ENCYCLOPAEDIA;
OR, A
DICTIONARY
OF
ARTS, SCIENCES,
AND
MISCELLANEOUS LITERATURE;
Constructed on a Plan,
BY WHICH
THE DIFFERENT SCIENCES AND ARTS
Are digested into the Form of Distinct
TREATISES OR SYSTEMS,
COMPREHENDING
THE HISTORY, THEORY, and PRACTICE, of each,
According to the Latest Discoveries and Improvements;
AND FULL EXPLANATIONS GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,
WHETHER RELATING TO
NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,
CIVIL, MILITARY, COMMERCIAL, &c.
Including ELUCIDATIONS of the most important Topics relative to RELIGION, MORALS, MANNERS,
and the OECONOMY of LIFE:
TOGETHER WITH
A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.
throughout the WORLD;
A General History, Ancient and Modern, of the different Empires, Kingdoms, and States;
AND
An Account of the Lives of the most Eminent Persons in every Nation,
from the earliest ages down to the present times.

Compiled from the writings of the best Authors, in several languages; the most approved Dictionaries, as well of general science as of its particular branches; the Transactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.
ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. I.  A—ANG

P H I L A D E L P H I A:
PRINTED BY THOMAS DOBSON, AT THE STONE HOUSE, NO 41, SOUTH SECOND STREET.
M. DCC. XCVIII.

[Copy-Right secured according to law.]
TO THE

PATRONS of the Arts and Sciences; the promoters of useful and ornamental Literature in the United States of America, whose communications have enriched this extensive and important work; and by whose generous encouragement this arduous enterprise has been brought to its completion;

The American Edition of the

ENCYCLOPÆDIA

is Dedicated,

with the most grateful respect,

by their much obliged servant,

THOMAS DOBSON.

PHILADELPHIA, 1798.
THE utility of science, and the delight which it affords to the human mind, are acknowledged by every man who is not immersed in the grōste ignorant. It is to the philosopher that the husbandman, the architect, the carpenter, and the seaman, &c. are indebted for the principles of those arts, by which they furnish us with most of the accommodations, and with all the elegances, of civilized life; whilst the pleasure experienced in the very progress of philosophical research is such, as both reason and revelation intimate, not obscurely, will constitute part of our happiness in a future state.

Small, however, would be the attainments of any man in science, were they confined within the limits of his own researches. Our knowledge of corporeal nature originates in those perceptions which we have by the organs of sense; and which, treasured up in the memory, we can, by the powers of reason and imagination, variously modify, arrange, and combine, so as from a number of particular truths to form to ourselves general principles. But these principles would be few indeed, had each individual no other materials of which to form them than the perceptions furnished immediately by his own senses. It has long been a matter of general regret, that the progress of science has been slow and laborious; but it never could have commenced, or could have only commenced, were every man obliged to begin his career from his own sensations, without availing himself of the discoveries of others who have travelled over the same ground before him.

To this narrow field, however, philosophical investigation is not confined. By means of the arts of writing and drawing, the discoveries of one individual may be made accessible to another, and the science of every age and of every country treasured up for the use of ages and countries the most remote. Hence arises the utility of what is generally called literature, or the knowledge of the languages, customs, and manners, which have prevailed among the various nations of the earth. Without this knowledge the science of the ancients would be locked up from the moderns; and even the discoveries of modern nations would be inaccessible to each other.

With all the aid which can be furnished by one age or nation to another, the labours of the philosopher still present themselves as immense and difficult. His object comprehends universal nature, of which nothing can be known but by sensation and reflection; but the objects of sense are all individuals, almost infinite in number, and for ever changing: so that instead of a system of science, the first view of the corporeal world would lead us to imagine, that from our most diligent researches nothing could be obtained but a vast collection of particular truths. Such a collection, whilst it would burden the memory, could be of little advantage to the arts of life; for we are very seldom brought, on different occasions, into circumstances so perfectly similar, as to require, without the smallest variation, the same conduct.
But though all the objects of sense, of memory, and of consciousness, are unquestionably individuals distinct from each other, the contemplative mind of man observes among them various resemblances and analogies. It observes, that the sensation communicated to the sight by snow is similar to that communicated by milk, paper, chalk, and a thousand other objects; that all external objects are solid, extended, divisible, and of some figure; that the path described by a planet round the sun resembles that described by a cannon ball over the surface of the earth; and that many of the actions of brutes are similar to those which we are impelled to perform by the internal feelings of desire and aversion.

This view of nature, quiescent and active, suggested to the philosopher the expediency of studying the vast multitude of objects which compose the universe; not individually, but in groups classified together according to their perceived resemblances or analogies. He saw that his labour would thus be at once shortened and rendered infinitely more useful; but he likewise saw, or ought to have seen, that it would by no means be taken wholly away. Much cautious attention is requisite to class objects in human systems as they are in fact classified in the system of nature. Analogies are apt to be mistaken for resemblances; a resemblance in a few particulars for a resemblance in all; and events, which have in reality very little in common, to be attributed to the same or similar causes. These mistakes can be avoided only by a painful induction of facts, by means of experiments accurately made on individual objects; and it was but very lately that induction was employed as the instrument of scientific research.

In ancient Greece, where philosophy first assumed a systematic form, all the objects of human thought were ranged under ten categories of predicaments; and every thing which could be affirmed or denied of these categories was supposed to be comprehended under five classes called predicables. Among the Greek philosophers, therefore, the use of induction was to ascertain the category to which any particular object belonged; after which, nothing more was to be done but, by a short process of syllogistic reasoning, to affirm or deny of that object whatever could be affirmed or denied of its category.

To this ancient arrangement of human knowledge many insuperable objections have been urged. But it must be confessed, that the arrangements which have been proposed in its stead, by the sages of modern times, have little claim to greater perfection. Locke classified all things under three categories; substances, modes, and ideas. Hume reduced the number to two; impressions and ideas. The former of these philosophers admitted of only four predicables, all different from those of the ancients; the latter at first extended the number to seven, but afterwards reduced it to three; among which none of the ancient predicables are to be found, and only one of those which had been admitted by Locke.

These different classifications of knowledge are the natural consequences of men's attempting what the greatest powers of the human intellect will never be able to accomplish. It certainly was the aim of Aristotle, or whoever was the inventor of the categories and the predicables, to delineate the whole region of human knowledge, actual and possible; to point out the limits of every district; and to assign to every thing which can be the object of human thought its proper place in the vast arrangement. Such an attempt evinces the ambition of its author: nor has the ambition been much less of some of those by whom the rash arrogance of the Stagyrite has been most severely cenured. Locke says expressly, that as the objects of our knowledge are confined to substances, modes, and ideas, so we can discover nothing of these, but 1st, their identity or diversity; 2nd, their relation; 3rd, their co-existence or necessary connection; and 4th, their real existence: while Hume declares, with some hesitation indeed, that we can know nothing but the resemblance, contiguity in time or place, and causation of our impressions and ideas.

These
These attempts, as well modern as ancient, to contrast the whole furniture of the human mind into the compass of a nut-shell, and to give at once a compleat chart of knowledge, have been cenured, not only as presumptuous, but as the fertile sources of error, by a philosopher whose writings do honour to this age and nation. "To make a perfect division (says Dr Reid), a man must have a perfect comprehension of the whole subject at one view. When our knowledge of the subject is imperfect, any division we can make must be like the first sketch of a painter, to be extended, contracted, or mended, as the subject shall be found to require. Yet nothing is more common, not only among the ancient but even among modern philosophers, than to draw from their work the whole ware, because there is no place in his ware room that fits it. We are apt to yield to make a division we can make, as the subject fits; for there is no place in his ware room that fits it. We are apt to yield to make a division, though it be not at all convenient order. The philosopher maintains, that such or such a thing is not, or should not be, in convenient order. The philosopher maintains, that such or such a thing is not, or should not be, in convenient order. The philosopher maintains, that such or such a thing is not, or should not be, in convenient order.

The truth of these observations will be controverted by no man who is not an absolute stranger to the various systems, ancient and modern, of what has been called the first philosophy.

But if every scientific arrangement of knowledge which has hitherto been proposed be so very imperfect,—what judgment are we to form of that which is adopted by the compilers of Dictionaries or Encyclopædias, in which the arts and sciences are arranged according to the order of the alphabet, and A, B, C, &c. considered as the categories? The author whom we have just quoted affirms, that of all methods of arrangement this is the most antiphilosophical; and if he allude only to such Encyclopædias as are mere dictionaries, in which the several arts and sciences are broken into fragments, scattered through the work according as the alphabet has happened to dispose of the various technical terms which have place in each, his assertion is unquestionably true. Its truth is indeed admitted by Chambers himself, the compiler of one of the first and most valuable of these dictionaries, who speaks of the works of his predeceffors as containing nothing but a multitude of materials, or a confused heap of incoherent parts. "Former lexicographers (says he) scarce attempted any thing like structure in their works; they seem not to have been aware that a dictionary is in some measure capable of the advantages of a continued discourse: and hence it is, that we see nothing like a whole in what they have done."

Proposing to remedy this defect in his own Dictionary of Arts and Sciences, he informs us, that "his view was to consider the several matters, not only in themselves, but relatively, or as they respect each other; both to treat them as so many wholes, and as so many parts of some greater whole; and to point out their connection with each other, and with that whole, by reference: so that by a course of references from generals to particulars, from premises to conclusions, from cause to effect, and vice versa, a communication might be opened between the several parts of the work, and the detached articles be in some measure replaced in the natural order of science, out of which the alphabetical order had removed them." To enable the reader with the greater ease to replace in the order of science the various articles scattered through the dictionary, he furnished him in the preface with what must be considered as an elegant analysis of human knowledge; by which may be seen, at one view, the mutual dependence of the several parts upon each other, and the intimate connection of the whole.

But though the sound judgment of Mr. Chambers thus directed him to make the arrangement of his Cyclopædia vastly preferable to that of any work of the same kind which had been published before it; we are afraid that, in its original form, it was still liable to the objections of Dr Reid. Had all the articles in the work been treated in sufficient detail to constitute, when reunited in the order of science, so many complete systems: yet the multitude of references was so great, that this reunion could not have been made but by a degree of irksome labour, to which few readers will ever submit.
mit (A). The work therefore, with all its improvements, was still a book of shreds and patches, rather than a scientific dictionary of arts and sciences; and considering the letters of the alphabet as the categories, the arrangement was certainly inconvenient as well as antiphilosophical.

Of this inconvenience, inseparable from a mere *dictionary* of arts and sciences, the original Compilers of the Encyclopædia Britannica were fully aware; and they resolved to construct their own Work upon a plan from which it might be completely removed. They were equally apprised with their predecessors of the utility of explaining by itself every technical term, and of illustrating every particular topic, in the wide circle of the arts and sciences; but they were at the same time sensible, that it is only by thinking in method, and reducing their ideas to the order of nature, that mankind can make

---

(A) To be convinced of the truth of this assertion, one needs but to cast his eye over the author’s table of arrangement. It is as follows.

**Knowledge is either**

- **Natural and Scientific**, which is either —
  - Sensible; consisting in the perception of phenomena or external objects—called **Physiology or Natural History**; and which, according to the different kinds of such objects, divides into—
    - **Metaphysics**, which subdivides into **Ontology**, **Hydrology**, **Mineralogy**.
    - **Phytopology**.
    - **Zoology**.
    - **Analytic**.
    - **Natural Philosopby**
  - Abstracts—called **Metaphysics**, which subdivides into **Ontology**, **Analytic**, **Pneumatology**.
    - **Algebra**.
    - **Trigonometry**.
    - **Statics**.
    - **Conics**.
    - **Spheres**.
  - Quantities—called **Pure Mathematics**—which divides, according to the subject of the quantity, into —
    - **Geometry**—which
    - **Statics**
    - **Optics**, **Cataoptics**, **Dioptrics**, **Perspective**.
    - **Painting**.
    - **Music**.
    - **Hydrostatics**, **Hydraulics**.
    - **Pneumatics**.
    - **Alchemy**—whence **Natural Magic, &c.**
    - **Optics**, **Cataoptics**, **Dioptrics**.
    - **Perspective**—whence **Painting**.
  - Relations to our happiness—called **Religion**, the doctrine of —**Religion**, whence **Law**.
    - **Theology**, or **Religion**
    - **Politics**.
    - **Law**.
    - **Ethics**.
    - **Natural Philosopby**
  - Latent powers and properties of bodies—called **Chemistry**—whence **Alchemy**.
    - **Natural Magic, &c.**
    - **Optics**, **Cataoptics**, **Dioptrics**.
    - **Perspective**—whence **Painting**.
    - **Architecture**.
    - **Sculpture**.
    - **Trades and Manufactures**.
    - **The Military Art**.
    - **Fortification**.
    - **Chronology**.
    - **Dialling**.
    - **Navigation**.
    - **The Commerce**.
    - **Medicine**.
    - **Pharmacy**.
    - **Agriculture**.
    - **Gardening**.
    - **Furtraying**.
    - **Hunting**.
    - **Falconry**.
    - **Fishing**.
    - **Writing**.
    - **Artificial and Technical**, consisting in the application of natural notices to farther purposes, which is either —
    - **Real**, employed in discovering and applying the —
      - **Alchemy**—whence **Natural Magic, &c.**
      - **Optics**, **Cataoptics**, **Dioptrics**.
      - **Perspective**—whence **Painting**.
      - **Architecture**.
      - **Sculpture**.
      - **Trades and Manufactures**.
      - **The Military Art**.
      - **Fortification**.
      - **Chronology**.
      - **Dialling**.
      - **Navigation**.
      - **The Commerce**.
      - **Medicine**.
      - **Pharmacy**.
      - **Agriculture**.
      - **Gardening**.
      - **Furtraying**.
      - **Hunting**.
      - **Falconry**.
      - **Fishing**.
      - **Writing**.
    - **Internal**; employed in discovering their agreement and disaffection; or their relations in respect of truth called **Logics**.
      - **Alchemy**—whence **Natural Magic, &c.**
      - **Optics**, **Cataoptics**, **Dioptrics**.
      - **Perspective**—whence **Painting**.
      - **Architecture**.
      - **Sculpture**.
      - **Trades and Manufactures**.
      - **The Military Art**.
      - **Fortification**.
      - **Chronology**.
      - **Dialling**.
      - **Navigation**.
      - **The Commerce**.
      - **Medicine**.
      - **Pharmacy**.
      - **Agriculture**.
      - **Gardening**.
      - **Furtraying**.
      - **Hunting**.
      - **Falconry**.
      - **Fishing**.
      - **Writing**.
    - **External**, which is either —
      - **Alchemy**—whence **Natural Magic, &c.**
      - **Optics**, **Cataoptics**, **Dioptrics**.
      - **Perspective**—whence **Painting**.
      - **Architecture**.
      - **Sculpture**.
      - **Trades and Manufactures**.
      - **The Military Art**.
      - **Fortification**.
      - **Chronology**.
      - **Dialling**.
      - **Navigation**.
      - **The Commerce**.
      - **Medicine**.
      - **Pharmacy**.
      - **Agriculture**.
      - **Gardening**.
      - **Furtraying**.
      - **Hunting**.
      - **Falconry**.
      - **Fishing**.
      - **Writing**.

