that it may be called the magazine or store-house of Europe. They import a vast deal of corn from the Baltic, so not much for present consumption, as to lay up against times of scarcity. The richest spices are entirely in the hands of the East India company, who furnish all Europe therewith. They have vast quantities of military stores, with which they supply several nations; which is owing to their engrossing most of the iron-works on the Rhine and other great rivers that run into Holland.

The longitude of Amsterdam is 4. 30. E.; the latitude, 52. 25. N.

Amsterdam, is also the name of an island in the south-sea, said to have been discovered by Tafman, a Dutch navigator. It was visited by Captain Cook in his late voyages. Its greatest extent from east to west is about 21 miles, and from north to south about 13. It is broad at the east end, and runs taper towards the west, where it turns, and runs to a point due north. It is about six leagues to the west of Middleburgh. The shore is surrounded by a coral rock, and its most elevated parts are not above six or eight yards above the level of the sea. S. Lat. 27. 11. W. Long. 175. It is wholly laid out in plantations, in which are cultivated some of the richest productions of nature.

Here are bread-fruit, cocoa-nut trees, plantains, bananas, shaddock, yams, and some other roots, sugar-canes, and a fruit like a nectarine, called by the natives fighega. There did not appear an inch of waste ground: the roads occupied no more space than was absolutely necessary: the fences did not take up above four inches each; and even these were not wholly loft, for in many grew some useful trees or plants: it was everywhere where the fame, change of place altered not the scene; nature, affilit by a little art, no where appeared with more splendour than on this island. Water is not so plentiful here as at the Society-islands; but the chief pointed out a pool of fresh water unfixed, to supply the ships with that necessary article. Cautuns, pandangs, and wild fago-palms, appear here with their various tints of green, and barringtonia as big as the loftiest oaks. The bread-fruit does not, however, thrive here with the same luxuriance as at the Society-islands; the coral rock, which composes the basis of this spot, being much more thinly covered with mould.

Both men and women are of the common size of Europeans, and their colour is that of a lightish copper; they are well-shaped, have regular features, are active, brisk, and lively. They have fine eyes, and in general good teeth, even to an advanced age. The women are the merriest creatures imaginable, and incessant talkers. In general, they appear to have the beards quite close, although there was no want of those of a different stamp. Among the natives, who swam about the ship very vociferously, were a considerable number of women, who wantoned in the water like amphibious creatures, and were easily perfuaded to come on board perfectly naked; but none of them ventured to stay there after funset, but returned to the shore to pass the night, like the greater part of the inhabitants, under the shade of the wild wood which lined the coast. There they lighted great fires, and were heard conversing almost the whole night. The hair of both sexes in general is black, but especially that of the women; both sexes wear it short, except a single lock on the top of the head, and a small quantity on each side. The men cut or shave their beards quite close, which operation they perform with two files. The hair of many was observed to be burnt at the ends, and burned with a white powder, which was found, on examining it, to be lime made of shell or coral, which had corroded or burnt the hair; some made use of a blue powder, and others, both men and women, of an orange-coloured powder made of turmeric.

The drefs of both sexes consists of a piece of cloth or
Amulet. or matting wrapped round the waist, and hanging down below the knees. From the waist upwards they are generally naked, and it seems to be a custom to anoint these parts every morning. The practice of tattooing, or puncturing the skin, likewise prevails. The men are tattooed from the middle of the thigh to above the hips: the women have it only on their arms and fingers, and on those parts but very slightly. Their ornaments are amulets, necklaces, and bracelets, the bone, shells, and beads of mother-of-pearl, tortoise-shell, &c. which are worn by men as well as women. The women also wear on their fingers neat rings made of tortoise-shell, and pieces in their ears about the size of a small quill; but here ornaments are not commonly worn, though all have their ears pierced. They have also a curious apron, made of the cocoanut shell, and composed of a number of small pieces sewed together in such a manner as to form stars, half-moons, little squares, &c.; it is studded with beads and shells, and covered with red feathers, so as to have a pleasing effect. They make the same kind of cloth, and of the same materials, as an O-Tahitian, though they have not such a variety, nor do they make any fine; but, as they have a method of glazing it, it is more durable, and will retain paint for some time, which the other cloth would not. Their colours are black, brown, yellow, purple, and red; all made from vegetables. They make various sorts of matting, some of a very fine texture, which is generally used for clothing; and the thick and stronger sort serves to sleep upon, and to make sails for their canoes, &c. Among other useful utensils, they have various sorts of baskets, some made of the same materials as the mats, and others of the twisted fibres of cocoanuts. These are not only durable, but beautiful, being generally composed of different colours, and studded with beads made of shells or bones. They have many little nicknacks among them, which show that they neither want taste to design, nor skill to execute, whatever they take in hand. Their fishing implements are much the same as in other islands: here was purchased a fish-net made like our casting-nets, knit of very firm though slender threads.

Notwithstanding their very friendly disposition, these people have very formidable weapons; some of their spears have many bars, and must be very dangerous when they take effect. A large flat shell or breast-plate was purchased, made of a round rib bone, white and polished like ivory, about 18 inches in diameter, which appeared to have belonged to an animal of the whale tribe. AMULET, a charm, or preservative against mischief, witchcraft, or diseases. Amulets were made of stone, metals, simples, animals, and in a word, of everything that imagination suggested.

Sometimes they confided of words, characters, and sentences, ranged in a particular order, and engraved upon wood, &c. and worn about the neck, or some other part of the body. See ABRACADABRA.

At other times they were neither written nor engraved; but prepared with many superfluous ceremonies, great regard being usually paid to the influence of the stars. The Arabian have given to this species of amulet the name of TALISMAN.

All nations have been fond of amulets; the Jews were extremely superstitious in the use of them, to drive away diseases; and the Minaforbids them, unless received from an approved man who had cured at least three persons before by the same means.

Among the Christians of the early times, amulets were made of the wood of the crosses, or ribbands with a text or scripture written in them, as preservatives against diseases. Notwithstanding the progress of learning and refinement, there is not any country in Europe, even at this day, who do not believe in some charms or other. The pope is supposed to have the virtue of making amulets, which he executes in the conferration of Agnus Deis, &c. The sponge which has washed his table, was formerly in great veneration as a preservative from wounds, and from death itself: on this account it was sent with great solemnity by Gregory II. to the duke of Aquitain.

Amulets are now much fallen from the repute they were anciently in: yet the great Mr Boyle alleges them as an instance of the increase of external effuvia into the habit, in order to show the great porosity of the human body. He adds, that he is persuaded some of these external medicines do answer; for that he himself, having once been subject to bleed at the nose, and reduced to use several remedies to check it, found the mofs of a dead man's skull, though only applied so as to touch the skin till the mofs was warm thereby, the most effectual of any. The same Mr Boyle shows how the effuvia, even of cold amulets, may, in tract of time, pervade the pores of a living animal; by supposing an agreement between the pores of the skin and the figure of the corpuscles. Beltini has demonstrated the possibility of the thing in his last propositions De Febribus; and the like is done by Dr Wainright, Dr Keill, &c.

AMURAT, or AMURATH, I. the fourth emperor of the Turks, and one of the greatest princes of the Ottoman empire, succeeded Solyman in 1360. He took from the Greeks, Gallipoli, Thrace, and Adrianople, which last he chose for the place of his residence. He defeated the prince of Bulgaria, conquered Miinua, chastified his rebellious bailiffs, and is said to have gained 36 battles. This prince, in order to form a body of devoted troops that might serve as the immediate guards of his person and dignity, appointed his officers to seize annually, as the imperial property, the fifth part of the Christian youth taken in war. These, after being instructed in the Mahometan religion, inured to obedience by severe discipline, and trained to warlike exercises, were formed into a body distinguished by the name of Janissaries, or New Soldiers. Every sentiment which enthusiasm can inspire, every mark of distinction that the favour of the prince could confer, were employed in order to animate this body with martial ardour, and with a consciousness of its own pre-eminence. The Janissaries soon became the chief strength and pride of the Ottoman armies, and were distinguished above all the troops whose duty it was to attend on the person of the Sultan.—At length the death of Lazarus, deipor of Servia, who had endeavoured in vain to stop the progress of Amurath's arms, touched Milo, one of his fervants, in so terrible a manner, that, in revenge, he flayed the sultan in the midst of his troops, and killed him upon the spot.
AMY

Amycle, spb, A. D. 1369, after he had reigned 23 Amygdalus years.

Amurat II. the 10th emperor of the Turks, was the eldest son of Mahomet I., and succeeded his father in 1421. He besieged Constantinople and Belgrade without success; but he took Thebaldonica from the Venetians, and compelled the prince of Bosnia and John Castrio prince of Albany to pay him tribute. He obliged the latter to send his three sons as hostages; among whom was George, celebrated by the name of Scanderbeg. John Huniades defeated Amurat's troops, and obliged him to make peace with the Christian princes, in 1442. These princes afterwards breaking the peace, Amurat defeated them in the famous battle of Varna, November 10th, 1444, which proved fatal to the Christians, and in which Ladillas king of Hungary was killed. He afterwards defeated Huniades, and killed above 20,000 of his men; but George Castrio, better known by the name of Scanderbeg, being re-established in the estates of his father, defeated the Turks several times, and obliged Amurat to raise the siege of Croia, the capital of Albania. Amurat died, chagrined with his ill success, and in his age, February 11th, 1453, at Adrianople. It is observed to this prince's honour, that he always kept his treaties with the Christians, and killed above those who never yet saw it, may easily conceive what a noble appearance this tree must make, when covered all over with a bloom of a delicate red, which will be in March; a time when very few trees are ornamented either with leaves or flowers. No ornamental plantation, therefore, of what sort or kind ever, should be without almond trees. Neither are the beauties of the flowers the only thing desirable in this tree: The fruit would render it worthy of planting, were there no other motive. It ripens well, and its goodness is well known. The white-flowering almond is a variety of this species, and is cultivated for the sake of the flowers and the fruit, though the flowers are inferior to the others.

1. The Communs, or Common Almond, a native of Africa, will grow to near 20 feet high; and whether planted singly in an open place, or mixed with others in clumps, shrubbery-quarters, &c. shows itself one of the finest flowering trees in nature. Those who have never seen it, may easily conceive what a noble appearance this tree must make, when covered all over with a bloom of a delicate red, which will be in March; a time when very few trees are ornamented either with leaves or flowers. No ornamental plantation, therefore, of what sort or kind ever, should be without almond trees. Neither are the beauties of the flowers the only thing desirable in this tree: The fruit would render it worthy of planting, were there no other motive. It ripens well, and its goodness is well known. The white-flowering almond is a variety of this species, and is cultivated for the sake of the flowers and the fruit, though the flowers are inferior to the others.

2. The Nana, Dwarf Almond, is a native of Africa. Of this shrub there are two sorts, the single and the double. Both grow to about four or five feet high, and are in the first and second flowering. The single sort has its beauty, but the double kind is matchless. In both, the flowers are arranged the whole length of the last year's shoots; their colour is a delicate red; and they show themselves early in the spring, which still enhances their value.

3. The Persica, or Peach, is said to be a native of Europe, but of what place is not known. Cultivation has produced many varieties of this fruit, of which the following are the most esteemed.

1. The White Nutmeg 15. The Bellegarde
2. The Red Nutmeg 16. The Bourdine
3. The Early Purple 17. The Rosliana
4. The Small Mignon 18. The Admirable
5. The White Magdalen 19. The Old Newington
6. The Yellow Alberge 20. The Royal
7. The Large French 21. The Rambouiller
8. The Beautiful Chevaune 22. The Portugal
9. The Red Magdalen 23. The Late Admirable
10. The Chancellor 24. The Nivette
12. The Montauban 26. The Late Purple
13. The Malta 27. The Perigie
14. The Vineuze 28. The Catharine

The White Nutmeg is the first peach in season, it being often in perfection by the end of July. The leaves are doubled ferrated, the flower large, and of a pale colour; the fruit is white, small, and round; the
Amygdalus the flesh, too, is white, parts from the stone, and has a fugary, musky flavour.

The Red Nutmeg hath yellowish green leaves, with serpentine edges, which are slightly ferrated. The flowers are large, open, and of a deep bluish colour. The fruit is larger and rounder than the former, and is of a bright vermillion next the fun, but more yellow on the other side. The flesh is white, parts from the stone, from which it separates, and has a rich musky flavour. It ripens just after the white nutmeg.

The Early Purple hath smooth leaves, terminated in a sharp point. The flowers are large, open, and of a lively red. The fruit is large, round, and covered with a fine deep red coloured down. The flesh is white, red next the stone, and full of a rich vinous juice. Ripe about the middle of August.

The small Mignon hath leaves slightly ferrated, and the flowers small and contracted. The peach is round, of a middling size, tinged with darkish red on the fun-side, and is of a pale yellowish colour on the other. The flesh is white, parts from the stone, where it is red, and contains plenty of a vinous fugary juice. Ripens rather before the former.

The White Magdalen hath long, shining, pale-green leaves, deeply ferrated on the edges, and the wood is most black at the pith. The flowers are large and open, appear early, and are of a pale red. The fruit is round, rather large, of a yellowish-white colour, except on the funny side, where it is slightly streaked with red. The flesh is white to the stone, from which it separates, and the juice is pretty well flavoured. Ripe at the end of August.

The Yellow Alberge hath deep red, middle-sized flowers; the peach is smaller than the former, of a yellow colour on the shady side, and of a deep red on the other. The flesh is yellow, red at the stone, and the juice is fugary and vinous.

The great French Mignon hath large, finely ferrated leaves, and beautiful red flowers. The fruit is large, quite round, covered with a fine fatty down, of a brownish red colour on the funny side, and of a greenish yellow on the other. The flesh is white, easily parts from the skin, and is copiously flored with a fugary high-flavoured juice. Ripe near the middle of August.

The beautiful Chevreufe hath plain leaves, and small contracted flowers. The fruit is rather oblong, of a middling size, of a fine red colour next the fun, but yellow on the other side. The flesh is yellowish, parts from the stone, and is full of a rich fugary juice. It ripens a little after the former.

The Red Magdalen hath deeply ferrated leaves, and large open flowers. The fruit is large, round, and of a fine red next the fun. The flesh is firm, white, parts from the stone, where it is very red; the juice is fugary, and of an exquisite rich flavour. Ripe at the end of August.

The Chancellor hath large, slightly ferrated leaves. The peach is about the size of the Beautiful Chevreufe, but rather rounder. The skin is very thin, of a fine red on the funny side; the flesh is white and melting, parts from the stone, and the juice is very rich and fugary. It ripens with the former.

The leaves of Smith’s Newington are ferrated, and the flowers are large and open. The fruit is of a middle size, of a fine red on the sunny side; the flesh white and firm, but very red at the stone, to which it sticks closely, and the juice has a pretty good flavour. Ripens with the former.

The Montauban hath ferrated leaves, and large open flowers. The fruit is about the size of the former; of a purplish red, but of a pale one on the shady side. The flesh is melting, white, except to the stone, from which it separates. The juice is rich, and well flavoured. It ripens a little before the former.

The Malta hath deeply ferrated leaves, and the flowers are large and open. The fruit is almost round, of a fine red next the fun, marbled with a deeper red, but the shady side is of a deep green. The flesh is fine, white, except at the stone, from which it parts, where it is of a deep red; the juice is a little musky, and agreeable. It ripens at the end of August, or beginning of September.

The Vineufa hath large deep green leaves, and full bright red flowers. The fruit is round, of a middle size; the skin is thin, of a fine red; the flesh is white, except at the stone, where it is very red, and the juice is copious and vinous. Ripe in the middle of September.

The Bellegarde hath smooth leaves, and small contracted flowers. The fruit is very large, round, and of a deep purple colour next the fun. The flesh is white, parts from the stone, where it is of a deep red, and the juice is rich and excellent. It ripens early in September.

The Bordine hath large, fine green, plain leaves, and small flesh-coloured contracted flowers. The fruit is round, of a dark red next the fun; the flesh is white, except at the stone, where it is of a deep red, and the juice is rich and vinous. Ripens with the former.

The Rossana hath plain leaves, and small contracted flowers. The fruit is rather longer than the al­berge, and some count it only a variety of the latter. The flesh is yellow, and parts from the stone, where it is red; the juice is rich and vinous. Ripe early in September.

The Admirable hath plain leaves, and small contracted flowers, which are of a pale red. The fruit is very large and round; the flesh is firm, melting, and white, parts from the stone, and is there red; and the juice has a sweet, fugary, high vinous flavour. Ripe early in September.

The Old Newington hath ferrated leaves, and large open flowers. The fruit is large, of a fine red next the fun; the flesh is white, sticks close to the stone, where it is of a deep red, and the juice has an excellent flavour. It ripens just after the former.

The Royal hath plain leaves, and small contracted flowers. The fruit is about the size of the admirable, and resembles it, except that it has sometimes a few knobs or warts. The flesh is white, melting, and full of a rich juice; it parts from the stone, and is there of a deep red. Ripe about the middle of September.

The Rambouillet hath leaves and flowers like the royal. The fruit is rather round than long, of a middling size, and deeply divided by a furrow, and is of a bright yellow on the shadie side, but of a fine red on the other. The flesh is melting, yellow, parts from the
The Portuguese have plain leaves, and large open flowers. The fruit is large, spotted, and of a beautiful red on the funny side. The flesh is firm, white, sticks to the stone, and is there red. The stone is small, deeply furrowed, and the juice is rich and sugary. Ripen towards the end of September.

The late Admirable hath serrated leaves, and brownish red small contracted flowers. The fruit is rather large and round, of a bright red next the fun, marbled with a deeper. The flesh is of a greenish-white, and sticks to the stone, where it hath several red veins; the juice is rich and vinous. Ripen about the middle of September.

The Nivette hath serrated leaves, and small contracted flowers. The fruit is large and roundish, of a bright red colour next the fun, but of a pale yellow on the shady side. The flesh is of a greenish yellow, parts from the stone, where it is very red, and is copiously flowed with a rich juice. It ripens about the middle of September.

The Nipple hath finely serrated leaves, and rosy-coloured, small contracted flowers, edged with carmine. The fruit is of a middling size, and has a rind like a breast. It is of a faint red on the funny side, and on the shady one of a straw-colour. The flesh is melting, white, separates from the stone, where it is red, and the juice is rich and sugary. Ripens late in September.

The Late Purple hath large, serrated leaves, which are variously contorted, and the flowers are small and contracted. The fruit is round, large, of a dark red on the funny side, and yellowish on the other. The flesh is melting, white, parts from the stone, where it is red, and the juice is sweet and high-flavoured. Ripens with the former.

The Persique hath large, very long indented leaves, and small contracted flowers. The fruit is large, oblong, of a fine red next the fun; the flesh firm, white, but red at the stone, juicy, and of a high pleasant flavour. The stalk has frequently a small knot upon it. Ripen late in September.

The Catarrine hath plain leaves, and small flowers. The fruit is large, round, of a very dark red next the fun. The flesh white, firm, sticks close to the stone, and is there of a deep red. The stone is rich and pleasant. It ripens early in October.

The Monfrous Pavy hath large, very slightly serrated leaves, and large, but rather contracted flowers. The fruit is round, and very large, whence its name. It is of a fine red on the funny side, and of a greenish-white on the other. The flesh is white, melting, sticks close to the stone, and is there of a deep red. It is pretty full of juice, which in dry seasons is sugary, vinous, and agreeable. Ripen towards the end of October.

The Bloody Peach hath rather large, serrated leaves, which turn red in autumn. The fruit is of a middling size, the skin all over of a dull red, and the flesh is red down to the stone. The fruit is but dry, and the juice rather dry and bitterish. It is well worth cultivating notwithstanding, for the fruit bake and preserve extremely well.

The peach-tree has hitherto been planted against walls for the sake of the fruit: "but, (says Hanbury), Amygdalus as I hardly ever knew a person who was not struck with the beauty of the flowers when in full blow against a wall, why should it not have a share in wilderens quarters, and shruberies, amongst the forst of almonds, &c.? It may be kept down, or permitted to grow to the height of the owner's fancy: and if the flowers are the same as on the other sorts. Add to this, they frequently, in well-sheltered places, produce fruit which will be exceeding well-flavoured; and thus the owner may enjoy the benefit of a double treat." The above observations respect the single peach; with regard to the double-flowered, it is generally propagated for ornamental plantations, and is universally acknowledged to be one of the finest flowering-trees yet known. Against a wall, however, these trees are always the fairest; and if they have this advantage, they are succeeded by very good fruit.

The Nectarine, according to Linnaeus, is only a variety of the peach, having a smooth coat being only an accident originally. Of this it may be observed, that the fruit is pretty large, of a yellowish red on the funny side, but of a bright yellow on the other. The flesh sticks to the stone, is there of a deep red colour, and the juice has an excellent rich flavour. Ripen towards the end of August.

The Scarlet is rather less than the former, of a fine scarlet colour next the fun, but fades to a pale red on the shady side. It ripens near the time of the former.

The Roman, or clutter red nectarine, hath plain leaves, and large flowers. The fruit is large, of a deep red towards the fun, but yellowish on the shady side. The flesh parts from the stone, and has a soft, melting, good flavoured juice. Ripen early in August.

The Newington hath serrated leaves, and large open flowers. The fruit is pretty large, of a buffet red on the funny side, but of a bright yellow on the other. The flesh sticks to the stone, is there of a deep red colour, and the juice has an excellent rich flavour. Ripen towards the end of August.

The Murrey is of a middling size, and when ripe, has a rich flavour, and ripens in September.

The Italian Nectarine hath smooth leaves and small flowers; the fruit is red next the fun, but yellowish on the other side; flesh firm, adheres to the stone, where it is red, and when ripe, which is early in September, has an excellent flavour.

The Golden Nectarine has an agreeable red colour next the fun, bright yellow on the opposite side; flesh very yellow, sticks to the stone, where it is a pale red, has a rich flavour, and ripens in September.

The Temple's Nectarine is of a middling size, of a fair red next the fun, of a yellowish green on the other side; flesh white near the stone, from which it separates.
Propagation, &c. All the above species are propagated by inoculating them into plum-fowls in August. The flocks should be first planted in the nurseries when of the size of a straw; and the first or second summer after they will be ready to receive the bud. The usual method of inoculation must be observed, and there is no danger of success; though it may be proper to ob-serve, that the double-blossomed peach should always be worked into the flocks of the mufcot-plum. The two sorts of dwarf-almond may also be propagated by layers, or from the suckers, which they sometimes send forth in great plenty.

The varieties of the peach are produced like those of the finer flowers, by fowing the seeds; and though many raised this way will be of little value; if properly planted on a bed of light dry earth, planting them three feet asunder, and one foot in the soil, and then the fowls should be immediately planted on a bed of light dry earth, planting them about three inches deep in the earth, and at about four inches asunder. The beds should be covered in pails with plumes of the belliah kind as high as they shall drop; and the wounds will then have time to heal before the severe frosts come on. In prunis of these trees it must always be observed, that it is best done under a wood bud, not a blossom bud; which may be distinguished by the wood bud's being less turgid, and longer and narrower than the blossom bud; for if the shoot have not a leading bud where it is cut, it will commonly die down to the leading bud. In nailing the shoots to the wall, they should be placed at such equal distances as possible; and so far apart that the leaves may have room; and they must always be trained as horizontally as possible, that the lower part of the tree may be well wooded, which will not be if the branches are suffered to run upright. When the fruit is set and grown to the size of a small nut, it should be thinned, and left five or six inches asunder: by this management the fruit will be larger and better tailed, and the trees in a condition to bear well the succeeding year. The quantity of fruit to be left on large full grown trees should never be greater than five dozen upon each; but on middling trees, three or four dozen will be enough. If the season should prove hot and dry, it will be proper to draw up the earth round the stems of each tree, to form a hollow basin of about six feet in diameter, and cover the surface of the ground in this basin with mulch; and once in a week or fortnight, according to the drought of the season, to pour down eight or ten gallons of water to the root of each tree; or the water may be sprinkled by an engine over the branches of the trees, which, shaking down to the roots, will promote the growth of the fruit and prevent it falling off the trees. This, however, should be continued only while the fruit is growing.

The peach-tree, as well as the rose-tree, are very subject to be over-run with the aphides; which may be destroyed by fumigating the house in which the plants are kept with tobacco; or, which is said to be the most effectual method, by steam raised from water poured over the fuses. Soap-suds are said to destroy effectively the different species of insects that infest fruit-trees growing against walls, and particularly the peach, cherry, and plum. For this purpose, a person on a ladder, should pour them from a watering-pot over both trees and wall, beginning at the top of the wall, and bringing it on in courses from top to bottom. The suds contribute likewise, it is said, to preserve the wood of the delicate and tender kinds of peaches.

Uses. Sweet almonds are reckoned to afford little nourishment; and, when eaten in fulbstance, are not easy of digestion, unless thoroughly comminuted: Peeled, and eaten six or eight at a time, they sometimes give present relief in the heart-burn. But in medicine they are mostly used for making emulsions; and they abound not only with an oil, but likewise with a mucilage fit for incorporating oil and water together. Emulsions are commonly prepared from almonds, by beating an ounce of them, after being blanched, into a fine pulp, in a marble or stone mortar; and triturating them well with half an ounce (more or less) of fine sugar; and then adding by little at a time, a quart of water; taking care to continue grinding them while the water is poured on; after which the white milky liquor is strained through a cloth, and put into a quart bottle. Some people add a drachm of blanched bitter almonds to an ounce of the sweet, which they think make the emulsions more agreeable. Such emulsions have been much used as drink in acute diseases, for diluting and blunting acrimonious juices in the first passages, and acid saline particles in the blood; and for softening and lubricating the fibres and membranes.

It has been a common practice to dissemble from half an ounce to an ounce, or more, of gum-arabic in the water
Amyntor

of abating heat, quenching
the belly. He
more efficacious,
others,
ordered to be rubbed with them, and made up into
pills or boluses, with the addition of some conserve
or gum-arabic mucilage; or they are incorperated
with watery liquors into the form of an emulsion.
Formerly the seeds of the lettuce, of the cucumber,
of the white poppy, and of a number of other plants,
employed for making emulsions; but now the sweet almonds compose the place of the rest.
The bitter almonds are not so much used as they
were formerly; because they have been found to de-
stroy some sorts of animals: this effect was related by
the ancients, but believed to be fictitious; because
when eaten by men they appear to be innocent, and
to produce no deleterious effects. The facts related by Wepfer in his Treatise de Cucuta Aquatica,
having been confirmed by latter experiments; and it
having been discovered that a water drawn from them
had deleterious effects, and that the distilled water
from the lauro-cerasus leaves, which have a bitter
taste resembling that of bitter almonds, was still more
poisonous; it raised a suspicion of the wholomefulness
of those bitter substances, and has made physicians more
cautious of using them, though they have been em-
ployed for making orgeate and other liquors, without
producing any bad effects.

As to the peach and nectarine, they are sufficiently
known as delicious fruits. Peach-flowers have an
agreeable smell, and a bittersh taste: distilled, with-
out any addition, by the heat of a water-bath, they
yield one-sixth their weight, or more, of a whitish li-
quor, which, as Mr Bolloc observes, communicates
to a large quantity of other liquids a flavour like that
of the kernels of fruits. An infusion in water of half
an ounce of the fresh gathered flowers, or a dram of
them when dried, sweetened with sugar, proves for
children an useful laxative and anthelmimtic: the
leaves of the tree are, with this intention, somewhat
more efficacious, though less agreeable. The fruit
has the same quality with the other sweet fruits, that
of abating heat, quenching thirst, and gently loofen-
ing the belly.

Amylaceous, from amylum "flarch;" a term
applied to the fine flour of farinaceous seeds, in which
confists their nutritive part. See Bread.

Amynta, in literary history, a beautiful pastoral
comedy, composed by Tasso; the model of all dramatic
pieces wherein shepherds are actors. The Pastor Fido,
and Filii di Scirr, are only copies of this excel-
ent piece.

Amyntor, amyntor, formed of the verb amynt, I
defend, or avenger, properly denotes a person who de-
defends or vindicates a cause. In this sense, Mr Toland
intitles his defence of Milton’s life, Amyntor, as being
a vindication of that work against Mr Blackhall and
others, who had charged him with questioning the au-

Amyot

Amyot, bishop of Auxerre and great al-
moner of France, was born of an obscure family at
Melun, the 30th of October 1514, and studied philo-

This doctrine principally consists of the following
particulars, viz. that God desers the happiest of all
men, and none are excluded by a divine decree; that
none can obtain salvation without faith in Christ; that
God refuses to none the power of believing, though
he does not grant to all his assistance, that they may
improve this power to saving purpofes; and that many
perish through their own fault. Those who embraced
this doctrine were called Univerfalifts; though it is evi-
dent they rendered grace universal in words, but par-
tial in reality, and are chargeable with greater incon-
teities than the Supraalpajrianists.

Amyrauld (Moses), an eminent French
Protestant divine, born at Bourgou in Touraine in 1596.
He studied at Saumur, where he was chosen professor
of theology; and his learned works gained him the
effem of Catholics as well as Protestants, particularly
of Cardinal Richelieu, who consulted him on a plan of re-
uniting their churches, which, however, as may
well be supposed, came to nothing. He published a
piece in which he attempted to explain the mystery of
predestination and grace, which occasioned a contro-
versy between him and some other divines. He
also wrote, An Apology for the Protestants; a Para-
phrase on the New Testament; and several other
books. This eminent divine died in 1664.

Amyris: A genus of the monogynia order, belong-
ing to the decandria clafs of plants. The characters
are: The calyx is a small single-leaved perianthium,
Amyris.  The corolla consists of four oblong petals, concave and expanding: The flamina consists of eight erect fimbriated filaments: the antherae are oblong, erect, and the length of the corolla: The pistillum has an ovate germen, above, a thickish filius, the length of the flamina; and a four-cornered stigma: The pericarpium is a round drupaceous berry: The seed is a globular glossy nut. — The most remarkable species are 1. The eleutheria, or tree which bears the gum-elemi, a native of South-America. It grows to the height of about six feet, producing trifoliated stiff shining leaves, growing opposite to one another on footstalks two inches long. At the ends of the branches grow four or five slender flanks set with many very small white flowers. 2. The giliadenis, or opobalsamum, is an evergreen shrub, growing spontaneously in Arabia-Felix, from whence the opobalsam, or balm of gilead, is procured. 3. Toxiferâ, or poison-wood, is a small tree, with a smooth light-coloured bark. Its leaves are winged: the middle rib is seven or eight inches long, with pairs of pinnae one against another on inch-long footstalks. The fruit hangs in bunches, is apple-shaped, and covered by an oblong hard stone. From the bark of this tree diffuses a liquid as black as ink. Birds feed on the fruit: particularly one, called the purple greja-book, on the mucilage that covers the stone. It grows usually on rocks, in Providence, lathery, and others of the Bahama islands. 4. The balsamifera, or rose-wood, is found on gravelly hills in Jamaica and others of the West India islands. It rises to a considerable height, and the trunks are remarkable for having large protuberances on them. The leaves are laurel-shaped; the small blue flowers are on a branched spike; and the berries are small and black.

Properties. From the first species, which is called by the natives of the Brazils teocariba, is obtained the resin improperly called gum-elemi, or gum-lemon. This drug is brought to us from the Spanish West Indies, and sometimes from the East Indies, in roundish cakes, generally wrapped up in fig leaves. The best fort is fiftith, somewhat transparent, of a pale whithish yellow colour, inclining a little to green, of a strong not unpleasant smell. It almost totally dissolves in pure spirit, and sends over some part of its fragrance along with this menstruum in distillation: distilled with water, it yields a considerable quantity of pale-coloured, thin, fragrant, essential oil. This resin gives name to one of the official unguents, and is at present scarcely any otherwise made use of; though it is certainly preferable, for internal purposes, to some others which are held in greater esteem. The second species yields the balsam of Mecca, of Syria, or of Gilead, which is the most fragrant and pleasant of any of the balsams. The true balsam tree is found near to Mecca, which is situated about a day’s journey from the Red Sea, on the Asiatic side. It has a yellowish or greenish yellow colour, a warm bittersh aromatic taste, and an acidulous fragrant smell. It has long been held in great esteem. The Turks, who are in possession of the country in which it grows, value it much as an odoriferous ungent and cosmetic, and sell such a high price upon it, that it is adulterated when it comes into the hands of the dealers, so that it is very difficult to get genuine specimens of it. It has been recommended in great variety of complaints; but now it is generally believed that the Canada and copiva balm are equally efficacious, and will answer every purpose for which it can be used. Dr Alton says, that the furcet mark of this balm being pure and unadulterated is, its spreading quickly on the surface of water when dropped into it; and that if a single drop of it is let fall into a large bucket full of water, it immediately spreads all over the surface, and as it spreads, dissolves and disappears; but in about half an hour it becomes a transparent pel­licle covering the whole surface, and may be taken up with a pin, having lost its fluidity and colour, and become white and soft, cohering, and communicating its smell and taste to the water. This test, he says, all the balm he saw in Holland bore, though it is rare to get any from London that answers it. The balmamfera, or rose-wood, affords an excellent timber: it is also replete with a fragrant balm or oil, and retains its flavour and solidity though exposed to the weather many years. By subjecting this wood to distillation, Dr Wright thinks, a perfume equal to the oleum rhodii may probably be obtained.

ANA, among physicians, denotes a quantity equal to that of the preceding ingredient. It is abbrevi­ated thus, æ, or a.

ANA, in matters of literature, a Latin termination, adopted into the titles of several books in other languages.—Anas, or books in ana, are collections of the memorable sayings of persons of learning and wit; much the same with what we otherwise call table-talk.

Wolius has given the history of books in ana, in the preface to the Caxabanioniana. He there observes, that though such titles be new, the thing itself is very old; that Xenophon’s books of the deeds and sayings of Socrates, as well as the dialogues of Plato, are Socratiana: that the apophthegms of the philo­phers collected by Diogenes Laerius, the sentences of Pythagoras and those of Epicurus, the works of Athenaus, Stobus, and divers others, are so many anas. Even the Gemara of the Jews, with several other oriental writings, according to Wolius, properly be­long to the same class. To this head of ana may likewise be referred the Orphica, the Pythagorasæ, Æphesia, Pyrrhonea, &c.

Scaligeriana was the first piece that appeared with a title in ana. It was composed by Ifan de Vaffian, a young Champanois, recommended to Joach Scaliger by a young Champanois, recommended to Joach Scaliger by a young Champanois. Being much with Scaliger, who was daily visited by the men of learning at Leyden, de Vaffian wrote down whatever things of any moment he heard Scaliger say. And thus arose the Scaligeriana, which was not printed till many years after, at Geneva, in 1666. Patin. Let. 431.—Soon after came the Ferroniana, Thuana, Naudeana, Patineana, Sor­biana, Menagiana, Anti-Menagiana, Fureiana, Chev­rapana, Leibnishiana, Arlequiniana, Poggiana, &c.

ANABAPTISTON, the fame with ABAPTISTON.

ANABAPTISTS, a name which has been indiscriminately applied to Christians of very different principles and practices; though many of them object to the denomination, and hold nothing in common, besides the opinion that baptism ought always to be performed by immersion, and not administered before the age of discretion.

The word Anabaptists is compounded of αν, "new," ana.
This sect was soon joined by great numbers, and (as usually happens in sudden revolutions of this nature) by many persons whose characters and capacities were very different, though their views seemed to turn upon the same object. Their progress was rapid; for, in a very short space of time, their discourses, visions, and predictions, excited commotions in a great part of Europe and drew into their communion a prodigious multitude, whose ignorance rendered them easy victims to the illusions of enthusiasm. The most pernicious faction of all these which composed this motley multitude, was that which pretended that the founders of the new and perfect church, already mentioned, were under the direction of a divine impulse, and were armed against all opposition by the power of working miracles. It was this faction that, in the year 1521, began their fanatical work, under the guidance of Munzer, Stubner, Storck, &c.

These persons were disciples of Luther; but well knowing that their opinions were such as would receive no sanction from him, they availed themselves of his absence to disseminate them in Wittemburgh, and had the address to over-reach the piety of Melancthon. Their principal purpose was to gain over the populace, and to form a considerable party. To effect this, says Bayle, they were industrious and active, each in his own way. Storck, wanting knowledge, boasted of inspiration; and Stubner, who had both genius and erudition, laboured at commodious explications of Scripture. Not content with discrediting the court of Rome, and decrying the authority of confidories, they taught, That among Christians, who had the precepts of the gospel to direct and the Spirit of God to guide them, the office of magistracy was not only unnecessary, but an unlawful encroachment on their spiritual liberty; that the distinctions occasioned by birth, or rank, or wealth, being contrary to the spirit of the gospel, which considers all men as equal, should be entirely abolished; that all Christians, throwing their possessions into one common flock, should live together in that state of equality which becomes members of the same family; that, as neither the laws of nature nor the precepts of the New Testament had placed any restraint upon men with regard to the number of wives which they might marry, they should use that liberty which God himself had granted to the patriarchs.

They employed at first the various arts of persuasion in order to propagate their doctrine. They preached, exhorted, admonished, and reasoned in a manner that seemed proper to impress the multitude, and related a great number of visions and revelations with which they pretended to have been favoured from above. But when they saw that these methods of making profelytes were not attended with such a rapid success as they fondly expected, and that the ministry of Luther and other eminent reformers were detrimental to their cause, they then had recourse to more expeditious measures, and madly attempted to propagate their fanatical doctrine by force of arms. Munzer and his associates, in the year 1525, put themselves at the head of a numerous army, composed for the most part of the peasants of Sabinia, Thuringia, Franconia, and Saxony, and declared war against all laws, government, and magistrates of every kind, under the chimerical
merical pretext that Christ was now to take the reins of civil and ecclesiastical government into his own hands, and to rule alone over the nations. But this sedition was routed and dispersed, without much difficulty, by the Elector of Saxony and other princes; and Munzer's ringleader ignominiously put to death, and his factious counsellors scattered abroad in different places.

Many of his followers, however, survived, and propagated their opinions through Germany, Switzerland, and Holland. In the year 1533, a party of them settled at Munster under the direction of two Anabaptist prophets, John Matthias a baker of Haerlem, and John Bockholdt a journeyman-taylor of Leyden. Having made themselves masters of the city, they deposed the magistrates, confiscated the estates of such as had escaped, and deposited the wealth they amassed together in a public treasury for common use. They made preparations of every kind for the defence of the city; and sent out emissaries to the Anabaptists in the Low Countries, inviting them to assemble at Munster, which was now dignified with the name of Mount Zion, that from hence they might be deputed to reduce all the nations of the earth under their dominion. Matthias, who was the first in command, was soon cut off in an act of, cruelty by the bishop of Munster's army; and was succeeded by Bockholdt, who was proclaimed by a special designation of Heaven, as he pretended, king of Zion, and invested with legislative powers by the choice of Moabites. The extravagances of Bockholdt were too numerous to be recited; it will be sufficient to add, that the city of Munster was taken after a long siege, and an obstinate resistance; and Bockholdt, the mock monarch, was punished with a most painful and ignominious death.

It must, however, be acknowledged that the true rite of the numerous insurrections of this period ought not to be attributed to religious opinions. The first insurrections groaned under the most grievous oppressions; they took up arms principally in defence of their civil liberties; and of the commotions that took place. The Anabaptists boasted that they had availed themselves, than to have been the prime movers. See the article Reformation.

—That a great part of the main body, indeed, consisted of Anabaptists seems indisputable; and whatever fanaticism existed among them would naturally be called forth or inflamed by the situations that occurred, and run riot in its wildest shapes. At the same time it appears from history, that a great part also consisted of Roman-Catholics, and a still greater of persons who had scarcely any religious principles at all. Indeed, when we read of the vast numbers that were concerned in those insurrections, of whom it is reported that 100,000 fell by the sword, it appears reasonable to conclude that a great majority of them were not Anabaptists.

Before concluding this article, it must be remarked, that the Baptists or Mennonites in England and Holland are to be considered in a very different light from the enthusiasts we have been describing: and it appears equally uncandid and invidious, to trace up their distinguing sentiment, as some of their adversaries have done, to thole obnoxious characters, and there to stop, in order as it were to associate with it the ideas of turbulence and fanaticism, with which it certainly has no natural connexion. Their insurrection with some of those oppressed and infatuated people in denying baptism to infants, is acknowledged by the Baptists: but they disavow the practice which the appellation of Anabaptists implies; and their doctrines seem referable to a more ancient and respectable origin. They appear supported by history in considering themselves as the descendants of the Waldensians, who were grievously oppressed and persecuted by the despotic heads of the Romish hierarchy; and they profess an equal aversion to all principles of rebellion on one hand, and to all suggestions of fanaticism on the other. See Baptists.

—The denomination of Mennonites, by which they are distinguished in Holland, they derive from Menno, the famous man who latterly gave consternation and instability to their sect. See Mennonites.

ANABASII, in antiquity, were couriers who were sent on horseback, or in chariots, with dispatches of importance.

ANABATHRA, in ancient writers, denote a kind of steps or ladder whereby to ascend to some eminence. In this sense we read of the anabathra of theatres, pulpits, &c. Anabathra appears to have been sometimes also applied to ranges of seats rising gradually over each other.

ANABATHRA is more particularly applied to a kind of stone blocks raised by the high-way fides, to assist travellers in mounting or alighting, before the use of stirrups was invented. —The first author of this contrivance among the Romans was C. Gracchus brother of Tiberius.

ANABLEPS, in ichthyology, the trivial name of a species of cobitis. See Cobitis.

ANABOA, a small island situated near the coast of Loango in Africa, in E. Long. 5°. N. Lat. 1°. Here are several fertile valleys, which produce plenty of bananas, oranges, pine-apples, lemons, citrons, tamarinds, coconuts, &c. together with vast quantities of cotton. In this island are two high mountains, which, being continually covered with clouds, occasion frequent rains.

ANABOLEUM, or ANABOLE, in antiquity, a kind of great or upper coat, worn over the tunica.

ANABOLEUS, in antiquity, an appellation given to grooms of the stall, or squerries, who assisted their masters in mounting their horses. As the ancients had no stirrups, or stirrups that are now in use for mounting a horse, they either jumped upon his back, or were aided in mounting by anabolei.

ANACALYPTERIA, according to Suidas, were presents made to the bride by her husband's relations and friends when the first uncovered her face and showed herself to men. These presents were also called προνόαι: for among the Greeks, virgins before marriage were under strict confinement, being rarely permitted to appear in public, or converse with the other sex; and when allowed that liberty, wore a veil over their faces termed καπειτας, or καπειτης, which was not left off in the presence of men till the third day after marriage; whence, according to Hesychius, this was also called anacalypteron.
**ANA** [ 655 ] **ANA**

**Anacampseros**, in botany, a synonyme of the portulacas and several other plants.

**Anacampsteria**, in ecclesiastical antiquity, a kind of little edifices adjacent to the churches, designed for the entertainment of strangers and poor persons.

**Anacamp tic**, a name applied by the ancients to that part of optics which treats of refexion, being the same with what is now called *catoptrics*.

**Anacardium**, or cashew-nut tree: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 12th order, Holarkaem. The characters are: The calyx is divided into four parts, the divisions ovate and deciduous: The corolla consists of five reflected petals, twice the length of the calyx: The filament consists of ten epiphal filaments shorter than the calyx, one of them calcarated; the antherae are small and roundish: The pistillum has a roundish germen: The styles is subulate, inflected, and the length of the corolla: The stigma oblique: There is no pericarpium; the receptaculum is very large and flieky: The seed is a large kidney-shaped nut, placed above the receptaculum.

Of this only one species is as yet known to the botanists, viz. the occidentale. It grows naturally in the west Indies, and arrives at the height of 20 feet in those places of which it is a native. The fruit of this tree is as large as an orange; and is full of an acid juice, which is frequently made use of in making punch. To the apex of this fruit grows a nut, of the size of a hare’s kidney, but much larger at the end than at the other. The shell is very hard; and the kernel, which is sweet and pleasant, is covered with a thin film. Before a spot of ground, to which they retreat, they are apt to rot. If the nuts are fresh, the plants will come up in about a month.

**Anachropheosis**, in rhetoric, the fame with recapitulation. See Recapitulation.

**Anacharsis**, a famous Scythian philosopher, converted with Solon, and lived an austere life. Upon his return from his travels through Greece, he attempted to change the ancient customs of Scythia, and to establish those of Greece; which proved fatal to him. The king shot him dead in the wood with an arrow. A great many flataxes were credited to him after his death. He is said to have invented tinder, the anchor, and the potter’s wheel; but the latter is mentioned by Homer, who lived long before him. Anacharsis flourished in the time of Cæcilius.

**Anachoret**, in church history, denotes a hermit, or solitary monk, who retires from the society of mankind into some desert, with a view to avoid the temptations of the world, and to more at leisure for meditation and prayer. Such were Paul, Anthony, and Hilarion, the first founders of monastic life in Egypt and Palestine.

Anachores, among the Greeks, consist principally of monks, who retire to caves or cellars, with the leave of the abbot, and an allowance from the monastery; or who, weary of the fatigues of the monastery, purchase a spot of ground, to which they retreat, never appearing again in the monastery, unless on solemn occasions.

**Anachronism**, in matters of literature, an error with respect to chronology, whereby an event is placed earlier than it really happened. — The word is compounded of aνα, “higher,” and χρονος, “time.” Such is that of Virgil, who placed Dido in Africa at the time of Æneas, though in reality she did not come there till 300 years after the taking of Troy. — Anachronism, in ecclesiastics, whereby a fact is placed later and lower than it should be, is called *barbaresco*.

**Anaclastic glasses**, a kind ofHonorous phials or glasses, chiefly made in Germany, which have the property of being flexible; and emitting a vehement noise by the human breath. — They are also called *oxyg glases* by the Germans (*oxyg gliaser*), on account of the fright and disturbance they occasion by their reflection. — The anaclastic glasses are a kind of phials, with flat bellies, resembling inverted funnels, whose bottoms are very thin, scarce surpassing the thickness of an onion peel; this bottom is not quite flat, but a little convex. But upon applying the mouth to the orifice, and gently inspiriting, or as it were fucking out the air, the bottom gives way with a prodigious crack, and of convex becomes concave. On the contrary, upon expiring or breathing gently into the orifice of the same glasses, the bottom with no less noise bounds back to its former place, and become gibbous as before. — The anaclastic glasses first taken notice of were...
Analectics were in the castle of Goldbach; where one of the academicians, Nature Curiosa, having seen and made experiments on them, published a piece expressly on their history and phenomena. They are all made of a fine white glass. It is to be observed of these, 1. That if the bottom be concave at the time of inspiration, it will burst; and the like will happen if it be convex at the time of expiration. 2. A strong breath will have the same effect even under the contrary circumstances.

Analectics, that part of optics which considers the refraction of light, and is commonly called Dioptrics. See Dioptrics.

Anacleteria, in antiquity, a solemn festival celebrated by the ancients when their kings or princes came of age, and assumed the reins of government. It was so called, because proclamation being made of this event to the people, they went to salute their prince during the anacleteria, and to congratulate him upon his new dignity.

Anaclyticum, in the ancient art of war, a particular blast of the trumpet, whereby the fearful and flying soldiers were rallied and recalled to the combat.

Anacrinopale, anacrinopale, in antiquity, a kind of wrestling, wherein the champions threw themselves voluntarily on the ground, and continued the combat by pinching, biting, scratching, and other methods of offence. The Anacrinopale was distinguished from the Orthopale, wherein the champions stood erect. In the Anacrinopale, the weaker combatants sometimes gained the victory.

Anaclytisia, in antiquity, a kind of pillows on the dining-bed, wherein the guests used to lean. The ancient tricliniary beds had four pillows, one at the head, another at the feet, a third at the back, and a fourth at the breast. That on which the head lay, was properly called by the Greeks ἀνακρίτισις, or anacritis; by the Romans fulcum, sometimes πλευτα.

Anaclysis, a composition of astringent powders, applied by the ancients to the head, to prevent defluxions on the eyes.

Anaclyticos, in natural history, is a name given in the island of Ceylon to a very large and terrible rattlesnake, which often devours the unfortunate traveller alive, and is itself accounted excellent and delicious fare.

Anacreon, a Greek poet, born at Teos, a city of Ionia, flourished about 552 years before the Christian era. Polycrates, tyrant of Samos, invited him to his court, and made him share with him in his business and his pleasures. He had a delicate wit, as may be judged from the ineffable beauties and graces that thine in his works: but he was fond of pleasure, was of an amorous disposition, and addicted to drunkenness: yet, notwithstanding his debaucheries, he lived to the age of 83; when, we are told, he was choked by a grape-stone which stuck in his throat as he was regaling on some new wine of a small part of Anacreon's works that remain; for, besides his odes and epigrams, he composed elegies, hymns, and iambics. His poems which are extant were rescued from oblivion by Hen-
ANAGALLIS, a genus of the plant family Plumbaginaceae, is a beautiful small perennial plant, and produces blue flowers. It is frequently taken as food; it makes no unpleasing smell in the fields, but is not so common as the first. The third field is sometimes found wild in the fields, but it is not so common as the first. The third field is a beautiful small perennial plant, and produces numbers of fine blue flowers. The fourth is a native of Spain, and likewise produces blue flowers. The plants are very easily propagated by seeds; and if suffered to remain till their seeds fatten, they become troublesome weeds.—The arvensis is not unfrequently taken as food; it makes no unpleasant smell, and in some parts of Great Britain is a common pot-herb. All the species are eat by cows and goats, but refused by sheep; small birds are greatly delighted with the seeds.—Great medicinal virtues were formerly expected from the first two species; but they are now fallly disregarded.

ANAGNIA, (anc. geog.), a town of Latium, capital of the Hernici; which after a short resistance, submitted to the Romans, was admitted to the freedom of the city, yet without the right of suffrage, (Livy). It was afterwards a colony of Dukes Caeser, and walled round, and its territory assigned to the veterans, (Frontinus). Here Antony married Cleopatra, and divorced Octavia. Now Anagni, 36 miles to the east of Rome. E. Long. 13° 45'. Lat. 42° 48'.

ANAGOSTHA, or ANAGROSTES, in antiquity, a kind of literary servant, retained in the families of persons of distinction, whose chief business was to read to them during meals, or at any other time when they were at leisure. Cornelius Nepos relates of Atticus, that he had always an anagrostes at his meals. He never fell without reading; so that the minds of his guests were no less agreeably entertained than their appetites. The same custom, Eginhard observes, was kept up by Charlemagne, who at table had the histories and acts of ancient kings read to him. This custom seems to have been of a relic of that of the ancient Greeks, who had the praires of great men and heroes sung to them while at table. The ancient monks and clergy kept up the like usage, as we are informed by St Augustine.

ANAGOGICAL, signifies mysteries, transporting; and is used to express whatever elevates the mind, not only to the knowledge of divine things, but of divine things in the next life. This word is seldom used, but with regard to the different senses of Scripture. The anagogical sense is, when the sacred text is explained with a regard to eternal life, the point which Christians should have in view: for example, the rest of the fabbath, in the anagogical sense, signifies the repose of everlasting happiness.

ANAGOGY, or ANAGOG, among ecclesiastical writers, the elevation of the mind to things celestial and eternal. It is particularly used, where words, in their natural and primary meaning, denote something sensible, but have a further view to something spiritual or invisible.

ANAGOGY, in a more particular sense, denotes the application of the types and allegories of the Old Testament to subjects of the New; thus called, because the veil being here drawn, what before was hidden, is exposèd to open sight.

ANAGRAM (from the Greek ἀνάĕδωσα, backwards, and πρῶτον letter), in matters of literature, a transposition of the letters of some name, whereby a new word is formed, either to the advantage or disadvantage of the person or thing to which the name belongs. Thus, the anagram of Galenus is angelus; that of Logica, colleg; that of Albidius, sedulus; that of Loraine is alerion, on which account it was that the family of Loraine took alerions of their armory.—Calvin, in the title of his Institutes, printed at Straßburg in 1539, calls himself Aclivius, which is the anagram of Calvinus, and the name of an eminently learned person in the time of Charlemagne, who contributed greatly to the restoring of learning in that age.

Those who adhere strictly to the definition of an anagram, take no other liberty than that of omitting...
or retaining the letter $h$, at pleasure; whereas others make no scruple to use $e$ for $h$, $v$ for $w$, $s$ for $z$, and $c$ for $k$; and vice versa.

Besides anagrams formed as above, we meet with another kind in ancient writers, made by dividing a single word into several; thus $f_{i} s_{t} i_{n} s_{u} m_{a}_{s}$, are formed out of the word $f_{i} u_{l}_{i} n_{c}_{a}_{n}_{m}_{a}_{s}$.

Anagrams are sometimes also made out of several words: such is that on the question put by Pilate to our Saviour, *Quid est veritas?* whereof we have this admirable anagram, viz. *Eli vir qui adest*.

The Cabalists among the Jews are professed anagrammatists; the third part of their art, which they call *theomancy*, i.e. "changing," being nothing but the art of making anagrams, or of finding hidden and mystical meanings in names; which they do by changing, transposing, and differently combining, the letters of those names. Thus, of the letters of Noah's name, they make *pri graece; of No deus the Deusiah*, they make $n_{u} w_{u} r_{h}$ be *fuit reip.*

**Anagrammatist**, a maker or composer of anagrams. Thomas Billon, a provincial, was a celebrated anagrammatist, and retained by Lewis XIII. with a pension of 1200 livres, in quality of anagrammatist to the king.

**Anagros**, in commerce, a measure for grain used in some cities in Spain, particularly at Seville; 46 anagros make about 100 quarters of London.

**Anagryis**, stinking bean-tree: A genus of the monogyne order, belonging to the decandria class of plants; and, in the natural method, ranking under the 32d-order, *Papilionaceae*. The characters are: The calyx is a bell-shaped perianthium; The corolla is papilionaceous; the vexillum cordated, straight, emarginated; and twice as long as the calyx; the ala ovate and longer than the vexillum; the carina straight and very long: The stigma consists of 10 filaments; the anther simple: The pistillum has an oblong germen, a simple style, and a villous stigma: The pericarpium is an oblong legumen: The seeds are fix or more, and kidney-shaped.

Of this genus there is but one species, the fetida, which grows naturally in the southern parts of Europe. It is a shrub which usually rises to the height of eight or ten feet, and produces its flowers in April or May. These are of a bright yellow colour, growing in spikes, somewhat like the laburnum.

**Culture.** This plant may be propagated either by seeds, or by laying down the tender branches in the spring; but the first method is preferable. The seeds should be sown towards the end of March in pots filled with light earth, and plunged in a gentle hot-bed. The plants usually appear in a month, when they should be gradually exposed to the open air, that they may be hardened before winter. In the autumn and winter, they must be sheltered under a hot-bed frame: the spring following, they must be transplanted, each into a separate small pot, placed in a sheltered situation, and again removed into a frame to shelter them during the following winter. The second spring after the plants come up, some of them may be taken out of the pots, and planted in a border near a south wall, where, if they are protected in winter, they may remain.

**ANAK** or **Anakims**, the name of a place in Attica, of the tribe Erechtheis, where a fetid plant, called **Anagryis**, probably the fame with the foregoing, grew in great plenty, (Dieuroides, PIny, Stephanus;) and the more it was handled, the stronger it smelted: hence *coromercere anagryis* (or *anagrynum*), is to bring a misfortune on one's self, (Aristophanes.)

**ANAK**, the father of the Anakims, was the son of Arba, who gave his name to Kirjath-arba, or Hebron, Josh. xiv. 15. Anak had three sons, Shechun, Ahiman, and Talmai, (chap. xv. 14 and Numb. xiii. 22.) who, as well as their father, were giants, and who, with their poteity, all terrible for their fierceness and extraordinary stature, were called the **Anakims**; in comparison of whom the Hebrews, who were sent to view the land of Canaan, reported that they were but as grasshoppers. Numb. xiii. 1. Caleb, afflicted by the tribe of Judah, took Kirjath-arba, and destroyed the Anakims, (Judges i. 20. and Josh. xv. 14.) in the year of the world 2559.

**Analecta**, or **Analcetis**, in antiquity, a servant whose employment it was to gather up the off-falls of the table.

**Analecja**, word, is used to denote a collection of small pieces; as essays, remarks, &c.

**Analenema**, in geometry, a projection of the sphere on the plane of the meridian, orthographically made by straight lines and ellipses, the eye being supposed at an infinite distance, and in the east, or west, points of the horizon.

**Analamma**, denotes likewise an instrument of brafs or wood, upon which this kind of projection is drawn with an horizon and curfors fett to it, whereon the folitious colour, and all circles parallel to it, will be concentric circles; all circles lying to the eye, will be ellipses; and all circles whole planes pass through the eye, will be right lines. The use of this instrument is to shew the common astronomical problems; which it will do, though not very exactly, unless it be very large.

**Analepsis**, the augmentation or nutrition of an emaciated body.

**Analeptics**, restorative or nourishing medicines.

**Analogy**, in philosophy, a certain relation and agreement between two or more things, which in other respects are entirely different.

There is likewise an analogy between beings that have some conformity or resemblance to one another; for example, between animals and plants; but the analogy is still stronger between two different species of certain animals.

Analogy enters much into all our reasoning, and serves to explain and illustrate. A great part of our philosophy, indeed, has no other foundation than analogy.

It is natural for mankind to judge of things left known, by some similitude, real or imaginary, between them and things more familiar or better known. And where the things compared have really a great similitude in their nature, when there is reason to think that they are subject to the same laws, there may be
A N A

A N A [ 659 ]

Analogy. A considerable degree of probability in conclusions drawn from analogy. Thus we may observe a very great similitude between this earth which we inhabit, and the other planets, Saturn, Jupiter, Mars, Venus, and Mercury. They all revolve round the sun, as the earth does, although at different distances, and in different periods. They borrow all their light from the sun, as the earth does. Several of them are known to revolve round their axis like the earth, and, by that means, must have a like succession of day and night. Some of them have moons, that serve to give them light in the absence of the sun, as our moon does to us. They are all, in their motions, subject to the same law of gravitation, as the earth is.

From all this similitude, it is not unreasonable to think, that those planets may, like our earth, be the habitation of various orders of living creatures. There is some probability in this conclusion from analogy.

But it ought to be observed, that, as this kind of reasoning can afford only probable evidence at best; so, unless great caution be used, we are apt to be led into error by it. To give an instance of this: Anatomists in ancient ages, seldom dissected human bodies; but very often the bodies of those quadrupeds whose internal structure was thought to approach nearest to that of the human body. Modern anatomists have discovered many mistakes the ancients were led into, by their conceiving a greater similitude between the structure of men and of some beasts than there is in reality.

Perhaps no author has made a more just and a more happy use of his mode of reasoning, than Bishop Butler in his Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature. In that excellent work, the author does not ground any of the truths of religion upon analogy, as their proper evidence. He only makes use of analogy to answer objections against them. When objections are made against the truths of religion, which may be made with equal strength against what we know to be true in the course of nature, such objections can have no weight.

Analogy, reasoning, therefore, may be of excellent use in answering objections against truths which have other evidence. It may likewise give a greater or a less degree of probability in cases where we can find no other evidence. But all arguments drawn from analogy are still the weaker, the greater disparity there is between the things compared; and therefore must be weakest of all when we compare body with mind, because there are no two things in nature more unlike.

There is no subject in which men have always been so prone to form their notions by analogies of this kind, as in what relates to the mind. We form an early acquaintance with material things by means of our senses, and are bred up in a constant familiarity with them. Hence we are apt to measure all things by them; and to ascribe to things most remote from matter the qualities that belong to material things. It is for this reason that mankind have, in all ages, been so prone to conceive the mind itself to be some subtle kind of matter; That they have been disposed to ascribe human figure, and human organs, not only to angels, but even to the Deity.

To illustrate more fully that analogical reasoning from a supposed similitude of mind to body, which appears to be the most fruitful source of error with regard to the operations of our minds, the following instance may be given. When a man is urged by contrary motives, those on one hand inclining him to do one action, those on the other to forbear it; he deliberates about it, and at last resolves to do it, or not to do it. The contrary motives are here compared to the weights in the opposite scales of balance; and there is not perhaps any infinace that can be named of a more striking analogy between body and mind. Hence the phrasing of weighing motives, of deliberating upon actions, are common to all languages.

From this analogy some philosophers draw very important conclusions. They say, that as the balance cannot incline to one side more than the other, when the opposite weights are equal; so a man cannot possibly determine himself if the motives on both hands are equal; and as the balance must necessarily turn to that side which has most weight, so the man must necessarily be determined to that hand where the motive is strongest. And on this foundation some of the schoolmen maintained, that if a hungry afs were placed between two bundles of hay equally inviting, the beast must stand still and starve to death, being unable to turn to either, because there are equal motives to both. This is an instance of that analogical reasoning, which, it is conceived, ought never to be trusted; for the analogy between a balance and a man deliberating, though one of the strongest that can be found between matter and mind, is too weak to support any argument. A piece of dead inactive matter, and an active intelligent being, are things very unlike; and because the one would remain at rest in a certain cafe, it does not follow that the other would be inactive in a cafe somewhat similar. The argument is no better than this, that, because a dead animal moves only as it is pushed, and, if pushed with equal force in contrary directions, must remain at rest; therefore the same thing must happen to a living animal; for surely the similitude between a dead animal and a living, is as great as that between a balance and a man.

The derivation of the word Analogy indicates, as professor Caullion of Berlin observes, a resemblance discernible by reason. This is confirmed by the word analogy in which the term is used in geometry, where it signifies an equality of ratios. In explaining this subject, it is observed, there may be a resemblance between sensations and a resemblance between perceptions: the former is called physical resemblance, because it acts upon the physical or sentient faculty; the latter moral resemblance, because it affects the moral or rational faculty of man.

Every resemblance may be reduced to an equality in sensations or perceptions; but this supposes some equality in their causes: we say some equality, because the disposition of the organs, or of the soul, must necessarily affect the sensations or perceptions; but this can influence only their degree, and not their nature.

The character of one person resembles that of another only when they both speak and act so as to excite equal
equal preceptions, or, to speak more strictly, the same perception: when they both display vivacity or indifference, anger or meekness, on the same occasions, and both excite in the soul of the observer identical perceptions, or rather the same perception of vivacity or indifference, of anger or meekness. These identical perceptions and the sense of which will depend much on the disposition of the observer's mind, must have identical causes, or, in other words, the same cause; which is the vivacity or indifference, the anger or meekness, displayed by each of these characters.

Every physical resemblance may therefore be reduced to one or more equalities; and every moral resemblance to one or more identities. Wherever there is moral resemblance there is analogy. Analogy may therefore be reduced to identity, and always supposes comparison.

Two objects are said to have an analogy to each other, or are called analogous, when some identity is discovered upon comparing them. An analogical conclusion, is a conclusion deduced from some identity. The principles of analogy are a comparison of two objects; and one or more identities resulting from their being thus compared. The characters of analogy are—that two objects be compared—that there be one or more identities between these objects—and that this is discernible only by reason or intellect.

Physical resemblance is to the senses what analogy is to the understanding.—The former, when perfect, becomes equality; but the latter identity.

Resemblance and analogy are the foundations both of probability and of certainty. When we are not satisfied that the resemblance or the analogy is complete, we stop at probability; which becomes certainty when we are, or think we are, assured that the resemblance or the analogy is perfect.

In reasoning by analogy, we should be careful not to confound it with resemblance; and also not to deduce from the identity or identities, on which the analogy is founded, a conclusion, which has either no relation, or only a partial relation, to these identities.

The principal use of analogy in the investigation of physical and moral truth, according to our author, may be reduced to the four following: 1. By means of our senses to improve, first, our own judgment, and afterwards that of others, with respect to intellectual subjects. 2. To deduce a general from a particular truth. Having discovered and proved the truth of a proposition with respect to any particular object, examine whether this truth flows from a quality peculiar to this single object, or common to several objects. In the latter case all these objects may be comprehended under one general idea, founded on their common quality. Subdivide this general idea instead of the particular object, and the proposition will become general, without ceasing to be true; because whatever evidently and fully results from the identity, on which analogy is founded, must necessarily be true with respect to all those objects in which the analogy is the same.

3. To prove the truth or falsehood of propositions which cannot be otherwise determined. To discover new truths in both natural and moral philosophy.

Analogy, among grammarians, is the correspondence which a word or phrase bears to the geniuses and received forms of any language.

ANALYSIS, in a general sense, implies the resolution of something compounded, into its original and constituent parts. The word is Greek, and derived from ἔνωσις, to resolve.

Analysis, in mathematics, is properly the method of resolving problems by means of algebraical equations; hence we often find that these two words, analysis and algebra, are used as synonymous.

Analysis, under its present improvements, must be allowed the Apex or height of all human learning: it is this method which furnishes us with the most perfect examples of the art of reasoning; gives the mind an uncommon readiness at deducing and discovering, from a few data, things unknown; and, by using signs for ideas, presents things to the imagination, which otherwise seemed out of its sphere: by this, geometrical demonstrations may be greatly abridged, and a long series of arguments, wherein the mind cannot without the utmost effort and attention discover the connection of ideas, are hereby converted into sensible signs, and the several operations required therein effected by the combination of these signs. But, what is more extraordinary, by means of this art, a number of truths are frequently expressed by a single line, which, in the common way of explaining and demonstrating things, would fill whole volumes. Thus, by mere contemplation of one single line, whole sciences may be sometimes learnt in a few minutes time, which otherwise could scarce be attained in many years.

Analysis is divided, with regard to its object, into that of finite and infinites. See ALGEBRA.

Analysis of Finite Quantities, is what we otherwise call specific arithmetic or algebra. See ALGEBRA.

Analysis of Infinites, called also the New Analysis, is particularly used for the method of fluxions, or the differential calculus. See FLUXIONS.

Analysis, in logic, signifies the method of tracing things backward to their source, and of resolving knowledge into its original principles. This is also called the method of resolution; and stands opposed to the synthetic method, or that of composition.—The art of logical analysis consists principally in combining our perceptions, claffing them together with addresses, and contriving proper expressions for conveying our thoughts, and representing their several divisions, classes, and relations.

Analysis in rhetoric, is that which examines the connections, tropes, figures, and the like, inquiring into the proposition, division, passions, arguments, and other apparatus of rhetoric.

Several authors, as Freigius and others, have given analyses of Cicero's Orations, wherein they reduce them to their grammatical and logical principles, strip them of all the ornaments and additions of rhetoric which otherwise disguise their true form, and conceal the connection between one part and another. The design of these authors is to have those admired harangues just such as the judgment disposed them, without the help of imagination: so that here we may coolly view the force of each proof, and admire the use Cicero made of rhetorical figures to conceal the weak part of a cause.

A collection has been made of the analyses formed by the most celebrated authors of the 16th century, in 3 vols. folio.

Analysis is also used, in chemistry, for the de-compounding
To analyze bodies, or resolve them into their component parts, is indeed the chief object of the art of chemistry. Chemistry furnishes the means for the decomposition of bodies, which are all founded on the differences of the properties belonging to the different principles of which the body to be analyzed is composed. If, for example, a body be composed of several principles, none of which have a great, and others a moderate degree of volatility, and, lastly, others are fixed, its most volatile parts may be at first separated by a gradual heat in distilling vessels; and then the parts which are next in volatility will pass over in distillation; and lastly, those parts which are fixed, and capable of refilling the action of fire, will remain at the bottom of the vessel.

Analysis is also used for a kind of syllabus, or table of the principal heads or articles of a continued discourse, disposed in their natural order and dependence. Analyses are more scientific than alphabetical indexes; but they are less used, as being more intricate.

Analysis is likewise used for a brief, but methodical, illustration of the principles of a science; in which sense it is nearly synonymous with what we otherwise call a synopsis.

Analytic, or Analytical, something that belongs to, or partakes of, the nature of analyzis.—Thus we say, analytical demonstration, analytical process, analytical table or scheme, analytical method of investigation, &c.

The analytic method stands opposed to the synthetic. In natural philosophy, as in mathematics, the investigation of difficult things by the analytic method ought to precede the method of composition. This analysis consists in making experiments and observations, and in drawing general conclusions therefrom by induction; and admitting of no objections against the conclusions, but such as are drawn from experiments, and other certain truths: and though the reasoning from experiments and observations by induction be no demonstration of general conclusions, yet it is the best method of reasoning which the nature of things admits of; and may be esteemed so much the stronger, as the incompatibility of beliefs; and if no exception occur from phenomena, the conclusion may be pronounced general. By this way of analysis, we may proceed from compounds to their ingredients; from motions to the forces producing them; and, in general, from effects to their causes, and from particular causes to more general ones, until we arrive at those which are the most general. This is the analytic method, according to the illustrious Newton.

The synthetic method consists in assuming the causes discovered and received as principles: and by them explaining the phenomena proceeding from them, and proving the explanations. See Synthesis.

Analytics, Analysis, the form and use of analysis. The great advantage of the modern mathematics above the ancient is in point of analysis.

Pappus, in the preface to his seventh book of Mathematical Collections, enumerates among the authors on the ancient analytics; being Euclid, in his Data and Porify: Apollonius, de Sectione Rationis; and in his Conics; Aristeaus, de Lois Suidis; and Erotofthones, de Meditii Proportionibus. But the ancient analytics were very different from the modern.

To the modern analytics principally belong algebra; an historical account of which, with the several authors thereon, see under the article Algebra.

ANAMABA, a populous town in the kingdom of Fantin, in Guinea. The natives are generally great cheats, and must be carefully looked after in dealing with them, and their gold well examined, for it is commonly adulterated. It lies under the cannon of an English caisle. The landing is pretty difficult on account of the rocks; and therefore those that come here to trade are forced to go afloat in canoes. The earth here is very proper to make bricks; the oysters, when burnt, afford good lime; and there is timber in great abundance; so that here are all the materials for building. The country at Anamaba is full of hills, beginning at a good distance from the town, and affording a very pleasant prospect. Indian corn and palm-wine are in great plenty. They have a green fruit called papas, as big as a small melon, and which has a taffe like cauliflower. Anamaba is much frequented by the English ships and others for corn and slaves, which last are sometimes to be had in great numbers. The English fort is built on the foundation of a large old house, which subsisted entire in 1679. It is a large edifice, flanked by two towers, and fortified towards the sea with two battisons; the whole of brick and stone cemented with lime. It stands upon a rock, at the distance of 30 paces from the sea. It is mounted with 12 pieces of cannon and 12 pateroernes; and defended by a garrison of 12 whites and 18 blacks, under the command of the chief factor.

The natives treat the garrison of this fort with great insolence, inasmuch as often to block them up, and frequently, if they dislike the governor, send him off in a canoe to Cape Coast with marks of the utmost contempt. Far from being able to oppose them, the English are glad to obtain their favour with presents. In 1701, they declared war against the English; and having assembled in a tumultuous manner before the fort, they set fire to the exterior buildings, and went on with their outrages, till they were dispersed by a discharge of the cannon from the batteries. The night following the English took their revenge, by setting fire to the town of Anamaba; and thus hostilities continued for 20 days, till at last the natives were obliged to sue for peace. This fort was abandoned in 1733; but has been restored by the English, who have continued in it ever since.

ANAMIM, the second son of Nizram (Gen. x. 12.) Ananias, if we may credit the paraphrast Jonathan the son of Uzziel, depopulated the Marcopolis of Cyrene, according to the paraphrast of Jerusalem. Bochart is of opinion that these Anamims were the people that dwelt in the parts adjacent to the temple of Jupiter Ammon, and in the Nasaamotna.
Calmet thinks the Amanians and Garmantes to be descended from Anamim.

ANAMORPHOSIS, in perspective drawings, is a deformed or distorted portrait or figure, generally confused and unintelligible to the common unaided view; but when seen at a certain distance and height, or as reflected from a plain or curved mirror, will appear regular and in right proportion. See Optics (the Index), and Perspective.

ANANAS, in botany, the trivial name of a species of broomel. See Broemel.

ANANCITIS, in antiquity, a kind of figured stone, otherwise called symchitis, celebrated for its magical virtue of raising the shadows of the infernal gods.

ANANIAS, a Sadducee, high-priest of the Jews, who put to death St James the brother of our Lord, and was deposed by Agrippa.

ANANISABTA, or Ananisapa, a magical word frequently inscribed on coins and other amulets, supposed to have a virtue of preserving the wearer from the plague.