Such
neither make any progress in useful knowledge. To accomplish therefore effectually what Mr Chambers by means of his prefatory scientifical analysis attempted in vain, they endeavoured to give a compendious, yet clear and satisfactory, account of the several arts and sciences under their proper denominations, whilst the subordinate articles in each were likewise explained under their technical terms. These subordinate articles they divided into three kinds; of which the first consists of such as, independent of particular systems, admit of a full and complete illustration under their proper names; the second, of such as require to be partly discussed under the systems to which they belong, and partly under their own denominations; and the third, of such as appertain to systems of which all the parts must be elucidated together. Articles of the first kind admit of no references; those of the second, being only partially explained under their proper denominations, demand references to the systems where the illustrations are completed; and those of the last are wholly referred to the systems of which they are constituents.

Such has been the arrangement of the Arts and Sciences in every edition of the Encyclopædia Britannica; and it surely falls not under that cenure which Dr Reid pronounced with justice on many other works bearing a similar title.

In the spirit of true philosophy, that great man observes, that the same subject may admit, and even require, various divisions, according to the different points of view from which it is contemplated; and we doubt not but, if he had been asked, he would candidly have acknowledged, that the divisions and arrangement of the Encyclopædia Britannica are calculated to answer every purpose which can be expected from a general repository of arts, sciences, and miscellaneous literature. They are such as must give to readers of every description the most easy access to the objects of their pursuit; for whilst the philosopher or systematic artist may be fully and regularly informed by turning to the general name of the science or art which he wishes to explore, the man who has occasion to consult only particular topics will find them illustrated under the terms by which they are denominated. Contemplated from this point of view, the arrangement of the Encyclopædia Britannica needs not shrink from a comparison even with that of the Encyclopædia Methodique; for though that voluminous work, consisting of a dictionary of dictionaries, may have the appearance of being more systematically arranged; yet we, who have had occasion to consult it frequently, have never found the object the more readily for having been obliged to travel in quest of it through different alphabets.

A dictionary, in which the several arts and sciences are digested into distinct treatises or systems, whilst the various detached parts of knowledge are explained in the order of the alphabet, seem indeed to have received the best form of which such a work is susceptible; and may certainly be made to answer one end, which more philosophical arrangements never can accomplish. Under the various letters of the alphabet, it is obvious that the whole circle of the sciences may be completely exhausted; and that every discovery, ancient or recent, may be referred to the particular system which it tends to.

Such is that great and general analysis of knowledge, which has by some of our correspondents been recommended to us in terms of the highest praise, and to which elegance and accuracy cannot perhaps be refused. Its utility, however, as prefixed to a dictionary of arts and sciences, is not very apparent. From each word, which in this table is printed in capitals, many branches are made to spring, which in the dictionary are all treated as separate articles. Thus from Meteorology we are referred, in a subordinate analysis, to Air and the Atmosphere; including, 1st, The history of its contents, æther, fire, vapour, exhalation, &c. 2d, Meteors formed therein; as cloud, rain, shower, drop, snow, hail, dew, damp, &c. Rainbow, Parhelion, Halo, Thunder, Waterspout, &c. Winds, Monsoon, Hurricane, and the like. As every word printed in capitals, as well as in this subordinate division as in the general table, is the title of an article treated separately in the Cyclopædia, we must turn backwards and forwards through more than 24 references before we come at the detached topics, which we are directed to unite into a system of Meteorology. The number of articles which must be united in the same manner to constitute the Compiler's system of Metaphysics is upwards of 48; and those which are referred to Theology above 300!
tends to confuse or to confirm, without having recourse to the awkward expedient of employing several alphabets, or the still more inconvenient arrangement by which the systems themselves are broken into fragments.

But on this topic it is needless to expatiate. The very favourable reception with which the two former editions of the Encyclopædia Britannica were honoured by the Public; the still greater encouragement which has been given to the present; and the adoption of the plan by the editors of other repositories of arts and sciences—bear ample testimony to the excellence of the arrangement. On this subject we express ourselves with the greater ease and the greater confidence, that we cannot be accused of flattering our own vanity, or publishing our own praifes; for the merit of forming the arrangement, as well as of introducing into the work various branches of knowledge, from which, as they are not generally to be found in dictionaries, it derives a just claim to the favour of the Public, belongs not to the Compilers of the present Edition.

After surveying any particular art or science, our curiosity is excited to acquire some knowledge of the private history of those eminent persons by whom it was invented, or has been cultivated and improved. To gratify this curiosity, those who formed the plan of the Encyclopædia Britannica resolved to enrich it with a department not to be found in any prior collection of the same kind except the French Encyclopédie.

Of all the various species of narrative-writing, it is acknowledged that none is more worthy of cultivation than Biography; since none can be more delightful or more useful, none can more certainly enchain the heart by irresistible interest, or more widely diffuse instruction to every variety of condition. Its tendency to illustrate particular passages in general history, and to diffuse new lights through such arts and sciences as were cultivated by the persons whose lives are related, are facts too obvious to require proof. It exhibits likewise the human character in every possible form and situation. It not only attends the hero through all the baffle of public life, but pursues him to his most sequestered retirements. It shows how distinguished characters have been involved in misfortunes and difficulties; by what means they were extricated; or with what degree of fortitude and dignity they discharged the various functions, or sustained the vicissitudes, sometimes prosperous and sometimes adverse, of a chequered and a fluctuating life. In such narratives men of all ranks must feel themselves interested; for the high and the low, as they have the same faculties and the same fentiments, have no less similarity in their pains and pleasures; and therefore in the page of honest biography, those whom fortune or nature has placed at the greatest distance, may mutually afford instruction to each other. For these reasons it is, that every man of learning and taste has esteemed the biographical labours of Plutarch among the most valuable and interesting remains of antiquity.

The lives and characters, therefore, of such persons as have excelled in the arts either of war or of peace, of such as have distinguished themselves either on the theatre of action or in the recesses of contemplation, will be found in the Encyclopædia Britannica alphabetically disposed under their proper names. Many indeed are omitted, for whom the reader will naturally look; some because, in the order of the alphabet, we had passed the initial letters of their names before we had intelligence of their deaths; others, through the inadvertency, whether excusable or not, of the Editors; several, for a reason which shall be afterwards assigned for omissions of a different kind, and perhaps of greater importance; and a very few from the contemptuous refusal of their friends to answer the Editor's letters respectfully requesting the necessary information (b).

But

(b) Of this treatment we have not indeed often had occasion to complain. While men of the first eminence in church and state have readily answered the letters that were addressed to them, and either communicated the in-
But while one part of our readers will regret that we have given no account of their favourite philosopher, hero, or statesman, others may be disposed to remark, that we have dragged from obscurity the names of many persons who were no proper objects of such public regard. To these we can only reply, that, with the greatest biographer of modern times, we have long thought that there has rarely passed a life of which a faithful narrative would not be useful; and that in the lives of the most obscure persons, of whom we have given any account, we saw something either connected with recent discoveries and public affairs, or which we thought capable of affording a lesson to great multitudes in similar circumstances.

Between eminent achievements and the scenes where they were performed, there is a natural and necessary connection. The character of the warrior is connected with the fields of his battles; that of the legislator, with the countries which he civilized; and that of the traveller and navigator, with the regions which they explored. Even when we read of the persons by whom, and the occasions on which, any particular branch of knowledge has been improved, we naturally wish to know something of the places where such improvements were made. This curiosity, so natural and so laudable, has been frequently felt by ourselves during the compilation of this Work; and to gratify it in others, we have subjoined to the name of every considerable place an account of its situation, its climate, its soil, its peculiarities, its inhabitants, with their manners, customs, and arts; its revolutions, laws, and government, with whatever else appeared necessary for the readers information, and at the same time admissible into a work of such variety and extent. It is indeed probable, that by many of our readers we shall be thought to have done too much rather than too little in this department; and to have filled our pages with accounts of towns and villages not of sufficient importance to demand general attention. But were it known how many of such places we have excluded from our Work, though recommended to us by some of our most obliging correspondents, those who reflect upon the different tastes of mankind, and consider that we wrote for the Public at large, would forgive us for having occasionally employed a few sentences in the description of others, which, whatever be their real importance, could not have been omitted without disappointing a very numerous class of readers.

The knowledge of history is so important, not only to the statesman and the legislator, to whom indeed it is absolutely necessary, but likewise to every man who moves in a sphere above that of the lowest vulgar, that a Work professing to be a general repository of arts, sciences, and literature, would be exceedingly defective, if it did not contain some information of the transactions of those who have been in possession of the world before us; of the various revolutions of states and empires; and of all the other means which have contributed to bring every thing into the state in which we behold it. Fully aware of this, the compilers of the Encyclopaedia Britannica, besides giving a general view of universal history and chronology, have enriched this edition with a short, though they hope luminous, detail of the progress of each particular nation, which from the remotest period to the present time has acted a conspicuous part on the theatre of the world. The reader therefore will here find a very comprehensive view of Civil History, ancient and modern, in all its branches. Nor have the histories of Nature and Religion been neglected. Of the former, it is not perhaps too much to say, that in all the subdivisions of its three great kingdoms, it will be found more fully, more accurately, and more scientifically, detailed in this Work than in any other dictionary which has yet been published. Of the latter, a brief view is given under the general article History; the unavoidable defects of which are in a great measure supplied

Information which was requested, or politely assigued reasons for withholding the lives of their friends not to be published in the Encyclopaedia Britannica, the Editor recollects but two men, who maintained a full silence; and these he cannot consider as moving in a sphere much higher than his own.
The accounts that will be found, under their proper denominations, of all the considerable sects and opinions which have prevailed in the religious world from the earliest periods to the present day.

Such was the plan of the second edition of the Encyclopædia Britannica; to which, as it seems hardly capable of improvement, the Compilers of the third have, with a few slight variations, strictly adhered. Still, however, there was ample room for the efforts of all their industry and all their learning; for the rapid progress of the physical sciences had rendered the labours of their predecessors in many departments useless. Besides the introduction of some thousands of new articles, there are not many of great importance, those in biography and geography alone excepted, which stand in this Edition as they stood in the last. Such recent discoveries as could be introduced, have been mentioned with reference to their proper authors; and, while the several sciences have been treated more fully and systematically, greater care has been employed to trace the history of each from its first invention, and to apply them all to the arts of life.

To accomplish a task so arduous and so important, neither labour nor expense has been spared. Literary journals; the memoirs and transactions of philosphic societies; and all the most valuable dictionaries of arts and sciences, both in our own and in other languages, have been constantly consulted. The works of the most eminent authors, as well ancient as modern, who have written on any particular art or science, have been collected and compared. Such of them as treat of topics, about which there is no room for controversy, and are at the same time susceptible of abridgment, have been abridged with the greatest care; whilst others, more concise and tenacious of their subjects, have been more closely pursued and more faithfully retained. Upon those branches of science on which the works of other authors furnished nothing fit for the purpose of the Editors, original essays and treatises are inserted, which were composed either by themselves, or by such of their friends as they knew to be intimately acquainted with the subject. On disputed points, whether in the physical or moral sciences, arguments and objections have been displayed in their full force; and of each of the various sects into which the Christian church is divided, the account is generally given by the most eminent clergyman of that sect to whom the Editors could find access.

After the utmost exertions, however, of our attention and industry, we are sensible, perhaps more sensibly than any of our readers, that the Work pales from our hands in a state far from perfection; and that the man who shall not discover in the Encyclopædia Britannica mistakes, needless repetitions, and even culpable omissions, will bring to the examination of it no great flock of general knowledge. But for these offences the Editors perhaps need no other apology than what will be furnished by the nature of the Work and the history of its publication.

In a collection so extensive and multifarious, a few mistakes, repetitions, and omissions, might surely be passed over without severity of censure, although the publication had from the beginning to the end been superintended by the same man; but they will be allowed to have been almost unavoidable, when it is known that, after the Work was far advanced, it was committed to the care of a new Editor, who, though he was in a great degree a stranger to the contents of the printed volumes, found no clue of his predecessor’s which could guide him accurately through those to be compiled.