ANAPEST, in ancient poetry, a foot consisting of two short syllables and one long: Such is the word scepulius. It is just the reverse of the dactyI.

ANAPestic Verses, those consisting wholly or chiefly of anapaests.

ANAPHORAE (anc. geog.), an island spontaneously emerging out of the Cretan sea, near Thira (Pliny, Strabo); now called Naxos. Its name is from the sudden appearance of the new moon to the Argonauts in a form (Apollonius), Anaphaerus, an epithet of Apollo, who was worshipped there. Anaphoro, the people.

ANAPHORA, in rhetoric, the repetition of the same word or words in the beginning of a sentence or verse: Thus Virgil,

Pan etiam Arcadia nascitur ilia.
Pan etiam Arcadia ducta fel judicis verit.

Anaphora, among physicians, the throwing off purulent matter by the mouth.

ANAPHRODISIA, signifies impotence, or want of power to procreate. See Impotence.

ANAPLASIS, signifies the replacing or setting a fractured bone.

ANAPLORETICS, medicines that promote the growth or granulation of the flesh in wounds, ulcers, &c.

ANARCHI, Anergic, in antiquity, a name given by the Athenians to four supernumerary days in their year, dating which they had no magistrates. The Attic year was divided into ten parts, according to the number of tribes, to whom the precedence of the senate fell by turns. Each division consisted of 33 days; what remained after the expiration of these, to make the lunar year complete, which according to their computation consisted of 354 days, were employed in the creation of magistrates; and called anarchia anerget and anachon.

Anarchy, the want of government in a nation, where no supreme authority is lodged, either in the prince or other rulers; but the people live at large, and all things are in confusion. The word is derived from the Greek privative α, and αρχη, command prin-
Anarropia, Anas. Anas.

The eggs are accounted good food; and the flesh, especially that of the young, is much esteemed by the inhabitants. The nes of the feathers are manifest to every one; and the skins of the body are worn by the inhabitants; besides which, that of the legs, taken off, is sold and appears not unlike flaggare. Wild swans, Linnaeus says, frequently visit Sweden after a thaw, and are caught with apples in which a hook is concealed. The wild swan frequents the coasts of Great Britain, in hard winters, in large flocks, but does not breed there. Martin acquaints us, that swans come in October in great number to Lingey, one of the Western lakes; and continue there till March, when they return northward to breed. A few continue in Mainland, one of the Orkneys, and breed in the little islands of the fresh-water lochs: but the multitude retires at the approach of spring. On that account, swans are there the countryman's almanack: on their quitting the lake, they preface good weather; on their arrival, they announce bad. These, as well as most other water-fowl, prefer, for the purpose of incubation, those places that are least frequented by mankind: accordingly we find that the lakes and forests of the distant Lapland are filled during summer with myriads of water-fowl;
fowl; and there swans, geese, the duck-tribe, geese, divers, &c. pass that season; but in autumn return to other, more hospitable, shores.

This species has several distinctions from the species which in Britain is called the tame swan. In Russia this species more fairly claims the name, it being the kind most commonly tamed in that empire. The whistling swan carries its neck quite erect, the other swans with it arched. This is far inferior in size. This has twelve ribs on a side, the mute only eleven. But the most remarkable is the strange figure of the windpipe; which falls into the chest, then turns back like a trumpet, and afterwards makes a second bend to join the lungs. Thus it is enabled to utter a loud and shrill note. The other swan, on the contrary, is the most silent of birds: it can do nothing more than hiss, which it does on receiving any provocation. The vocal kind emits its loud notes only when flying or calling. Its sound is, _whoosh, whoosh_, very loud and shrill, but not disagreeable, when heard far above one's head and modulated by the winds. The natives of Russia compare it to the sound of a violin. It is a fact they hear it (says Mr Pennant) at the end of their long and gloomy winter; when the return of the swans announces the return of summer; every note must be therefore melodious which prefaces the speedy thaw, and the release from their tedious confinement.

It is from this species alone that the ancients have given the fable of the swan being ended with the powers of melody. Embracing the Pythagorean doctrine, they made the body of this bird the manifon of the souls of departed poets; and after that, attributed to the birds the same faculty of harmony which their inmates possessed in a pre-existent state. The vulgar, not distinguishing between sweetness of numbers and melody of voice, thought that real which the poets for the great poetical brethren in the same manner:

\[ Vars, tuum nomen \]

_Cantantes sublime ferent ad sidera cygni._

En. Lib. xi. 458.

It was also a popular opinion among the ancients, that the swan foretold its own end. To explain this, we must consider the twofold character of the poet, _vates_ and _poeta_, which the fable of the transmigration continues to the bird, or they might be supposed to derive that faculty from Apollo their patron deity, the god of prophecy and divination.

As to their being supposed to sing more sweetly at the approach of death, the cause is beautifully explained by Plato, who attributes that quality to their being in the same state of effigy that good men are sometimes said to enjoy at that awful hour, forseeing the joys that are preparing for them on putting off mortality.

The _manfactus_, or mute swan, is the largest of the British birds. It is distinguished externally from the wild swan; first, by its size, being much larger; secondly, by its bill, which in this is red, and the tip and sides black, and the skin between the eyes and bill is of the same colour. Over the back of the upper mandible, projects a black callous knot; the whole plumage, in old birds, is white; in young ones, all-coloured till the second year: the legs are dusky; but Dr Plot mentions a variety found on the Trent near Rugeley, with red legs.

The swan is found wild in Russia and Siberia, most plentiful in the last. It arrives later from the south, and does not spread so far north. Those about the southern part of the Caspian Sea are very large, and much esteemed for the use of the table. The swan is held in high estimation by the Mahometans. It is a very strong bird, and sometimes exceeding fierce: has not unfrequently been known to throw down and trample under feet youths of fifteen or sixteen years of age, and an old one to break the leg of a man with a stroke of the wings. It is said to be very long-lived, and frequently to arrive at the hundredth year. The young are not perfect in plumage till the second year.

The swan lays the first egg in February, and continues laying every other day to the amount of six, seven, or eight eggs; these it places on a bed of grass near the water, and fits six weeks. It feeds on both fish and herbage.

No bird, perhaps, makes so inellegant a figure out of the water, or has the command of such beautiful attitudes on that element, as the swan: almost every poet has taken notice of it; but none with that justness of description, and in so picturesque a manner, as Milton.

The swan, with arched neck

Between her white wings mantling, proudly rows Her state with oary feet. Far. Lok, B. vii.

In former times, it was served up at every great feast, when the elegance of the table was measured by the size and quantity of the good cheer. Cygnets are to this day fattened at Norwich about Christmas, and are sold for a guinea a-piece.

Swans were formerly held in such great esteem in England, that by an act of Edward IV. c. 6. "no one that possessed a freehold of less than a yearly value of five marks, was permitted to keep any, _other than the_ the swan of our sovereign lord, the king." And by the eleventh of Henry VII. c. 17. the punishment for taking their eggs was imprisonment for a year and a day, and a fine at the king's will. Though at present they are not so highly valued as a delicacy, yet great numbers are preserved for their beauty; multitudes are to be seen on the Thames and Trent, but no where greater numbers than the salt-water inlet of the sea near Abberbury in Dorsetshire.

2. The cygnoids, with a semicylindrical bill, gibus wax, and tumid eye-brows. It is the swan-goose of Ray, from Guinea. There is likewise a variety of this species, of a lefs size, called the geese of Missey. They are found wild about the Lake Balkal in the east of Siberia, and on the Nambotshaka. They are also kept tame in most parts of the Russian empire. These birds likewise inhabit China, and are common at the Cape of Good Hope. This is no doubt the species mentioned
mentioned by Kolben, called crop-goose; who says, that the failors make tobacco-pouches and purses of the membrane which hangs beneath the throat, as it is sufficiently tough for such purposes, and will hold two pounds of tobacco.

They are sufficiently common in Britain, and readily mix with the common goose; the breasts uniting as freely, and continuing to produce as certainly, as if no such mixture had taken place. They are much more noisy than the common tame goose, taking alarm at the least noise; and even without disturbance will emit their harsh and disagreeable scream the whole day through. They walk very erect, with the neck much elevated; and, as they bear a middle line between that of the swan and goose, they have not improperly been called wan-goose.

3. The tadorna, or fielddrake, has a flat bill, a compressed forehead, a greenish black head, and the body is variegated with white. This species is found as far as Iceland to the north. It visits Sweden and the Orkneys in the winter, and returns in spring. It is found in Asia about the Caspian Sea, and all the salt lakes of the Tartarian and Siberian deserts, as well as in Kamtchata. Late voyagers, if right in the species, have met with it at Falkland Isles and Van Diemen's Land. It breeds in deserted rabbit holes, or occupies them in the absence of the owners, who, rather than make an attempt at dislodging the intruders, form others; though, in defect of ready-made quarters, these birds will frequently dig holes for themselves. They lay fifteen or sixteen roundish white eggs. These are placed at the farther end of the hole, covered with down supplied from the breast of the female, who sits about 30 days. She is very careful of her young, and will often carry them from place to place in her bill: “This we are certain of (says Mr Latham), from a young one having been dropt at the foot of an intelligent friend unhurt, by the mother flying over his head.” When a person attempts to take their young, the old birds fly great address in diverting his attention from the brood; they will fly along the ground as if wounded, till the former are got into a place of security, and then return and collect them together. From this insinuating cunning, Turner, with good reason, imagines them to be the chenoapex or fox-goose of the ancients. The natives of the Orkneys to this day call them the fly-goose, from an attribute of that quadroon.

The young, as soon as hatched, take to the water, and swim surprisingly well; but do not come to their full plumage till the second year. This species, Mr Latham informs us, may be hatched under a tame duck, and the young readily brought up; but are apt, after a few years, to attempt the mastery over the rest of the poultry. In a state of nature, their food seems chiefly to be small fish, marine insects, and shells; herbage has likewise been found in their stomachs. In a tame state, they eat bread, grain, and greens. Their great beauty would tempt us to endeavour at domestickating the race; but it will not thrive completely, except in the neighbourhoood of salt water, which somehow seems essential to its well-being. The flesh Likewise is rank and unfavourable, though the eggs have at all times been thought very good.

4. The spéctabilis, has a compressed bill, gibbous at the base, a black feather carina, and a hoary head. It is the grey-headed duck of Edwards, and the king-duck of Pennant. This beautiful species is found at Hudson's Bay, at Churchill River, and (though scarce) at York Fort; in winter it is met with as far north as New-York. It is pretty frequent in the north of Siberia and Kamtchata; it is found also on the coast of Norway, and has been killed in the Orkneys. It is common in Greenland, where the flesh is accounted excellent, and the crude gibbous part of the bill a great delicacy. It produces a down equally valuable as the eider. The skins are sewed together, and make warm garments. The natives kill them with darts, and use the following method to succeed;—A number of men in canoes falling in with a flock while swimming, on a sudden set up a flouting, making as much noise as they can; on which, the birds being too much frightened to fly away, dive under the water; but as the place at which they are to rise again is known by the bubbling of the water above, the hunters follow them up as close as may be; and after acting this three or four times, the birds become so fatigued as to be easily killed. This species builds on the sides of ponds and rivers, making its nest of sticks and mosses, and lining it with feathers from the breast. It lays four or five whitish eggs, as large as those of the goose. The young fly in July. The food consists chiefly of worms and grafs.

5. The fusca, or velvet duck; is of a blackish colour, has a white spot behind the eyes, and a white line on the wings. The male of this species is distinguished by a gibbosity at the base of the bill. It is the black duck of Ray, and is in length about 20 inches. This species frequents Hudson's Bay in summer, where it breeds. The nest is composed of grafs; in which it lays from four to six white eggs, and hatches in July. It feeds on grafs, and is known by the names of cast ofä quatuor. It retires south in winter; when it is frequently seen as far south as New-York. Late navigators met with it at Aoonalaffika. It is now and then seen on the coasts of England, but is not common. It is more frequent on the continent, inhabiting Denmark and Rhufia. In some parts of Siberia it is very common; and it enters the list of those found at Kamtchata. In breeding-time, it goes far inland to lay the eggs; which are eight or ten in number, and white. After the seafon is over, the males are few, and wait to depart; the females staying behind till the young are able to fly, when the two last go likewise off, but to what part is not certain. It is in great plenty at Ochotska, especially about the equinox. Fifty or more of the natives go in boats and surround the whole flock, driving them into the flood of the river Ochotska; and, as soon as they are, the whole company fall on them at once with clubs, and often knock so many of them on the head that each man has 20 or 30 for his share.

6. The nigra, or scoter, is totally black, and has a gibbosity at the base of the bill; the tail resembles a wedge; the female is brownish. It is the leiffer black diver of Ray, and measures in length 22 inches. These birds are found on the northern coasts of England and the isle of Scotland in the winter seafon; but no where so common as on the French coasts, where they are seen in prodigious numbers from November to March, especially...
Their chief food is a glairy bivalve shell, near an inch long, called by the French "vainieux." These they are perpetually diving after, frequently to the depth of some fathoms; and an usual method of catching them is by placing nets under the water in such places as the shells are most numerous; by which means 30 or 40 dozen of them have been taken in one tide. The day seems to be spent by these birds between diving and flying to small distances from the water, which it does so as frequently to dip the legs therein. It swallows the food whole, and soon digests the shells, which are found quite crumbled to powder among the excrements. It has been kept tame for some time, and will feed on foaked bread. The flesh tastes fishy to an extreme; on which account is allowed by the Roman-Catholics to be eaten on fast days and in lent; and indeed must be a sufficient mortification.—These birds abound in all the northern parts of the continent, Lapland, Sweden, Norway, and Ruflia; and are found in great plenty on the great lakes and rivers of the north and east of Siberia, as well as on the sea shores. It likewise inhabits North-America; being met with at New-York; and in all probability much more to the north on this continent and that of Asia. Oftentimes having met with them in 30 and 34 degrees south latitude, between the island of Java and St. Paul, in the month of June.

7. The anser, feræ et manufactus; or gray lag, and tame geese. The grey lag or wild goose, is two feet nine inches in length, and five feet in extent. The bill is large and elevated; of a flesh colour, tinged with yellow; the head and neck cinereous; breast and belly whitish, clouded with gray or ash colour; back, grey; the legs of a flesh colour. This species resides in the fens the whole year; breeds there, and hatches about eight or nine young, which are often taken, easily tamed, and esteemed most excellent meat, superior to the domestic goose. Towards winter they collect in great flocks, but in all seasons live and feed in the fens. On the continent they are migratory, changing place in large flocks, often 500 or more: in this case, the flock is triangular in shape, with one point foremost; and as the goose which is first is tired sooner, it has been seen to drop behind, and another to take his place. In very small flocks, however, they are sometimes seen to follow one another in a direct line. Geese seem to be general inhabitants of the globe. The manufactus, is the grey lag in a state of domestication, and from which it varies in colour, though much less so than either the mallard or coot, being ever more or less vering to grey: though in all cases the whiteness of the vent, and upper tail coverts, is manifest. It is frequently found quite white, especially the males; and doubts have arisen, which of the two colours should have the preference in point of eating. Tame geese are kept in great multitudes in the fens of Lincolnshire, in England; a single person will have 1000 old geese, each of which will rear seven; so that towards the end of the season he will become possessed of 8000. During the breeding-season these birds are lodged in the same houses with the inhabitants, and even in their very bed-chambers: in every apartment are three rows of coarse wooden pens, placed one above another; each bird has its separate lodge divided from the other, which it keeps possession of during the time of sitting. A person called a "gozzard," i.e. goose-herd, attends the flock, and twice a day drives the whole to water; then brings them back to their habitations, helping those that live in the upper stories to their nests, without ever misplacing a single bird. The geese are plucked five times in the year: the first plucking is at Lady-day, for feathers and quills; the same is renewed, for feathers only, four times more between that and Michaelmas. The old geese submit quietly to the operation, but the young ones are very noisy and unruly. If the season proves cold, numbers of them die by this barbarous custom. Vast numbers of geese are driven annually to London, to supply the markets; among them, all the superannuated geese and ganders, which, by a long course of plucking, prove uncommonly tough and dry. The goose in general breeds only once in a year; but will frequently have two hatches in a season, if well kept. The time of sitting is about 30 days. They will also produce eggs sufficient for three broods, if they are taken away in succession. It is said to be very long-lived, as we have authority for their arriving at no less than 100 years.

8. The bean-geese, or two feet seven inches in length; in extent four feet eleven. The bill, which is the chief distinction between this and the former, is small, much compressed near the end, whitish, and somewhat pale red in the middle, and black at the base and nail: the head and neck are cinereous brown, tinged with ferruginous; breast and belly dirty white, clouded with cinereous; the back of a pale ash colour; feet and legs of a faffron colour: claws black. This species arrives in Lincolnshire in autumn; and is called the bean-geese, from the likeness of the nail of the bill to a horse-bean. They always light on corn-fields, and feed much on the green wheat. They never breed in the fens; but all disapper in May. They retreat to the sequestered wilds of the north of Europe; in their migration they fly a great height, cackling as they go. They prefer a great regularity in their motions; sometimes forming a straight line; at others, assuming the shape of a wedge, which facilitates their progress, for they cut the air reader in that form than if they flew pell-mell.

9. The erythropus, or laughing goose of Edwards, is a native of Europe and America. The length of this species is about two feet four; the extent four feet fix; the bill is elevated, of a pale yellow colour, with a white ring at the base; the forehead is white; the breast and belly are of a dirty white, marked with great spots of black; and the legs yellow. These visit the fens and other parts of England during winter, in small flocks; they keep always in marshy places, and never frequent the corn-lands. They disappear in the earliest spring, and none are seen after the middle of March. Linnaeus makes this goose the female of the bernacle; but Mr Pennant thinks his opinion not well founded.

The bernacle (erythropus mas Lin.) is two feet one inch in length, the breadth four feet five inches: the bill is black; the forehead and cheeks are white; from the bill to the eyes, there is a black line; the hind part of the head, the whole neck, and upper part of the breast and back, are of a deep black; the bill is black, the legs are of the same colour, and small. These birds appear
appear in vast flocks during winter, on the north-west coasts of Great-Britain; they are very fly and wild; but on being taken, grow in a few days as familiar as the tame goose. In February they retire as far as Lapland, Greenland, and even Spitzbergen, to breed. They live to a great age: the Rev. Dr Backworth of Spalding, had one which was kept in the family above 32 years, but was blind during the two last; what its age was when first taken, was unknown.

These are the birds that about 400 years ago were believed to be generated out of wood, or rather a species of shell that is often found flicking to the bottoms of ships, or fragments of them; and were called *tree-geese*. These were also thought by some writers to have been the *benedopeces* of Pliny; they should have had *cherenotes*, for those were the birds which that naturalist said were found in Britain: but as he has scarce left us any description of them, it is difficult to say which species he intended. Mr Pennant imagines it to be the following; which is far inferior in size to the wild-geese, and very delicate food, in both respects fulfilling his description of the *cherenotes*.

10. The race-horse or loggerhead goose, is in length 32 inches, and weighs from 20 to 30 pounds. The bill is three inches long, and of an orange colour: the irides are orange, surrounded with black, and then with orange: the head, neck, and upper parts of the body are of a deep ash-colour: the outer edge of the secondaries white, forming a band of the fame on the wing: the under parts of the body dusky down the middle; over the thighs cinereous blue; vent white; quills and tail black: the wings are very short, not reaching to the rump: on the bend of the wing is a yellow knob, half an inch in length; the legs are brownish orange, the webs dusky, and the claws black. These inhabit Falkland Islands, Staaten Land, &c. and were mofily seen in pairs, though sometimes they were observed in large flocks. From the shortness of their wings they were unable to fly; but they made considerable use of them when in the water, on which they seemed as much at ease, as they do on land, and were frequently seen swimming in great numbers.

II. The snow-geese is in length two feet eight inches, and weighs between five and six pounds. The bill is somewhat ferrated at the edges: the upper mandible scarlet, the lower white: the general colour of the plumage is snow-white, except the first ten quills, which are black, with white shafts: the legs are of a deep red. The young are of a blue colour, till they are two years old. These are very numerous at Hudson's-Bay, and called by the natives *Way-way* and *Wapa whe whe*. They visit Severn River in May, and stay a fortnight; but go farther north to breed; they return to Severn-Fort the beginning of September, and fly to the middle of October, when they depart for the south, and are observed to be attended with their young, in flocks innumerable. At this time many thousands are killed by the inhabitants; who pluck them, and take out the entrails, and putting the bodies into holes dug in the ground cover them with earth, which freezing above them, keeps them perfectly sweet throughout the severe season; during which there is no more to do than occasionally to open one of these hovels, when they find them sweet and good. They seem to occupy also the western side of America. In the summer months, they are plenty on the arctic coast of Siberia, but never migrate beyond longitude 130. They are sup posed to pass the winter in more moderate climates, as they have been seen flying at a great height over Siberia; probably on their passage to some other country, as it does not appear that they continue there. In like manner, those of America pass the winter in Carolina. Here they arrive in vast flocks; and feed on the roots of fage and grafs, which they tear up like hogs. It used to be a common practice in that country to burn a piece of a marsh, which enclosed the *cherenotes* there, as they could then more readily get at the roots, which gave the sportman opportunity of killing as many as he pleased. This species is the most numerous, and the most stupid of all the goose race. They seem to want the instinct of others, by their arriving at the mouth of the Arctic Atlantic rivers before the seafon in which they can possibly subsist. They are annually guilty of the same mistake, and annually compelled to make a new migration to the south in quest of food, where they pass their time till the northern estuaries are freed from the bonds of ice. They have no little of the thyness of other geese, that they are taken in the most ridiculous manner imaginable about Jakut, and the other parts of Siberia, which they frequent. The inhabitants first place, near the banks of the rivers, a great net, in a straight line, or else form a hovel of skins sewed together. This done, one of the company dresses himself in the skins of a white reindeer, advances towards the flock of geese, and then turns back towards the net or the hovel; and his companions go behind the flock, and by making a noise drive them forward. The simple birds mistake the man in white for their leader, and follow him within reach of the net, which is suddenly pulled down and captures the whole. When he chooses to conduct them to the hovel, they follow in the same manner; he creeps in at a hole left for that purpose, and out at another on the opposite side, which he closes up. The geese follow him through the first; and as soon as they are got in, he closes round, and secures every one.

12. The great goose is of a very large size, weighing near 25 or 30 Ruffian pounds. The bill is black; bale of tawny: body dusky; the under parts are white; the legs scarlet. It is found on the coast of Siberia, from the river Lena to Kamtchatka; and is taken in great numbers.

13. The rucoolls, or red-breasted goose, is in length 21 inches; weight three pounds troy. The bill is small and brown; the tail black; the irides are yellow brown; round the eyes fringed with brown; fore part of the head and crown black, passing backwards in a narrow stripe quite to the back; on the breast is a narrow band of white feathers with black ends forming
ing a band of white and another of black; the sides are striped with black; back and wings black, the left even with the tail; legs black. This most elegant of geese is found to breed from the mouth of the Ob, along the coasts of the icy sea, to that of the Lena. Its winter quarters are not certainly known. Small flocks are observed in the spring flying from the Caspian sea along the Volga northward, and are feared about Zanzey, between the sixth and tenth of April. They rest a little time on the banks of the Sarpa, but soon resume their arctic course. Their winter retreat is probably in Perse. They are highly esteemed for the table, being quite free from any filthy taste.

14. The casarca, or ruddy-geese, is larger than a mallard, and seems even larger than it really is, from the length of wing, and standing high on its legs. The bill is black; the irides are yellowish brown; forehead, cheeks, and throat, yellowish; fore part of the neck ferruginous, encircled with a collar of black, inclining to deep rufous on the throat; the breast and side are pale rufous; the belly is obscure; the back is pale; the lower part is undulated, hoary, and brown; not veering from dark rufous on the head and tail; the legs long and black. This species is found in all the southern parts of Russia and Siberia in plenty. In winter it migrates into India, and returns northward in spring. It makes the nest in the craggy banks of the Volga and other rivers, or in the hollows of the deferted hillocks of marmots; making it after the manner of the shieldrake, and is faith to form burrows for itself in the manner of that bird. It has been known also to lay in a hollow tree, lining the nest with its own feathers. It is monogamous: the male and female fit in turns. The eggs are like those of the common duck. When the young come forth, the mother will often carry them from the place of hatching to the water with her bill. They have been attempted to be domesticated, by rearing the young under tame ducks; but without success, as they are ever wild, effecting their escape the first opportunity; or, if the old ones are taken and confined, they lay the eggs in a dispersed manner, and never sit. The voice is not unlike the note of a clarinet, while flying; at other times they cry like a peacock, especially when kept tame; and now and then chuck like a hen. It is very choice of its mate; for if the male is killed, the female will not leave the young till she has been two or three times shot at. The flesh is thought very good food.

15. The bernicle is of a brown colour; with the head, neck, and breast, black; and a white collar. These birds, like the bernicles, frequent the British coasts in winter; and are particularly plenty, at times, on those of Holland and Ireland, where they are taken in nets placed across the rivers. In some dry seasons they have returned to the coasts of Picardy, in France, in such prodigious flocks, as to prove a pest to the inhabitants, especially in the winter of the year 1740, when these birds destroyed all the corn near the sea-coasts, by trampling it up by the roots. A general war for this reason was declared against them, and carried on in earnest, by knocking them on the head with clubs; but their numbers were so prodigious, that this availed but little: however, the inhabitants relieved from this scourge till the north wind which had brought them ceased to blow, when they took leave. They easily become tame; and, being fattened, are thought to be a delicate food. They breed pretty far north, returning southward in autumn. They fly in the shape of a wedge, like the wild geese, with great clamour. They are called in Shetland, Herra geese, from being found in that sound. They are common also in America; breeding in the islands, and along the coast, and feeding on high-water mark. Their food consists of plants, such as the small bitterns, and black-berried heads, sea-worms, berries, and the like. They are apt to have a filthy taste, but are in general thought good food. The same fable has been told of this bird as of the bernacle, in respect to its being bred from trees. Called at Hudson's-Bay, Wetha may pa new.

16. The canadenensis is brown; its head and neck are black, and the throat is white. It measures three and a half feet in length. It is found during the summer in Hudson's-Bay, and parts beyond; also in Greenland; and, in the summer months, in various parts of North-America, as far as Carolina. Numbers breed at Hudson's-Bay, and lay six or seven eggs; but the major part retire still farther north. Their first appearance in the Bay is from about the middle of April to about the middle of May, when the inhabitants wait for them with impatience, being one of the chief articles for food, and many years kill 3000 or 4000, which are salted and barrelled. Their arrival is the harbinger of spring, and the month is named by the Indians the geese-month. The British send out their servants, as well as Indians, to fleece these birds on their passage. It is in vain to pursue them; they therefore form a row of huts made of boughs, at musket-shot distance from each other, and place them in a line across the vast marshes of the country. Each hovel, or, as they are called, stand, is occupied by only a single person. These attend the flight of the birds, and on their approach mimic their call so well, that the geese will answer, and wheel, and come nearer the stand. The sportman keeps motionless, and on his knees, with his gun cocked, the whole time; and never fires till he has seen the eyes of the geese. He fires as they are going from him, then picks up another gun that lies by him, and discharges that. The geese which he has killed he sets upon sticks as if alive, to decoy others; he also makes artificial birds for the same purpose. In a good day (for they fly in very uncertain and unequal numbers) a single Indian will kill 200. Norwithstanding every species of goose has a different call, yet the Indians are admirable in their imitation of every one. In this sport, however, they must be very careful to secrete themselves; for the birds are very shy, and on the least motion fly off directly. On their return south, which is from the middle of August to the middle of October, much havoc is made among them; but these are preserved fresh for winter store, but putting them, feathers and all, into a large hole dug in the ground, and covering them with mould; and these, during the whole time of the frost's lasting, are found perfectly sweet and good. The Indians at Hudson's Bay call them Apigishiih. This species is now pretty common, in a tame state, both on the continent and in England; the great canal of Versailles hundreds are seen mixing with the swans with the greatest cordiality, and the name at Chantilly. In England, likewise, they are thought a great ornament to the pieces of water.
The flesh of the young birds is accounted good; and the feathers equal to those of other geese, in so much as to prove an article of commerce much in the favour of those places where they are in sufficient numbers.

17. The mollissima, or eider-duck, is double the size of the common duck, has a cylindrical bill, and the wax is divided behind, and wrinkled. The feathers which are very soft and valuable, fall off during incubation. The male is white above, but black below and behind: the female is greenish. This species is found in the Western Isles of Scotland, particularly on Oran­fa, Barra, Rona, and Hebrides, and on the Parn Isles; but in greater numbers in Norway, Iceland and Greenland; from whence a vast quantity of the down, known by the name of eider or edder, which these birds furnish, is annually exported. It is remarkably light, elastic, and warm qualities, make it highly esteemed as a stuffing for coverslets, by such whom age or infirmities render unable to support the weight of common blankets. This down is produced from the breast of the birds in the breeding season. It lays its eggs among the stones or plants near the shore; and prepares a soft bed for them, by plucking the down from its own breast: the natives watch the opportunity, and take away both eggs and nest: the ducks lays again, and repeats the pluck­ing of its breast: if she is robbed after that, she will still lay; but the ducks must supply the down, as her flock is now exhausted: but if her eggs are taken a third time, she wholly deserts the place. See Down.

These birds are not numerous on the isles; and it is observed that the drakes keep on those most remote from the sitting places. The ducks continue on their nests till you come almost close to them; and when they rife, are very low fliers. The number of eggs in each nest are from three to five, warmly bedded in the down; of a pale olive colour; and very large, glossy, and smooth. They now and then, however, lay so many as eight; for Van Trol informs us that no less than 16 have been found in one nest, with two females, who agree remarkably well together.—In America, this bird is found as far south as New-York, and breeds on the defart isles of New-England; but not common every where to the north. They are said to be con­stant to the same breeding places, and that a pair has been observed to occupy the same nest for 20 years to­gether. They take their young on their backs instantly to sea; then dive, to shake them off and teach them to swim for themselves. It is said, that the males are five years old before they come to their full colour: that they live to a great age, and will at length grow quite grey. Their food is shells, for which they dive to great depths. They are very numerous in the Eu­quinoxuslands, where, and in Greenland, they are called muttuck. The natives kill them on the water with darts, striking them the moment they appear after diving; and know the place from their being preceded by the rising of bubbles. The flesh is said to be much valued.

18. The maula, or scapu-duck, is less than the common duck. The bill is broad, flat, and of a greyish blue colour; the head and neck are black, glossed with green; the breast is black; the back, the coverts of the wings, and the scapulars, are finely marked with numerous narrow transverse bars of black and grey; the legs are dusky. Mr Willoughby acquaints us, that these birds take their name from feeding on scap, or broken shell-fish; they differ infinitely in colour, so that in a flock of 40 or 50 there are not two alike.

19. The mufchata, or Mufcovy duck of Ray, has a naked papillos face, and is a native of India.—It is bigger than the wild duck, being in length two feet. This species is pretty common in a domesticated state in almost every nation; and the breed ought to be encour­aged, as there is more flesh on it than on the common duck, and of a very good flavour. The eggs are rounder than those of a duck, and in young birds frequently incline to green. They lay more eggs, and are fitter than other ducks. In an unconfined state, they make the nest on the stumps of old trees, and perch during the heat of the day on the branches of such as are well clothed with leaves. When kept tame, they are sufficiently docile; and the male will not un­frequently associate and produce a mongrel breed with the common ducks. The name of Mufcovy duck was given to them from their exhaling a mucky odour, which proceeds from the gland placed on the rump in common with other birds.

20. The clypeata, or houveral of Ray, has the end of its bill broad, rounded, and furnished with a small hook. It is in length 27 inches; the female a trifle smaller. Both sexes are apt to vary much in colour; the male likewise differs from the female inwardly, hav­ing just above the divarication of the windpipe where it passes into the lungs, an enlargement, or, as it is called by some, a labyrinth.—This bird is now and then met with in England, though not in great numbers. It is said to come into France in February, and some of them to stay during the summer. It lays 10 or 12 rufous-coloured eggs, placed on a bed of rushes, in the same places as the summer-teal; and departs in September, at least the major part of them, for it is rare that one is seen in winter. The chief food of this bird is insects, for which it is continually muddling in the water with its bill. It is also said dexterously to catch flies which pafs in its way over the water. Shrimps, among other things, have been found in its stomach on dissection. This species is also found in most parts of Germany; throughout the Russian dominions, as far as Kamtschatka; and in North-America, in New-York and Carolina, during the winter season. It is accounted pretty good food.

21. The irepera, or gad-wall, has the wings varie­gated with black, white, and red. It inhabits England in the winter months, and is also found at the same season in various parts of France and Italy. It migrates as far as Sweden, as summer advances, in order to breed; and is found throughout Ruffia and Siberia, except in the eastern part of the last, and Kamtschatka. Being a very quick diver, it is difficult to be shot. It feeds morning and evening only, being hid among the reeds and rushes during the day. The noise it makes is not unlike that of a mallard, but louder. The flesh is good.

22. The clangula, or golden eye of Ray, is varie­gated with black and white, and the head is inter­feread with blackish green feathers: it has a white spot near the mouth; and the eyes are of a tining gold col­our. It is not unfrequent on the sea-coasts in winter, and
Frequently in order to breed. It inhabits Sweden and Norway during the summer. It is an excellent diver, and feeds on small shells. It is mostly seen in the water, as it is very awkward in walking. It has been attempted to be domesticated, but seems out of its element on land. With difficulty it can be caught; and the feet soon grow injured, in so much as at last to hinder it from walking. The flesh is much esteemed, and the birds are often seen in the market at the proper season. This species is found in America; in winter as low as New-York; in summer, at Hudson's Bay, where it frequents the fresh-water lakes, and makes in hollow trees a round nest of grass lined with feathers from its breast; lays from seven to ten white eggs.

23. The merfa, or Ural duck of Pallas, is somewhat bigger than the common teal. The bill is large, broad, very tumid above the nostrils, and bird in the adult bird, the end marked with diverging fleshy; colour blue: the head, and part of the neck, are white; on the crown is a large patch of black: the middle of the neck is black: the fore-parts of the body are a yellowish brown, undulated with black: the back is clouded with a cinereous and pale yellow, powdered with brown: the wings are small: the tail longish, wedge-shaped, and black: the legs are brown, on the fore-part bluish, and placed as far back as in the diver genus. This species is not unfrequent in the greater lakes of the Ural mountains, and the rivers Ob and Irifich. It is not seen on the ground, for from the situation of its legs it is unable to walk; but it swims very well and quick: at which time the tail is immerced in the water as far as the rump, serving by way of rudder, contrary to the common method of a duck's swimming. The nest is formed of reeds, and floats, something like to that of the grebe.

24. The American wigeon (le canard jenfon of Buffon), is rather bigger than the European wigeon. The bill is of a lead colour: the crown and forehead of a yellowish white: the hind-part of the neck and head is black and white, speckled: and behind the eye is a black mark, changing in some lights to green: the back and scapulars are of a pale rust-colour, waved with transverse black lines; in the middle of the wing coverts there is a large bed of white: the quills and tail are deep brown: the legs dusky. It inhabits North-America, from Carolina to Hudson's Bay; but is no where a common bird. It is called at New-York the Phoebant Duck. It is more plenty at St Domingo and Cayenne, where it is called wingeon or gingeon. At Martinico great flocks of them often take short flights from one rice plantation to another, where they make much havoc, particularly during the rainy season. They are said to perch on trees. They feed in company and have a sentinel on the watch like some other birds. They are seldom seen during the day, lying hid in places shaded from the sun: but so soon as that luminary disappears, they come forth from their hiding-places to feed; and, during this, make a particular kind of noise, by which the sportsman is directed in his search after them: at other times their note is a kind of feeble whistle, which is often imitated in order to decoy them within reach of the gun. They fit in January; and in March the young are seen running about. They lay many eggs.

Sometimes these are hatched under hens; in which case they are, white young, familiar, though when grown up exceedingly quarrelsome with other ducks; their flesh is most excellent, especially such as are brought up tame. They appear upon the coast of Hudson's Bay in May, as soon as the thaw comes on, chiefly in pairs: they lay there only from six to eight eggs; and feed on flies and worms in the swamps. They depart in flocks in autumn. They are known by the name of atbikimo.
The wild-ducks pair in Bay; also in Greenland, where it frequents, during summer, bays and rivers, especially near their mouths, found from Carolina to Newfoundland, and Handol's and ly, and is very clamorous. It feeds on it frequents, as well as the feeds of the

30. The creca, or common teal, has the prime feathers of the wings blackish. This and the

31. The minuta, or little white and brown duck of Edwards, is of a greyish colour, with white ears, and the prime feathers of the wings blackish. This and the former, according to Latham, are found both on the Old and new continents. On the first, it is seen as far south as the lake Baikal to Kamtschatka; and breeds there, as well as every where else about the most rapid rivers and raging torrents. It is of a small size, only 1 4 inches in length. The teal is frequent in the London markets along with the wild duck. It is met with in Duddingston-loch, a fresh-water lake, within a mile of Edinburgh. In France it plays throughout the year, and makes a nest in April among the rushes, on the edges of ponds; it is composed of the tenderest flanks of them, with the addition of the pith, and a quantity of feathers. The nest is of a large size, and placed in the water, so as to rife and fall with it. The eggs are the size of those of a pigeon, of a dirty white, marked with small hazel spots. It is said to feed on the grasses and weeds which grow on the

32. The bobchas, common wild-duck of Ray, or mallard, the intermediate tail-feathers of the drake are turned backward, and the bill is stiffer. It frequents the lakes of different countries, and feeds upon frogs and several sorts of insects.—The wild-ducks pair in the spring: build their nests among rushes near the water, and lay from 10 to 16 eggs. The female is a very artful bird; and does not always make the nest close to the water, but frequently at a good distance from it; in which case the duck will take the young in its beak or between its legs. It is known sometimes to lay the eggs in a high tree, in a deserted magpie's or crow's nest. At molting-time, when they cannot fly, they are caught in great numbers. They abound greatly in Lincolnshire, the great magazine of wild-fowl in Great Britain; where prodigious numbers are taken annually in the Decays. Birds with flat bills, that find their food by groping, have three pair of nerves that extend to the end of their bills: these nerves are remarkably conspicuous in the head and bill of the wild-duck, and, are larger than those of a goose or any other bird yet known: this is the reason they grope for food more than any other bird whatever.—The common tame species of ducks take their origin from these, and may be traced to it by unerring characters. The drakes, howsoever they vary in colours, always retain the curled feathers of the tail, and both fixes the form of the bill, of the wild kind. Nature sports in the colours of all domestic animals; and, for a wife and useful end, that mankind may the more readily distinguish and claim their respective property.

In France this species is not often seen, except in winter; appearing in October, and going north in spring. They are caught in various manners; among the reeds, in decoys, as in England; the chief place for which is Picardy, where prodigious numbers are taken, particularly on the river Somme. It is also customary there to wait for the flocks passing over certain known places, and the sportsman, having a wicker cage, containing a quantity of tame birds, lets out one at a time, at a convenient season, which enticing the strangers within go, and are often killed at once by an expert markman. They are caught and then taken also by a hook baited with a bit of sheep's lights, which swimming on the water, the bird swims after the bait, and with it the hook. Various other means of catching ducks and geese are peculiar to certain nations; of which one seems worth mentioning from its singularity: The person willing to take these, wades into the water up to the chin, and having his head covered with an empty calabash, approaches the place where the ducks are; when they, not regarding an object of this sort, suffer the man freely to mix with the flock; after which he has only to pull them by the legs under the water, one after another, till he is satisfied; returning as unsuspected by the remainder as when he first came among them. This method is frequently put into practice on the river Ganges, using the earthen vessels of the Genoos instead of the calabashes: these vessels are what the Genoos boil their rice in, and are called Kutcharee pots (they likewise make a dish for the tables in them, which goes by the same name); after these are once used they look upon them as defiled, and in course throw them into the river as useless; and the duck-takers find them convenient for their purpose, as the ducks,
ducks, from constantly seeing the vessels float down the stream, look upon them as objects of full as little regard as a calabash. The above, or some such method, is also practised in China as well as in India. The Chineese, however, though they make great use of ducks, do not prefer the wild, being in general extremely fond of tame ones: and is aHo practised eggs, being laid in boxes of sand, are placed on a brick hearth, to which is given a fortnight time required for hatching. The ducklings are fed on oat return at command. This method is used nine months succeeding; and is so far from put of cutting the rice and glean ing the crop, when the vide them an old ilepmother, who leads them where rice plantations, as they are overflowed at high water. feed at large on the same fpot, and on a signal given for'fome thoufands, belonging It is will follow their leader to their respective fampanes, to see how the ducks .is a black body and the wings spotted with white. This {pecies'is found in Europe as far as Norway. In the winter months it is not unfrequent in England; being met with in the markets in that feaon, and is much efeemed. It is common also throughout the Ruffian empire, going northward to breed. Is frequente seen that the male dis appears during the incubation of the female.

There are 62 other species enumerated by ornithologists; the whole number hitherto described being 98.

ANASARCA, a species of droppy. See Medici ne.

ANASSUS, or ANAXUS (anc. geog.), a river in the territory of Venice, (Pliny); now the Piave, which riling from the mountains of Tyrol, not far from the borders of Carinthia, runs from north to south, thro' the territories of Cadorn, Belluno, Feltre, and, after running from west to east, through Trevisi, falls into the Adriatic, 13 miles to the south-east of Ve ni ce.

ANASTASIS, a term among ancient physicians, for a rising up to go to food. It also signifies the passage of any humour, when expelled from one part, and obliged to remove to another.

ANASTASUS I. emperor of the caft, succeeded Zeno in the year 491, and was inaugurated that same year on April the rith. The Manicheans and Arians were greatly in hopes of being supported by the new emperor; the former because his mother was their friend, and favoured their sect; the latter because the emperor's uncle was of their opinion: but if Ana stasius did not persecute them (as we do not find he ever did), yet it does not appear that he supported either of these sects. But in order to maintain the peace of the church, upon which the tranquility of the state very much depended, he declared, that such bishops or other clergymen who should disturb the public tranquility, by maintaining with too much heat either side of the question for or against the Council of Chalcedon, should be deprived of their benefits. Accordingly the disputes concerning Eutychianism running to a very great height, and Euphemius being deeply con cerned

869 at the fourth general council, the acts and canons of which he translated from the Greek into Latin. He also composed the lives of several popes, and other works; the best edition of which is that of the Vatican.

ANASTATICA, the rose of Jericho: A genus of the filiculosa order, belonging to the tetradyamia class of plants; and, in the natural method, ranking under the 39th order, Siliquojoe. The characters are: The calyx is a perianthium consisting of four leaves, and pistilliferous; the corolla consists of four cruciform petals: The samina consists of fix subulate filaments the length of the calyx; the anthera are roundish: The pisiflum has a small bifid germen; the stylus mucronated and oblique; the stigma headed: The pericarpium is a short bilocular fistle, retuse, and crowned on the margin with valvulae twice as long as the partition: The seeds are solitary and roundish.—Of this genus there are two

Species. 1. The syriaca, a native of Syria, is not cultivated or known in Britain. 2. The hierochina is a native of the sandy parts of Palestine and the Red Sea. It is a low annual plant, dividing into many irregular woody branches near the root. At each joint is placed a single, oblong, hairy leaf; and at the same places come out small fingle flowers, of a whitish green colour, composed of four leaves placed in the form of a crofs. These are succeeded by short wrinkled pods, having four small horns; these open into four cells, in each of which is lodged a single brown seed.—When the seeds of this plant are ripe, the branches will draw up and contract; so that the whole plant forms a kind of ball or globular body, which will expand on laying it a short time in warm water. This property it retains for many years, on which account it is preferred as a curiosity by some people. From this property the monks have given it the name of Rose Maria, pret­ending that the flowers open on the night in which our Saviour was born.

Culture. This plant is propagated by seeds, which should be sown in the beginning of March, in a moderate hot-bed in pots, in which the plants are designed to remain. When they come up, the plants should be thinned, leaving them about six inches asunder, and observing to keep them clear of weeds, which is all the care they require. If the felen proves favourable they will flower in August; but unless the autumn proves warm and dry, they will not perfect their seeds in Britain.

ANASTOMOSIS, in anatomy, the opening of the mouths of vessels, in order to discharge their contained fluids. It is likewise used for the communication of two vessels at their extremities: as the inoculation of a vein with a vein, of an artery with an artery, or of an artery with a vein.

ANASTOMATIC, medicines supposed to have the power of opening the mouths of the vessels, and promoting the circulation; such as deobstruente, cathartique, and sudorifique medicines.

ANASTROPHE, in rhetoric and grammar, denotes the inversion of the natural order of the words: such is, fana per et scopulis, for per fana et scopulis.

ANASUS, or ANIUS (anc. geog.) now the Enz, a river of Germany; which, rising on the borders of
A N A

The art of dissecting, or artificially separating and taking to pieces, the different parts of the human body, in order to an exact discovery of their situation, structure, and economy. —The word is Greek, ἀνατομία, derived from ἀνατομεῖν, to dissect, or separate by cutting.

INTRODUCTION.

§ 1. History of Anatomy.

This art seems to have been very ancient; though for a long time, known only in an imperfect manner. —The first men who lived must have soon acquired some notions of the structure of their own bodies, particularly of the external parts, and of some even of the internal, such as bones, joints, and sinews, which are exposed to the examination of the fowens in living bodies.

This rude knowledge must have been gradually improved, by the accidents to which the body is exposed, by the necessities of life, and by the various customs, ceremonies, and superstitions, of different nations. Thus, the observance of bodies killed by violence, attention to wounded men, and to many diseases, the various ways of putting criminals to death, the funeral ceremonies, and a variety of such things, must have shown men every day more and more of themselves; especially as curiosity and self-love would here urge them powerfully to observation and reflection.

The brute-creation having such an affinity to man in outward form, motions, senses, and ways of life; the generation of the species, and the effect of death upon the body, being observed to be so nearly the same in both; the conclusion was not only obvious, but unavoidable, that their bodies were formed nearly upon the same model. And the opportunities of examining the bodies of brutes were so easily procured, indeed so necessarily occurred in the common business of life, that the hunter in making use of his prey, the priest in sacrificing, the angler in divination, and, above all, the butcher, or those who might out of curiosity attend upon his operations, must have been daily adding to the little stock of anatomical knowledge. Accordingly we find, in fact, that the South-sea-islanders, who have been left to their own observation and reasoning, without the assistance of letters, have yet a considerable share of rude or wild anatomical and physiological knowledge. Dr Hunter informs us, that when Omai was in his museum with Mr Banks, though he could not explain himself intelligibly, they plainly saw that he knew the principal parts of the body, and something like the use of their ures, and manifested a great curiosity or desire of knowing the functions of the internal parts of the body explained to him; particularly the relative functions of the two sexes, which with him seemed to be the most interesting object of the human mind.

We may further imagine, that the philosophers of the

ANATOMY,
History.

Anatomy.

the most early ages, that is, the men of curiosity, observation, experience and reflection, could not overlook an instinct of natural organization, which was so interesting, and at the same time so wonderful, more especially of them as applied to the study and cure of diseases. We know that physic was a branch of philosophy till the age of Hippocrates.

Thus the art must have been circumstanced in its beginning. We shall next see from the testimony of historians and other writers, how it actually appeared as an art, from the time that writing was introduced among men; how it was improved and conveyed down to us through a long series of ages.

Civilization, and improvements of every kind, would naturally begin in fertile countries and healthful climates, where there would be leisure for reflection, and an appetite for amusement. Accordingly, writing, and many other useful and ornamental inventions and arts, appear to have been cultivated in the eastern parts of Asia long before the earliest times that are treated of by the Greek or other European writers; and that the arts and learning of those eastern people were in subsequent times gradually communicated to adjacent countries, especially by the medium of traffic. The customs, superstitions, and climate of eastern countries, however, appear to have been as unfavourable to practical anatomy, as they were inviting to the study of astronomy, geometry, poetry, and all the other arts of peace.

Animal bodies there, run so quickly into noxious putrefaction, that the early inhabitants must have avoided such offensive employments, as anatomical inquiries, like their polarity at this day. And, in fact, it does not appear, by the writings of the Grecians, or Jews, or Phoenicians, or of other eastern countries, that anatomy was particularly cultivated by any of those eastern nations. In tracing it backwards to its infancy, we cannot go farther into antiquity than the times of the Grecian philosophers. As an art in the state of infancy, it may be said to have been brought forth and bred up among them as a branch of natural knowledge.

The æra of philosophy, as it was called, began with Thales the Miletian being declared by a very general consent of the people, the most wise of all the Grecians, 480 years before Christ. The philosophers of his school, which was called the Ionian, cultivated principally natural knowledge. Socrates, the seventh in succession of their great teachers, introduced the study of morals, and was thence said to bring down philosophy from heaven, to make men truly wise and happy.

In the writings of his scholar and successor Plato, we see that the philosophers had carefully considered the human body, both in its organization and functions; and though they had not arrived at the knowledge of the more minute and intricate parts, which required the successive labour and attention of many ages, they had made up very noble and comprehensive ideas of the subject in general. The anatomical descriptions of Xenophon and Plato have had the honour of being quoted by Longinus (§ xxxii.) as specimens of full-time writing: and the extract from Plato is still more remarkable for its containing the rudiments of the circulation of the blood. "The heart (says Plato) is the centre or knot of the blood vessels; the spring, or fountain of the blood which is carried impetuously round; the blood is the pabulum or food of the flesh; and, for the purpose of nourishment, the body is laid out into canals, like those which are drawn through gardens, that the blood may be conveyed, as from a fountain, to every part of the pervious body."

Hippocrates was nearly contemporaneous with the great physicians of whom we have been speaking, about 400 years before the Christian era. He is said to have separated the profession of philosophy and physic, and to have been the first who applied to physic alone as the business of his life. He is likewise generally supposed to be the first who wrote upon anatomy. We know of nothing that was written expressly upon the subject before; and the first anatomical dissection which has been recorded, was made by his friend Democritus of Abdera.

If, however, we read the works of Hippocrates with impartiality, and apply his accounts of the parts to what we now know of the human body, we must allow his descriptions to be imperfect, incorrect, sometimes extravagant, and often unintelligible, that of the bones only excepted. He seems to have studied these with more success than the other parts, and tell us that he had an opportunity of seeing an human skeleton.

From Hippocrates to Galen, who flourished towards the end of the second century, in the decline of the Roman empire, that is, in the space of 600 years, anatomy was greatly improved; the philosophers still considering it as a most curious and interesting branch of natural knowledge, and the physicians, as a principal foundation of their art. Both of them, in that interval of time, contributed daily to the common flock, by more accurate and extended observations, and by the lights of improving philosophy.

As these two great men had applied very particularly to the study of animal bodies, they not only made great improvements, especially in physiology, but raised the credit of natural knowledge, and spread it as wide as Alexander's empire.

Few of Aristotle's writings were made public in his lifetime. He affected to say that they would be unintelligible to those who had not heard them explained at his lectures; and, except the use which Theophrastus made of them, they were lost to the public for above 150 years after the death of Theophrastus; and at last came out defective from bad preservation, and corrupted by men, who, without proper qualifications, presumed to correct and supply what was lost.

From the time of Theophrastus, the study of natural knowledge was long in decline: and the reputation of the Lyceum and Academy was almost confined to the studies which are subverient to oratory and public speaking.

The other great institution for Grecian education, was at Alexandria in Egypt. The first Ptolemies, both from their love of literature, and to give true and permanent dignity to their empire, and to Alexander's favourite city, set up a grand school in the palace itself, with a museum and library, which, we may say, has been the most famed in the world. Anatomy, among other sciences, was publicly taught; and the two distinguished anatomists were Erasistratus the pupil and friend of Theophrastus, and Herophilus. Their voluminous
ANATOMY.

History.  

A T T H I S  a period of investigation and discovery, the study of anatomy was in a state of flux and evolution. It was during this time that some of the most significant contributions to the field were made, both by ancient and modern scholars. The work of Galen, in particular, was foundational to the development of anatomical knowledge. His works are still studied and referenced today, although many of his theories have been revised and corrected.

The Roman empire, under the leadership of Julius Caesar and others, was a time of great expansion and exploration. It was during this period that the word "anatomy" was first used. The Romans were known for their medical advancements, and their work continued to influence the field even after their fall.

Throughout history, anatomy has been a subject of great interest and study. From the ancient Greeks and Romans to the modern day, scientists and physicians have sought to understand the human body and its functions. The study of anatomy is a vital part of medical education, and it continues to be a field of active research and discovery.
History.

A N A T O M Y.

continued to be almost the only book which was read up-
on the subject for above 200 years. Corethius gives
him the credit of being the great refiner of anatomy,
and the first who dissected human bodies among the
moderns.

A general prejudice against dissection, however, pre-
vailed till the 16th century. The emperor Charles V.
ordered a consultation to be held by the divines of Sal-
amanca, in order to determine whether or not it was
lawful in point of confidence to dissect a dead body.
In Muinfoy, till very lately, both anatomy and the
use of skeletons were forbidden, the first as inhuman,
and the latter as subversive to witchcraft.

In the beginning of the 16th century, learning re-
ceived considerable in Europe, and particularly physi-
ical, by means of copies of the Greek authors brought from
the library of Constantinople; after which the number of
anatomists and anatomical books increased to a prodig-
gious degree.—The Europeans becoming thus perfec-
ted of the ancient Greek fathers of medicine, were for
a long time so much occupied in correcting the copies
they could obtain, studying the meaning, and com-
menting upon them, that they attempted nothing of
their own, especially in anatomy.

And here the late Dr Hunter introduces into the
annals of this art, a genius of the first rate, Leonardo
da Vinci, who had been formerly overlooked, because
he was of another profession, and because he published
nothing upon the subject. He is considered by the
Doctor as by far the best anatomist and physiologist
of his time, and was certainly the first man we know of
who introduced the practice of making anatomical
drawings.

Vasari, in the lives of the painters, speaks of Leo-

nardo thus, after telling us that he had composed a
book of the anatomy of a horse, for his own study:

"He afterwards applied himself with more diligence
to the human anatomy; in which study he reciprocally
received and communicated assistance to Marc Anto-
nio della Torre, an excellent philosopher, who then
read lectures in Padua, and wrote upon this subject, and
who was the first, as I have heard, who began to il-
lustrate medicine from the doctrine of Galen, and to give
true light to anatomy, which till that time had been
involved in clouds of darkness and ignorance. In this
he availed himself exceedingly of the genius and labour
of Leonardo, who made a book of studies, drawn with
red chalk, and touched with a pen, with great diligence,
of such subjects as he had himself dissected; where he
made all the bones, and to those he joined, in their or-
der, all the nerves, and covered them with the muscles.

And concerning those, from part to part, he wrote
marks in letters of an ugly form, which are written by
the left hand, backwards, and not to be understood but
by those who know the method of reading them; for
they are not to be read without a looking-glass. Of
these papers of the human anatomy, there is a great
part in the possession of M. Francesco da Melzo, a Mi-
lanese-gentleman, who, in the time of Leonardo, was a
most beautiful boy, and much beloved by him, as he is
now a beautiful and genteel old man, who reads those
writings, and carefully preserves them, as precious re-
liefs, together with the portrait of Leonardo, of happy
memory. It appears impossible that that divine spirit
should reason so well upon the arteries, and muscles,
and nerves, and veins; and with such diligence of
every thing, &c. &c."

Those very drawings and the writings are happily
found to be preferred in the Britannic Majesty's great
collection of original drawings, where the Doctor
was permitted to examine them; and his sentiments upon
the occasion he thus expresses: "I expected to see lit-
tle more than such delineings in anatomy, as might be
useful to a painter in his own profession; but I saw,
and indeed with astonishment, that Leonardo had been
a general and a deep student. When I consider what
pains he has taken upon every part of the body, the
superiority of his universal genius, his particular ex-
cellence in mechanics and hydraulics, and the atten-
tion with which such a man would examine and ice
objects which he was to draw, I am fully persuaded
that Leonardo was the best anatomist at that time in the
world. We must give the 16th century the credit of
Leonardo's anatomical studies, as he was 55 years of
age at the close of that century."

In the beginning of the 16th century, Achillins and
Benedictus, but particularly Berengarius and Massa,
followed out the improvement of anatomy in Italy,
where they taught it, and published upon the subject.
These first improvers made some discoveries from
their own dissections; but it is not surprising that they
should have been deficient of themselves, and have
followed Galen almost blindly, when his authority
had been so long established, and when the enthusi-
asm for Greek authors was rising to such a pitch.

Soon after this, we may say about the year 1540,
the great Vesalius appeared. He was industrious, labo-
rious, and ambitious. From Brussels, the place of his
birth, he went to Louvain, and thence to Paris, where
anatomy was not yet making a considerable figure, and
then to Louvain to teach; from which place, very for-
tunately for his reputation, he was called to Italy,
where he met with every opportunity that such a gen-
us for anatomy could desire, that is, books, subjects,
and excellent draughtsmen. He was equally laborious
in reading the ancients, and in dissecting bodies. And
in making the comparison, he could not but see, that
Galen was great room for improvement, and that many
of Galen's descriptions were erroneous. Vesalius,
but a young man, he published a noble system of anat-
omy, illustrated with a great number of elegant fig-
ures.—In this work he found so many occasions of
correcting Galen, that his contemporaries, partial to
antiquity, and jealous of his reputation, complained
that he carried his turn for improvement and critique
to licentiousness. The spirit of opposition and emula-
tion was presently roused; and Sylvins in France, COLUMBUS,
Galen's Fellipus, and Eustachi in Italy, who were all
in high anatomical reputation about the middle of this
16th century, endeavoured to defend Galen at the ex-
pense of Vesalius. In their disputes they made their
appeals to the human body; and thus in a few years
the art was greatly improved. And Vesalius being de-
tected in the very fault which he condemned in Galen,
to wit, describing from the dissections of brutes, and
not of the human body, he exposed so fully that blun-
der of the older anatomists, that in succeeding times
there has been little reason for such complaint. Bes-
ides the above, he published several other anatomical
treatises. He has been particularly serviceable by im-
posing-
posing names on the muscles, most of which are retained to this day. Formerly they were distinguished by numbers, which were differently applied by almost every author.

In 1561, Gabriel Fallopius, professor of anatomy at Padua, published a treatise of anatomy under the title of Observationes Anatomicae. This was designed as a supplement to Vesalius; many of whose descriptions he corrects, though he always makes mention of him in an honourable manner. Fallopius made many great discoveries, and his book is well worth the perusal of every anatomist.

In 1623, Bartholomaeus Eustachius published his Opera Anatomica at Venice, which have ever since been justly admired for the exactness of the descriptions, and the discoveries contained in them. He published afterwards some other pieces, in which there is little of anatomy; but never published the great work he had promised, which was to be adorned with copperplates representing all the parts of the human body. These plates, after lying buried in an old cabinet for upwards of 150 years, were at last discovered and published in the year 1714, by Lancisi the pope's physician; who added a short explication text, because Eustachius's own writing could not be found.

From this time the study of anatomy gradually diffused itself over Europe; infomuch that for the last hundred years it has been daily improving by the labour of a number of professed anatomists almost in every country of Europe.

We may form a judgment about the state of anatomy even in Italy, in the beginning of the 17th century, from the information of Cortesio. He had been professor of anatomy at Bologna, and was then professor of medicine at Massana; where, though he had a great desire to improve himself in the art, and to finish a treatise which he had begun on practical anatomy, in 24 years he could twice only procure an opportunity of dissecting a human body, and then it was with difficulties and in hurry; whereas he had expected to have done so, he says, once every year, according to the custom in the famous academies of Italy.

In the very end of the 16th century, the great Harvey was the custom of the times, went to Italy to study medicine; for Italy was still the favourite seat of the arts: And in the very beginning of the 17th century, soon after Harvey's return to England, his master in anatomy, Fabricius ab Aquapendente, published an account of the valves in the veins, which he had discovered many years before, and no doubt taught in his lectures when Harvey attended him.

This discovery evidently affected the established doctrine of all ages, that the veins carried the blood from the liver to all parts of the body for nourishment. It fet Harvey to work upon the use of the heart and vascular systems in animals; and in the course of some years he was so happy as to discover, and to prove beyond all possibility of doubt, the circulation of the blood. He taught his new doctrine in his lectures about the year 1616, and printed it in 1628.

It was by far the most important step that had been made in the knowledge of animal bodies in any age. It not only reflected useful lights upon what had been already found out in anatomy, but also pointed out the means of further investigation. And accordingly we see, that from Harvey to the present time, anatomy has been so much improved, that we may reasonably question if the ancients have been further outdone by the moderns in any other branch of knowledge. From one day to another there has been a constant succession of discoveries, relating either to the structure or functions of our body; and new anatomical processes, both of investigation and demonstration, have been daily invented. Many parts of the body, which were not known in Harvey's time, have since then been brought to light: and of those which were known, the internal composition and functions remained unexplained; and indeed must have remained unexplicable without the knowledge of the circulation.

Harvey's doctrine at first met with considerable opposition: but in the space of about 20 years it was so generally and so warmly embraced, that it was imagined every thing in phycic would be explained. But time and experience have taught us, that we still are, and probably must long continue to be, very ignorant; and that in the study of the human body, and of its diseases, there will always be an extensive field for the exercise of sagacity.

After the discovery and knowledge of the circulation of the blood, the next question would naturally have been about the passage and route of the nutritious part of the food or chyle from the bowels to the blood-vessels: And, by good fortune, in a few years after Harvey had made his discovery, Aellius, an Italian physician found out the lacteals, or velsels which carry the chyle from the intefines; and printed his account of them, with coloured prints; in the year 1627, the very year before Harvey's book came out.

For a number of years after these two publications, the anatomists in all parts of Europe were daily opening living dogs, either to see the lacteals or to observe the phenomena of the circulation. In making an experiment of this kind, Pecquet in France was fortunate enough to discover the thoracic duct, or common trunk of all the lacteals, which conveys the chyle into the subclavian vein. He printed his discovery in the year 1631. And now the lacteals having been traced from the intefines to the thoracic duct, and that duct having been traced to its termination in a blood-vessel, the passage of the chyle was completely made out.

The same practice of opening living animals furnished occasions of discovering the lymphatic velsels. This good fortune fell to the lot of Rudbec first, a young Swedish anatomist; and then to Thomas Bartholine, a Danish anatomist, who was the first who appeared in print upon the lymphatics. His book came out in the year 1653, that is two years after that of Pecquet. And then it was very evident that they had been seen before by Dr Higmore and others, who had mistaken them for lacteals. But none of the anatomists of those times could make out the origin of the lymphatics, and none of the physiologists could give a satisfactory account of their use.

The circulation of the blood and the passage of the chyle having been satisfactorily traced out in full-grown animals, the anatomists were naturally led next to consider how these animal processes were carried on in the child while in the womb of the mother. Accordingly the male and female organs, the appearances and contents of the pregnant uterus, the incubated egg, and every
every phenomenon which could illustrate generation, became the favourite subject, for about 30 years, with the principal anatomists of Europe.

Thus it would appear to have been in theory: but Dr Hunter believes, that in fact, as Harvey’s master Fabricius laid the foundation for the discovery of the circulation of the blood by teaching him the valves of the veins, and thereby inviting him to consider that subject; so Fabricius by his lectures, and by his elegant work De formatione, et de formatione ovii at pulli, probably made that likewise a favourite subject with Dr Harvey. But whether he took up the subject of generation in consequence of his discovery of the circulation, or was led to it by his renowned master Fabricius, he spent a great deal of his time in the inquiry; and published his observations in a book De generatione animalium, in the year 1657, that is six years before his death.

In a few years after this, Swammerdam, Van Horne, Steno, and De Graaf, excited great attention to the subject of generation, by their supposed discovery that the females of viviparous animals have ovaria, that is, clusters of eggs in their loins, like oviparous animals; which, when impregnated by the male, are conveyed into the uterus: so that a child is produced from an egg as well as a chick; with this difference, that one is hatched within, and the other without, the body of the mother.

Malpighi, a great Italian genius, some time after, made considerable advances upon the subject of generation. He had the good fortune to be the first who used magnifying glasses with address in tracing the first appearances in the formation of animals. He likewise made many other observations and improvements in the minutiae of anatomy by his microscopic labours, and by cultivating comparative anatomy.

This distinguished anatomist gave the first public specimen of his abilities, by printing a dissertation on the lungs anno 1661; a period so remarkable for the study of nature, that it would be injustice to pass it without particular notice.

At the same time flourished Laurentius Bellinus at Florence, and was the first who introduced mathematical reasoning in ph地貌. In 1652, Simon Pauli published a treatise De albando officii. He had long been admired for the white skeletons he prepared; and at last discovered his method, which was by expelling the bones all winter to the weather. Johannes Swammerdam of Amsterdam also published some anatomical treatises; but was most remarkable for his knowledge of preserving the parts of bodies entire for many years, by injecting their vessels. He also published a treatise on respiration; wherein he mentioned his having figures of all the parts of the body as big as the life, cut in copper, which he designed to publish, with a complete system of anatomy. These, however, were never made public by Swammerdam; but in 1659, Gothofridus Bidloo, professor of anatomy at Leyden, published a work entitled Anatomia corporis humani, where all the parts were delineated in very large plates almost as big as the life. Mr Cowper, an English surgeon, bought 300 copies of these figures; and in 1698, published them with an English text, quite different from Bidloo’s Latin one; to which were added letters in Bidloo’s figures, and some few figures of Mr Cowper’s own. To this work Cowper’s name was prefixed, without the least mention of Bidloo, except on purpose to confuse him. Bidloo immediately published a very ill-natured pamphlet, called Guilelmus Cowperus citatort comen tribunalis; appealing to the Royal Society, how far Cowper ought to be punished as a plagiary of the work kind, and endeavouring to prove him an ignorant deceitful fellow. Cowper answered him in his own style, in a pamphlet called his Vindiciae; endeavouring to prove, either that Bidloo did not understand his own tables, or that they were none of his. It was even alleged that those were the tables promis- 2 by Swammerdam, and which Bidloo had got from his widow. This, however, appears to have been only an invicious furnile, there being unquestionable evidence that they were really the performance of Bidloo.

Soon after, Iifbrandi Diembroeck, professor of anatomy at Utrecht, began to appear as an author. His work contained very little original; but he was at great pains to collect from others whatever was valuable in their writings, and his system was the common standard among anatomical students for many years.

About the same time, Antonius Liewenhoweck of Delft, improved considerably on Malpighi’s use of microscopes. These two authors took up anatomy where others had dropt it; and, by this new art, they brought a number of amazing things to light. They discovered the red globules of the blood; they were enabled to see the actual circulation of the blood in the transparent parts of living animals, and could measure the velocity of its motion; they discovered that the arteries and veins had no intermediate cells or spongy substance, as Harvey and all the preceding anatomists had supposed, but communicated one with the other by a continuation of the same tube.

Liewenhoweck was in great fam ebook for his discovery of the animalcules in the semen. Indeed there was scarcely a part of the body, solid or fluid, which escaped his examination; and he almost everywhere found, that what appeared to the naked eye to be rude undigested matter, was in reality a beautiful and regular compound.

After this period, Nuck added to our knowledge of the absorbent system already mentioned, by his injections of the lymphatic glands; Ray, by his description of the valves of the lymphatic vessels; and Dr Meckel, by his accurate account of the whole system, and by tracing those vessels in many parts where they had not before been described.

Befides these authors, Drs Hunter and Monro have called the attention of the public to this part of anatomy, in their controversy concerning the discovery of the office of the lymphatics. When the lymphatic vessels were first seen and traced into the thoracic duct, it was natural for anatomists to suppose, that as the lacteals absorbed from the cavity of the intestines, the lymphatics, which are similar in figure and structure, might possibly do the same office with respect to other parts of the body: and accordingly, Dr Gilfoyle, who wrote in 1654, supposed these vessels arose from cavities, and that their use was to absorb; and Frederic Hoffman has very explicitly laid down the doctrine of the lymphatic vessels being a system of absorbents. But anatomists in general have been of a contrary opinion; for, from experiments, particularly
particularly such as were made by injections, they have been persuaded that the lymphatic vessels did not arise from cavities, and did not absorb, but were merely continuations from small arteries. The doctrine, therefore, that the lymphatics, like the lacccals, were abortibrants, as had been suggested by Gilioli and by Hoff- man, has been revived by Dr Hunter and Dr Monro, who have controverted the experiments of their predecessors in anatomy, and have endeavored to prove that the lymphatic vessels are not continued from arteries, but are abortibrants.

To this doctrine, however, several objections have been started, particularly by Haller (Elem. Phys. l. 24. § 2, 3.), and it has been found, that before the doctrine of the lymphatics being a system of abortibrants can be established, it must first be determined whether this system is to be found in other animals besides man and quadrupeds. Mr. Hewson claims the merit of having proved the affirmative of this question, by discovering the lymphatic system in birds, fish, and amphibious animals. See Phil. Trans. vol. viii. and xix.

And latterly, Mr. Cruikshank has traced the ramifications of this system in almost every part of the body; and from his dissections, figures have been made and lately published to the world. To Mr. Sheldon also we are much indebted for his illustration of this system, which promises to give great satisfaction, but of which only a part has yet been published.

The gravid uterus is a subject likewise which has received considerable improvements, particularly relating to one very important discovery; viz. that the internal membrane of the uterus, which Dr. Hunter has named decidua, constitutes the exterior part of the fecondines or after-birth, and separates from the rest of the uterus every time that a woman either bears a child or suffers a miscarriage. This discovery includes another, to wit, that the placenta is partly made up of an excrescence or efflorescence from the uterus itself.

These discoveries are of the utmost consequence, both in the physiological question about the connection between the mother and child, and wife in explaining the phenomena of births and abortions, as well as in regulating obstetrical practice.

The anatomists of this century have improved anatomy, and have made the study of it much more easy, by giving us more correct as well as more numerous figures. It is amazing to think of what has been done in that time. We have had four large folio books of figures of the bones, viz. Cheffelden's, Albinus's, Sue's and Trew's. Of the muscles, we have had two large folio's, one from Cowper, which is elegant; and one from Albinus, which, from the accuracy and labour of the work, may suppose will never be outdone. Of the blood-veins we have a large folio from Dr. Haller. We have had one upon the nerves from Dr. Meckel, and another by Dr. Monro junior. We have had Albinus's, Roederer's, Jenty's, and Hunter's works upon the pregnant uterus; Wibritche and Leber on the joints and fresh bones; Sommerring on the brain; Zin on the eye; Cotannius, Mekel junior, &c. on the ear; Walterus on the nerves of the thorax and abdomen; Dr. Monro on the bowels mucous, &c.

It would be endless to mention the anatomical figures that have been published in this century, of particular and smaller parts of the body, by Morgagni, Ruyfch, Val- salva, Sandorini, Heüter, Vater, Cant, Zimmerman, Walterus, and others.

Those elegant plates of the brain, however, just published by M. Vieq. d' Azyr, must not pass without notice, especially as they form part of an universal system of anatomy and physiology, both human and comparative, proposed to be executed in the same splendid style. Upon the brain alone 19 folio plates are employed; of which several are coloured. The figures are delineated with accuracy and cleanliness; but the colouring is rather beautiful than correct. Such parts of this work as may be published, cannot fail to be equally acceptable to the anatomist and the philosopher; but the entire design is apparently too extensive to be accomplished within the period of a single life. In Great Britain, also, a very great anatomical work is carrying on by Andrew Bell, F. S. A. S. engraver to his Royal Highness the Prince of Wales, with the approbation of Dr. Monro, and under the inspection of his very ingenious assistant, My Fyfe. It is to compose a complete illustration, both general and particular, of the human body, by a selection from the best plates of all the greatest anatomists, as well foreign as British, exhibiting the latest discoveries in the science, and accompanied with copious explanations. The whole number of plates mentioned in the Prospectus is 240, of which 152 are already done; all in royal folio.