We beg it to be understood, that this observation is not made with a view to remove any share of blame from the second to the first Editor; for Mr Colin Macfarquhar, who conducted the publication beyond the middle of the twelfth volume, was a man whom few who knew him will be disposed to blame, and on whose industrious integrity those who knew him best must admit that it would be difficult to bestow too much praise. Born in Edinburgh of parents respectable, though not affluent, he was, at an early period of life, bound an apprentice to a printer. This profession gave him a taste for science and literature, or rather furnished him with opportunities
tunities of cultivating the taste which he derived from nature: and he soon became well acquainted with the most popular writers in natural history and in natural and moral philosophy. When he opened a printing-house of his own, rectitude of conduct quickly recommended him to friends and to employment; and the unremitting prosecution of his studies eminently qualified him for superintending the publication of a new dictionary of arts, sciences, and literature; of which, under the title of Encyclopædia Britannica, the idea had been conceived by him and his friend Mr Andrew Bell engraver. By whom these gentlemen were assailed in digesting the plan which attracted to that Work so much of the public attention, or whether they had any assistance, are questions in which our readers cannot be interested. Suffice it to say, that Mr Macfarquhar had the sole care of compiling the present Edition; and that, with the aid of a very few literary friends, he brought it down to the article Mysteries, in the twelfth volume, when he was cut off in the 48th year of his age by a death which, though not sudden, was perhaps unexpected. His career was indeed short; but of him it may be said with as much propriety as of most men, Nemo parum diu vixit, qui virtutis perfecta perfecto funtus est munere.

Among his literary correspondents was the Reverend Dr Gleig of Stirling, who had written for him various articles, of which some were published during his lifetime and others in their order after his death. These shall be afterwards enumerated with those furnished by other occasional contributors; but they are mentioned at present, because they account for that partial regard of Mr Macfarquhar for their author, which, on the death of the former, induced the trustees for his children, together with Mr Bell the surviving partner, to request the latter to undertake the task which their deceased friend had hitherto discharged with so much credit to himself. In this proposal, after some hesitation on account of his distance from Edinburgh, Dr Gleig acquiesced; but when he entered on his new office, he found matters in a state of no little confusion. Mr Macfarquhar, though his death had not been long expected, had laboured long under a complication of diseases; the consequence of which was, that the materials which he had prepared for the press were almost exhausted; and of those which were first called for, some had not passed through his correcting hand.

This circumstance may perhaps account for some defects and inaccuracies in that part of the Work, to which the second Editor looks back with the least satisfaction: but that which must be his apology for several repetitions and omissions, was the neglect of his predecessor during his last illness to make an intelligible index to his own labours. From the want of such a necessary guide, Dr Gleig was perpetually liable, notwithstanding his utmost circumspection, to give under one title an explanation of subjects which had been before explained under another; and to omit articles altogether, from a persuasion that they had been discussed in some preceding volume under the general system to which they belong.

Neither his repetitions nor omissions, however, are so many as some have supposed them; for what has been hastily cen.cured as a repetition, is frequently nothing more than the necessary resumption of some important subject. Availing himself of the excellence of the plan upon which the Encyclopædia Britannica is constructed, he took the opportunity, when he found any system superficially treated, to supply its defects under some of the detached articles belonging to it. Of this he shall mention as one instance Hydrostatics; which, considered as a system, must be considered to be defective; but he trusts that its defects are in a great measure supplied under the separate articles Resistance of Fluids, River, Specific Gravity, and Water-Works.

That in the Encyclopædia Britannica no account is given of some things which should have a place in a general repository of arts, sciences, and miscellaneous literature, must be acknowledged; but it must likewise be acknowledged that such omissions are neither numerous nor very important; for many subjects, which have been supposed to be omitted, are treated under titles different from those under which they have
have been looked for. Thus the method of calculating compound interests, which one of our correspondents cannot find in our Work, is taught in the article Algebra; that of coating mirrors, of which another complains that no account is given, will be found under the term Foliating; and though it may be true, according to the peevish remark of a third, that the reader is nowhere directly instructed how to grind optical glasses, yet if he read the article Glass-Grinding, and understand the doctrine of lenses as laid down in the article Optics, he will easily, if an artist, discover a method of performing that operation for himself.

Omissions, however, there are towards the end of the Work; not the consequence of carelessness, but the offspring of necessity.

In an address to the Purchasers of the Encyclopaedia Britannica, subjoined to the ninth volume, the proprietors gave a rash promise to comprehend the whole of their undertaking within the limits of eighteen; and if intervening discoveries should make it necessary, to enlarge the last volumes in quantity without any additional charge to Subscribers.

That the promise was rash, a moment's reflection should have taught them; for in the present rapid progress of physical science, when new discoveries are daily made, it was obviously impossible, at so early a period, to ascertain with precision how many volumes would be necessary to bring a Work of such comprehensive variety to the utmost perfection of which it is capable. This was indeed soon discovered; but the proprietors shrunk not from their engagement, which they determined to fulfil to the utmost extent of its meaning, till the additional tax, which in 1795 was laid upon paper, involved them in difficulties which they had not foreseen. By the act of parliament they were indeed authorized to reimburse themselves by raising the subscription-price of their volumes; but they chose rather to submit to a diminution of profit, than to take even a legal advantage of that public by which they had hitherto been so generously supported.

To complete their plan, however, in its original extent, was now impossible, without a violation of the sacred duties which they owe to themselves and to their families. In this dilemma the Editor proposed that they should state the case to their Subscribers, of whom he is confident that nine-tenths would have released them from the obligation of their promise: but after long deliberation, they judged that it would be more acceptable to the public at large to comprehend the Work in the proposed number of volumes, though they should exclude from the last such articles as might be omitted without injury to science or the arts of life. If by any of their readers they shall be thought to have erred in this judgment, let them not, however, be too severely blamed; for they have done much to adhere to the spirit of their promise; and, in the large addition made to the bulk of the last volume, have shewn that they prefer their honour to their interest. Several things have indeed been excluded; but except such recent discoveries as could not be noticed under the last letters of the alphabet, it is believed that very little has been omitted which can be considered as of great or general importance. At any rate, the Editor flatters himself, that the last six volumes of the Encyclopaedia Britannica do not disgrace those by which they are preceded, and that the whole will bear to be compared with any other Work of the same kind extant. Imperfect it certainly is: "but if much has been omitted, let it be remembered that much has likewise been performed;" that perfection is not to be looked for in the works of man; and that every compilation of such variety and extent should be examined with the spirit which actuated one of the greatest critics of antiquity when perusing the works of his brother poets:

Verum ubi plura niteant in carmine, non ego paucis
Offendam maculis, quas aut incuria judit,
Aut humana parum cavit natura.—

Hor. De Art. Poet.
We mentioned our obligations to occasional contributors; and many of our correspondents have expressed an earnest desire to know who these contributors have been. As there can be no impropriety in gratifying such a desire, we shall conclude this Preface, by assigning the various articles, not compiled by the Editors themselves, to their respective authors: but as many of the writers for the first twelve volumes were known to Mr. Macfarquhar alone, they will not attribute the omission of their names to culpable design, but to irremediable ignorance.

For whatever instruction may be conveyed in the articles Anatomy and Surgery the Public is indebted to Andrew Bell, F. S. A. one of the proprietors, and the ingenious Mr. Fyfe. From the former of these gentlemen the world will soon receive one of the most splendid anatomical works which it has yet seen; and as the latter has long officiated under Dr. Monro as dissector in the anatomical school of the University of Edinburgh, it is needless for us to say how well he must be acquainted with the subjects on which we employed him to write. Aerology, Aerostation, Chemistry, Electricity, Gunnery, Hydrometrical, Mechanics, Meteorology, with most of the separate articles in the various branches of natural history, we have reason to believe were compiled by Mr. James Tytler chemist; a man who, though his conduct has been marked by almost perpetual imprudence, possesses no common share of science and genius. The article Blind was furnished by Dr. Blacklock and Dr. Moyes, both blind themselves, and both men of superior attainments; the former in elegant literature, and the latter in the physical sciences. We believe that the article Education was composed by Mr. Robert Heron, author of a history of Scotland now publishing, who likewise furnished the greater part of what we have published under the titles Religion and Society. The lives of Johnson and Mary Queen of Scots, with the articles Instinct, Love, Metaphysics, Miracle, the history Ethics under Moral Philosophy, Oath, Passion, Plastic Nature, Polytheism, Prayer, Slavery, and Supper of the Lord, were contributed by Dr. Gleig, Editor of the last six volumes; Grammar (c) and Theology by Dr. Gleig and the Reverend James Bruce, A. B. late of Emanuel College, Cambridge; and Motion by Dr. Gleig and Mr. Tytler. The system of Medicine, which was published in the former edition, was revised and improved for the present by Andrew Duncan, M. D. Fellow of the Royal Society of Edinburgh, and Professor of the Institutes of Physic in the University. The notes to the article Music were contributed by Dr. Blacklock, and the history of the art by William Maxwell Morison, Esq.; advocate, who likewise favoured us with what we have published on the science of Physiognomy. The articles Mysteries, Mythology, and Philology, we owe to the erudition of David Doig, L. L. D. F. S. A. Master of the Grammar-School of Stirling, and author of two very ingenious Letters on the Savage State, addressed to the late Lord Kames. Navigation, Parallax, Pendulum, Projection of the Sphere, Ship-Building, and Naval Tactics, were furnished by Andrew Mackay, L. L. D. F. R. S. E. of Aberdeen, and known to the Public as author of a treatise on the Theory and Practice of finding the Longitude.

(c) Mr. Bruce, who communicated the most valuable parts of the article Grammar, and who was for many years a student in the University of St. Andrews, will, from gratitude to his old master, to declare, in this public manner, that, to the instructions of Dr. Hunter, professor of Humanity in that University, he is indebted for much of what philological knowledge he may possess. We believe indeed that Dr. Hunter may claim as his own the theory which we have given of the cases of nouns, the doctrine concerning the inverse acceptation of the adjective, and the resolution of the relative pronoun by means of the preposition of instead of the conjunction and. There is nothing else in our article which the attentive reader may not find in the grammatical writings of Vossius, Scaliger, Sanesius, Perizonius, Wallis, Rudddman, Harris, Horne-Tooke, and Dr. Gregory of Edinburgh. Discoveries in grammar are not indeed to be looked for. They are nearly allied to those in metaphysics; of which, it has been well observed by one of the acutest writers of the age, that the very appearance should be rejected as an error, if not as an imposition, upon mankind.
Longitude at Sea or Land. John Robison, M. A. secretary to the Royal Society of Edinburgh, and professor of natural philosophy in the University, did the Editor the honour of contributing to the Encyclopædia Britannica the valuable articles Physics, Pneumatics, Precession of the Equinoxes, Projectiles, Pumps, Resistance of Fluids, River, Roof, Rope-Making, Rotation, Seamanship, Signals, Sound, Specific Gravity, Statics, Steam and Steam Engine, Strength of Materials, Telescope, Tide, Articulating Trumpet, Variation of the Compass, and Water-Works. Philosophy is the joint production of Professor Robison and Dr Gleig. Physiology was furnished by John Barclay, M. D. of Edinburgh, whose merits, if the Editor be not partial to his friend, it will raise high in the estimation of men of science. The essays on Predestination and Providence were contributed by Robert Forsyth, Esq. advocate; the account of the French Revolution by Mr. Forsyth and Dr Gleig; and Oxygen and Phlogiston by John Rotheram, M. D. professor of natural philosophy in the University of St Andrew's.

The other contributors to the first part of the Work we cannot enumerate; but we know that much useful information was occasionally communicated by Dr Latham of Dartford in Kent, the celebrated ornithologist; by Dr William Wright Physician-general to the forces in the West Indies under the command of Sir Ralph Abercrombie; by the Reverend J. Hawkins, vicar of Halstead in Essex; by the late Mr Adams, mathematical instrument-maker to his Majesty; and by Mr William Jones, optician in Holborn, London. There is, however, no man to whom the Proprietors of the Encyclopædia Britannica feel themselves under greater obligations than to Dr Black, for the very handsome offer which he made to the person who was at first entrusted with the chemical department of the Work. And while they express thus publicly their gratitude to him, may not the Editor declare how much he is indebted to his two assistants, the Reverend James Walker, M. A. of St John's College, Cambridge, and Mr James Thomson of Crieff, preacher in the church of Scotland? Of these gentlemen, who successively had the care of the Work when he was necessarily absent, he could always say, Lyibus in rebus ipsi interesse non possimus, in his, opera nobis vicaria fides amicorum supponitur.

TO the above preface of the European Editors the publisher of the American Edition begs leave to add, that neither care nor expense have been spared to render the work worthy of the Public attention. Some articles have been written anew, several of original matter have been inferted, and many have been revifed and important improvements made in them, indeed, through every volume useful though minute improvements have been introduced which contributed to the excellence of the work. The engravings, the paper, and the general execution of the work must speak for themselves, on this score the publisher thinks he has not much cenfure to fear; for typographical inaccuracies, which are comparatively few, he has no apology to offer, but flatters himself that in a work of such variety and extent the candid reader will view them with indulgence.

From the nature of the work many things must be expected to be imperfect, and some through inadvertence omitted, thefe, with a variety of original materials are proposed to be taken up in a supplementary volume.

ENCYCLOPAEDIA.
A. THE first letter of the alphabet, in all the known languages of the world, that of Ethiopia excepted, in which it is the 13th. It has deferredly the first place in the alphabet on account of its simplicity, very little more being necessary to its pronunciation than opening the mouth.

In the English language A is the mark of three different sounds, termed, by our grammarians the broad, the open, and the flender A. The flinding sound of the German A, is found in several monosyllables, as wall, talk, &c. and is pronounced as au in cause. It is probable that the Saxons expressed only this broad sound of the letter, as it is still commonly retained in the northern districts of England, and universally throughout Scotland; as talk for talk, wake for walk or wake. The open A resembles that of the Italians in adagio, and is the same with that of a in father, rather, &c. The flender sound is peculiar to the English language, and resemles the sound of the French diphthong ai in paix, or their a masculine, or perhaps it is a middle sound between them: it is exemplified in place, waste, &c. also in mitigation, justification, and all other words ending with aion.

A is sometimes added after words in burlesque poetry; in which case it only makes an additional syllable without any alteration of the sense, as the interjection O very often does in our ballads. It is also sometimes redundant, as in the words arise, awake, &c. which are not different in significiation from rise, wake, &c.

It is sometimes a word, either noun or interjection; in which case it is commonly an expression of grief, and joined with the aspirate, as ab! When a noun, it is only with respect to itself; as great A, little a, &c.

A is very frequently used as an article; in which case it has no plural significiation, and is used to denote the number one, as a house, a field, &c. When placed as an article before any of the vowels, y and w only excepted, it is joined with the letter u; as, an island, an orator, &c. In the three following cases it is a preposition.

1. When it goes before a participle, or noun derived from a participle; as, I am a doing this or that. 2. When used before local surnames, as Cornelian a Lapide, Thomas a Kemps, &c. 3. When it is used in composition; as, a foot, a steep, &c. In some infinances it denotes the proportion of one thing to another; as so much a week, a man, a head, &c.

A, among the ancients, was a numeral letter, and signified 500; and when a dash was added on the top, A, 5000.

A, in the Julian calendar, is the first of the seven dominical letters. It had been in use among the Romans long before the establishment of Christianity, as the first of the eight mundanes litterae; in imitation whereof it wasthat the dominical letters were first introduced.

A is also an abbreviation used with different intentions. Hence, A, among logicians, is used to denote an universal affirmative proposition; according to the verfe, Affertit A, negat E, verbum generaliter ambe. Thus, in the first figure, a syllogism consisting of three universal affirmative propositions, is said to be in Bár-bā-rā; the A thrice repeated, denoting so many of the propositions to be universal, &c. See BÁRBARA.

A, among the Romans, was used in the giving of votes or suffrages. When a new law was proposed, each voter had two wooden ballots put in his hand; the one marked with a capital A, signifying antiquo, q. d. antiquum volo; and the other with V. R. for ut regas. Such as were against the law, cast the first into the urn; as who should say, I refuse it, I antiquate it; or, I like the ancient law, and despise no innovation. A, in the trials of criminal causes, also denoted absolution; whence Cicero, pro Milone, calls A, littera falutari, a saving letter. Three ballots were distributed to each judge, marked with the letters, A for absolvere, I acquir; C for condemnare, I condemn; and N. L. for non iugis. It is not clear. From the number of each cast into the urn, the prætor pronounced the prisoner's fate. If they were equal in number, he was abvolved.

A, in the ancient inscriptions of marbles, &c. occasionally stands for Augustus, ager, aevum, &c. When double it denotes Augusti; when triple, urum, artem, as; and sometimes its meaning can only be known by the rest of the inscription. Isidore adds, that when it occurs after the word miles (soldier), it denotes him young. On the reverse of ancient medals, it denotes them struck by the city of Argos, sometimes by that of Athens; but on coins of modern date, it is the mark of Paris.

A, as an abbreviation, is also often found in modern writers: as, A. D. for anno Domini: A. M. artium magister, master of arts, &c.

A, the letter a, with a line above it, thus, a, is used in
Aaron, the name of several rivers in Germany and Switzerland.

AACH, a little town in Germany, in the circle of Suabia, near the source of the river Aach, and almost equally distant from the Danube and the lake Constance. It belongs to the house of Austria. E. Long. 9. 6. Lat. 47. 55.

AAHUS, a little town in Germany, in the circle of Westphalia, and bishopric of Munster. It is the capital of Ahus, a small district; has a good cattle; and lies north-east of Coesfeldt. E. Long. 7. 1. Lat. 52. 10.

AAM, or HAAM, a liquid measure in common use among the Dutch, and containing 128 measures called mingles, each weighing nearly 16 ounces avoidapoise; whence the Aam contains 218 English, and 148 French Paris measure.

AAR, the name of two rivers, one in Switzerland, and another in Westphalia in Germany. It is also the name of a small island in the Baltic.

AARASUS (anc. geogr.), a town of Pilidia, in the Hither Asia, thought to be the Analias of Ionia.

AARON, high-priest of the Jews, and brother to Moses, was by the father's side great grandson, and by the mother's grandson, of Levi. By God's command he met Moses at the foot of mount Horeb, and they went together into Egypt to deliver the children of Israel; he had a great share in all that Moses did for their deliverance; the scriptures call him the prophet of Moses, and he acted in that capacity after the Israelites had crossed over the Red Sea. He attended mount Sinai with two of his sons, Nadab and Abihu, and seventy elders of the people; but neither he nor they went higher than half way, from whence they saw the glory of God: only Moses and Joshua went to the top, where they slaid forty days. During their absence, Aaron, overcome by the people's eager entreaties, set up the golden calf, which the Israelites worshipped by his consent. This calf has given rise to various conjectures. Some rabbis maintain that he did not make the golden calf; but only threw the gold into the fire, to get rid of the importunities of the people; and that certain magicians, who mingled with the Israelites at their departure from Egypt, cast this gold into the figure of a calf. According to some authors, the fear of a falling a sacrifice to the recompence of the people by giving a refusal, made Aaron comply with their desire; and they all did the like, that he hoped to elude their request, by demanding of the women to contribute their ear-rings, imagining they would rather choose to remain without a visible deity, than be deprived of their personal ornaments. This affair of the golden calf happened in the third month after the Israelites came out of Egypt. In the first month of the following year, Aaron was appointed by God high-priest; which office he executed during the time that the children of Israel continued in the wilderness. He died in the fortieth year after their departure from Egypt, upon mount Hor, being then 123 years old; A.M. 3522, of the Julian period 3262, before the Christian era 1452. With regard to the attempts of the Egyptian magicians to imitate the miracles performed by his rod, see some remarks under the article MAGICIAN.

AARON and JULIUS (Saints) suffered martyrdom together, during the persecution under the emperor Diocletian, in the year 303, about the same time with St. Alban, the protomartyr of Britain. We are no where told what their British names were, it being usual with the Christian Britons, at the time of baptism, to take new names from the Greek, Latin, or Hebrew. Nor have we any certainty as to the particulars of their death; only that they suffered the most cruel tortures. They had each a church erected to his memory; and their festival is placed, in the Roman martyrology, on the first of July.

AARON, or Harun, Al Rafehid, a celebrated khalif, or Mahometan sovereign of the Saracen empire; whose history is given under the article of BAGDAD.

AARON Harfledon, a learned rabbi and CARAITE in the 15th century, wrote an Hebrew grammar, printed at Constantinople in 1581; probably the same with Aaron the caraite, who wrote a commentary on the five books of Moses, which is in MS. in the French king's library.

AARSENS (FRANCIS), Lord of Somedlyck and Spyck, was one of the greatest ministers for negociation the United Provinces could ever boast of. His father, Cornelius Aarfsens, was Regifter to the States; and being acquainted with Mr Pleiffs Mornay, at the Court of William Prince of Orange, he prevailed upon him to take his son under him, with whom he continued some years. John Olden Barnewelt, who presided over the affairs of Holland and all the United Provinces, sent him afterwards agent into France, where he learned to negociate under those profound politicians Henry IV, Villeroi, Sillery, Bossu, Jaonin, &c. and he acquitted himself in such a manner as to obtain their approbation. Soon after, he was invested with the character of ambassador, being the first who was recognized as such by the French court; at which time Henry IV, declared, that he should take precedence next to the Venetian minister. He resided in France 15 years; during which time he received great marks of esteem from the king, who created him a knight and baron; and for this reason he was received amongst the nobles of the province of Holland. However, he became at length so odious to the French court, that they desired to have him recalled. He was afterwards deputed to Venice, and to several German and Italian princes, upon occasion of the troubles in Bohemia. He was the first of three extraordinary ambassadors sent into England in 1620, and the second in 1641; in which latter embassy he was accompanied by the Lord of Brerode as first ambassador, and Heemvuyt as third, to treat about the marriage of Prince William, son to the Prince of Orange. He was likewise ambassador-extraordinary to the French court in 1624, and the Cardinal de Richelieu having jut
ABA [ 3 ]

ABA. (or Abad) Hanifah or Hanfah, surnamed Al-Nooma, was the son of Thaber, and born at Coufah in the 80th year of the Hegira. This is the most celebrated doctor of the orthodox Mussulmans, and his sect holds the principal cectism among the four which they indifferently follow. Notwithstanding this, he was not very well esteemed during his life, inasmuch that the khalif Almanfar caused him to be imprisoned at Bagdad, for having refused to subcribe to the opinion of abolute predestination, which the Mussulmans call Cadha. But afterwards Abou Jofeph, who was the sovereign judge or chancellor of the empire under the khalif Hadi, brought his doctrine into such credit, that it became a prevailing opinion, That to be a good Mussulman was to be a Hanifite. He died in the 150th year of the Hegira, in the prison of Bagdad aforesaid: and it was not till 335 years after his death, that Melick Schah, a sultan of the Seljoucidan race, built for him a magnificent monument in the same city, whereunto he joined a college peculiarly appropriated to such as made a profession of this sect. This was in the 485th year of the Hegira, and Anno Christi 1093. The most eminent succedors of this doctor were Ahmed Benali, Ali Giadas, and Al Razi who was the master of Naftari; and there is a mosque particularly appropriated to them in the temple of Mecca.

ABA, Abas, Abos, or Abis, (anc. geog.), the name of a mountain of Greater Armenia, situated between the mountains Niphatos and Nibonis. According to Strabo, the Ephruses and Araxes rose from this mountain; the former running eastward, and the latter westward.

ABA. See ABA.

ABACENA (anc. geog.), a town of Media, and another of Caria in the higher Asia.

ABACENUM (anc. geog.), a town of Sicily, whose ruins are supposed to be those lying near Trippi, a citadel on an high and steep mountain not far from Messina. The inhabitants were called Abaceniini.

ABACATUAIA, in ichthology, a barbarous name of the zee womer. See ZEUS.

ABACH, a market town of Germany, in Lower Bavaria, seated on the Danube. It is remarkable for Roman antiquities, and for springs of mineral waters, which are said to be good for various diletments. E. Long. 11. 36. N. Lat. 48. 53.

ABACINARE, or ABACINARE, in writers of the middle age, a species of punishment, confining in the binding of the criminal, by holding a hot basin or bowl of metal before his eyes.

ABACK (a sea-term), the situation of the falls when their surfaces are slacked against the masts by the force of the wind. The falls are said to be taken aback when they are brought into this situation, either by a sudden change of the wind, or by an alteration in the ship's course. They are laid aback, to effect an immediate retreat, without turning to the right or left; or, in the sea phrase, to give the ship stern-way, in order to avoid some danger discovered before her in a narrow channel, or when she has advanced beyond her station in the line of battle, or otherwise. The falls are placed in this position by slackening the lee-bridges, and hanging in the weather ones; so that the whole effort of the wind is exerted on the forepart of the surface, which readily pulses the ship after, unless she is restrained by some counteracting force. It is also usual to spread some fall aback near the stern, as the mizzen top-sail, when a ship rides with a single anchor in a road, in order to prevent her from approaching it so as to entangle the flukes of it with her slackened cable, and thereby loosen it from the ground.

A 2

ABACOT,
ABACOT, the name of an ancient cap of state worn by the kings of England, the upper part whereof was of the form of a double crown.

ABACTORS, or ABACTORES, a name given to those who drive away, or rather steal, cattle by herds, or great numbers at once; and are therefore very properly distinguished from furets, or thieves.

ABACUS, among the ancients, was a kind of cupboard or buffet. Livy, describing the luxury into which the Romans degenerated after the conquest of Asia, says, They had their abaci, beds, &c. plated over with gold.

ABACUS, among the ancient mathematicians, signified a table covered with dust, on which they drew their diagrams; the word in this sense being derived from the Phoenician abak, dust.

ABACUS, in architecture, signifies the superior part or member of the capital of a column, and serves as a kind of crowning to both. Vitruvius tells us the abacus was originally intended to represent a square tile laid over an urn, or rather over a basket. See Architecture, note 15. The form of the abacus is not the same in all orders; in the Tucan, Doric, and Ionic, it is generally square; but in the Corinthian and Composite, its four sides are arched inwards, and embellished in the middle with some ornament, as a rose or other flower. Scamozzi ues abacus for a concave moulding on the capital of the Tucan pedestal; and Palladio calls the plinth above the echinus, or boul- tin, in the Tucan and Doric orders, by the same name.

ABACUS is also the name of an ancient instrument for facilitating operations in arithmetic. It is variously contrived. That chiefly used in Europe is made by drawing any number of parallel lines at the distance of two diameters of one of the counters used in the calculation. A counter placed on the lowest line signifies 1; on the 2d, 10; on the 3d, 100; on the 4th, 1000, &c. In the intermediate spaces, the same counters are estimated at one half of the value of the line immediately superior, viz. between the 1st and 2d, 5; between the 2d and 3d, 50; &c. See the figure on Plate 1. where the same number, 1788 for example, is represented under both divisions by different dispositions of the counters.