To the foreign treatises already mentioned may be added those recently published by Sabattier and Plencel on anatomy in general. In Great Britain, the writings of Keil, Douglas, Cheffelden, the first Monro, Winlow, &c. are too well known to need description. The list of these useful as a standard for the students of anatomy; but it has of late given place to a more accurate and comprehensive system, in three volumes, published by Mr. Elliot of Edinburgh, upon a plan approved of by Dr. Monro, and executed by My Fyfe. Dr. Simmons of London has also obliged the world with an excellent system of anatomy; and another work, under the title of "Elements of Anatomy and the Animal Oeconomy" in which the subjects are treated with uncommon elegance and perspicuity.

In the latter part of the last century, anatomy made two great steps, by the invention of injections, and the method of making what we commonly call preparations. These two modern arts have really been of infinite use to anatomy; and besides have introduced an elegance into our administrations, which in former times could not have been supposed to be possible. They arose in Holland under Swammerdam and Ruyfch, and afterwards in England under Cowper, St Andrè, and others, where they have been greatly improved.

The anatomists of former ages had no other knowledge of the blood-veins, than what they were able to collect from laborious dissections, and from examining the smaller branches of them, upon some lucky occasion, when they were found more than commonly loaded with red blood. But filling the vascular system with a bright coloured wax, enables us to trace the large veins with great ease, renders the smaller more conspicuous, and makes thousands of the very minute
Introd.

**ANATOMY.**

ones visible, which from their delicacy, and the transparency of their natural contents, are otherwise imperceptible.

The modern art of corrodling the fleshy parts with a men[trenum, and of leaving the moulded wax entire, is so exceedingly useful, and at the same time so fundamental, that it does great honour to the ingenious inventor Dr. Nicholls.

The wax-work art of the moderns might deserve notice in any history of anatomy, if the masons in that way had not been so careless in their imitation. Many of the wax-figures are so tawdry with a show of unnatural colours, and so very incorrect in the circumstances of figure, situation, and the like, that though they strike a vulgar eye with admiration, they must appear ridiculous to an anatomist. But those figures which are cast in wax, plaster or lead, from the real subject, and of which late years have been frequently made, are, of course, very correct in all the principal parts, and may be considered as no insignificant acquisition to modern anatomy. The proper, or principal use of this art is, to preserve a very perfect likeness of such subjects as we but seldom can meet with, or cannot well preserve in a natural state; a subject in pregnancy for example.

The modern improved methods of preserving animal bodies, or parts of them, has been of the greatest service to anatomy; especially in saving the time and labour of the anatomist in the nicer dissections of the small parts of the body. For now, whatever he has prepared with care, he can preserve; and the object is ready to be seen at any time. And in the same manner he can preserve anatomical curiosities, or rarities of every kind; such as, parts that are uncommonly formed; parts that are disfigured; the parts of the pregnant uterus and its contents. Large collections of such curiosities, which modern anatomists are striving almost everywhere to procure, are of infinite service to the art, especially in the hands of teachers. They give students clear ideas about many things which it is very essential to know, and yet which it is impossible that a teacher should be able to show otherwise, were he ever so well supplied with fresh subjects.

§ 2. View of the Subject in General, and Plan of the following Treatise.

The etymology of the word anatomy, as above given, implies simply *dissection*; but by this term something more is usually understood.

It is every day made use of to express a knowledge of the human body; and a person who is said to understand anatomy, is supposed to be conversant with the structure and arrangement of the different solid parts of the body.

It is commonly divided into Anatomy, properly so called; and Comparative Anatomy: the first of these is confined solely to the human body; the latter includes all animals, so far as a knowledge of their structure may tend to perfect our ideas of the human body. See Comparative Anatomy.

The term anatomy may also have another and more extensive signification: it may be employed to express not only a knowledge of the structure and disposition of the parts, but likewise of their economy and use. Considered in this light, it will seldom fail to excite the curiosity of people of taste, as a branch of philosophy; since, if it is pleasing to be acquainted with the structure of the body, it is certainly more so to discover all the springs which give life and motion to the machine, and to observe the admirable mechanism by which so many different functions are executed without any concern those who are to be the guardians of health, as this study is necessary to lay a foundation for all the branches of medicine. The more we know of our fabric, the more reason we have to believe, that if our senses were more acute, and our judgment more enlarged,
ANATOMY.

In order to acquire a satisfactory general idea of this subject, and find a solution of all such questions, let us, in our imaginations, make a man: in other words let us suppose that the mind, or immaterial part, is to be placed in a corporeal fabric, in order to hold a correspondence with other material beings by the intervention of the body; and then consider, a priori, what will be wanted for her accommodation. In this inquiry, we shall plainly see the necessity or advantage, and therefore the final cause, of most of the parts which we actually find in the human body. And if we consider that, in order to answer some of the requisites, human wit and invention would be very insufficient; we need not be surprised if we meet with some parts of the body whose use we cannot yet perceive, and with some operations and functions which we cannot explain. We can see that the whole bears the most striking characters of excelling wisdom and ingenuity: but the imperfect tenets and capacity of man cannot pretend to reach every part of a machine, which nothing less than the intelligence and power of the Supreme Being could contrive and execute.

First, then, the mind, the thinking, immaterial agent, must be provided with a place of immediate residence, which shall have all the requisites for the union of spirit and body; accordingly she is provided with the brain, where she dwells as governor and superintendent of the whole fabric.

In the next place, as she is to hold a correspondence with all the material beings around her, she must be supplied with organs fitted to receive the different kinds of impressions which they will make. In fact, therefore, we see that she is provided with the organs of sense, as we call them: the eye is adapted to light; the ear to sound; the nose to smell; the mouth to taste; and the skin to touch.

Further: She must be furnished with organs of communication between herself in the brain and those organs of sense, to give her information of all the impressions that are made upon them: and she must have organs between herself in the brain and every other part of the body, fitted to convey her commands and influence over the whole. For these purposes the nerves are actually given. They are chords, which rise from the brain, the immediate residence of the mind, and diffuse themselves in branches through all parts of the body. They convey all the different kinds of sensations to the mind, in the brain; and likewise carry out from thence all her commands and influence to the other parts of the body. They are intended to be occasional monitors against all such impressions as might endanger the well-being of the whole, or of any particular part; which vindicates the Creator of all things, in having actually subjected us to those many disagreeable and painful sensations which we are exposed to from a thousand accidents in life.

Moreover, the mind, in this corporeal system, must be endued with the power of moving from place to place, that she may have intercourse with a variety of objects; that she may fly from such as are disagreeable, dangerous or hurtful, and pursue such as are pleasant or useful to her. And accordingly she is furnished with limbs, and with muscles and tendons, the instruments of motion, which are found in every part of the fabric where motion is necessary.

But to support, to give firmness and shape to the fabric; to keep the looser parts in their proper places; to give fixed points for, and the proper direction to its motions, as well as to protect some of the more important and tender organs from external injuries: there

(a) The following beautiful representation is taken from the late Dr Hunter's Introductory Lecture in Anatomy.
there must be some firm prop-work interwoven througout the whole. And, in fact, for such purposes the bones are given.

The prop-work must not be made into one rigid fabric, for that would prevent motion. Therefore there are a number of bones.

These pieces must all be firmly bound together, to prevent their dislocation. And this end is well answered by the ligaments.

The extremities of these bony pieces, where they move and rub upon one another, must have smooth and slippery surfaces for easy motion. This is most happily provided for, by the cartilages and mucus of the joints.

The interfaces of all these parts must be filled up with some soft and ductile matter, which shall keep them in their places, unite them, and at the same time allow them to move a little upon one another. And these purposes are answered by the cellular membrane or adipofe substance.

There must be an outward covering over the whole apparatus, both to give it compactness and to defend it from a thousand injuries: which, in fact, are the very purposes of the skin and other integuments.

Lastly, the mind being formed for society and intercourse with beings of her own kind, she must be endued with powers of expressing and communicating her thoughts by some sensible marks or signs; which shall be both easy to herself, and admit of great variety; and accordingly she is provided with the organs and faculty of speech, by which she can throw out signs with amazing facility, and vary them without end.

Thus we have built up an animal body which would seem to be pretty complete; but as it is the nature of matter to be altered and worked upon by matter; so in a very little time such a living creature must be destroyed, if there is no provision for repairing the injuries which she must commit upon herself, and those which she must expose to from without. Therefore a treasure of blood is actually provided in the heart and vaso-vascular system, full of nutritious and healing particles, fluid enough to penetrate into the minutest parts of the animal; impelled by the heart, and conveyed by the arteries, it washes every part, builds up what was broken down, and sweeps away the old and useless materials. Hence we see the necessity or advantage of the heart and arterial system.

What more there was of this blood than enough to repair the present damages of the machine, must not be lost, but should be returned again to the heart; and for this purpose the venous system is actually provided. These requires in the animal explain, a priori, the circulation of the blood.

The old materials which were become useless, and are swept off by the current of blood, must be separated and thrown out of the system. Therefore glands, the organs of secretion, are given for straining whatever is redundant, vapid, or noxious, from the mafs of blood; and when strained, they are thrown out by emunctories, called organs or excretion.

But now, as the machine must be constantly wearing, the repair must be carried on without intermission, and the strainers must always be employed. Therefore there is actually a perpetual circulation of the blood, and the secretions are always going on.

Even all this provision, however, would not be sufficient: for that store of blood would soon be consumed, and the fabric would break down, if there were not a provision made for fresh supplies. These we observe, in fact, are profusely scattered round her in the animal and vegetable kingdoms; and she is furnished with hands, the fittest instruments that could have been contrived, for gathering them, and for preparing them in a variety of ways for the mouth.

But these supplies, which we call food, must be considerably changed; they must be converted into blood. Therefore she is provided with teeth for cutting and bruising the food, and with a stomach for melting it down: in short, with all the organs subservient to digestion. — The finer parts of the aliment only can be useful in the constitution: these must be taken up and conveyed into the blood, and the dregs must be thrown off. With this view the intestinal canal is actually given. It separates the nutritious part, which we call chyle, to be conveyed into the blood by the system of absorbent vessels; and the faces pass downwards, to be conducted out of the body.

Now we have got our animal not only furnished with what is wanted for its immediate existence, but also with the powers of protracting that existence to an infinite length of time. But its duration, we may presume, must necessarily be limited; for as it is nourished, grows, and is raised up to its full strength and utmost perfection; so it must, in time, in common with all material beings, begin to decay, and then hurry on to final ruin. Hence we see the necessity of a scheme for renovation. Accordingly wise Providence, to perpetuate, as well as preserve his work, besides giving a strong appetite for life and self-preservation, has made animals male and female, and given them such organs and passions as will secure the propagation of the species to the end of time. —

Thus we see, that by the very imperfect survey which human reason is able to take of this subject, the animal man must necessarily be complex in his corporeal system, and in its operations.

He must have one great and general system, the vascular, branching through the whole for circulation: Another, the nervous, with its appendages the organs of sense, for every kind of feeling: And a third, for the union and connection of all those parts.

Besides these primary and general systems, he requires others which may be more local or confined: One for strength, support, and protection; the bony compages: Another for the requisite motions of the parts among themselves, as well as from moving from place to place; the muscular part of the body: Another to prepare nourishment for the daily recruit of the body: the digestive organs: And one for propagating the species: the organs of generation.

And in taking this general survey of what would appear, a priori, to be necessary for adapting an animal to the situations of life, we observe, with great satisfaction, that man is accordingly made of such systems, and for such purposes. He has them all; and he has nothing more, except the organs of respiration. Breathing it seemed difficult to account for a priori: we only knew it to be in fact essentially necessary to life. Norwithstanding this, when we saw all the other parts of the body, and their functions, to well ac-
counted for, and so wisely adapted to their several purposes, there could be no doubt that respiration was so likewise: And accordingly, the discoveries of Dr Priestley have lately thrown light upon this function also, as will be shown in its proper place.

Of all the different systems in the human body, the use and necessity are not more apparent, than the wisdom and contrivance which has been exerted in putting them all into the most compact and convenient form: in dividing them so, that they shall mutually receive, and give help to one another; and that all, or many of the parts, shall not only answer their principal end or purpose, but operate successfully and usefully in a variety of secondary ways.

If we consider the whole animal machine in this light, and compare it with any machine in which human art has exerted its utmost; suppose the best constructed ship that ever was built, we shall be convinced beyond the possibility of doubt, that there are intelligence and power far far surpassing what humanity can boast of.

One superiority in the natural machine is peculiarly striking.—In machines of human contrivance or art, there is no internal power, no principle in the machine itself, by which it can alter and accommodate itself to any injury which it may suffer, or make up any injury which admits of repair. But in the natural machine, the animal body, this is most wonderfully provided for by internal powers in the machine itself; many of which are not more certain and obvious in their effects, than they are above all human comprehension as to the manner and means of their operation. Thus, a wound heals up of itself; a broken bone is made firm again by a callus; a dead part is separated and thrown off; noxious juices are driven out by some of the emunctories; a redundancy is removed by some spontaneous bleeding; a bleeding naturally stops of itself; and a great loss of blood, from any cause, is in some measure compensated, by a contracting power in the vascular system, which accommodates the capacity of the vessels to the quantity contained. The stomach gives information when the supplies have been expended; represents, with great exactness, the quantity and the quality of what is wanted in the present state of the machine; and in proportion as the meets with neglect, riles in her demand, urges her petition in a louder tone, and with more forcible arguments. For its protection, an animal body refits heat and cold in a very wonderful manner, and prefers an equal temperature in a burning and in a freezing atmosphere.

A farther excellence or superiority in the natural machine, if possible, still more astonishing, more beyond all human comprehension, than what we have been speaking of, is the following. Besides those internal powers of self-preservation in each individual, when two of them co-operate, or act in concert, they are endowed with powers of making other animals or machines like themselves, which again are possessed of the same powers of producing others, and so of multiplying the species without end.

There are powers which mock all human invention or limitation. They are characteristics of the divine Architect.

Having promised this general account of the subject, we shall next consider the method to be observed in treating it.

The study of the human body, as already noticed, is commonly divided into two parts. The first, which is called Anatomy, relates to the matter and structure of its parts; the second, Physiology and Animal economy, relates to the principles and laws of its internal operations and functions.

As the body is a compound of solids and fluids, Anatomy is divided into,

1. The Anatomy of the solids, and
2. The Anatomy of the fluids.

I. The Solids, by which we mean all parts of our body which are not fluid, are generally divided into two classes, viz.

1. The hard solids or bones. This part of anatomy is called Osteology; which signifies the doctrine of the bones.
2. The softer solids; which part is called Sarcology, viz. the doctrine of flesh.

This division of the solids, we may observe, has probably taken its origin from the vulgar observation, that the body is made of bone and flesh. And as there are many different kinds of what are called soft or fleshly parts, Sarcology is subdivided into,

1. Angiology, or the doctrine of vessels: by which is commonly understood blood-vessels:
2. Adenology, or glands:
3. Neurology, or nerves:
4. Myology, or muscles: and,
5. Splanchonology, of the visera or bowels. There is, besides, that part which treats of the organs of sense and of the integuments.

This division of the solids has been here mentioned, rather for the sake of explaining so many words, which are constantly used by anatomists, than for its importance or accuracy. For besides many other objections that might be urged, there are in the body three species of solids, viz. gristle or cartilage, hair, and nails; which are of an intermediate nature between bone and flesh; and therefore cannot so properly be brought into the osteology or the sarcology. The cartilages were classified with the bones; because the greatest number of them are appendages to bones: and for the like reason the hair and the nails were classified with the integuments.

II. The Fluids of the human body may be divided into three kinds, which Dr Hunter calls the crude, the general or perfect, and the local or secreted fluid.

1. By the crude fluid is meant the chyle, and whatever is absorbed at the surfaces of the body; in other words, what is recently taken into the body, and is not yet mixed with or converted into blood.
2. The general or perfect fluid is the blood itself; to wit, what is contained in the heart, arteries, and veins, and is going on in the round of the circulation.
3. The local or secreted, are those fluids peculiar to particular parts of the body, which are strained off from the blood, and yet are very different in their properties from the blood. They are commonly called secretions; and some are useful, others excretions.

In treating of the Physiology, it is very difficult to say what plan should be followed; for every method which has been yet proposed, is attended with manifest in-convenience.
convenience. The powers and operations of the machine have such a dependence upon one another, such connections and reciprocal influence, that they cannot well be underfloor or explained separately. In this sense our body may be compared to a circular chain of powers, in which nothing is first or last, nothing solitary or independent; so that wherever we begin, we find that there is something preceding which we ought to have known. If we begin with the brain and the nerves, for example, we shall find that these cannot exist, even in idea, without the heart: if we set out with the heart and vascular system, we shall presently be sensible, that the brain and nerves must be supposed; or, should we take up the mouth, and follow the course of the aliment, we should see that the very first organ which presented itself, supposed the existence of both the heart and brain: Wherefore we shall incorporate the Physiology with the Anatomy, by attempting to explain the functions after we have demonstrated the organs.

PART I. OSTEOLoGY.

We begin with the bones, which may be considered as the great support of the body, tending to give it shape and firmness. But before we enter into the detail of each particular bone, it will be necessary to describe their composition and connections, and to explain the nature of the different parts which have an immediate relation to them; as the cartilages, ligaments, periosteum, marrow, and synovial glands.

Sect. I. Of the Bones in general, with their Appendages, &c.

The bones are of a firm and hard (a) substance, of a white colour, and perfectly inelastic. They are the most compact and solid parts of the body, and serve for the attachment and support of all the other parts.

Three different substances are usually distinguished in them; their exterior or bony part, properly so called; their spongy cells; and their reticular substance. The first of these is formed of many laminae or plates, composing a firm hard substance — the spongy or cellular part is so called on account of its resemblance to a sponge, from the little cells which compose it. This substance forms almost the whole of the extremities of cylindrical bones. The reticular part is composed of fibres, which cross each other in different directions. This net-work forms the internal surface of these bones which have cavities.

The flat bones, as those of the head, are composed only of the laminae and the cellular substance. This last is usually found in the middle of the bone dividing it into two plates, and is there called diplás.

Gagliardi, who pretended to have discovered an infinite number of clavicles (c), or bony processes, which he describes as traversing the laminae to unite them together, has endeavoured to support this pretended discovery by the analogy of bones to the bark of trees, in which certain woody nails have been remarked; but this opinion seems to be altogether fanciful.

Some writers have supposed, that the bones are formed by layers of the periosteum, which gradually ossify, in the same manner as the timber is formed in trees by the hardening of the white substance that is found between the inner bark and the wood. M. Duhamel, who has adopted this opinion, fed different animals with madder and their ordinary food alternately during a certain time; and he affirms, that in digesting their bones, he constantly observed distinct layers of red and white, which corresponded with the length of time they had lived on madder or their usual aliment. But it has since been proved by Dextoff, that M. Duhamel's experiments were inaccurate, and that neither the periosteum nor the cartilages are tinged by the use of the madder, which is known to affect the bones only.

We usually consider in a bone, its body and its extremities. The ancients gave the name of diaphysis to the body or middle part, and divided the extremities into apophyses and epiphyses. An apophysis, or process, as it is more commonly called, is an eminence continued from the body of the bone, whereas an epiphysis is at first a sort of appendage to the bone, by means of an intermediate cartilage. Many epiphyses, which appear as distinct bones in the foetus, afterwards become apophyses; for they are at length so completely united to the body of the bone as not to be distinguishable from it in the adult state. It is not unusual, however, at the age of 18 and even 20 years, to find the extremities of bones still in the state of epiphysis.

The names given to the processes of bones are expressive of their shape, size, or use; thus if a process is large and of a spherical form, it is called capitulum; or head; if the head is flattened, it is termed condyle.

Some processes, from their resemblance to a filletto, a breast, or the beak of a crow, are called styloid, unguis, or coracid; others are styled ridges or spines. The two processes of the os femoris derive their name of trochanters from their use.

A bone has its cavities as well as processes. These cavities either extend quite through its substance, or appear only as depressions. The former are called foramina or holes, and these foramina are sometimes termed canalis or conductus, according to their form and extent. Of the depressions, some are useful in articulation. These are called cotylus when they are deep, as is the case with the os innominatum, where it receives the head of the os femoris; or glenoid when they are superficial, as in the acapula, where it receives the os humeri. Of the depressions that are not designed for

(a) Mr Scheele has lately discoveryed that bones contain the phosphoric acid united with calcareous earth, and that to this combination they owe their firmness.

(c) In his Anat. Officium nov. invent. illustrat. he describes four kinds of these clavicles or nails, viz. the perpendicular, oblique, headed, and crooked.
for articulation, those which have small apertures are called synovial; others that are large, and not equally surrounded by high brims, are styled fossa; such as are long and narrow, furrows; or if broad and superficial without brims, synoviosities. Some are called digital impressions, from their resemblance to the traces of a finger on foot bodies.

We shall abridge this article, which is exceedingly diffuse in the generality of anatomical books, and will endeavour to describe it with all the clearness it will allow.

The bones composing the skeleton are so constructed, that the end of every bone is perfectly adapted to the extremity of that with which it is connected, and this construction forms what is called their articulation.

Articulation is divided into diarthrosis, synarthrosis, and amphiarthrosis, or moveable, immovable, and mixed articulation. Each of the two first has its subdivisions. Thus the Diarthrosis, or moveable articulation, includes 1. The enarthrosis, as it is called, when a large head is admitted into a deep cavity, as in the articulation of the os femoris with the os innominatum. 2. Artrodia, when a round head is articulated with a superficial cavity, as in the case of the os humeri and scapula. 3. Ginglimus, or hinge-like articulation, as in the connection of the thigh bone with the tibia. The enarthrosis and artrodia allow of motion to all sides; the ginglimus only of flexion and extension.

The Synarthrosis, or immovable articulation, includes, 1. The future, when the two bones are interdigitated into each other, as is the case with the patellar bones. 2. Gomphosis, when one bone is fixed into another, in the manner the teeth are placed in their sockets.

The term amphiarthrosis is applied to those articulations which partake both of the synarthrosis and diarthrosis, as is the case with the bones of the vertebras, which are capable of motion in a certain degree, although they are firmly connected together by intermediate cartilages.

What is called symphys is the union of two bones into one; as in the lower jaw, for instance, which in the fetus consists of two distinct bones, but becomes one in a more advanced age, by the ossification of the uniting cartilage.

When bones are thus joined by the means of cartilages, the union is styled synchondrosis; when by ligaments, synereusis.

Cartilages are white, solid, smooth, and elastic substances, between the hardness of bones and ligaments, and seemingly of a fibrous texture. We are not able to trace any vessels into their substance by injection, nor are they ever found tinged in animals that have been fed with madder.

They may be distinguished into, 1st, Those which are connected with the bones; and, 2dly, Those which belong to other parts of the body. The first serve either to cover the ends and cavities of bones intended for motion, as in the articulations, where by their smoothness they facilitate motions, which the bones alone could not execute with so much freedom; or they serve to unite bones together, as in the emphysema pubis, or to lengthen them, as in the ribs.

Many of them ossifying as we advance in life, their number is less in the adult than in the fetus, and of course there are fewer bones in the old than in the young subject.

Of the second class of cartilages, or those belonging to the soft parts, we have instances in the larynx, where we find them useful in the formation of the voice, and for the attachment of muscles.

The periosteum is a fine membrane of a compact cellular texture, reflected from one joint to another, and serving as a common covering to the bones. It has sanguiferous and lymphatic vessels, and is supplied with nerves from the neighbouring parts. It adheres very firmly to their surface, and by its smoothness facilitates the motion of muscles. It likewise supports the vessels that go to be distributed through the substance of the bones, and may serve to strengthen the articulations.

At the extremities of bones, where it is found covering a cartilage, it has by some been improperly considered as a distinct membrane, and named perichondrium. This, in its use and structure, resembles the periosteum. Where it covers the bones of the skull, it has gotten the name of perieranium.

The periosteum is not a production of the dura mater, as the ancients, and after them Havers, imagined; nor are the bones formed by the ossification of this membrane, at least when it is in a found state, as some late writers have supposed.

The periosteum is deficient in the teeth above the sockets, and in those parts of bones to which ligaments or tendons are attached.

The marrow is a fat oily substance, filling the cavities of bones. In the great cavities of long bones it is a matter of controversy, whether the marrow is spongy or not. We are certainly not able to trace any nerves to it; and from this circumstance, and its analogy to fat, Haller has ventured to consider it as insensible. On the other hand, Duvverney afferts, that...
that an injury done to this sub stance in a living animal was attended with great pain. In this dispute physiologists do not seem to have sufficiently discriminated between the marrow itself and the membranous cells in which it is contained. The former, like the fat, being nothing more than a secreted, and of course an inorganized, matter, may with propriety be ranked among the insensible parts, as much as intimated mucus or any other secreted matter in the body; whereas the mem brana medullaris being vascu lar, though it possesses but an obscure degree of feeling in a found state, is not perfectly insensible.

The marrow was formerly supposed to be intended for the nourishment and renewal of the bones; but this doctrine is now pretty generally and deservedly exploded. It seems probable that the marrow is to the bones what fat is to the soft parts. They both serve for some important purposes in the animal econ omy; but their particular use has never yet been clearly ascertained. The marrow, from the transudation of the oil through the bones of a skeleton, is supposed to diminish their brittleness; and Havers, who has written professedly on the bones, describes the canals by which the marrow is conveyed through every part of their substance, and divides them into longitudinal and transverse ones. He speaks of the first as extending through the whole length of the bone, and of the latter, as the passage by which the longitudinal ones communicate with each other. The similarity of these to the large canals in burnt bones, and the transudation of the oil through the bones of the skeleton, seems to prove that some such passages do actually exist.

The synovial glands are small bodies (n), sup posed to be of a glandular structure, and exceedingly vascular, secreting a fluid of a clear mucilaginous nature, which serves to lubricate the joints. They are placed in small cavities in the articulations, so as to be capable of being gently compressed by the motion of the joint, which expresses its juice in proportion to the degree of friction. When the synovia is wanting, or is too thick a consistence, the joint becomes stiff and incapable of flexion or extens ion. This is what is termed ankylosis.

Ligaments are white, glistening, inelastic bands, of a compact substance, more or less broad or thick, and serving to connect the bones together. They are distinguished by different names adapted to their different forms and uses. Those of the joints are called either round or capsular. The round ligaments are white, tendinous, and inelastic. They are strong and flexible, and are found only in the joint of the knee, and in the articulation of the os femoris with the os innominatum. The capsular, or capsular ligaments, surround the whole joint like a puree, and are to be found in the articulations which allow motion every way, as in the articulation of the arm with the scapula.

Of those cases called Burse mucosae, a few were known to former anatomists, but by much the greater number have been since discovered by Dr Monro (x), who observes, that they are to be met with in the ex tremities of the body only; that many of them are placed entirely on the inner sides of the tendons, between thse and the bones. Many others cover not only the inner, but the outer sides of the tendons, or are interposed between the tendons and external parts, as well as between those and the bones.

Some are situated between the tendons and external parts only or chiefly, some between contiguous tendons, or between the tendons or the ligaments and the joints. A few such cases are observed where the processes of bones play upon the ligaments, or where one bone plays upon another. Where two or more tendons are contiguous, and afterwards separate from each other, we generally find a common burse divided into branches, with which it communicates; and a few burseae of contiguous tendons communicate with each other.

Some, in healthy children communicate with the cavities of the joints; and in many old people he has seen such communications formed by use or worn by friction, independent of disease.

Their proper membrane is thin and transparent, but very dense, and capable of confining air or any other fluid. It is joined to the neighbouring parts by the common cellular substance. Between the burse and the hard substance of bone, a thin layer of cartilage or tough membrane is very generally interposed. To the cellular substance on the outside of the burse, the adipose substance is connected; except where the burse covers a tendon, cartilage, or bone, much exposed to pressure or friction.

In several places a mass of fat, covered with the continuation of the membrane of the burse, projects into its cavity. The edges of this are divided into fringes.

The inner side of the membrane is smooth, and is extremely slippery from the liquor secreted in it.

The structure of the burse bears a strong resemblance to the capsular ligaments of the joints. 1. The inner layer of the ligament, like that of the burse, is thin and dense. 2. It is connected to the external ligaments by the common cellular substance. 3. Between it and the bones, layers of cartilage, or the articular cartilages, are interposed. 4. At the sides of the joints, where it is not subjected to violent pressure and friction, the adipose substance is connected with the cellular membrane.

Within the cavities of the joints we observe masses of fat projecting, covered with similar blood-vei fels, and with similar sinews hanging from their edges. 6. In the knee the upper part of such a mass of fat forms what has been called the mucilaginous gland of the joint, and the under part projects into the burse behind the ligament which ties the patella to the tibia. 7. The liquor which lubricates the burse has the same colour, consistence, and properties as that of the joints, and both are affected in the same manner by heat, mineral acids, and ardent spirits. 8. In some places the burse constantly communicate with the cavities of the joints, in others they generally do so; from which we may infer a fameness of structure.

When we examine the sinews common to the fatty bodies of the joints and burseae, and which have been supposed to be the ducts of glands lodged within the

---

(n) It is now much doubted, however, whether the appearances in the joints, which are usually called glands, are any thing more than assemblages of fat.

(x) See Description of the Burse Mucosae, &c.
ANATOMY.

Part I.

These bones are all harder at their surface than in bone; and on this account they are divided into two tables, and a middle spongy substance called diploe.

In this, as in all the other bones, we shall consider of the OSE-

s its figure, structure, processes, depressions, and cavities; and the manner in which it is articulated with the other bones.

The os frontis has some resemblance in shape to the shell of the cockle. Externally it is convex, its concave side being turned towards the brain. This bone in the places where it is united to the temporal bones, is very thin, and has there no diploe. It is likewise exceedingly thin in that part of the orbit of the eye which is nearest to the nose. Hence it is, that a wound in the eye, by a sword or any other pointed instrument, is sometimes productive of immediate death.

In these cases, the sword passing through the weak part of the bone, penetrates the brain, and divides the nerves at their origin; or perhaps opens some blood-vessel, the consequences of which are soon fatal.

We observe on the exterior surface of this bone five apophyses or processes, which are easily to be distinguished. One of these is placed at the bottom and narrowest part of the bone, and is called the nasal process, from its supporting the upper end of the bones of the nose. The four others are called angular or orbitar processes. They assist to form the orbits, which are the cavities on which the eyes are placed. In each of these orbits there are two processes, one at the interior or great angle, and the other at the exterior or little angle of the orbit. They are called the angular processes. Between these a ridge is extended in form of an arch, and on this the eye-brows are placed. It is called the orbitar or superciliary ridge, and in some measure covers and defends the globe of the eye. There is a hole in this for the passage of the frontal vessels and nerves. This arch is interrupted near the nose by a small pit, in which the tendon of the muscleus obliquus major of the eye is fixed. From the under part of each superciliary ridge a thin plate runs a considerable way backwards, and has the name of orbitar; the external and fore-part of this plate forms a finity for lodging the lacrymal gland. Between the orbitar plates there is a large disconnection of the bone, which is filled up by the cribiform part of the os ethmoidei.

On examining the inner surface of this bone at its under and middle part, we observe an elevation in form of a ridge, which has been called the simbra processus; it ascends for some way, dividing the bone into two considerable fossae, in which the anterior lobes of the brain are placed. To a narrow furrow in this ridge is attached the extremity of the falx, as the membrane is called, which divides the brain into two hemispheres. The furrow becoming gradually wider, is continued to the upper and back part of the bone. It has the falx

\((s)\) The bones of the cranium being perfectly distinct, and the muscles in young persons not acting much, the shape of the head has been supposed to depend much on the management of children when very young. Ve-

velius, who has remarked the difference in people of different nations, observes, for instance, that the head of a Turk is conical, from the early use of the turban; whilst that of an Englishman is flattened by the chin-slap. Some of the latest physiologists suppose, with good reason, that this difference is chiefly owing to certain natural causes with which we are as yet unacquainted.
Part I. ANATOMY.

Of the longitudinal sinuses lodged in the head, there are many depressions, which appear like digital impressions, and owe their formation to the prominent circumvolutions of the brain. In the occiput, the forehead is composed of two distinct bones; so that in them the sagittal future reaches from the os occipitis to the note. This bone is almost every where composed of two tables and a diploe. These two tables separating from each other under the eyes, form two cavities, one on each side of the face, called the frontal sinuses. These sinuses are lined with a soft membrane, called mucous ptilitaria. In these sinuses a mucus is secreted, which is constantly passing through two small holes into the nostrils, which it serves to moisten. It passes regularly so; at its inferior part, where it is covered with cartilage, it serves the opening of the Eustachian tube, a canal which is joined by the sphenoidal future. To the os sphenoides and petrosum, this bone, called the lambdoidal future.

The os occipitis is of greater strength and thickness than either of the other bones of the head, though irregularly so; at its inferior part, where it is thinned, it is covered by a great number of muscles. This bone, from its situation, being more liable to be injured by falls, than any other bone of the head, nature has wisely given it the greatest strength at its upper part, where it is most exposed to danger.

It is joined to the parietal bones by the lambdoidal future, and to the os temporal, by the addition of a bony prominence to the cranial circumference. This prominence is connected to the os sphenoides by the cuneiform processes. It is by means of the os occipitis that the head is united to the trunk, the two condyles of this bone being connected to the superior oblique processes of the first vertebra of the neck.

There are two temporal bones, one on each side. Of the temporal bone.

We may distinguish in them two parts; one of which is called the squamous or zygaprobit, and the other the petrosa from its hardness. This last is shaped like a pyramid.

Each of these divisions affords processes and cavities: externally there are three processes; one anterior, called the zygomatic processes; one posterior, called the mastoid or mastoidal processes, from its resemblance to a nipple; and one inferior, called the styloid processes, because it is shaped like a filletto, or dagger.

The cavities are, 1. The meatus auditorius externus. 2. A large fossa which serves for the articulation of the lower jaw; it is before the meatus auditorius, and immediately under the zygomatic processes. 3. The hylo-malloid hole, so called from its situation between the styloid and mastoid processes; it is likewise filled by the aqueduct of Fallopus, and affords a passage to the porio duae of the auditory, or seventh pair of nerves.

Below, and on the fore-part of the last foramen, we observe part of the jugular fossa, in which the beginning of the internal jugular vein is lodged. Anterior and superior to this fossa is the orifice of a foramen, through which passes the carotid artery. This foramen runs first upwards and then forwards, forming a kind of elbow, and terminates at the end of the os petrosum. At this part of each temporal bone, we may observe the opening of the Eustachian tube, a canal which passes from the ear to the back part of the nose.

In examining the internal surface of these bones, we may remark the triangular figure of their petrous part which separates two fossae; one superior and anterior, the other inferior and posterior; the latter of these compposes part of the fossa, in which the cerebellum is placed;
Of the ossa sphenoides.

This bone, from its situation amidst the other bones of the head, has been sometimes called unumformes. It is of a very irregular figure, and has been compared to a bat with its wings extended.

It is commonly divided into its middle part or body, and its sides or wings.

The fore part of the body has a spine or ridge, which makes part of the septum narium. The upper part of each wing forms a share of the temple. The fore part of this belongs to the orbit; while the under and back part, termed spinous process, is lodged in the base of the skull at the point of the pars petrosa. But two of the most remarkable processes are the pterygoid or aliform, one on each side of the body of the bone, and at no great distance from it. Each of these processes is divided into two wings, and of these the exterior one is the widest. The other terminates in a hook-like process.

The internal surface of this bone affords three fosse.

Two of these are formed by the wings of the bone, and make part of the lesser fossa of the basis of the cranium. The third, which is smaller, is on the top of the body of the bone; and is called cella turcica, from its resemblance to a Turkish saddle. This fossa, in which the pituitary gland is placed, has posteriorly and anteriorly processes called the clinoform processes.

There are twelve holes in this bone, viz. six on each side. The first is the passage of the optic nerve and ocul ar artery; the second, or large slit transmits the third, fourth, fifth, and sixth part of the fifth pair of nerves with the ocul ar vein; the third hole gives passage to the second branch of the fifth pair; and the fourth hole to the third branch of the fifth pair of nerves. The fifth hole is the passage of the artery of the dura mater. The sixth hole is situated above the pterygoid processes of the sphenoid bone; through it a reflected branch of the second part of the fifth pair passes.

Within the substance of the os sphenoides there are, two sinuses separated by a bony plate. They are lined with the pituitary membrane; and like the frontal sinuses, separate a mucous which passes into the nostrils.

The os sphenoides is joined to all the bones of the cranium; and likewise to the os maxillarium, os malarum, os palatii, and vomer.

This bone makes part of the basis of the skull, affords forming the orbits, and affords attachment to several muscles.

The os ethmoides is situated at the fore part of the basis of the cranium, and is of a very irregular figure.

Of the os ethmoides.

It consists of a middle part and two sides. The middle part is formed of a thin bony plate, in which are an infinite number of holes that afford a passage to filaments of the olfactory nerve. From the middle of this plate, both on the outside and from within, there rises up a process, which may be easily distinguished. The inner one is called cribrum galli, from its supposed resemblance to a cock's comb. To this process the falix of the dura mater is attached. The exterior process, which has the fame common basis as the cribrum galli, is a fine lamella which is united to the vomer; and divides the cavity of the nostrils, though unequally, it being generally a little inclining to one side.

The lateral parts of this bone are composed of a cellular substance; and these cells are so very intricate, that their figure or number cannot be described. Many writers have on this account called this part of the bone the labyrinth. These cells are externally covered with a very thin bony lamella. This part of the bone is called the os planum, and forms part of the orbit.

The different cells of this bone, which are numerous, and which are everywhere lined with the pituitary membrane, evidently serve to enlarge the cavity of the nose, in which the organ of smelling resides.

This bone is joined to the os sphenoides, os frontis, os maxillarium, os palatii, os nasi, os unguis, and vomer.

The ancients, who considered the brain as the seat of all the humours, imagined that this viscus discharged its redundant moisture through the holes of the ethmoid bone. And the vulgar still think, that abscesses of the brain discharge themselves through the mouth and ears, and that snuff is liable to get into the head; but neither snuff nor the matter of an abscess are more capable of passing through the cribiform bone, than the ferocity which they suppos'd was discharged through it in a common cold. All the holes of the ethmoid bone are filled up with the branches of the olfactory nerve. Its inner part is likewise covered with the dura mater, and its cells are everywhere lined with the pituitary membrane; so that neither matter nor any other fluid can possibly pass through this bone either externally or internally. Matter is indeed sometimes discharged through the nostrils: but the seat of the disease is in the sinuses of the nose, and not in the brain; and impollubatations are observed to take place in the ear, which suffurate and discharge themselves externally.

Before we leave the bones of the head, we wish to make some general observations on its structure and figure.—As the cranium might have been composed of a single bone, the articulation of its several bones being absolutely without motion, it may be asked perhaps, Why such a multiplicity of bones, and so great number of futures? Many advantages may possibly arise from this plurality of bones and futures, which may not yet have been observed. We are able, however, to point out many useful ends, which could only be accomplished by this peculiarity of structure. In this, as in all the other works of nature, the great wisdom of the Creator is evinced, and cannot fail to excite our admiration and gratitude.
Of the bones of the face.

The face, which consists of a great number of bones, is commonly divided into the upper and lower jaws. The upper jaw consists of thirteen bones, exclusive of the teeth. Of these, six are placed on each side of the maxilla superior, and one in the middle.

The bones, which are in pairs, are the os mala-

rum, os maxillarium, os nasi, os unguis, os palati, and os sphenoides inferius. The single bone is the vomer.

These are the prominent square bones which are placed under the eyes, forming part of the orbits and the upper parts of the cheeks. Each of them affords three surfaces; one exterior and a little convex; a second superior and concave, forming the inferior part and sides of the orbit; and a third posterior, irregular, and hollowed for the lodgment of the lower part of the temporal muscle.

The angles of each bone form four processes, two of which may be called orbitar processes; of these the upper one is joined by future to the os frontis, and that below to the maxillary bone. The third is connected with the os sphenoides by means of the trig-}

A N A T O M Y. 691

verse future; and the fourth is joined to the zygoma.

Of the os malarum, the bones, as we have before observed, are perfectly distinct from each other. Their differentiation begins in the middle of each bone, and proceeds gradually to the circumference. Hence the os malarum and the maxilla (or the zygoma) are both growing at the same time. Hence it happens, that the heads of young people, in which the bones begin to touch each other, increase slowly; and that the proportionate increase of the volume of the head is greater in three months in the face, than it is perhaps in twenty-four months at the age of fourteen or fifteen years.

The futures, exclusive of their advantages in sustaining the processes of the dura mater, are evidently of great utility in preventing the too great extent of fractures of the skull. Suppose, for instance, that by a fall or blow, one of the bones of the cranium becomes fractured. The injury, which in a head composed of only one bone, would be liable to extend itself through the whole of it, is checked; and sometimes perhaps stopped by the first face it meets, and the effects of the injury are confined to the bone on which the blow was received. Ruyfch indeed, and some others, will not allow the futures to be of any such use; but cases have been known in which the parts seemed to have had this effect, and in young subjects their utility in this respect must be still more obvious.

The spherical form of the head seems likewise to render it more capable of resisting external violence than any other shape would do. In a vault, the parts mutually support and strengthen each other, and this happens in the cranium.

§ 2. Proper Bones of the Face.

The face, which consists of a great number of bones, is commonly divided into the upper and lower jaws. The upper jaw consists of thirteen bones, exclusive of the teeth. Of these, six are placed on each side of the maxilla superior, and one in the middle.

The bones, which are in pairs, are the os malarum, os maxillarium, os nasi, os unguis, os palati, and os sphenoides inferius. The single bone is the vomer.

These are the prominent square bones which are placed under the eyes, forming part of the orbits and the upper parts of the cheeks. Each of them affords three surfaces; one exterior and a little convex; a second superior and concave, forming the inferior part and sides of the orbit; and a third posterior, irregular, and hollowed for the lodgment of the lower part of the temporal muscle.

The angles of each bone form four processes, two of which may be called orbitar processes; of these the upper one is joined by future to the os frontis, and that below to the maxillary bone. The third is connected with the os sphenoides by means of the tran-
ANATOMY.

Part I.

The ossa unguis are of an irregular figure. Their external surface consists of two smooth parts, divided by a middle ridge. One of these parts, which is concave and near to the nose, serves to support the lachrymal face and part of the lachrymal duct. The other, which is flat, forms a small part of the orbit.

Each of these bones is connected with the os frontis, os ethmoides, and os maxillare superius.

These bones, which are situated at the back part of the roof of the mouth, between the os sphenoides and the os maxillaria superius, are of a very irregular shape, and serve to form the nasal and maxillary fossa, and a small part of the orbit. Where they are united to each other, they rise up into a spine on their internal surface. This spine appears to be a continuation of that of the superior maxillary bones, and helps to form the septum narium.

These bones are joined to the os maxillaria superius, os ethmoides, os sphenoides, and vomer.

This bone derives its name from its resemblance to the vomer. This bone is formed of two smooth parts, divided cartilage. The inferior portion of this bone is placed on the nasal spine of the maxillary and palatum bones, which we mentioned in our description of the os palati.

The vomer is united to the os sphenoides, os ethmoides, os maxillaria superius, and os palati. It forms part of the septum narium, by dividing the back part of the nose into two nostrils.

These bones are covered with the pituitary membrane; and, besides their connection with the ethmoid bone, are joined to the os maxillaria superius, os palati, and os unguis.

The maxilla, or lower jaw, which in its shape resembles a horse-shoe, consists of two distinct bones in the foetus; but these unite together soon after birth, so as to form only one bone. The upper edge of this bone, like the os maxillare superius, is an alveolar process, furnished with sockets for the teeth.

On each side the posterior part of the bone rises almost perpendicularly into two processes. The highest of these, called the coronoid process, is pointed and thin, and serves for the insertion of the temporal muscle. The other, or condylar process, as it is called, is shorter and thicker, and ends in an Oblong rounded head, which is received into a fossa of the temporal bone, and is formed for a moveable articulation with the cranium. This joint is furnished with a moveable cartilage. At the bottom of each coronoid process, on its inner part, we observe a foramen extending under the roots of all the teeth, and terminating at the outer surface of the bone near the chin. Each of these canals transmits an artery, vein, and nerve, from which branches are sent off to the teeth.

The lower jaw is capable of a great variety of motion. By sliding the condyles from the cavity towards the eminences on each side, we bring it horizontally forwards, as in biting; or we may bring the condyles only forward, and tilt the rest of the jaw backward, as in opening the mouth. We are likewise able to slide the condyles alternately backwards and forwards from the cavity to the eminence, and vice versa, as in grinding the teeth. The cartilages, by adapting themselves to the different inequalities in these several motions of the jaw, serve to secure the articulation, and to prevent any injuries from friction.

The alveolar process is composed of an outer and inner bony plate, united together by thin partitions, which at the fore part of the jaw divide the processes into as many sockets as there are teeth. But at the back part of the jaw, where the teeth have more than one root, we find a distinct cell for each root. In both jaws these processes begin to be formed with the teeth; they likewise accompany them in their growth, and gradually disappear when the teeth are removed.

§ 3. Of the Teeth.

The teeth are bones of a particular structure, formed for the purposes of mastication and the articulation of the voice. It will be necessary to consider their composition and figure, their number and arrangement, and the time and order in which they appear.

In each tooth we may distinguish a body, a neck, and a root or fangs.

The body of the tooth is that part which appears above the gums. The root is fixed into the socket, and the neck is the middle part between the two.

The teeth are composed of two substances, viz. enamel and bone. The enamel, or the vitreous or cortical part of the tooth, is a white and very hard and compact substance peculiar to the teeth, and appears fibrous or irritated when broken. This substance is thickest on the grinding surface, and becoming gradually thinner, terminates insensibly at the neck of the tooth. Ruych * affirmed, that he could trace the arteries into the hardest part of the teeth; Liewen. to no. 15. hoek * supposed the fibres of the enamel to be fo many vessels; and Monro † says, he has frequently injected the vessels of the teeth in children, so as to make the inside of the corona appear perfectly red. Anatom. But it is certain, that it is not tinged by a madder diet, the Human and that no injection will ever reach it, so that it has no appearance of being vascular.

The bony part, which composes the inner substance on the Teeth, of the body, neck, and root of the tooth, resembles other bones in its structure, but it is much harder than the most compact part of bones in general. As a tooth when once formed receives no tinge from a madder diet, and as the minutest injections do not penetrate into its substance, this part of a tooth has, like the enamel, been supposed not to be vascular. But when we consider that the fangs of a tooth are invested by

* Rusch
† Monro
ANATOMY.

The two first of the molares, or those nearest to the canine teeth on each side, differ from the other three, and are with great propriety named bicuspides by Mr Hunter. They have sometimes only one root, and seem to be of a middle nature between the incifores and the larger molares. The two next are much larger. The fifth or last grinder on each side is smaller and shorter than the rest; and from its not cutting the gum till after the age of twenty, and sometimes not till much later in life, is called dens fissure.

There is in the structure and arrangement of all these teeth an art which cannot be sufficiently admired. To understand it properly, it will be necessary to consider the under jaw as a kind of lever, with its fixed points at its articulations with the temporal bones:—it will be right to observe, too, that its powers arise from its different muscles, but in elevation chiefly from the temporalis and masseter; and that the alveolus constitutes the object of resistance. It will appear, then, that the molares, by being placed nearest the centre of motion, are calculated to pref with a much greater force than the other teeth, independent of their grinding powers which they possess by means of the pterygoid muscles; and that it is for this reason we put between them any hard body we wish to break.

The canini and incifores are placed farther from this point, and of course cannot exert so much force; but they are made for cutting and tearing the food, and this form seems to make amends for their deficiency in strength.

There are examples of children who have come into the world with two, three, and even four teeth; but these examples are very rare; and it is seldom before the seventh, eighth, or ninth month after birth, that the incifores, which are the first formed, begin to pass through the gum. The symptoms of dentition, however, in consequence of irritation from the teeth, frequently take place in the fourth or fifth month.—About the twentieth or twenty-fourth month, the canini and two molares make their appearance.

The dangerous symptoms that sometimes accompany dentition, are owing to the pressure of the teeth on the gum, which they irritate so as to excite pain and inflammation. This irritation seems to occasion a gradual wasting of the gum at the part, till at length the tooth makes its appearance.

The symptoms are more or less alarming, in proportion to the resistance which the gum affords to the teeth, and according to the number of teeth which may chance to seek a passage at the same time. Were they all to appear at once, children would fall victims to the pain and excessive irritation; but Nature has so very wisely disposed of them, that they usually appear one after the other, with some distance of time between each. The first incisor that appears is generally in the lower jaw, and is followed by one in the upper

(n) Mr Hunter has thought proper to vary this division. He retains the old name of incifores to the four fore teeth, but he distinguishes the canine teeth by the name of the canispidat. The two teeth which are next to these, and which have been usually ranked with the molares, he calls the bicuspides; and he gives the name of grinders only to the three last teeth on each side.

1) Mr Hunter remarks of these teeth, that we may trace in them a similarity in shape, situation, and use, from the most imperfectly carnivorous animal, which we believe to be the human species, the lion, which is the most perfectly carnivorous.
The trunk of the skeleton consists of the spine, the thorax, and the pelvis.

The spine is composed of a great number of bones called vertebrae, forming a long bony column, in figure not much unlike the letter T. This column, which extends from the head to the lower part of the body, may be said to consist of two irregular and unequal pyramids, united to each other in that part of the loins where the last lumbar vertebra joins the os sacrum.

The vertebrae of the upper and longest pyramid are called true vertebrae, in contradistinction to those of the lowermost pyramid, which, from their being immovable in the adult, are styled false vertebrae. It is upon the bones of the spine that the body turns; and it is to this circumstance they owe their name, which is derived from the Latin verb vertere, to turn.

The true vertebrae are divided into three classes of cervical, dorsal, and lumbar vertebrae.—The false vertebrae consist of the os sacrum and os coecygis. In each vertebrae, as in other bones, it will be necessary to remark the body of the bone, its processes, and cavities.

The body, which is convex before, and concave behind, where it affixes in forming the cavity of the spine, may be compared to part of a cylinder cut off transversely. Each vertebra affords seven processes. The first is at the back part of the vertebra, and from its shape and direction is named the spinous process. On each side of this are two others, which, from their situation with respect to the spine, are called transverse processes. The four others are styled oblique or articular processes. They are much smaller than the spinous or transverse ones. Two of them are placed on the upper, and two on the lower part of each vertebrae, rising from near the bases of each transverse process. They have gotten the name of oblique processes, from their situation with respect to the processes with which they are articulated; and they are sometimes styled articular processes, from the manner in which they are articulated with each other; the two superior processes of one vertebra being articulated with

(k) This bone is very seldom preserved with the skeleton, and cannot be included among the bones of the head, or any other division of the skeleton. Thomas Bartholin has perhaps very properly describ'd it among parts contained in the mouth; but the generality of anatomical writers have plac'd it, as it is here, after the bones of the face.
with the two inferior processes of the vertebra above it. Each of these processes is covered with cartilage at its articulation, and their articulations with each other are by a species of ginglymus.

In each vertebra, between its body and its processes, we find a hole large enough to admit a finger. These holes or foramina, correspond with each other through all the vertebrae, and form the long bony channel in which the spinal marrow is placed. We may likewise observe four notches in each vertebra. Two of these notches are at the upper, and two at the lower part of the bone, between the oblique processes and the body of the vertebra. Each of these notches meeting with a similar opening in the vertebra above or below it, forms a foramen for the passage of blood-vessels, and of the nerves out of the spine.

The bones of the spine are united together by means of a sub stance, which in young subjects appears to be of a ligamentous, but in adults more of a cartilaginous nature. This intervertebral substance, which forms a kind of partition between the several vertebrae, is thicker and more flexible between the lumbar vertebrae than in the other parts of the spine, the most considerable motions of the trunk being performed on those vertebrae. This substance being very elastic, the extension and flexion of the body, and its motion backwards and forwards, to either side, are performed with great facility. This elasticity seems to be the reason why people who have been long standing, or have carried a considerable weight, are found to be shorter than when they have been long in bed. In the two first instances the intervertebral cartilages (as they are usually called) are evidently more exposed to compression than when we are in bed in an horizontal posture.

In advanced life these cartilages become shrivelled, and of course lose much of their elasticity. This may serve to account for the decrease in stature and the sloping forward which are usually to be observed in old people.

Besides the connection of the several vertebrae by means of this intervertebral sub stance, there are likewise many strong ligaments, both external and internal, which unite the bones of the spine to each other. Their union is also strengthened by a variety of strong mufcles that cover and surround the spine.

The bones of the spine are found to diminish in density, and to be less firm in their texture in proportion as they increase in bulk; so that the lowermost vertebrae, though the largest, are not so heavy in proportion as the upper ones. By this means the size of these bones is increased without adding to their weight: a circumstance of no little importance in a part like the spine, which, besides flexibility and suppleness, seems to require lightness as one of its essential properties.

In young children, each vertebra consists of three bony pieces united by cartilages which afterwards ossify.

There are seven vertebrae of the neck—they are of a firmer texture than the other bones of the spine. Their transverse processes are forked for the lodgement of muscles, and at the bottom of each we observe a foramen, through which pass the cervical artery and vein. The first and second of these vertebrae must be described more particularly. The first approaches almost to an oval shape. On its superior surface it has two cavities which admit the condyles of the occipital bone, with which it is articulated. This vertebra, which is called atlas from its supporting the head, cannot well be described as having either body or spinous processes, being a kind of bony ring. Anteriorly, where it is articulated to the odontoid process of the second vertebra, it is very thin. On its upper surface it has two cavities which admit the condyles of the occipital bone. By this connection the head is allowed to move forwards and backwards, but has very little motion in any other direction.

The second vertebra has gotten the name of dentata, from its having, at its upper and inferior part, a process called the odontoid or tooth-like process, which is articulated with the atlas, to which this second vertebra may be said to serve as an axis. This odontoid process is of a cylindrical shape, somewhat flattened, however, anteriorly and posteriorly. At its fore-part where it is received by the atlas, we may observe a smooth, convex, articulating surface. It is by means of this articulation that the head performs its rotatory motion, the atlas in that case moving upon this odontoid process as upon a pivot. But when this motion is in any considerable degree, or, in other words, when the head moves much either to the right or left, all the cervical vertebrae seem to affilt, otherwise the spinal marrow would be in danger of being divided transversely by the first vertebra.

The spinous processes of each of the cervical vertebrae are shorter, and their articular processes more oblique, on the back than in the other bones of the spine. These two vertebrae are of a middle size between those of the neck and loins. At their sides we may observe two depressions, one at the upper and the other at the lower part of the body of each vertebra; which unites with similar depressions in the vertebrae above and below, form articulating surfaces, covered with cartilages, for receiving the heads of the ribs; and at the fore part of their transverse processes (excepting the two last) we find an articulating surface for receiving the tubercles of the ribs.

These five vertebrae differ only from those of the back in being larger, and in having their spinous processes at a greater distance from each other. The most considerable motions of the trunk are made on these vertebrae; and these motions could not be performed with so much ease, were the processes placed nearer to each other.

The os sacrum, which is composed of five or six pieces in young subjects, becomes one bone in more advanced age.

It is nearly of a triangular figure, its inferior portion being bent a little forwards. Its superior part has two oblique processes which are articulated with the left of the lumbar vertebrae; and it has likewise commonly three small spinous processes, which gradually become shorter, so that the lowermost is not so long as the second, nor the second as the uppermost. Its transverse processes are formed into one oblong process, which becomes gradually smaller as it descends. Its concave or anterior side is usually smooth, but its posterior convex side has many prominences (the most remarkable of which are the spinous processes just now mentioned), which are filled up and covered with the muscular and tendinous parts behind.
This bone has five pairs of holes, which afford a passage to blood-vessels, and likewise to the nerves that are derived from the spinal marrow, which is continued even here, being lodged in a triangular cavity, that becomes smaller as it descends, and at length terminates obliquely at the lower part of this bone. Below the third division of the os sacrum, this canal is not completely bony as in the rest of the spine, being secured at its back part only by a very strong membrane, so that a wound at that part must be extremely dangerous.

The os sacrum is united laterally to the os inominata or hip-bones, and below to the coccyx.

The coccyx, which, like the os sacrum, is in young people made up of three or four distinct parts, usually becomes one bone in the adult state.

It serves to support the intestinum rectum; and, by its being capable of some degree of motion at its articulation with the sacrum, and being like that bone bent forwards, we are enabled to sit with ease.

This bone is nearly of a triangular shape, being broadest at its upper part, and from thence growing narrower to its apex, where it is not bigger than the little finger.

It has got its name from its supposed resemblance to a cuckow's beak. It differs greatly from the vertebræ, being commonly without any processæ, and having no cavity for the spinal marrow, or foramina for the transmission of nerves.

The spine, of which we have now finished the anatomical description, is destined for many great and important uses. The medulla spinalis is lodged in its bony canal secure from external injury. It serves as a defence to the abdominal and thoracic visceræ, and at the same time supports the head, and gives a general firmness to the whole trunk.

We have before compared it to the letter J, and its different turns will be found to render it not very unlike the figure of that letter. In the neck we see it projecting somewhat forward to support the head, which without this assistance would require a greater number of muscles. — Lower down, in the thorax, we find it taking a curved direction backwards, and of course increasing the cavity of the chest. After this, in the loins, it again projects forwards in a direction with the centre of gravity, by which means we are easily enabled to keep the body in an erect posture, for otherwise we should be liable to fall forward. Towards its inferior extremity, however, it again recedes backward, and thus assists in forming the pelvis, the name given to the cavity in which the urinary bladder, intestinum rectum, and other visceræ are placed.

If this bony column had been formed only of one piece, it would have been much more easily fractured than it is now: and by confining the trunk to a stiff situation, a variety of motions would have been altogether prevented, which are now performed with ease by the great number of bones of which it is composed.

It is firm, and yet to this firmness there is added a perfect flexibility. If it be required to carry a load upon the head, the neck becomes stiff with the assistance of its musculæ, and accommodates itself to the load, as if it was composed only of one bone.—In stooping like wise, or in turning to either side, the spine turns itself in every direction, as if all its bones were separated from each other.

In a part of the body, like the spine, that is made up of so great a number of bones, and intended for such a variety of motion, there must be a greater danger of dislocation than fracture; but we shall find, that this is very wisely guarded against in every direction by the processes belonging to each vertebra, and by the ligaments, cartilages, &c. by which these bones are connected with each other.

§ 2. Of the Bones of the Thorax.

The thorax, or chest, is composed of many bones, viz. the sternum which is placed at its anterior part, twelve ribs on each side which make up its lateral parts, and the dorsal vertebrae which constitute its posterior part. These last have been already described.

The sternum is the long bone which extends itself from the upper to the lower part of the breast anteriorly, and to which the ribs and the clavicles are articulated.

In children it is composed of several bones united by cartilages; but as we advance in life, most of these cartilages ossify, and the sternum in the adult state is found to consist only of three pieces, and sometimes becomes one bone. It is however generally described as being composed of three parts—one superior, which is broad, thick, and short; and one in the middle, which is thinner, narrower, and longer than the other.

It terminates at its lower part by a third piece, which is called the xyphoid, or sword-like cartilage, from its supposed resemblance to the blade of a sword, and because in young subjects it is commonly in a cartilaginous state.

We have already observed, that this bone is articulated with the clavicle on each side. It is likewise joined to the fourteen true ribs, viz. seven on its right and seven on its left side.

The ribs are bones shaped like a bow, forming one of the sides of the chest. There are twelve on each side. They are distinguished into true and false ribs: The seven upper ribs which are articulated to the sternum are called true ribs, and the five lower ones that are not immediately attached to that bone are called false ribs.

On the inferior and interior surface of each rib, we observe a sinuosity for the lodgement of an artery, vein, and nerve.

The ribs are not bony through their whole length, their anterior part being cartilaginos. They are articulated with the vertebrae and sternum. Every rib (or at least the greater number of them) has at its posterior part two processæ; one at its extremity called the head of the rib, by means of which it is articulated with the body of two vertebrae; and another, called its tuberosity, by which it is articulated with the transverse process of the lowest of these two vertebrae. The first rib is not articulated by its extremity to two vertebrae, being simply attached to the upper part of the first vertebra of the back. The seven superior or true ribs are articulated anteriorly with the sternum by their cartilages; but the false ribs are supported in a different manner—the eighth, which is the first of these ribs,
Ofteology.

39. Os ilium.

The pelvis is composed of the os sacrum, os coccygis, and two osa innominata. The two first of these bones were included in the account of the spine, to which they more properly belong.

In children, each os innominatum is composed of three distinct bones; but as we advance in life the intermediate cartilages gradually ossify, and the marks of the original separation disappear, so that they become one irregular bone; still however continuing to retain the names of ilium, ischium, and pubis, by which their divisions were originally distinguished, and to be described as three different bones by the generality of anatomists. The os ilium forms the upper and most considerable part of the bone, the os ischiun lower and posterior portion, and the os pubis its fore part.

The os ilium or haunch bone, is articulated posteriorly to the os sacrum by a firm cartilaginous substance, and is united to the os pubis before and to the os ischiun below. Its superior portion is thin, and terminates in a ridge called the crista or spine of the ilium, and more commonly known by the name of the haunch. This crista rises up like an arch; being turned somewhat outwards, so as to resemble the wings of a phaeton.

Externally this bone is unequally prominent and hollowed for the lodging of muscles; internally we find it smooth and concave. At its lower part there is a considerable ridge on its inner surface. This ridge extends from the os sacrum, and corresponds with a similar prominence both on that bone and the ischium; forms with the inner part of the os pubis what in midwifery is termed the brim of the pelvis.

The crista, or spine, which at first is an epiphyseal, has two considerable tubercules; one anteriorly, and the other posteriorly, which is the largest of the two. These, from their projecting more than the parts of the bones below them, have given the name of spinous processes. From the anterior spinous processes, the sartorius and tenor vagus femoris muscles have their origin; and below the posterior processes we observe a considerable niche in the bone, which, in the recent subject, is formed into a large foramen, by means of a strong ligament that is stretched over its lower part from the os sacrum to the sharp-pointed process of the ischium. This hole affords a passage to the great sciatic nerve, and to the posterior crural vessels under the pyramidal muscle, part of which likewise passes out here.

The os ischium, or hip-bone, which is of a very irregular figure, constitutes the lower lateral parts of the pelvis, and is commonly divided into its body, tuberosity, and ramus. The body forms the lower and more considerable portion of the acetabulum, and sends a sharp-pointed process backwards, called the spine of the ischium. To this process the ligament adheres, which was just now spoken of, as forming a foramen for the passage of the sciatic nerves. — The tuberosity which is the lowest part of the trunk, and supports us when we sit, is large and irregular, affording origin to several muscles. From this tuberosity we find the bone becoming thinner and narrower. This part, which has the name of ramus or branch, passes forwards and upwards, and concurs with the ramus of the os pubis, to form a large hole called the foramen magnum ilchii, or thyroidem, as it is sometimes named from its resemblance to a door or shield. This hole, which in the recent subject is closed by a strong membrane called the obturator ligament, affords through its whole circumference attachment to muscles. At its upper part where we observe a niche in the bone; it gives passage to the obturator vessels and nerves, which go to the inner part of the thigh. Nature seems everywhere to avoid an unnecessary weight of bone, and this foramen, no doubt, serves to lighten the bones of the pelvis.

The os pubis or thorne-bone, which with its fellow forms the fore-part of the pelvis, is the smallest division of the os innominatum. It is united to its fellow by means of a strong cartilage, which forms what is called the symphysium pubis.

In each os pubis we may distinguish the body of the bone, its angle, and ramus. The body or outer part is united to the os ilium. The angle comes forward to form the symphysium, and the ramus is a thin process which unites with the ramus of the ischium, to form the foramen thyroidem.

The three bones we have described as composing each os innominatum, all afflitt in forming the acetabulum, in which the head of the os femoris is received.

This cavity is every where lined with a smooth cartilage, excepting at its inner part, where we may observe a little fold, in which are lodged the muisilaginous glands of the joint. We may likewise observe the pit or depression made by the round ligament, as it is improperly called, which, by adhering to this cavity and to the head of the thigh-bone, helps to secure the latter in the socket.

These bones, which are united to each other and to the spine by many very strong ligaments, serves to support the trunk, and to connect it with the lower extremities; and at the same time to form the pelvis or basin, in which are lodged the intestines and urinary bladder, and in women the uterus; so that the study of this part of osteology is of the utmost importance to midwifery.

It is worthy of observation, that in women the os sacrum is usually shorter, broader, and more hollowed, the os ilium more expanded, and the inferior opening of the pelvis larger than in men. 

40.
43. These parts of the skeleton consist of the upper extremity and the lower.

§ 1. Of the Upper Extremity.

This consists of the shoulder, the arm, and the hand.

1. Of the Shoulder.

The shoulder consists of two bones, the clavicles and the scapula.

The former, which is so named from its resemblance to the key in use amongst the ancients, is a little curved at both its extremities like an italic :. It is likewise called jugulum, or collar-bone, from its situation. It is about the size of the little finger, but longer, and being of a very spongy substance is very liable to be fractured. In this, as in other long bones, we may distinguish a head and a body, and two extremities. The body is rather flattened than rounded. The anterior extremity is formed into a slightly convex head, which is nearly of a triangular shape. The inferior surface of the head is articulated with the sternum. The posterior extremity, which is flatter and broader than the other, is connected to a process of the scapula, called acromion.

Both these articulations are secured by ligaments, and in that with the sternum we meet with a moveable cartilage, to prevent any injury from friction.

The clavicle serves to regulate the motions of the scapula, by preventing it from being brought too much forwards, or carried too far backwards. It affords origin to several muscles, and helps to cover and protect the subclavians vessels, which derive their name from their situation under this bone.

47. Of the scapula.

The scapula, or shoulder-blade, which is nearly of a triangular shape, is fixed to the posterior part of the true ribs, somewhat in the manner of a buckle. It is of a very unequal thickness, and like all other broad, flat bones, is somewhat cellular. Externally it is convex, and internally concave, to accommodate itself to the convexity of the ribs. We observe in this bone three unequal sides, which are thicker and stronger than the body of the bone, and are therefore termed its corsets. The largest of the three, called also the basin, is turned towards the vertebrae. Another, which is less than the former, is below this; and the third, which is the least of the three, is at the upper part of the bone. Externally the bone is elevated into a considerable spine, which rising small at the basin of the scapula, becomes gradually higher and broader, and divides the outer surface of the bone into two fossa. The superior of these, which is the smallest, serves to lodge the supraspinatus muscle; and the inferior fossa, which is much larger than the other, gives origin to the infra spinatus. This spine terminates in a broad and flat process at the top of the shoulder, called the processus acromion, to which the clavicle is articulated. This process is hollowed at its lower part to allow a passage to the supraspinatus and infraspinatus muscles. The scapula has likewise another considerable process at its upper part, which, from its resemblance to the beak of a bird, is called the coracoid process. From the outer side of this coracoid process, a strong ligament passes to the processus acromion, which prevents a luxation of the os humeri upwards. A third process begins by a narrow neck, and ends in a cavity called glenoid, for the connection of the os humeri.

The scapula is articulated with the clavicle and os humeri, to which it serves as a fulcrum; and by varying its position it affords a greater scope to the bones of the arm in their different motions. It likewise gives origin to several muscles, and posteriorly serves as a defence to the trunk.

2. Bones of the Arm.

The arm is commonly divided into two parts, which are articulated to each other at the elbow. The upper part retains the name of arm, properly so called, and the lower part is usually called the forearm.

The arm is composed of a single bone called os humeri. This bone, which is almost of a cylindrical shape, may be divided into its body and its extremities.

The upper extremity begins by a large, round smooth head, which is admitted into the glenoid cavity of the scapula. On the upper and fore part of the bone there is a groove for lodging the long head of the biceps muscle of the arm; and on each side of the groove, at the upper end of the bone, there is a tubercle to which the spinatus muscles are fixed.

The lower extremity has several processes and cavities. The principal processes are its two condyles, one exterior and the other interior, and of these the is the largest. Between these two we observe two lateral protuberances, which, together with a middle cavity, form as it were a kind of pulley upon which the motions of the forearm are chiefly performed. At each side of the condyles, as well exteriorly as interiorly, there is another eminence which gives origin to several muscles of the hand and fingers.

Posteriorly and superiorly, speaking with respect to the condyles, we observe a deep fossa which receives a considerable process of the ulna; and anteriorly and opposite to this fossa, we observe another, which is much less and receives another process of the same bone.

The body of the bone has at its upper and anterior part a furrow which begins from behind the head of the bone, and serves to lodge the tendon of a muscle. The body of the os humeri is hollow through its whole length, and, like all other long bones, has its marrow.

This bone is articulated at its upper part to the scapula. This articulation, which allows motion every way, is surrounded by a capsular ligament; that is sometimes torn in luxation, and becomes an obstacle to the easy reduction of the bone. Its lower extremity is articulated with the bones of the forearm.

The forearm is composed of two bones, the ulna and radius.

Of the forearm.

The ulna or elbow-bone is much less than the os humeri, and becomes gradually smaller as it descends to the wrist. At its upper part it has two processes, and two cavities. Of the two processes, the largest, which is situated posteriorly, and called the olecranon, is admitted into the posterior fossa of the os humeri. The other process is placed anteriorly, and is called the coronoid process. In bending the arm it enters into the anterior fossa of the os humeri. This process being
Osteology

being much smaller than the other, permits the fore-arm to bend inwards; whereas the olecranon, which is shaped like a hook, reaches the bottom of its fossa in the os humeri as soon as the arm becomes straight, and will not permit the fore-arm to be bent backwards.

The ligaments likewise oppose this motion.

Between the two processes we have described, there is a considerable cavity called the fygmoid cavity, divided into two fossae by a small eminence, which pales from one process to the other; it is by means of this cavity and the two processes, that the ulna is articulated with the os humeri by ginginums.

At the bottom of the coronoid process, there is a small fygmoid cavity, which serves for the articulation of the ulna with the radius.

The body of the ulna is of a triangular shape; its lower extremity terminates by a small head and a little styloid process. The ulna is articulated above to the os humeri—both above and below to the radius, and to the wrist at its lower extremity. All these articulations are secured by means of ligaments. The chief use of this bone seems to be to support and regulate the motions of the radius.

The radius, which is so named from its supposed resemblance to the spoke of a wheel, is placed at the inside of the fore-arm. It is somewhat larger than the ulna, but not quite so long as that bone. Its upper part is cylindrical, hollowed superficially to receive the outer condyle of the os humeri. Laterally it is admitted into the little fygmoid cavity of the ulna, and the cylindrical part of the bone turns in this cavity in the motions of pronation and supination (1). This bone follows the ulna in flexion and extension, and may likewise be moved round its axis in any direction. The lower extremity of the radius is much larger and stronger than its upper part; the ulna, on the contrary, is smaller and weaker below than above; so that they serve to supply each other deficiencies in both those parts.

On the external side of this bone, we observe a small cavity which is defined to receive the lower part of the ulna; and its lower extremity is formed into a large cavity, by means of which it is articulated with the bones of the wrist, and on this account it is sometimes called manusprum manus. It supports the two first bones of the wrist on the side of the thumb, whereas the ulna is articulated with that bone of the wrist which corresponds with the little finger.

Through the whole length both of this bone and the ulna, a ridge is observed, which affords attachment to an interosseous ligament. This ligament fills up the space between the two bones.

The carpus or wrist consists of eight small bones of an irregular shape, and disposed in two unequal rows. Those of the upper row are articulated with the bones of the fore-arm, and those of the lower one with the metacarpus.

The ancient anatomists described these bones numerically; Lyterus seems to have been the first who gave to each of them a particular name. The names he adopted are founded on the figure of the bones, and are now pretty generally received, except the first, which instead of styloid proc. (the name given to it by Lyterus, on account of its sinus, that admits a part of the os magnum), has by later writers been named Scaphoides or Navicularis. This, which is the outermost of the upper row (considering the thumb as the outer side of the hand), is articulated with the radius; on its inner side it is connected with the os lunare, and below to the trapezium and trapezoides. Next to this is a smaller bone called the os lunare; because its outer side, which is connected with the scaphoides, is shaped like a crescent. This is likewise articulated with the radius. On its inner side it joins the os cuneiforme, and anteriorly, the os magnum and os unciforme.

The os cuneiforme, which is the third bone in the upper row, is compared to a wedge, from its being broader above, at the back of the hand, than it is below. Posteriorly it is articulated with the ulna, and anteriorly with the os unciforme.

These three bones form an oblong articulating surface, covered by cartilage, by which the hand is connected with the fore-arm.

The os pisiforme, or pea-like bone, which is smaller than the three just now described, though generally clasped with the bones of the upper row, does not properly belong to either series, being placed on the under surface of the os cuneiforme, so as to project into the palm of the hand. The four bones of the second row correspond with the bones of the thumb and fingers; the first, second, and fourth, are from their shapes named trapezium, trapezoides, and unciforme; the third, from its being the largest bone of the carpus, is styled os magnum.

All these bones are convex towards the back, and slightly concave towards the palm of the hand; their articulating surfaces are covered with cartilages, and secured by many strong ligaments, particularly by two ligamentous expansions, called the external and internal annular ligaments of the wrist. The former extends in an oblique direction from the os pisiforme to the styloid process of the radius, and is an inch and an half in breadth; the latter or internal annular ligament is stretched from the os pisiforme and os unciforme, to the os scaphoides and trapezium. These annular ligaments likewise serve to bind down the tendons of the wrist and fingers.

The metacarpus consists of four bones, which support the fingers; externally they are a little convex, and internally somewhat concave, where they form the palm of the hand. They are hollow, and of a cylindrical shape.

At each extremity they are a little hollowed for their articulation; superiorly with the bones of the carpus, and inferiorly with the first phalanges of the fingers, in the same manner as the several phalanges of the fingers are articulated with each other.

The five fingers of each hand are composed of fifteen bones, disposed in three ranks called phalanges: The bones of the first phalanx, which are articulated with
The metacarpus, are the largest, and those of the last phalanx the smallest. All these bones are larger at their extremities than in their middle part.

We observe at the extremities of the bones of the carpals, metacarpus, and fingers, several inequalities that serve for their articulation with each other; and these articulations are strengthened by means of the ligaments which surround them.

It will be easily understood that this multiplicity of bones in the hand (for there are 27 in each hand) is essential to the different motions we wish to perform. If each finger was composed only of one bone instead of three, it would be impossible for us to grasp anything.

§ 2. Of the Lower Extremities.

Each lower extremity is divided into four parts, viz. the os femoris, or thigh bone; the rotula, or knee-pan; the leg; and the foot.

1. Of the Thigh.

The thigh is composed only of this bone, which is the largest and strongest we have. It will be necessary to distinguish its body and extremities: its body, which is of a cylindrical shape, is convex both in front and concave behind, where it serves to lodge several muscles. Throughout two-thirds of its length we observe a ridge called linea aspera, which originates from the trochanters, and after running for some way downwards, divides into two branches, that terminate in the tuberosities at the lower extremity of the bone. At its upper extremity we must describe the neck and smooth head of the bone, and likewise two considerable processes: The head, which forms the greater portion of a sphere unequally divided, is turned inwards, and received into the great cotyloid cavity of the os innominatum. At this part of the bone there is a little socket to be observed, to which the round ligament is attached, and which we have already described as tending to secure the head of this bone in the great acetabulum. The neck is almost horizontal, asfured with respect to its situation with the body of the bone. Of the two processes, the external one, which is the largest, is called trochanter major, and the other, which is placed on the inside of the bone, trochanter minor. They both afford attachment to muscles. The articulation of the os femoris with the trunk is strengthened by means of a capular ligament, which adheres everywhere where round the edge of the great cotyloid cavity of the os innominatum, and surrounds the head of the bone.

The os femoris moves upon the trunk in every direction. At the lower extremity of the bone are two processes called the condyles, and an intermediate smooth cavity, by means of which it is articulated with the leg by ligaments.

All round the under end of the bone there is an irregular surface where the capular ligament of the joint has its origin, and where blood-veins go into the substance of the bone.

Between the condyles there is a cavity posteriorly, in which the blood-veins and nerves are placed, secured from the compression to which they would otherwise be exposed in the action of bending the leg, and which would not fail to be hurtful.

At the side of each condyle externally, there is a tuberosity, from whence the lateral ligaments originate, which are extended down the tibia.

A ligament likewise arises from each condyle posteriorly. One of these ligaments passes from the right to the left, and the other from the left to the right, so that they intersect each other, and for that reason are called the cres ligaments.

The lateral ligaments prevent the motion of the leg upon the thigh to the right or left; and the cres ligaments, which are also attached to the tibia, prevent the latter from being brought forwards.

In new-born children all the processes of this bone are cartilaginous.

2. The Rotula, or Knee-pan.

The rotula, patella, or knee-pan, as it is differently called, is a flat bone about four or five inches in circumference, and is placed at the fore-part of the joint of the knee. In its shape it is somewhat like the common figure of the heart, with its point downwards.

It is thinner at its edge than in its middle part; at its fore-part it is smooth and somewhat convex; its posterior surface, which is more unequal, affords an elevation in the middle which is admitted between the two condyles of the os femoris.

This bone is retained in its proper situation by a strong ligament which every where surrounds it, and adheres both to the tibia and os femoris; it is likewise firmly connected with the tibia by means of a strong tendinous ligament of an inch in breadth, and upwards of two inches in length, which adheres to the lower part of the patella, and to the tuberosity at the upper end of the tibia.

On account of this connection, it is very properly considered as an appendage to the tibia, which it follows in all its motions, so as to be to it what the olecranon is to the ulna. There is this difference, however, that the olecranon is a fixed process; whereas the patella is moveable, being capable of sliding from above downwards and from below upwards. This mobility is essential to the rotatory motion of the leg.

In very young children this bone is entirely cartilaginous.

The principal use of the patella seems to be to defend the articulation of the knee from external injury; it likewise tends to increase the power of the extensor muscles of the leg, by removing their direction farther from the centre of motion in the manner of a pulley.

3. Of the Leg.

The leg is composed of two bones: Of these the inner one, which is the largest, is called tibia; the other is much smaller, and named fibula.

The tibia, which is so called from its resemblance to the musical pipe of the ancients, has three surfaces, and is not very unlike a triangular prism. Its posterior surface is the broadest; anteriorly it has a considerable ridge called the shin, between which and the skin there are no muscles. At the upper extremity of this bone are two surfaces, a little concave, and separated from each other by an intermediate elevation. The two little cavities receive the condyles of the os femoris, and the eminence between them is admitted into the cavity which we spoke of as being between the two condyles, so that this articulation affords a specimen of the complete
Of the os navicularis, or capitate, (for these two terms have the same signification,) is so called on account of its resemblance to a little bark. At its posterior part, which is concave, it receives the astragalus; anteriorly it is articulated with the cuneiform bones, and laterally it is connected with the os cuboideus.

The os cuboideus forms an irregular cube. Posteriorly it is articulated with the os calcis; anteriorly it supports the two last bones of the metatarus, and laterally it joins the third cuneiform bone and the os navicularis.

Each of the osa cuneiformia, which are three in number, resembles a wedge, and from this similarity their name is derived. They are placed next to the metatarus by the sides of each other, and are usually distinguished into os cuneiforme externum, medium or minimum, and internum or maximum. The superior surface of these bones, from their wedge-like shape, is broader than that which is below, where they help to form the sole of the foot; posteriorly they are united to the os navicularis, and anteriorly they support the three first metatarsal bones.

When these seven bones composing the tarus are viewed together in the skeleton, they appear convex above, where they help to form the upper part of the foot; and concave underneath, where they form the hollow of the foot, in which the vessels, tendons, and nerves of the foot are placed secure from pressure.

They are united to each other by very strong ligaments, and their articulation with the foot is secured by a capsular and two lateral ligaments; each of the latter is covered by an annular ligament of considerable breadth and thickness, which serves to bind down the tendons of the foot, and at the same time to strengthen the articulation.

The os cuneiforme externum is joined laterally to the os cuboideus.

These bones complete our account of the tarus. Though what we have said of this part of the osteology has been very simple and concise, yet many readers may not clearly understand it: but if they will be pleased to view these bones in their proper situation in the skeleton, all that we have said of them will be easily understood.

The metatarsus is made up of five bones, whereas the metacarpus consists only of four. The cause of this difference is, that in the hand the thumb is not included among the metacarpal bones; whereas in the foot the great toe has only two bones. The first of these bones supports the great toe and is much larger than the rest, which nearly resemble each other in size.

These bones are articulated by one extremity with the cuneiform bones and the os cuboideus, and by their other end with the toes.

Each of the toes, like the fingers, consists of three bones, except the great toe, which is formed of two bones. The base of the others are distinguished into three phalanges. Although the toes are more confined in their motion than the fingers, yet they appear to be perfectly fitted for the purposes they are designed for. In walking, the toes bring the centre of gravity perpendicular to the advanced foot; and as the soles of the feet are naturally concave, we can at pleasure increase this concavity, and form a kind of vault, which adjuts itself to the different inequalities that occur
Besides the bones we have already described, there are several small ones that are met with only in the adult skeleton, and in persons who are advanced in life; which, from their supposed general resemblance to the seeds of the fesamum, are called \textit{offa sesamoidea}. They are commonly to be seen at the lower extremity of the fibula, upon the condyles of the thigh-bone, under the os cuboidei of the tarsus, and in other parts of the body. Their size and number seem constantly to be increased by age and hard labour; and as they are generally found in situations where tendons and ligaments are most exposed to the action of muscles, they are now generally considered as ossified portions of ligaments or tendons.

The upper surface of these bones is usually convex, and adherent to the tendon that covers it; the side which is next to the joint is smooth and flat. Though their formation is accidental, yet they seem to be of some use, by raising the tendons farther from the centre of motion, and consequently increasing the power of the muscles. In the great toe and thumb they are likewise useful, by forming a groove for the flexor tendons.

ANATOMY.

Part II.

Of the Common Integuments, with their Appendages; and of the Muscles.

ANATOMICAL writers usually proceed to a description of the muscles after having finished the osteology: but we shall deviate a little from the common method, with a view to describe every thing clearly and distinctly, and to avoid a tautology which would otherwise be unavoidable. All the parts of the body are so intimately connected with each other, that it seems impossible to convey a just idea of any one of them, without being in some measure obliged to say something of others; and on this account we wish to mention in this place the names and situation of the principal viscera of the body, that when mention is hereafter made of any one of them in the course of the work, the reader may at least know where they are placed.

After this little digression, the common integuments, and after them the muscles will be described; we then propose to enter into an examination of the several viscera, and their different functions. In describing the brain, occasion will be taken to speak of the nerves and animal spirits. The circulation of the blood will follow the anatomy of the heart, and the secretions and excretions of all other matter will be introduced in their proper places.

The body is divided into three great cavities. Of these the uppermost is formed by the bones of the cranium, and includes the brain and cerebellum.

The second is composed of the vertebræ of the back, the sternum, and true ribs, with the additional assistance of muscles, membranes, and common intumens, and is called the thorax—It contains the heart and lungs.

The third and inferior cavity is the abdomen. It is separated from the thorax by means of the diaphragm, and is formed by the lumbar vertebrae, the os sacrum, the osa innominata, and the false ribs, to which we may add the peritoneum, and a variety of muscles. This cavity incloses the stomach, intestines, omentum, liver, pancreas, spleen, kidneys, urinary bladder, and parts of generation.

Under the division of common intumens are usually included the epidermis, or scarf-skin, the reticulum mucous of Malpighi, the cutis, or true skin, and the membrana adiposa—The hair and nails, as well as the sebaceous glands may be considered as appendages to the skin.

Section I. Of the Skin.

I. Of the Scarf-skin.

Cuticula. The epidermis, cuticula, or scarf-skin, is a fine, transparent, and insensible pellicle, destitute of nerves and blood-veins, which invests the body, and every where covers the true skin. This scarf-skin, which seems to be very simple, appears, when examined with a microscope, to be composed of several laminae or scales which are increased by pressure, as we may observe in the hands and feet, where it is frequently much thickened, and becomes perfectly callous. It seems to adhere to the cuts by a number of very minute filaments, but may easily be separated from it by heat, or by maceration in water. Some anatomical writers have supposed that it is formed by a moisture exhaled from the whole surface of the body, which gradually hardens when it comes into contact with the air. They were perhaps induced to adopt this opinion, by observing the speedy regeneration of this part of the body when it has been by any means destroyed, it appearing to be renewed on all parts of the surface at the same time; whereas other parts which have been injured, are found to direct their growth from their circumference only towards their centre. But a demonstrative proof that the epidermis is not a fluid hardened by means of the external air, is that the fetus in utero is found to have this covering. Lieuwenhoeck supposed its formation to be owing to the expansion of the extremities of the excretory vessels which are found every where upon the surface of the true skin. Ruysch attributed its origin to the nervous papillæ of the skin; and Heister thinks it probable, that it may be owing both to the papillæ and the excretory vessels. The celebrated Morgagni, on the other hand, contends, that it is nothing more than the surface of the cutis, hardened and rendered insensible by the liquor amni covers the umbilicus in utero, and by the insensible perspiration of the air. This is a subject, however, on which we can advance nothing with certainty.

The cuticle is pierced with an infinite number of pores or little holes, which afford a passage to the hairs, sweat, and insensible perspiration, and likewise to warm water, mercury, and whatever else is capable of being taken in by the absorptions of the skin. The lines which we observe on the epidermis belong to the true skin. The cuticle absorbs itself to them, but does not form them.

II. Of the Reticulum mucosum.

Between the epidermis and cutis we meet with an appearance to which Malpighi, who first described it, gave the name of reticulum mucosum, supposing it to be of a membranous structure, and pierced with an infinite number of pores; but the fact is, that it seems to be nothing more than a mucous substance which may be disdolled by macerating in water, while the cuticle and cutis preserve their texture.
The colour of the body is found to depend on the
colour of this rete mucosum: for in negroes it is ob-
served to be perfectly black, whilst the true skin is of
the ordinary colour.

The blisters which raise the skin when burnt or
scalded, have been suppos'd by some to be owing to a
rarefaction of this mucous; but they are more proba-
bly occasioned by an increased action of the vessels of
the part, together with an afflux and effusion of the
thinner parts of the blood.

§ 3. Of the Cutis, or True Skin.

The cutis is composed of fibres closely compac
ted together, as we may observe in leather, which is the
prepared skin of animals. These fibres form a thick net-
work, which everywhere admits the filaments of nerves,
and an infinite number of blood-vessels and lymphatics.

The cutis, when the epidermis is taken off, is found to
have, throughout its whole surface, innumerable papil-
lae, which appear like very minute granulations, and
seem to be calculated to receive the impressions of the
touch, being the most easily observable where the
sense of feeling is the most delicate, as in the palms of
the hands and on the fingers.

These papillæ are suppos'd by many anatomical writers
to be continuations of the pulpy substance of nerves,
which coats have terminated in the cellular texture of
the skin. The great freblility of these papillæ evidently
proves them to be exceedingly nervous; but surely the
nervous fibrillæ of the skin are of themselves scarcely
equal to the formation of these papillæ, and it seems to be more probable that they are formed like the
rest of the cutis.

The cutis being described, the uses of the epidermis and
the reticulum mucosum will be more easily under-
stood; the latter serving to keep them constantly moist,
while the former protects them from the external
air, and modifies their too great freblility.

§ 4. Of the Glands of the Skin.

In different parts of the body we meet, within the
substance of the skin, with certain glands or follicles,
which discharge a fat and oily humour that serves to
lubricate and soften the skin. When the fluid they se-
crete has acquired a certain degree of thickness, it ap-
proaches to the colour and consistence of sweat; and
from this appearance they have derived their name of
sebaceous glands. They are found in the greatest num-
ber in the nose, ear, nipple, axilla, groin, scrotum,
vagina, and prepuce.

Besides these sebaceous glands, we read, in anatomical
books, of others that are described as small spherical
bodies placed in all parts of the skin, in much greater
abundance than those just now mentioned, and named
miliary, from their suppos'd resemblance to millet-
seed. Steno, who first described these glands, and Mal-

pighi, Ruyfch, Verheyen, Winslow, and others, who
have adopted his opinions on this subject, speak of them
as having excrementory ducts, that open on the surface of
the cuticle, and distil the sweat and matter of infensible
perspiration; and yet, notwithstanding the positive
manner in which these pretend'd glands have been
spoken of, we are now sufficiently convinced that
their existence is altogether imaginary.

5. Of the Insensible Perpiration and Sweat.

The matter of insensible perspiration, or in other
words, the subtile vapour that is continually exhaling
from the surface of the body, is not secreted by any
particular glands, but seems to be derived wholly from
the extremities of the minute arteries that are every
where dispersed through the skin. These exhalving
vessels are easily demonstrated in the dead subject, by
throwing water into the arteries; for then small drops
evade from all parts of the skin, and raise up the cuti-
tle, the pores of which are closed by death; and in
the living subject, a looking-glass placed against the
skin, is soon obscured by the vapour. Blichio fancied
he had discovered ducts leading from the cutis to the
cuticle, and transmitting this fluid; but in this he was
mistaken.

When the perspiration is by any means increased,
and several drops that were insensible when separate,
are united together and condens'd by the external
air, they form upon the skin small, but visible, drops called
fuscat (n). This particularly happens after much ex-
ercise, or whatever occasions an increased determina-
tion of fluids to the surface of the body; a greater quan-
tity of perspirable matter being in such cases carried
through the passages that are destined to convey it off.

It has been disputed, indeed, whether the insensible
perspiration and sweat are to be considered as one and
the same excretion, differing only in degree; or whether
they are two distinct excretions derived from different
sources. In support of the latter opinion, it has been
alleged, that the insensible perspiration is agreeable to
nature, and essential to health, whereas sweat may be
considered as a species of disease. But this argument
proves nothing; and it seems probable, that both the
insensible vapour and the sweat are exhaled in a simi-
lar manner, though they differ in quantity, and proba-
bly in their qualities; the former being more limpid,
and seemingly less impregnated with salts than the lat-
ter; at any rate we may consider the skin as an emic-
tory through which the redundant water, and sometimes
the other more saline parts of the blood, are carried off.

But the insensible perspiration is not confined to the
skin only—a great part of what we are constantly
throwing off in this way is from the lungs. The quan-
tity of fluid exhaled from the human body by this in-
sensible perspiration is very considerable. Sancorius (o)
an Italian physician, who indefatigably puffed a great

(n) Lienwenboeck affers that one drop of sweat is formed by the conflux of fifteen drops of persipible
vapour.

(o) The insensible perspiration is sometimes distinguished by the name of this physician, who was born in
the territories of Venice, and was afterwards a professor in the university of Padua. After estimating the ailm-
ment he took in, and the sensible secretions and discharges, he was enabled to ascertain with great accuracy the
weight or quantity of insensible perspiration by means of a flatical chair which he contriv'd for this purpose;
Part II.

ANATOMY.

Of the many years in a series of statical experiments, demonstrated long ago what has been confirmed by later observations, that the quantity of vapour exhaled from the skin and from the surface of the lungs, amounts nearly to 5ths of the aliment we take in. So that if in the warm climate of Italy a person eats and drinks the quantity of eight pounds in the course of a day, five pounds of it will pass off by insensible perpiration, while three pounds only will be evacuated by stool, urine, saliva, &c. But in countries where the degree of cold is greater than in Italy, the quantity of perspired matter is less, in some of the more northern climates, it being found not to equal the discharge by urine. It is likewise observed to vary according to the season of the year, and according to the constitution, age, sex, diseases, diet, exercise, passion, &c. of different people.

From what has been said on this subject, it will be easily conceived, that this evacuation can be either much increased or diminished in quantity without affecting the health.

The perspirable matter and the sweat are in some measure analogous to the urine, as appears from their taste and falling nature. And it is worthy of observation, that when either of the secrections is increased in quantity, the other is diminished; so that they who perspire the least, usually pass the greatest quantity of urine, and vice versa.

§ 6. Of the Nails.

The nails are of a compact texture, hard and transparent like horn. Their origin is still a subject of dispute. Malpighi supposed them to be formed by a continuation of the papilla of the skin; Ludwig, on the other hand, maintained, that they were composed of the extremities of blood-vessels and nerves; both these opinions are now deservedly rejected.

They seem to possess many properties in common with the cuticle; like it they are neither vascular nor sensitive, and when the cuticle is separated from the true skin by maceration or other means, the nails come away without a trace.

They appear to be composed of different layers, of unequal size, applied one over the other. Each layer seems to be formed of longitudinal fibres.

In each nail we may distinguish three parts, viz. the root, the body or middle, and the extremity. The root is soft, thin, and white substance, terminating in the form of a crescent; the epidermis adheres very strongly to this part; the body of the nail is broader, of the redder, and thicker; and the extremity is of still greater firmness.

The nails increase from their roots, and not from their upper extremity.

Their principal use is to cover and defend the ends of the fingers and toes from external injury.

§ 7. Of the Hair.

The hairs, which from their being generally known, do not seem to require any definition, arise from distinct capsules or bulbs seated in the cellular membrane under the skin. Some of these bulbs inclose several hairs. They may be observed at the roots of the hairs which form the beard or whiskers of a cat.

The hairs, like the nails, grow only from below by a regular propulsion from their root, where they receive their nourishment. Their bulbs, when viewed with a microscope, are found to be of various shapes. In the head and forehead they are roundish; in the eyebrows they are oval; and in other parts of the body they are nearly of a cylindrical shape. Each bulb seems to consist of two membranes, between which there is a certain quantity of moisture. Within the bulb the hair separates into three or four filaments; the bodies of the hairs, which are the parts without the skin, vary in softness and colour according to the difference of climate, age, or temperance of body.

Their general use in the body does not seem to be absolutely determined; but hairs on particular parts, as on the eyebrows and eyelids, are declined for particular uses, which will be mentioned when those parts are described.

§ Of the Cellular Membrane and Fat.

The cellular membrane is found to invest the most minute fibres we are able to trace; so that by modern physiologists, it is very properly considered as the universal connecting medium of every part of the body.

It is composed of an infinite number of minute cells united together, and communicating with each other. The two diseases peculiar to this membrane are proofs of such a communication; for in the emphysema all its cells are filled with air, and in the anaes (a) they are universally diffused with water. Besides these proofs of communication from disease, a familiar instance of it may be observed among butchers, who usually puncture this membrane, and by infusing it with air add to the good appearance of their meat.

and from his experiments, which were conducted with great industry and patience, he was led to determine what kinds of solid or liquid aliment increased or diminished it. From these experiments he formed a system, which he published at Venice in 1672, in the form of aphorisms, under the title of "Ars de Medicina Statica." 

(p) Minute chrysalids have been observed to shoot upon the cloaths of men who work in glass-houses. 

(q) Malpighi, and after him the celebrated Ruych, supposed the hairs to be continuations of nerves, being of opinion that they originated from the papilla of the skin, which they considered as nervous; and as a corroborating proof of what they advanced, they argued the pain we feel in plucking them out; but later anatomists seem to have rejected this doctrine, and consider the hairs as particular bodies, not arising from the papilla for in the parts where the papilla abound mol there are no hairs), but from bulbs or capsules, which are peculiar to them.

(a) The hairs likewise differ from each other, and may not improperly be divided into two classes; one of which may include the hair of the head, chin, pubes, and axillae; and the other, the softer hairs, which are to be observed almost everywhere on the surface of the body.
The cells of this membrane serve as reservoirs to the oily part of the blood or Fat, which seems to be deposited in them, either by transudation through the coats of the arteries, that ramify through these cells, or by particular vessels, continued from the end of arteries. These cells are not of a glandular structure, as Malpighi and others after him have supposed. The fat is absorbed and carried back into the system by the lymphatics. The great waste of it in many dis ease, particularly in the consumption, is a sufficient proof that such an absorption takes place.

The fulness and size of the body are in a great measure proportioned to the quantity of fat contained in the cells of this membrane.

In the living body it seems to be a fluid oil, which concretes after death. In graminivorous animals, it is found to be of a firmer consistence than in man.

The fat is not confined to the skin alone, being met with everywhere in the interfices of muscles, in the subcutaneous coats about the kidneys, at the base of the heart, in the orbit, &c.

The chief uses of the fat seems to be to afford moisture to all the parts with which it is connected; to facilitate the action of the muscles; and to add to the beauty of the body, by making it everywhere smooth and equal.

Sect. II. Of the Muscles.

The muscles are the organs of motion. The parts that are usually included under this name consist of distinct portions of flesh, susceptible of contraction and relaxation; the motions of which, in a natural and healthy state, are subject to the will, and for this reason they are called voluntary muscles. But besides these, there are other parts of the body that owe their power of contraction to their muscular fibres; thus the heart is of a muscular texture, forming what is called a hollow muscle; and the urinary bladder, stomach, intestines, &c. are enabled to act upon their contents, merely because they are provided with muscular fibres. These are called involuntary muscles, because their motions are not dependent on the will. The muscles of respiration, being in some measure influenced by the will, are said to have a mixed motion.

The names by which the voluntary muscles are distinguished, are, according to their size, figure, situation, use, or the arrangement of their fibres, or their origin and insertion. But besides these particular distinctions, there are certain general ones that require to be noticed. Thus, if the fibres of a muscle are placed parallel to each other in a straight direction, they form what is styled a rectilinear muscle; if the fibres cross and intersect each other, they constitute a compound muscle; a radiated one, if the fibres are disposed in the manner of rays; or a penniform muscle, if, like the plume of a pen, they are placed obliquely with respect to the tendon.

Muscles that act in opposition to each other, are called antagonists; thus every extensor or muscle has a flexor for its antagonist, and vice versa. Muscles that concur in the same action are styled congenerous.

The muscles being attached to the bones, the latter may be considered as levers that are moved in different directions by the contraction of those organs.

The end of a muscle which adheres to the most fixed part is usually called the origin, and that which adheres to the more moveable part, the insertion, of the muscle.

In every muscle we may distinguish two kinds of fibres; the one soft, of a red colour, tender, and irritable, called flesh fibres; the other of a firmer texture, of a white glistening colour, insensible, without irritability or the power of contracting, and named tendinous fibres. They are occasionally intermixed; but the flesh fibres generally prevail in the belly or middle part of a muscle, and the tendinous ones in the extremities. If these tendinous fibres are formed into a round slender chord, they form what is called the tendon of the muscle; on the other hand, if they are spread into a broad flat surface, the extremity of the muscle is styled aponeurosis.

The tendons of many muscles, especially when they are long and exposed to pressure or friction in the grooves formed for them in the bones, are surrounded by a tendinous sheath or fascia, in which we sometimes find a small mucous sac or bursa muscula, which obviates any inconvenience from friction. Sometimes we find whole muscles, and even several muscles, covered by a fascia of the same kind, that affords origin to many of their fibres, dipping down between them, adhering to the ridges of bones, and thus preventing them from swelling too much when in action. The most remarkable instance of such a covering is the fascia lata of the thigh.

Each muscle is enclosed by a thin covering of cellular membrane, which has been sometimes improperly considered as peculiar to the muscles, and described under the name of propria membrana muscula. This cellular covering dips down into the substance of the muscle, connecting and surrounding the most minute fibres we are able to demonstrate, and affording a support to their vessels and nerves.

Lieuwenhoeck fancied he had discovered, by means of his microscope, the ultimate division of a muscle, and that he could point out the simple fibre, which appeared to him to be an hundred times less than a hair; but he was afterwards convinced how much he was mistaken on this subject, and candidly acknowledged, that what he had taken for a simple fibre was in fact a bundle of fibres.

It is easy to observe several of these fasciculi or bundles in a piece of beef, in which, from the clearness of its texture, they are very evident.

The red colour which so particularly distinguishes the muscular or fleshly parts of animals, is owing to an infinite number of blood-vessels that are dispersed through their sub stance. When we macerate the fibres of a muscle in water, it becomes of a white colour like all other parts of the body divested of their blood. The blood-vessels are accompanied by nerves, and they are both distributed in such abundance to these parts, that in endeavouring to trace the course of the blood-vessels in a muscle, it would appear to be formed altogether by their ramifications: and in an attempt to follow the branches of its nerves, they would be found to be equal in proportion.

If a muscle is pricked or irritated, it immediately contracts. This is called its irritable principle; and this...
Part II.

**ANATOMY.**

Of the

Muscles.

this irritability is to be considered as the characteristic of muscular fibres, and may serve to prove their existence in parts that are too minute to be examined by the eye. This power, which imparts to the muscles to contract when stimulated, independent of the will, is supposed to be inherent in them; and is therefore named *vis inïtis.* This property is not to be confounded with elatiçity, which the membranes and other parts of the body possess in a greater or less degree in common with the muscles; nor with sensibility, for the heart, though the most irritable, seems to be the least sensible of any of the muscular parts of the body.

After a muscular fibre has contracted, it soon returns to a state of relaxation, till it is excited afresh; and then it contracts and relaxes again. We may likewise produce such a contraction, by irritatiçg the nerve leading to a muscle, although the nerve itself is not affected.

This principle is found to be greater in small than in large, and in young than in old, animals.

In the voluntary muscles these effects of contraction and relaxation of the fleshy fibres are produced in obedience to the will, by what may be called the *vis nervosa,* a property that is not to be confounded with the *vis inïtis.* As the existence of a *vis inïtis* different from a *vis nervosa,* was the doctrine taught by Doctor Haller in his *Elem. Phys.* but is at present called in question by several, particularly Dr. Monro, we think it necessary to give a few objections, as stated in his Observations on the Nervous System:

"The chief experiment (says the Doctor,) which seems to have led Dr. Haller to this opinion, is the well-known one, that the heart and other muscles, after being detached from the brain, continue to act spontaneously, or by stimulis being roused into action for a considerable length of time; and when it cannot be alleged, says Dr. Haller, that the nervous fluid is by the mind, or otherwise, impelled into the muscle.

"That in this instance, we cannot comprehend by what means the nervous fluid or energy can be put in motion, must perhaps be granted: But has Dr. Haller given a better explanation of the manner in which his supposed *vis inïtis* becomes active?

"If it be as difficult to point out the cause of the action of the *vis inïtis* as that of the action of the *vis nervosa,* the admission of that new power, instead of relieving, would add to our perplexity.

"We should then have admitted, that two causes of a different nature were capable of producing exactly the same effect: which is not in general agreeable to the laws of nature.

"We should find other consequences arise from such an hypothesis, which tend to weaken the credibility of it. For instance, if in a found animal the *vis nervosa* alone produces the contraction of the muscles, we will ask what purpose the *vis inïtis* serves? If both operate, are we to suppose that the *vis nervosa,* impelled by the mind, or living principle, gives the order, which the *vis inïtis* executes, and that the nerves are the intermuntl? and so admit two wise agents employed in every the most simple act? But instead of speculating further, let us learn the effect of experiments, and endeavour from there to draw plain conclusions.

1. When I poured a solution of opium in water under the skin of a frog, the muscles, to the surface of which it was applied, were very soon deprived of the power of contraction. In like manner, when I poured this solution into the cavity of the heart, by opening the venæ cava, the heart was almost instantly deprived of its powers of action, whether the experiment was performed on it fixed in its place, or cut out of the body.

2. I opened the thorax of a living frog; and then tied or cut the aorta, so as to put a stop to the circulation of its blood.

I then opened the venæ cava, and poured the solution of opium into the heart; and found, not only that this organ was instantly deprived of its powers of action, but that in a few minutes the most distant muscles of the limbs were extremely weakened. Yet this weakness was not owing to the want of circulation, for the frog could jump about for more than an hour after the heart was cut out.

"In the first of these two experiments, we observed the supposed *vis inïtis* destroyed by the opium; in the latter, the *vis nervosa;* for it is evident that the limbs were affected by the sympathy of the brain, and of the nervous system in general, with the nerves of the heart.

3. When the nerve of any muscle is first divided by a transverse section, and then burnt with a hot iron, or punctured with a needle, the muscle in which it terminates contracts violently, exactly in the same manner as when the irritation is applied to the fibres of the muscle. But when the hot iron, or needle, is confined to the nerve, Dr. Haller himself must have admitted, that the *vis nervosa,* and not the *vis inïtis,* was excited. But here I would ask two questions.

"First, Whether we do not as well understand how this *vis nervosa* is excited when irritation is applied to the muscle as when it is applied to the trunk of the nerve, the impelling power over the mind seeming to be equally wanting in both cases?

"Secondly, If it appears that irritation applied to the trunk of a nerve excites the *vis nervosa,* why should we doubt that it can equally well excite it when applied to the small and very sensible branches and terminations of the nerve in the muscle?

"As, therefore, it appears that the supposed *vis inïtis* is destroyed or excited by the same means as the *vis nervosa;* nay, that when, by the application of opium to the heart of a frog, after the aorta is cut and the circulation interrupted, we have destroyed the *vis inïtis,* the *vis nervosa* is so much extinguished, that the animal cannot act with the distant muscles of the limb; and that these afterwards grow very torpid, or lose much of their supposed *vis inïtis*; it seems clearly to follow, that there is no just ground for supposing that any other principle produces the contraction of a muscle."

The *vis nervosa,* or operation of the mind, if we may so call it, by which a muscle is brought into contraction, is not inherent in the muscle like the *vis inïtis*; neither is it perpetual, like this latter property. After long continued or violent exercise, for example, the
Of the Integuments, &c.

Of the voluntary muscles become painful, and at length incapable of further action; whereas the heart and other involuntary muscles, the motions of which depend solely on the *vis in fissa*, continue through life in a constant state of action, without any inconvenience or waste of this inherent principle.

The action of the *vis nervosa* on the voluntary muscles, constitutes what is called *muscular motion*; a subject that has given rise to a variety of hypotheses, many of them ingenious, but none of them satisfactory.

Borelli and some others have undertaken to explain the cause of contraction, by supposing that every muscular fibre forms as it were the cause of the motion, which the nerves which are distributed through the muscles, bring with them a supply of animal spirits, which at our will fill these bladders, and by increasing their diameter in width, shorten them, and of course the whole fibre.

Borelli supposes these bladders to be of a rhomboidal shape; Bernouilli on the other hand contends that they are oval. Our countryman, Cowper, fancied he had filled them with mercury; the cause of this mistake was probably owing to the mercury’s insinuating itself into some of the lymphatic vessels. The late ingenious Mr. Elliot undertook to account for the phenomenon of muscular motion on principles very different from those just now mentioned. He supposed that a dephtlified state of the blood is requisite for muscular action, and that a communication of phlogiston to the blood is a necessary effect of such action.

We know that the muscular fibre is shortened, and that the muscle itself swells when in action; but how these phenomena are produced, we are unable to determine. We likewise know that the nerves are essential to muscular motion; for upon dividing or making a ligature round the nerve leading to a muscle, the latter becomes incapable of motion. A ligature made on the artery of a muscle produces a similar effect; a proof this, that a regular supply of blood is also equally necessary to muscular motion. The cause of palsy is usually not to be sought for in the muscle affected, but in the nerve leading to that muscle, or in that part of the brain or spinal marrow from which the nerve derives its origin.

Of the particular Muscles.

As the enumeration and description of the particular muscles must be dry and unentertaining to the generality of readers, yet cannot be altogether omitted in a work of this nature, it appeared eligible to throw this part of the subject into the form of a table; in which the name, origin, insertion, and principal use of each muscle, will be found described in few words, and occasionally its etymology when it is of Greek derivation or difficult to be understood.

A TABLE of the MUSCLES arranged according to their Situation.

[N. B. This table does not include all the muscles of the body; those belonging to the eyes, internal ear, intestines rectum, and the male and female organs of generation, being described in other parts of the work. The reader will be pleased to observe likewise, that although all the muscles (a few only excepted) are in pairs, mention is here made only of the muscles of one side.]

3. Re-
Part II. 

Muscles of the cartilages of the ear

1. Tragicus. From the outer and Into the upper part To depress the concha, and pull the point of the tragus a little outwards.

2. Anti-tragicus. From the root of the Into the upper part To dilate the mouth of the concha.

3. Transversus-auriculæ. From the upper part Into the inner part To stretch the concha and scapha, and likewise to pull the parts it is connected with towards each other.

4. Helicis major. From the upper, anterior, and acute part of the helix. Into the cartilage of the helix, a little above the tragus. To depress the upper part of the helix.

5. Helicis minor. From the lower and ante-part of the helix. Into the helix, near the fissure in its cartilage. To contract the fissure.

Muscles of the nose

1. Compressor (T) From the outer part Into the nasal process of the os maxillae. To straighten the nose, and to corrugate the skin of the nose.

2. Levator labii superioris, alæque nasi. From the outer part of the orbitar process of the os maxillaré, and from the nasal process of that bone, where it joins the os frontis. Into the upper lip and ala of the nose. To draw the upper lip and skin of the nose upwards and outwards.

3. Zygomaticus major. From the os maxillaré near the zygomatic future. Into the angle of the mouth. To raise the angle of the mouth, and make the cheek prominent, as in laughing.

4. Zygomaticus minor. Immediately above the origin of the zyg major. Into the angle of the mouth. To raise the angle of the mouth obliquely outwards.

5. Buccinator. From the alveoli of the dentes molares in the upper and lower jaws. Into the angle of the mouth. To contract the mouth and draw the angle of it outwards and backwards.

6. Depressor labii superioris, alæque nasi. From the os maxillaré. Into the root of the ala nasi and upper lip. To draw the ala nasi and upper lip downwards.

7. Depressor

---

(s) These are three small tender muscles. The inferior one is sometimes wanting.

(r) The nose is affected by fibres of the occipito frontalis, and by several muscles of the face; but this pair, the compressores, is the only one that is proper to it.
ANATOMY.

Muscles of the lower jaw,

1. Temporalis.

From part of the os bregmatis and os frontis; squamous part of the os temporis; back part of the os male, and the temporal processes of the os sphenoides (v).

2. Masseter (w).

From the malar processes of the maxillare, and the lower edges of the os male, and of the zygomatic processes of the os temporis.

3. Pterygoideus internus.

From the inner surface of the outer wing of the pterygoid processes of the os sphenoides, and from the processes of the os palati that helps to form the pterygoid fossa.

4. Pterygoideus externus.

From the external ala of the pterygoid processes, a small part of the adjacent os maxillare, and a ridge in the temporal processes of the os sphenoides.

5. Orbicularis oris (u).

From near the gums of the incisores and caninus of the maxilla inferior.

6. Depressor anguli oris.

At the side of the chin from the lower edge of the maxilla inferior.

7. Depressor labii inferioris.

Into the angle of the mouth.

8. Levator labii superioris.

From near the gums of the incisores and caninus of the maxilla inferior.

9. Levator labii inferioris.

To draw the corner of the mouth downwards.

10. Orbicularis oris.

Into the coronoid processes of the lower jaw.

11. Levator labii superioris.

To raise the under lip and skin of the chin.

12. Orbicularis oris.

To move the lower jaw upwards.

13. Temporalis.

To raise and likewise to move the jaw a little forwards and backwards.

Into the lower jaw on its inner side and near its angle.

15. Latissimus colli (v).

From the cellular membrane covering the chin and integument of the face.

(v) This muscle is, in a great measure, if not wholly, formed by the buccinator, zygomatici, depressores, and other muscles that move the lips. Its fibres surround the mouth like a ring.

(w) Some of its fibres likewise have their origin from a strong fascia that covers the muscle and adheres to the bone round the whole circumference of its origin. When we remove this covering, we find the muscle of a semicircular shape with its radiated fibres, converging and forming a strong middle tendon.

(x) This happens when the muscle acts singly. When both act, the jaw is brought horizontally forwards.

(y) This broad and thin muscular expansion, which is situated immediately under the common integuments, is by Winlock named meusculus cutaneus. Galen gave it the name of m. zygomaticus (Platymanymides); the etymology of which is from διατιτομή, dilatatio, and μύς, muscularis, and φώνα, forma.

### Situated between the os hyoides and lower jaw
1. Diaphragmaticus (b) | From the fossa of the root of the mastoid process, and likewise from the os hyoides. | Into the lower and anterior part of the chin. | To draw the lower jaw downwards. |
2. Stylo-hyoideus (c) | From the basis of the styloid process. | Into the side and fore part of the os hyoides near its base. | To draw the os hyoides obliquely upwards. |

### Notes

- **(z)** This, on account of its two origins, is by Albinus described as two distinct muscles, which he names *sterno-mastoideus* and *cleido-mastoideus*.
- **(a)** This muscle does not always arise from the coracoid process, it seems to have been improperly named *coraco-hyoideus* by Douglas and Albinus. Winlow calls it *omo-hyoideus*, on account of its general origin from the scapula.
- **(b)** From *diaphragma* (biventer), because it has two fleshly bellies with a middle tendon. This tendon passes through the stylo-hyoideus.
- **(c)** In some subjects we meet with another muscle, which from its having nearly the same origin, insertion, and use as this, has been named *stylo-hyoideus alter*.

(d) So named from its arising near the dentes molares (molar), and being inserted into the os hyoides.

(e) From *mentum*, the "chin."

(v) From *corpus*, *cornu*, and *lingua*, "the tongue."

(c) This muscle in its course forms a round tendon, which, after passing over a kind of hook formed by the inner plate of the pterygoid process of the sphenoid bone, expands into a tendinous membrane.

(u) The few fibres that arise from the Eustachian tube are described as a distinct muscle by Albinus, under the name of Salpingo pharyngus. They serve to dilate the mouth of the tube.

---

**Constrictor**
ANATOMY.

Of the Muscles.

Part II.

Name. Origin. Insertion. Use.

2. Constrictor larynx. From near the bals. of the tongue laterally. Into the velum pendentulum palatii, near the bals and fore part of the uvula. To raise the tongue and draw the velum towards it. (1).

3. Azygos uvula. From the end of the future that units the soft palatii. Into the extremity of the uvula. To shorten the uvula, and bring it forwards and upwards.

Muscles at the back part of the pharynx

1. Constrictor pharyngis superior. From the cuneiform process of the occipital bone; the pterygoideus os sphenoides, and from each jaw near the last dens molares (k).

Into the middle of the pharynx. To move the pharynx upwards and forwards, and to compress its upper part.

2. Constrictor pharyngis medius (l).

From the horn and appendix of the os hyoïdes, and from the ligament that unites it with the thyroid cartilage.

Into the middle of the pharynx. To draw the os hyoïdes and pharynx upwards, and to compress the latter, near the extremity of it is connected with the other arytenoid cartilage.

3. Constrictor pharyngis inferior (m).

From the cricoid and thyroid cartilages.

Into the middle of the pharynx. To compress part of the pharynx.

Muscles about the glottis.

1. Arytrenoideus transversus. From the side of the cricoid cartilage.

Into the basis of the arytenoid cartilage laterally. To open the glottis.

2. Arytrenoideus posticus.

From the cricoid cartilage posteriory.

Into the basis of the arytenoid cartilage posteriory. To open the glottis.

3. Arytænoides obliquus.

From the basis of one of the arytenoid cartilages.

Near the extremity of the arytenoid cartilage. To shut the glottis.

4. Arytænoides transversus.

From one of the arytenoid cartilages laterally.

Into the other arytenoid cartilage laterally. To pull the epiglottis outwards.

5. Thyreo-arytænoides.

From the posterior and under part of the thyroid cartilage.

Into the arytenoid cartilage laterally. To draw the arytenoid cartilage forwards.

6. Arytænepiglot- tideus.

From the upper part of the arytenoid cartilage laterally.

Into the side of the epiglottis. To move the epiglottis outwards.

7. Thyreoepiglottideus.

From the thyroid cartilage. Into the side of the epiglottis. To pull the epiglottis obliquely downwards (n).

Muscles

(1) This muscle, and the palato-pharyngæus, likewise serve to close the passage into the fauces, and to carry the food into the pharynx.

(k) The three orders of fibres here mentioned, with a few others derived from the tongue, have given occasion to Douglas to describe them as four distinct muscles, under the names of cephalo-pharyngæus, mylo-pharyngæus, ptery-pharyngæus, and glotto-pharyngæus.

(l) Douglas makes two muscles of this, the hypo-pharyngæus and stylopharyngæus.

(m) The crico-pharyngæus and thyro-pharyngæus of Douglas.

(n) When either this or the preceding muscle acts with its fellow, the epiglottis is drawn directly downwards upon the glottis.

| | | vertebrae, the back part of the os sacrum, the spine of the ilium, and back part of Fallopius's ligament (r). | | | |
| | 3. Transversalis. | From the cartilages of the seven inferior ribs; the transverse processes of the last dorsal, and four upper lumbar vertebrae; the inner part of Fallopius's ligament and the spine of the ilium. | Into the linea alba and cartilago eniformis. | To compress the abdominal viscera. | |
| | 4. Rectus abdominis. | From the upper edge of the pubis and the symphysis pubis. | Into the cartilages of the 5th, 6th, and 7th ribs, and the edge of the cartilago eniformis (w). | To compress the fore part of the abdomen, and to bend the trunk forwards. | |
| | 5. Pyramidalis (v). | From the anterior and upper part of the pubis. | Into the linea alba and inner edge of the rectus, commonly about two inches above the pubis. | To assist the lower portion of the rectus. | |

**Muscles at the fore part of the thorax.**

1. **Pectoralis Major.** From the cartilages of the 5th and 6th ribs, the sternum, and anterior part of the clavicle. Into the upper and inner part of the os humeri (w). To draw the arm forwards or obliquely forwards.

2. **Subclavius.** From the cartilage of the first rib. Into the under surface of the clavicle. To move the clavicle forwards and downwards and to assist in raising the first rib.

3. **Pectoralis minor (x).** From the upper edges of the 3d, 4th and 5th ribs. Into the coracoid process of the scapula. To move the scapula forwards and downwards or to elevate the ribs.

4. **Serratus Magnus.** From the eight superior ribs. Into the basis of the scapula. To bring the scapula forwards.

---

(t) From this part it detaches some fibres which extend downwards upon the spermatic chord, and from what is described as the cremaster muscle.

(v) The fibres of the rectus are generally divided by three tendinous interseions. The two upper thirds of this muscle passing between the tendinous layers of the obliquus internus, are inclosed as it were in a sheath; but at its lower part we find it immediately contiguous to the peritoneum, the inferior portion of tendon of the transversalis passing over the rectus, and adhering to the anterior layer of the obliquus internus.

(v) This muscle is sometimes wanting.

(w) The fibres of this muscle pass towards the axilla in a folding manner, and with those of the latissimus dorsi from the armpit.

(x) This and some other muscles derive their name of serratus, from their arising from a number of tendinous or bony digitations, resembling the teeth of a saw (ferra).
ANATOMY.

3. Latifmmus dorsi. From part of the spinous of the 1st, the spinous processes of the 2nd, 3rd, 4th, and of six or eight of the dor- To draw the scapula downwards and backwards, and to roll it upon its axis.

---

(v) For a description of the diaphragm, see Part IV. Sect. IV.

(A) The origin, insertion, and use of the internal intercostals, are similar to those of the external. The reader, however, will be pleased to observe, that the intercostals externi occupy the spaces between the ribs only from their spine to their cartilages; from thence to the sternum, there being only a thin membrane, which is spread over the intercostals interni; and that the latter, on the contrary, extend only from the sternum to the angles of each rib.

The fibres of the external muscles run obliquely forwards; those of the internal obliquely backwards. This difference in the direction of their fibres induced Galen to suppose that they were intended for different uses; that the external intercostals, for instance, serve to elevate, and the internal ones to depress the ribs. Fallopius seems to have been the first who ventured to dispute the truth of this doctrine, which has since been revived by Boyle, and more lately still by Hamberger, whose theoretical arguments on this subject have been clearly refuted by the experiments of Haller.

(b) These consist of four, and sometimes five distinct muscles on each side. Vesalius, and after him Douglas and Albinus, consider them as forming a single muscle, which, on account of its shape, they name triangularis. Verheyen, Winstow, and Haller, more properly describe them as so many separate muscles, which, on account of their origin and insertion they name sternocostal.

(c) So named by Riolanus, from its quadrilateral shape. Columbus and others gave it the name of cuculare, from its resemblance to a monk's hood.

(d) The tendinous fibres of this muscle, united with those of its fellow in the nape of the neck, from what is called the ligamentum colli.

(b) This muscle consists of two distinct portions, which are described as separate muscles by Albinus, under the names of rhomboideus minor and rhomboideus major.
4. Serratus inferior posticus. From the spinous processes of the two lowermost dorsal, and of three of the lumbar vertebrae. Into the lower edges of the three or four lowermost ribs near their cartilages. To draw the ribs outwardly, downwards, and backwards.

5. Levator scapulae. From the transverse processes of the four uppermost vertebrae colli. Into the upper angle of the scapula. To move the scapulae forwards, and upwards.

6. Serratus superior posticus. From the lower part of the ligamentum colli, the spinous processes of the lowermost cervical vertebrae, and of the two superior dorsal vertebrae. Into the 4th ribs. To expand the thorax.

7. Splenius (f). From the spinous processes of the four or five uppermost vertebrae of the back, and of the lowermost cervical vertebra. Into the transverse processes of the two first cervical vertebrae, the upper and back part of the mastoid processes, and a ridge on the os occipitis. To move the head backwards.

8. Complexus (c). From the transverse processes of the four or five uppermost dorsal, and of the six lowermost cervical vertebrae. Into the os occipitis. To draw the head backwards.

9. Trachelo-mastoideus (n). From the transverse processes of the first dorsal vertebrae and four or five of the lowermost, cervical vertebrae. Into the mastoid processes. To draw the head backwards.

10. Rectus capitis posterior major. From the spinous processes of the second cervical vertebrae. Into the os occipitis. To extend the head and draw it backwards.

11. Rectus capitis posterior minor. From the first vertebra of the neck. Into the os occipitis. To assist the rectus major.

12. Obliquus superior capitis. From the transverse processes of the first cervical vertebrae. Into the os occipitis. To draw the head backwards.

13. Obliquus inferior capitis. From the spinous processes of the second cervical vertebrae. Into the transverse processes of the first cervical vertebrae. To draw the face towards the shoulder, and to move the first vertebra upon the second.

(v) According to some writers, this muscle has gotten its name from its resemblance to the spleen; others derive it from splenium splint.

(g) So named on account of its complicated structure.

(n) So named from its origin from the neck (ντροχαλος) and its insertion into the mastoid processes.

(1) Several thin fasci of fleshly fibres arise from the lower ribs, and terminate in the inner side of this muscle. Steno names them musculi ad facro lumbalem accedentis. The sacro-lumbalis likewise sends off a fleshly fib from its upper part, which by Douglas and Albinus is described as a distinct muscle, under the name cervicis descendentis. Morgagni has very properly considered it as a part of the sacro-lumbalis.

At the upper part of this muscle a broad thin layer of fleshly fibres is found crossing, and intimately adhering to it. This portion, which is described by Albinus, under the name of transversalis cervicis, may very properly be considered as an appendage to the longissimus dor-si. It arises from the transverse processes of the five or six superior dor-sal vertebræ, and is inserted into the transverse processes of the six inferior cervical vertebræ. By means of this appendage the longissimus dor-si may serve to move the neck to one side, or obliquely backwards.

(2) Anatomists in general have unnecessarily multiplied the muscles of the spine. Albinus has the merit of having introduced greater simplicity into this part of myology. Under the name of multifidus spinæ, he has very properly included those portions of muscular flesh intermixed with tendinous fibres, situated close to the back part of the spine, and which are described by Douglas under the name of transversales colli, dor-si, & lumberum.

(m) The ancients gave it this name from its resemblance to an irregular triangle (transvers). It consists of three fleshly portions. The anterior one affords a passage to the axillary artery, and between this and the middle portion we find the nerves going to the upper extremities. The middle is in part covered by the posterior portion, which is the longest and thinnest of the three.

</table>

Muscles within the cavity of the abdomen, on the anterior and lateral parts of the spine.

1. Psoas parvus (p). From the sides and transverse processes of the uppermost lumbar vertebrae, and sometimes of the lowermost dorsal vertebrae. Into the brim of the pelvis, at the junction of the os pubis with the ilium. To bend the loins forwards.

2. Psoas magnus. From the bodies and transverse processes of the last dorsal, and all the lumbar vertebrae. Into the os femoris, a little below the trochanter minor. To bend the thigh forwards.

3. Iliacus internus. From the inner lip, hollow part, and edge of the os ilium. In common with the psoas magnus. To assist the psoas magnus.

4. Quadratus lumborum (q). From the posterior part of the spine of the ilium. Into the transverse processes of the four uppermost lumbar vertebrae, the inferior edge of the last rib, and the side of the lowermost dorsal vertebra. To support the spine, or to draw it to one side.

5. Coccygeus. From the posterior and inner edge of the spine of the ischium. Into the lower part of the os coccygis forwards and inwards (r). To draw the os coccygis laterally.

---

(n) In the generality of anatomical books we find these muscles divided into inter-spinalis cervicis, dorfi, and lumborum, but we do not find any such muscles either in the loins or back.

(o) These muscles are to be found only in the neck and loins; what have been described, as the inter-transversales dorfi being rather small tendons than muscles.

(p) This and the following pair of muscles derive their name of psoas from psoas, lumbus, on account of their situation at the anterior part of the loins.

(q) So called from its shape, which is that of an irregular square.

(r) Some of the fibres of this muscle are united with those of the levator ani, so that it assists in closing the lower part of the pelvis.

(s) So named from its supposed resemblance to the Greek Δ reversed.

**Muscles on the os humeri,** - - 1. **Biceps flexor cubiti.**

**Muscles on the forearm,** - - 1. **Supinator longus.**

2. **Extensor carpi radialis longus.**

3. **Extensor carpi radialis brevis.**

4. **Extensor digitorum communis.**

5. **Extensor.
ANATOMY.

5. **Extensor minimi**
   - **Name:** From the outer condyle of the os humeri.
   - **Origin:** To the little finger.
   - **Use:** To extend the little finger.

6. **Extensor carpi ulnaris**
   - **Name:** From the outer condyle of the os humeri.
   - **Origin:** To the metacarpal bone of the little finger.
   - **Use:** To extend the forearm.

7. **Anconeus (v)**
   - **Name:** From the outer condyle of the os humeri.
   - **Origin:** To the outer edge of the ulna.
   - **Use:** To extend the forearm.

8. **Flexor carpi ulnaris**
   - **Name:** From the inner condyle of the os humeri, and interior edge of the olecranon (w).
   - **Origin:** Into the os pisiforme.
   - **Use:** To extend the hand.

9. **Palmaris longus**
   - **Name:** From the inner condyle of the os humeri.
   - **Origin:** Into the internal annular ligament, and aponeurosis palmaris (x).
   - **Use:** To bend the hand.

10. **Flexor carpi radialis**
    - **Name:** From the inner condyle of the os humeri.
    - **Origin:** Into the metacarpal bone of the forefinger.
    - **Use:** To extend the hand.

11. **Pronator radii teres**
    - **Name:** From the outer condyle of the os humeri, and coronoid processes of the ulna.
    - **Origin:** Into the anterior and convex edge of the radius near its middle.
    - **Use:** To roll the hand inwards.

12. **Flexor sublimis perforatus (v)**
    - **Name:** From the inner condyle of the os humeri, inner edge of the coronoid processes of the ulna, and upper and anterior part of the radius.
    - **Origin:** Into the second bone of each finger.
    - **Use:** To bend the second joint of the fingers.

13. **Supinator radii brevis**
    - **Name:** From the outer condyle of the os humeri, and posterior surface and outer edge of the ulna.
    - **Origin:** Into the anterior, inner part of the radius, and upper part outwards.
    - **Use:** To roll the radius.

14. **Abductor pollicis longus**
    - **Name:** From the middle and back part of the ulna, interosseous ligament, and radius.
    - **Origin:** By two tendons into the os trapezium, and first bone of the thumb.
    - **Use:** To stretch the first bone of the thumb.

15. **Extensor minor pollicis**
    - **Name:** From the back part of the ulna, and interosseous ligament and radius.
    - **Origin:** Into the convex part of the second bone of the thumb.
    - **Use:** To extend the second bone of the thumb obliquely outwards.

16. **Extensor major pollicis**
    - **Name:** From the back of the ulna and interosseous ligament.
    - **Origin:** Into the third and last bone of the thumb.
    - **Use:** To stretch the thumb obliquely backwards.

17. **Indicator**
    - **Name:** From the middle of the ulna.
    - **Origin:** Into the metacarpal bone of the forefinger.
    - **Use:** To extend the forefinger.

18. **Flexor**

(v) So called from *aman*, cubitus.
(w) Between the two origins of this muscle we find the ulnar-nerve going to the forearm.
(x) The aponeurosis palmaris is a tendinous membrane that extends over the palm of the hand. Some anatomists have supposed it to be a production of the tendon of this muscle, but without sufficient grounds; for in some subjects we find the palmaris longus inserted wholly into the annular ligament, so as to be perfectly distinct from this aponeurosis; and it now and then happens, that no palmaris longus is to be found, whereas this expansion is never deficient.
(y) This muscle is named perforatus, on account of the four tendons in which it terminates, being perforated by those of another muscle, the perforans.

**Muscles on the hand.**

1. **Lumbricales (z).** From the tendons of the perforans. Into the tendons of the extensor digitorum communis. To extend the two last joints of the fingers (a).

2. **Abductor brevis pollicis.** From the fore part of the internal annular ligament, os scaphoides, and one of the tendons of the abductor longus pollicis. Into the outer side of the 2d bone of the thumb, near its root. To move the thumb from the fingers.

3. **Opponens pollicis.** From the inner and anterior part of the internal annular ligament, and from the os scaphoides. Into the first bone of the thumb. Inwards, and to turn it upon its axis.

4. **Flexor brevis pollicis.** From the os trapezoides, internal annular ligament, os magnum, and os unciforme. Into the extensor seamen dea and second joint of the thumb. To bend the second bone of the thumb.

5. **Abductor pollicis.** From the metacarpal bone of the middle finger. Into the basis of the thumb. To move the thumb towards the fingers.

6. **Abductor indices.** From the inner side of the first bone of the thumb, and from the os trapezium. Into the first bone of the fore finger posteriorly. To move the fore finger towards the thumb.

7. **Palmaris brevis.** From the internal annular ligament, and aponeurosis palmaris. Into the os pisiforme, To contract the palm and the skin covering the abductor minimi digitii.

8. **Abductor minimi digitii.** From the internal annular ligament and os pisiforme. Into the side of the thumb. To draw the little finger from there. To bend the little finger.

9. **Flexor parvus minimi digitii.** From the os unciforme and internal annular ligament. Into the first bone of the little finger. To bend the little finger.

10. **Abductor metacarpal minimi digitii.** From the os unciforme and internal annular ligament. Into the metacarpal bone of the little finger. To move that bone towards the rest. To extend the fingers and move them towards the thumb (b).

11. **Intercostal interni.** Situated between the metacarpal bones. Into the roots of the fingers. To move the thumb (b).
ANATOMY

Part II.

Name. Origin. Insertion. Use.

12. Interosseus externi. Situated between the roots of the metacarpal bones on the back of the hand. To extend the fingers; but the first draws the middle finger inwards, the second draws it outwards, and the third draws the ring finger inwards.

MUSCLEs AT THE BACK PART OF THE PELVIS, AND UPPER PART OF THE THIGH.

1. Gluteus (c) maximus. From the spine of the ilium, posterior facet of the iliac crest. To extend the thigh and draw it outwards.

2. Gluteus medius. From the spine and superior surface of the ilium. Into the outer and back part of the great trochanter of the os femoris. To draw the thigh outwards and a little backwards, and when it is bent, to roll it.

3. Gluteus minimus. From the outer surface of the ilium and the border of its great niche. Into the upper and anterior part of the great trochanter. To lift the former.

4. Pyriformis (p). From the anterior part of the os sacrum. Into a cavity at the root of the trochanter major. To roll the thigh outwards.

5. Gemini (e). By two portions, one from the outer surface of the spine of the ilium; the other from the tuberosity of the ilium and posterior facet of the iliac crest ligament. Into the same cavity as the pyriformis. To roll the thigh outwards, and likewise to confine the tendon of the obturator internus, when the latter is in action.

6. Obturator internus. From the superior half of the inner border of the foramen thyroideum. Into the same cavity with the former. To roll the thigh outwards.

7. Quadratus (p) femoris. From the tuberosity of the ilium. Into a ridge between the trochanter major and trochanter minor. To move the thigh outwards.

ON THE THIGH

1. Biceps flexor crucis. By two heads; one from the tuberosity of the ilium, the other from the inner border of the os femoris. Into the upper and back part of the fibula (h). To bend the leg.

(c) From γλαντ, nates (p) So named from its pear-like shape.
(e) The two portions of this muscle having been described as two distinct muscles by some anatomists, have occasioned it to be named gemini. The tendon of the obturator internus runs between these two portions.
(p) This muscle is not of the square shape its name would seem to indicate.
(c) The muscles of the leg and thigh are covered by a broad tendinous membrane called fascia lata, that surrounds them in the manner of a sheath. It is fastened from the tendons of the glutei and other muscles, and dipping down between the muscles it covers, whereas to the linea aspera, and spreading over the joint of the knee, gradually disappears on the leg. It is thickest on the inside of the thigh.
(h) The tendon of this muscle forms the outer ham-string.

---

(n) This and the two following muscles have been usually, but improperly, considered as forming a single muscle with three heads, and on that account named triceps femoris.

(o) Γαστροκενημιον, 'sura, "the calf of the leg."

(p) This muscle is by some anatomists named solleus, on account of its being shaped like the sole-fish.

(q) This muscle has gotten the name of plantaris, from its being supposed to furnish the aponeurosis that covers the sole of the foot; but it does not in the least contribute to the formation of that tendinous expansion.

(r) So called on account of its situation at the ham (poples).

(s) This muscle, about the middle of the foot, unites with a fleshy mass, which, from its having first been described by Sylvius, is usually called mæna carnea JACOBI SYLVII.

PLATE XXIII. AND XXIV.

EXPLANATION OF PLATES XXIII. AND XXIV.

Fig. 1. The muscles immediately under the common teguments on the anterior part of the body are represented on the right side; and on the left side the muscles are seen which come in view when the exterior ones are taken away.

Superior Extremity.—U, Deltaoid. V, Pectoralis major. W, Part of the latissimus dorsi. X, X, Biceps flexor cubiti. Y, Y, Part of the brachialis externus. Z, Z, The beginning of the tendinous aponeurosis (from the biceps), which is spread over the muscles of the fore-arm. a, Its strong tendon inserted into the tubercle of the radius. b, Part of the brachialis internus. c, Pronator radii teres. d, Flexor carpi radialis. e, Part of the flexor carpi ulnaris. f, Palmaris longus. g, Aponeurosis palmaris. h, Palmaris brevis. i, Ligamentum carpi annulare. 22, Abductor minimi digiti. h, Supinator radii longus.

1. The tendons of the thumb. k, Adductor pollicis. l, Flexor pollicis longus. m, The tendons of the flexor sublimis perforatus, profunus perforans, and lumbricales. The sheaths are entire in the right hand.—in the left cut open to show the tendons of the flexor profundus perforating the sublimis.

Muscles not referred to—in the left superior extremity.—a, Pectoralis minor, tendon profundus and sublimis. o, The two heads of (x x) the biceps. p, Coraco-brachialis. q q, The long head of the triceps extensor cubiti. r r, Teres major. s, Subcapularis. t, T, Extensor radiales. u, Spinatar brevis. v, The cut extremity of the pronator teres. w, Flexor sublimis perforatus. x, Part of the flexor profundus. y, Flexor pollicis longus. z, Part of the flexor pollicis brevis. 4, Adductor minimi digitii. 5. The four lumbricales.

Trunk.—6, Serrate extremities of the serratus anterior major. 7, 7, Obliquus externus abdominis. 8, 8, The linea alba. 9, The umbilicus. 10, Pyramidalis. 11, 11, The spermatic cord. On the left side it is covered by the cremaster. 12, 12, Rectus abdominis. 13, Obliquus internus. 14, 14, External oblique muscles.

Inferior Extremities.—a a, The gracilis. b b, Parts of the triceps. c c, Pectineus. d d, Plosus magnus. e e, Biceps internus. f, Part of the gluteus medius. g, Part of the gluteus minimus. h, Cut extremity of the rectus cruris. i i, Vastus externus. k, Tendon of the rectus cruris. l l, Vastus internus.

Z Z. 2. Sartorius

(1) The interossei interni are three in number; their use is to draw the smaller toes towards the great toe.
(2) The interossei externi are four in number; the first serves to move the fore-toe towards the great toe; the rest move the toes outwards. All the interossei assist in extending the toes.
ANATOMY.

Of the Muscles.

* Sartorius muscle. ** Flethy origin of the tenor vaginae femoris or membranous. Its tendinous aponeurosis covers (i) the vastus externus on the right side.

m m, Patella. n n, Ligament or tendon from it to the tibia. o, Rectus cruris. p, Cruratus. q g, The tibia. r r, Part of the Gemellus or gastrocnemius externus. s s, Part of the soleus or gastrocnemius internus. t, Tibialis anterior. u, Tibialis posterior. v v, Peroneus muscles. w w, Extensor longus digitorum pedis. x x, Extenfor longus pollis pedis. y, Abducitor pollis pedis.

Fig. 2. The Muscles, Glands, &c. of the Left Side of the face and neck, after the common Teguments and Platyma myoides have been taken off. a, The frontal muscles. b, Temporalis and temporal artery. c, Orbicularis palpebrarum. d, Levator labii superioris alaeque nasi. e, Levator anguli oris. f, Zygomaticus. g, Depressor labii inferioris. h, Depressor anguli oris. i, Buccinator. k, Masseter. l, Parotid gland. m, Its duct. n, Sterno-cleidomastoideus. o, Part of the trapezius. p, Sternohyoides. q, Sterno-hyoideus. r, Omo-hyoides. s, Levator scapulae. t t, Scaleni. u, Part of the pleuris.

Fig. 3. The Muscles of the Face and Neck in view after the exterior ones are taken away. a a, Corrugator supercilii. b, Temporalis. c, Tendon of the levator palpebrarum superioris. d, Tendon of the orbicularis palpebrarum. e, Masseter. f, Buccinator. g, Levator anguli oris. h, Depressor labii inferioris alaeque nasi. i, Orbicularis oris. k, Depressor anguli oris. l, Muscles of the os hyoides. m, Sterno-cleido-mastoideus.

Fig. 4. Some of the Muscles of the Os Hyoides and Submaxillary Gland.

a, Part of the masseter muscle. b, Posterior head of the digastric. c, Its anterior head. d, Sternohyoides. e, Omo-hyoides. f, Stylo-hyoides. g, Submaxillary gland in situ.

Fig. 5. The Submaxillary Gland and Duèt.

a, Musculus mylo-hyoides. b, Hyo-glossus. c, Submaxillary gland extra situ. d, Its duct.

PLATE XXIV.

Fig. 1. The Muscles immediately under the common teguments on the posterior part of the body are represented in the right side; and on the left side the Muscles are seen which come in view when the exterior ones are taken away.

Superior Extremity.—Left side. a, Supra-spinatus. b, Infra-spinatus. c, Teres minor. d, Teres major. e, Triceps extensor cubiti. f f, Extensor carpi radiales. g, Supinator brevis. h, Indicater. 1 2 3, Extensors pollicis. i, Abducitor minimi digit. k, Interosseus.

Inferior Extremity.—Right side. L, Gluteus maximus. m, Part of the Gluteus medius. n, Tensor vaginalis femoris. o, Gracilis. p p, Abducitor femoris magnus. q, Part of the vastus internus. r, Semimembranosus. s, Semitendinosus. t, Long head of the biceps flexor cruris. u u, Gastrocnemius externus fem. v, Tendo Achillis. w, Soleus. x x, Peroneus longus and brevis. y y, Tendons of the flexor longus digitorum pedis; and under them * flexor brevis digitorum pedis. z, Abducitor minimi digit. p p, Interosseus.

Inferior Extremity.—Left side. m m, n n, p p, q q, r r, s s, t t, u u, v v, w w, x x, y y, z z. Point the same parts as in the right side. a, Pyriformis. b b, Gemini. c c, Obturator internus. d, Quadratus femoris. e e, Coccygeus. f f, The short head of the biceps flexor cruris. g g, Plantaris. h h, Popliteus. i, Flexor longus pollicis pedis.

Fig. 2. The Palm of the Left Hand after the common Teguments are removed to show the Muscles of the Fingers.

a, Tendon of the flexor carpi radialis. b, Tendon of the flexor carpi ulnaris. c, Tendons of the flexor sublimis perforatus, profundus perforans and lumbricales. d, Abducitor pollicis. e e, Flexor pollicis longus. f f, Flexor pollicis brevis. g g, Palmaris brevis. h, Abducitor minimi digit. i, Ligamentum carpi radialis. k, A probe put under the tendons of the flexor digitorum sublimis; which are performed by 1, the flexor digitorum profundus. m m m, Lumbricales. n, Abducitor pollicis.

Fig. 3. A fore-view of the foot and Tendons of the Flexores Digitorum.

a, Cut extremity of the tendo Achillis. b, Upper part of the astragal. c, Os calcis. d, Tendon of the tibialis anterior. e e, Tendon of the extensor pollicis longus. f, Tendon of the peroneus brevis. g g, Tendons of the flexor digitorum longus, with the naves Vefali. h h, The whole of the flexor digitorum brevis.

Fig. 4. Muscles of the Anus.

a a, An out line of the buttocks, and upper part of the thighs. b, The tefles contained in the frenum. c c, Sphincter ani. d, Anus. e e, Levator ani. f f, Erector penis. g g, Accelerator urinæ. h h, Corpus cavernosum urethæ.

Fig. 5. Muscles of the Penis.

a a, b b, c c, d d, e e, f f, h h, point the same as in fig. 4. c c, Sphincter ani. g g, Transverfallis penis.

PART II.
THE abdomen, or lower belly, extends from the lower extremity of the sternum, or the hollow, usually called the pit of the stomach, and more properly the hypochondriac region, to the lower part of the trunk.

Its distinguished into three divisions called regions; of these the upper one, which is called the epigastric region, begins immediately under the sternum, and extends to within two fingers breadth of the navel, where the middle or umbilical region begins, and reaches to the same distance below the navel. The third, which is called the hypogastric, includes the rest of the abdomen, as far as the os pubis.

Each of these regions is subdivided into three others; two of which compose the sides, and the other the middle part of each region.

The middle part of the upper region is called epigastric, and its two sides hypochondriac. The middle part of the next region is the umbilical region, properly so called, and its two sides are the flanks, or iliac regions. Lastly, the middle part of the lower region retains the name of hypogastric, and its sides are called inguinal or groin. The back part of the abdomen bears the name of lumbar region.

These are the divisions of the lower belly, which are necessary to be held in remembrance, as they frequently occur in surgical and anatomical writing. We will now proceed to examine the contents of the abdomen; and after having pointed out the names and arrangement of the several visceræ contained in it, describe each of them separately.

After having removed the skin, adipose membrane, and abdominal muscles, we discover the peritoneum or membrane that envelopes all the visceræ of the lower belly. This being opened, the first part that presents itself is the omentum or cawl, floating on the surface of the intestines, which are likewise seen everywhere loose and moist, and making a great number of circumvolutions through the whole cavity of the abdomen. The stomach is placed in the epigastric region, and under the stomach is the pancreas. The liver fills the right hypochondriac region, and the spleen is situated in the left. Their kidneys are seen between the middle of the lumbar region, and the urinary bladder and parts of generation are seated in the lower division of the belly.

Sect. I. Of the Peritoneum.

The peritoneum is a strong simple membrane, by which all the visceræ of the abdomen are surrounded, and in some measure supported. Many anatomical writers, particularly Winlow, have described it as being composed of two distinct membranous laminae; but their description seems to be erroneous. What perhaps appeared to be a second lamina, being found to be simply a cellular coat, which sends off productions to the blood-vessels passing out of the abdominal cavity. The aorta and vena cava likewise derive a covering from the same membrane, which seems to be a part of the cellular membrane we have already described.

The peritoneum, by its productions and reduplications, envelopes the greatest part of the abdominal visceræ. It is soft, and capable of considerable extension; and is kept smooth and moist by a vapour, which is constantly exhaling from its inner surface, and is returned again into the circulation by the absorbents.

This moisture not only contributes to the softness of the peritoneum, but prevents the attrition, and other ill effects which would otherwise probably be occasioned, by the motion of the visceræ upon each other.