ABACUS is also used by modern writers for a table of numbers readily cast up, to expedite the operations of arithmetic. In this sense we have Abaci, or multiples, of division.

Chiefly ABACUS. See SWANPAK.

ABACUS Pythagoricus, the common multiplication table, so called from its being invented by Pythagoras. Abacus Logiformus, is a rectangular triangle, whose sides, forming the right angle, contain the numbers from 1 to 60; and its area, the product of each two of the numbers perpendicularly opposite. This is also called a formula of factors, or in turn of the counters.

Abacuss or Palmula, in the ancient mufeum, denote the machinery, whereby the strings of Polyplectra, or instruments of many strings, were struck with a plectrum made of quills.

ABACUS Harmonicus, is used by Kircher for the structure and disposition of the keys of a musical instrument, whether to be touched with the hands or the feet.

ABACUS Major, in metallurgic operations, the name of a trough used in the mines, wherein the ore is washed.

ABADDON, is the name which St John in the Revelation gives to the king of the locusts, the angel of the bottomless pit. The inspired writer says, this word is Hebrew, and in Greek signifies Apollyon, i.e. a destroyer. That angel-king is thought to be Satan or the devil; but Mr le Clerc thinks, with Mr. Hammond, that by the locusts which came out of the abyss, may be understood the zealous and robbers, who miserably afflicted the land of Judea, and laid it in a manner waste before Jerusalem was taken by the Romans; and that Abaddon, the king of the locusts, may be John of Gischala, who having treacherously left that town a little before it was surrendered to Titus, came to Jerusalem, where he soon headed part of the zealots, who acknowledged him as their king, whilst the rest would not submit to him. This subdivision of the zealot party brought a thousand calamities on the Jews.

ABADIR, a title which the Carthaginians gave to gods of the first order. In the Roman mythology, it is the name of a flower, which Saturn swallowed, by the contrivance of his wife Ops, believing it to be his new-born son Jupiter: hence it ridiculously became the object of religious worship.

ABÆ, or ABA (anc. geog.) a town of Phocis in Greece, near Helicon; famous for an oracle of Palmute, or rather over a basket.

ABALABA, the ancient name of APALLABA, the ancient name of Apallaba, a town of Phocis in Greece, near Helicon; famous for an oracle of Palmute, or rather over a basket.

ABALAK, a town of Siberia, two miles from Tobolik. E. Long. 64. 10. N. Lat. 57. 1.

ABALIENATION, in law, the act of transferring one man's property to another.

ABALLABA, the ancient name of Apallaba, a town in Wemoreiland, remarkable only for its antiquity, having been a Roman station. W. Long. 4. N. Lat. 55. 38.

ABALUS, (anc. geog.), supposing by the ancients to be an island in the German ocean, called by Timaeus Bafilia, and by Xenophon Lampacenus Battia; now the peninsula of Scandinavia. Here, according to Pliny, some imagined that amber dropped from the trees.
ABANA, or AMANA (anc. geog.), a river of Phocinia, which, rising from Mount Hermon, washed the fourth and west sides of Damascus, and falls into the Phocinian sea to the north of Tripolis, called Chyforbeas by the Greeks.

ABANGA. See ADY.

ABANO, a town of the Padaneo, in the republic of Venice, famous among the ancients for its hot baths. ABAIITES, a people who came originally from Thrace, and settled in Phoccea, a country of Greece, where they built a town which they called Aha, after the name of Abas their leader; and, if we may credit some ancient authors, the Abantes went afterwards into the island Eubea, now called Negropont; others say the Abantes of Eubea came from Athens. The Abantes were a very warlike people, closing with their enemies, and fighting hand to hand.

ABANTIAS, or ABANTIS (anc. geog.), a name of the island Eubea in the Egean sea, extending along the coast of Greece, from the promontory Sannium of Attica to Thessaly, and separated from Boeotia by a narrow strait called Euripus. From its length the island was formerly called Usa; afterwards Abantias, or Abantis, from the Abantes, a people originally of Thrace, called by Homer omothes Eubeans, from wearing their hair long behind, having in a battle experienced the inconvenience of wearing long hair before. From cutting their hair before, they were called Curetes.

ABAPTISTON, in surgery, the perforating part of the instrument called a trepan.

ABARA, a town in the Greater Armenia, under the dominion of the Turks; it is often the residence of the archbishop of Nakivan. E. Long. 46. 25. N. Lat. 39. 45.

ABARANE, a town of Asia, in Grand Armenia, belonging to the Turks: it is seated on the river Alinanga. E. Long. 46. 30. N. Lat. 39. 50.

ABARCA, an ancient kind of shoe used in Spain for passing the mountains with. It was made of raw hides, and bound with cords, which secured the feet of travellers against the snow.

ABARIM, high mountains of steep ascent, separating the country of the Ammonites and Moabites from the land of Canaan, where Moses died. According to Josephus, they stood opposite to the territory of Jericho, and were the last station but one of the Israelites coming from Egypt. Nebah and Pilgah were parts of these mountains.

ABARIS, the Hyperborean; a celebrated sage of antiquity, whose history and travels have been the subject of much learned discussion. Such a number of fabulous stories were told of him, that Herodotus himself seems to have been at a loss to relate them. He tells us only, that this Barbarian was said to have travelled with an arrow, and to have taken no food; but this does not acquit us with the marvellous properties which were attributed to that arrow; nor that it had been given him by the Hyperborean Apollo. With regard to the occasion of his leaving his native country, Heparion tells us, that the whole earth being infested with a deadly plague, Apollo, upon being consulted, gave no other answer, than that the Athenians should offer up prayers in behalf of all other nations: upon which several countries deputed ambassadors to Athens, among whom was Abaris the Hyperborean. In this journey he renewed the alliance between his countrymen and the inhabitants of the island of Debris. It appears that he also went to Lacedaemon; since, according to some writers, he there built a temple, consecrated to Proserpine the Sibyl. It is asserted, that he was capable of foretelling earthquakes, driving away plagues, laying forests, &c. He wrote several books, Porphyry as Suidas informs us, viz. Apollo's arrival into the in Pileus-country of the Hyperboreans; The megalops of the river Hebrus; Sainia, or the Generation of the Gods; Ahyger. Under the word collection of oracles; &c. Herminus the sophist applied him for speaking pure Greek; which attainment will be no matter of wonder to such as consider the ancient intercourse there was between the Greeks and Hyperboreans. If the Hebrides, or Western Island of Scotland (says Mr Tolland), were the Hyperboreans of Diodorus, then the celebrated Abaris was of that country; and likewise a Druid, belonging to the Turks: for we may credit the distinction of the infular Hyperboreans, makes him a Scythian; as do some others, milled by the fame vulgar error; though Diodorus has truly fixed his country lib. iii. in an island, and not on the continent. Indeed, the fictions and mistakes concerning our Abaris are infinite: however, it is by all agreed that he travelled quite over Greece, and from thence into Italy, where he converted familiarly with Pythagoras, who favoured him beyond all his disciples, by instructing him in his doctrines (especially his thoughts of nature), in a planter and more compendious method than he did any other. This distinction could not but be very advantageous to Abaris. The Hyperborean, in return, presented the Samian, as though he equalled Apollo himself in wisdom, with the sacred arrow, on which the Greeks have fabulously related, that he fat astride, and flew himself upon, through the air, over rivers and lakes, forests and mountains, in like manner as the vulgar till belief, particularly those of the Hebrides, that wizards and witches fly whithersoever they please on their broomsticks. The orator Hemius abovementioned, though one of those who, from the equivocal sense of the word Hyperborean, seems to have mistaken Abaris for a Scythian, yet describes his person accurately, and gives him a very noble character. "They relate (says he) that Abaris the sage was by nation a Hyperborean, "appeared a Grecian in speech, and resembled a Scythan, after he was accustomed to fortune, and having every thingYiiopyli, and Hyperboreans of Diodorus, then the celebrated Abaris was of that country; and likewise a Druid, belonging to the Turks: for we may credit the distinction of the infular Hyperboreans, makes him a Scythian; as do some others, milled by the fame vulgar error; though Diodorus has truly fixed his country lib. iii. in an island, and not on the continent. Indeed, the fictions and mistakes concerning our Abaris are infinite: however, it is by all agreed that he travelled quite over Greece, and from thence into Italy, where he converted familiarly with Pythagoras, who favoured him beyond all his disciples, by instructing him in his doctrines (especially his thoughts of nature), in a planter and more compendious method than he did any other. This distinction could not but be very advantageous to Abaris. The Hyperborean, in return, presented the Samian, as though he equalled Apollo himself in wisdom, with the sacred arrow, on which the Greeks have fabulously related, that he sat astride, and flew himself upon, through the air, over rivers and lakes, forests and mountains; in like manner as the vulgar till believe, particularly those of the Hebrides, that wizards and witches fly whithersoever they please on their broomsticks. The orator Hemius abovementioned, though one of those who, from the equivocal sense of the word Hyperborean, seems to have mistaken Abaris for a Scythian, yet describes his person accurately, and gives him a very noble character. nations, about affairs no less arduous than important. As if we further attentively consider his moderation in eating, drinking, and the use of all those things which our natural appetites incessantly crave; joining the candour and simplicity of his manners with the fidelity and wisdom of his answers, all which we find sufficiently attested: it must be owned, that the world at that time had few to compare with Abaris.

ABARTICULATION, in anatomy, a species of articulation admitting of a manifest motion; called also Diarthrotic, and Dearticulation, to distinguish it from that fort of articulation which admits of a very obscure motion, and is called Synarthrosis.

ABAS, a weight used in Peria for weighing pearls. It is one-eighth less than the European carat.

Abas, in the heathen mythology, was the son of Hypothon and Meganira, who entertained Ceres, and to her presented a cup, on which he became a newt or Hypothoon and Meganira, who entertained Ceres, and Diarthrotis, and Dearticulation, to distinguish it from that of articulation which admits of a very obscure motion, and is called Synarthrosis.

ABAS, in the heathen mythology, was the son of Hypothon and Meganira, who entertained Ceres, and to her presented a cup, on which he became a newt or Hypothoon and Meganira, who entertained Ceres, and Diarthrotis, and Dearticulation, to distinguish it from that of articulation which admits of a very obscure motion, and is called Synarthrosis.

ABASCA, or Abacas, a country in Asia, tributary to the Turks, situated on the coast of the Black Sea. The people are poor, thievish, and treacherous, infomuch that there is no trading with them without the utmost caution. Their commodities are furs, buck and tigger skins, linen yarn, boxwood, and bees-wax: but their greatest traffic is in felling their own children, and even one another, to the Turks; infomuch that they live in perpetual distress. They are deftitute of many necessaries of life, and have nothing among them that can be called a town; though we find Anacopia, Dundar, and Czernorok, mentioned in the maps. They have the name of Christians; but having nothing left but the name, any more than the Mingrelsians their northern neighbours. The men are robust and active, and the women are fair and beautiful; on which account the Turks have given the value for the purchase which they pretend from among them. Their customs are full as much the same as tho' of the Mingrelsians; which see E. Long. from 39 to 43. N. Lat. from 43 to 45.

ABASCUS, a river of Asia Minor, which, rising from Mount Cucanost, falls into the Euxine, between Pityus to the east, and Nisia to the west.

ABASITIS (anc. geog.), a tract of Asia Minor, in which was situated the city of Cacea.

ABASSI, or Abas, a silver coin current in Persia, equivalent in value to a French livre, or ten times the value of a penny Sterling. It took its name from Schah Abbas II, king of Persia, under whom it was struck.

ABASSUS (anc. geog.), a town of the Greater Phrygia, on the confines of the Toliellozagi, a people of Galatia in Asia.

ABATAMENTUM, in law, is an entry to lands by interpolation, i.e. when a person dies seised, and another who has no right enters before the heir.

To ABATE, (from the French abbatre, to pull down, overthrow, demolish, batter down, or destroy), a term used by the writers of the English common-law, both in the active and negative sense; as, To abate a causu, is to beat it down. To abate a writ, is, by some exception, to defeat or overthrow it. A stranger abateth; that is, entereth upon a house or land void by the death of him that last poiseffed it, before the heir takes possession; and so keepeth him out: wherefore, as he that puttheth out him in possession is faid to defeize, so he that keepeth in between the former poifeessor and his heir is faid to abate. In the name of the demandant thus: The writ of the demandant shall abate; that is, shall be disabled, frustrated or overthrown. The appeal abateth by covin; that is, the accusatjon is defeated by deceit.

ABATE, in the manage, implies the performing any downward motion properly. Thus a horse is faid to abate to take down his curves, when he puts both his hind legs to the ground at once, and observes the same exactness in all the times.

ABATEMENT, in commerce, a term used for a prohibition of trade to all French merchants in the ports of the Levant who will not stand to their bargains, or refuse to pay their debts. It is a sentence of the French conful, which must be taken off before they can sue any person for the payment of their debts.

ABATEMENT, in heraldry, an accidental figure supposed to have been added to coats of arms, in order to denote some dishonourable demeanour or infamy, whereby the dignity of coat-armour was rendered of less esteem. See HERALDRY.

ABATEMENT, in law. See To ABATE.

ABATEMENT, in the customs, an allowance made upon the duty of goods, when the quantum damas is determined by the judgment of two merchants upon oath, and ascertained by a certificate from the surveyor and land-waiter.

ABATIS, an ancient term for an officer of the stables.

ABATON, an erection at Rhodes, as a fence to the trophy of Artemis, queen of Haliacarmathius, Coos, &c. raised in memory of her victory over the Rhodians; or rather as a screen to conceal the disgrace of the Rhodians from the eyes of the world, the efficaciou or destroying the trophy being with them a point of religion.