When this fluid is supplied in too great a quantity, or the absorbents become incapable of carrying it off, it accumulates, and constitutes an ascites or drophi of the belly; and when by any means the exhalation is discontinued, the peritoneum thickens, becomes disfigured, and the visceræ are sometimes found adhering to each other.

The peritoneum is not a very vascular membrane. In a sound state it seems to be endowed with little or no feeling, and the nerves that pass through it appear to belong to the abdominal muscles.

Sect. II. Of the Omentum

The omentum, epiploon, or cawl, is a double membrane, produced from the peritoneum. It is interlarded with fat, and adheres to the stomach, spleen, duodenum, and colon; from whence hanging down loose and floating on the surface of the intestines. Its size is different in different subjects. In some it descends as low as the pelvis, and it is commonly longer at the left side than the right.

This part, the situation of which we have just now described, was the only one known to the ancients under the name of epiploon; but at present we distinguish three omenta, viz. omentum magnum colico gastricum, omentum parvum hepatico gastricum, and omentum colicium. They all agree in being formed of two very delicate laminae, separated by a thin layer of cellular membrane.

The omentum magnum colico gastricum, of which we have already spoken, derives its arteries from the splenic and hepatic. Its veins terminate in the vena portæ. Its nerves, which are very few, come from the splenic and hepatic plexus.

The omentum parvum hepatico gastricum, abounds less with fat than the great epiploon. It begins at the upper part of the duodenum, extends along the lesser curvature of the stomach as far as the cæophagus, and terminates about the neck of the gall-bladder, and behind the left ligament of the liver, so that it covers the lesser lobe: near the beginning of which we may observe a small opening, first described by Winlow, through which the whole pouch may easily be distend-
ANATOMY.

Of the Stomach.

The stomach is a membranous and muscular bag, in shape not unlike a bagpipe, lying across the upper part of the abdomen, and inclining rather more to the left than the right side.

It has two orifices, one of which receives the end of the oesophagus, and is called the cardia, and sometimes the left and upper orifice of the stomach; though its situation is not much higher than the other, which is styled the right and inferior orifice, and more commonly the pylorus; both these openings are more elevated than the body of the stomach.

The aliment passes down the oesophagus into the stomach through the cardia, and after having undergone the necessary digestion, passes out at the pylorus where the intestinal canal commences.

The stomach is composed of four tunics or coats, which are so intimately connected together that it requires no little dexterity in the anatomist to demonstrate them. The exterior one is membranous, being derived from the peritoneum. The second is a muscular tunic, composed of fibrous fibres which are in the greatest number about the two orifices. The third is called the nervous coat, and within this is the villous or velvet-like coat which composes the inside of the stomach.

The two last coats being more extensive than the two first, form the folds, which are observed every where in the cavity of this viscus, and more particularly about the pylorus; where they seem to impede the too hasty exclusion of the aliment, making a considerable plait, called voluta pylori.

The inner coat is constantly moistened by a mucus, which approaches to the nature of the saliva, and is called the gastric juice; this liquor has been supposed to be secreted by certain minute glands (v) seated in the nervous tunic, whose excretory ducts open on the surface of the villous coat.

(x) This membranous bag, though exceedingly thin and transparent, is found capable of supporting mercury, thrown into it by the same channel.

(v) Heister, speaking of these glands, very properly says, "in peris facile, in homine raro obseruarius;" for although many anatomical writers have described their appearance and figure, yet they do not seem to have been hitherto satisfactorily demonstrated in the human stomach; and the gastric juice is now more generally believed to be derived from the exhalant arteries of the stomach.

THE arteries of the stomach called the gastric arteries are principally derived from the coeliac; some of its veins pass to the splenic, and others to the vena portae; and its nerves are chiefly from the eighth pair or par vagum.

The account given of the tunics of the stomach may be applied to the whole alimentary canal; for both the oesophagus and intestines are, like this viscus, composed of four coats.

Before we describe the course of the aliment and the uses of the stomach, it will be necessary to speak of other parts which assist in the process of digestion.

Sect. IV. Of the Oesophagus.

The oesophagus or gullet is a membranous and muscular canal, extending from the bottom of the mouth to the upper orifice of the stomach. Its upper part where the aliment is received is shaped somewhat like a funnel, and is called the pharynx.

From hence it runs down close to the bodies of the vertebrae as far as the diaphragm, in which there is an opening through which it passes, and then terminates in the stomach about the eleventh or twelfth vertebra of the back.

The oesophagus is plentifully supplied with arteries from the external carotid, bronchial, and superior intercostal arteries; its veins empty themselves into the vena azygos, internal jugular, and mammary veins, &c.

Its nerves are derived chiefly from the eighth pair. We likewise meet with a mucus in the oesophagus, which every where lubricates its inner surface, and tends to assist in deglutition.—This mucus seems to be secreted by very minute glands, like the mucus in other parts of the alimentary canal.

Sect. V. Of the Intestines.

The intestines form a canal, which is usually five times longer than the body to which it belongs. This canal extends from the pylorus, or inferior orifice of the stomach, to the anus.

It will be easily understood, that a part of such great length must necessarily make many circumvolutions, to be confined to so many other visceras within the cavity of the lower belly.

Although the intestines are in fact, as we have observed, only one long and extensive canal, yet different parts have been distinguished by different names. The intestines are first distinguished into two parts, one of which begins at the stomach, and is called the thin, or small intestines, from the small size of the canal when compared with the other part, which is called the large intestines, and includes the lower portion of the canal down to the anus.

Each of these parts has its subdivisions.—The small
Part III.

ANATOMY.

Of the intestines being distinguished into duodenum, jejunum, and ileum, and the larger portion into cecum, colon, and rectum.

The small intestines fill the middle and fore parts of the belly, while the large intestines fill the sides and both the upper and lower parts of the cavity.

The duodenum, which is the first of the small intestines, is so called, because it is about 12 inches long. It begins at the pylorus and terminates in the jejunum, which is a part of the canal observed to be usually more empty than the other intestines. This appearance gives it its name, and likewise serves to point out where it begins.

The next division is the ileum, which of itself exceeds the united length of the duodenum and jejunum, and has received its name from its numerous circumvolutions. The large circumvolution of the ileum covers the first of the large intestines called the cecum (x), which seems properly to belong to the colon, being a kind of pouch of about four fingers in width, and nearly of the same length, having exteriorly a little appendix, called appendix ceci.

The cecum is placed in the cavity of the os ileum on the right side, and terminates in the colon, which is the largest of all the intestines.

This intestine ascends by the right kidney to which it is attached, pausing under the hollow part of the liver, and the bottom of the stomach, to the spleen, to which it is likewise secured, as it is also to the left kidney; and from thence passes down towards the os sacrum, where, from its straight course, the canal begins to take the name of rectum.

There are three ligamentous bands extending thro' the whole length of the colon, which, by being shorter than its two inner coats, serve to increase the plaits on the inner surface of this gut.

The anus which terminates the intestine rectum, is furnished with three muscles; one of these is composed of circular fibres, and from its use in shutting the passage of the anus is called sphincter ani.

The other two are the levatores ani, so called, because they elevate the anus after defecation. When these by palsy, or any other disease, lose the power of contracting, the anus prolapses; and when the sphincter is affected by similar causes, the faeces are voided involuntarily.

It has been already observed, that the intestinal canal is composed of four tantes; but it remains to be remarked, that here, as in the stomach, the two inner tunics being more extensive than the other two, from the plaits which are to be seen in the inner surface of the intestines, and are called valvula conniventes.

Some authors have considered these plaits as tending to retard the motion of the faeces, in order to afford more time for the separation of the chyle; but there are others who attribute to them a different use: they contend, that these valves, by being naturally inclined downwards, cannot impede the descent of the faeces, but that they are intended to prevent their return upwards.

They are probably destined for both these uses; for although these folds incline to their lower side, yet the inequalities they occasion in the canal are sufficient to retard, in some measure, the progressive motion of the faeces, and to afford a greater surface for the absorption of chyle, and their natural position seems to oppose itself to the return of the aliment.

Besides these valvula conniventes, there is one more considerable than the rest, called the valve of the colon; which is found at that part of the canal where the intestine ileum is joined to the colon. This valve permits the alimentary pulp to pass downwards, but serves to prevent its return upwards; and it is by this valve, that gylsters are prevented from passing into the small intestines (y).

Of the little vermiform appendix of the cecum, it will be sufficient to say, that its uses have never yet been ascertained. In birds we meet with two of these appendices.

The intestines are lubricated by a constant supply of mucus, which is probably secreted by very minute follicles (z). This mucus promotes the descent of the alimentary pulp, and in some measure defends the inner surface of the intestines from the irritation to which it would, perhaps, otherwise be continually exposed from the aliment; and which, when in a certain degree, excites a painful disorder called colic, a name given to the disease, because its most usual seat is in the intestines colon.

The intestines are likewise frequently distended with air, and this dilatation sometimes occasions pain, and constitutes the flatulent colic.

The arteries of the intestines are continuations of the mesenteric arteries, which are derived in two considerable branches from the aorta.--The redundant blood is carried back into the vein porus.

In the rectum the veins are called hemorrhoidal, and are there distinguished into internal and external; the first are branches of the inferior mesenteric vein, but the latter pass into other veins. Sometimes these veins are distended with blood from ulcra, from weakness of their coats, or from other causes, and what we call the hemorrhoids takes place. In this disease they are sometimes ruptured; and the discharge of blood which

(x) Anatomists have differed with respect to this division of the intestines. The method here followed is now generally adopted; but there are authors who allow the name of cecum only to the little appendices, which has likewise been called the vermiform appendix, from its resemblance to a worm in size and length.

(y) This is not invariably the case, for the contents of a gylster have been found not only to reach the small intestines, but to be voided at the mouth. Such instances, however, are not common.

(z) Some writers have distinguished these glands into miliary, lenticular, &c.--Brunner and Peyer were the first anatomists who described the glands of the intestines, and their descriptions were chiefly taken from animals, these glandular appearances not seeming to have been hitherto satisfactorily pointed out in the human subject. It is now pretty generally believed, that the mucus which everywhere lubricates the alimentary canal, is exhaled from the minute ends of arteries; and that these extremities first open into a hollow vehicle, from whence the deposited juice of several branches flows out through one common orifice.
which consequently follows, has probably occasioned them to be called hemorrhoidal veins.

The nerves of the intestines are derived from the eighth pair.

Sect. VI. Of the Mesentery.

The name of the mesentery implies its situation amidst the intestines. It is in fact a part of the peritonæum, being a reduplication (A) of that membrane from each side of the lumbar vertebra, to which it is firmly attached, so that it is formed of two laminae, connected to each other by cellular membrane.

The intestines, in their different involutions, form a great number of arches, and the mesentery accompanies them through all these turns; but by being attached only to the hollow part of each arch, it is found to have only a third of the extent of the intestines.

That part of this membrane which accompanies the small intestines is the mesentery, properly so called; but those parts of it which are attached to the colon and rectum are distinguished by the names of meso-colon and meso-rectum.

There are many conglomerate glands diffused thro' this double membrane, through which the lacteals and lymphatics pass in their way to the thoracic veins. The blood-vessels of the mesentery were described in speaking of the intestines.

This membrane, by its attachment to the vertebrae, serves to keep the intestines in their natural situation. The idea usually formed of the colic called mifserere, is perfectly erroneous; it being impossible that the intestines can be twisted, as many suppose they are, in that disease, their attachment to the mesentery effectually preventing such an accident—but a disarrangement sometimes takes place in the intestinal canal itself, which is productive of disagreeable and sometimes fatal consequences.—This is by an introversion of the intestine, an idea of which may be easily formed, by taking the finger of a glove, and involving one part of it within the other.

If inflammation takes place, the fistula in this case is inverted, and the peristaltic motion of the intestines (by which is meant the progressive motion of the faces downwards) is inverted, and what is called the lisse paffon takes place. The same effects may be occasioned by a deficient of the intestine, or of the omentum either with it or by itself, and thus constituting what is called an hernia or rupture; a term by which in general is meant the falling down or protrusion of any part of the intestine or omentum, which ought naturally to be contained within the cavity of the belly.

(A) He who only reads of the reduplication of membranes, will perhaps not easily understand how the peritonæum and pleura are reflected over the viscera in their several cavities; for one of these serves the same purposes in the thorax that the other does in the abdomen. This disposition, for the discovery of which we are indebted to modern anatomists, constitutes a curious part of anatomical knowledge; but the student, unaided by experience, and assisted only by what the limits of this work would permit us to say on the occasion, would probably imitate only confused ideas of the matter; and it will perfectly answer the present purpose, if he considers the mesentery as a membrane attached by one of its sides to the lumbar vertebrae, and by the other to the intestines.

(a) The hernia congenita will be considered with the male organs of generation, with which it is intimately connected.
Part III.

ANATOMY.

Of the Abdomen.

The liver is a viscus of considerable size, and of a reddish colour; convex superiorly and anteriorly where it is placed under the ribs and diaphragm, and of an unequal surface posteriorly. It is chiefly situated in the right hypochondrium, and under the false ribs; but it likewise extends into the epigastric region, where it borders upon the stomach. It is covered by a production of the peritoneum, which serves to attach it by three of its reduplications to the false ribs. These reduplications are called ligaments, though very different in their texture from what are called by the same name in other parts of the body. The umbilical cord, too, which in the foetus is previous, gradually becomes a simple ligament after birth; and, by passing to the liver, serves likewise to secure it in its situation.

At the posterior part of the organ where the umbilical vessels enter, it is found divided into two lobes. Of these, the largest is placed in the right hypochondrium; the other, which covers part of the stomach, is called the little lobe. All the vessels which go to the liver pass at the fissure we have mentioned; and the production of the peritoneum, which invests the liver, was described by Glisson, an English anatomist, as accompanying them in their passage, and surrounding them like a glove; hence this production has been commonly known by the name of capsula of Glisson: but it appears to be chiefly a continuation of the cellular membrane which covers the vena portae interna. The liver was considered by the ancients as an organ destined to prepare and perfect the blood; but later discoveries have proved, that this opinion was wrong, and that the liver is a glandular substance formed for the secretion of the bile.

The blood is conveyed to the liver by the hepatic artery and the vena portae. This is contrary to the mode of circulation in other parts, where veins only serve to carry off the redundant blood: but in this viscus the hepatic artery, which is derived from the celiac, is principally destined for its nourishment; and the vena portae, which is formed by the union of the veins from most of the abdominal viscera, furnishes the blood from which the bile is chiefly to be separated; so that these two series of vessels serve very distinct purposes. The vena portae, as it is ramified through the liver, performs the office both of a vein and an artery; for like the former it returns the blood from the extremities of arteries, while as the latter it prepares it for secretion.

The nerves of the liver are branches of the intercostal and par vagum. The bile, after being separated from the mass of blood, in a manner of which mention will be made in another place, is conveyed out of this organ by very minute excretory ducts, called porti-biliarii; these uniting together like the excretory ducts in the pancreas, gradually form larger ones, which at length terminate in a considerale canal called ductus hepaticus.

Sect. VIII. Of the Liver.

The gall-bladder is a little membranous bag, shaped like a pear, and attached to the posterior and alaless inferior part of the great lobe of the liver. It has two unions, of which the exterior one is a production of the peritoneum. The interior, or villous coat, is supplied with a mucous layer that defends it from the acidity of the bile. These two coverings are intimately connected by means of cellular membrane, which from its firm glistening appearance has generally been spoken of as a mucular tunic.

The gall-bladder is supplied with blood-vessels from the hepatic arteries. These branches are called the cystic arteries, and the cystic veins carry back the blood.

Its nerves are derived from the same origin as those of the liver.

The neck of the gall-bladder is continued in the form of a canal called ductus cysticus, which soon unites with the ductus hepaticus we described as the excretory duct of the liver; and forming one common canal, takes the name of ductus coledochus communis, through which both the cystic and hepatic bile are discharged into the duodenum. This canal opens into the intestine in an oblique direction, first passing through the exterior tunic, and then piercing the other coats after running between each of them a very little way. This economy serves two useful purposes; — to promote the discharge of bile and to prevent its return.

The bile may be defined to be a natural liquid soap, somewhat tenacious and bitter, and of a yellowish colour, which easily mixes with water, oil, and vineous spirits, and is capable of dissolving resinos substances. From some late experiments made by M. Cadet, it appears to be formed of an animal oil, combined with an alkaline base of sea-salt, a salt of the nature of bones, milk, and a calcareous earth which is chiefly ferruginous.

Its definition seems sufficiently to point out the usages for which it is intended (c). It blends the alimentary masts, by dividing and attenuating it; corrects the too great disposition to acidency, which the aliment acquires in the stomach; and, finally, by its acidity, tends to excite the peristaltic motion of the intestines.

After what has been said, it will be conceived that there are four parts of bile; one of which is derived immediately from the liver through the hepatic duct, and the other from the gall-bladder. These twobreeds, however, do not essentially differ from each other. The hepatic bile indeed is milder, and more liquid than the cystic, which is constantly thicker and yellower; and

(c) The ancients, who were not acquainted with the real use of the liver, considered the bile as an excrementitious and useless fluid.
and by being bitterer, seems to possess greater activity than the other.

Every body knows the source of the hepatic bile, that it is secreted from the masts of blood by the liver; but the origin of the cystic bile has occasioned no little controvert amongst anatomical writers. There are some who contend, that it is separated in the substance of the liver, from whence it passes into the gall-bladder through particular vesicles. In deer, and in some other quadrupeds, as well as in several birds and fishes, there is an evident communication, by means of particular vesicles, between the liver and the gall-bladder. Bianchi, Winslow, and others, have asserted the existence of such vesicles in the human subject, and named them hepaticc vesicles; but it is certain that no such ducts exist.

In obstructions of the cystic duct, the gall-bladder has been found thrivelled and empty; so that we may consider the gall-bladder as a reservoir of hepatic bile; and that it is an established fact, that the whole of the bile contained in the gall-bladder is derived from the liver; that it passes from the hepatic to the cystic duct, and from that to the gall-bladder.

The difference in the colour, consistence, and taste of the bile, is merely the consequence of stagnation and absorption. When the stomach is distended with aliment, this reservoir undergoes a certain degree of compression, and the bile passes out into the intestinal canal, and in the efforts to vomit, the gall-bladder charges itself of its contents, and at such times discharges itself of its contents.

Sometimes the bile concretes in the gall-bladder, so as to form what are called gall stones (v). When these concretions pass into the cystic duct, they sometimes occasion exquisite pain, by distending the canals in their way to the duodenum; and by lodging in the ductus choledochus communis, and obstructing the course of the bile, this fluid will be absorbed, and by being carried back into the circulation occasion a temporary jaundice.

Sect. X. Of the Spleen.

The spleen is a soft and spongy viscus, of a bluish colour, and about five or six fingers breadth in length, and three in width, situated in the left hypochondrium, between the stomach and the falciform ria. That side of it which is placed on the side of the ribs is convex; and the other, which is turned toward the stomach, is concave.

The splenic artery, which is a branch from the coeliac, supplies this viscus with blood, and a vein of the same name carries it back into the vena porta.

Its nerves are derived from a particular plexus called the pleura, which is formed by branches of the intercostal nerve, and by the eighth pair, or par vagum.

The ancients, who supposed two sorts of bile, considered the spleen as the receptacle of what they called atra bilis. Havers, who wrote professedly on the bones, determined its use to be that of secreting the synovia; and the late Mr Hewson imagined, that it concurred with the thymus and lymphatic glands of the body in forming the red globules of the blood. All these opinions seem to be equally fanciful. The want of an excretory duct has occasioned the real use of this viscus to be still doubtful. Perhaps the blood undergoes some change in it, which may assist in the preparation of the bile. This is the opinion of the generality of modern physiologists; and the great quantity of blood with which it is supplied, together with the course of its veins into the vena portae, seem to render this notion probable.

Sect. XI. Of the Glandula Renalis, Kidneys, and Ureters.

The glandula renalis, which were by the ancients supposed to secrete the atra bilis, and by them named cæsula atrabilis, are two flat bodies of an irregular figure, one on each side of the abdomen and the aorta.

In the fetus they are as large as the kidneys; but they do not increase afterwards in proportion to those parts, and in adults and old people they are generally found thrivelled, and much wasted. They have their arteries and veins. Their arteries usually arise from the splenic or the celiac, and terminate in the aorta; and their veins go to the neighbouring veins, or to the vena cava. Their nerves are branches of the intercostal.

The use of these parts is not yet perfectly known. In the fetus the secretion of urine must be in a very small quantity, and a part of the blood may perhaps then pass through these channels, which in the adult is carried to the kidneys to supply the matter of urine.

The kidneys are two in number, situated one on the right and the other on the left side in the lumbar region, between the last false rib and the os illium, by the sides of the vertebrae. Each kidney in its figure resembles a fort of bean, which from its shape is called kidney bean. The concave part of each kidney is turned towards the aorta and vena cava ascendens. They are surrounded by a good deal of fat, and receive a coat from the peritoneum; and when this is removed, a very fine membrane is found investing their substance and the vesicles which ramify through them.

Each kidney has a considerable artery and vein, which are called the renal. The artery is a branch from the aorta, and the vein passes into the vena cava. Their nerves, which every where accompany the blood-veins, arise from a considerable plexus, which is derived from the intercostal.

In each kidney, which in the adult is of a pretty firm texture, there are three substances to be distinguished (e). The outer part is glandular or cortical, beyond

---

(o) These concretions sometimes remain in the gall-bladder without causing any uneasiness. Dr Heberden relates, that a gall-stone weighing two drams was found in the gall-bladder of the late Lord Bath, though he had never complained of the jaundice, nor of any disorder which he could attribute to that cause. Med. Trans. Vol. ii.

(e) The kidneys in the fetus are distinctly lobulated; but in the adult they become perfectly firm, smooth, and regular.
beyond this is the vascular or tubular substance, and the inner part is papillary or membranous.

It is in the cortical part of the kidney that the secretion is carried on; the urine being here received from the minute extremities of the capillary arteries, is conveyed out of this cortical substance by an infinite number of very small cylindrical canals or excretory vessels, which constitute the tubular part. These tubes, as they approach the inner substance of the kidneys, gradually unite together; and thus forming larger canals, at length terminate in ten or twelve little protuberances called papillæ, the orifices of which may be seen without the assistance of glasses. These papillæ open into a small cavity or pelvis of the kidney, and formed by a distinct membranous bag which embraces the papillæ. From this pelvis the urine is conveyed through a membranous canal which issues out from the hollow side of the kidney, a little below the blood vessels, and is called ureter.

The ureters are each about as large as a common writing-pen. They are somewhat curved in their course from the kidneys, like the letter J, and at length terminate in the posterior and almost inferior part of the bladder, at some distance from each other. They pass into the bladder in the same manner as the ductus choledochus communis passes into the intestine duodenum, not by a direct passage, but by an oblique course between the two coats; so that the discharge of urine into the bladder is promoted, whilst its return is prevented. Nor does this mode of structure prevent the passage of fluids only from the bladder into the ureters, but likewise air:—for air thrown into the bladder inflates it, and it continues to be distended in a certain degree, whilst the evacuation depends on the quantity of air contained in the bladder, and its state. The urine varies much in its colour and contents. These varieties depend on age, sex, climate, diet, and other circumstances. In infants it is generally a clean watery fluid, without smell or taste. As we advance in life, it acquires more colour and smell, and becomes more impregnated with salts. In old people it becomes still more acid and fetid.

In a healthy state it is nearly of a straw colour. After being kept for some time, it deposits a tarry matter, which is found to be composed chiefly of earth and salt, and soon incrusts the sides of the vessel in which it is contained. While this separation is taking place, appearances like minute fibres or threads of a whitish colour may be seen in the middle of the urine, and an oily scum observed floating on its surface. So that the most common appearances of the urine are sufficient to ascertain that it is a watery substance, impregnated with earthy, saline, and oily particles.

The urine is not always voided of the same colour and consistence; for these are found to depend on the proportion of its watery part to that of its other constituent principles. Its colour and degree of fluidity seem to depend on the quantity of saline and inflammable particles contained in it: so that an increased proportion of these parts will constantly give the urine a higher colour, and add to the quantity of sediment.

The variety in the appearance of the urine, depends on the nature and quantity of solid and fluid aliment we take in; and it is likewise occasioned by the different state of the urinary vessels, by which we mean the channels through which it is separated from the blood, and conveyed through the pelvis into the ureters. The causes of calculous concretions in the urinary passages, are to be looked for in the natural constitution of the body, mode of life, &c.

It having been observed, that after drinking any light wine or Spa water, it very soon passed off by urine, it has been supposed by some, that the urine is not altogether conveyed to the bladder by the ordinary course of circulation, but that there must certainly exist some other shorter means of communication, perhaps by certain vessels between the stomach and the bladder, or by a retrograde motion in the lymphatics. But it is certain, that if we open the belly of a dog, press out the urine from the bladder, pass a ligature round the emulgent arteries, and then few up the abdomen, and give him even the most diuretic liquor to drink, the stomach and other channels will be distended.
ed with it, but not a drop of urine will be found to have passed into the bladder; or the same thing happens when a ligature is thrown round the two ureters. This experiment seems to be a sufficient proof, that all the urine we evacuate, is conveyed to the kidneys through the emulgent arteries, in the manner we have described. — It is true, that wine and other liquors promote a speedy evacuation of urine: but the discharge seems to be merely a speed of the fluxus they occasion; by which the bladder and urinary parts are solicited to a more copious discharge of the urine, which was before in the body, and not immediately of that which was last drunk; and this increased discharge, if the supply is kept up, will continue: nor will this appear wonderful, if we consider the great capacity of the vessels that go to the kidneys; the constant supply of fresh blood that is essential to health; and the rapidity with which it is incessantly circulated through the heart to all parts of the body.

Sect. XIII. Of Digestion.

We are now proceeding to speak of digestion, which seems to be introduced in this place with propriety, after a description of the abdominal visceræ, the greater part of which contribute to this function. By digestion is to be understood, the changes the aliment undergoes for the formation of chyle: these changes are effected in the mouth, stomach, and small intestines.

The mouth, of which every body has a general knowledge, is the cavity between the two jaws, formed anteriorly and laterally by the lips, teeth, and cheeks, and terminating posteriorly in the throat.

The lips and cheeks are made up of fat and muscles, covered by the cuticle, which is continued over the whole inner surface of the mouth, like a fine and delicate membrane. — Beside this membrane, the inside of the mouth is furnished with a spongy and very vascular substance called the gums, by means of which the teeth are secured in their sockets. A similar substance covers the roof of the mouth, and forms what is called the velum pendulum palati, which is fixed to the extremity of the arch formed by the soft maxillaries, and soft palate, and terminates in a soft pulp before it is conveyed into the mouth.

The velum pendulum palati performs the office of a valve between the cavity of the mouth and the pharynx, being moved by several muscles. — The tongue is composed of several muscles which enable it to perform a variety of motions for the articulation of the voice; for the purposes of mastication; and for conveying the aliment into the pharynx. Its upper part is covered with papillæ, which constitute the organ of taste, and are easily to be distinguished; it is covered by the same membrane that lines the underside of the mouth, and which makes at its inferior part towards its basis a reduplication called frenum. — Posteriorly, under the velum palati, and at the basis of the tongue, is the pharynx: which is the beginning of the oesophagus, stretched out every way, so as to resemble the top of a funnel, through which the aliment passes into the stomach.

The mouth has a communication with the nostrils at its posterior and upper part; with the ears, by the Eustachian tubes; with the lungs, by means of the larynx; and with the stomach, by means of the oesophagus.

The pharynx is constantly moistened by a fluid, secreted by two considerable glands called the tonsils, one on each side of the velum palati. These glands, from their supposed resemblance to almonds, have likewise been called amygdales.

The mouth is moistened by a considerable quantity of saliva. This fluid is derived from the parotid glands; a name which by its etymology points out its situation to be near the ears. They are two in number, one on each side under the os male: and they are of the conglomerate kind; being formed of many smaller glands, each of which sends out a very small excretory duct, which unites with the rest, to form one common channel, that runs over the cheek, and piercing the buccinator muscle, opens into the mouth on each side, by an orifice into which a bristle may be easily introduced. — Besides these, the maxillary glands, which are placed near the inner surface of the angle of the lower jaw on each side; the sublingual glands, which are situated at the root of the tongue; the glands of the palate, which are seated in the velum palati; and those of the cheeks, lips, &c. together with many other less considerable ones, — pour the saliva into the mouth through their several excretory ducts.

The saliva, like all the other humours of the body, is found to be different in different people: but in general, it is a limpid and insipid fluid, without smell in healthy subjects; and these properties would seem to prove that it contains very few saline or inflammable particles.

The uses of the saliva seem to be to moisten and lubricate the mouth, and to assist in reducing the aliment into a soft pulp before it is conveyed into the stomach.

The variety of functions which are constantly performed by the living body, must necessarily occasion a continual waste and dilipation of its several parts. A great quantity is every day thrown off by the insensible perspiration and other discharges; and were not these lothes constantly recruited by a fresh supply of chyle, the body would soon affect its own dilution. But nature has very wisely favoured us with organs fitted to produce such a supply: and has at the same time endowed us with the sensations of hunger and thirst, that our attention may not be diverted from the necessary business of nutrition. The sensation of hunger is universally

Part III.

ANATOMY.

Of the Abdomen.

Versally known; but it would perhaps be difficult to describe it perfectly in words. It may, however, be done to a certain extent in the stomach, which is the organ of digestion, and which likewise serves to point out the proper quantity, and time for taking it. In describining the stomach, mention was made of the gastric juice, as every where lubricating its inner coat. This humour mixes itself with the aliment in the stomach, and helps to prepare it for its passage into the intestines; but when the stomach is perfectly empty, this same fluid irritates the coats of the stomach itself, and produces the sensation of hunger.

A certain proportion of liquid aliment is required to sift in the progress of digestion, and to afford that moisture to the body, of which there is such a constant dilution. —Thirst induces us to take this necessary supply of drink; and the fear of this dilution is in the tongue, fauces, and palatoglossus, which from their great sensitivity are required to be kept moist; for though the fauces are naturally moistened by the mucous and salival juices; yet the blood, when deprived of its watery part or rendered acrimonious by any natural causes, never fails particularly to affect these parts, and the whole alimentary canal, and to occasion thirst. —This is the common effect of fevers and of hard labour, by both which too much of the watery part of the blood is dilipated.

It has been observed, that the aliment undergoes some preparation in the mouth before it passes into the stomach; and this preparation is the effect of mastication. In treating of the upper and lower jaws, mention was made of the number and arrangement of the teeth. The upper jaw was described as being immovable; but the lower jaw was spoken of as being capable of elevation and depression, and of a grinding motion. The aliment, when first carried into the mouth, is pressed between the teeth of the two jaws by a very strong and frequent motion of the lower jaw; and the tongue and the cheeks assisting in this process, continue to replace the food between the teeth till it is perfectly divided, and reduced to the consistence of pulp. The incisors and canini divide it first into smaller pieces, but it is between the surfaces of the dentes molares by the grinding motion of the jaw that the mastication is completed.

During this process, the salival glands being gently compressed by the contraction of the muscles that move the lower jaw, pour out their saliva: this helps to divide and break down the food, which at length becomes a kind of pulp, and is then carried over the bals of the tongue into the fauces. But to effect this passage into the cesophagus, it is necessary that the other openings which were mentioned as having a communication with the mouth as well as the pharynx, should be closed; that none of the aliment, whether solid or liquid, may pass into them, whilst the pharynx alone is dilated to receive it: —And such a disposition actually takes place in a manner we will endeavour to describe.

The trachea arteria, or windpipe, through which the air is conveyed to the lungs, is placed before the cesophagus—In the act of swallowing; therefore, if the larynx (for the upper part of the trachea is called) is not closed, the aliment will pass into it in its way to the cesophagus. But this is prevented by a small and very elastic cartilage, called epiglottis, which is attached only to the fore-part of the larynx; so that the food in its passage to the cesophagus presses down this cartilage, which then covers the glottis of the larynx; and at the same time the velum palati, being capable of some degree of motion, is drawn backwards by its muscles, and closes the openings into the nose and the Eustachian tubes. —This, however, is not all. The larynx, which being composed of cartilaginous rings, cannot fail in its ordinary state to compress the membranous canal of the cesophagus, is in the act of deglutition carried forwards and upwards by muscles defined for that purpose; and consequently drawing the fore-part of the pharynx with it, that opening is fully dilated. When the aliment has reached the pharynx, its descent is promoted by its own proper weight, and by the mucular fibres of the cesophagus, which continue to contract from above downwards, until the aliment has reached the stomach. That these fibres have no considerable share in deglutition, any person may experience, by swallowing with his head downwards, when the descent of the aliment cannot possibly be effected by its weight.

It is necessary that the nostrils and the lungs should communicate with the mouth, for the purposes of speech and respiration; but if the most minute part of our food happens to be introduced into the trachea, it never fails to produce a violent cough, and sometimes the most alarming symptoms. This is liable to happen whenever we laugh or talk in the act of deglutition; the food is then said to have passed the wrong way. And indeed this is not improperly expressed: for death would soon follow, if the quantity of aliment introduced into the trachea should be sufficient to obstruct the respiration only during a very short time; or if the irritating particles of food should not soon be thrown up again by means of a cough, which in these cafes very feazonably increases in proportion to the degree of irritation.

If the velum palati did not close the passage to the nostrils, deglutition would be performed with difficulty, and perhaps not at all, for the aliment would return through the nose, as is frequently the case in drinking. Children, from a delicacy in this velum palati, have been seen to die a few hours after birth; and they who from disease or any other cause have not this part perfectly, swallow with difficulty.

The aliment, after having been sufficiently divided by the action of the teeth, and attenuated by the tali,va, is received into the stomach, where it is destined to undergo a more considerable change.

The properties of the aliment not being much altered at its first entrance into the stomach, and before it is thoroughly blended with the gastric juice, is capable of irritating the inner coat of the stomach to a certain degree, and occasions a contraction of its two orifices. —In this membranous bag, surrounded by the abdominal viscera, and with a certain degree of natural heat, the aliment undergoes a constant agitation by means of the abdominal muscles and of the diaphragm, and likewise by a certain contraction or expansion of the mucular fibres of the stomach itself. By this motion, every part of the food is exposed to the action of the gastric juice, which gradually divides and attenuates it, and prepares it for its passage into the intestines.

Some.
Some observations lately published by Mr Hunter in the Philosophical Transactions, tend to throw considerable light on the principles of digestion. There are few dead bodies in which the stomach, at its great end, is not found to be in some degree digested (u). Animals, or parts of animals, that have been digested, or subjected to their digestive powers, or that have been in the stomach, are not in the least affected by the action of that viscus; but the moment they lose the living principle, they become subject to its digestive powers. This seems to be the case with the stomach, which is enabled to refist the action of its juices in the living body: but when deprived of the living principle, it is then no longer able to refist the powers of that membrane, which it had itself formed for the digestion of its contents; the process of digestion appearing to be continued after death. This is confirmed by what happens in the stomachs of fish: They frequently swallow, without mastication, filth which are larger than the digesting parts of their stomach can contain; and in such cases, that part which is taken into the stomach is more or less dissolved, while that part which remains in the oesophagus is perfectly found; and here, as well as in the human body, the digesting part of the stomach is often reduced to the same state as the digested part of the food. These appearances tend to prove, that digestion is not effected by a mechanical power, by contractions of the stomach, or by heat; but by a fluid secreted in the coats of the stomach, which is poured into its cavity, and there animalizes the food, or assimilates it to the nature of blood.

From some late experiments by M. Sage, it appears, that inflammable air has the property of destroying and dissolving the animal texture: And as we swallow with the substances which serve us for food a great quantity of atmospheric air, M. Sage thinks it possible, that denphilogliticated, which is its principle, may be converted in the stomach into inflammable air, or may modify into inflammable air a portion of the oily substance which is the principle of aliments. In this case, would not the inflammable air (he asks), by dissolving our food, facilitate its conversion into chyle?

Be this as it may, the food, after having remained one, two, or three hours in the stomach, is converted into a creythil pulp, which is usually called chymus. A word of Greek etymology, signifying juice, and some few milky or chylous particles begin to appear. But the term of its residence in this bag is proportioned to the nature of the aliment, and to the state of the stomach and its juices. The thinner and more perfectly digested parts of the food pass by a little at a time into the duodenum, through the pylorus, the fibres of which relax to afford its passage; and the groffer and less digested particles remain in the stomach, till they acquire a sufficient fluidity to pass into the intestines, where the nature of the chymus is perfectly changed. The bile and pancreatic juice which flow into the duodenum, and the mucous, which is every where diffus'd from the surface of the intestines, mix themselves with the alimentary pulp which they still further attenuate and diffuse, and into which they seem to infuse new properties.

Two matters very different from each other in their nature and destination, are the result of this combination. One of these, which is composed of the liquid parts of the aliment, and of some of its more solid particles, extremely divided and mixed with the juices we have described, constitutes a very mild, sweet, and whitish fluid, resembling milk, and distinguished by the name of chyle. This fluid is absorbed by the lacteal veins, which convey it into the circulation, where, by being assimilated into the nature of blood, it affords that supply of nutrition, which the continual waste of the body is found to require. The other, is the remains of the alimentary mafa deprived of all its nutritious particles, and containing only such parts as were rejected by the absorbing mouths of the lacteals. This greater part, called the fæces, passes on through the course of the intestines, to be voided at the anus, as will be explained hereafter; for this process in the economy cannot be well understood till the motion of respiration has been explained. But the structure of the intestines is a subject which may be properly described in this place, and deserves to be attended to.

It has been already observed, that the intestinal canal is five or six times as long as the body, and that it forms many circumvolutions in the cavity of the abdomen, which it traverses from the right to the left, and again from the left to the right; in one place descending, and in another extending itself upwards. It was noticed likewise, that the inner coat of the intestines, by being more capacious than their exterior tunics, formed a multitude of plaits placed at a certain distance from each other, and called valvulæ conniventes. Now this disposition will be found to afford a farther proof of that divine wisdom, which the anatomist and physiologist cannot fail to discover in all their pursuits.

—For if the intestinal canal was much shorter than it naturally is; if instead of the present circumvolutions it passed in a direct course from the stomach; and if its inner surface was smooth and destitute of valves; the aliment would consequently pass with great rapidity to the anus, and sufficient time would be wanting to assimilate the chyle, and for the necessary absorption of it into the lacteals: so that the body would be deprived of the supply of nutrition, which is so essential to life and health; but the length and circumvolutions of the intestines, the inequality of their internal surface,

(u) The Abbé Spallanzani, who has lately written upon digestion, finds, from a variety of experiments, made upon quadrupeds, birds, and fishes, that digestion goes on for some time after death, though far less considerable than in living animals; but heat is necessary in many animals, or at least promotes it in a much greater degree. He found also, that when the stomach was cut out of the body, it had somewhat of the power of digestion, though this was trifling when compared with that which took place when the stomach was left in the body. In not one of the animals was the great curvature of the stomach dissolved, or much eroded after death. There was often a little erosion, especially in different fishes; in which, when he had cleared the stomach of its contents, the internal coat was wanting. In other animals there was only a slight excoriation; and the injury

ANATOMY.

Sec. XIV. Of the Course of the Chyle, and of the Lymphatic System.

An infinite number of very minute vessels, called the lacteal veins, arise like net-work from the inner surface of the intestines, (but principally from the jejunum and ilium,) which are defined to imbibe the nutritious fluid or chyle. These vessels, which were discovered by Asellius in 1622 (1), pass obliquely through the coats of the intestine, and running along the mesentery, unite as they advance, and form larger branches, all of which pass through the mesenteric or conglobate glands, which are very numerous in the human subject. As they run between the intestines and these glands, they are styled vena lactea primus genus: but after leaving these glands, they are found to be less numerous, and being increased in size, are then called vena lactea secundum genus, which go to deposit their contents in the thoracic duct, through which the chyle is conveyed into the blood.

This thoracic duct begins about the lower part of the first vertebra lumbarum, from whence it passes up by the side of the aorta, between that and the vena azygos, close to the vertebrae, being covered by the pleura. Sometimes it is found divided into two branches; but they usually unite again into one canal, which opens into the left subclavian vein, after having run a little way in an oblique course between its coats. The subclavian vein communicates with the vena cava, which passes to the right articles of the heart.

The lower part of this duct being usually larger than any other part of it, has been named receptaculum chyli, or Pequot’s receptacle, in honour of the anatomist who first discovered it in 1651. In some quadrupeds, * Henfax’s in turtle* and in fowl, this enlargement * is more considerable in proportion to the size of the duct, than it usually is in the human subject, where it is not commonly found large enough to merit the name of receptaculum.

Opportunities of observing the lacteals in the human subject do not often occur; but they may be easily demonstrated in a dog or any other quadruped that is killed two or three hours after feeding upon milk, for then they appear filled with white chyle.

But these lacteals which we have described, as passing from the intestines through the mesentery to the thoracic duct, compose part only of a system of vessels which perform the office of absorption, and which constitute, with their common trunk the thoracic duct, and the conglobate glands that are dispersed through the body, what may be styled the lymphatic system. So that what is said of the structure of one of these series of vessels may very properly be applied to that of the other.

The lymphatic veins (K) are minute pellucid tubes, Lymphatic, which, like the lacteals, direct their course towards the centre of the body, where they pour a colourless fluid into the thoracic duct. The lymphatics from all the lower parts of the body gradually unite as they approach this duct, into which they enter by three or four very large trunks, that seem to form the lower extremity of this canal, or receptaculum chyli, which may be considered as the great trunk of the lymphatic system. The lacteals open into it near the same place; and the lymphatics, from a large share of the upper parts of the body, pour their lymph into different parts of this duct as it runs upwards, to terminate in the left subclavian vein. The lymphatics from the right side of the neck, thorax, and right arm, &c. terminate in the right subclavian vein.

As the lymphatics commonly lie close to the large blood-vessels, a ligature passed round the crural artery in a living animal, by including the lymphatics, will occasion a distention of these vessels below the ligature, so as to demonstrate them with ease; and a ligature passed round the thoracic duct, instantly after killing an animal, will, by stopping the course of its contents,
A NAT O M Y.

* Sur le mouvement du sang. Ex. 293, 298.

1. The Male Organs.

THE male organs of generation have been usually divided into the parts which serve to prepare the semen from the blood, and those which are destined to convey it into the womb. But it seems to be more proper to distinguish them into the preparing, the containing, and the expelling parts, which are the different offices of the testes, the vesiculae seminales, and the penis; and this is the order in which we propose to describe them.

The testes are two glandular bodies, serving to secrete the semen from the blood. They are originally formed and lodged within the cavity of the abdomen; and it is not till after the child is born, or very near that time, that they begin to pass into the groin, and from thence into the ferorum (m). By this disposition they

In the dead body they may be easily demonstrated by opening the artery ramifying through any viscus, as in the spleen, for instance, and then throwing in air; by which the lymphatics will be dilated. One of them may then be punctured, and mercury introduced into it through a blow-pipe.

It sometimes happens in dissecting ruptures, that the intestine is found in the same sac, and in contact with the testes. This appearance was at first attributed to a supposed laceration of the peritoneum; but later observations, by pointing out the fixation of the testicles in the fossa, have led to prove, that the testicles, as it defends into the ferorum, carries with it a portion or elongation of the peritoneum, which becomes its tunica vaginalis, or a kind of sac, in which the testicle is lodged, as will be explained in the course of this section.

The communication between this sac and the cavity of the abdomen, is usually soon cut off; but in some subjects
Part III. ANATOMY.

Of the Abdomen.

they are very wisely protected from the injuries to which they would be liable to be exposed, from the different positions of the child at the time of parturition.

The testicles in this state are loosely attached to the psoas muscles, by means of the peritoneum by which they are covered; and they are at this time of life connected in a very particular manner to the parietes of the abdomen, and likewise to the ferrotum, by means of a sub stance which Mr. Hunter calls the ligament or gubernaculum testis, because it connects the testicles with the ferrotum, and directs its course in its descent. This gubernaculum is of a pyramidal form, with a bulbous head fixed to the lower end of the testicle and epididymis, and looses its lower and slender extremity in the cellular membrane of the ferrotum. It is difficult to ascertain what the structure and composition of this gubernaculum is, but it is certainly vascular and fibrous; and, from certain circumstances, it seems to be in part composed of the cremaster muscle, running upwards to join the lower end of the testicle.

We are not to suppose that the testicle, when descended into the ferrotum, is to be seen loose as a piece of gut or omentum would be in a common hernial sac. But the same is, no doubt, to be seen loose in the ferrotum before the gubernaculum testis, from the abdomen they descend through the abdominal furrounds the testicle, closely attached behind to the peritoneal, which is closely invested with the cremaster muscle, and becomes united to the posterior part, and thus perfectly surrounds the testicle as it were in a purse.

The testicles of the fetus differ only in their size and situation from those of the adult. In their passage from the abdomen they descend through the abdominal rings into the ferrotum, where they are supported and defended by various integuments.

What the immediate cause of this descent is, has not yet been satisfactorily determined. It has been ascribed to the effect of respiration, but the testicles have sometimes been found in the ferrotum before the child has breathed; and it does not seem to be occasioned by the action of the cremaster muscle, because the same effect would be liable to happen to the hedgehog, and some other quadrupeds, whose testicles remain in the abdomen during life.

The ferrotum, which is the external or common covering of both testicles, is a kind of sac formed by the common integuments, and externally divided into two equal parts by a prominent line called the raphe.

In the inner part of the ferrotum we meet with a cellular coat called the dartos (s), which by its duplicature divides the ferrotum into two equal parts, and forms what is called the septum ferarii, which corresponds with the raphe. The division which is so often observed to take place in the ferrotum of the healthy subject, when excited by cold or by the stimulus of venery, seems to be very properly attributed to the contractile motion of the skin, and not to any muscular fibres, as is the case in dogs and some other quadrupeds.

The ferrotum, then, by means of its septum, is found to make two distinct bags, in which the testicles, in their passage through the abdominal cavity, are loosely lodged and separated from each other. These coats are the cremaster, the tunica vaginalis, and the tunica albuginea. The first of these is composed of muscular fibres, and is to be considered only as a partial covering of the testicle; for it surrounds only the spermatic chord, and terminates upon the upper and external parts of the tunica vaginalis testis, serving to draw up and suspend the testicle (o). The tunica vaginalis testis has already been described as being a thin production of the peritoneum, loosely adhering everywhere to the testicle, which it includes as it were in a bag. The tunica albuginea is a firm, white, and very compact membrane of a glistering appearance, which immediately invests the body of the testicle and the epididymis; serving in some measure to connect them to each other, but without extending itself at all to the spermatic chord. This tunica albuginea serves to confine the growth of the testicle and epididymis within certain limits, and by giving them a due degree of firmness, enables them to perform their proper functions.

Having removed this last tunic, we discover the substance of the testicle itself, which appears to be made up of an infinite number of very elastic filaments, which may be best distinguished after macerating the testicle in water. Each testicle is made up of the spermatic artery and vein, and the excretery vessels or tubuli feminiferi. There are likewise a great number of absorbent vessels, and some branches of nerves to be met with in the testicles.

The spermatic arteries arise one on each side from the aorta, generally about an inch below the emunctory. The right spermatic vein commonly passes into the vena cava; but the left spermatic vein usually empties itself into the emunctory on that side; and it is suppos...
ANATOMY.

Of the Abdomen.

As this latter fluid of the testicle is obliged to do in its course to the seminal vesicle, it deposits the semen, which by an infinite number of convolutions form a quantity of spermatogenous semen, that is discharged by ten or twelve excretory ducts into the urethra, on each side of the openings of the vesiculae seminales at the same time, and from the same causes that the semen is expelled. As this latter fluid is found to be exceedingly limpid in the vesiculae seminales of the dead subject, it probably owes its whiteness and viscidity to this liquor of the prostatc.

The penis, which is to be considered as the vehicle or active organ of procreation, is composed of two columns, the corpora cavernosa, and corpus spongiosum. The corpora cavernosa, which constitute the greatest part of the penis, may be described as two cylindrical ligamentous tubes, each of which is composed of an infinite number of minute cells of a spongy texture, which communicate with each other. These two bodies are of a very plant texture, and capable of considerable dilatation; and being united laterally to each other, occasion by this union a space above and another below. The uppermost of these spaces is filled by the blood vessels, and the lower one, which is larger than the other, by the urethra and corpus spongiosum. These two cavernous bodies are at first only separated by a partition of tendinous fibres, which allow them to communicate with each other; but they afterwards deviate from each other like the branches of the letter Y, and diminishing gradually in size, are attached.

(p) The testicles were named didymi by the ancients, and the name of this part was given to it on account of its situation upon the testicle.

(q.) That the bags called vesiculae seminales are reservoirs of semen, is a circumstance which has been by anatomists universally believed. Mr. J. Hunter, however, from several circumstances, has been induced to think this opinion erroneous.

He has examined these vesiculae in people who have died suddenly, and he found their contents to be different in their properties from the semen. In those who had lost one of the testicles, or the use of one of them, by disease, both the vesiculae were full, and their contents similar. And in a fetus naturae, where there was no communication between the vasa deferentia and vesiculae, nor between the vesiculae and penis, the same thing took place.

From these observations, he thinks we have a presumptive proof, that the semen can be absorbed in the body of the testicle and in the epididymis, and that the vesiculae secrete a mucus which they are capable of absorbing when it cannot be made use of: That the semen is not retained in reservoirs after it is secreted, and kept there till it is used; but that it is secreted at the time, in consequence of certain affections of the mind stimulating the testicles to this action.

He corroborates his observations by the appearance on dissection in other animals; and here he finds, That the shape and contents of the vesiculae vary much in different animals, while the semen in most of them he has examined is nearly the same: That the vasa deferentia in many animals do not communicate with the vesiculae: That the contents of the vesiculae of castrated and perfect animals are similar, and nearly equal in quantity, in no way resembling the semen as emitted from the animal in covo, or what is found in the vasa deferentia after death. He observes likewise, that the bulb of the urethra of perfect males is considerably larger than in castrated animals.

From the whole, he thinks the following inferences may be fairly drawn: That the bags called vesiculae seminales are not seminal reservoirs, but glands secreting a peculiar mucus; and that the bulb of the urethra is properly speaking the receptacle of the semen, in which it is accumulated previous to ejection.

But although he has endeavoured to prove that the vesiculae do not contain the semen, he has not been able to ascertain their particular use. He thinks, however, we may be allowed upon the whole to conclude, that they are, together with other parts, subservient to the purposes of generation.

Although the author has treated this subject very ably, and made many ingenious observations, some things may be objected to what he had advanced; of which the following are a few: That those animals who have
of the abdomen.

The corpus spongiosum penis, or corpus spongiosum urethrae, as it is styled by some authors, begins as soon as the urethra has passed the profate, with a thick origin almost like a heart, first under the urethra, and afterwards above it, becoming gradually thinner, and surrounding the whole canal of the urethra, till it terminates in a considerable expansion, and constitutes what is called the glans penis, which is exceedingly vascular, and covered with papillae like the tongue. The cuticle which lines the inner surface of the urethra, is continued over the glans in the same manner as it is spread over the lips.

The penis is invested by the common integuments, but the cutis is reflected back every where from the glans as it is in the eye-lids; so that it covers this part, when the penis is in a relaxed state, as it were with a hood, and from this use is called prepuce.

The prepuce is tied down to the under part of the glans by a small ligament called frenum, which is in fact only a continuation of the cuticle and cutis. There are many simple sebaceous follicles called glandulae odoriferae, placed round the basis of the glans; and the fluid they secrete serves to preserve the exquisite fineness of this part of the penis, and to prevent the ill effects of attrition from the prepuce.

The urethra may be defined to be a membranous canal, passing from the bladder through the whole extent of the penis. Several very small openings called lacunae, communicate with this canal, through which a mucous is discharged into it; and besides these, there are two glands, first described by Cowper, as secreting a fluid for lubricating the urethra, and called Cowper's glands (a); and Littre* speaks of a gland situated near the prostatic, as being destined for the same use.

The urethra being continued from the neck of the bladder, is to be considered as making part of the urinary passage; and it likewise affords a conveyance to the fermen, which we have observed is occasionally discharged into it from the vesicles feminales. The direction of this canal being first under and then before the pubis, occasions a winding in its course from the bladder to the penis not unlike the turns of the letter S.

The penis has three pair of muscles, the erecctores, acceleratores, and tranversales. They push the blood from the crura to the fore part of the corpora cavernosa. The first originate from the tuberosity of the ischium, and terminate in the corpora cavernosa. The acceleratores arise from the sphincter, and by their involuntary motion to compress the bulbous part of the urethra; and the tranversales are destined to afford a passage to the fermen, by dilating the canal of the urethra.

The arteries of the penis are chiefly derived from the internal iliacs. Some of them are supposed to terminate by a considerable number of orifices within the corpora cavernosa and corpus spongiosum; and others terminate in veins, which at last make up the vena magna dorsi penis, and other smaller veins, which are in general distributed in like order with the arteries.

Its nerves are large and numerous. They arise from the great sciatic nerve, and accompany the arteries in their course through the penis.

We have now described the anatomy of this organ; and there only remains to be explained, how it is enabled to attain that degree of firmness and duration which is essential to the great work of generation.

The greatest part of the penis has been spoken of as being of a spongy and cellular texture, plentifully supplied with blood-vessels and nerves, and as having muscles to move it in different directions. Now, the blood is constantly passing into its cells through the small branches of the arteries which open into them, and from thence as constantly returned by the veins, so long as the corpora cavernosa and corpus spongiosum continue to be in a relaxed and flaccid state. But when, from any nervous influence, or other means, which it is not necessary here to define or explain, the erecctores penis, ejaculatori feminis, levatores ani, &c. are induced to contract, the veins undergo a certain degree of compression, and the passage of the blood through them is so much impeded, that it collects in them in a greater proportion than they are enabled to carry off, so that the penis gradually enlarges; and being more and more forcibly drawn up against the os pubis, the vena magna itself is at length compressed, and the penis becomes fully distended. But as the cause which first occasioned this diffusion subsides, the penis gradually returns to its state of relaxation.

ANATOMIC writers usually divide the female organs of generation into external and internal. In the first division they include the montveseris, labia pudendi, perineum, clitoris, mons, and carunculae myrtiformes; and in the latter, the vagina with the uteru and its appendages.

§ 2. Female Organs of Generation.

ANATOMICAL writers usually divide the female organs of generation into external and internal. In the first division they include the mons veneris, labia pudendi, perineum, clitoris, mons, and carunculae myrtiformes; and in the latter, the vagina with the uterus and its appendages.

(a) Both Heister and Morgagni observe, that they have sometimes not been able to find these glands; so that they do not seem to exist in all subjects.

bags called vesiculae feminales perform copulation quickly; whereas others that want them, as in the dog kind, are tedious in copulation: That in the human body, at least, there is a free communication between the vasa deferentia and vesiculae; and in animals where the author has observed no communication between the vasa deferentia and vesiculae, there may be a communication by vesiculae not yet discovered, and which may be compared to the hepato-cystic ducts in fowls and fishes: That the fluid in the end of the vasa deferentia and the vesiculae feminales are similar, according to the author's own observation: That the vesiculae in some animals increase and decrease with the tenuity at particular seasons: That in birds and certain fishes, there is a dilatation of the ends of the vasa deferentia, which the author himself allows to be a reservoir for the fermen.

With regard to the circumstance of the bulb of the urethra answering the purpose of a reservoir, the author has mentioned no facts which tend to establish this opinion. See observations on certain parts of the Animal Economy.
The meson cocudri, which is placed on the upper part of the symphysis pubis, is internally composed of adipose membranes, which makes it soft and prominent: it divides into two parts called labia pudendi, which descending towards the rectum, from which they are divided by the perineum, form what is called the fourchette. The perineum is that flabby space which extends about an inch and an half from the fourchette to the anus, and from thence about two inches to the coccyx.

The labia pudendi being separated, we observe a fulcus called fossa magna; in the upper part of which is placed the clitoris, a small round spongy body, in some measure resembling the male penis; but impervious, composed of two corpora cavernosa, arising from the tuberosities of the os ischii; furnished with two pair of nurface, the erecrotor clitoridis, and the sphincter or constrictor offii vaginae; and terminating in a glans, which is covered with its prepuce. From the lower part, on each side of the fossa, past the nympha, two membranous and spongy folds which seem defined for useful purposes in parturition, by tending to enlarge the volume of the vagina as the child's head passes through it. Between these, about the middle of the fossa magna, we perceive the orifice of the vagina or os externum, closed by folds and wrinkles; and about half an inch above this, and about an inch below the clitoris, appears the meatus urinary or orifice of the urethra, much shorter, though somewhat larger, than in men, with a little prominence at its lower edge, which facilitates the introduction of the catheter.

The os externum is surmounted internally by several membranous folds called sarunulae myrtiformes, which are partly the remains of a thin membrane called hymen, that covers the vagina in children. In general the hymen is sufficiently open to admit the passage of the menstes, if it exists at the time of their appearance; sometimes, however, it has been found perfectly closed.

The vagina, situated between the urethra and the rectum, is a membranous cavity, surmounted especially at its external extremity with a spongy and vacular substance, which is covered by the sphincter offii vaginae. It terminates in the uterus, about half an inch above the os tinece, and is wider and shorter in women who have had children than in virgins.

All these parts are plentifully supplied with blood vessels and nerves. Around the nympha there are sebaceous follicles, which pour out a fluid to lubricate the inner surface of the vagina; and the meatus urinarius, like the urethra in the male subject, is constantly moistened by a nucus, which defends it against the acrimony of the urine.

The uteru is a hollow viscus, situated in the hypogastrie region between the rectum and bladder. It is destined to receive the first rudiments of the foetus, and to afford in the development of all its parts, till it arrives at a state of perfection, and is fitted to enter into the world, at the time appointed by the wife author of nature.

The uteru, in its unimpregnated state, resembles a pear in shape, somewhat flattened, with its fundus or bottom part turned towards the abdomen, and its cervix or neck surrounded by the vagina. The entrance into its cavity forms a little protuberance, which has been compared to the mouth of a trench, and is therefore called os tinece.

The substance of the uterus, which is of a confiderable thickness, appears to be composed of mucous and small ligamentous fibres, small branches of nerves, some lymphatics, and with arteries and veins innumerable. Its nerves are chiefly derived from the intercostal, and its arteries and veins from the hypogastric and spermatic. The membrane which lines its cervix, is a continuation of the inner membrane of the vagina, but the outer surface of the body of the uterus is covered with the peritoneum, which is reflected over it, and descends from thence to the intestinum rectum. This duplication of the peritoneum, by passing off from the sides of the uterus to the sides of the pelvis, is there firmly connected, and forms what are called ligamenta uteri latera; which not only serve to support the uterus, but to convey nerves and blood vessels to it.

The ligamenta uteri rotunda arise from the sides of the fundus uteri, and passing along within the fore-part of the ligamenta lata, descend through the abdominal rings, and terminate in the substance of the mons veneris. The substance of these ligaments is vascular, and although both they and the ligamenta lata admit the uterus in the virgin state, to move only about an inch up and down, yet in the course of pregnancy they admit of considerable defension, and after parturition return nearly to their original state with surprising quicknesses.

On each side of the inner surface of the uterus, in the angle near the fundus, a small orifice is to be discovered, which is the beginning of one of the tubes fallopiana. Each of these tubes, which are two in number, passing through the substance of the uterus, is extended along the broad ligaments, till it reaches the edge of the pelvis, from whence it reflects back; and turning over behind the ligaments, about an inch of its extremity is seen hanging loose in the pelvis, near the ovarium. These extremities, having a jagged appearance, are called fimbrize, or morfus diaboli. Each tube fallopiana is usually about three or four inches long. Their cavities are at first very small, but become gradually larger, like a trumpet, as they approach the fimbrize.

Near the fimbrize of each tube Fallopiana, about an inch from the uterus, is situated an oval body called ovarium, of about half the size of the male testicle. Each of these ovaria is covered by a production of the peritoneum, and hangs loose in the pelvis. They are of a flat and angular form, and appear to be composed of a white and cellular substance, in which we are able to discover several minute vessels filled with a coagulable lymph, of an uncertain number, commonly exceeding 12 in each ovary. In the female of ripe years, these vessels become exceedingly turgid, and a kind of yellow coagulum is gradually formed within one of them, which increases for a certain time. In conception, one of these mature ova is supposed to be impregnated with the male semen, and to be squeezed out of its nidus into the Fallopian tube; after which the ruptured part forms a substance which in some animals is of a yellow colour, and is therefore called corpus luteum; and it is observable, that the number of these scars or sifures in the ovarium, constantly corresponds with the number of foetuses excluded by the mother.
Man, being ever curious and inquisitive, has naturally been led to inquire after the origin of his existence; and the subject of generation has employed the philosophical world in all ages: but in following nature up to her minute recitals, the philosopher soon finds himself bewildered, and his imagination often supplies that which he so eagerly wishes to discover, but which is defined perhaps never to be revealed to him. Of the many theories which have been formed on this subject, that of the ancient philosophers seems to have been the most simple: they considered the male semen as alone capable of forming the fetus, and believed that the female only afforded it a lodging in the womb, and supplied it with nourishment after it was perfectly formed. This opinion, however, soon gave place to another, in which the female was allowed a more considerable share in conception.

This second system considered the fetus as being formed by the mixture of the seminal liquor of both sexes, by a certain arrangement of its several particles in the uterus. But in the 16th century, vehicles or eggs were discovered in the ovaria or female testicles; the fetus had been found sometimes in the abdomen, and sometimes in the Fallopian tubes; and the two former opinions were exploded in favour of a new doctrine. The ovaria were compared to a bunch of grapes, being supposed to contain vehicles, each of which had a stalk; so that it might be disengaged without hurting the rest, or spilling the liquor it contained. Each vehicle was said to include a little animal, almost complete in all its parts; and the vapour of the male semen being conveyed to the ovarium, was supposed to produce a fermentation in the vehicle, which approached the nearest to maturity; and thus inducing it to disengage itself from the ovarium, it passed into the tuba Fallopiana, thro' which it was conveyed to the uterus. Here it was supposed to take root like a vegetable seed, and to form, with the vehicles originating from the uterus, what is called the placenta; by means of which the circulation is carried on between the mother and the fetus.

This opinion, with all its absurdities, continued to be almost universally adopted till the close of the same century, when Liewenhoek, by means of his glasses discovered certain opaque particles, which he described as so many animalcules, floating in the seminal fluid of the male.

This discovery introduced a new scheme among the philosophers of that time, and gave rise to a system which is not yet entirely exploded. According to this theory the male semen passing into the tube Fallopiana, one of the animalcules penetrates into the substance of the ovarium, and enters into one of its vehicles or ovum. This impregnated ovum is then squeezed from its hull, through the coats of the ovarium, and being feized by the fimblure, is conducted through the tube to the uterus, where it is nourished till it arrives at a state of perfection. In this system there is much ingenuity; but there are certain circumstances supposed to take place, which have been hitherto inexplicable. A celebrated modern writer, M. Buffon, endeavours to restore, in some measure, the most ancient opinion, by allowing the female semen a share in this office; affirming, that animalcules or organic particles are to be discovered in the seminal liquor of both sexes: he derives the female semen from the ovaria, and he contends that no ovum exists in those parts. But in this idea he is evidently mistaken; and the opinion now most generally adopted is, that an impregnation of the ovum, by the influence of the male semen, is essential to conception (a). That the ovum is to be impregnated, there can be no doubt; but as the manner in which such an impregnation is supposed to take place, and the means by which the ovum afterwards gets into the Fallopian tube, and from thence into the uterus, are still founded chiefly on hypothesis, we will not attempt to extend farther the investigation of a subject concerning which so little can be advanced with certainty.

Opportunities of differing the human gravid uterus occurring but seldom, the state of the embryo (b) immediately after conception cannot be perfectly known.

When the ovum descends into the uterus, it is supposed to be very minute; and it is not till a considerable time after conception that the rudiments of the embryo begin to be ascertained.

About the third or fourth week the eye may discover the first lineaments of the fetus; but these lineaments are as yet very imperfect, it being only about the size of a horse-fly. Two little vehicles appear in an almost transparent jelly; the largest of which is defined to become the head of the fetus, and the other smaller one is reserved for the trunk. But at this period no extremities are to be seen; the umbilical cord appears only as a very minute thread, and the placenta does not as yet absorb the red particles of the blood. At six weeks, not only the head but the features of the face begin to be developed. The nose appears like a small prominent line, and we are able to discover another line under it, which is defined for the separation of the lips. Two black points appear in the place of eyes, and two minute holes mark the ears. At the sides of the trunk, both above and below, we see four minute protuberances, which are the rudiments of the arms and legs. At the end of eight weeks the body of the fetus is upwards of an inch in length, and both the hands and feet are to be distinguished. The upper extremities are found to increase faster than the lower ones, and the separation of the fingers is accomplished sooner than that of the toes.

At this period the human form may be decisively ascertained; all the parts of the face may be distinctly distinguished.

it has a caduca, though formerly it served as a place, its

But as we have not an opportunity of examining the same fetus at different periods of pregnancy, and as their size and length may be influenced by the constitution and mode of life of the mother, calculations of this kind must be very uncertain.

The fetus during all this time assumes an oval figure, which corresponds with the shape of the uterus. Its chin is found reclining on its breast with its knees drawn up towards its chin, and its arms folded over them. But it seems likely, that the posture of some of these parts is varied in the latter months of pregnancy, so as to cause those painful twitches which its mother usually feels from time to time. In natural cases, its head is probably placed towards the os tincae from the time of conception to that of its birth; though formerly it was considered as being placed towards the fundus uteri till about the eighth or ninth month, when the head, by becoming specifically heavier than the other parts of the body, was supposed to turn as it descends.

The capacity of the uterus increases in proportion to the growth of the fetus, but without becoming thinner in its substance, as might naturally be expected. The nourishment of the fetus, during all this time, seems to be derived from the placenta, which appears to be originally formed by that part of the ovum which is next the fundus uteri. The remaining part of the ovum is covered by a membrane called the spongy chorion (v); within which is another called true chorion, which includes a third termed amnios (v): this contains a watery fluid, which is the liquor amnii (w), in which the fetus floats till the time of its birth. On the side next the mother it has a production continued from the spongy chorion. The amnios and chorion are remarkably thin and transparent, having no blood-vessels entering into their composition. The spongy chorion is opaque and vascular.

In the first months of pregnancy, the involucre bears a large proportion to its contents; but this proportion is afterwards reversed as the fetus increases in bulk.

The placenta, which is the medium through which the blood is conveyed from the mother to the fetus, and the manner in which this conveyance takes place, deserve next to be considered.

The placenta is a broad, flat, and spongy substance, like a cake, closely adhering to the inner surface of the womb, usually near the fundus, and appearing to be chiefly made up of the ramifications of the umbilical arteries and vein, and partly of the extremities of the uterine vessels. The arteries of the uterus discharge their contents into the substance of this cake; and the veins of the placenta, receiving the blood either by a direct communication of vessels, or by absorption, at length form the umbilical vein, which passes on to the sinus of the vena portae, and from thence to the vena cava, by means of the canalis venofus, a communication that is closed in the adult. But the circulation of the blood through the heart is not conducted in the fetus as in the adult: in the latter, the blood is carried from the right auricle of the heart through the pulmonary artery, and is returned to the left auricle by the pulmonary vein; but a dilatation of the lungs is essential to the passage of the blood through the pulmonary veins, and this dilatation cannot take place till after the child is born and has expired. This deficiency, however, is supplied in the fetus by the immediate communication between the right and left auricle, through an oval opening, in the septum which divides the two auricles, called foramen ovale. The blood is likewise transmitted from the pulmonary artery to the aorta, by means of a duct called canalis arteriosus, which, like the canalis venosus, and foramen ovale, gradually closes after birth.

The blood is returned again from the fetus through two arteries called the umbilical arteries, which arise from the iliacs. These two vessels taking a winding course with the vein, form with that, and the membranes by which they are surrounded, what is called the umbilical chord. These arteries, after ramifying through the substance of the placenta, discharge their blood into the veins of the uterus; in the same manner as the uterine arteries discharged their blood into the branches

(v) Dr Hunter has described this as a lamella, from the inner surface of the uterus. In the latter months of pregnancy it becomes gradually thinner and more connected with the chorion: he has named it membrana caduca, or decidua, as it is cast off with the placenta. Signior Scarpa, with more probability, considers it as being composed of an infiltrated coagulable lymph.

(v) In some quadrupeds, the urine appears to be conveyed from the bladder through a canal called uracus, to the atlantois, which is a reservoir, resembling a long and blind gut, situated between the chorion and amnios. The human fetus seems to have no such reservoir, though some writers have supposed that it does exist. From the top of the bladder a few longitudinal fibres are extended to the umbilical chord; and these fibres have been considered as the uracus, though without having been ever found pervious.

(w) The liquor amnii coagulates like the lymph. It has been supposed to pass into the esophagus, and to afford nourishment to the fetus; but this does not seem probable. Children have come into the world without an esophagus, or any communication between the stomach and the mouth; but there has been no well at the birth of a child's having been born without a placenta; and it does not seem likely, that any of the fluid can be absorbed through the pores of the skin, the skin in the fetus being every where covered with a great quantity of mucus.
Part III.

Anatomy.

Of the branches of the umbilical vein. So that the blood is constantly passing in at one side of the placenta and out at the other; but in what particular manner it gets through, the placenta is a point not yet determined.

**PART III.**
THE thorax, or chest, is that cavity of the trunk which extends from the clavicles, or the lower part of the neck, to the diaphragm, and includes the vital organs, which are the heart and lungs; and likewise the trachea and oesophagus. This cavity is formed by the ribs and vertebrae of the back, covered by a great number of muscles, and by the common integuments, and anteriorly by two glandular bodies called the breasts. The spaces between the ribs are filled up by muscular fibres, which from their situation are called intercostal muscles.

Sect. I. Of the Breasts.

The breasts may be defined to be two large conglomerate glands, mixed with a good deal of adipose membrane. The glandular part is composed of an infinite number of minute arteries, veins, and nerves.

The arteries are derived from two different trunks; one of which is called the internal, and the other the external mammary artery. The first of these arteries, from the subclavian, and the latter from the axillary.

The veins every where accompany the arteries, and are distinguished by the same name. The nerves are chiefly from the vertebral pairs. Like all other conglomerate glands, the breasts are made up of a great many small distinct glands, in which the milk is secreted from the ultimate branches of arteries. The excretory ducts of these several glands gradually uniting as they approach the nipple, from the tubuli lacticiferi, which are usually more than a dozen in number, and open at its apex, but have little or no communication, as has been supposed, at the root of the nipple. These ducts, in their course from the glands, are surrounded by a ligamentary elastic fibulature, which terminates with them in the nipple. Both this fibulature, and the ducts which it contains, are capable of considerable extension and contraction; but in their natural state are moderately corrugated, so as to prevent an involuntary flow of milk, unless the deftending force be very great from the accumulation of too great a quantity.

The whole substance of the nipple is very spongy and elastic: its external surface is uneven, and full of small tubercles. The nipple is surrounded with a disc or circle of a different colour, called the areola; and on the inside of the skin, under the areola, are many sebaceous glands, which pour out a mucous to defend the areola and nipple: for the skin upon these parts is very thin; and the nervous papillæ lying very bare, are much exposed to irritation.

The breasts are formed for the secretion of milk, which is destined for the nourishment of the child for some time after its birth. This secretion begins to take place soon after the delivery, and continues to flow for many months in very large quantities, if the woman suckles her child.

The operation of suction depends on the principles of the air-pump, and the flow of milk through the lactiferous tubes is facilitated by their being stretched out.

The milk, examined chemically, appears to be composed of oil, mucilage, and water, and of a considerable quantity of sugar. The generality of physiologists have supposed that, like the chyle, it frequently retains the properties of the aliment and medicines taken into the stomach; but from some late experiments, this supposition appears to be ill-founded.

Sect. II. Of the Pleura.

The cavity of the thorax is every where lined by a membrane of a firm texture called pleura. It is composed of two distinct portions or bags, which, by being applied to each other laterally, form a septum called mediastinum; which divides the cavity into two parts, and is attached posteriory to the vertebrae of the back, and anteriorly to the sternum. But the two laminae of which this septum is formed, do not every where adhere to each other; for at the lower part of the thorax they are separated, to afford a lodgement to the heart; and at the upper part of the cavity, they receive between them the thymus.

The pleura is plentifully supplied with arteries and veins from the internal mammary and the intercostals. Its nerves, which are very inconsiderable, are derived chiefly from the dorsal and intercostal nerves.

The surface of the pleura, like that of the peritoneum and other membranes lining cavities, is constantly bedewed with a serous moisture (w) which prevents adhesion of the visceræ.

The mediastinum, by dividing the breast into two cavities, obviates many inconveniences, to which we should otherwise be liable. It prevents the two lobes of the lungs from compressing each other when we lie on one side; and consequently contributes to the freedom of respiration, which is disturbed by the least pressure on the lungs. If the point of a sword penetrates between the ribs into the cavity of the thorax, the lungs on that side cease to perform their office; because the air being admitted through the wound, prevents the dilatation of that lobe; while the other lobe, which is separated from it by the mediastinum, remains unhurt, and continues to perform its function as usual.

Sect. III. Of the Thymus.

The thymus is a glandular substance, the use of which is not perfectly ascertained, its excretory duct not having yet been discovered. It is of an oblong shape.

(w) When this fluid is exhaled in too great a quantity, or is not properly carried off, it accumulates and constitutes the hydrops pectoris.
ANATOMY.

Part IV.

Sect. V. Of the Trachea.

The trachea or windpipe, is a cartilaginous and membranous canal, through which the air paffes into the lungs. Its upper part, which is called the larynx, is composed of five cartilages. The uppermost of these cartilages is placed over the glottis or mouth of the larynx, and is called epiglottis, which has been before spoken of, as closing the passage to the lungs in the act of swallowing. At the sides of the glottis are placed the two arytenoide cartilages, which are of a very complex figure, not easy to be described. The anterior and larger part of the larynx is made up of two cartilages: one of which is called thyroides or stenophysis, from its being shaped like a buckler; and the other ericoides or annularis, from its resembling a ring. Both these cartilages may be felt immediately under the skin, at the fore part of the throat, and the thyroids, by its convexity, forms an eminence called pomum adam, which is usually more considerable in the male than in the female subject.

All these cartilages are united to each other by means of very elastic, ligamentous fibres; and are enabled, by the assistance of their several muscles, to dilate or contract the passage of the larynx, and to perform that variety of motion which seems to point out the larynx as the principal organ of the voice; for when the air paffes out through a wound in the trachea, it produces no sound.

These cartilages are moistened by a mucus, which seems to be secreted by minute glands situated near them. The upper part of the trachea is covered anteriorly and laterally by a considerable body, which is supposed to be of a glandular structure, and from its situation near the thyroid cartilage is called the thyroid gland; though its excretory duct has not yet been discovered, or its real use ascertained.

The glottis is interiorly covered by a very fine membrane, which is moistened by a conflant supply of a watery fluid. From the larynx the canal begins to take the name of trachea or affera arteria, and extends from thence as far down as the third or fourth vertebra of the back, where it divides into two branches, which are the right and left bronchial tube. Each of these bronchi (v) ramifies through the substance of that lobe of the lungs to which it is distributed, by an infinite number of branches, which are formed of cartilages separated from each other like those of the trachea, by an intervening membranous and ligamentary substance. Each of these cartilages is of an angular figure; and as they become gradually less and less in their diameter, the lower ones in some measure received into those above them, when the lungs, after being inflated, gradually collapse by the air being pulsed

(x) Anatomical writers have usually described the diaphragm as being made up of two muscles united by a middle tendon; and these two portions or crura form what they speak of as the inferior muscul, arising from the fides and fore part of the vertebra.

(v) The right bronchial tube is usually found to be somewhat shorter and thicker than the left; and M. Portal, who has published a memoir on the action of the lungs on the aorta in respiration, observes, that the left bronchial tube is closely connected by the aorta; and from some experiments he is induced to conclude, that in the first respirations, the air only enters into the right lobe of the lungs. *Memoires de l' Academie Royale des Sciences, 1769.*
Of the Thorax.

Part IV. ANATOMY.

Thorax. ed out from them in expiration. As the branches of the bronchi become more minute, their cartilages become more and more angular and membranous, till at length they are found to be perfectly membranous, and at last become invisible.

The trachea is furnished with fleshy or muscular fibres; some of which pass through its whole extent longitudinally, while the others are carried round it in a circular direction; so that by the contraction or relaxation of these fibres, it is enabled to shorten or lengthen itself, and likewise to dilate or contract the diameter of its passage.

The trachea and its branches, in all their ramifications, are furnished with a great number of small glands which are lodged in their cellular substance, and discharge a mucous fluid on the inner surface of these tubes.

The cartilages of the trachea, by keeping it constantly open, afford a free passage to the air, which we are obliged to inceasingly respire; and its membranous part, by being capable of instantly open, are obliged to be greater or less quantity, and with more or less velocity, as may be required in singing or in declamation. This membranous structure of the trachea posteriorly, seems likewise to assist in the digest of the food, by preventing that impediment to its passage down the oesophagus, which might be expected if the cartilages were complete rings.

The trachea receives its arteries from the carotid and subclavian arteries, and its veins pass into the jugulars. Its nerves arise from the recurrent branch of the eighth pair, and from the cervical plexus.

Sect. VI. Of the Lungs.

The lungs fill the greater part of the cavity of the breast. They are of a soft and fpongy texture, and are divided into two lobes, which are separated from each other by the mediastinum, and are externally covered by a production of the pleura. Each of these is divided into two or three lesser lobes; and we commonly find three in the right side of the cavity, and two in the left.

To discover the structure of the lungs, it is required to follow the ramifications of the bronchi, which were described in the last section. These becoming gradually more and more minute, at length terminate in the cellular spaces or vesicles, which make up the greatest part of the substance of the lungs, and readily communicate with each other.

The lungs seem to possess but little sensibility. Their nerves, which are small, and few in number, are derived from the intercostal and eighth pair. This last pair having reached the thorax, sends off a branch on each side of the trachea, called the recurrent, which reconstitutes the back of the trachea, to which it furnishes branches in its ascent, as well as to the oesophagus, but it is chiefly distributed to the larynx and its mucous. By dividing the recurrent and superior laryngeal nerves at their origin, an animal is deprived of its voice.

There are two series of arteries which carry blood to the lungs: these are the arterial bronchial, and the pulmonary artery.

The arterial bronchial branches begin usually by two branch-
blood, the pulmonary artery begins again to be distended, the stimulus is renewed, and the same progress is repeated, and continues to be repeated, in a regular succession, during life: for though the muscles of respiration, having a mixed motion, are (unlike the heart) in some measure dependent on the will, yet no human being, after having once expired, can live many moments without it. In an attempt to hold one's breath, the blood soon begins to distend the veins, which are unable to empty their contents into the heart; and we are able only, during a very little time, to resist the stimulus to inspiration. In drowning, the circulation seems to be stopped upon this principle: and in hanging, the pressure made on the jugular veins, may cooperate with the stoppage of respiration in bringing on death.

Till within these few years physiologists were entirely ignorant of the use of respiration. It was at length discovered in part by the illustrious Dr Priei'sley. He found that the air expired by animals was phlogisticated; and that the air was fitted for respiration, or for supporting animal life, in proportion as it was free from the phlogistic principle. It had long been observed, that the blood in passing through the lungs acquired a more florid colour. He therefore suspected, that it was owing to its having imparted phlogiston to the air: and he satisfied himself of the truth of this idea by experiments, which showed, that the cistern of extravasated blood, phlogisticated air in proportion as it left its dark colour. He farther found, that blood thus reddened had a strong attraction for phlogiston; insomuch that it was capable of taking it from phlogisticated air, thereby becoming of a darker colour.

From hence it appeared that the blood, in its circulation through the arterial vessels, imbibes a considerable quantity of phlogiston, which is discharged from it to the air in the lungs.

This discovery has since been prosecuted by two very ingenious physiologists, Dr Crawford and Mr Elliot. It has been shown by professors Black and Irvine, that different bodies have different capacities for containing fire. For example, that oil and water, when equally hot to the fene and the thermometer, contain different proportions of that principle; and that unequal quantities of it are required, in order to raise those substances to like temperatures. The enquiries of Dr Crawford and Mr Elliot tend to prove, that the capacities of bodies for containing fire are diminished by the addition of phlogiston, and increased by its separation: the capacity of calx of antimony, for example, being greater than that of the antimony itself. Common air contains a great quantity of fire; combustible bodies very little. In combustion, a double elective attraction takes place: the phlogiston of the body being transferred to the air, the fire contained in the air to the combustible body. But as the capacity of the latter is not increased so much as that of the former is diminished, only part of the extricated fire will be absorbed by the body. The remainder therefore will raise the temperature of the compound; and hence we may account for the heat attending combustion. As the use of respiration is to dephlogisticate the blood, it seems probable, that a like double elective attraction takes place in this process; the phlogiston of the blood being transferred to the air, and the fire contained in the air to the blood; but with this difference, that the capacities being equal, the whole of the extricated fire is absorbed by the latter. The blood in this state circulating through the body, imbibes phlogiston, and of course gives out its fire; part only of which is absorbed by the parts furnishing the phlogiston, the remainder, as in combustion, becoming sensible; and is therefore the cause of the heat of the body, or what is called animal heat.

In confirmation of this doctrine it may be observed, that the venous blood contains less fire than the arterial; combustible bodies less than incombustible ones; and that air contains less of this principle, according as it is rendered, by combination with phlogiston, less fit for respiration (z).

In ascending very high mountains, respiration is found to become short and frequent, and sometimes to be attended with a spitting of blood. These symptoms seem to be occasioned by the air being too rare and thin to dilate the lungs sufficiently; and the blood gradually accumulating in the pulmonary vessels, sometimes bursts through their coats, and is brought up by coughing. This has likewise been accounted for in a different way, by supposing that the air contained in the blood, not receiving an equal pressure from that of the atmosphere, expands, and at length ruptures the very minute branches of the pulmonary vessels; upon the same principle that fruits and animals put under the receiver of an air-pump, are seen to swell as the outer air becomes exhausted. But Dr Darwin of Litchfield has lately published some experiments, which seem to prove, that no air or elastic vapour does exist in the blood-vessels, as has been generally supposed; and he is induced to impute the spitting of blood, which has sometimes taken place in ascending high mountains, to accident, or to violent exertions: as it never happens to animals that are put into the exhausted receiver of an air-pump, where the diminution of pressure increases in every rising lights greater than on the summit of the highest mountains.

Sect. VIII. Of the Voice.

Respiration has already been described as affording us many advantages; and next to that of life, its most important use seems to be that of forming the voice and speech. The ancients, and almost all the moderns, have considered the organ of speech as a kind of musical instrument, which may be compared to a flute, to an hautboy, to an organ, &c. and they argue after the following manner.

The trachea, which begins at the root of the tongue, and goes to terminate in the lungs, may be compared to the pipe of an organ, the lungs dilating like bellows during the time of inspiration; and as the air is driven out from them in expiration, it finds its passage striated by the cartilages of the larynx, against which it strikes.

(z) See Crawford's Experiments and Observations on Animal Heat, and Elliot's Philosophical observations.
Part IV. ANATOMY.

Of the Thorax.

Strikes. As these cartilages are more or less elastic, they occasion in their turn more or less vibration in the air, and thus produce the sound of the voice; the variation in the found and tone of which depends on the state of the glottis, which, when strained, produces an acute tone, and a grave one when dilated.

The late M. Ferein communicated to the French Academy of Sciences a very ingenious theory on the formation of the voice. He considered the organ of the voice as a fpring, as well as a wind, instrument; so that what art has hitherto been unable to construct, and what both the fathers Mersenne and Kircher, so much wished to see, M. Ferein imagined he had at length discovered in the human body. He observes, that there are at the edges of the glottis certain tendinous chords, placed horizontally across it, which are capable of considerable vibration, so as to produce sound, in the same manner as it is produced by the strings of a violin or a harp-chord; and he supposes that the air, as it passes out from the lungs, acts as a bow on these strings, while the efforts of the breast and lungs regulate its motion, and produce the variety of tones. So that according to this system the variation in the voice is not occasioned by the dilatation or contraction of the glottis, but by the diffusion or relaxation of these strings, the found being more or less acute in proportion as they are more or less stretched out. Another writer on this subject supposes, that the organ of voice is a double instrument, which produces in unison two sounds of a different nature; one by means of the air, and the other by means of the chords of the glottis. Neither of these systems, however, are universally adopted. They are both liable to insuperable difficulties; so that the manner in which the voice is formed has never yet been satisfactorily ascertained: we may observe, however, that the sound produced by the glottis is not articulate. To effect this, it is required to pass through the mouth, where it is differently modified by the action of the tongue, which is either pushed against the teeth, or upwards towards the palate; detaining it in its passage, or permitting it to flow freely, by contracting or dilating the mouth.

Sect. IX. Of Dejection.

By dejection we mean the act of voiding the faces at the anus; and an account of the manner in which this is conducted was reserved for this part of the work, because it seemed to require a knowledge of respiration to be perfectly understood.

The intestines were described as having a peristaltic motion, by which the faces are gradually advancing towards the anus. Now, whenever the faces are accumulated in the intestinum rectum in a sufficient quantity to become troublesome, either by their weight or acrimony, they excite a certain uneasiness which induces us to go to stool. To effect this, we begin by making a considerable inspiration; in consequence of which the diaphragm is carried downwards towards the lower belly; the abdominal muscles are at the same time contracted in obedience to the will; and the intestines being compressed on all sides, the resistance of the sphincter is overcome, and the faces pass out at the anus; which is afterwards drawn up by its longitudinal fibres, which are called levator ani, and then by means of its sphincter is again contracted; but it sometimes happens, as in dysenteries for instance, that the faces are very liquid, and have considerable acrimony; and then the irritation they occasion is more frequent, so as to promote their discharge without any pressure from the diaphragm or abdominal muscles; and sometimes involuntarily, as is the case when the sphincter becomes paralytic.

Sect. X. Of the Pericardium, and of the Heart and its Auricles.

The two membranous bags of the pleura, which were described as forming the mediastinum, recede one from the other, so as to afford a lodgement to a firm membranous fasciculus, in which the heart is securely lodged; this fasciculus, which is the pericardium, appears to be composed of two tunics, united to each other by cellular membrane. The outer coat, which is thick, and in some places of a tendinous complexion, is a production of the mediastinum; the inner coat, which is extremely thin, is reflected over the auricles and ventricles of the heart, in the same manner as the tunica conjunctiva, after lining the eye lids, is reflected over the eye. This bag adheres to the tendinous part of the diaphragm, and contains a coagulable lymph, the liquor pericardii, which serves to lubricate the heart and facilitate its motions; and seems to be secreted and absorbed in the same manner as it is in the other cavities of the body.

The arteries of the pericardium are derived from the phrenic, and its veins pass into veins of the same name; its nerves are likewise branches of the phrenic. The size of the pericardium is adapted to that of the heart, being usually large enough to contain it loosely. As its cavity does not extend to the sternum, the lungs cover it in inspiration; and as it everywhere invests the heart, it effectually secures it from being injured by lymph, pus, or any other fluid, extravasated into the cavities of the thorax.

The heart includes two cavities or ventricles, which are separated from each other by a fibrous septum: one of these is called the right, and the other the left ventricle; though perhaps, with respect to their situation, it would be more proper to distinguish them into the anteriour and posterior ventricles.

The heart is externally covered by a very fine membrane; and its structure is perfectly muscular or fibrous, being composed of fibres which are described as passing in different directions; some as being extended longitudinally from the basis to the apex; others, as taking an oblique or spiral course; and a third sort as being
ANATOMY.

Of the Thorax.

258

being placed in a transverse direction (a).—Within the two ventricles we observe several furrows; and there are likewise tendinous sinuses, which arise from fibrous columns in the two cavities, and are attached to the valves of the auricles: That the use of these and the other valves of the heart may be understood, it must be observed, that four large vessels pass out from the bases of the heart, viz. two arteries and two veins; and that each of these vessels is furnished with a thin membranous production, which is attached all round to the borders of their several orifices, from whence hanging loosely down they appear to be divided into two or three smaller portions. But as the valves in the arteries and veins are different, so are they differently disposed. Those of the arteries are intended to give way to the passage of the blood into them from the ventricles, but to oppose its return: and, on the contrary, the valves of the veins are constructed so as to allow the blood only to pass into the heart. In consequence of these different uses, we find the valves of the pulmonary artery and of the aorta attached to the orifices of those vessels, so as to have their concave surfaces turned towards the artery: and their convex surfaces, which mutually meet together, being placed towards the ventricle, only permit the blood to pass one way, which is into the arteries. There are usually three of these valves belonging to the pulmonary artery, and as many to the aorta; and from their figure they are called valvulae semilunares. The communication between the two great veins and the ventricles is by means of the two appendages or auricles into which the blood is discharged; so that the other valves which may be said to belong to the veins, are placed in each ventricle, and correspond with the cavities. But as the valves in the right ventricle are usually three in number, and are named valvulae tricuspidae; but in the left ventricle we commonly observe only two, and these are the valvulae mitrales. The membranes which form these valves in each cavity are attached so as to project somewhat forward; and both the tricuspidae and the mitrales are connected with the tendinous sinuses, which were described as arising from the fibrous columns. By the contraction of either ventricle, the blood is driven into the artery which communicates with that ventricle; and the tendinous sinuses being gradually relaxed as the sides of the cavity are brought nearer to each other, the valves naturally close the opening into the auricle, and the blood necessarily directs its course into the then only open passage, which is into the artery; but after this contraction, the heart becomes relaxed, the tendinous sinuses are again stretched out, and, drawing the valves of the auricle downwards, the blood is poured by the veins into the ventricle, from whence, by another contraction, it is again thrown into the artery, as will be described hereafter. The right ventricle is not quite so long, though somewhat larger, than the left; but the latter has more substance than the other: and this seems to be, because it is intended to transmit the blood to the most distant parts of the body; whereas the right ventricle distributes it only to the lungs.

The heart receives its nerves from the par vagum and the intercostals. The arteries which serve for its nourishment are two in number, and arise from the aorta. They surround in some measure the basis of the heart, and from this course are called the coronary arteries. From these arteries the blood is returned by veins of the same name into the auricles, and even into the ventricles.

The muscular bags called the auricles are situated at the basis of the heart, at the sides of each other; and correspond with the auricles, are like those two cavities distinguished into right and left. These faces, which are internally unequal, have externally a jagged appendix; which, from its having been compared to the extremity of an ear, has given them their name of auricles.

Sect. XI. Angiology, or a Description of the Blood-vessels.

The heart has been described as contracting itself, and throwing the blood from its two ventricles into the pulmonary artery and the aorta, and then as relaxing itself and receiving a fresh supply from two large veins, which are the pulmonary vein and the venae cavae. We shall now point out the principal distributions of these vessels.

The pulmonary artery arises from the right ventricle by a large trunk, which soon divides into two considerable branches, which pass to the right and left lobes of the lungs: each of these branches is afterwards subdivided into an infinite number of branches and ramifications, which extend throughout the whole substance of the lungs; and from these branches the blood is returned by the veins, which, contrariwise to the course of the arteries, begin by very minute canals, and gradually become larger, forming at length four large trunks called pulmonary veins, which terminate in the left auricle by one common opening, from whence the blood passes into the left ventricle. From this same ventricle raises the aorta or great artery, which at its beginning is nearly an inch in diameter: it soon sends off two branches, the coronaries, which go to be distributed to the heart and its auricles. After this, at or about the third or fourth vertebra of the back, it makes a considerable curvature; from this curvature (n) arise three arteries; one of which soon divides into two branches. The first two are the left subclavian and the left carotid, and the third is a common trunk to the right subclavian and right carotid; though sometimes both the carotids arise distinctly from the aorta.

The two carotida ascend within the subclavians, along the sides of the trachea; and when they have reached the larynx, divide into two principal branches, the internal and external carotid. The first of these runs a little

(a) Authors differ about the course and distinctions of these fibres; and it seems right to observe, that the structure of the heart being more complex than that of other muscles, its fibres are not easily separated.

(b) Anatomists usually call the upper part of this curve aorta ascendens; and the other part of the artery to its division at the iliacs, aorta descendens; but they differ about the place where this distinction is to be introduced; and it seems sufficiently to answer every purpose, to speak only of the aorta and its curvature.
little way backwards in a bending direction; and hav­
ing reached the under part of the ear, passes through the
canal into the os petrosum, and entering into the

cavity of the cranium, is distributed to the brain and the

membranes which envelop it, and likewise to the
eye. The external carotid divides into several branches,

which are distributed to the larynx, pharynx, and other

parts of the neck; and to the jaws, lips, tongue,

eyes, temples, and all the external parts of the head.

Each subclavian is likewise divided into a great

number of branches. It sends off the vertebral artery,

which passes through the openings we see at the bot­
tom of the transverse processes of the vertebrae of the

neck, and in its course sends off many ramifications to

the neighbouring parts. Some of its branches are
distributed to the spinal marrow, and after a considera­
able infection it enters into the cranium, and is dis­
tributed to the brain. The subclavian likewise sends
off branches to the muscles of the neck and scapula;

and the mediafunium, thymus, pericardium, diaphragm,

the breasts, and the muscles of the thorax, and even

even of the abdomen, derive branches from the subclavian,

which are distinguished by different names, alluding to

the parts to which they are distributed; as the mam­
nary, the phrenic, the intercostal, &c. But notwith­
standing the great number of branches which have

been described as arising from the subclavian, it is still

a considerable artery when it reaches the axilla, where

it drops its former name, which alludes to its

position under the clavicle, and is called the axillary artery; 

from which a variety of branches are distributed to the

muscles of the breast, scapula, and arm.—But its main

trunk taking the name of brachialis, runs along on the in­
side of the arm near the os humeri, till it reaches the joint

of the fore-arm, and then it divides into two branches.

This division however is different in different subjects;

for in some it takes place higher up and in others lower

down. When it happens to divide above the joint, it

may be considered as a happy disposition in case of

an accident by bleeding; for supposing the artery to

be unfortunately punctured by the lancet, and that the

haemorrhage could only be stopped by making a liga­
ture on the vessel, one branch would remain unhurt,

through which the blood would pass uninterrupted to the

fore-arm and hand. One of the two branches of the

brachialis plunges down under the flexor muscles, and

runs along the edge of the ulna; while the other

is carried along the outer surface of the radius, and is

easily felt at the wrist, where it is only covered by the

common integuments. Both these branches commonly

unite in the palm of the hand, and form an arterial arch

from whence branches are detached to the fin­
gers.

The aorta, after having given off at its curvature the
carotids and subclavians which convey blood to all the
upper parts of the body, descends upon the bodies of the
vertebrae a little to the left, as far as the os facrum,

where it drops the name of aorta, and divides into
two considerable branches. In this course, from its

curvature to its bifurcation, it sends off several arteries

in the following order: 1. One or two little arteries,

first demonstrated by Ruych as going to the branchi,

and called arteria branchiales Ruyfchi. 2. The arteriae

of the pharynx. These are commonly three or four in num-

ber. They arise from the fore-part of the aorta, and

are distributed chiefly to the oesophagus. 3. The

inferior intercostal arteries, which are distributed be­

tween the ribs in the same manner as the arteries of the

three or four superior ribs are, which are derived

from the subclavian. These arteries send off branches
to the mediulla spinalis. 4. The pharyngeal or in­

ferior phrenic arteries, which go to the diaphragm,

omum, duodenum, pancreas, spleen, liver, and gall-bladder.

5. The celiac, which sends off the coronary-biache, the splenic, and the hepatic artery. 6. The superior mesenteric artery,

which is distributed to the mesentery and small intestines. 7. The emulgents, which go to the kidneys. 8. The

arteries, which are distributed to the glandular renales. 

9. The spermatic. 10. The inferior mesenteric artery,

which ramifies through the lower portion of the

mesentery and the large intestines.—A branch of this

artery which goes to the rectum is called the internal

hemorrhoidal. 11. The lumbar arteries, and a very

small branch called the sura, which are distributed to

the muscles of the loins and abdomen, and to the os

crucem and medulla spinalis.

The trunk of the aorta, when it has reached the

last vertebra lumbarum, or the os facrum, drops the

name of aorta, and separates into two forked branches
called the iliacs. Each of these soon divides into two

branches; one of which is called the internal iliac; or

hypogastric artery, and is distributed upon the contents

of the pelvis and upon the muscles on its outer side.

One branch, called pudenda communis, sends small ra­
mifications to the end of the rectum under the name of

hemorrhoidales externes, and is afterwards distributed

upon the penis. The other branch, the external iliac,

after having given off the circumflex artery of the os

ilium and the epigastric, which is distributed to the

recti-muscles, passes out of the abdomen under Poupart's

ligament, and takes the name of crural artery. It de­

scends on the inner part of the thigh close to the os

femoris, sending off branches to the muscles, and then

mingling deeper in the hind part of the thigh, reaches

the hain, where it takes the name of popliteal: after

this it separates into two considerable branches; one of

which is called the anterior tibial artery; the other di­

vides into two branches, and these arteries all go to be

distributed to the leg and foot.

The blood, which is thus distributed by the aorta to

all parts of the body, is brought back by the veins,

which are supposed to be continued from the ultimate

branches of arteries; and uniting together as they ap­

proach the heart, at length form the large trunks, the

vena cava ascends, and vena cava descends.

All the veins which bring back the blood from the

upper extremities, and from the head and breast, pas­
s into the vena cava descends; and those which return

it from the lower parts of the body terminate in the

vena cava ascends; and these two veins uniting to­
gether as they approach the heart, open by one com­

mon orifice into the left auricle.

It does not here seem to be necessary to follow the

different divisions of the veins as we did those of the

arteries; and it will be sufficient to remark, that in

genemical every artery is accompanied by its vein, and

that both are distinguished by the same name. But,
Of the Thorax:

Like many other general rules, this too has its exceptions (c). The veins, for instance, which accompany the external and internal carotid, are not called the carotid veins, but the external and internal jugular.

In the thorax, there is a vein distinguished by a proper name, and this is the azygos, or vein sine pari. This vein, which is a pretty considerable one, runs along by the right side of the vertebræ of the back, and is chiefly destined to receive the blood from the intercostal on that side, and from the lower half of those on the left side, and to convey it into the vena cava descendens. In the abdomen we meet with a vein, which is still a more remarkable one, and this is the vena portæ, which performs the office both of an artery and a vein. It is formed by a re-union of all the veins which come from the liver, intestines, stomach, liver, pancreas, spleen, so as to compose one great trunk, which goes to ramify through the liver; and after having deposited the bile, its ramifications unite and bring back into the vena cava, not only the blood which the vena portæ had carried into the liver, but likewise the blood from the hepatic artery. Every artery has a vein which corresponds with it; but the trunks and branches of the veins are more numerous than those of the arteries. The reasons for this disposition are perhaps more difficult to be explained; the blood in its course through the veins is much farther removed from the source and cause of its motion, which are in the heart, than it was when in the arteries; so that its course is consequently less rapid, and enough of it could not possibly be brought back to the heart in the moment of its dilatation, to equal the quantity which is driven into the arteries from the two ventricles, at the time they contract; and the equilibrium which is so essential to the continuance of life and health would consequently be destroyed, if the capacity of the veins did not exceed that of the arteries, in the same proportion that the rapidity of the blood’s motion through the arteries exceeds that of its return through the veins.

A large artery ramifying through the body, and continued to the minute branches of veins, which gradually unite together to form a large trunk, may be compared to two trees united to each other at their tops; or rather as having their ramifications so divided that the two trunks terminate in one common point; and if we farther suppose, that both these trunks and their branches are hollow, and that a fluid is incessantly circulated through them, by entering into one of the trunks and returning through the other, we shall be enabled to conceive how the blood is circulated through the vessels of the human body.

Every trunk of an artery, before it divides, is nearly cylindrical, or of equal diameter through its whole length, and so are all its branches when examined separately. But every trunk seems to contain less blood than the many branches do into which that trunk separates; and each of these branches probably contains less blood than the ramifications do into which it is subdivided; and it is the same with the veins; the volume of their several ramifications, when considered together, being found to exceed that of the great trunk which they form by their union.

The return of the blood through the veins to the heart, is promoted by the action of the muscles, and the pulsation of the arteries. And this return is likewise greatly assisted by the valves which are to be met with in the veins, and which constitute one of the great distinctions between them and the arteries. These valves, which are supposed to be formed by the inner coat of the veins, permit the blood to flow from the extremities towards the heart, but oppose its return. They are most frequent in the smaller veins. As the column of blood increases, they seem to become less necessary; and therefore in the vena cava ascendens, we meet with only one valve, which is near its origin.

The arteries are composed of several tunics. Some writers enumerate five of these tunics; but perhaps we may more properly reckon only three, viz. the nervous, muscular, and cuticular coats. The veins are by some anatomists described as having the same number of coats as the arteries; but as they do not seem to be irritable, we cannot with propriety suppose them to have a muscular tunic. We are aware of Dr Verchuir’s experiments to prove that the jugular and some other veins possess a certain degree of irritability; but it is certain, that his experiments, repeated by others, have produced a different effect; and even he himself allows, that sometimes he was unable to distinguish any such property in the veins. Both these series of vessels are nourished by still more minute arteries and veins, which are seen creeping over their coats, and ramifying through their whole substance, and are called vasa vasorum; they have likewise many minute branches of nerves.

The arteries are much stronger than the veins, and they seem to require this force to be enabled to reft the impetus with which the blood circulates through them, and to impel it on towards the veins.

When the heart contracts, it impels the blood into the arteries, and sensibly divides them; and these vessels again contract, as the heart becomes relaxed to receive more blood from the auricles; so that the cause of the contraction and dilatation of the arteries seems to be easy to be understood, being owing in part to their own contractile power, and in part to the action of the heart; but in the veins, the effects of this impulse not being so sensibly felt, and the vessels themselves having little or no contractile power, the blood seems to flow in a constant and equal stream; and this, together with its passing gradually from a small channel into a larger one, seems to be the reason why the veins have no pulsatory motion, except the large ones near the heart; and in these it seems to be occasioned by the motion of the diaphragm, and by the regurgitation of the blood in the cavæ.

Sect.

(c) In the extremities, some of the deep-seated veins, and all the superficial ones, take a course different from that of the arteries.
The heart, at the time it contracts, drives the blood from its ventricles into the arteries; and the arteries being thus filled and distended, are naturally inclined to contract the moment the heart begins to dilate, and cease to supply them with blood. The alternate motions of contraction and dilatation of the heart and arteries, are distinguished by the names of systole and dia­stole. When the heart is in a state of contraction or systole, the arteries are at that instant distended with blood, and in their dia­stole, and it is in this state we feel their pulsatory motion, which we call the pulse. When the heart dilates, and the arteries contract, the blood is impelled onwards into the veins, through which it is returned back to the heart. While the heart, however, is in its systole, the blood cannot pass from the veins into the ventricles, but is detained in the auricles, which are two reservoirs formed for this use, till the dia­stole, or dilatation of the heart, takes place; and then the distended auricles contract, and drive the blood into the ventricles: so that the auricles have an alternate systole and dia­stole as well as the heart.

Although both the ventricles of the heart contract at the same time, yet the blood passes from one to the other. In the same moment, for instance, that the left ventricle drives the blood into the aorta, the right ventricle impels it into the pulmonary artery, which is distributed through all the substance of the lungs. The blood is afterwards brought back into the left ventricle by the pulmonary vein, at the same time that the blood is returned to the cavas, into the right ventricle, from all the other parts of the body.

This seems to be the mode of action of the heart and its vessels: but the cause of this action has, like all other intricate and interesting subjects, been differently explained. It seems to depend on the stimulus made on the different parts of the heart by the blood itself, which by its quantity and heat, or other properties, is perhaps capable of first exciting that motion, which is afterwards continued through life, independent of the will, by a regular return of blood to the auricles, in a quantity proportioned to that which is thrown into the arteries.

The heart possesses the vice infecta, or principle of irritability, in a much greater degree than any other muscle of the body. The pulse is quicker in young than in old subjects, because the former are cat. par. more irritable than the latter. Upon the same principle we may explain, why the pulse is constantly quicker in weak than in robust persons.

After what has been observed of the structure and action of the heart and its auricles, and likewife of the arteries and veins, there seem to be but very few arguments required to demonstrate the circulation of the blood, which has long since been established as a medical truth. This circulation may be defined to be a perpetual motion of the blood, in consequence of the action of the heart and arteries, which impel it through all the parts of the body, from whence it is brought back by the veins to the heart.

A very satisfactory proof of this circulation, and a proof easy to be understood, may be deduced from the different effects of pressure on an artery and a vein. If a ligature, for instance, is passed round an artery, the vessel swells considerably between the ligature and the heart; whereas if we tie up a vein, it only becomes filled between the extremity and the ligature, and this is what we every day observe in bleeding. The ligature we pass round the arm on these occasions, compresses the superficial veins; and the return of the blood through them being impeded, they become distended. When the ligature is too loose, the veins are not sufficiently compressed; and the blood continues its progress towards the heart; and, on the contrary, when it is made too tight, the arteries themselves become compressed; and the flow of the blood through them being impeded, the veins cannot be distended.

Another phenomenon, which effectually proves the circulation, is the loss of blood that every living animal sustains by opening only a single artery of a moderate size; for it continues to flow from the wounded vessel till the equilibrium is destroyed which is essential to life. This truth was not unknown to the ancients; and it seems strange that it did not lead them to a knowledge of the circulation, as it sufficiently proves, that all the other vessels must communicate with that which is opened. Galen, who lived more than 1500 years ago, drew this conclusion from it; and if we further observe, that he describes (after Erasistratus, who flourished about 450 years before him) the several valves which have long since been distinguished as erasistinum and serum. The erasistinum is the red coagulum, and the serum is the water in which it floats. Each of these may be again separated into two others; for the erasistinum, by being...
repeatedly washed in warm water, gives out all its red globules, and what remains appears to be composed of the coagulable lymph (r), which is a gelatinous substance, capable of being hardened by fire till it becomes perfectly horne: and if we expose the ferum to a certain degree of heat, part of it will be found to coagulate like the white of an egg, and there will remain a clear and limpid water, resembling urine both in its appearance and smell.

The ferum and crassaflamentum differ in their proportion in different constitutions; in a strong person, the crassaflamentum is in a greater proportion to the serum than in a weak one; and the same difference is found to take place in diseases (c).

**Sect. XV. Of Nutrition.**

The variety of functions which we have described as being incessantly performed by the living body, and the continual circulation of the blood through it, must necessarily occasion a constant dissipation of the several parts which enter into its composition. In speaking of the insensible perpiration, we observed how much was incessantly passing off from the lungs and the surface of the skin. The discharge by urine is likewise every day considerable; and great part of the bile, fæliva, &c. are excluded by stool. But the solid, as well as the fluid parts of the body, require a constant renewal of nutritious particles. They are exposed to the attrition of the fluids which are circulated through them; and the contraction and relaxation they repeat so many thousand times in every day, would necessarily occasion a diffusion of the machine, if the renewal was not proportioned to the waste.

It is easy to conceive how the chyle formed from the aliment is assimilated into the nature of blood, and repairs the loss of the fluid parts of our body; but how the solids are renewed, has never yet been satisfactorily explained. The nutritious parts of the blood are probably deposed by the arteries by exsudation through their pores into the tela cellulosæ; and as the solid parts of the body are in the embryo only a kind of jelly, which gradually acquires the degree of consistence they are found to have when the body arrives at a more advanced age; and these same parts which consist of bones, cartilages, ligaments, muscles, &c. are sometimes reduced again by disease to a gelatinous state; we may, with some degree of probability, consider the coagulable lymph as the source of nutrition.

If the supply of nourishment exceeds the degree of waste, the body increases; and this happens in infancy and in youth: for at those periods, but more particularly the former one, the fluids bear a large proportion to the solids; and the fibres being soft and yielding, are proportionably more capable of extension and increase. But when the supply of nutrition only equals the waste, we neither increase nor decrease; and we find this to be the case when the body has attained its full growth or acme: for the solids having then acquired a certain degree of firmness and rigidity, do not permit a farther increase of the body. But as we approach to old age, rigidity begins to be in excess, and the fluids (n) bear a much less proportion to the solids than before. The dissipation of the body is greater than the supply of nourishment; many of the smaller vessels become gradually impervious (t); and the fibres losing their moisture and their elasticity, appear flaccid and wrinkled. The lilies and the roses disappear, because the fluids by which they were produced can no longer reach the extremities of the capillary vessels of the skin. As these changes take place, the nervous power being proportionally weakened, the irritability and sensibility of the body, which were formerly so remarkable, are greatly diminished; and in advanced life, the hearing, the eye-sight, and all the other senses, become gradually impaired.

**Sect. XVI. Of the Glands and Secretions.**

The glands are commonly understand to be small, roundish, or oval bodies formed by the convolution of a great number of vessels, and destined to separate particular humours from the mass of blood.

They are usually divided into two classes; but it seems more proper to distinguish three kinds of glands, viz. the mucus, conglobate, and conglomerate.

The mucous glands, or follicles, as they are most commonly called, are small cylindrical tubes continued from...
from the ends of arteries. In some parts of the body, as in the tonsils, for example, several of these follicles may be seen folded together in one common covering, and opening into one common sinus. These follicles are the vessels that secrete and pour out mucus in the mouth, oesophagus, stomach, intestines, and other parts of the body.

The conglutinate glands are peculiar to the lymphatic system. Every lymphatic vein passes through a gland of this kind in its way to the thoracic duct. They are met with in different parts of the body, particularly in the axilla, groin, and mefentery, and are either solitary or in distinct clusters.

The conglutinate glands are of much greater bulk than the conglutinate, and seem to be an allemeage of many smaller glands. Of this kind are the liver, kidneys, &c. Some of them, as the pancreas, parotids, &c. have a granulated appearance. All these conglutinate glands are plentifully supplied with blood vessels; but their nerves are in general very minute, and few in number. Each little granulated portion furnishes a small tube, which unites with other similar ducts, to form the common excretory duct of the gland.

The principal glands, and the humours they secrete, have been already described in different parts of this work; and there only remains for us to examine the general structure of the glands, and to explain the mechanism of secretion. On the first of these subjects two different systems have been formed; each of which has had, and still continue to have, its adherents. One of these systems was advanced by Malpighi, who suppos'd that an artery entering into a gland ramifies very minutely through its substance, and that its branches ultimately terminate in a vescicular cavity or follicle, from whence the secreted fluid passes out through the excretory duct. This doctrine at first met with few opponents; but the celebrated Ruych, who first attempted minute injections with wax, afterwards disputed the existence of these follicles, and asserted, that every gland appears to be a continued series of vessels, which after being repeatedly convoluted in their course through its substance, at length terminate in the excretory duct. This doctrine is still divided between these two systems: that of Malpighi, however, seems to be the best founded. The mode of secretion has been explained in a variety of ways, and they are all perfectly hypothetical. In such an inquiry it is natural to ask, how one gland constantly separates a particular humour, while another gland secretes one of a very different nature from the blood? The bile, for instance, is separated by the liver, and the urine by the kidneys. Are these secretions to be imputed to any particular dispositions in the fluids, or is their cause to be looked for in the fluids? It has been suppos'd, that every gland contains within itself a fermenting principle, by which it is enabled to change the nature of the blood it receives, and to endue it with a particular property. So that, according to this system, the blood, as it circulates through the kidneys, becomes mixed with the fermenting principle of those glands, and a part of it is converted into urine; and again, in the liver, in the biliary and other glands, the bile, the saliva, and other juices, are generated from a similar cause. But it seems to be impossible for any liquor to be confined in a place exposed to the circulation, without being carried away by the torrent of blood, every part of which would be equally affected; and this system of fermentation has long been rejected as vague and chimerical. But as the cause of secretion continued to be looked for in the fluids, the former system was succeeded by another, in which recourse was had to the analogy of the humours. It was observed, that if paper is moistened with water, and oil and water are afterwards poured upon it, that the water only will be permitted to pass through it; but that, on the other hand, if the paper has been previously soaked in oil instead of water, the oil only, and not the water, will be filtered through it. These observations led to a supposition, that every secretory organ is originally furnished with a humour analogous to that which it is afterwards defined to separate from the blood; and that in consequence of this disposition, the secretory vessels of the liver, for instance, will only admit the bilious particles of the blood, while all the other humours will be excluded. This system is an ingenious one, but the humour with which it abounds are unanswerable; for oil and water are immiscible; whereas the blood, as it is circulated through the body, appears to be an homogeneous fluid. Every oil will pass through a paper moistened only with one kind of oil; and wine, or spirits mixed with water, will easily be filtered through a paper previously soaked in water. Upon the same principle, all our humours, though differing in their other properties, yet agreeing in that of being perfectly miscible with each other, will all easily pass through the same filter.—But these are not all the objections to this system. The humours which are supposed to be placed in the secretory vessels for the determination of similar particles of the blood, must be originally separated without any analogous fluid; and that which happens once, may as easily happen always. Again, it sometimes happens from a vicious disposition, that humours are filtered through glands which are naturally not intended to afford them a passage; and when this once has happened, it ought, according to this system, to be expected always to do so: whereas this is not the case; and we are, after all, naturally led to seek for the cause of secretion in the solids. It does not seem right to ascribe it to any particular figure of the secretory vessels; because the soft texture of those parts does not permit them to preserve any constant shape, and our fluids seem to be capable of accommodating themselves to every kind of figure. Some have imputed it to the difference of diameter in the oriifices of the different secretory vessels. To this doctrine objections have likewise been raised; and it has been argued, that the vessels of the liver, for instance, would, upon this principle, afford a passage not only to the bile, but to all the other humours of less consistence with it. In reply to this objection, it has been suppos'd, that secondary vessels exist, which originate from the first, and permit all the humours thinner than the bile to pass through them.

Each of these hypotheses is probably very remote from the truth.
This plate represents the Heart in situ, all the large Arteries and Veins, with some of the Muscles, &c.

Muscles, &c.—Superior Extremity.—a, M. Maffeter. b, Complexus. c, Digastricus. d, Os hyoides. e, Thyroid gland. f, Levator scapulae. g, Cuillaris. h, The clavicles cut. i, The deltoid muscle. k, Biceps flexor cubiti cut. l, Coraco-brachialis. m, Triceps extensor cubiti. n, The heads of the pronator teres, flexor carpi radiales, and flexor digitorum superficialis, cut. o, The flexor carpi-ularis, cut at its extremity. p, Flexor digitorum profundus. q, Supinator radii longus, cut at its extremity. r, Ligamentum carpi transversale. s, Extensor carpi radiales. t, Latissimus dorsi. u, Anterior edge of the serratus anterior major. v, v, The inferior part of the diaphragmn. w, w, Its anterior edge cut. x, x, The kidneys. y, Transversus abdominis. z, Os ilium.

Inferior Extremity.—a, Psoas magnus. b, Iliacus internus. c, The dfly origin of the tenor vaginae femoris. d, d, The obliquus pubis cut from each other. e, Musculus pectineus cut from its origin. f, Short head of the triceps abdominis femoris cut. g, The great head of the triceps. h, The long head cut. i, Vasa interna. k, Vastus externus. l, Crureus. m, Gemellus. n, Soleus. o, Tibia. p, Peroneus longus. q, Peroneus brevis. r, Fibula.

Heart and Blood-vessels.—a, The heart, with the coronary artery and veins. b, The right auricle of the heart. c, The aorta ascendens. d, The left subclavian artery. e, The left carotid artery. f, The common trunk which sends off the right subclavian and right carotid arteries. g, The carotis externa. h, The carotis interna, which sends off the coronary arteries of the lips. i, Arteria temporalis profunda. k, Aorta descendens. l, The iliac arteries,—which sends off M.M., The femoral or crural arteries. N.B. The other arteries in this figure have the same distribution as the veins of the same name:—And generally, in the anatomical plates, the description to be found on the one side, points out the same parts in the other.

1, The frontal vein. 2, The facial vein. 3, Vena temporalis profunda. 4, Vena occipitalis. 5, Vena jugularis externa. 6, Vena jugularis interna, covering the arteria carotis communis. 7, The vasa cerebri arcus on the palm of the hand, which is formed by, 8, The radial artery and vein, and 9, The ulnar artery and vein. 10, 10, The cephalic vein. 11, Basilic vein, that on the right side cut. 12, Median vein. 13, The humeral vein, which, with the median, covers the humeral artery. 14, 14, The external thoracic or mammary artery and veins. 15, The axillary vein, covering the artery. 16, 16, The subclavian veins, which, with the jugulars, form, 17, The vena cava superior. 18, The cutaneous arch of veins on the fore part of the foot. 19, The vena tibiflásis antica, covering the artery. 20, The vena profunda femoris, covering the artery. 21, The upper part of the vena saphena major. 22, The femoral vein. 23, 23, The iliac veins. 24, 24, Vena cava inferior. 25, 25, The renal veins covering the arteries. 26, 26, The diaphragmatic veins.

Part V. Of the Brain and Nerves.

Sect. I. Of the Brain and its Integuments.

The bones of the cranium were described in the opeological part of this work, as including the brain, and defending it from external injury: but they are not its only protection; for when we make an horizontal section through these bones, we find this mass everywhere surrounded by two membranes (X), the dura and pia mater.—The first of these lines the interior surface of the cranium, to which it everywhere adheres strongly (t), but more particularly at the futures, and at the many foramina through which vessels pass between it and the pericranium. The dura mater (X) is perfectly smooth and inelastic, and its inner surface is constantly bedewed with a fine pellicular fluid, which every where separates it from the pia mater. The dura mater sends off several considerable processes, which divide the brain into separate portions, and prevent them from compressing each other. Of these processes there is one superior, and longitudinal, called the falx, or falxiform process, from its resemblance to a clyythe. It arises from the spine of the os frontis, near the chrysia galli, and extending along in the direction of the sagittal future, to beyond the lamboidal future, divides the brain into two hemi-
Of Cerebrum. Of the hemispheres. A little below the lambdoidal suture, it divides into two broad wings or expansions called the tranverse or lateral processes, which prevent the lobes of the cerebrum from pressing on the cerebellum. Besides these there is a fourth, which is situated under the transverse processes, and being continued to the spine of the occiput, divides the cerebellum into two lobes.

The blood, after being distributed through the cavity of the cranium by means of the arteries, is returned, as in the other parts of the body, by veins which all pass on to certain channels, situated behind these several processes.

These canals or sinuses communicate with each other, and empty themselves into the internal jugular veins, which convey the blood into the vena cava. They are supplied as in the other parts of the body, by vessels which return the blood at the union of these two veins, is as it were, in a plexus, as in the other parts of the body, by vessels which return the blood at the union of these two veins, is as it were, in a plexus. Besides these four canals, which were known to the ancients, modern anatomists enumerate many others, by giving the appellation of sinuses to other veins of the dura mater, which for the most part empty themselves into some of those we have just now described. There are the inferior longitudinal sinus, the superior and inferior petrous sinuses, the cavernous sinuses, the circular sinuses, and the anterior and posterior occipital sinuses.

These sinuses or veins, by being conveyed through a thick dense membrane, firmly suspended, as the dura mater is, within the cranium, are less liable to rupture; at the same time they are well supported, and by running every where along the inner surface of the bones, they are prevented from pressing on the substance of the brain. To prevent too great a dilatation of them, we find filaments (called chorda Willisii, from their having been first noticed by Willis) stretched across their cavities; and the oblique manner in which the veins from the brain run through the substance of the brain into these channels, serves the purpose of a valve, which prevents the blood from turning back into the smaller and weaker vessels of the brain.

The pia mater is a much fother and finer membrane than the dura mater; being exceedingly delicate, transparent, and vaeferular. It invests every part of the brain and sends off an infinite number of elongations, which infinuate themselves between the convolutions, and even into the substance of the brain. This membrane is composed of two laminae; of which the external one is named tunica arachnoidea, from its thinness, which is equal to that of a spider's web. These two laminae are intimately adherent to each other at the upper part of the brain, but are easily separable at the basis of the brain, and through the whole length of the medulla spinalis. The external layer, or tunica arachnoidea, appears to be spread uniformly over the surface of the brain, but without entering into its furrows as the inner layer does; the latter being found to intermingle itself between the convolutions, and even into the interior cavities of the brain. The blood-vessels of the brain are distributed through it in their way to that organ, and are therefore divided into very minute ramifications, before they penetrate the substance of the brain.

There are several parts included under the general denomination of brain. One of these, which is of the softest consistence, and fills the greatest part of the cavity of the cranium, is the cerebrum, or brain, properly so called. Another portion, which is seated in the inferior and posterior part of the head, is the cerebellum; and a third, which derives its origin from both theee, is the medulla oblongata.

The cerebrum is a medullary mass of a moderate consistence, filling up exactly all the upper part of the cavity of the cranium, and divided into two hemispheres by the falx of the dura mater. Each of these hemispheres is usually distinguished into an anterior, a middle, and a posterior lobe. The first of these is lodged on the orbital processes of the os frontis; the middle lobes lie on the middle fossa of the basis of the cranium, and the posterior lobes are placed on the transverse septum of the os occipitis, immediately over the cerebellum, from which they are separated by the lateral processes of the dura mater. These two portions afford no distinguishing mark of separation; and on this account Haller, and many other modern anatomists, omit the distinction of middle lobe, and speak only of the anterior and posterior lobes of the brain.

The cerebrum appears to be composed of two distinct substances. Of these, the exterior one, which is of a greyish or ash-colour, is called the cortex, and is somewhat softer than the other, which is very white, and is called medulla or substantia alba.

After having removed the falx, and separated the two hemispheres from each other, we perceive a white convex body, the corpus callosum, which is a portion of the medullary substance, uniting the two hemispheres to each other, and not invested by the cortex. By making an horizontal incision in the brain, on a level with this corpus callosum, we discover two oblong cavities, named the anterior or lateral ventricles, one in each hemisphere. These two ventricles, which communicate with each other by a hole immediately under the plexus choroides, are separated laterally by a very fine medullary partition, called septum lucidum, from its thinness and transparency. The lower edge of this septum is fixed to the fornix, which is a kind of medullary arch (as its name implies) situated under the corpus callosum, and nearly of a triangular shape. Anteriorly the fornix sends off two medullary chords, called its anterior crura; which seem to be united to each other by a portion of medullary substance, named commissura anterior cerebri. These crura diverging from one another, are lost at the outer side of the lower and fore-part of the third ventricle. Posteriorly the fornix is formed into two other chords, which unite with two medullary protuberances called pedes hippocampi, and sometimes cornua ammonis, that extend along the back-part of the lateral ventricles. The concave edge of the pedes hippocampi is covered by a medullary lamina, called corpus subhriatum.

Neither the edges of the fornix, nor its posterior crura, can be well distinguished, till we have removed the plexus choroides. This is a production of the pia mater, which is spread over the lateral ventricles. Its loofe
loose edges are collected, so as to appear like a vascular band on each side.

When we have removed this plexus, we discover several of these protuberances included in the lateral ventricles. These are the corpora striata, the thalami nervorum opticorum, the tubercula quadrigemina, and the pineal gland.

The corpora striata are two curved oblong eminences, that extend along the anterior part of the lateral ventricles. They derive their name from their striated appearance, which is owing to an intermixture of the cortical and medullary substances of the brain. The thalami nervorum opticorum are so called, because the optic nerves arise chiefly from them, and they are likewise composed both of the cortex and medulla. They are separated from the corpora striata only by a kind of medullary chord, the geminum centrum semi-circulare. The thalami are nearly of an oval shape, and are situated at the bottom of the upper cavity of the lateral ventricles. They are closely united, and at their convex part seem to become one body.

Anteriorly, in the space between the thalami, we observe an orifice by which the lateral ventricles communicate, and another leads down from this, under the different appellations of foramen commune anterius, vulva iter ad infundibulum, but more properly iter ad tertium ventriculorum; and the separation of the thalami from each other posteriorly, forms another opening or interface called annus. This has been supposed to communicate with the third ventricle; but it does not, the bottom of it being shut up by the pia mater.

The back part of the annus is formed by a kind of medullary band, which connects the thalami to each other, and is called commissura posterior cerebri.

Behind the thalami and commissura posterior, we observe a small, soft, greyish, and oval body, about the size of a pea. This is the glandula pinealis; it is described by Galen under the name of convulsion, and has been rendered famous by Descartes, who supposed it to be the seat of the soul. Galen seems formerly to have entertained the same opinion. Some modern writers have, with as little reason, imagined that the soul is placed in the corpus callosum.

The pineal gland rests upon four remarkable eminences, disposed in pairs, and seated immediately below it. These tubercles, which by the ancients were called testis and nates, have, since the time of Winlow, been more commonly named tubercula quadrigemina.

Under the thalami we observe another cavity, the third ventricle, which terminates anteriorly in a small medullary canal, the infundibulum, that leads to the glandula pituitaria. It has been doubted, whether the infundibulum is really hollow; but some late experiments on this part of the brain by Professor Murray of Upsal, clearly prove it to be a medullary canal, surrounded by both lamina of the pia mater. After freezing the brain, this channel was found filled with ice; and de Haen tells us, he found it dilated, and filled with a calcareous matter (N).

The soft spongy body in which the infundibulum terminates, was by the ancients supposed to be of a glandular structure, and defined to filter the ferosity of the brain. Spigelius pretended to have discovered its excretory duct, but it seems certain that no such duct exists. It is of an oblong shape, composed, as it were, of two lobes. In ruminant animals it is much larger than in man.

From the posterior part of the third ventricle, we see a small groove or channel, descending obliquely backwards. This channel, which is called the aqueducus Sylvii, though it was known to the ancients, opens into another cavity of the brain, placed between the cerebellum and medulla oblongata, and called the fourth ventricle.

The cerebellum, which is divided into two lobes, is commonly supposed to be of a firmer texture than the cerebrum; but the truth is, that in the greater number of subjects, there appears to be no sensible difference in the consistence of these two parts. It has more of the cortical than of the medullary substance in its composition.

The furrow that divides the two lobes of the cerebellum leads anteriorly to a process, composed of medullary and cortical substances, covered by the pia mater, and which, from its being divided into numerous furrows, resembling the rings of the earth-worm, is named procedus vermis. This process forms a kind of ring in its course between the lobes.

The surface of the cerebellum does not afford those circumvolutions which appear in the cerebrum; but instead of these, we observe a great number of minute furrows, running parallel to each other, and nearly in a transverse direction. The pia mater invests itself into these furrows.

When we cut into the substance of the cerebellum, from above downwards, we find the medullary part running in a kind of ramifying course, and exhibiting an appearance that has got the name of arbor vitae. These ramifications unite to form a medullary trunk; the middle, anterior, and most considerable part of which forms two processes, the crus cerebrali; which unite with the crus cerebelli, to form the medulla oblongata. The last furnishes two other processes, which lose themselves under the nates, and thus unite the lobes of the cerebellum to the posterior part of the cerebrum. Under the nates we observe a transverse medullary line, or linea alba, running from one of these processes to the other; and between them we find a very thin medullary lamina, covered with the pia mater, which the generality of anatomists have (though seemingly without reason) considered as a valve formed for closing the communication between the fourth ventricle and the aqueductus Sylvii. Vieussens named it vulvula major cerebri.

The medulla oblongata is situated in the middle, lower, and posterior part of the cranium, and may be considered as a production or continuation of the whole medullary substance of the cerebrum and cerebellum, being formed by the union of two considerable medullary processes of the cerebrum, called crura cerebri.
The crura cerebri arise from the middle and lower parts of each hemisphere. They are separated from each other at their origin, but are united below, where they terminate in a middle protuberance, the *pons Varolii*, so called, because Varolius compared it to a bridge. This name, however, can convey no idea of its real appearance. It is, in fact, nothing more than a medullary protuberance, nearly of a semi-spherical shape, which unites the crura cerebri to those of the cerebellum.

Between the crura cerebri, and near the anterior edge of the *pons Varolii*, are two tubercles, composed externally of medullary, and internally of cinneritous substance, to which Eufrachius first gave the name of *eminentes mamillares*.

Along the middle of the posterior surface of the medulla oblongata, where it forms the anterior part of the fourth ventricle, we observe a kind of furrow which runs downwards and terminates in a point. About an inch above the lower extremity of this fissure, several medullary filaments are to be seen running towards it on each side in an oblique direction, so as to give it the appearance of a writing-pen; hence it is called *calamus scriptorius*.

From the posterior part of the *pons Varolii*, the medulla oblongata descends obliquely backwards: at its fore-part, immediately behind the *pons Varolii*, we observe two pair of eminences, which were described by Eufrachius, but received no particular appellation till the time of Vieuwens, who gave them the names of *corpora olivaria* and *corpora pyramidalia*. The former are the outermost, being placed one on each side. They are nearly of an oval shape, and are composed of medulla, with streaks of cortical substance. Between these are the *corpora pyramidalia*, each of which terminates in a point. In the human subject these four eminences are sometimes not easily distinguished.

The *medulla spinalis*, or spinal marrow, which is the name given to the medullary chord that is extended down the vertebral canal, from the great foramen of the occipital bone to the bottom of the last lumbar vertebra, is a continuation of the medulla oblongata. Like the other parts of the brain, it is invected by the dura and pia mater. The first of these, in its passage out of the cranium, adheres to the foramen of the os occipitis. Its connection with the ligamentary substance that lines the cavity of the spine, is only by means of cellular membrane; but between the several vertebrae, where the nerves pass out of the spine, it sends off prolongations, which adhere strongly to the vertebral ligaments. Here, as in the cranium, the dura mater has its sinuses or large veins. There are two in number, and are seen running on each side of the medullary column, from the foramen magnum of the os occipitis to the lower part of the os facetum. They communicate together by ramifying branches at each vertebra, and terminate in the vertebral, intercostal, and facral veins.

The pia mater is connected with the dura mater by means of a thin transparent substance, which from its indentations between the spinal nerves has obtained the name of *ligamentum denticulatum*. It is somewhat firmer than the unica arachnoidea, but in other respects resembles that membrane. Its use is to support the spinal marrow, that it may not affect the medulla oblongata by its weight.

The spinal marrow itself is externally of a white colour; but upon cutting into it we find its middle-part composed of a darker coloured mass, resembling the cortex of the brain. When the marrow has reached the first lumbar vertebra, it becomes extremely narrow, and at length terminates, in an oblong protuberance; from the extremity of which the pia mater sends off a prolongation or ligament, resembling a nerve, that perforates the dura mater, and is fixed to the os coccygis.

The medulla spinalis gives rise to 30 or 31 pair of nerves, but they are not all of the same size, nor do they all run in the same direction. The upper ones are thinnest than the rest, and are placed almost transversely: as we descend we find them running more and more obliquely downwards, till at length their course is almost perpendicular, so that the lowermost nerves exhibit an appearance that is called *coda equina*, from its resemblance to a horse's tail.

The arteries that ramify through the different parts of the brain, are derived from the internal carotid and from the vertebral arteries. The *medulla spinalis* is supplied by the anterior and posterior spinal arteries, and likewise receives branches, from the cervical, the inferior and superior intercostal, the lumbar, and the facral arteries.

**Sect. II. Of the Nerves.**

The nerves are medullary chords, differing from each other in size colour and consistence and deriving their origin from the medulla oblongata and *medulla spinalis*. There are 39, and sometimes 40, pair of these nerves; nine (o) of which originate from the medulla oblongata, and 30 or 31 from the *medulla spinalis*. They appear to be perfectly inelastic, and like wire to pullets no irritability. If we irritate muscular fibres, they immediately contract; but nothing of this sort happens if we irritate a nerve. They carry with them a covering from the pia mater; but derive no tunic from the dura mater, as hath been generally, though erroneously, supposed, ever since the time of Galen (p),

(o) It has been usual to describe the ten pair of nerves as arising from the medulla oblongata; but as the tenth pair arise in the same manner as the other spinal nerves, Santorini, Heister, Haller, and others, seem very properly to have clasped them among the nerves of the spine.

(p) Baron Haller and Professor Zinn seem to have been the first who demonstrated, that the dura mater is reflected upon and adheres to the periosteum at the edges of the foramina that afford a passage to the nerves out of the cranium, and vertebral canal, or is soon lost in the cellular substance.
ANATOMY

Part V.

Of the Brain and Nerves.

the outer covering of the nerves being in fact nothing more than the cellular membrane. This covering is very thick where the nerve is exposed to the action of muscles; but where it runs through a bony canal, or is secure from pressure, the cellular tunic is extremely thin, or altogether wanting. We have instances of fasciculi being separated by the ligamentum denticulatum, this in the partio mollis of the auditory nerve, and in after which we find them contiguous to one another.

By elevating, carefully and gently, the brain from the basin of the cranium, we find the first nine pairs arising in the following order: 1. The nervi olfactorii, distributed through the pia mater, which constitutes the organ of smell. 2. The optical, which go to the eyes, where they receive the impressions of visible objects. 3. The oculorum motorius, so called because they are distributed to the muscles of the eye. 4. The pathetici, distributed to the superior oblique muscles of the eye, the motion of which is expressive of certain passions of the soul. 5. The nerves of this pair soon divide into three principal branches, and each of these has a different name. Its upper division is the opthalmalicus, which is distributed to various parts of the eyes, eye-lids, forehead, nose, and integuments of the face. The second is called the maxillarius superior, and the third maxillarius inferior; both which names allude to their distribution. 6. The abductores; each of these nerves is distributed to the abductor muscle of the eye, so called, because it helps to draw the globe of the eye from the nose. 7. The auditorii (q), which are distributed through the organs of hearing. 8. The par vagum, which derives its name from the great number of parts to which it gives branches both in the thorax and abdomen. 9. The linguales, or hypo-glossi, which are distributed to the tongue, and appear to contribute both to the organ of taste and to the motions of the tongue (s).

It has already been observed, that the spinal marrow sends off 30 or 31 pair of nerves; these are chiefly distributed to the exterior parts of the trunk and to the extremities. They are commonly distinguished into the cervical, dorsal, lumbar, and sacral nerves. The cervical, which pass out through the intercostal nerve of the cranium, is eight (s) in number; the dorsal, twelve; the lumbar, five; and the sacral, five or six; the number of the latter depending on the number of holes in the os sacrum. Each spinal nerve at its origin is composed of two fasciculi of medullary fibres. One of these fasciculi arise from the anterior, and the other from the posterior, surface of the medulla. These fasciculi are separated by the lamina denticulatum, after which we find them contiguous to one another. They then perforate the dura mater, and unite to form a considerable knot or ganglion. Each of these ganglions sends off two branches; one anterior, and the other posterior. The anterior branches communicate with each other at their coming out of the spine, and likewise send off one, and sometimes more branches, to assist in the formation of the intercostal nerve.

The knots or ganglions of the nerves just now spoken of, are not only to be met with at their exit from the spine, but likewise in various parts of the body. They occur in the nerves of the medulla oblongata, as well as in those of the spine. They are not the effects of disease, but are to be met with in the same parts of the same nerves, both in the fetus and adult. They are commonly of an oblong figure, and of a greyish colour, somewhat inclined to red, which is perhaps owing to their being extremely vascular. Internally we are able to distinguish something like an intermixture of the nervous filaments.

Some writers have considered them as so many little brains; Lancisi fancied he had discovered muscular fibres in them, but they are certainly not of an irritable nature. A late writer, Dr Johnstone, imagines the ganglia are intended to deprive us of the power of the will. If in other cases, the ganglia were well founded, we should meet with them only in the nerves leading to involuntary muscles; whereas it is certain, that the voluntary muscles receive their nerves through ganglions. Doctor Monro, from observing the accurate intermixture of the minute nerves which compose them, considers them as new sources of nervous energy.

The nerves, like the blood-veins, in their course through the body, communicate with each other; and each of these communications constitutes what is called a plexus, from whence branches are again detached to different parts of the body. Some of these are constant.

(a) This pair, soon after its entrance into the meatus auditorius internus, separates into two branches. One of these is of a very soft and pulpy consistence, is called the portio mollis of the seventh pair, and is spread over the inner part of the ear. The other passes out through the aqueduct of Falloppius in a firm chord, which is distinguished as the portio dura, and is distributed to the external ear and other parts of the neck and face.

(r) Heister has summed up the uses of these nine pair of nerves in the following Latin verses:

"Olficientis, cerumn, souloque movens, patiensque,"

"Genitans, abducens, audientisque, vagansque, loquensque."

(s) Besides these, there is another pair called accesorii, which arise from the medulla spinalis at its beginning, and ascending through the great foramen of the os occipitis into the cranium, passes out again close to the eighth pair, with which, however, it does not unite; and it is afterwards distributed chiefly to the muscles of the neck, back, and scapula. In this course it sends off filaments to different parts, and likewise communicates with several other nerves. Physiologists are at a loss how to account for the singular origin and course of these nervi accessorii. The ancients considered them as branches of the eighth pair, distributed to muscles of the scapula: Willis likewise considered them as appendages to that pair, and on that account named them accesorii. They are sometimes called the spinal pair: but as this latter name is applicable to all the nerves of the spine indiscriminately, it seems better to adopt that given by Willis.
Part V.

ANATOMY.

Of the Brain and Nerves.

The nerves are produced, no one has ever yet been able to determine. The inquiry has been founded altogether on hypothesis; but it seems to be an hypothesis derived from much more probable principles, and there are many ingenious arguments to be brought in its support.

Some physiologists have considered a trunk of nerves as a solid chord, capable of being divided into an infinite number of filaments, by means of which the premonitions of feeling are conveyed to the meninges commune. Others have supposed it to be a canal, which afterwards separates into more minute channels; or, perhaps, as being an assemblage of many very small and distinct tubes, connected to each other, and thus forming a cylindrical chord. They who contend for the being solid bodies, are of opinion, that feeling is occasioned by vibration; so that, for instance, according to this system, by prickings the finger, a vibration would be occasioned in the nerve, distributed through its substance; and the effects of this vibration, when extended to the meninges, would be an excitation of pain. But the inelasticity, the softness, the connection, and the situation of the nerves, are so many proofs that vibration has no share in the caufe of feeling.

Others have supposed, that in the brain and spinal marrow, a very subtle fluid is secreted, and from thence conveyed through the imperceptible tubes, which they consider as existing in the nerves. They have further supposed, that this very subtle fluid, to which they have given the name of animal spirit, is secreted in the cortical substance of the brain and spinal marrow, from whence it passes through the medullary substance. This, like the other system, is founded altogether on hypothesis; but it seems to be an hypothesis derived from much more probable principles, and there are many ingenious arguments to be brought in its support.

EXPLANATION

of PLATE XXIX.

Fig. 1. Represents the inferior part of the brain;—the anterior part of the whole Spine, including the Medulla Spinalis;—with the origin and large portions of all the nerves.

Nerves—11, The first pair of nerves, named olfactory, which go to the nose. 22, The second pair, named opticus, which goes to form the tunica retina of the eye. 33, The third pair, named motor ocularis; it supplies most of the muscles of the eye-ball. 44, The fourth pair, named ophthalmonicus,—which is wholly spent upon the muscles trochlearis of the eye. 55, The fifth pair; the division is made branches. The first, named opthalmonicus, goes to the orbit; supplies the lacrimal gland, and sends branches out to the forehead and nose. The second, named superior maxillary, supplies...

PART VI. OF THE SENSES, AND THEIR ORGANS.

In treating of the senses, we mean to confine ourselves to the external ones of touch, taste, smelling, hearing, and vision. The word sense, when applied to these five, seems to imply not only the sensation excited in the mind by certain impressions made on the body, but likewise the organ destined to receive and transmit these impressions to the sensum. Each of these organs being of a peculiar structure, is susceptible only of particular impressions, which will be pointed out as we proceed to describe each of them separately.

SEC. I. OF TOUCH.

The sense of touch may be defined to be the faculty of perceiving certain properties of bodies by the feel. In a general acceptation, this definition might perhaps not improperly be extended to every part of the body possessed of sensibility (τ), but it is commonly confined to the nervous papillae of the cutis, or true skin, which, with its appendages, and their several uses, have been already described.

The exterior properties of bodies, such as their form, solidity, moisture, inequality, smoothness, dryness, or fluidity, and likewise their degree of heat, seem all to be capable of making different impressions on the papillae, and consequently of exciting different ideas in the sensum commune. But the organ of touch, like all the other senses, is not equally delicate in every part of the body, or in every subject; being in some much more exquisite than it is in others.

Sect. II. OF THE TASTE.

The sense of taste is seated chiefly in the tongue; the situation and figure of which are sufficiently known. On the upper surface of this organ we may observe a great number of papillae, which, on account of their difference in size and shape, are commonly divided into three classes. The largest are situated towards the base of the tongue. Their number commonly varies from seven to nine, and they seem to be mucous follicles. Those of the second class are somewhat smaller, and of a cylindrical shape. They are most numerous about the middle of the tongue. Those of the third class are very minute, and of a conical shape. They are

(τ) In the course of this article, mention has often been made of the sensibility or insensibility of different parts of the body: it will therefore, perhaps, not be amiss to observe in this place, that many parts which were formerly supposed to possess the most exquisite sense, are now known to have but little or no feeling, at least in a sound state; for in an inflamed state, even the bones, the most insensible parts of any, become susceptible of the most painful sensations. This curious discovery is due to the late Baron Haller. His experiments prove, that the bones, cartilages, ligaments tendons, epidermis, and membranes (as the pleura, pericardium, dura and pia mater, periosteum, &c.), may in a healthy state be considered as insensible. As sensibility depends on the brain and nerves, of course different parts will possess a greater or less degree of feeling, in proportion as they are supplied with a greater or smaller number of nerves. Upon this principle it is, that the skin, muscles, stomach, intestines, urinary bladder, ureters, uterus, vagina, penis, tongue, and retina, are extremely sensible, while the lungs and glands have only an obscure degree of feeling.
ANATOMY.

Part VI.

The sense of smelling, like the sense of taste, seem intended to direct us to a proper choice of aliment, and is chiefly seated in the nose, which is distinguished into its external and internal parts. The situation and figure of the former of these do not seem to require a definition. It is composed of bones and cartilages, covered by muscular fibres and by the common integuments. The bones make up the upper portion, and the cartilages the lower one. The septum narium, like the nose, is likewise in part bony, and in part cartilaginous. These bones and their connections were described in the osteology.

The internal part of the nose, besides the osseous spongiosa, has six cavities or sinuses, the maxillary, the frontal, and the phrenoid, which were all described with the bones of the head. They all open into the nostrils; and the nose likewise communicates with the mouth, larynx, and pharynx, posteriorly behind the velum palatii.

All these several parts, which are included in the internal division of the nose, viz. the inner surface of the nostrils, the lamellæ of the osseous spongiosa, and the sinuses, are lined by a thick and very vascular membrane, which, though not known to the古代人, was first well described by Schneider*, and is therefore now commonly named membrana papillaria Schneideri. This membrane is truly the organ of smelling; but its real structure does not yet seem to be perfectly understood. It appears to be a continuation of the cuticle, which lines the inner surface of the mouth. In some parts of the nose it is smooth and firm, and in others it is loose and spongy. It is constantly moistened by a mucous secretion; the finer parts of which are carried off by the air we breathe, and the remainder, by being retained in the sinuses, acquires considerable consistence.

The manner in which this mucus is secreted has not yet been satisfactorily ascertained; but it seems to be by means of mucous follicles.

Its arteries are branches of the internal maxillary and internal carotid. Its veins empty themselves into the internal jugulars. The first pair of nerves, the olfactory, are spread over every part of it, and it likewise receives branches from the fifth pair.

After what has been said of the pituitary membrane, it will not be difficult to conceive how the air we draw in at the nostrils, being impregnated with the effluvia of bodies, excites in us that kind of sensation we call smelling. As these effluvia, from their being exceedingly light and volatile, cannot be capable in a small quantity of making any great impression on the extremities of the olfactory nerves, it was necessary to give considerable extent to the pituitary membrane, that by this means a greater number of odoriferous particles might be admitted at the same time. When we wish to take in much of the effluvia of any thing, we naturally close the mouth, that all the air we inspire may pass through the nostrils; and at the same time, by means of the muscles of the nose, the nostrils are dilated, and a greater quantity of air is drawn in.