ABATOR, in law, a term applied to a person who enters to a house or lands void by the death of the last poiseessor, before the true heir.

ABATOS (anc.geog.), an island in the lake Moeris, formerly
ABB [7] ABB

ABBAS, formerly famous for its papyrus. It was the burial-place of Oiris.

ABBAY, in botany a synonym of the Adansonia.

ABB, a term; among clothiers, applied to the yarn of a weaver's warp. They say also Ab, or Abbot, in the same sense.

ABBAS a term; among clothiers, Ab, and Chaldee languages, and, figuratively, a superior, or the title which he bore before the bishop of Rome. It is a Jewish title of honour given to certain rabbins called Tannaim; and it is also particularly used by some writers of the middle age, for the superior of a monastery, usually called Abbot.

ABBADIE (James), an eminent Protestant divine, born at Nay in Bern in 1654; first educated there under the famous John la Placeette, and afterward at the university of Sedan. From thence he went to Holland and Germany, and was minister in the French church of Berlin. He left that place in 1690; came into England; was sometime minister in the French church in the Savoy, London; and was made dean of Killalow in Ireland. He died at St Mary le Bonne near London, in 1727, aged 73. He was strongly attached to the cause of King William, as appears in his elaborate defence of the revolution, and his history of the afflication-plot. He had great natural abilities, which he improved by true and useful learning. He was a most zealous defender of the primitive doctrine of the Protestants, as appears by his writings; and that strong nervous eloquence, for which he was so remarkable, enabling him to enforce the doctrines of his profession, from the pulpit with great spirit and energy. He published several works in French that were much esteemed; the principal of which are, A Treatise on the Truth of the Christian Religion; The Art of Knowing one's Self; A Defence of the British Nation; The Deity of Jesus Christ essential to the Christian Religion; The History of the last conspiracy in England, written by order of King William III.; and The Triumph of Providence and Religion, or the opening the Seven Seals by the Son of God.

ABBAS, son of Abdalmohleb, and Mahomet's uncle, opposed his nephew with all his power, esteeming him an impostor and infidel; but in the second year of the Hegira, being overcome and made a prisoner at the battle of Badr in 623, a great ranfom being demanded for him, he represented to Mahomet, that his paying it would reduce him to poverty, which would redound to the dishonour of the family. But Mahomet having been informed of Abbas's having sequestered large sums of money, aed them after the purges of gold he had left in his mother's custody at Mecca. Abbas, upon this, conceiving him to be really a prophet, embraced his new religion; became one of his principal captains: and saved his life when in eminent danger at the battle of Henaia, against the Thakifites, soon after the reduction of Mecca. But besides being a great commander, Abbas was a famous doctor of the Moslem law, in whose lectures upon every chapter of the Koran, as his nephew pretended to receive them one by one from heaven. He died in 652, and his memory is held in the highest veneration among the Moslems to this day.

Abul Abbas, son of Safiah, was proclaimed khali; and in him began the Dynasty of the Abbassides, who possessed the khilifate for 524 years; and there were 37 khilifs of this race who succeeded one another without interruption.

ABBIE, in a monastic sense, the same with Abbott.

ABBIE, in a modern sense, is the name of a curious popular character in France, very much mentioned, but very little known, in Britain. The term is not to be rendered in our language, as the existence of the being which it designates is posterior to the reformation, and no such character was known among the Romanists till about a century and a half ago.

Abbés, according to the strictest definition, are persons who have not yet obtained any specific or fixed settlement in church or state, but most heartily wish for and would accept of either, just as it may happen. In the mean while, their privileges are many. They are admissible in all companies, and no degradation to the best, notwithstanding they are sometimes found in the worst. Their drees is rather that of an academic, of a professor scholar, than of an ecclesiastic; and, never varying in colour, is no incumbrance on the pocket. These abbés are variously numerous, and no less useful. They are, in colleges, the instructors of youth; in private families, the tutors of young gentlemen; and many procure a decent livelihood by their literary and witty compositions of all kinds, from the profoundest philosophy to the most airy romances. They are, in short, a body of men who possess a fund of universal talents and learning, and are incessantly employed in the cultivation of every various branch of literature and ingenuity. No subject whatever escapes them; serious or gay, solid or transitory, sacred or profane, all pay tribute to their researches; and as they are conversant in the lowest as well as the highest topics, their fame is equally great in the learned and in the scribbling world. A distinguishing part of their character, too, whether we shall but slightly touch on is their devotion to the fair sex; whose favourites, in return, they have the honour of being in the most estimable degree; the wit and smartness for which they are usually remarkable, being just the very things that suit the French ladies. In fine, these abbés are sought after by most people, on various accounts; as they are equally men of business and pleasure, not less expert in the most serious transactions, than fond of enjoying their share in whatever occupies the gay world. Hence they diligently frequent all public spectacles, which are thought incomplete without them; as they compose the most intelligent part of the company, and are the most weighty approvers or condemners of what passes in almost all places.

ABBESS, the superior of an abbey or convent of nuns. The abbés has the same rights and authority over her nuns that the abbés regular have over their monks. The sex indeed does not allow her to perform the spiritual functions annexed to the priesthood, wherewith the abbés is usually invested; but there are influences of some abbés who have a right or rather a privilege,
ABB [8] ABB

ABBAY, a monastery, or religious house, governed by a superior under the title of abbot or abbess.

Abbeys differ from priories, in that the former are under the direction of an abbot, and the others of a prior: but abbot and prior (we mean a prior conventual) are much the same thing, differing in little but the name.

Fauchet observes, that in the early days of the French monarchy, dukes and counts were called abbots, and duchies and counties abbey. Even some of their kings are mentioned in history under the title of abbots. Philip I. Louis VI. and afterwards the dukes of Orleans, are called abbots of the monastery of St. Agnan. The dukes of Aquitaine were called abbots of the monastery of St. Hilary, at Ponsiflie; and the ears of Anjou, of St. Aubin, &c.

Monasteries were at first nothing more than religious houses, whither persons retired from the battle of the world to spend their time in solitude and devotion. But they soon degenerated from their original institution, and procured large privileges, exemptions, and riches. They prevailed greatly in Britain before the reformation; particularly in England; and as they increased in riches, so the state became poor; for the lands, which these regulars possessed were in mortua manu, i.e. could never revert to the lords who gave them. This inconvenience gave rise to the statutes against gifts in mortmain, which prohibited donations to religious houses: and Lord Coke tells us, that several lords, at their creation, had a clause in their grant, that the donor might give or sell his land to whom he would (exceptis viris religiosis & judaeis) excepting monks and Jews.

The places were wholly abolished in England at the time of the Reformation; Henry VIII. having first appointed visitors to inspect into the lives of the monks and nuns, which were found in some places very disorderly: upon which, the abbots, perceiving their dissolution unavoidable, were induced to resign their houses to the king, who by that means became invested with the abbey-lands: these were afterwards granted to different persons, whose dependents enjoy them to this day: they were then valued at 2,853,000l. per annum; an immense sum in those days.

Though the suppression of religious houses, even considered in a political light only, was of a very great national benefit, it must be owned, that at the time they flourished, they were not entirely useless. Abbeys or monasteries were then the repositories, as well as the seminaries, of learning; many valuable books and national records, as well as private evidences, have been preserved in their libraries; the only places wherein they could have been safely lodged in those turbulent times. Many of these, which had escaped the ravages of the Danes, were destroyed with more than Gothic barbarity at the dissolution of the abbeys. These ravages are pathetically lamented by John Bale, in his Declaration upon Le- land's Journal 1549. "Coveteousness," says he, "was at that time so high, that private commodity, that public wealth, in that most necessary and of repute, was not any where regarded. A number of them which purchased the superstitious mantles, reserved of the library-books, some to serve their jacks, some to scour the candlesticks, and some to rub their boots; some they sold to the grocer and soap-feller; and some they sent over sea to the book-binders, not in small numbers, but in whole ships full; yea, the universities of this realm are not clear of fo detestable a fact. I know a merchant that bought the contents of two noble libraries for 40s. price; a shame it is to be spoken! This fluff hath he occupied instead of gray paper, by the space of more than these ten years, and yet he hath stored enough for as many years to come. I shall judge this to be true, and utter it with heaviness, that neither the Britons under the Romans and Saxons, nor yet the English people under the Danes and Normans, had ever such damage of their learned monuments as we have seen in our time."

In these days every abbey had at least one person whose office it was to instruct youth; and the historians of this country are chiefly beholden to the monks for the knowledge they have of former national events. In these houses the arts of painting, architecture, and printing, were cultivated. The religious houses also were hospitals for the sick and poor; affording like-wise entertainment to travellers at a time when there were no inns. In them the nobility and gentry who were heirs to their founders could provide for a certain number of ancient and faithful servants, by procuring them cordes, or stated allowances of meal, drink, and clothes. They were likewise an asylum for aged and indigent persons of good family. The neighbouring places were also greatly benefited by the fair procure for them, and by their exemption from forest-laws; add to which, that the monastic ezates were generally let at very easy rents, the fines given at renewals included.

ABBEYBOYLE, a town of Ireland, in the county of Roscommon, and province of Connaught. W. Long. 8. 32. N. Lat. 56. 44. It is remarkable for an old abbey.
ABBET, or Abbate, the superior of a monastery of monks erected into an abbey or prelacy.

The name Abbet is originally Hebrow, where it signifies father. The Jews call father, in their language, Ab; whence the Chaldeans and Syrians formed Abba, thence the Greeks Ἀβας, which the Latins retained, Abbat; and hence our Abbot, the French Abbé, &c. St Mark and St Paul use the Syriac Abba in their Greek, by reason it was then commonly known in the synagogues and the primitive assemblies of the Christians: adding to it, by way of interpretation, the word father, Ἀβας ἀπατός, *Abba, father; †q. d. Abba, that is to say, Father. But the name Ab, or Abbs, which was at first a term of tenderness and affection in the Hebrew and Chaldee, became at length a title of dignity and honour: The Jewish doctors affected it; and one of their most ancient books, containing the sayings or apophthegms of divers of them, is intitled Pirke Abbat, or Avoth; i.e. Chapters of the Fathers. It was in allusion to this affection, that Jesus Christ forbade his disciples to call any man their father on earth; which word St Jerome turns against the superiors of the monasteries of his time, for affuming the title of Abbots, or Fathers.

The name Abbet, then, appears as old as the institution of monks itself. The governors of the primitive monasteries assumed indifferently the titles Abbots, Abbates, and Archimandrites*. They were really distinguished from the clergy; though frequently confounded with them, because a degree above laymen.

In those early days, the abbots were subject to the bishops and the ordinary pastors. Their monasteries being remote from cities, built in the farthest solitudes, they had no share in ecclesiastical affairs. They went on Sundays to the parish-church with the rest of the people; or, if they were too remote, a priest was sent them to administer the sacraments; till at length they were allowed to have priests of their own body. The abbots or archimandrites himself were priests, but his function extended no farther than to the spiritual assistance of his monastery; and he remained still in obedience to the bishop. There being among the abbots several persons of learning, they made a vigorous opposition to the rising heresies of those times; which oft occasioned the bishops to call them out of their deserts, and fix them among the outskirts of cities, and at length in the cities themselves: from which area their degeneracy is to be dated. The abbots, now, soon wore off their former plainness and simplicity, and began to be looked on as a sort of little prelates. They affected being independent of the bishops; and became so insupportable, that some severe laws were made against them at the council of Chalcedon; this notwithstanding, in time many of them carried the point of independence, and got the appellation of lords, with other badges of the episcopate, particularly the mitre. Hence arose new species of distinctions between the abbots. Thence were termedmitred abbots, who were privileged to wear the mitre, and exercise episcopal authority within their respective precincts, being exempted from the jurisdiction of the bishop. Others were called roistered abbots, from their bearing the crozier or pastoral staff. Others were styled solemnized or universal abbots, in imitation of the patriarch of Constantinople; while others were termed cardinal abbots, from their superiority over all other abbots. In Britain, the mitred abbots were lords of parliament; and called abbots-sovereign, and abbots-general, to distinguish them from the other abbots. And as there were lords abbots, there were also lords priors who had exempt jurisdiction, and were likewise lords of Parliament. Some reckoned 26 of these lords abbots and priors that sate in parliament. Sir Edward Coke says, that there were 27 parliamentary abbots and two priors. In the parliament 20 Rich. II. there were but 25 abbots and two priors: but in the summons to parliament anno 4 Ed. III. more are named.

At present, in the Roman-Catholic countries, the principal distinctions observed between the abbots are those of regular and recto-monastery. The former take the vow and wear the habit of their order; whereas the latter are seculars, though they are obliged by their bulls to take orders when of proper age.

Anciently the ceremony of assuming an abbot consisted in clothing him with the habit called cucullus, or cowl, putting the pastoral staff into his hand, and the shoes called pedales on his feet; but at present, it is only a simple benediction, improperly called, by some, consecration.

Abb in also a title given to others beside the superiors of monasteries: thus bishops, whose fees were formerly abbots, are called abbots; as are the superiors of some congregations of regular canons, particularly that of St Geneviève at Paris: and among the Genoese, the chief magistrate of their republic formerly bore the title of Abbat of the people. It was likewise usual, about the time of Charlemagne, for several lords to assume the title of count-abbots, abba comites; and that for no other reason, but because the superintendence of certain abbeys was committed to them.