In many quadrupeds, the sense of smelling is much more extensive and delicate than it is in the human subject; and in the human subject it seems to be more perfect the less it is vitiated by sickness and in health. The great use of the taste seems to be to enable us to distinguish wholesome and salutary food from that which is unhealthy; and we observe that many quadrupeds, by having their papillæ (v) very large and long, have the faculty of distinguishing flavours with infinite accuracy.

Sect. III. Of Smelling.

...
found to have several muscles. Different parts of it are distinguished by different names; all its cartilaginous part is called aia or wing; to distinguish it from the soft and pendent part below, called the lobe. Its outer or border is called antihelix, and the semicircle within this, antihelix. The movable cartilage placed immediately before the meatus auditorius, which it may be made to close exactly, is named tragus; and an eminence opposite to this at the extremity of the antihelix, is called antitragus. The concha is a considerable cavity formed by the extremities of the helix and antihelix. The meatus auditorius, which at its opening is cartilaginous, is lined with a very thin membrane, which is a continuation of the cuticle from the surface of the ear.

In this canal we find a yellow wax, which is secreted by a number of minute glands or follicles, each of which has an excretory duct. This secretion, which is at first of an oily consistence, defends the membrane of the tympanum from the injuries of the air; and by its bitterness, prevents minute insects from entering into the ear. But when from neglect or disease it accumulates in too great a quantity, it sometimes occasions deafness. The inner extremity of the meatus is closed by a very thin transparent membrane, the membrana tympani, which is set in a bony circle like the head of a drum. In the half century Rinvius, professor at Liepzig, fancied he had discovered a hole in this membrane, surrounded by a sphincter, and affording a passage to the air, between the external and internal ear. Cowper, Heister, and some other anatomists, have admitted this supposed foramen, which certainly does not exist. Whenever there is any opening in the membrana tympani, it may be considered as accidental. Under the membrana tympani runs a branch of the fifth pair of nerves, called chorda tympani; and beyond this membrane is the cavity of the tympanum, which is about seven or eight lines wide, and half so many in depth; it is semicircular, and every where lined by a very fine membrane. There are four openings to be observed in this cavity. It communicates with the mouth by means of the Eustachian tube. This canal, which is in part bony and in part cartilaginous, begins by a very narrow opening at the anterior and almost superior part of the tympanum, increasing in size as it advances towards the palate of the mouth, where it terminates by an oval opening. This tube is every where lined by the same membrane that covers the inside of the mouth. The real use of this canal does not seem to have been hitherto satisfactorily ascertained; but found would seem to be conveyed through it to the membrana tympani, deaf persons being often observed to listen attentively with their mouths open. Opposite to this is a minute passage, which leads to the sinuosity of the mastoid process; and the other openings, which are in the internal process of the os petrosum, are the fenestra ovalis, and fenestra rotunda, both of which are covered by a very fine membrane.

There are three distinct bones in the cavity of the tympanum; and these are the malleus, incus, and stapes. Besides these there is a fourth, which is the os orbitolare, considered by some anatomists as a process of the stapes, which is necessarily broken off by the violence we are obliged to use in getting at these bones; but when accurately considered, it seems to be a distinct bone.

The malleus is supposed to resemble a hammer, being larger at one extremity, which is its head, than it is at the other, which is its handle. The latter is attached to the membrana tympani, and the head of the bone is articulated with the incus.

The incus, as it is called from its shape, though it seems to have less resemblance to an anvil than to one of the dente molares with its roots widely separated from each other, is distinguished into its body and its legs. One of its legs is placed at the entry of the canal which leads to the mastoid process; and the other, which is somewhat longer than the stapes, or rather with the os orbitolare, which is placed between them.

The third bone is very properly named stapes, being perfectly shaped like a stirrup. Its basis is fixed into the fenestra ovalis, and its upper part is articulated with the os orbitolare. What is called the fenestra rotunda, though perhaps improperly, as it is more oval than round, is observed a little above the other, in an eminence formed by the os petrosum, and is closed by a continuation of the membrane that lines the inner surface of the tympanum. The stapes and malleus are each of them furnished with a little nodule, the flape-deus and tenor tympani. The first of these, which is the smallest in the body, arises from a little cavern in the posterior and upper part of the cavity of the tympanum; and its tendon, after passing through a hole in the same cavern, is inserted at the back part of the head of the stapes. This nodule, by drawing the stapes obliquely upwards, affists in stretching the membrana tympani.

The tenor tympani (x), or internus mallei, as it is called by some writers, arises from the cartilaginous extremity of the Eustachian tube, and is inserted into the back part of the handle of the malleus, which it serves to pull inwards, and of course helps to stretch the membrana tympani.

The labyrinth is the only part of the ear which remains to be described. It is situated in the os petrosum, and is separated from the tympanum by a partition which is every where bony, except at the two fenestrae. It is composed of three parts; and these are the vestibulum, the semicircular canals, and the cochlea.

The vestibulum is an irregular cavity, much smaller than the tympanum, situated nearly in the centre of the os petrosum, between the tympanum, the cochlea, and the semicircular canals. It is open on the side of the tympanum by means of the fenestra ovalis, and communicates with the upper portion of the cochlea by an oblong foramen, which is under the fenestra ovalis, from which it is separated only by a very thin partition.

Each of the three semicircular canals forms about half

---

(x) Some anatomists describe three muscles of the malleus; but only this one seems to deserve the name of muscle; what are called the externus and obliquus mallei, seeming to be ligaments rather than muscles.
ANATOMY

Part VI.

Of the senses.

Half a circle of nearly a line in diameter, and running in each a different direction, they are distinguished into vertical, oblique, and horizontal. These three canals open by both their extremities into the vestibulum; but the vertical and the oblique being united together at one of their extremities, there are only five orifices to be seen in the vestibulum.

The cochlea is a canal which takes a spiral course, not unlike the shell of a snail. From its base to its apex it makes two turns and a half; and is divided into two canals by a very thin lamina or septum, which is in part bony and in part membranous, in such a manner that these two canals only communicate with each other at the point. One of them opens into the vestibulum, and the other is covered by the membrane that cloths the fenestra rotunda. The bony lamella which separates the two canals is exceedingly thin, and fills about two thirds of the diameter of the canal.

The rest of the septum is composed of a most delicate membrane, which lines the whole inner face of the cochlea, and seems to form this division in the same manner as the two membranous bags of the pleura, by being applied to each other, form the mediastinum.

Every part of the labyrinth is furnished with a very delicate peritoneum, and filled with a watery fluid, destined as in other cavities. This fluid transmits to the nerves the vibrations it receives from the membrane cloing the fenestra rotunda, and from the bases of the flares, where it refils on the fenestrum ovale. When this fluid is collected in too great a quantity, or is compressed by the flares, it is fupposed to escape through two minute canals or aqueducts, lately described by Dr Coturni, an ingenious physician at Naples. One of these aqueducts opens into the bottom of the vestibulum, and the other into the cochlea, near the fenestra rotunda. They both pass through the os petrosum, and communicate with the cavity of the cranium where the fluid that paffes through them is absorbed; and they are lined by a membrane which is supposed to be a production of the dura mater.

The arteries of the external ear come from the temporal and other branches of the external carotid, and its veins pafs into the jugular. The internal ear receives branches of arteries from the basillary and carotids, and its veins empty themselves into the sinuses of the dura mater, and into the internal jugular.

The porroto dura of the seventh pair is distributed through the cochlea, the vestibulum, and the semicircular canals; and the porroto dura sends off a branch to the tympanum, and other branches to the external ear and parts near it.

The sense of hearing, in producing which all the parts we have described affift, is occasioned by a certain modulation of the air collected by the funnel-like shape of the external ear, and conveyed through the meatus auditivus to the membrana tympani. That sound is propagated by means of the air, is very easily proved by ringing a bell under the receiver of an air-pump; the sound affords being found to diminish gradually as the air becomes exhausted, till at length it ceases to be heard at all. Sound moves through the air with infinite velocity; but the degree of its motion seems to depend on the state of the air, as it constantly moves faster in a dense and dry, than in a moist and rarefied air.

That the air vibrating on the membrana tympani communicates its vibration to the different parts of the labyrinth, and by means of the fluid contained in this cavity affects the auditory nerve so as to produce sound, seems to be very probable; but the situation, the minuteness, and the variety of the parts which compose the ear, do not permit much to be advanced with certainty concerning their mode of action.

Some of these parts seem to constitute the immediate organ of hearing, and these are all the parts of the vestibulum; but there are others which seem intended for the perfection of this sense, without being absolutely essential to it. It has happened, for instance, that the membrana tympani, and the little bones of the ear, have been destroyed by disease, without depriving the patient of the sense of hearing.

Sound is more or less loud in proportion to the strength of the vibration; and the variety of sounds seems to depend on the difference of this vibration; for the more quick and frequent it is, the more acute will be the sound, and vice versa.

Before we conclude this article, it will be right to explain certain phenomena, which will be found to have a relation to the organ of hearing.

Every body has, in consequence of particular sounds, occasionally felt that disagreeable sensation which is usually called setting the teeth on edge: and the cause of this sensation may be traced to the communication which the porroto dura of the auditory nerve has with the branches of the fifth pair that are distributed to the teeth, being probably occasioned by the violent tremor produced in the membrana tympani by these very acute sounds. Upon the same principle we may explain the strong idea of sound which a person has who holds a vibrating string between his teeth.

The hummimg which is sometimes perceived in the ear, without any exterior cause, may be occasioned either by an increased action of the arteries in the ears, or by convulsive contractions of the muscles of the malleus and flares, affecting the auditory nerve in such a manner as to produce the idea of sound.

An ingenious philosophical writer has lately discovered, that there are sounds liable to be excited in the ear by irritation, and without any assistance from the vibrations of the air.

SECT. V. Of Vision.

The eyes which constitute the organ of vision are situated in two bony cavities named orbitae, where they are surrounded by several parts, which are either intended to protect them from external injury, or to affect their motion.

The

(y) This observation has led to a supposition, that a perforation of this membrane may in some cases of deafness be useful; and Mr Chefelden relates, that, some years ago, a malefactor was pardoned on condition that he should submit to this operation; but the public clamour raised against it was so great, that it was thought right not to perform it.
The globe of the eye is immediately covered by two eye-lids or palpebrae, which are composed of mucous fibres covered by the common integuments, and lined by a very fine and smooth membrane, which is from thence extended over the surface of the globe of the eye, and is called tunica conjunctiva. Each eye-lid is cartilaginous at its edge; and this border which is called tarso, is furnished with a row of hairs named cilia or eye-lashes.

The cilia serve to protect the eye from insects and minute bodies floating in the air, and likewise to moderate the action of the rays of light in their passage to the retina. At the roots of these hairs there are febaceous follicles, first noticed by Melibomius, which discharge a glutinous limiment. Sometimes the fluid they secrete has too much viscidity, and the eye-lids become glued to each other.

The upper border of the orbit is covered by the eye-brows or supercilia, which by means of their two muscles are capable of being brought towards each other, or of being carried upwards. They have been considered as serving to protect the eyes, but they are probably intended more for ornament than utility (2).

The orbits, in which the eyes are placed, are furnished with a good deal of fat, which affords a soft bed on which the eye performs its several motions. The inner angle of each orbit, or that part of it which is near the nose, is called canthus major, or the great angle; and the outer angle, which is on the opposite side of the eye, is the canthus minor, or little angle.

The little reddish body which we observe in the great angle of the eye-lids, and which is called caruncula lacrymalis, is supposed to be of a glandular structure, and, like the follicles of the eye-lids, to secrete an oily humour. But its structure and use do not seem to have been hitherto accurately determined. The surface of the eye is constantly moistened by a very fine limpid fluid called the tears, which is chiefly, and perhaps wholly, derived from a large gland of the conjon- 

The motions of the eye are performed by fix muscles; four of which are straight and two oblique. The straight muscles are distinguished by the name of elevator, depressor, adductor, and abductor, from their several uses in elevating and depressing the eye, drawing it towards the nose, or carrying it from the nose towards the temple. All these four muscles arise from the bottom of the orbit, and are inserted by flat tendons into the globe of the eye. The oblique muscles are intended for the more compound motions of the eye. The first of these muscles, the obliquus inferior, does not, like the other four muscles we have described, arise from the bottom of the orbit, but from the edge of the foramen that transmits the optic nerve, which separates the origin of this muscle from that of the others. From this beginning it passes in a straight line towards a very small cartilaginous ring, the situation of which is marked in the skeleton by a little hollow in the internal orbital proces of the os frontis. The tendon of the muscle, after passing through this ring, is inserted into the upper part of the globe of the eye, which it serves to draw forwards, at the same time turning the pupil downwards.

The obliquus inferior arises from the edge of the orbit, under the opening of the ductus lacrymalis; and is inserted somewhat posteriorly into the outer side of the globe, serving to draw the eye forwards and turn the pupil upwards. When either of these two muscles acts separately, the eye is moved on its axis; but when they act together, it is compressed both above and below. The eye itself, which is now to be described, with its tunics, humours, and component parts, is nearly of a spherical figure. Of its tunics, the conjunctiva has been already described as a partial covering, reflected from the inner surface of the eye-lids over the anterior portion of the eye. What has been named albuginea cannot properly be considered as a coat of the eye, being in fact nothing more than the tendons of the straight muscles spread over some parts of the fletorica.

The immediate tunics of the eye, which are to be demonstrated when its partial coverings, and all the other parts with which it is surrounded, are removed, are the fletorica, cornes, choroides, and retina.

The fletorica, which is the exterior coat, is every where

(2) It is observable, that the eye-brows are peculiar to the human species.

(a) It sometimes happens, that this pure, limid, fluid, which moistens the eye, being poured out through the excretory ducts of the lachrymal gland faster than it can be carried off through the puncta, trickles down the cheek, and is then strictly and properly called tears.

(b) When the ductus ad nares becomes obstructed in consequence of disease, the tears are no longer able to pass into the nostrils; the facculus lachrymalis becomes distended; and inflammation, and sometimes ulceration taking place, constitute the disease called fistula lacrymalis.
where white and opaque, and is joined at its anterior edge to another, which has more convexity than any other part of the globe, and being exceedingly transparent is called cornea (c). These two parts are perfectly different in their structure; so that some anatomists suppose them to be as distinct from each other as the glass of a watch is from the case into which it is fixed. The sclerotic is of a compact fibrous structure; the cornea, on the other hand, is composed of a great number of laminae united by cellular membrane. By macerating them in boiling water, they do not separate from each other, as some writers have asserted; but the cornea soon softens, and becomes of a glutinous nature.

The ancients supposed the sclerotic to be a continuation of the dura mater. Morgagni and some other modern writers are of the same opinion; but this point is disputed by Winlow, Haller, Zinn, and others. The truth seems to be, that the sclerotic, though not a production of the dura mater, adheres intimately to that membrane.

The choroides is so called because it is furnished with a great number of vessels. It has likewise been named uvea, on account of its resemblance to a grape. Many modern anatomical writers have conceived it as a production of the pia mater. This was likewise the opinion of the ancients; but the strength and thickness of the choroides, when compared with the delicate structure of the pia mater, are sufficient proofs of their being two distinct membranes.

The choroides has of late generally been described as consisting of two laminae; the innermost of which has been named after Ruyfch, who first described it. It is certain, however, that Ruyfch's division is ill founded, at least with respect to the human eye, in which we are unable to demonstrate any such structure, although the tunica choroides of sheep and some other quadrupeds may easily be separated into two layers.

The choroides adheres intimately to the sclerotic round the edge of the cornea; and at the place of this union, we may observe a little whitish areola, named ligamentum ciliare, though it is not of a ligamentous nature.

They who suppose the choroides to be composed of two laminae, describe the external one as terminating in the ligamentum ciliare, and the internal one as extending farther to form the iris, which is the circle we are able to distinguish through the cornea; but this part is of a very different structure from the choroides; so that some late writers have perhaps not improperly considered the iris as a distinct membrane. It derives its name from the variety of its colours, and is perforated in its middle. This perforation, which is called the pupil or sight of the eye, is closed in the focus by a very thin vascular membrane. This membrana pupillaris commonly disappears about the seventh month.

On the under side of the iris we observe many minute fibres, called ciliary processes, which pass in radii or parallel lines from the circumference to the centre. The contraction and dilatation of the pupil are supposed to depend on the action of these processes. Some have considered them as muscular, but they are not of an irritable nature; others have supposed them to be filaments of nerves: but their real structure has never yet been clearly ascertained.

Besides these ciliary processes, anatomists usually speak of the circular fibres of the iris, but no such seem to exist.

The posterior surface of the iris, the ciliary processes, and part of the tunica choroides, are covered by a black mucus for the purposes of accurate and distinct vision; but the manner in which it is secreted has not been determined.

Immediately under the tunica choroides we find the third and inner coat, called the retina, which seems to be merely an expansion of the pulpy substance of the optic nerve, extending to the border of the crystalline humour.

The greatest part of the globe of the eye, within these several tunics, is filled by a very transparent and gelatinous humour of considerable consistence, which, from its supposed resemblance to leaded glass, is called the vitreous humour. It is invested by a very fine and delicate membrane, called tunica vitrea, and sometimes arachnoides. It is supposed to be composed of two laminae; one of which dips into its substance, and by dividing the humour into cells adds to its firmness. The fore-part of the vitreous humour is a little hollowed, to receive a very white and transparent substance of a firm texture, and of a lenticular form, somewhat convex in shape, named the crystalline humour. It is included in a capsule, which seems to be formed by a separation of the two laminae of the tunica vitrea.

The fore-part of the eye is filled by a very thin and transparent fluid, named the aqueous humour, which occupies all the space between the crystalline and the prominent cornea. That part of the choroides which is called the iris, and which comes forward to form the pupil, appears to be suspended as it were in this humour, and has occasioned this portion of the eye to be distinguished into two parts. One of these, which is the little space between the anterior surface of the crystalline and the iris, is called the anterior chamber; and the other, which is the space between the iris and the cornea, is called the anterior chamber of the eye (b). Both these spaces are completely filled with the aqueous humour (a).

The eye receives its arteries from the internal carotid:

(c) Some writers, who have given the name of cornea to all this outer coat, have named what is here and most commonly called scleroticus, cornea opaca; and its anterior and transparent portion, cornea lucida.

(b) We are aware that some anatomists, particularly Lieutaud, are of opinion, that the iris is every where in close contact with the crystalline, and that it is of course right to speak only of one chamber of the eye; but as this does not appear to be the case, the situation of the iris and the two chambers of the eye are here described in the usual way.

(x) When the crystalline becomes opaque, so as to prevent the passage of the rays of light to the retina, it constitutes what is called a catactus; and the operation of couching consists in removing the disced crystalline from...
Anatomy. Part VI.

Of the Eye.

A young gentleman who was born blind, and who was
coached by Mr. Chefdelden, every object (as he ex-
pressed himself) seemed to touch his eyes as what he
felt did his skin; and he thought no objects so agree-
able as those which were smooth and regular, although
for some time he could form no judgment of their shape,
or guess what it was in any of them that was pleasing
to him.

In order to paint objects distinctly on the retina,
the cornea is required to have such a degree of con-
 convexity, that the rays of light may be collected at a
certain point, so as to terminate exactly on the retina.

If the cornea is too prominent, the rays, by diverging
too soon, will be reunited before they reach the retina,
as is the case with near-sighted people or myopes; and
on the contrary, if it is not sufficiently convex, the rays
will not be perfectly united when they reach the back
part of the eye; and this happens to long-sighted peo-
ple or presby, being found constantly to take place as
we approach to old age, when the eye gradually flat-
tens (r). These defects are to be supplied by means of
glasses. He who has too prominent an eye, will find
his vision improved by means of a conoe glafs; and
upon the same principles, a convex glafs will be found
useful to a person whose eye is naturally too flat.

Explanation

Figure 1. Shows the Lachrymal Canals, after the
Common Teguments and Bones have been cut away.

a, The lachrymal gland. b, The two puncta lachry-
malis, from which the two lachrymal canals pro-
ceed to c, The lachrymal sac. d, The large lachrymal
duct. e, Its opening into the nose. f, The caruncu-
la lachrymalis. g, The eye-ball.

Figure 2. An interior View of the Coats and Humours
of the Eye.

ANATOMY.
Anc

Anaximenes, the son of Aristocles of Lampacus an orator, the disciple of Diogenes the Cynic, and of Zelius the raider against Homer. He was preceptor to Alexander of Macedon, and followed him to the wars. Alexander being infatuated against the people of Lampacus, they sent this philosopher to Intercede for them. Alexander knowing the causé of his coming, swore that he would do the very reverse of whatever he desired of him. Anaximenes begged of him to destroy Lampacus. Alexander, unwilling to break his oath, and not able to elude this stratagem, pardoned Lampacus much against his will.

Anaximandrians, in the history of philosophy, the followers of Anaximander; the most ancient of the philosophical atheists, who admitted of no other substance in nature than matter.

Anazarbus (Pliny), Anazarbas (Stephanus); a town of Cilicia, on the river Pyramus, the birth place of Dioecesides, and of the poet Oppian. It was sometimes called Cæsarea, in honour either of Augustus or of Tiberius. The inhabitants are called Anazarbani (Pliny), and on coins Anazarrites, after the Greek idiom. It was destroyed by a dreadful earthquake in the year 535, along with several other important cities; but they were all repaired at a vast expense by the emperor Justin; who was so much affected with their misfortune, that, putting off the diadem and purple, he appeared for several days in sackcloth.

Anbertkend, in the eastern language, a celebrated book of the Brahmanas, wherein the Indian philosophy and religion are contained. The word in its literal sense denotes the cittern wherein is the water of life. The anbertkend is divided into 50 beth, or discourses, each of which consists of ten chapters. It has been translated from the original Indian into Arabic, under the title of Morat al Fahan, q. d. the marrow of intelligence.

Ancarano, a town of Italy, in the march of Ancona, situate in E. Long. 14° 54'. N. Lat. 42° 48'.

Ancaster, a town of Lincolnshire, situate in W. Long. 30°. N. Lat. 52° 30'. It gives title of duke to the noble family of Bertie.

Ancenis, a town of France, in the province of Brittany. W. Long. 1° 9'. N. Lat. 47° 20'.

Ancestors, those from whom a person is descended in a straight line. The word is derived from the Latin ancestor, contrived from antecessor, q. d. goer before.

Most nations have paid honours to their ancestors. It was properly the deputed fouls of their forefathers that the Romans worshipped under the denominations of raius, honour, and boeskold gods. Hence the ancient tombs were a kind of temples, or rather altars, wherein oblations were made by the kindred of the deceased.

The Russians have still their anniversary feasts in memory of their ancestors, which they call roditois fabet, q. d. kinship's jubilee, wherein they make formal visits to the dead in their graves, and carry them provisions, eatables, and presents of divers other kinds. They interrume them, with loud lamentable cries, What are they doing? How they spend their time? What it is they want? and the like.

The Orajes, a people of Africa, offer sacrifices of rice and wine to their ancestors before ever they undertake any considerable action. The anniversaries of their deaths are always kept by their families with great solemnity. The king invokes the soul of his father and mother to make trade flourish and the chaste succeed.

The Chinese seem to have distinguished themselves above all other nations in the veneration they bear to their ancestors. By the laws of Confucus, part of the duty which children owe to their parents consists in worshipping them when dead. This service, which makes a considerable part of the natural religion of the Chinese, is said to have been instituted by the emperor Kan, the fifth in order from the foundation of that ancient empire. Bibl. Un. tom. vii. The Chinese have both a solemn and ordinary worship which they pay to their ancestors. The former is held regularly twice a year, viz. in spring and autumn, with much pomp. A person who was present at it gives the following account of the ceremonies on that occasion: The sacrifices were made in a chapel well adorned, where there were fix altars furnished with centers, tapers, and flowers. There were three ministers, and behind them two young acolytes. The three former went with a profound silence, and frequent genuflexions, towards the five altars, pouring out wine: afterwards they drew near to the sixth, and when they came to the foot of the altar, half bowed down, they said their prayers with a low voice. That being finished, the three ministers went to the altar, the officiating priest took up a vessel full of wine, and drank; then he lifted up the head of a deer or goat; after which, taking fire from the altar, they all lighted a bit of paper, and the minister of the ceremonies turning towards the people, said with a high voice, that he gave them thanks in the name of their ancestors for having so well honoured them; and in recompence he promised them, on their part, a plentiful harvest, a fruitful illsue, good health, and long life, and all those advantages that are most pleasing to men.

The Chinese give their ancestors another simpler and more private worship. To this end they have in their houses a niche or hollow place, where they put the names of their deceased fathers, and make prayers and offerings of perfumes and spices to them at certain times, with bowing, &c. They do the like at their tombs.

The Jews settled in China are said to worship their ancestors like the heathens, and with the same ceremonies, except that they offer not swine's flesh. Near their synagogue they have a hall, or court of ancestors, wherein are niches for Abraham, Isaac, &c. The Jews also confirnmed, and were permitted by their general
ANCHILOPS, or, in medicine, denotes an abscess, or collection or matter, between the great angle of the eye and the nose. If suffering to remain too long, or unskilfully managed, it degenerates, the flagrating humours corrupt, and the tears flow involuntarily, whilst the os lachrymale is not carious, it is an *aglopis*; but when the ulcer is of a long standing, deep, festish, and the os lachrymale becomes carious, it is a *fellinus*. The cure is by restriction and excision, tying it at the root on the glandula lachrymatis, and, when ready, cutting it off. 

ANCHISES, in fabulous history, a Trojan prince, descended from Dardanus, and the son of Capys. Venus made love to him in the form of a beautiful nymph; and bore him *Anaes*, the hero of Virgil's *Aeneid*.

ANCHOR (ancora, Lat. from αγκόρα, Greek), a heavy, strong, crooked instrument of iron, dropped from a ship into the bottom of the water, to retain her in a convenient station in a harbour, road, or river.

The most ancient anchors are said to have been of stone; and sometimes of wood, to which a great quantity of lead was usually fixed. In some places, bales full of stones, and stakes filled with sand, were employed for the same use. All these were let down by cords into the sea, and by their weight stayed the course of the ship. Afterwards they were composed of iron, and furnished with teeth, which, being fastened to the bottom of the sea, preserved the vessel immovable; whence *discrevix* and *denter* are frequently taken for anchors in the Greek and Latin poets. At first there was only one tooth, whence anchors were called *monotere*; but in a short time the second was added by Eupalamus, or Anacharis, the Scythian philosopher. The anchors with two teeth were called *biferei* or *biferei*, and from ancient monuments appear to have been much the same with those used in our days, only the transverse piece of wood upon their handles (the *flock*) is wanting in all of them. Every ship had several anchors; one of which, surpassing all the rest in bigness and strength, was peculiarly termed *sacra*, and was never used but in extreme danger; whence *sacrum anchoras sacrum* is proverbially applied to such as are forced to their last refuge.

The anchors now made are contrived so as to sink into the ground as soon as they reach it, and to hold a great strain before they can be loosened or dislodged from their station. They are composed of shank, a flock, a ring, and two arms with their flukes. The flock, which is a long piece of timber fixed across the shank, serves to guide the flukes in a direction perpendicular to the surface of the ground; so that one of them sinks into it by its own weight as soon as it falls, and is still preferred steadily in that position by the flock, which together with the shank, lies flat on the bottom. In this situation it must necessarily sustain a great effort before it can be dragged through the earth horizontally. Indeed this can only be effected by the violence of the wind or tide, or both of them, sometimes increased by the turbulence of the seas, and acting upon the ship so as to stretch the cable to its utmost tension, which accordingly may dislodge the anchor from its bed, especially if the ground be soft and oozy, or rocky. When the anchor is thus displaced, it is said, in the Greek phrase, *to come home*.

That the figure of this useful instrument may be more clearly understood, let us suppose a long nailed beam of iron erected perpendicularly, $h$, at the lower end of which are two arms, $a, e$, of equal thickness with the beam (usually called the *shank*) only that they taper towards the points, which are elevated above the horizontal plane at an angle of 30 degrees, or inclined to the shank at an angle of 60 degrees; on the upper part of each arm, (in this position) is a fluke or thick plate of iron, $g, h$, commonly shaped like an idiole triangle whose base reaches to the middle of the arm. On the upper end of the shank is fixed the flock transversely with the flukes; the flock is a long beam of oak, $f$, in two parts, strongly bolted, and hooped together with iron rings. See also No. 2. Closer above the shank is the ring $k$, to which the cable is fastened, or bent; the ring is curiously covered with a number of pieces of short rope, which are twisted about it so as to form a very thick texture or covering called the *pudding*, and used to prefer the cable from being fretted or chafed by the iron.

Every ship has, or ought to have, three principal anchors, with a cable to each, viz. the *flet*, *maillotte*, *sacra*, (which is the *ancora sacra* of the ancients); the beft bowe, *second anor*; and small bowe, *ancor d'affarche*, so called from their usual situation on the ship's bows. There are besides smaller anchors, for removing a ship from place to place in a harbour or river, where there may not be room or wind for sailing; these are the stream-anchor, *ancor de toue*; the kedge, and grappling, *grapine*; this last, however, is chiefly designed for boats.

**Method of Making Anchors.** The good use of the anchor is a point of great importance. Great care is therefore to be taken, that the metal it is made of be neither too soft nor too brittle; the latter rendering it liable to break and the former to strain.

The shank, arms, and flukes, are first forged separately; then the hole is made at one end of the shank for the ring, which being also previously forged, is
ANCHOR

Anchor. put into the hole of the shank, and the two ends shut together. After which the arms are shut to the shank one after the other, and the anchor is finished.

Proof is made of anchors, by raising them to a great height, and then letting them fall again on a kind of iron block placed across for the purpose. To try whether the flukes will turn to the bottom and take hold of the ground, they place the anchor on an even surface, with the end of one of the flukes, and one of the ends of the stock resting on the surface; in case the anchor turns, and the point of the fluke rises upwards, the anchor is good.

In England, France, and Holland, anchors are made of forged iron; but in Spain they are sometimes made of copper, and likewise in several parts of the South-Sea.

For the proportions of anchors, according to Man-waring, the shank is to be twice the length of one of the flukes, and half the length of the beam. According to Aubin, the length of the anchor is to be four tenths of the greatest breadth of the ship; so that the shank, e. gr. of an anchor in a vessel 30 feet wide, is to be 12 feet long. When the shank is, for instance, eight feet long, the two arms are to be seven feet long, measuring them according to their curvature. As to the degree of curvature given the arms, there is no rule for it; the workmen are here left to their own discretion.

The latter writer observes, that the anchor of a large heavy vessel is smaller, in proportion, than that of a lighter one. The reason he gives is, that though the sea employs an equal force against a small vessel as against a great one, supposing the extent of wood upon which the water acts to be equal in both, yet the little vessel, by reason of its superior lightness, does not make so much resistance as the greater; the defect whereof must be supplied by the weight of the shank.

From these, and other hydrostatic principles, the following table has been formed; wherein is shown, by means of the ship's breadth within, how many feet the beam or shank ought to be long, giving it four-tenths or two-fifths of the ship's breadth within: by which proportion might be regulated the length of the other parts of the anchor. In this table is represented likewise the weight an anchor ought to be for a ship from eight feet broad to 45, increasing by one foot's breadth; supposing that all anchors are similar, or that their weights are as the cubes of the lengths of the shanks.

M. Bouguer, in his Traité de Navire, directs to take the length of the shank in inches, and to divide the cube of it by 1160 for the weight. The reason is obvious; because the quotient of the cube of 20\frac{1}{2} inches, which is the length of an anchor weighing 7000 lb., divided by the weight, is 1160; and therefore, by the rule of three, this will be a common divisor for the cube of any length, and a single operation will suffice.

The same author gives the following dimensions of the several parts of an anchor. The two arms generally form the arch of a circle, whose centre is three-eighths of the shank from the vertex, or point where it is fixed to the shank; and each arm is equal to the same length, or the radius; so that the two arms together make an arch of 180 degrees: the flukes are half the length of the arms, and their breadth two-fifths of the said length. With respect to the thickness, the circumference at the throat, or vertex of the shank, is generally made about the fifth part of its length, and the small end two-thirds of the throat; the small end of the arms of the flukes, three-fourths of the circumference of the shank at the throat. These dimensions should be bigger, when the iron is of a bad quality, especially if cast iron is used instead of forged iron.

At Anchor, the situation of a ship which rides by her anchor in a road or haven, &c. Plate XXXI. fig. 1. No 3, represents the fore part of a ship as riding in this situation. See also Buoy-Rope.

To Fish the Anchor, to draw up the flukes upon the ship's side after it is catted. See the articles DAVIT and Fish.

To Fish the Ship to her Anchor, is to steer the ship's head towards the place where the anchor lies when they are heaving the cable into the ship; that the cable may thereby enter the haufe with less resistance, and the ship advance towards the anchor with greater facility.
ANCHOR-GROUND is a bottom which is neither too deep, too hollow, nor rocky; as in the first the cable bears too nearly perpendicular, and is thereby apt to jerk the anchor out of the ground; in the second, the ship's bottom is apt to strike at low water, or when the sea runs high, by which she is exposed to the danger of sinking; and in the third, the anchor is liable to hook the broken and pointed ends of rocks, and tear away its flukes, whilst the cable, from the same cause, is constantly in danger of being cut through as it rubs on their edges.

ANCHORS, in architecture, is a sort of carving, somewhat resembling an anchor. It is commonly placed as part of the enrichments of the boultings of capitals of the Tuscan, Doric, and Ionic orders, and also of the boultings of bed-mouldings of the Doric, Ionic, and Corinthian cornices, anchors and eggs being carved alternately through the whole building.

ANCHORS, in heraldry, are emblems of hope, and are taken for such in a spiritual as well as a temporal sense.

ANCHORAGE, in law, is a duty upon ships for the use of the port or harbour where they cast anchor.

ANCHOVY, in ichthyology, the English name of the clupea encrasicolus. See CLUPEA.

ANCHOVY-PEAR. See GRIAS.

ANCHUSA. ALKANET or BUGLOSS: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 44th order, ephemcrifolae. The calyx is a quinquepartite perianthium, oblong and perifent: The corolla is monopetalous and funnel-shaped, the throat closed with scales: The flamina consist of five short filaments: the antheräe oblong and covered: The pistillum has four germina, a filiform stylum, and obtuse stigma: There is no pericarpium, the calyx containing the seeds in its bolum: The seeds are four, oblong, gibbosus, and engraven at the base.

Species. 1. The officinalis, or greater garden-bugloss, is a native of France and of the warmer parts of Europe, but will thrive well enough in the climate of Britain; though the roots seldom continue longer than two years there, unless they happen to grow in rubbish, or out of an old wall, where they will live three or four years.

2. The anguilfolia, or perennial wild bugloss, grows to the height of two feet when cultivated in gardens; but in those places where it grows wild is seldom more than a foot and a half high. The leaves of this sort are narrow; the spikes of flowers come out double, and have no leaves about them; the flowers are small, and of a red colour. The roots will continue two years in a poor soil.

3. The undulata, or Portugal bugloss, is a biennial plant, which grows to the height of two feet, and sends out many lateral branches. The flowers are of a bright blue colour, and grow in an imbricated spike.

4. The orientalis, or eastern bugloss, is a native of the Levant. It is a perennial plant, with long trailing branches which lie on the ground. The flowers are yellow, and about the size of the common bugloss, and there is a succession of these on the same plants great part of the year.

5. The virginiana, or punctoon, grows naturally in the woods of North-America; and being an early plant, generally flowers before the new leaves come out on the trees; so that in some woods where it abounds, the ground seems entirely covered with its yellow flowers. It is a perennial plant, which seldom rises a foot high in good ground, but not above half that height where the soil is poor. The flowers grow in loose spikes upon smooth stalks. 6. The sempervirens, or ever-green borage, is a very hardy perennial plant, with weak trailing branches. It grows naturally in some parts of Britain and Spain. The flowers are blue, and come out between the leaves on the spike, like the fourth sort. They appear during a great part of the year.

7. The cirtica, or warted bugloss of Crete, is a low trailing annual plant, whose branches seldom extend more than six inches. The flowers are small, of a bright blue colour, and are collected into small bunches at the extremity of the branches. The plants perish soon after their seeds are ripe.

8. The tinctoria, or true alkanet, grows naturally in the Levant, but is equally hardy with the first species. The flowers grow in long spikes, coming out imbricate, like the tiles of a house.

Culture. All the species of anchusa may be propagated by seeds; which should be sown, either in the spring or autumn, upon a bed of light sandy earth; and when the plants are strong enough to be removed, they must be planted on beds at two feet distance from another, and watered, if the season requires it, till they have taken root; after which they will require no other care than to keep them free from weeds.

Medicinal Uses, &c. The flowers of the first species have obtained the name of cordial flowers; to which they have no other title than that they moderately cool and soften, without offending, the palate or stomach; and thus, in warm climates, or in hot diseases, may in some measure refresh the patient. The root of the tinctoria is likewise used, not as pounded of any medicinal virtue, but on account of its imparting an elegant red colour to oily substances; so is frequently directed as a colouring ingredient for ointments, plasters, &c.

As the colour is confined to the cortical part, the small roots are to be preferred, as having proportionally more bark than the large ones. The alkanet root which grows in England is greatly inferior to what comes from France, and some other parts of Europe.

ANC

Ancones

15. 5. N. Lat. 43° 36'.

Ancones, in architecture, the corners or quoin

of walls, cross-beams, or rafters.—Vitruvius calls the

corners the same name.

ANCONY, in the iron-works, a piece of half-

wrought iron, of about three quarters of 100 weight,

and of the shape of a bar in the middle, but rude and

unwrought at the ends. The process for bringing the

iron to this state is this: They first melt off a piece

from a few of cast iron, of the proper size; these

they hammer at the forge into a mass of two feet long,

and of square shape, which they call a bloom; when this

is done, they send it to the foundry, where, after two or

three heats and workings, they bring it to this figure,

called an ancony. The middle part being out at the

foundry, is about three feet long, and of the shape and

thickness the whole is to be; this is then sent to the

chafery, and there the ends are wrought to the shape

of the middle, and the whole made into a bar. See

Bar.

ANCORARUM URBIS, Ancyren Polis, a city in

the Nomos Aphroditoepolitos, towards the Red Sea;

so called because there was in the neighbourhood a stone

quarry, in which they hewed stone anchors (Pio-

lemo), before iron anchors came to be used. The gen-

tilious name is Ancyropolis, (Stephanus).

ANCOURT (Florent-Carton'd), an eminent French

actor and dramatic writer, born at Pontoise, Octo-

ber 1661. He studied in the Jesuit's college at

Paris, under father de la Rue; who, discovering in him a re-

markable vivacity and capacity for learning, was ex-

tremely desirous of engaging him in their order; but

Ancourt's aversion to a religious life rendered all his

efforts ineffectual. After he had gone through a course

of philosophy, he applied himself to the civil law, and

was admitted advocate at 17 years of age. But falling

in love with an actress, he was induced to go upon the

stage, and he married her. As he had all the qualifi-
cations necessary for the theatre, he soon greatly distin-
guished himself: and not being satisfied with the ap-

plause only of an actor, he began to write pieces for the

stage; many of which had such prodigious success, that

most of the players grew rich from the profits of

them. His merit in this way procured him a very fa-

vourable reception at court; and Lewis XIV. show-

ed him many marks of his favour. His sprightly conver-
sation and polite behaviour made his company agreeable
to all the men of figure both at court and in the city and
the most considerate persons were extremely plea-

ted to have him at their houses. Having taken a jour-

ney to Dunkirk, to see his eldest daughter who lived

there, he took the opportunity of paying his compli-

ments to the elector of Bavaria, who was then at Brus-

seis: this prince received him with the utmost civility;

and having detained him a considerable time, dismissed

him with a present of a diamond valued at 1000 pi-

stoles: he likewise rewarded him in a very generous

manner, when, upon his coming to Paris, Ancourt com-
poused an entertainment for his diversion. Ancourt be-

gan at length to grow weary of the theatre, which he

quitted in Lent 1718, and retired to his estate of Cour-

cellesie Roy, in Berry, where he applied himself whol-

ly to devotion, and composed a translation of David's

Prums in verse, and a sacred tragedy, which were ne-

ver printed. He died the 6th of December, 1726, be-

ing 65 years of age.—The plays which he wrote are

52 in all; most of which were printed separately at the

time when they were first represented; they were after-

wards collected into five volumes, then into seven, and

at last nine. This last edition is the most complete.

ANCRE, a small town of France, in Picardy, with

the title of a marquisate, seated on a little river of the

same name. E. Long. 2. 45. N. Lat. 49° 59'.

ANCUS MARTIUS, the fourth king of the Ro-

mans, succeeded by Tullius Hostilius, 629 years before

Christ. He defeated the Latins, subdued the Rude-

nates, conquered the Sabines, Volscii, and Venetines,

enlarged Rome by joining it to Mount Janicula, and

made the harbour of Ostia. He died about 615 years

before the Christian era.

ANCY, in antiquity, a kind of shield that fell,
as was pretended, from heaven, in the reign of Numa

Pompilius; at which time, likewise, a voice was heard

declaring that Rome should be mistress of the world as

long as she should preserve this holy buckler. It was

kept with great care in the temple of Mars, under the

direction of twelve priests; and least any should attempt
to steal it, eleven others were made so like, as not to

be distinguished from the sacred one. These ancylia

were carried in procession every year round the city of

Rome.

ANCY, in surgery. See Ancylosis.

ANCYLOBARON, (from ανκυλος an eye-lid), a disea-
s of the eye, which cloes the eye-lids. Sometimes the eye-
lids grow together, and also to the uncina albiguine of

eye, which comes from carelessness when there is an ulcer in these parts.

Both these cases are called ancylobaros by the

Greeks. This disorder must be distinguished from that

coalition of the eye-lids which happens from vitio­
matter gluing them together. If the cohesion is on the

cornea, the sight is inevitably lost. This hath some-
times happened in the small-who. If there is only a

growing together of the eye-lids, they into two, and are

separated by the spectacle, and pledges kept between them to

prevent their re-union. If the eye-lids adhere to the

eye, they are to be separated by a fine-edged knife;

and their re-union is to be prevented by a proper use of

injections, and lint placed between them, after dipping

it in some proper liniment.

ANCYLOGLOSSUM, (from ανκυλος crooked and

γλωσσα the tongue); a contraction of the ligaments

of the tongue. Some have this imperfection from their

birth, others from some disease. In the first case, the

membrane which supports the tongue is too short or

too hard; in the latter, an ulcer under the tongue, heal-

ing and forming a cicatrix, is sometimes the cause:

These speak with some difficulty. The ancyloglossus

by nature are late before they speak; but when they

begin, they soon speak properly. These we call tongu-

tied. Maricanius says, that in this case it is a small mem-

branous production, which extends from the frenulum

to the tip of the tongue, that hinders the child from

fucking, &c. He justly condemns the cruel practice

among nurses, of tearing this membrane with their

nails; for thus ulcers are sometimes formed, which are

of
of difficult cure: he advises to slip it with cæcils in
ferum on the coast of Siam. They are but little known;
two or three places, taking care not to extend the
only the East India ships sometimes touch at them, and
points of the cæcils so far as the frænum. The in-
are supplied by the natives with rice, herbs, and fruits:
stances rarely occur which require any kind of allia-
the inhabitants are by some represented as a harmless
scape: for if the child can thrall the tip of its tongue
to the outer edge of its lip, this diseafed does not exist;
and if the tongue is not greatly refrained, the frænu-
and crying.
Ancylosis, in surgery, implies a distortion or stiftenes-
sum. It is separated by the
these in the region of the

ANDERMAN, or Andeman Islands, situated about 80 leagues distance from Tana-
Andrefon. was made lord chief justice of the common pleas, and
in the year following was knighted. He held his of-
file to the end of his life, died in the year 1605, and
was buried at Ewythor in Bed fordshire. He was an
able, but punctilious lawyer, a founce to the Pur-
tans; and a feneuous supporter of the ftablifhed
church. His works are, 1, Reports of many prin-
cipal cases argued and adjudged in the time of queen
Elizabetb, in the common bench. Lond. 1644, fol.
2. Resolutions and judgments on the cases and matters
agitated in all the courts of Welfminifter, in the latter
end of the reign of queen Elizabeth. Published by
John Goldborough, Efq; Lond. 1673, 4to. Beside:
there, is a manuscript copy of his Readings still in
being.

Anderson (Adam), a native of Scotland, was
brother to the reverend James Anderson, D. D. editor
of the Diplomata Scotiae and Royal Genealogies, many
years fince minifter of the Scots prebyterian church
in Swallow-street, Piccadilly, and well known in those
days among the people of that persuasion resident in
London, by the name of Bishop Anderson, a learned
but imprudent man, who left a confiderable part of his
property in the fatal year 1720. He married, and had
fiiue a fon, and a daughter, who was the wife of an
officer in the army.

Adam Anderson was for 40 years a clerk in the
South Sea Houfe; and at length arrived to his acmé
there, being appointed chief clerk of the Stock and
New Annuities, which office he retained till his death.
He was appointed one of the traffees for ftabilifying
the colony of Georgia, in America; and was also one
of the court of affiliates of the Scots corporation in
London. The time of the publication of his "His-
torical and Chronological Deduction of Trade and
Commerce," a work replete with useful information,
was about the year 1762. He was twice married;
by the firft wife he had fiiue a daughter, married to
one Mr Hardy, an apothecary in the Strand, who are
both dead without fiiue; he afterwards became the
third husband of the widow of Mr Coulter, formerly
a wholefafe linen-draper in Cornhill, by whom he
had no fiiue. She was, like him, tall and graceful;
and her face has been thought to have borne resem-
blance to that of the ever-living countefs of Defmond,
given in Mr Pennant's firft Tour in Scotland. Mr An-
derfon died at his house in Red Lion-street, Clerken-
well, January 10, 1775. He had a good library of
books, which were fold by his widow, who survived
him feveral years, and died in 1791.

Andes, a great chain of mountains in South Ame-
rica, which, running from the moft northern part of
Peru to the Straits of Magellan, between 3 and 4000
miles, are the longest and moft remarkable in the
world. The Spaniards call them the Cordillera de los
Andes; they form two ridges, the lower moft of which
is overfpread with woods and groves, and the upper-
moft covered with everlafting snow. Thofe who have
been at the top, affirm, that the fky is always fenere
and bright; the air cold and piercing; and yet fo thin,
that they were fcarce able to breathe, and the respiration
was much thicker than ordinary; and this is attended
with reaching and vomiting; which, however, has
been confidered by fome as merely accidental. When
they looked downwards, the country was hid by the
clouds that hovered on the mountain's fides. The
mountains juft mentioned, which have been frequently
afcended, are much inferior in height to many others
in this enormous chain. The following is the account
given of the mountain called Pichincha, by the mathe-
maticians fent by the kings of France and Spain to
make obervations in relation to the figure of the earth.

Soon after our artists arrived at Quito, they deter-
dined to continue the feries of the triangles for mea-
suring an arch of the meridian to the S. of that city;
the company accordingly divided themselves into two
bodies, consisting of French and Spaniards, and each
retired to the part assigned them. Don George Juan
and M. Godin, who were at the head of one party,
gl went to the mountain of Pambamarca, while M.
Bougur, de la Condamin, and Don Ulloa, together
with their affiliates, climbed up to the highest summit
of Pichincha. Both parties fuffered extremely, as
well from the feverity of the cold as from the impe-
tuality of the winds, which on their heights blow
with incessant violence; difficulties the more painful,
as they had been little used to fuch fentations. Thus,
in the torrid zone, nearly under the equinoctial, where
it is natural to fuppofe they had moft to fear from the
heat, their greateft pain was caufed by the excefive-
nefs of the cold.

Their firft fcheme for felter and lodging in these
uncomfortable regions, was to pitch a field-tent for
each company; but on Pichincha this could not be
done from the narrownefs of the fummit: they were
therefore obliged to be contented with a hut fo small
that they could hardly all creep into it. Nor will this
appear strange, if the reader confiders the bad difpo-
sion and smallnefs of the place, it being one of the
loftift crags of a rocky mountain, 100 fathoms above
the highest part of the defart of Pichincha. Such
was the situation of their manifon, which, like all the
other adjacent parts, soon became covered with ice and
snow. The acent up this stupendous rock from the
base, or the place where the mules could come, to
their habitation, was fo craggy as only to be climbed
on foot; and to perform it cost them four hours con-
tinuous labour and pain, from the violent efforts of the
body, and the infubility of the air; the latter being fuch
as to render respiration difficult.

The strange manner of living to which our artists
were reduced during the time they were employed in
a geometrical menfuration of fome degrees of the me-
ridian, may not perhaps prove unentertaining to the
reader; and therefore the following account is given
as a fpecimen of it. The defart of Pichincha, both
with regard to the operations performed there and its
inconveniences, differing very little from others, an
idea may be very eafily formed of the fatigues, hard-
ships, and dangers, to which they were continually
exposed during the time they were prosecuting the en-
terprise, with the conduct of which they had been ho-
oured. The principal difference between the feveral
defarts confifted in their greater or leffer distance
from places where they could procure provisions; and
in the inclemency of the weather, which was propor-
tionate to the height of the mountains, and the fefion
of the year.

They generally kept within their hut. Indeed they
were obliged to do this, both on account of the in-
G P tendency
The tenors of the cold, the violence of the wind, and
their being continually involved in so thick a fog, that
an object at six or eight paces was hardly discernible.
When the fog cleared up, the clouds by their gravity
moved nearer to the surface of the earth, and on all
sides surrounded the mountains to a vast distance, rep-
resenting the sea, with their rock like an island in the
centre of it. When this happened they heard the
horrid noises of the tempests, which then discharged
themselves on Quito and the neighbouring country.
They saw the lightnings issue from the clouds, and
heard the thunders roll far beneath them: and whilst
the lower parts were involved in tempests of thunder
and rain, they enjoyed a delightful serenity; the wind
blows; their lips swelled, the sun moderated the severity
of the cold. But their frequently they were obliged to
rise: their thickness rendered respiration difficult; the
lips, it produced such
snow and hail fell continually; and the wind returned
with all its violence; so that it was impossible entire-
ly to overcome the fears of being, together with their
hut, blown down the precipice, on whose edge it was
frequently

Their common food in this inhospitable region was
a little rice boiled with some fliess or fowl, procured from
Quito; and, instead of fluid water, their pot was fill-
ed with ice; they had the fame reliance with regard
to what they drank; and while they were eating, ev-
evry one was obliged to keep his plate over a chafing-
dish of coals, to prevent his provisions from freezing.
The fame was done with regard to the water. At first
they imagined the drinking strong liquors would dif-
fuse a heat through the body, and consequently ren-
der it less sensible of the painful sharpness of the cold;
but, to their surprize, they felt no manner of
strength in such liquors, nor were they any greater preservative
against the cold than the common water.

The days were
The nights were
Their

Though their

but their.

They were not indeed without servants and Indians; but these were so
bemused with the cold, that it was with great diffi-
culty they could get them out of a small tent, where
they kept a continual fire. So that all our artists could
obtain from them was to take their turns in this la-
bour; and even then they went very unwillingly about
it, and consequently performed it very slowly.

It may easily be conceived what this company suf-
fered from the aperities of such a climate. Their feet
were swelled; and so tender, that they could not even
bear the heat; and walking was attended with extra-
geme.

Their hands were covered with chil-
blains; their lips swelled and chopped; so that every
motion in speaking, or the like, drew the blood; con-
sequently they were obliged to strict taciturnity, and
little disposed to laugh, as, by causing a diffusion of
the lips, it produced such
fich figures as were very painful for two or three days after.

At the same time they found it impossible to keep
the Indians together. On their first feeling of the climate,
their thoughts were immediately turned on dei-
serting their matters. The first instance they had of
this kind was so unexpected, that, had not one, of a
better disposition than the rest, flied and acquainted
them of their design, it might have proved of very bad
consequence. The affair was this: There being on the
top of the rock no room for pitching a tent for the In-
dians, they used every evening to retire to a cave at
the foot of the mountain; where, beside a natural diminu-
tion of the cold, they could keep a continual fire; and,
consequently enjoyed more comfortable quarters than
their matters. But when the hut 

They

The

the cloth of leather, and on the inside not the
final crevice was left unchopped: beside which, it was
very compactly covered with straw: but, notwithstanding
all their care, the wind penetrated through.
The days were often little better than the nights; and
all the light they enjoyed was that of a lamp or two,
which they kept continually burning.

Though their hut was small, and crowded with in-
habitants, beside the heat of the lamps; yet the
tenor's of the cold was such, that every one of them
was obliged to have a chafing dish of coals. These pre-
cautions would have rendered the rigour of the climate
supportable, had not the imminent danger of perishing
by being blown down the precipice roused them, every
time it snowed, to encounter the severity of the out-
ward air, and to rally out with shovels to free the roof of
their hut from the masses of snow which were gathering
on it. Nor would it, without this precaution, have
been able to support the weight. They were not in-
der times{4272}

As soon as the snow was cleared away

the door, they dispatched the Indian to the corregidor of Quito, who with equal dispatch sent other Indians, threatening to chastise them severely if they were wanting in their duty.

But the fear of punishment was not sufficient to induce them to support the rigour of this situation; for within two days they departed. The corregidor therefore, to prevent any other inconvenience, sent four Indians under the care of an alcalde, and gave orders for their being relieved every fourth day.

Twenty-three tedious days our artists spent on this rock, viz. to the 6th of September, and even without any possibility of finishing their observations of the angles: for when it was fair and clear weather with them, the others, on whose summits the signals which formed the triangles for measuring the degrees of the meridian, were hid in the clouds; and when those were clear, Pichincha was involved in clouds. It was therefore necessary to erect their signals in a lower situation, and in a more favourable region. This, however, did not produce any change in their habitation till the beginning of December; when, having finished the observations which particularly concerned Pichincha, they proceeded to others; but with no abatement either of inconveniences, cold, or fatigue; for the places where they made their observations being necessarily on the highest parts of the defarts, the only refuge in which they enjoyed some little ease was during the short interval of falling from one to the other.

In all their stations subsequent to those on Pichincha, during their fatiguing meditation of the degrees of the meridian, each company lodged in a field-tent, which, though small, they found less inconvenient than the hut on Pichincha; though at the same time they had more trouble, being oftener obliged to clear it from the snow, as the weight of it would otherwise have demolished the tent. At first, indeed, they pitched it in the most sheltered places; but on taking a resolution that the tents themselves should serve for signals, to prevent the inconvenience of EW of W, they removed them to a more exposed situation, where the impetuosity of the winds sometimes tore up the piquets, and blew them down.

Though this mountain is famous for its great height, it is considerably lower than the mountain of Cocopaxi: but it is impossible to conceive the coldness of the summit of the last-mentioned mountain from that felt on this; since it must exceed every idea that can be formed by the human mind, tho' they are both seated in the midst of the torrid zone. In all this range of mountains, there is said to be a constant inferior boundary, beyond which the snow never melts: this boundary, in the midst of the torrid zone, is said by some to be 2,434 fathoms above the level of the sea; by others, only 2,400 feet. The snow indeed falls much lower, but then it is subject to be melted the very same day. It is affirmed, that there are in the Andes 16 volcanoes or burning mountains, which throw out fire and smoke with a terrible noise. The height of Chimborazo, said to be the highest peak of the Andes, has been determined by geometrical calculations to be 20,282 feet. But the great differences between the calculations of the height of mountains in other parts of the world, must very much diminish the credit of such calculations. Instances of this we have already given under the article Æra-

Andes, a hamlet of Mantua in Italy, the birthplace of Virgil. Hence the epithet Andinus (Silius Italicus). Now called Piosola, two miles to the west of Mantua.

Andes, a volcane in the province of Loja, in Peru. It is situated in 14° 30' south latitude, and 60° 50' west of the meridian of Greenwhich. It is considered as the highest volcano in the world, and is celebrated for its production of gold and silver. The top of the mountain is composed of stone, and the sides are covered with snow. The height of the mountain is estimated at 24,000 feet, and it is visible from a distance of 20 miles. The volcano is very active, and frequently erupts, throwing up columns of fire and smoke. The inhabitants of the surrounding country are said to be rich in gold and silver, which they obtained by mining in the mountains. There are many springs of hot springs in the vicinity, which are used for the cure of diseases. The climate around the volcano is cold, and the air is charged with the smoke and ashes of the eruption. The volcano is the object of much interest to geologists, as it affords valuable information respecting the formation of mountains and the phenomena of volcanic action.

And Euse, a city of Languedoc in France, situated in 44° 50' north latitude, and 2° 30' west of the meridian of Paris. It is the capital of the department of Gard, and is the seat of a bishopric. The city is situated on a hill, and is surrounded by a wall. The castle of the bishops is a large and magnificent building, and is one of the most ancient in France. The city is celebrated for its manufactures of glass and porcelain, and is also noted for its fine gardens. The surrounding country is fertile, and produces a wealth of corn, fruit, and vegetables. The climate of the city is mild, and the air is invigorating. Andes, a mountain in the Andes, consisting of a series of high peaks, including the highest point of the Andes, known as Chimborazo. The mountain is covered with snow for much of the year, and is a source of great beauty and interest to visitors in the region. It is also known for its volcanic activity, with frequent eruptions that have created a unique and fascinating landscape. The Andes mountain range is one of the most well-known and visited tourist destinations in the world, offering a range of activities such as hiking, climbing, and cultural exploration. In addition, the region is home to a rich and diverse array of wildlife, including various species of birds, mammals, and plants. Andes has a long and complex history, with native populations who have lived in the area for thousands of years, and a more recent history influenced by Spanish and other colonial forces.
as and eloquence necessary to a good preacher; and Rolwicd says, that he brought to the council of Trent the understanding of a most profound divine, and the eloquence of a consummate orator.

ANDRACHNE, BASTARD ORPINE: A genus of the gynandra order, belonging to the monoeica class of plants; and in the natural method ranking under the 38th order, Tricoccce. The characters are: 1. The male callus consists of five leaves; the corolla has five petals; and the flamina, which are also five in number, are inserted into the stylos: The female calyx is divided into five leaves; there is no corolla; the style is three; and the carpelle is trilocular, containing three seeds.

Species. 1. The telephoides, or herbaceous trailing andrachne, is a low plant, whose branches trail upon the ground. The leaves are small, of an oval shape, smooth, and of a sea-green colour. It is found wild in some parts of Italy and the Archipelago; but is a plant of no great beauty, and therefore seldom cultivated.

2. The fruitcola, or thorny bastard orpine, is a native of China and some places of America, or brought by him from seeds sent from Jamaica. It has a stem, 12 or 14 feet high. The leaves are spear-shaped, pointed, and smooth; and under them are produced the footstalks of the flowers, which are small, and of a herbaceous white colour. 3. The arborea, with a tree-like stalk. This species was discovered by the late Dr William Houlton, growing naturally at Campseachy.

It has a strong woody item, which rises more than 20 feet high, and sends out many branches on every side. A fourth fort is also mentioned by Dr Miller as raised by him from seeds sent from Jamaica. It agrees in general with the third fort; but the leaves are somewhat like the laurel, only much larger.

Culture. The first species may be raised, by sowing the seeds in March, on a moderate hot-bed. The plants may be removed into small pots, and plunged into another very moderate hot-bed, to bring them forward; but in mild weather they should have plenty of air admitted to them, and be frequently refreshed with water. In June they will produce flowers, and the seeds will ripen in August and September. The other species are very tender, and therefore must be kept constantly in the bank-floes. It is very difficult to procure good seeds of these sorts; the flowers often containing nothing, though they appear very fair outwardly.

ANDRAPODISMUS, in ancient writers, the telling of perfoms for slaves. Hence also andrapodisfe, a dealer in slaves, more particularly a kidnapper, who steals men or children to sell them; a crime for which the Thesallians were noted.

ANDRAPODACEI, in antiquity, a kind of dealers in slaves. The andrapodaceei had a particular procyes for taking off molees and the like disfigurements on the faces of the slaves they kept for sale, by rubbing them with bran. At Athens, several places in the 39th order were appointed for the sale of slaves. Upon the first day of every month, the merchants called andrapodaceei brought them into the market, and exposed them to sale; the crier standing upon a stone erected for that purpose, called the people together.

ANDREA (St), a small village on the Malabar coast in the East-Indies, founded originally by the Portuguese. It takes its name from a church dedicated to St Andrew, and served by the priests of St Thomas.

ON the shore of St Andrea, about half a league out in the sea, lies Mud-bey, a place which few in the world can parallel. It is open to the wide ocean, and has neither island nor bank to break the force of the billows, which come rolling with great violence from all parts, in the south-west monsoons: but on this bank of mud they lose themselves, and flaps lie on it as freely as in the best harbour, without motion or disturbance. It reaches about a mile along shore, and has been observed to shift its place from the northward about three miles in 30 years. From St Andrea to Kraganor, about 12 leagues to the south, the water has the bad property of causing swellings in the legs of those who drink it constantly. Some it affects in one leg, and some in both. It caueses no pain, but itching; nor does the swelled leg seem heavier to the owner than the small one, though some have been seen a yard in circumference at the ankle. The Romish legends impute the cause of this distemper (for which they have no cure) to the earth having been his to found) to a curse laid by St Thomas upon his murderers and their posterity; though, according to the Romans themselves, St Thomas was killed by the Tillinga priests at Melaphur, on the coast of Coromandel, about 400 miles distant, and where the natives have not this distemper.

ANDREAS (John), a celebrated canonist in the 14th century, was born at Mugello, near Florence; and was professer of canon-law at Padua, Pisa, and afterwards at Bologna. It is said that he macerated his body with fasting; and lay upon the bare ground every night for 20 years together, covered only with the skin of a bear. This is attested by very good authors; but if the story which Poggio tells of him in his Italia be true, he must afterwards have relaxed much of this continency: "Joannes Andreas, (says he), dicit Bononiensem, ejus fame admodum vulgata est, subagitamem ubi infleta fapientiae mulier in virum verfa, Ubis nunc, qui Joannes, est sapientia vestra? Ille nil amplius locutus, in vulva latus, respondit, loca admodum sapientiae accommodata." The French translation of this perhaps will not be displeasing.

Jean, dit Andrés, fameux Docteur des Lois,
Fut pris un jour au pêché d'amourcette:
Il avoit une jeune fosbrette.
Sa femme vint, fit un signe de croix.
"Hé bien, dit elle, est ce vous? mon je poyse?
Vous, dont par tout en cause la prudence.
Qu'est devenu cet esprit si fubtil?
Le bon André, pour suivant fou nœgoe,
Honteux pourtant, ma foi, répondit il,
Prudence, esprit, tout gîst dans cette foîte.

Since it is agreed that John Andreas had a bastard, this story is at the bottom very probable; and it was perhaps with the mother of Basadonius that his wife found him. Andreas had a beautiful daughter, named Novella, whom he loved extremely: and he is said to have introduced her so well in all parts of learning, that when he was engaged in any affair which hindered him from reading lectures to his scholars, he sent his daughter in his room; and left her beauty should prevent the
Andreu, a learned canonist, mentions of his writings, he had been befown upon him. He has been called "Rabbi dolfior" by being present and minifier baptized; and, in attention of the hearers, of salvation. After this, I was sent for by the kingdom, which their majesties had conquered: by catholic princes king Ferdinand and queen Isabella, God's blessing on my preaching, an infinite number of queen Isabella to Aragon, that I might be employed in the conversion of the Moors of those kingdoms, who ineffectual excellent and pious design of her Majesty was rendered Garcia, Confusión impofures, forgeries, brutalities, follies, obfcenities, abfurditics, impoffibilities, lies, and contradictions, which Mahomet, in order to deceive the fimple people, has difperfed in the writings of that fect, and especial-ly in the alcoran, which, as he fays, was revealed to Andreini him in one night by an angel, in the city of Meke; in another place he endeavoureth himself, and affirms that he was 20 years in composing it. Andreini tells us, he wrote this work, that not only the learned among Christians, but even the common people might know the different belief and doctrine of the Moors: and on the one hand might laugh and ridicule fuch infolent and brutal notions, and on the other might lament their blindnefs and dangerous condition. This book, which was published at firft in Spanish, has been translated into feveral languages; all thofe who write against the Mahometans quote it very much.

ANDREINI (Isabella), a native of Padua, was an excellent poetef, and one of the best comedians in Italy, towards the beginning of the 17th century. The Intent of Pavia thought they did their Society an honour by admitting her a member of it; and she, in acknowledgement of this honour, never forgot to mention amongst her titles that of Academica Infanta: her titles were thefe, "Isabella Andreini, comica gelosa, academica infanta, detta l'accesa." She was alfo a woman of extraordinary beauty; which, added to a fine voice, made her charm both the eyes and ears of the audience. She died of a miscarriage, at Lyons, the 10th of June, 1604, in the 42d year of her age. Her death being a matter of general concern and lamentation, there were many Latin and Italian elegies printed to her memory; feveral of thofe pieces were placed before her poems in the edition of Milan, in 1605. Besides her laments, madrigals, fongs, and elegies, there is a pastoral of hers intitled Myrtilla, and letters, printed at Venice in 1619. She fung extremely well, played admirably on feveral instruments, understood the French and Spanifh languages, and was not unacquainted with philofophy.

ANDREINUS (Publius Faunus), born at Forli in Italy, he was a long time professor of poetry and philofophy in the university of Paris. Lewis XII. of France made him his poet laureat; and Erasminus tells us he was likewise poet to the queen. His pen was not wholly employed in making verses for her; he wrote alfo moral and proverbial letters in prose, which were printed several times. His poems, which are chiefly in Latin, are inserted in Vol. I. of the Deliciae poetarum Ita­lorum. Mr De la Monnoie tells us, "that Andreinus, when he was but 22 years old, received the crown of laurel: that his love-verfes, divided into four books, intitled Livia, from the name of his mistrefes, were esteemed fo fine by the Roman Academy, that they adjudged the prize of the Latin elegy to the author. He died in 1518. This author's manner of life was not very exemplary; yet he was fo fortunate, fays Erasminus, that though he took the liberty of rallying the divines, he was never brought into trouble about it."

ANDREW (St.), the apostle, born at Bethsaida in Galilee, brother to Simon Peter. He had been a disciple of John the baptift, and followed Jesus upon the testimony given of him by the baptift, (John i. 30, 37, &c.) He followed our Saviour with another of John's disciples, and went into the house where Jesus lodged: here he continued from about four o'clock in the afternoon till it was night. This was the firft disciple whom our Saviour received into his train. Andrew introduced his brother Simon, and they paffed a day with
with Christ, after which they went to the marriage in Cana (id. ii.), and at last returned to their ordinary occupation. Some months after, Jesus meeting them while they were both fishing together, called them to him, and promised to make them fishers of men. Immediately they left their nets, followed him, (Matt. iv. 19.) and never afterwards separated from him.

After our Saviour's ascension, his apostles having determined by lot what parts of the world they should severally take, Scythia and the neighbouring countries fell to St Andrew, who according to Eusebius, after he had planted the gospel in several places, came to Patrae in Achaia, where, endeavouring to convert the proconsul Ægeas, he was by that governor's orders scourged and then crucified. The particular time of his suffering martyrdom is not known; but all the ancient and modern martyrologies, both of the Greeks and Latins, agree in celebrating his festival upon the 30th of November. His body was embalmed, and decently interred at Patrae by Maximilla, a lady of great quality and estate. Afterward it was removed to Constantinople by Constantin the Great, and buried in the great church, which he had built to the honour of the Forfar, and Kincardine thenceforward. Forfar, and Kincardine (See CROSS.) St Andrew's church of Hippolytus the places it was an olive-tree. valid with what would at once increase the fame that Peter Chrysologus says, colm II. is preserved in Constantinople by Constantin the Great, and buried in the greatest part of the archbishopric.

There is a cross to be seen in the three principal churches of St Andrew's, one in form of the letter X, and is inclosed in a silver shrine. Peter Chrysologus says, that he was crucified upon a tree; and the ipurious Hippolytus affures us it was an olive-tree.

Andrew, or Knights of St Andrew, an order of knights, more usually called the order of the thistle. (See THISTLE.)

Knights of St Andrew, is also an order instituted by Peter the Great of Muscovy in 1698; the badge of which is a golden medal; on one side whereof is represented St Andrew's cross, with these words, Cæsar Pierre monarque de tout la Raffle. This medal, being fastened to a blue ribbon, is suspended from the right shoulder.

St Andrew's Cross, one in form of the letter X. (See CROSS.)

St Andrew's Day, a festival of the Christian church, celebrated on the 30th of November in honour of the apostle St Andrew.

Andrew's (St), a town of Fife-shire, in Scotland, once the metropolis of the pifiith kingdom, lying in W. Long. 1° 25'. N. Lat. 56° 18'. If we may credit legend, St Andrew's owes its origin to a singular accident. St Regulus (or St Rule, as he is likewise called), a Greek of Achaia, was warned by a vision to leave his native country, and visit Albion, an isle placed in the remotest part of the world; and to take with him the arm-bone, three fingers, and three toes of St Andrew. He obeyed, and set sail with his companions, but had a very tempestuous passage. After being tossed for some time on a stormy sea, he was at last shipwrecked on the coasts of Otholania, in the territories of Hercules king of the pifi, in the year 370. On hearing of the arrival of the Strangers, with their precious relics, the king immediately gave orders for their reception, afterwards presenting the saint with his own palace, and building near it the church, which still bears the name of St Regulus.

At this time the place was filled Macraft, or the land of boars: all round was forest, and the lands belonging on the Saint were called Byrehid. The boars equalled in size the ancient Erymanthian; as a proof of which, two tulk, each sixteen inches long and four thick, were chained to the altar of St Andrew's. St Regulus changed the name to Kilrymont; and established here the first Christian priests of the country, called Gilders. This church was supreme in the kingdom of the Pifi; Ungus having granted to God and St Andrew, that it should be the head and mother of all the churches in his dominions. He also directed that the cross of St Andrew should become the badge of the country. In 518, after the conquest of the Pifi, he removed the episcopal see to St Andrew's, and the Bishop was styled maximus Scottorum episcopus. In 1141, it was erected into an archbishopsic by Sextus IV. at the intercession of James III. In 1606, the priory was suppressed; and, in 1617, the power of election was transferred to eight bishops, the principal of St Leonard's college, the archdeacon, the vicars of St Andrew's, Lenchars, and Curwar. This see contained the greatest part of the shire of Fife, with a part of Perth, Forfar, and Kincardine shires, and a great number of parishes, churches, and chapels in other dioceses.

The town of St Andrew's was erected into a royal borough by David I. in the year 1140, and their privileges afterwards confirmed. The charter of Malcolm II. is preferved in the tolbooth; and appears written on a bit of parchment, but the contents equally valid with what would at this time require whole skins. Here also are kept the silver keys of the city; which, for form's sake, are delivered to the king, if he should visit the place, or to a victorious enemy, in token of submission. In this place, likewise, is to be seen the magnificent x which, in 1646, took off the heads of Sir Robert Spotwood and other distinguished loyalists. The town underwent a siege in 1537: at which time it was possessed by the English, and other partizans of Balios; but the loyalists, under the earls of March and Fife, made themselves masters of it in three weeks, by the help of their battering machines.

St Andrew's is now greatly reduced in the number of inhabitants, at present scarcely exceeding 2000. It is impossible to ascertain the sum of the inhabitants: All that can be known is, that during the period of its splendour, there were between 60 and 70 bakers; but now 9 or 10 are sufficient for the place. It is a mile in circuit, and contains three principal streets. On entering the west port, a well- built street, straight, and of vast length and breadth, appears; but so grass-grown, and presenting such a dreary solitude, that it forms the perfect idea of having been laid waste by the pestilence.

The cathedral of St Andrew's was founded by Bishop Arnold in 1161, but did not attain its full magnificence till 1318. Its length from east to west was 370 feet; that of the transept, 222. But tho' this vast pile was 157 years in building, John Knox, in June 1559, effected its demolition in a single day; and so efficiently has it been destroyed, that nothing now remains but part of the east and west ends, and of the south side.

Near the east end is the chapel of St Regulus; the tower of which is a lofty equilateral triangle, of 20 feet each side, and 103 feet high; the body of the chapel remains,
Andrew's remains, but the two side chapels are ruined. The arches of the windows and doors are round, and some even more than semicircles: an undoubted proof of their antiquity.

The priory was founded by Alexander I. in 1122; and the monks (canons regular of St Augustine) were brought from Scone, in 1140, by Robert, bishop of this see.

By an act of parliament, in the time of James I. the prior had precedence of all abbots and priors, and brought with him the monks (canons regular of St Augustine) were formerly except the walls of the Church of Kirk, the ugh, originally founded by Bishop Kennedy, and extended near the high altar of the cathedral, with this singular epitaph:

Hic fuit ecclesia direc. columna, fenestra
Lucida thoribulum redolens, compana fana.

This castle was the residence of cardinal Beaton; who, after the death of George Wiliart, apprehending some danger, caused it to be fortified so strongly as to be at that time deemed impregnable. In this fortress, however, he was surprized and assassinated by Norman Lely with 15 others. They seized on the gate of the castle early in the morning of May 29, 1546; it having been left open for the workmen who were finishing the cloisters, and having placed centinels at the door of the cardinal's apartment, they awakened his numerous domestics one by one; and, turning them out of the castle, they, without violence, tumult, or offering any injury to any other person, inflicted on Beaton the death he justly merited. The conspirators were immediately beseiged in this castle by the regent, earl of Arran; and notwithstanding they had acquired no greater strength than 150 men, they resifted all his efforts for five months. This, however, was owing to the unskillfulness of the besiegers more than to the strength of the place or the valor of the besieged; for in 1547 the castle was reduced and demolished. The entrance of it is still to be seen; and the window is shown, out of which it is said the cardinal leaned to glit his eyes with the cruel martyrdom of George Andrew's friend Wilhart, who was burnt on a spit beneath.

In the church of St Salvator is a most beautiful tomb of bishop Kennedy, who died, an honour to his family, in 1466. The Gothic work is uncommonly elegant. Within the tomb were discovered six magnificent maces, which had been concealed here in troubous times. One was given to each of the other three Scotch universities, and three are preserved here. In the top is represented our Saviour; around are angels, with the instruments of the passion.

With these are shown some silver arrows, with large silver plates affixed to them, on which are inscribed the arms and names of the noble youth, visitors in the annual competitions in the generous art of archery, which were dropped but a few years ago; and golf is now the reigning game. That sport, and foot-ball, were formerly prohibited, as unseemly and unprofitable to the public; and at all weapon shewings, or reviews of the people, it was ordered, that foot-ball and golf be utterly cried down, and that bow-markets be paid at ilk parish kirk, a pair of butts and schuttin be used, and that man schutte fish fottes at leaf, under the pains to be raised upon them that commits not, at least two pence, to be given to them that commits to the bow-markets a drink.

The celebrated university of this city was founded in 1411, by bishop Wardlaw; and the next year he obtained from Benedict III. the bull of confirmation. It consisted of three colleges.

1. St Salvator's, founded in 1538, by bishop Kennedy. This is a handsome building, with a court or quadrangle within: on one side is the church, on another the library; the third contains apartments for students; the fourth is unfinished.

2. St Leonard's college was founded by Prior Hepburn, in 1522. This is now united with the hall, and the buildings fold and converted into private houses.

3. The new, or St Mary's college, was establlished by archbishop Hamilton in 1553: but the house was built by James and David Bethune, or Beaton, who did not live to complete it. This is said to have been the site of a schola Siliarius long before the establishment of the university; where several eminent clergymen taught, gratis, the sciences and languages. But it was called the new college, because of its late erection into a divinity college by the archbishop.

The university is governed by a chancellor, an archdeacon, a registrar, and several other officers. It is conducted by the two principals, and the professors of both the colleges.

The rector is the next in order of succession; to whose care is committed the privileges, discipline, and statutes of the university. The colleges have their rectors, and professors of different sciences, who are indefatigable in their attention to the instruction of the students, and to that essential article, their morals. This place possesses several very great advantages respecting the education of youth. The air is pure and wholesome; the place for exercise dry and extensive; the exercises themselves are healthy and innocent. The university is fixed in a most unfitted country, remote from all commerce with the world, the haunt of dissipation. From the smallness of the society every student's character is perfectly known.
No little irregularity can be committed, but it is instantly discovered and checked: vice cannot attain a head in this place, for the incorrigible are never permitted to remain the corrupters of the rest.

The trade of St Andrew's was of very considerable. So late as the reign of Charles I. this place had 30 or 40 trading vessels, and carried on a considerable herring and white fishery, by means of busses, in deep water; which fisheries had for ages been the grand source of their commerce, wealth, and splendour. After the death of the king, this whole coast, and St Andrew's in particular, became a scene of murder, plunder, and rapine: every town suffered in proportion to its magnitude and opulence. Nor were those hypothetical rumours satisfied with the shipping, merchandise, plate, cattle, and whatever came within their sight; they also laid the whole coast under contribution. St Andrew's was required to pay rent, but the inhabitants not being able to raise that sum after being thus plundered, the general compounded for 500l., which was raised by a loan at interest, and hath remained a burden upon the corporation, it is believed, ever since.

The harbour is artificial, guarded by piers, with a narrow entrance, to give shelter to vessels from the violence of a very heavy sea, from the encroachments of which it hath suffered much. The manufactures this city might in former times possess, are now reduced to one, that of golf-balls; which, trifling as it may seem, maintains a great number of people. It is, however, commonly fatal to the artist; for the balls are made by fusing a great quantity of feathers into a leathern case, by help of an iron rod, with a wooden handle, pressed against the breast, which seldom fails to bring on a consumption.

Andrew's (Lancelot), bishop of Winchester, was born at London in 1555, and educated at Cambridge. After several preferments, he was made bishop, first of Chichester, then of Ely; and, in 1618, was raised to the see of Winchester. This very learned prelate, who was distinguished by his piety, charity and integrity, may be justly ranked with the best preachers and complete scholars of his age; he appeared to much greater advantage in the pulpit than he did in low in his works, which abound with Latin quotations and trivial witlings. His sermons, though full of puns, were rated to the taste of the times in which he lived, and were consequently greatly admired. He was a man of polite manners and lively conversation; and could quote Greek and Latin authors, or even pun with king James. There is a pleasant story related of him in the life of Waller the poet. When that gentleman was young, he had the curiosity to go to court, and sift in the circle to see king James dine; where, among other company, there sat at table two bishops, Neale and Andrews. The king propounded this question, Whether he might not take his subjects money when he needed it, without all this formality of parliament? Neale replied, "God forbid you should, for you are the breath of our nostrils." Whereupon the king turned, and said to the bishop of Winchester, "Well, my lord, what say you?" "Sir, (replied the bishop,) I have no skill to judge of parliamentary cafes." The king answered, "No puts-off, my lord; answer me presently." "Then, Sir (said he), I think it lawful for you to take my brother Neal's money, for he offers it." Mr Waller says, the company was pleased with this answer, but the wit of it seemed to affect the king; for a certain lord coming after, his majesty cried out, "O, my lord, they lay you lie with my lady." "No, Sir (says his Lordship, in coulusion), but I like her company because she has to much wit." "Why then (says the king) do you not lie with my lord of Winchester there?"—This great prelate was in no less reputation and esteem with king Charles I. than he had been with his predecessors. He died at Winchester-house in Southwark, September 27, 1626, in the 71st year of his age; and was buried in the parish-church of St Saviour's, where his executors erected to him a very fair monument of marble and alabaster, on which is an elegant inscription, in Latin, written by one of his chaplains. Mr Milton also, at 17 years of age, wrote a beautiful elegy on his death, in the same language. Bishop Andrews had, 1. A share in the translation of the Pentateuch, and the historical books from Joshua to the first book of Chronicles exclusively. He also wrote, 2. Tortu.s Torti, in answer to a work of Cardinal Bellarmine, in which that cardinal affinnes the name of Matthew Tortus. 3. A Manual of Private Devotions: and, 4. A Manual of Directions for the Abstinence of the Sick; besides the Sermons and Treatises in English and Latin, published after his death.

ANDRIA, in Grecian antiquity, public entertainments first instituted by Minos of Crete, and, after his example, appointed by Lycurgus at Sparta, at which a whole city or tribe assembled. They were managed with the utmost frugality, and persons of all ages were admitted, the younger fort being obliged by the lawgiver to repair thither as to schools of temperance and sobriety.

ANDRIA, is a city and a bishop's see in the territory of Bar, in the kingdom of Naples. It is pretty large, well peopled, and seated in a spacious plain, four miles from the Adriatic coast. E. Long. 17. 4. N. Lat. 41. 15.

ANDRISCUS, a man of mean extraction, who, pretending to be the son of Pheius last king of Macedonia, took upon him the name of Philip, for which reason he was called Pseudo-Philippus, the False Philip. After a complete victory over Juventus, the Roman Praetor sent against him, he assumed kingly power, but exercised it with vast cruelty. At last, the Romans obliged him to fly into Thrace, where he was betrayed and delivered into the hands of Metellus. This victory gained Macedonia once more into the power of the Romans, and to Metellus the name of Macedonius, but cost the Romans 25,000 men. Andricus adorned the triumph of Metellus, walking in chains before the general's chariot.

ANDROAS, or ANDRODAMAS, among ancient naturalists, a kind of pyrite, to which they attributed certain magical virtues.

ANDROGENUS, in fabulous history, the son of Minos king of Crete, was murdered by the Athenian youth and throe of Megara, who envied his being always victor at the Attic games. But Minos having afterwards taken Athens and Megara, obliged the inhabitants to send him an annual tribute of seven young men and as many virgins, to be devoured by the Minotaur; but Theseus delivered them from that tribute.

ANDROGYNE, in natural history, a name gi-
Androgynes, as we have seen, are the living creatures which, by a monstrous formation of their generative parts, seem (for it is only seeming) to unite in themselves the two sexes, that of the male and of the female. This is a departure in the structure of the parts intended by nature, which they found, which they believed, were the best adapted for the discharge of procreative functions, the pudenda of the other sex likewise appear. This monstrous production of nature is diversified in four different ways; of which three appear in males and one in females. In men, the female pudendum clothed with hair, sometimes appears contiguous to the perineum; at other times in the middle of the scrotum; at other times, which constitutes the third variety, through that part itself which in the midst of the scrotum exhibits the form of a pudendum, urine is emitted. Near that part which is the seat of puberty, and above the pudendum, even in females, the masculine genitals appear in some, conspicuous in all their three forms, belonging to the female; on the other hand, like the testicles; but for the most part it happens, that of the two instruments of generation, one is feeble and inert; and it is extremely rare that both are found sufficiently valid and proper for feats of love; nay, even in a great many, both these members are deficient and impotent; so that they can perform the office neither of a man nor of a female.

With respect to them, it appears, from a collation of all the circumstances which have been observed by naturalists worthy of credit, that there is no such thing as a perfect androgynous, or real hermaphrodite; that is to say, a living creature which, by its natural, or rather prenatur al, structure, possesses the genuine powers of both sexes, in such a manner as to be qualified for performing the functions of either with facility; the irregularity of their fabrication almost always consists in something superfluous added to one of the sexes, which gives it the appearance of the other, without befogging the real and characteristic distinction; and every hermaphrodite is almost always a very woman. Since this monstrous exhibition of nature is not such as to abrogate the rights or destroy the character of humanity amongst human beings, this involuntary misfortune implies no right to deprive those upon whom it is inflicted by nature, of the privileges natural to every citizen; and this deficiency is no more an insult than any other corporeal mutilation, it is not easy to see why marriage should be prohibited to one of these unhappy beings, merely on account of its equivocal appearance, which acts in the character of its prevailing sex. If such a creature, by the defect of its construction, should be barren; this does not infer any right of dislodging the marriage which it may have contracted, more than the same fertility proceeding from any cause whether known or unknown, if his or her conduct should not on that account require a divorce. It is only the licentious abuse either of one or the other sex which can be follow ed to the animadversion of the police. See Hermaphrodit.

Such are the sentiments of the authors of the French Encyclopaedia. After all, we cannot forbear to add, that from such heterogenous matches nature seems to recoil with innate and inextinguishable horror. Nor are any of these invincible aversions implanted in our frame without a final cause worthy of its Author. We would gladly ask these free-thinking gentlemen, in cases where the sexes are four naturally confounded, how the police can, by its most severe and rigorous animadversions, either detect or prevent these licentious abuses against nature? Since, therefore, an evil so baseless to human society could no other way be prevented than by the function of Nature against such horrible conjunctions, the instinctive antipathy which they inspire was highly worthy of her wisdom and purity.

Androgynes, in ancient mythology, creatures of whom, according to the fable, each individual possessed the powers and characters of both sexes, having two heads, four arms and two feet. The word itself is compounded of two Greek radical words, andro, in genitive andros, a male; and gon, a female. Many of the rabbinical writers pretend, that Adam was created double, one body being male, the other female, which in their origin not being essentially joined, God afterwards did nothing but separate them.

The gods, says Plato, in his Banquet, had formed the structure of man round, with two bodies and two sexes. This fantastic being, possessing in itself the whole human system, was endowed with a gigantic force, which rendered it infolent, inofficious that it resolved to make war against the gods. Jupiter, exasperated, was going to destroy it; but, sorry at the same time to annihilate the human race, he satisfied himself with debasing this double being, by disjoining the male from the female, and leaving each half to subsist with its own powers alone. He assigned to Apollo the task of repopulating these two half bodies, and of extending their skins so that their whole force might be covered. Apollo obeyed, and fastened it at the stumbus: If this half should fall rebel, it was once more to be subdivided by another section, which would only leave it one of the parts of which it was then constituted; and even this fourth of a man was to be annihilated, if it should persist in its obstinacy and mischief.

The idea of these androgy nes might well be borrowed from a passage in Moes, where that historian of the birth and infancy of nature describes Adam as calling Eve bone of his bone and flesh of his flesh. However this may be, the fable of Plato has been used with great ingenuity by a French poet, who has been rendered almost as conspicuous by his misfortunes as by his verses. With the ancient philosopher, he attributes the propensity which attracts one of the sexes towards the other, to the natural ardor which each half of the androgynes feel for reunion; and their inconftancy, to the difficulty which each of the separated parts encounters in its efforts to recover its proper and original half. If a woman appears to us amiable, we instantly imagine her to be that moiety with whom we should only have continued one whole, had it not been for the infolence of our double-sexed progenitor:

The heart, with fond credulity impres's'd,
Tells us the half is found, then hopes for rest;
But 'tis our curse, that sad experience shows,
We neither find our half nor gain repose.

Androgynous, in zoology, an appellative given to animals which have both the male and female sex.
Androïdes, sex in the same individual.—In botany, the term is applied to such plants as bear both male and female flowers upon the same root.

Androïdes, in mechanics, a human figure, which, by certain springs or other movements, is capable of performing some of the natural motions of a living man. The motions of the human body are more complicated, and consequently more difficult to be imitated, than those of any other creature; whence the construction of an Androïdes, in such a manner as to imitate any of those actions with tolerable exactness, is justly supposed to indicate a greater skill in mechanics than any other piece of workmanship whatever.

A very remarkable figure of this kind appeared in Paris, in the year 1738. It represented a flute-player, and was capable of performing many different pieces of music on the German flute; which, considering the difficulty of blowing that instrument, the different contractions of the lips necessary to produce the distinct tones between the high and low notes, and the complicated motions of the fingers, must appear truly wonderful.

This machine was the invention of M. Vaucanson, member of the Royal Academy of Sciences; and a particular description of it was published in the Memoirs of the Academy for that year. The figure itself was about five feet and a half in height, situated at the end of an artificial rock, and placed upon a square pedestal four feet and a half high and three and an half broad. The air entered the body by three pipes separated from one another. It was conveyed to them by nine pairs of bellows, three of which were placed above and six below. These were made to expand and contract regularly in succession, by means of an axis of steel turned round by some clock-work. On this axis were different protuberances at proper distances, to which were fixed cords thrown over pulleys, and terminating in the upper boards of the bellows, so that, as the axis turned, these boards were alternately raised and let down. A contrivance was also used to prevent the disagreeable hissing fluttering noise usually attending the motion of bellows.

This was by making the cord, by which the bellows were moved, pass in its descent, upon one end of a smaller lever, the other end of which ascending forced open the small leathern valve that admitted the air, and kept it so till, the cord being relaxed by the descent of the upper board, the lever fell, and the air was forced out. Thus the bellows performed their functions, continually without the least hissing or other noise by which it could be judged in what manner the air was conveyed to the machine. The upper boards of three of the pairs of bellows were pressed down by a weight of four pounds, those of three others by a weight of two pounds, and those of the remaining ones by nothing but their own weight.

The three tubes, by which the air entered, terminated in three small reed pipes in the trunk of the figure. There they united, and, ascending towards the throat, formed the cavity of the mouth, which terminated in two small lips adapted in some measure to perform their proper functions. Within this cavity also was a small movable tongue; which, by its play, produced the different notes, admitted the air, and conducted its passage to the flute.

The fingers, lips, and tongue, received their proper directions by means of a steel cylinder turned by clock-work. It was divided into 15 equal parts, which Androïdes, by means of pegs, pressing upon the ends of 15 different levers, caused the other extremities to ascend. Seven of these levers directed the fingers, having wires and chains fixed to their ascending extremities, which being attached to the fingers, caused them to ascend in proportion as the other extremity was pressed down by the motion of the cylinder; and vice versa. Thus the ascent or descent of one end of a lever produced a similar ascent or descent in the corresponding finger, by which one of the holes of the flute was occasionally opened or stopped, as by a living performer. Three of the levers served to regulate the ingress of the air, being contrived so as to open and shut, by means of valves, the three reed pipes of air above mentioned, so that more or less strength might be given, and a higher or lower note produced as occasion required. The lips were by a similar mechanism, directed by four levers, one of which opened them, to give the air a freer passage; the other contracted them; the third drew them backward; and the fourth pulled them forward. The lips were projected upon that part of the flute which receives the air; and, by the different motions already mentioned, modified the tone in a proper manner.

The remaining lever was employed in the direction of the tongue, which it easily moved, so as to shut or open the mouth of the flute.

Thus we see how all the motions necessary for a German-flute-player could be performed by this machine; but a considerable difficulty still remains, namely, how to regulate these motions properly, and make each of them follow in just succession. This, however, was effected by the following simple method. The extremity of the axis of the cylinder was terminated on the right side by an endless screw, consisting of twelve threads, each placed at the distance of a line and a half from the other. Above this screw was fixed a piece of copper, and in it a steel pivot, which, falling in between the threads of the screw, obliged the cylinder to follow the threads, and, instead of turning directly round, it was continually pulled to one side. Hence, if a lever was moved, by a peg placed on the cylinder in any one revolution, it could not be moved by the same peg in the succeeding revolution, because the peg would be moved a line and a half beyond it by the lateral motion of the cylinder. Thus, by an artificial disposition of these pegs in different parts of the cylinder, the flautist, as made, by the successive elevation of the proper levers, to exhibit all the different motions of a flute-player, to the admiration of every one who saw it.

The construction of machines capable of imitating even the mechanical actions of the human body, show exquisite skill; but what shall we say of one capable, not only of imitating actions of this kind, but of acting as external circumstances require, as though it were endowed with life and reason? This, nevertheless, has been done. M. de Kempelen, a gentleman of Pressburg in Hungary, excited by the performances of M. de Vaucanson, at first endeavoured to imitate them, and at last far excelled them. This gentleman constructed an Androïdes capable of playing at chess! Every one who is in the least acquainted with this game must know, that it is so far from being mechanically performed, as to require a greater exertion of the judgment...
ment and rational faculties than is sufficient to accomplish many matters of greater importance. An attempt therefore, to make a wooden chef-player, must appear as ridiculous as to make a wooden preacher or counsellor of state. That this machine really was made, however, the public have had ocular demonstration. The inventor went to Britain in 1783, where he remained above a year with his automaton.

It is a figure as large as life, in a Turkish dress, sitting behind a table with doors, of three feet and a half in length, two in depth, and two and a half in height. The chair on which it sits is fixed to the table, which runs on four wheels. The automaton leans its right arm on the table, and in its left hand holds a pipe: with this hand it plays after the pipe is removed. A chef-board of 18 inches is fixed before it. This table, or rather cupboard, contains wheels, levers, cylinders, and other pieces of mechanism; all which are publicly displayed. The vibrations of the automaton are then lifted over its head, and the body is seen full of similar wheels and levers. There is a little door in its thigh, which is likewise opened; and with this, and the table also open, and the automaton uncovered, the whole is wheeled about the room. The doors are then shut, and the automaton is ready to play; and it always takes the first move.

As every move of the wheels are heard; the image moves its head, and looks over every part of the chef-board. When it checks the queen, it shakes its head twice, and thrice in giving check to the king. Its likewife shakes its head when a false move is made, replaces the piece, and makes its own move; by which means the adversary loses one.

M. de Kempelen remarks, as the most surprising circumstance attending his automaton, that it had been exhibited at Presburg, Vienna, Paris, and London, to thousands, many of whom were mathematicians and chef-players, and yet the secret by which he governed the motion of its arm was never discovered. He prided himself solely on the construction of the mechanical powers, by which the arm could perform ten or twelve moves. It then required to be wounded up like a watch, after which it was capable of continuing the same number of motions.

The automaton could not play unless M. de Kempelen or his substitute was near it to direct its moves. A small square box, during the game, was frequently consulted by the exhibitor; and herein consulted the secret, which he said he could in a moment communicate. He who could beat M. de Kempelen was, of course, certain of conquering the automaton. It was made in 1769. His own account of it was; "C'est une bagatelle qu'ont neuf fans merite du coeur du mechanism, mais les effets n'en paroissent ni merveilleux que par la hardieffce de Pidee, & par l'honneur choyez moyens employes pour faire illusion."

The strongest and best-armed loadstone was allowed to be placed on the machine by any of the spectators.

As the inventor of this admirable piece of mechanism hath not yet thought proper to communicate to the public the means by which it is actuated, it is in vain for any, except those who are exquisitely skilled in mechanics, to form conjectures concerning them.—Many other curious imitations of the human body, as well as that of other animals, have been exhibited, though none of them equal to the last mentioned one. See the 2d Androlepsy.

Androlepsy, in Grecian antiquity, an action allowed by the Athenians against such as protected perfons guilty of murder. The relations of the deceased were empowered to seize three men in the city or house whether the malefactor had fled, till he were either surrendered, or satisfaction made some way or other for the murder.

Andromache, the wife of the valiant Hector, the mother of Astyanax, and daughter of Eton king of Thebes in Cilicia. After the death of Hector and the defection of Troy, she married Pyrrhus; and afterwards Helenus the son of Priam, with whom she reigned over part of Epirus.

Andromeda, in astronomy, a northern constellation, behind Pegesus, Cassiopeia, and Perseus. It represents the figure of a woman chained; and is said to have been formed in memory of Andromeda, daughter of Cepheus and Cassiopeia, and wife of Perseus, by whom she had been delivered from a sea-monster, to which she had been exposed to be devoured for her mother's pride. Minerva translated her into the heavens.

The stars in the constellation Andromeda in Ptolomy's catalogue are 23, in Tycho's 22, in Bayer's 27, in Mr Flamstead's no less than 84.

Andromeda, the name of a celebrated tragedy of Euripides, admired by the ancients above all the other compositions of that poet, but now lost.

It was the representation of this play, in a hot summer day, that occasioned that epidemic fever, or phrenzy, for which the Abbeites are often mentioned, wherein they walked about the streets, rehearsing verses, and acting parts of this piece. See Andere.

Andromeda, or Mars' Gysus: A genus of the monogany order, belonging to the decandria class of plants; and in the natural method ranking under the 18th order, Bicornes. The characters are: The calyx is a quinquepartite perianthium, small, coloured, and peltate; the stamens are very numerous, roundish, and fragile; the style is longer than the stamens, and persistent; the carpels are five, united, and united to the ovary, which is divided into five cells: The pericarpium is a roundish five-collared capsule, with five cells and five valves: The seeds are very numerous, roundish, and glossy.

Species. 1. The polifolia is a low plant, growing naturally in bogs in the northern countries. It is difficultly preserved in gardens; and, being a plant of no great beauty, is seldom cultivated. 2. The mariana, a native of North America. It is a low shrub, sending out many woody flarks from the root, which are garnished with oval leaves placed alternately; the flowers are collected in small bunches, are of an herbaceous colour, and shaped like those of the strawberry-tree. They appear in June and July. 3. The paniculata is a native of Virginia and Carolina, growing in moist places. XXXI. The plants usually arrive at the height of ten feet, with thin leaves set alternately, and having their edges finely serrated. The flowers areubulous, small, and of a greenish white, closely set horizontally on one side of the slender flarks. These flowers are faced by berries, which open when ripe; and divide into five sections,
ANDROMEDA, including many small seeds. 4. The arborea are native to the same countries, where it is called the

Androna. 5. The cultivata, a native of Siberia, and like those of North-America. It grows on mucky land, and is therefore very difficult to keep in gardens. The leaves are shaped like those of the box-tree, and are of the same consistence, having several small punctures on them. The flowers grow in short spikes from the extremity of the branches. They are produced single between two leaves, are of a white colour, and a cylindrical or picker-like shape. There are ten other species.

Propagation and Culture. All these sorts, except four, are hardy plants. The fourth species requires to be sheltered from frost in winter, but in the summer should be frequently watered.

The above plants succeed best upon boggy and moist grounds. You must procure the seeds from the places where they grow naturally; a year before which hang many small white flowers like those of the strawberry-tree. 5. The cultivata, a native of Siberia, and like those of North-America. It grows on mucky land, and is therefore very difficult to keep in gardens. The leaves are shaped like those of the box-tree, and are of the same consistence, having several small punctures on them. The flowers grow in short spikes from the extremity of the branches. They are produced single between two leaves, are of a white colour, and a cylindrical or picker-like shape. There are ten other species.

ANDROS, between Tenedos and Euboea: being one mile distant from the former, and ten from the latter. The ancients gave it various names, viz. Carus, Lybia, Naxia, Epirus, Andros, and Hydryus. The name of Andros received from one Andrusus, appointed, according to Diodorus Siculus, by Rhadamantus, one of the generals, to govern the Cyclades, after they had of their own accord submitted to him. As to the name of Androsus, the same author tells us, that Acharius the son of Eucus, being taken prisoner by the Pelasgians, gave them this island for his ransom, which on that account was called Androsus, or "delivered for one man." The name of Hydra did not obtain in common with other places well supplied with water. It had formerly a city of great note, bearing the same name, and situated very advantageously on the brow of an hill which commanded the whole coast. In this city, according to Strabo and Pliny, stood a famous temple dedicated to Bacchus. Near this temple Mutianus, as quoted by Pliny, tells us, there was a spring called the gift of Jupiter; the water of which had the taste of wine in the month of January, during the feast of Bacchus, which lasted seven days. The same author makes no mention of this spring; but says, that, during the feast of Bacchus, wine flowed, or was at least by the Andrians believed to flow, from the temple of that god. The priests, no doubt, found their account in keeping up this belief, by conveying, through secret conduits, a great quantity of wine into the temple.

The Andrians were the first of all the islanders who joined the Persians at the time Xerxes invaded Greece; and therefore Themistocles, after the victory at Salamis, resolved to attack the city of Andros, and oblige the inhabitants to pay large contributions for the maintenance of his fleet. Having landed his men on the island, he sent heralds to the magnates, acquainting them, that the Athenians were coming against them with two powerful divinities, PERSONATION and force; and therefore they must part with their men, property, or both, as they pleased. The Andrians replied, that they likewise had two mighty deities who were very fond of their island, viz. Poverty and impossibility; and therefore could give no money. Themistocles, not satisfied with this answer, laid siege to the town; which he probably made himself master of and destroyed, as we are informed by Plutarch, that Pericles, a few years after, sent thither a colony of 250 Athenians. It was, however, soon retaken by the Persians; and, on the overthrow of that empire by Alexander the Great, submitted to him, along with the other islands. On his death it sided with Antigonus, who was driven out by Ptolemy. The succedors of the last mentioned prince held it, till it came to the Romans; when Attalos, king of Pergamus, besieged the metropolis at the head of a Roman army; and, having taken it, was by them put in possession of the whole island. Upon the death of Attalos, the republic claimed this island, as well as his other dominions, in virtue of his last will.

Andros is now subject to the Turks; and contains a town of the same name, with a great many villages. It is the most fruitful island in all the Archipelago, and yields a great quantity of silk. There are said to be about 6000 inhabitants, besides those of the villages Arni and Amolchos, who are about two hundred, with a different language and customs, and are called Albaneeus. There are 7 monasteries, a great number of churches, and a cathedral for the bishops of the Roman Catholic persuasion; but most of the inhabitants are of the Greek communion. The Jews had a house and a church in this island; but they were forced to quit them long ago. Here are some delightful valleys; but the air is bad, and the water of the city worse. The women would be agreeable enough, if it was not for their dresses, which is very unbecoming; for they stuff their clothes without the least regard to their shape; but the Albanian women make a much better appearance. The peasants make wicker-baskets, wherewith they supply the greatest part of the Archipelago. They have all sorts of game in the woods and mountains, but know not how to take them for want of guns. Their principal food is goats flesh; for there is no fish to be met with on their coasts. When they are sick, they are obliged to let the disease take its natural course, having neither physician nor surgeon on the island. A cadis, assisted by a few of the principal persons of the island, has the management of civil affairs, and his residence is in the castle: an aga, who presides over the military force, lives in the tower without the city. About two miles from the present town are still to be seen the ruins of a strong wall with the fragments of many columns, chapels, baths, broken statues, and several inscriptions, some of which mention the name and people of Andros, and the priests of Bacchus; from which it is probable that this was the site of the ancient city. E. Long 25° 30'. N. Lat. 37° 30'.

ANDROS (anc. geog.), an island in the Irish sea, (Pliny), called Hedros by Ptolemy: Now Bardsey, distant about a mile from the coast of North-Wales.

ANDROSACE: a genus of the monogynia order, belonging to the pentandra class of plants; and in the natural method ranking under the 21st order, Precisae. The essential characters are, The male calyx is five-leafed; the corolla is five-petaled; the stamens are five, inserted in the rudiment of the style; The female calyx is five-leafed; the corolla is wanting; the style is three; the capsule is trilocular; the seeds are two of this genus Dr Linnaeus reckons six.

Species. 1. The maxima grows naturally in Austria and Bohemia, among the corn. It hath broad leaves, which spread near the ground; from the centre of these the footstalks arise, which are terminated by an unbel of white flowers like those of the curculia. These appear in April and May, and the seeds ripen in June; soon after which the plants perish. 2. The pententriaxis, villata, corna, and lactes, grow naturally on the Alps and Helvetian mountains, as also in Siberia. They are much smaller than the former, seldom growing more than three inches high. Of other species called the Cangara, we have no particular description.

Culture. These plants are propagated by seeds, which should be sown soon after they are ripe, otherwise they seldom come up the same year. If permitted to scatter, they will grow better than when they are sown.

ANDRUM, a kind of hydrocele, to which the people of Malabar are very subject. Its origin is derived from the vitious quality of the country waters, impregnated
ANEAU (Bartholomew), a native of Bourges in France, a man of eminent learning in the 16th century, educated under Melchior Volmar. He was professor at Lyons, where he propagated the doctrines of the Reformation secretly for a long time: but on the festival of the Holy Sacrament 1565, as the procession was passing on towards the college, there was a large stone thrown from one of the windows, upon the Hoët and priest who carried it. The people, enraged at this, broke into the college, and affiliated Mr Aneau, whom they imagined to have been the occasion, and the college itself was shut up next day by order of the city.

ANECDOTE, ANECDOTA, a term used by some authors, for the title of Secret Histories; but it more properly denotes a relation of detached and interesting particulars. The word is Greek μνημονευρια, q. d. things not yet known, or hitherto kept secret. Procopius gives this title to a book which he published against Justinian and his wife Theodora; and he seems to be the only person among the ancients who has represented princes such as they are in their domestic relation.—Varillas has published Anecdotes of the House of Medicis.

ANECDOTES is also an appellation given to such works of the ancients as have not yet been published. In which sense, M. Muratori gives the name Anecdota Graecarum to several writings of the Greek fathers, found in the libraries, and first published by him.—F. Martene has given a Thesaurus Anecdotarum Novus, in folio, 5 vols.

ANEE, in commerce, a measure for grain, used in some provinces of France. At Lyons, it signifies a certain quantity of wine, which is the load an ass can carry at once: which is fixed at 80 English quarts, wine-measure.

ANEMOMETER, in mechanics, implies a machine for measuring the force and velocity of the wind.

Various machines of this kind have been invented at different times, and by different persons. The following has been often experienced, and found to answer the intention.

An open frame of wood, ABCDEFGHI, is supported by the shaft or arbor J. In the two cross-pieces XXXI. H, K, L, M is moved a horizontal axis QM, by means of the four falls ab, cm, off, gb, exposed to the wind in a proper manner. Upon this axis is fixed a cone of wood, MNO; upon which, as the falls move round, a weight R, or S, is raised by a string round its super- fices, proceeding from the smaller to the larger end NO. Upon this larger end or base of the cone, is fixed a rocket wheel, whose teeth the click X falls, to prevent any retrograde motion from the depending weight.

The structure of this machine sufficiently shows that it may be accommodated to estimate the variable force of the wind; because the force of the weight will continually increase as the string advances on the conical surface, by acting at a greater distance from the axis of motion; consequently, if such a weight be added on the smaller part M, as will just keep the machine in equilibrio in the weakest wind, the weight to be raised as the wind becomes stronger, will be increased in proportion, and the diameter of the cone NO may...

downy fubfance. You muft preferve this

feed till the beginning of August, when you may ei­

and not the dung and turf, and to let it have the ad­

vantages of the free air. In doing this work, be care­

ful to rake out all the great stones, and break the

clods; but by no means lift or screen the earth, which has

been found very hurtful to many forts of roots. This earth

should be mixed twelve months before it is used, if po­

ible; but if contrained to use it looser, it muft be the

of tener turned over to mellow and break the

oberving to rake out all the parts of the green flar­

that are not quite rotten, before it is used, as they

would be prejudicial to the roots if suffered to remain.

The beginning of September is a proper feafon to

prepare the beds for planting, which (if in a wet foil) should

be raifed with this fort of earth fix or eight inches above

the surface of the ground, laying at the bottom fome

of the rakings of the heap to drain off the moifure;

but, in a dry foil, three inches above the surface will be

fufficient; this compoft should be laid at leat two feet

and a half thick, and in the bottom there fhould be

about four or five inches of rotten neats dung, or the

rotten dung of an old melon or cucumber bed. The

beds muft be laid (if in a wet foil) a little round, to

flood off the water; but in a dry one, nearer to a

level. In wet land, where the beds are raised above the

surface, it will be proper to fill up the paths between

them, in winter, either with rotten tan or dung, to pre­

vent the froft from penetrating into the fides of the beds,

which otherwife may defroy their roots. The earth

should be laid in the beds at leat a fortnight or three 

weeks before the roots are planted, and a longer

time would be yet better, that it may fette; and when

the wood-anemone; and, according to Linnaeus and Gunner, many observations have proved that it causes the bloody flux among them.

Sea-Anemone. See Animal-Flower.

ANEMOSCOPE. See Wind-Gauge.

The machine which shows the course of the wind, or from what point of the compass it blows, consists of an index moving about an upright circular plate, like the dial of a clock, on which the 32 points of the compass are drawn instead of the hours. The index, which points to the divisions on the dial, is turned by a horizontal axis, having a trundle-head at its external extremity. This trundle-head is moved by a cog-wheel on a perpendicular axis; on the top of which a vane is fixed, that moves with the course of the wind, and puts the whole machine in motion. The whole contrivance is extremely simple; and nothing required in the construction, but that the number of cogs in the wheel, and rounds in the trundle-head, be equal; because it is necessary, that when the vane moves entirely round, the index of the dial also make a complete revolution.

The anemoscope, calculated for indicating the force or velocity of the wind, is the same with what most writers call an anemometer; and we have accordingly described one of those machines under that article. We shall here add another, contrived by the late Mr. Pickering, and published in the Philosophical Transactions, No. 473.

This anemoscope is a machine four feet and a quarter high, consisting of a broad and weighty pedestal, a pillar fastened into it, and an iron axis of about half an inch diameter fastened into the pillar. Upon this axis turns a wooden tube; at the top of which is placed a vane, of the same materials, 21 inches long, consisting of a quadrant, graduated, and jointed with an iron ring, notched to each degree; and a counterpoise of wood, as in the figure, on the other. Through the centre of the quadrant runs an iron pin, upon which are fastened two small round pieces of wood, which serve as moveable radii to desribe the degrees upon the quadrant, and as handles to a velum or sail, whose plane is one foot square, made of canvas, stretched upon four battens, and painted. On the upper batten, next to the hod rim of the quadrant, is a small spring which catches at every notch corresponding to each degree, as the wind shall, by pressing against the sail, raise it up; and prevents the falling back of the sail, upon the lessening of the force of the wind. At the bottom of the wooden tube, is an iron index, which moves round a circular piece of wood fastened to the top of the pillar on the pedestal, on which are described the 32 points of the compass. The figure of this machine is given on Plate XXXI. fig. 4, where a is the pedestal; b, the pillar on which the iron axis is fitted; c, the circle of wood, on which are described the 32 points of the compass; d, the wooden tube upon its axis; e, the velum; f, the graduated quadrant; h, the counterpoise of the vane. The adjoining figure represents the velum, which takes off: a is the plane of the velum; b, the spring; c, the wooden radius, d, e, the holes through which the pin in the centre of the quadrant goes. Its uses are the following.

Having a circular motion round the iron axis, and its divided length, is a faithful indication of 
the wind and its direction. The ingenious contriver of this machine tells us, 
that he carefully examined what dependence may be had upon it, during the forms of February 1743-4, 
and found that it answered extremely well; for that, 
In such winds as the sailors call violent storms, the ma-
chine had six degrees to spare for a more violent gulf, 
before it comes to a horizontal position. It is certainly 
to be depended upon in ordinary weather, the vane 
being hung so tenderly as to feel the most gentle 
breeze. There is, however, reason to fear, that the 
exposing the anemoscope to all winds for a continuance, 
must disorder it, especially irregular blasts and squalls.
It may not therefore be amis, in violent weather, for 
the observer to take the tube with its vane and venum 
in his hand, in order to know the force of the wind 
and, when he has finished his observations, to carry 
the machine into the house, till the violence of the 
storm is abated, when it may be replaced in its former 
position.

ANETHUM, DILL and FENNEL: A genus of the 
digynia order, belonging to the peperarum class of 
plants; and, in the natural method, ranking under 
the 45th order, Umbellatae. The essential characters 
are: The fruit is oval, compressed, atriate; and the 
petals (five) are involute, entire, and very short.
Species. 1. The graveolens, or dill, is an annual 
plant: the root is long, slender, and white; the leaves 
are divided into a multitude of fine, long, narrow seg-
ments, like those of fennel, but of a bluish green co-
lour, and leaves free. The stalk is round and firm, 
growing to the height of four feet, with yellow 
flowers in moderately large umbels. 2. The fc-
iculum, or fennel; of which there are two varieties, 
the common and the sweet. The sweet fennel is smaller 
in all its parts than the common, except the seeds, 
which are considerably larger. The seeds of the two 
forts differ likewise in shape and colour; those of the 
common are roundish, obovate, flatish on one side, and 
protrubant on the other, of a dark almost blackish co-
lour; those of the sweet are longer, narrower, not so 
flat, generally crooked, and of a whitish or pale yel-
lowish colour. Both forts are cultivated in gardens: 
the common is a perennial plant; the sweet fennel pe-
rishes after it has given seed.

Medicinal Uses. 1. Of the first species, dill, only 
the seeds are used. They are of a pale yellowish co-
lour, in shape nearly oval, convex on one side, and 
flat on the other. Their taste is moderately warm and 
pungent; their smell aromatic, but not of the most a-
greeable kind. Several preparations of them are kept 
in the shops. They are recommended as a carminative, 
in flatulent colics, proceeding from a cold cause or a 
vividicity of the juices.—2. Of fennel both the seeds 
and roots are used in medicine. The seeds of both the 
fennels have an aromatic smell, and a moderately 
warm pungent taste: the taste of the sweet fennel is in 
flavour most agreeable, and also have a considerable 
degree of sweetness; hence the use of these only have 
been directed. They are ranked among the four 
greater hot feeds, and not unfavourably looked up 
as good phoanatics and carminatives. A simple water 
is prepared from them in the shops; they are ingredi-
teals also in the compound spirit of juniper, and some 
other officinal compositions. The root is far less warm, 
but has more of a sweetish taste, than the seeds; it is 
one of the five roots called openers; and has some-
times been directed in aperient apomes. Boerhava 
says, that this root agrees in taste, smell, and medical 
qualities, with the celebrated ginseng of the Chinese; 
from which, however, it appears to be very consider-
dibly different. The leaves of fennel are weaker than 
either the roots or seeds, and have very rarely been 
employed for any medicinal use.

ANEURISIM, in surgery, a throbbing tumor, di-
tended with blood, and formed by a dilatation or ru-
ture of an artery. See Surgery-Index.

ANGARI, or Angaril, in antiquity, denote pub-
lic couriers appointed for the carrying of messages. 
The ancient Persians, Budaens observes, had their 
angari, or angari, which was a set of couriers on horse-
back, poised at certain places or distances, always 
readiness to receive the dispatches from one, and 
forward them to another, with wonderful celerity, an-
swering to what the moderns call postes. q. d. postis, as 
being posted at certain places or stages.—The angari 
were also called by the Persians, sana, by the Greeks 
agnathos, upon account of the long journeys they made 
in one day, which, according to Suidas, amounted not 
to less than 1500 Stadia.

ANGARIA, in Roman antiquity, a kind of pub-
lic service imposed on the provincials, which consisted 
in providing horses and carriages for the conveyance of 
military forces, and other public burdens. It is some-
times also used for a guard of soldiers, posted for the 
defence of a place. In a more general sense, it is used for 
young kind of oppression or services performed through 
compulsion.

ANGAZYA, one of the Comoro islands, lying 
between the north end of Madagascar and the coast 
of Zanguebar in Africa, from Lat. 10° to 15° S. It 
is inhabited by Moors, who trade with divers parts of 
the continent, in cattle, fruits, and other commodities 
of the island; which they exchange for callicoes and 
other cotton cloths. The houses here are built of stone, 
and lime made of calcined oyster-shells; with which 
the walls and roof are plastered in a very elegant man-
ner. The government of Angaza is a pure arithocra-
cy; the island being subject to lords, who have all 
the title of Sultan. The people are very careful of 
their women; never permitting strangers to see them, 
without permission from a sultan, or an order which
the stranger brings with him. Many of them read and write Arabic with great facility; and some even understand Portuguese, which they learn from their intercourse with Mosambiques, whither they trade in vessels of 40 tons berthen.

ANGEIOTOMY, in surgery, implies the opening of a vein or artery, as in bleeding: and consequently includes both arteriotomy and phlebotomy.

ANGEL, a spiritual intelligent substance, the first in rank and dignity among created beings. The word angel is Greek, and signifies a messenger: the Hebrew מלאך signifies the same thing. The angels are in Daniel (chap. iv. ver. 13, &c.) called שָׁמִיר, or Watchers, from their vigilance: for the same reason they are, in the remains we have of the prophecy attributed to Enoch, named キュルジオリ; which word imports the same in Greek.

Angels, therefore, in the proper significations of the word, do not import the nature of any being, but only the office to which they are appointed, especially by way of message, or intercourse between God and his creatures; in which sense they are called the ministers of God, who do his pleasure, and ministering spirits sent forth to minister for them that shall be heirs of salvation. That there are such beings as we call angels, that is, certain permanent substances, invisible, and imperceptible to our senses, endowed with understanding and power superior to that of human nature, created by God, and subject to him as the supreme Being; ministering to his divine providence in the government of the world by his appointment, and more especially attending the affairs of mankind; is a truth so fully attested by Scripture, that it cannot be doubted. Nay, the existence of such invisible beings was generally acknowledged by the ancient heathens, though under different apppellations: the Greeks called them δαίμονια; and the Romans genii, or lares. Epicurus seems to have been the only one among the old philosophers who absolutely rejected them. Indeed, the belief of middle intelligences influencing the affairs of the world, and serving as ministers or interpreters between God and man, is as extensive as the belief of a God; having never, so far as we know, been called in question by those who had any religion at all.

The creation of angels is not indeed expressly mentioned by Moses in the first of Genesis, yet it is generally considered by judicious expounders as implied. The reason why the sacred historian is silent on this subject, is supposed by Berrington to be the natural proneness of the Gentile world, and even of the Jews, to idolatry. And it is thought, if they worshipped mere material elements, which was the case, much more might they be inclined to worship such superior and sublime beings as angels. But a better reason is perhaps given by other writers, viz. that this first history was purposely and principally for information concerning the visible world; the invisible, of which we know but in part, being referred for a better life.

On what day they were created has been matter of conjecture. It is a point on which learned men have differed. The Socinians, indeed, hold, says Bishop Hooker, that they were long ago accounted by Moses, but it must have been within the six days' creation; because, as we are informed, that within this space God made heaven and earth, and all things that are therein. All the writers that we have seen on this subject, think they were included in the first day's work, when the heavens were framed.

It has been thought by some persons, that the words of Job, "When the morning stars sang together, and all the sons of God shouted for joy," militate against the creation of angels within the six days. About the meaning of these words, however, expositors are not agreed; but admitting that they refer literally to angels, Dr Lightfoot, Cary, and others, see no difficulty in the passage. The Doctor thinks they were created on the first day, with the heavens; and that they were spectators of God's works in the other parts of creation, and praised and magnified the Lord for his works all along; singing and shouting when God laid the foundation of the earth, as the Jews did at the laying the foundation of the temple, Ezra iii.

On a subject of this nature it would be imprudent to indulge a spirit of conjecture: Scripture is the only standard by which truth and error can be tried, and to this we must ultimately appeal. It is acknowledged that Moses has not expressly mentioned angels by name; yet as we have remarked, their creation is undoubtedly implied; for the heavens must include all that are in them; and therefore it is that the divine penman says, in the conclusion of his creative, "Thus the heavens and the earth were created, and all the host of them." Of the hosts of heaven, the angels must form a considerable part; they are expressly called the heavenly hosts and the armies of heaven, Dan.iv. 30. Lukeii. 13. And if divine authority be admitted as decisive, the reasons adduced by Jehovah for the sanctification of a sabbath, demonstrate that they did not exist previous to the creation of the heavens. It is, surely, inferred with propriety, that in six days the Lord made heaven and earth, the sea, and all that in them is. Similar to which is a declaration of the divine historian relating to the same fact.—"And God blessed the seventh day and sanctified it; because that in it he had rested from all his work which God created and made," Gen. ii. 3. Now if angels existed prior to the six days of creation, the language of Moses is far from being accurate and intelligible; and especially when it is considered that the obscurity might have been removed by adding, "from all the work which God had then created and made." But if angels were created before the heavens, where could they exist? For, as the learned Gill has remarked, "though angels have no bodies, and so are not in the place circumscriptively; yet as they are creatures, they must have an ubi, a somewhere, in which they are definitively; so that they are here, and not there, and much less every where: Now where was there an ubi, a somewhere, for them to exist in, before the heavens and the earth were made? It is most reasonable, therefore to conclude, that as God prepared an habitation for all the living creatures before he made them: as the sea for the fishes, the expanze, or air, for the fowls, and the earth for men and beasts; so he made the heavens first, and then the angels to dwell in them."

That this was the fact, will appear very evident, if the words of Moses be impartially considered. "In the beginning (says he), God created the heavens and the earth," which words must refer to either the beginning of creation or of time; it to the former, and angels previously existing, the language is neither intelligible.
ANG [ 803 ]

Angels

The difficulty remains; for what is time but the measure of creation, or the beginning of the creation and the beginning of time, there could be nothing but eternity; nothing but what was uncreated, that is, nothing but what was without beginning. But if angels were in a pre-existent state, the historian's language is unaccountably strange and inaccurate: for if the phrase in the beginning, which is remarkably emphatical, refer to the creation of the heavens and the earth only, they are unhappily expresed: to expresed, indeed, as to convey no meaning to those who consider words as the vehicle of thought, and as intended to express clearly to others the meaning of the writer. For the natural obvious sense is as follows: in the beginning of the creation of the heavens and the earth, God created the heavens and the earth, language is not only a departure from that perspicuity andprecision which distinguishes all his narrations, but entirely irrational and absurd.

That the words in the beginning refer to the first creation, cannot be doubted, if it be remembered that Jehovah himself founds a claim to eternity on this very ground: before the day was, I am he. Before the mountains were brought forth, or ever thou hadst formed the earth or the world, even from everlasting to everlasting, thou art God. Isa. xlvii. 13. Pf. ix. 2. See also Prov. viii. 23, 24. &c. Now there could be no propriety in this kind of reasoning, if angels or any other creature existed before the creation of the world, because all claims to eternity from such premises would apply even to Gabriel as well as to Jehovah, before the world was, is, in Scripture language, a phrase always expressive of eternity; and on this principle the evangelist John afferts the pre-existence of Jesus Christ in the first chapter of his history. For this purpose he alludes to the words of Moses, and introduces his divine nature to notice by celebrating the first act of his creative power. In the beginning (says he) was the Word; that is, Dr Doddridge remarks, before the foundation of the world, or the first production of any creature; and Dr Sherlock is clear of all opposition, that the words, in their most common and usual acceptation, signify the first creation of all things, and are a demonstration of the divinity of Christ. Of the same mind was Dr Owen. He says, that if the phrase beginning does not absolutely and formally express eternity, yet it doth a pre-existence to the whole creation, which amounts to the same thing; for nothing can pre-exist before all creatures but the nature of God, which is eternal, unless we suppose a creature before the creation of any. But what is meant by this expression is fully declared by other passages of Scripture: I was set up from everlasting, before the beginning, or even the earth was: Glorify thou me with thine own self, with the glory which I had with thee before the world was; both which passages not only explain the text, but undeniable prove the pre-existence of Christ the son of God. It should be remembered, that, in the passage under consideration, the Evangelist's argument for the divinity of Jesus Christ is grounded on his pre-existing the creation of the world; and it is consequently afferted, that he is the creator of all things; but if angels had a being before the period to which he alludes, the argument loses all its force, and no more proves the divinity of Christ than the divinity of an angel (A).

If, therefore, the words of Moses be impartially viewed in their obvious natural meaning, and compared with other passages of Scripture that relate to the same subject, we have no doubt, but every unprejudiced mind will perceive, that as he intended to give a summary history of the creation of all things both in heaven and in earth, he has done it in language intelligible and accurate, and in terms sufficiently explicit.

As to the nature of these beings, we are told, that their nature, power, employment, &c. have been a controversy of long standing. Not only the ancient philosophers, but some of the Christian fathers were of opinion, that angels were cloathed with ethereal, or fiery, bodies, of the same nature with those which we shall one day have when we come to be equal to them. But the more general opinion especially of later times, has been, that they are substances entirely spiritual, though they can at any time assume bodies, and appear in human or other shapes.

That the angelical powers and abilities vastly exceed those of man, cannot be denied, if we consider, that their faculties are not clogged or impeded, as ours are, by any of those imperfections which are inseparable from corporeal being; so that their understandings are always in perfect vigour; the inclinations regular; their motions strong and quick; their actions irreducible by material bodies; whose natural qualities they can control, or manage to their purposes, and occasion either blessings or calamities, public or private, here below; Influences of which are too numerous to mention.

Besides their attendance on God, and their waiting and executing of his commands, they are also presumed to be employed in taking care of mankind and their concerns: and that every man had such a tutelar or guardian angel, even from his birth, was a firm belief and tradition among the Jews; and our Saviour himself seems to have been of the same sentiment. The heathens were all of the same persuasion, and thought it a crime to neglect the admonitions of so divine a guide. Socrates publicly confessed himself to be under the direction of such an angel, or daemon, as several others have since been. And in this tutelar genius of each person they believed his happiness and fortune depended. Every genius did his best for the interest of his client; and if a man came by the world, it was a sign the strength of his genius was inferior to that.

(A) Of this Socinus and his followers were aware; and therefore artfully endeavoured to evade the force of the apostle's reasoning, by interpreting the phrase in the beginning either in a figurative sense, or as referring to the beginning of John the Baptist's ministry. We will only subjoin, that we do not remember to have seen any writer deviate from the primary obvious meaning of the passage, who had not some hypotheses to support imaginary to truth.
that of his opponent, that is, of an inferior order; and this was governed by chance. There were some genii, whose ascendency was so great over others, that their very presence entirely disconcerted them; which was the case of that of Augustus in respect to that of Marc Antony: and for the same reason, perhaps, some persons have wit, and speak well, when others are absent, in whose presence they are confounded, and out of countenance. The Romans thought the tutilar genii of those who attained the empire, to be of an eminent order; on which account they had great honours shown them. Nations and cities also had their several genii. The ancient Persians so firmly believed the ministry of angels, and their superintendence over human affairs, that they gave their names to their months, and the days of their month; and assigned them different offices and provinces: and it is from them the Jews confefs to have received their names of the months and angels, which they brought with them when they returned from the Babylonish captivity. After which, we find, they also assigned charges to the angels, and in particular the patronage of empires and nations; Michael being the prince of the Jews, as Raphael is supposed to have been of the Persians.

The Mahometans have so great a respect for the angels, that they account a man an infidel who either denies their existence, or loves them not. They believe them to be free from sin, enjoying the preference of God, to whom there are never disobedient: and they have sublime pure bodies, being created of light; and have no distinction of sexes, nor do they need the refreshment of food or sleep. They suppose them to have different forms and offices: that some adore God in several poffures; others sing his praises, and intercede for men: some carry and encompass his throne; others write the actions of men, and are assigned guardians of them.

As the number of these celestial spirits is very great, it is likewise reasonable to believe that there are several orders and degrees among them; which is also confirmed by Scripture; whence some speculative men have distributed them into nine orders, according to the different names by which they are there called; and reduced those orders into three hierarchies, as they call them: to the first of which belong seraphim, cherubim, and thrones; to the second, dominions, virtues, and powers; and to the third, principalities, archangels, and angels. They imagine further, that there are some who constantly reside in heaven; others who are ministers, and went forth, as there is occasion, to execute the orders they receive from God by the former. The Jews reckon but four orders or companies of angels, each headed by an arch-angel; the first order being that of Michael, the second of Gabriel, the third of Uriel, and the fourth of Raphael: but though the Jews believe them to be four, yet it seems there were rather seven. The Persians also held, there were subordinate degrees among the angels.

Although the angels were originally created perfect, of the good, and obedient to their master's will, yet some of them sinned, and kept not their first estate, but left their habitation; and of the most blessed and glorious became the most vile and miserable of all God's creatures. They were expelled the regions of light, and cast down to hell, to be reserved in everlasting chains under darkness, until the day of judgment. With heaven they lost their heavenly disposition, which delighted once in doing good and praising God; and fell into a fettled rancour against him, and malice against men: their inward peace was gone; all desire of doing good departed from them; and, instead thereof, revengeful thoughts and despair took possession of them, and created an eternal hell within them.

When, and for what offence, these apostate spirits fell from heaven and plunged themselves into such an abyss of wickedness and wo, are questions very hard, if not impossible, to be determined by any clear evidence of Scripture. As to the time, we are certain that it could not be before the sixth day of creation; because on that day it is said, "God saw every thing that he had made, and beheld it was very good:" but that it was not long after is very probable, as it must have preceded the fall of our first parents. Some have imagined it to have been after; and that carnality, or lusting to converse with women upon earth, was the sin which ruined them: an opinion (a) built on a mistaken interpretation of Scripture, as if angels were meant by the sons of God who are said to have begotten the mighty men of old on the daughters of men. Others have supposed, that the angels, being informed of God's intention to create man after his own image, and to dignify his nature by Christ's assuming of it, and thinking their glory to be eclipsed thereby, envied man's happiness, and so reviled: and with this opinion that of the Mahometans has some affinity: who are taught, that the devil, who was once one of those angels who are nearest God's preference, and named Azazel, forfeited paradise for refusing to pay homage to Adam at the command of God. But on what occasion ever he first showed it, pride seems to have been the leading sin of the angels; who, admiring and valuing themselves too much on the excellence of their nature and the height of their station, came at length to entertain so little respect for their Creator.

(a) This opinion seems to have been originally occasioned by some copies of the Septuagint, which, in the days of St. Athan, had in this place the angels of God. Laconatus supposes the angels, who were guilty of this enormity, had been sent down by God to guard and take care of mankind; and being ended with free-will, were charged by him not to forfeit the dignity of their celestial nature, by defiling themselves with the corruptions of the earth; but that the devil at length enticed them to debauch themselves by women. He adds, that, being not admitted into heaven by reason of the wickedness into which they had plunged themselves, they fell down to the earth, and became the devil's ministers; but that those that were begotten by them, being neither angels nor men, but of a middle nature, were not received into hell, no more than their parents were into heaven. Hence arose two kinds of daemons, celestial and terrestrial. These are unclean spirits, the authors of whatever evils are committed, and whose prince is the devil. From hence very probably proceeded the notion of Incubi, or daemons who are supposed to have carnal knowledge of women.
ANGEL

Creator, as to be guilty of downright rebellion and apostacy. It is certain from Scripture, that the fallen angels were in great numbers, and that there were also some order and subordination preferred among them; one especially being considered as their prince, and called by several names, Beelzebub, Satan, or Samael by the Jews; Adrammelech, by the Persians; and Eblis, by the Mahometans. Their constant employment is, not only doing evil themselves, but endeavouring by all arts and means to seduce and pervert mankind, by tempting them to all kind of sin, and thereby bringing them into the same desperate state with themselves.

Angel is likewise a title given to bishops of several churches. In this sense is St Paul undercropped by some authors, where he says, Women ought to be covered in the church, because of the angels. The learned Dr Prideaux observes, that the minister of the synagogue, who officiated in offering up the public prayers, being the mouth of the congregation, delegated by them as their representative, messenger, or angel, to speak to God in prayer for them, was therefore, in the Hebrew language, called the angel of the church; and from thence the bishops of the seven churches of Asia are, by a name borrowed from the synagogue, called the angels of the seven churches.

Angel, in commerce, the name of a gold coin formerly current in England. It had its name from the figure of an angel represented upon it, weighed four pennyweights, and was twenty-three and a half carats fine. It had different values in different reigns; but is at present only an imaginary sum, or money of account, implying ten shillings.

ANGEL-FISH, in ichthyology, a species of Squalus. See SQUALUS.

ANGELIC, or Angelical, something belonging to, or that partakes of the nature of angels. We say an angelical life, &c. St Thomas is styled the angelical doctor. The angelical fatuation is called by the Romanists Ave Maria; sometimes simply angelus.

ANGELICA (Angelica officinalis), in ancient times, was a monkish garment, which laymen put on a little before their death, that they might have the benefit of the prayers of the monks. It was from them called angelical, because they were called angels who by those prayers anima faltitiusfucurrentant. Hence, where we read the phrase monachus ad jecundandum in old books, it must be understood of one who had put on the habit when he was at the point of death.

ANGELICA: A genus of the digynia class of plants, and in the natural method ranking under the 4th order Umbelatae. The essential characters are: The fruit is roundish, angled, solid, with reflected style; the corolla are equal, and the petals incurvated.

Species. 1. The fativa, or common angelica, which is cultivated in gardens for medicinal use, and likewise for a sweetmeat, grows naturally in the northern countries. The root of this species is brown, oblong, and an inch or two thick, fragrant, and acrid. The leaves are very large, composed of pinnated folia, of an oblong oval figure, dentated at the edge, and the odd leaf at the end of the pinna lobated; the stalk is round, fristated, and as thick as a child's arm. The umbels are very large, and of a globific figure; the flowers very small and greenish.

ANGELICA is a native of Hungary and Germany. The leaves are much larger than those of the former, and the flowers are yellow. 3. The sylvætris grows naturally in moist meadows, and by the fides of rivers, in many parts of Britain; it is seldom admitted into gardens. 4. The †atro-purpurea canadensis: 5. The lucida canadensis: These are natives of North America, but have neither beauty nor use.

Culture. The common angelica delights to grow in a moist soil: the seeds should be sown soon after they are ripe. When the plants come up about six inches high they should be transplanted very wide, as their leaves spread greatly. If they are planted on the fides of ditches or pools of water, about three feet distance, they will thrive exceedingly.

Medicinal Uses. For the purposes of medicine, Bohemia and Spain produces the best kinds of angelica. The London college direct the roots brought from Spain to be alone made use of. Angelica roots are apt to grow moulidly, and to be preyed upon by insects, unless thoroughly dried, kept in a dry place, and frequently aired. It is probable that the roots which are subject to this inconvenience might be preferred, baking them in boiling spirit, or exposing them to its steam after they are dried.

All the parts of angelica, especially the root, have a fragrant aromatic smell, and a pleasant bitterish warm taste, glowing upon the lips and palate for a long time after they have been chewed. The flavour of the seeds and leaves is very pernicious, particularly that of the latter, which, on being barely dried, lose the greatest part of their taste and smell: the roots are more tenacious of their flavour, though even these lose part of it upon keeping. The fresh root, wounded early in the spring, yields an odorous yellow juice, which slowly exuded, proves an elegant gummy resin, very rich in the virtues of the angelica. On drying the root, this juice concretes into distinct yellowish, which, on cutting it longitudinally, appear distributed in little veins: in this state, they are extracted by pure spirit, but not by watery liquors.

Angelica is one of the most elegant aromatics of European growth, though little regarded in the present practice. The root, which is the most efficacious part, is used in the aromatic tincture: and the stalks make an agreeable sweetmeat.

ANGELICS (Angelici), in church history, an ancient sect of heretics, supputed by some to have got this appellation from their excessive veneration of angels; and by others from their maintaining that the world was created by angels.

ANGELICS is also the name of an order of knights, instituted in 1191, by Angleus Flavius Commenius, emperor of Constantinople.

ANGELICS is also a congregation of nuns, founded at Milan in 1534, by Louisa Tocelli, countess of Guatalla. They observe the rule of St Augustine.

ANGELITES, in ecclesiastical history, a sect of Christian heretics, in the reign of the emperor Anatha- tius, and the pontificate of Symmachus, about the year 494, so called from Angeliam, a place in the city of Alexandria, where they held their first meetings. They were called likewise Soterites, from one Severus, who was the head of their sect; as also Theodotus, from
one among them named Theodosius, whom they made pope at Alexandria. They held, that the persons of the Trinity are not the same; that none of them exists of himself, and of his own nature; but that there is a common god or deity existing in them all, and that each is God, by a participation of this deity.

ANGELO (Michael). There were five celebrated Italian painters of his name, who flourished in the 16th and 17th centuries; but the two most distinguished of them are these.—First, Michael Angelo Buonarroti, who was a most incomparable painter, sculptor, and architect, born in 1474, in the territory of Arezzi in Tuscany. He was the disciple of Dominico Ghirlandajo; and erected an academy of painting and sculpture in Florence, under the protection of Lorenzo di Medici; which, upon the troubles of that house, was obliged to remove to Bologna. About this time he made an image of Cupid, which he carried to Rome, broke off one of its arms, and buried the image by him. It was accordingly found, and sold to Cardinal St. Gregory for an antique; until Michael, to their confusion and his own credit, discovered his artifice, and confirmed it by the deficient arm which he produced: it is rather unuseful for the manufacturers of antiques to be so ingenious. His reputation was so great at Rome, that he was employed by pope Sixtus V. to build his chapel; and by the command of Pope Paul III. executed his most celebrated piece The left judgment. He has the character of being the greatest designer that ever lived; and it is universally allowed that no painter ever understood anatomy so well. He died immemorially rich at Rome, in 1564.—Secondly, Michael Angelo de Caravaggio, born at that village in Milan, in 1569. He was at first no more than a bricklayer's labourer: but he was so charmed with seeing some painters at work, that he immediately applied himself to the art; and made such a progress in a few years, that he was admired as the author of a new style in painting. He was observed of Michael Angelo Buonarroti, that he was incomparable in designing, but knew little of colouring; and by Caravaggio an excellent colourer was brought up. His colouring is either delicate or simulated, like a heart. There is one picture of his in the Dominican church at Antwerp, which Rubens used to call his master. It is said of this painter, that he was so strangely contentious, that the pencil was no sooner out of his hand but his sword was in it. He died in 1609.

ANGELO (St.) a small but strong town of Italy, in the Capitanata. There are several other towns and castles of the same name in Italy, and particularly the castle of St. Angelo at Rome. E. Long. 15. 56. N. Lat. 41. 45.

ANGELOS (103), a province of Mexico, the ancient republic of Tlaica, of which a city called Tlaica was once the capital. That city is now reduced to an inaccessible village, and has given place to another called Puebla de los Angeles, or the city of Angels. It is situated in W. Long. 103. 12 and N. Lat. 19. 13. It was formerly an Indian town; but in 1530 was entirely abandoned by the natives, on account of the cruelties of the Spaniards. A succeeding viceroy of Mexico, by a milder treatment, recalled them; and the town is now exceedingly rich and populous, as even to vie with Mexico itself in magnificence. It is situated on the river Zacatula, in a fine valley, about 25 leagues to the eastward of Mexico. In the middle is a beautiful and spacious square, from whence run the principal streets in direct lines, which are crossed by others at right angles. One side is almost entirely occupied by the magnificent front of the cathedral; while the other three consist of piazzas, under which are the shops of tradesmen. The city is the see of a bishop, suffragan to the archbishop of Mexico, and we may form a judgment of the wealth of the place by the revenue of the cathedral and chapter, which amounts to 300,000 pieces of eight annually. It must be remembered, however, that in all populous countries the wealth of the laity by no means bears a due proportion to that of the clergy. What contributes greatly to increase the riches of this province is, that here is situated the city of Vera Cruz, the natural centre of all the American treasures belonging to Spain. See Vera Cruz.

ANGELOT, an ancient English gold coin, struck at Paris, while under subjection to the English. It was thus called from the figure of an angel supporting the escutcheon of the arms of England and France. There was another coin of the same denomination struck under Philip de Valois.

ANGELOT is also used in commerce to denote a small flat rich fort of chese brought from Normandy. Skinner supposes it to have been thus called from the name of the person who first made up in that form, and perhaps stamped it with his own name. Menage takes it to have been denominated from the resemblance it bears to the English coin called angelot. It is made chiefly in the Pays de Bray, whence it is also denominated angelot de Bray. It is commonly made in vats, either square or shaped like a heart.

ANGER, a violent passion of the mind, consisting in a propensity to take vengeance on the author of some real or supposed injury done to the offended party.

Anger is either deliberative or ininitivé; and the latter kind is rash and ungovernable, because it operates blindly, without affording time for deliberation or forethought. Bishop Butler was well understood when he said, 'anger is far from being a selfish passion, for it is naturally excited by injuries offered to others as well as to ourselves; and was designed by the Author of nature not only to excite us to act vigorously in defending ourselves from evil, but to interest us in the defence or rescue of the injured and helpless, and to raise us above the fear of the proud and mighty oppressors.'

Neither, therefore, is all anger sinful: hence the precept, 'Be ye angry and sin not.'—It becomes sinful, however, and contradicts the rule of scripture, when it is conceived upon flight and Inadequate provocations, and when it continues long. It is then contrary to the amiable spirit of charity, which 'differs only in the world, and is not easily provoked.' Hence these other precepts, 'Let every man be slow to anger;' and, 'Let not the Sun go down upon your wrath.'

These precepts, and all reasoning indeed upon the subject, suppose the passion of anger to be within our power; and this power consists not so much in any faculty we have of appeasing our wrath at the time (for we are passive under the smart which an injury or affront occasions, and all we can then do is to prevent its breaking out into action), as in mollifying our minds
minds by habits of just reflection, as to be less irritated by impieties of injury, and to be sooner pacified.

As reflections proper for this purpose, and which may be called the sedatives of anger, the following are suggested by Archdeacon Paley in his excellent treatise of Moral and Political Philosophy*—"The possibility of mistaking the motives from which the conduct that offends us proceeded; how often our offences have been the effect of inadvertence; when they were mistaken for malice; the inducement which prompted our adversary to set as he did, and how powerfully the same inducement has, at one time or other, operated upon ourselves; that he is suffering perhaps under a contrition, which he is ashamed, or wants opportunity, to confess; and how ungenerous it is to triumph by coldness or insult over a spirit already humbled in secret; that the returns of kindness are sweet, and that there is neither honour, nor virtue, nor usefulness, in which on one account or other, has sometimes betrayed us; the inducement which prompted our passions, their prejudices, their favorite aims, their fears, their cautiousness, their interests, their sudden impulses, their varieties of apprehension, as well as we: we may recollect what hath sometimes passed in our own minds, when we have got on the wrong side of a quarrel, and imagine the fame to be passing in our adversary’s mind now; when we became sensible of our misbehaviour, what palliations we perceived in it, and expected others to perceive; how we were affected by the kindness, and felt the superiority of a generous reception and ready forgiveness: how perseverance revived our spirits with our enmity, and seemed to justify the conduct in ourselves which we before blamed. Add to this, the indecency of extravagant anger; how it renders us, whilst it lafts, the scorn and sport of all about us, of which it leaves us, when it ceases, sensible and ashamed; the inconveniences and irretrievable misconduct into which our irascibility has sometimes betrayed us: the friendships it has lost us; the difficulties and embarrassments in which we have been involved by it, and the fore repentance which on one account or other it always costs us.

But the reflection calculated above all others to allay that haughtiness of temper which is ever finding out provocation, and which renders anger so impetuou s, is that which the gospel propone s; namely, that we ourselves are, or shortly shall be, suppliants for mercy and pardon at the judgment-seat of God. Imagine our secret sins all disclosed and brought to light; imagine us thus humbled and exposed; trembling under the hand of God; calling ourselves on his compassion; crying out for mercy—imagine such a creature to talk of satisfaction and revenge, refusing to be interested, dishonoring to forgive, extreme to mark and to resent what is done amidst; imagine, I say, this; and you can hardly feign to yourself an instance of more impious an unnatural arrogance."

Physicians and naturalists afford instances of very extraordinary effects of this passion. Borrichius cured a woman of an inveterate tertian ague, which had baffled the art of physic, by putting the patient in a furious fit of anger. Valeriana made use of the same means, with the like success, in a quartan ague. The same passion has been equally salutary to paralytic, gouty, and even dumb persons; to which last it has sometimes given the use of speech. Etculmer gives divers instances of very singular cures wrought by anger; among others, he mentions a person laid up in the gout, who, being provoked by his physician, flew upon him, and was cured. It is true, the remedy is somewhat dangerous in the application, when a patient does not know how to use it with moderation. We meet with several instances of princes to whom it has proved mortal; e. g. Valentinian the first, Wenceslaus, Matthias, Corvinus king of Hungary, and others. There are also instances wherein it has produced the epilepsy, jaundice, cholera morbus, diarrhœa, &c. In fact, this passion is of such a nature, that it quickly throws the whole nervous system into preternatural commotions, by a violent stricture of the nervous and muscular parts; and surpris- ingly augments not only the systole of the heart and of its contiguous vesicles, but also the tone of the fibrous parts in the whole body. It is also certain, that this passion, by the spasmotic stricture it produces in the parts, exerts its power principally on the stomoch and intestines, which are highly nervous and membranous parts; whence the symptoms are more dangerous, in proportion to the greater content of the stomoch and intestines with the other nervous parts, and almost with the whole body.—The unhappy influence of anger likewise, on the biliary and hepatic ducts, is very surprising; since, by an intense conftriction of these, the liver is not only rendered stierrous, but stones also are often generated in the gall-bladder and biliary ducts: these accidents have scarce any other origin than an obstruction of the free motion and efflux of the bile, by means of this violent stricture. From such a stricture of these ducts likewise proceeds the jaundice, which in process of time lays a foundation for calculous concretions in the gall-bladder. Lastly, by increasing the motion of the fluid, or the spasms of the fibrous parts, by means of anger, a larger quantity of blood is propelled with an impetus to certain parts; whence it happens that they are too much distended, and the orifices of the veins distributed there opened. It is evident from experience, that anger has a great tendency to excite enormous hemorrhagies, either from the nose, the aperture of the pulmonary artery, the veins of the anus; or in women, from the uterus, especially in those previously accustomed and disposed to such evacuations.