ABBOT (George), archbishop of Canterbury, was born Oct. 29, 1562, at Guildford in Surrey. He went through his studies at Oxford, and in 1597 was chosen principal of University College. In 1599, he was installed dean of Winchester: the year following, he was chosen vice-chancellor of the university of Oxford, and a second time in 1603. In 1604, that translation of the bible now in use was begun by the direction of king James; and Dr. Abbot was the second of eight divines of Oxford, to whom the care of translating the whole New Testament (excepting the epistles) was committed. The year following, he was a third time vice-chancellor. In 1668, he went to Scotland with George Hume Earl of Dunbar, to affist in establishing an union between the Kirk of Scotland and the Church of England; and in this affair he behaved with so much address and moderation, that it laid the foundation of all his future preferment. For King James ever after paid great deference to his advice and counsel: and upon the death of Dr. Overton bishop of Lichfield and Coventry, he named Dr. Abbot for his successor, who was accordingly conftituted bishop of those two united sees in December 1629. About a month afterwards he was translated to the see of London, and on the second of November thereafter was raised to the archiepiscopal see.
It is not however improbable, that his extravagant adulation of his royal master, in which he went as far as any other court chaplain could do, contributed not a little to the acceleration of his preferment. In the preface to a pamphlet he published, the following specimen of ridiculous flattery occurs: Speaking of the king, he says, "whose life hath been so immaculate and unspoiled, &c. that even mankind itself, which leaves nothing unchristian, could never find true blemish in it, nor call probable aperfection on it."—Zealous of David, learned and wise, the Son of our age, religious as Josias; careful of spreading Christ's faith as Constantine the Great; just as Moses; undefiled in all his ways as Jeshophat and Hezekias; full of clemency as another Theodosius."—If Mr Walpole had seen this passage, he certainly would not have said, that "honest Abbot could not flatter,"

His great zeal for the Protestant Religion made him a strenuous promoter of the match between the Elector Palatine and the Princess Elizabeth; which was accordingly concluded and solemnized the 14th of February 1612, the archbishop performing the ceremony on a stage erected in the royal chapel. In the following year happened the famous case of divorce between the lady Francis Howard, daughter of the earl of Suffolk, and Robert earl of Essex: an affair which has been by many considered as one of the greatest blemishes in king James's reign; but the part therein acted by the archbishop added much to the reputation he had already acquired for incorruptible integrity. The matter was by the king referred to a court of delegates. The archbishop said plainly, that his Majesty was very desirous the lady should be divorced: but he was, in his own judgment, directly against the divorce. He laboured all he could to extricate himself from this difficulty, by having an end put to the cause by some other way than by sentence; but it was to no purpose: for those who drove on this affair, had got too great power to be restrained from bringing it to the conclusion the king desired. The archbishop prepared a speech, which he intended to have spoken against the nullity of the marriage, in the court at Lambeth; but he did not make use of it, because the king ordered the opinions to be given in few words. He contended, however, inflexible in his opinion against the divorce; and drew up his reasons, which the king thought fit to answer himself. It need scarce be added, that sentence was given in the lady's favour. In 1611, the king published a declaration, which he ordered to be read in all the churches, permitting servants and patiences on the Lord's day: this gave great uneasiness to the archbishop, who, happening to be at Croydon when it came hither, had the courage to forbid its being read. Being now in a declining state of health, the archbishop used in the summer to go to Hampshire for the sake of recreation; and being invited by lord Zouch to hunt in his park at Bramshill, he met there with the greatest misfortune that ever befell him; for he accidentally killed the game keeper by an arrow from a cross-bow which he shot at one of the deer. This accident threw him into a deep melancholy; and he ever afterwards kept a monthly fast on Tuesday, the day on which this fatal mischief happened, and he fettled an annuity of 200. on the vicar of Croydon, dow. There were several persons who took an advantage of this misfortune, to lessen him in the king's favour; but his Majesty said, "An angel might have miscarried in this fort." His enemies alleging that he had incurred an irregularity, and was thereby incapacitated for performing the office of a prince; the king directed a commissio to ten persons to inquire into this matter.

The result, however, was not satisfactory to his Graces' enemies: it being declared, that as the murder was involuntary, he had not forfeited his archiepiscopal character. The archbishop thenceforward fiel dom attended at the council, being chiefly hindered by his infirmities; but in the king's last illness he was sent for, and attended with great constancy till his Majesty expired on the 27th of March 1625. He performed the ceremony of the coronation of king Charles I. though very infirm and much troubled with the gout. He was never greatly in this king's favour; and the duke of Buckingham being his declared enemy, watched an opportunity of making him feel the weight of his displeasure. This he at last accomplished, upon the archbishop's refusing to licence a sermon, preached by Dr Sibthorpe to justify a loan which the king had demanded, and pregnant with principles which tended to overthrow the constitution. The archbishop was immediately after suspended from all his functions as primate; and they were exercised by certain bishops commissioned by the king, of whom Laud, the archbishop's enemy, and afterwards his successor, was one: while the only cause alligned for this procedure was, That the archbishop could not at that time personally attend those services which were otherwise proper for his congnisance and direction. He did not, however, remain long in this situation; for a parliament being absolutely necessary, his Grace was sent for, and restored to his authority and jurisdiction. But not proving friendly to certain rigorous measures adopted by the prevailing church-party, headed by Laud, whose power and interest at court were now very considerable, his presence became unwelcome there; so that upon the birth of the Prince of Wales, afterwards Charles II. Laud had the honour to baptize him, as dean of the chapel. The archbishop being worn out with cares and infirmities, died at Croydon, the 5th of August 1633, aged 71 years; and was buried at Guilford, the place of his nativity, and where he had endowed an hospital with lands to the amount of 300. per annum. A stately monument was erected over the grave, with the effigy of the archbishop in his robes.

He shewed himself, in most circumstances of his life, a man of great moderation to all parties; and was desirous that the clergy should attract the efficacy of the law by the sanctity of their manners, rather than claim it as due to their function. His notions and principles, however, not sifting the humour of some writers, have been drawn upon him many severe reflections; particularly, which is to be regretted, from the earl of Clarendon. But Dr Welwood has done more justice to his merit and abilities. He wrote several tracts upon various subjects; and, as already mentioned, translated part of the New Testament, with the rest of the Oxford version, 1611.

It is proper to observe here, that there was another writer of both his names, who flourished somewhat later. This George Abbot wrote A Paraphrase on the
ABBOT (Robert), elder brother to the former, and born at Guildford in 1560, went through his studies in Balacli college, Oxford. In 1582, he took his degree of master of arts, and soon became a celebrated preacher; and to this talent he chiefly owed his preferment. Upon his first sermon at Worcester, he was chosen lecturer in that city, and soon after rector of All-Saints in the same place. John Stanley, Esq.; happening to hear him preach at Paul's-cho'ps, was so pleased with him, that he immediately presented him to the rich living of Bingham in Nottinghamshire. In 1597, he took his degree of doctor in divinity: and, in the beginning of king James's reign, was appointed chaplain in ordinary Bingham in Nottinhamshire. In 1597, he was made prebendary of Normanfor: In 1609, he was appointed him regius professor of divinity at Oxford. November 1610, he was made prebendary of Normanford. The fame of his lectures became very great; and those which he gave upon the supreme power of kings against Bellarmine and Suarez, so much pleased his Majesty, that, when the see of Salisbury became vacant, he named him to that bishopric, and he was consecrated by his own brother at Lambeth, December 3, 1615. When he came to Salisbury, he found the cathedral running to decay, through the negligence and profaneness of the clergy belonging to it: however, he found means to draw five hundred pounds from the prebendaries, which he applied to the reparation of this church. He then gave himself up to the duties of his function with great diligence and affiduity, visiting his whole diocese in person, and preaching every Sunday whilst health would permit. But this was not long: for his sedentary life, and close application to study, brought upon him the gravel and stone, of which he died on the 2d of March 1618, in the fifty-eighth year of his age; having not filled the see quite two years and three months, and being one of the five bishops which Salisbury had in six years. He was buried opposite to the bishop's seat in the cathedral. Dr Fuller,* speaking of the two brothers, says, "that George was the more plausible preacher, Robert the greatest scholar; George the abler statesman, Robert the deepest divine: gravity did frown in George, and smile in Robert." He published several pieces: he also left behind him sundry manuscripts, which Dr Corbet made a present of to the Bodleian library.

ABBOTSBROXLEY, a town in Staffordshire, with a market on Tuesday. After the dissolution of the monasteries, it was given to the Lord Paget; and has since been called Paget's Broxley, and is so denominated in the county map. But it retains its old name in the king's books, and is a difcharged vicarage of 50l. clear yearly value. It likewise retains its old name with regard to the fairs. W. Long. i. 2. Lat. 52 45.

ABBOTSBURY, a small town in Dorsetshire, with a market on Thursday. W. Long. i. 17. Lat. 50. 42. Abbreviate 1. 2. Lat. 52 45.

ABBREVIAE of ADJUDICATIONS, in Scots law, an abridgment or abbreviation of a decree of adjudication, which is recorded in a register kept for that purpose.

ABBREVIATION, or ABBREVIATOR, a contrivance of a word or passage; made by dropping some of the letters, or by substituting certain marks or characters in their place.---Lawyers, physicians, &c. use abundance of abbreviations, partly for the sake of expeditiousness, partly for the sake of mystery; but of all people the Rabbins are the most remarkable for this practice, so that their writings are unintelligible without the Hebrew abbreviations. The Jewish authors and copyists do not content themselves with abbreviating words like the Greeks and Latins, by shortening some of the letters of the words; but they frequently take away all but the initial letters. They even frequently take the initials of several succeeding words, join them together, and, adding vowels to them, make a sort of barbarous word, representative of all those which they have thus abridged. Thus, Rabi Mofes ben Maimon, in their abbreviations is Rambam, &c.

ABBREVIATOR, in a general sense, a person who abridges any large book into a narrower compass.

ABBREVIATORS, a college of 72 persons in the chancery of Rome, who draw up the pope's briefs, and reduce petitions, when granted by him, into proper form for being converted in bulls.

ABUTALS, signify the buttiments or boundaries of lands towards any point. Limits were anciently distinguished by artificial hillocks, which were called boteines; and hence butting. In a description of the site of land, the sides on the breadth are more properly adjuncts, and these terminating the length are abutantes; which, in old surveys, were sometimes expressed by capitare, to head, whence abutments are now called head-lands.

ABCEDARY, or ABCEDARIAN, an epitome given to compositions, the parts of which are disposed in the order of the letters of the alphabet; thus we say, Abcedarian psalms, lamentations, hymns, &c.

ABCOURT, a town near St Germain, four leagues from Paris. Here is a brisk chalybeate water, impregnated with fixed air and the fossil alkali; and refculbling the waters of Spa and Ilmington.

ABDALLA, the son of Abdalmothib, was the father of the prophet Mahomet. Several other Arabians of eminence bore the same name.

ABDALMALEK, the son of Miryan, and the 5th Khalif of the race of the Omriades, furnished Rashid al-Hegmat, i.e. the thinner of a cone, because of his extreme avarice; as also Abdulzebed, because his breath was said to be so poisonous as to kill all the flies which rested on his face. Yet he surpassed all his predecessors in power and dominion: for in his reign the Indies were conquered in the east, and his armies penetrated Spain in the west: he likewise extended his empire toward the south, by making himself master of Medina and Mecca. He began his reign in the 67th of the hegira, A.D. 648; reigned 15 years; and was the son of his father, the Khalifate one after another.

B 2 ABDALMALEK.
ABDAMELEK (Ben Zohar), an eminent physician, commonly called by the Europeans AVINZCAR.

ABDAMOTILEB, or ABDEL MATELIEH, the son of Hathem, the father of Abdalla, and grandfather of Mahomet the prophet of the Mussulmans, was, it is said, of such wonderful comeliness and beauty, that all women who saw him became enamoured: which may have given occasion to that prophetic light, which, according to the Arabians, shone on the heads of him, his ancestors, and descendents; it being certain that they were very handsome and graceful men. He died when Mahomet, of whom he had taken peculiar care, was only 8 or 9 years old; aged, according to some, 110, and according to other writers 120.

ABDALONYMUS, or ABDOLONYMUS, (in classic history), of the royal family of Sidon, and descendent from king Cinyras, was contented to live in obscurity, and get his subsistence by cultivating a garden, while Strato was in possession of the crown of Sidon. Alexander the Great having deposed Strato, inquired whether any of the race of Cinyras was living, that he might set him on the throne. It was generally thought that the whole race was extinct; but at last Abdalonymus was thought of, and mentioned to Alexander; who immediately ordered some of his soldiers to fetch him. They found the good man at work, happy in his poverty, and entirely a stranger to the noise of arms, with which all Asia was at that time disturbed; and they could scarcely persuade him that they were in earnest. Alexander was convinced of his high descent by the dignity that appeared in his person; but was desirous of learning from him in what manner he bore his poverty.

"I will," said Abdalonymus, "I may bear my new condition as well: these hands have supplied my necessities: I have had nothing, and I have wanted nothing." This answer pleased Alexander so much, that, besides giving him all that was Strato's, he augmented his dominions, and gave him a large present out of the Persian spoils.

ABDALS, in the Eastern countries, a kind of saints supposed to be inspired to a degree of madness. The word comes, perhaps, from the Arabic, Abdallah, the servant of God. The Persians call them devotes khoda, similar to the Latins way of speaking of their prophets and sibyls, g. d. furentes deos, raging with the gods. They are often carried by excess of zeal, especially in the Indies, to run about the streets and kill all they meet of a different religion; of which travelers furnish many instances. The English call this, running a mitra, from the name of the infrument, a sort of pole, which they employ on theses desperate occasions. If they are killed, as it commonly happens, before they have done much mischief, they reckon it highly meritorious; and are esteemed, by the vulgar, martyrs for their faith.

ABDARA, or ADEERA, (anc. geog.) a town of Boeotia in Spain, a Phoenician colony; now ALDE, to the west of Almeria in the kingdom of Granada.

ABDERA, (anc. geog.) a maritime town of Thrace, not far from the mouth of the river Nessus, on the coast side. The foundation, according to Herodotus, was attempted to be laid by Timaeus the Cilician; but he was forced by the Thracians to quit the design. The Telians undertook it, and succeeded; setting there, in order to avoid the influx of the Persians. Several singularities are told of Aderos. The grapes of the country round it was so strong, that such horses as caed of it ran mad. In the reign of Caffander king of Macedonia, this city was besieged with frogs and rats, lib. xxvi. c. 8, that the inhabitants were forced to quit it for a time. The Abderites, or Abderians, were very much de-}
ABDOmen, in anatomy, is that part of the trunk of the body which lies between the thorax and the bottom of the pelvis. See Anatomy.

ABDOMINATE, or ABDOMINAL FISHES, constitute the IVth Order of the Fourth Class of Animals, in the Linnean System. See Zoology.

ABDUCTION, in logic, a kind of argumentation, by the Greeks called apagoge, wherein the greater extreme is evidently contained in the medium, but the medium not so evidently in the lesser extreme as not to require some farther medium or proof to make it appear. It is called abdiction, because, from the conclusion, it draws us on to prove the proposition assumed. Thus in the syllogism, "All whom God abdolves are free from sin; but God abdolves all who are in Christ; therefore all who are in Christ are free from sin,"—the major is evident; but the minor, or assumption, is not so evident without some other proposition to prove it, as, "God received full satisfaction for sin by the sufferings of Jesus Christ."

ABDICATION, in surgery, a species of fracture, wherein the broken parts of the bone recede from each other.

ABDUCTOR, or ABDUCENT, in anatomy, a name given to several of the muscles, on account of their tending to withdraw, open, or pull back the parts to which they belong.

ABEL, second son of Adam and Eve, was a shepherd. He offered to God some of the firstlings of his flock, at the same time that his brother Cain offered the fruits of the earth. God was pleased with Abel's oblation, but displeased with Cain's; so he exasperated the latter, that he rose up against his brother and killed him. These are the only circumstances Moses relates of him; though, were we to take notice of the several particulars to which curiosity has given birth on this occasion, they would run to a very great length. But this will not be expected. It is remarkable, that the Greek churches, who celebrate the feasts of every other patriarch and prophet, have not done the same honour to Abel. His name is not to be found in any catalogue of saints or martyrs till the 10th century; nor even in the new Roman Martyrology. However he is prayed to, with some other saints, in several Roman litanies said for persons who lie at the point of death.

Abel Keramitis, or Vincereus, beyond Jordan, in the country of the Ammonites, where Jephthah defeated them, seven miles distant from Philadelphia, abounding in vines, and hence the name. It was also called Abelos.

ABEL-Mehola, the country of the prophet Elisha, situated on this side Jordan, between the valley of Jezreel and the village Bethmaela in the plains of Jordan, where the Midianites were defeated by Gideon. Judges, vii. 22.
ABELIANS, or ABELIANS, of Abelontia, in church-history, a sect of heretics mentioned by St. Austin, which arose in the diocese of Hippo in Africa, and is supposed to have begun in the reign of Arcadius, and ended in that of Theodosius. Indeed it was not calculated for being of any long continuance. Tho' of this sect regulated marriage after the example of Abel; who, they pretended, was married, but died without ever having known his wife. They therefore allowed each man to marry one woman, but enjoined when a man and woman entered into this society, they adopted a boy and a girl, who were to inherit their sexes. From the name of this sect a colony of Chalcidians, the inhabitants were called Abelontians, or Abelontians, which gave rise to the name impotent, as the name imports, after in the British implying such a situation. It is a small but flourishing place, well built, and still increasing. The town has been in an improving state for the forty last years, and the number of inhabitants greatly augmented, which is owing to the introduction of manufactures. The number, at this time, is said to be about four thousand: these principally consist of weavers of coarse brown linens, and some sail-cloth; others are employed in making white and coloured threads; others are engaged in the spinning of the place, or in the necessary and common mechanic trades. The brown linens, or ofnaburghs, were manufactured here before any encouragement was given by Government, or the linen company erected at Edinburgh. It appears from the books of the flamp-office in this town, that seven or eight hundred thousand yards are annually made in the place, and a small district round. Besides this export and that of thread, much barley and some wheat is sent abroad. The foreign imports are flax, flax seed, and timber, from the Baltic. The coasting trade consists of coals from Borrowdounes, and lime from Lord Elgin's kilns in Fife. At this place, in default of a natural harbour, a tolerable artificial one of piers has been formed, where, at spring-tides, which rise here fifteen feet, ships of two hundred tons can come, and of eighty at neap-tides; but they must lie dry at low water. This port is of great antiquity: there is an agreement yet extant between the abbot and the burgess of Aberbrothick, in 1594, concerning the making of the harbour. Both parties were bound to contribute their proportions; but the largest fell to the share of the former, for which he was to receive an annual tax payable out of every rood of land lying within the borough. The glory of this place was the abbey, whose very ruins give some idea of its former magnificence. It was founded by William the Lion in 1178, and dedicated to the celebrated prince Thomas à Becket. The founder was buried here; but there are no remains of his tomb, or of any other, excepting that of a monk of the name of Alexander Nicol. The monks were of the Tyro-

Aberconway,
The harbour was long a great detriment to its trade; in 1593, but since greatly improved by the addition of a new quay, which was put in at the mouth of the river Don, over which is a bridge. The New Town, situated at the mouth of the river Don, is 67 feet wide at the bottom, and 34 feet high above the surface of the river, which at ebb-tide is deep enough for a ship of 200 tons, and above two miles in circumference.

The buildings (which are of granite from the neighbouring quarries) are generally four stories high, and have, for the most part, gardens behind them, which gives it a beautiful appearance. On the high-street is a large church, formerly belonging to the Franciscans. This church was begun by Bishop William Elphinston, and finished by Gavinus Dunbar, bishop of Aberdeen, about the year 1560. Bishop Dunbar is said to have built the bridge over the Dee, which consists of seven arches. In the middle of Cattle-street is an octagon building, with neat bas-reliefs of the kings of Scotland from James I. to James IV. This town-house makes a good figure, and has a handsome spire in the centre. The grammar-school is a low but neat building. Gordon's hospital is handsome; in front is a good statue of the founder: it maintains forty boys, who are apprenticed at proper ages. The infirmary is a large plain building, and sends out between eight and nine hundred cured patients annually. But the chief public building in the town is the Marischal-college, founded by George Keith earl of Marischal, in the year 1593; but since greatly augmented with additional buildings. There are about 140 students belonging to it. In both the Marischal and King's college the languages, mathematics, natural philosophy, divinity, &c. are taught by very able professors. The convents in Aberdeen were: One of Mathurines, of the order of the Trinity, founded by William the Lion, who died in 1214; another of Dominicans, by Alexander II.; a third of Observants, a building of great length in the middle of the city, founded by the citizens and Mr. Richard Vanes, &c.; and a fourth of Carmelites, or White Friars, founded by Philip de Arbutnot in 1350.

Aberdeen, including the Old Town, is supposed to contain 25,000 people. Its trade is considerable, but might be greatly extended by an attention to the white fisheries.

The harbour was long a great detriment to its trade, and occasioned the loss of many lives and much property. A stranger could never depend upon finding it as he left it; while vessels lay at anchor in the road till the tide should make, they have often been wrecked by storms.
forms which suddenly arose. It was very narrow at the mouth, having the easterly rocky point of the Grampian mountains on the south, and a flat sloping land on the north, extending along the coast for many miles. By the easterly and north-easterly flood the sand was driven in a long ridge across the harbour's mouth, and formed what was called the bar. Upon this bar the depth of water at low tide was sometimes not above three feet. Clearing away the sand, though but a partial and temporary remedy, was a matter of great expense to the community. If it was cleared one week so as to have five or six feet of water at ebb, a fresh storm next week undid all that had been done. The town at last came to a resolution of erecting a strong pier on the north side of the harbour. This pier is 1200 feet in length, and gradually increases in thickness and height as it approaches the sea, where the head or rounding is 60 feet diameter at the base, and the perpendicular elevation is 38 feet. The whole is built of granite, the most durable stone known; many of the outer lawns of houses are about three tons weight, with hewn beds. It was built under the direction of Mr. Snaiton; and the expense, amounting to above £17,000, is defrayed by doubling the harbour-dues, which are chiefly paid by the inhabitants. A little to the south of the bar, they have now a depth of 7 fathoms at low water; and at the harbour mouth, from eight to nine fathoms, where they had formerly but a few feet.

Aberdeen once enjoyed a good share of the tobacco trade. At present, its imports are from the Baltic, and a few merchants trade to the West Indies and North America. Its exports are stockings, thread, salmon, and oatmeal. The first is a most important article, as appears by the following state of it. For this manufacture, 20,800 pounds worth of wool is annually imported, and 1600 pounds worth of oil. Of this wool are annually made 69,333 dozen pairs of stockings; worth, at an average, 1 l. 10s. per dozen. These are the work of the country-people in almost all parts of this great county, who get 45. per dozen for spinning, and 14s. per dozen for knitting; so that there is annually paid them £5,500. There is, besides a large number of flocking, though not from the fine wool of the county. The thread manufacture is another considerable article, though trifling in comparison of the woollen. The salmon fisheries on the Dee and the Don are a good branch of trade. About 46 boats, and 130 men, are employed on the first; and, in some years, 167,000 lbs. of fish have been sent pickled to London, and about 930 barrels of salted fish exported to France, Italy, &c. — The fishery on the Don is far less considerable. The fish of this river are taken in creuses above the bridge; a practice contrary to the ancient laws of the kingdom, unless where the nature of the water rendered the net-fishery impracticable. The inhabitants likewise export considerable quantities of pickled pork, which they sold to the Dutch for victualing their East India ships and men of war; the Aberdeen pork having the reputation of being the best cured of any in Europe for keeping on long voyages.

It is however remarkable, (Mr. Knox observes), that there is not a single decked vessel fitted out from Aberdeen for the herring or white fisheries; here is now, an excellent harbour; an active people, conversant in Aberdeenshire trade, and possessed of capital, seated within six hours sailing of Long Forths, and two days sailing of the Shetland Isles. This inattention is the more extraordinary, as the exports of Aberdeen, though very considerable, do not balance the imports in value. The herring and white fisheries, therefore, if prosecuted with vigour, cured and dried with judgment, would not only extend the scale of exports, but also furnish the outward bound vessels with freights, and better remunerations for the foreign markets. The salmon of the Dee and Don are taken in great abundance, cured in the highest perfection, and greatly valued at the European markets. If the merchants, in addition to these, should also export the cargoes of 50 or 60 vessels constantly employed in the herring and white fisheries, the port of Aberdeen would in a few years become the most celebrated mart of fish now existing.

From a round hill at the west end of the city, flow two springs, one of pure water and the other of a quality resembling the German Spa. Aberdeen, with Aberbrothick, Brecbin, Monrofe, and Inverbervie, return one member to Parliament.

ABERDEENSHER, comprehends the districts of Mar, Garioch, Strathbogie, and the greater part of Buchan; and sends one member to Parliament. It is washed on the east and north by the ocean; and abounds in sea-ports, from whence there is a safe and ready passage to the Orkneys and Shetland Isles, the Greenland fisheries, Norway, and the regions round the Baltic, the German coast, Holland, Flanders, France. It is watered by numerous streams, all of them the reft of salmon, and which banks display the most extensive plantations as well as natural woods in Britain.

ABERDOUR, a small town in Fifeshire, Scotland, on the frith of Forth, about ten miles N. W. of Edinburgh. In old times it belonged to the Vipouts; in 1126 it was transferred to the Mortimers by marriage, and afterwards to the Douglasses. William, lord of Liddesdale, burned the Flower of chivalry. in the reign of David II., and also conveyed it to James Douglas, ancestor of the present noble owner the Earl of Morton. The monks of Aberdour were suppressed for a burial-place here from Allan de Mortimer, in the reign of Alexander III. The nuns, usually styled the poor Clare, had a convent at this place.

ABERFORD, a market-town in the west riding of Yorksire, stands in a bottom; and is about a mile long, and indifferently well built. It is near a Roman road, which is raised very high, and not far from the river Cock; between which and the town there is the foundation of an old castle still visible. It is 131 miles north-by-west from London. W. Long. 2° 45'. Lat. 55° 12'.

ABERGAVENNY, a large, populous, and flourishing town in Monmouthshire, seated at the confluence of the rivers Usk and Gavenny. It has a fine bridge over the Usk, consisting of fifteen arches; and being a great thoroughfare from the west part of Wales to Bath, Bristol, Gloucester, and other places, is well supplied with accommodations for travellers. It is surrounded with a wall, and had once a castle. It carries on a considerable trade in flannels, which are brought hither for sale from the other parts of the county.
ABERDEEN, county. It is 142 miles distant from London. W. ab.
aberration. Long. 2. 45. Lat. 51. 50. Abercawny appears to
have been the Gabinuna of Ammianus, and the town
of Ct. his Barrican.

ABERNETHY (John), an eminent dissenting minis-
ter, was the son of Mr John Abernethy a dissenting
minister in Coltraine, and was born on the 19th of Oc-
tober 1680. When about nine years of age, he was
separated from his parents, his father being obliged to
attend to public affairs in London; and his mother,
to shelter herself from the mad fury of the Irish rebels,
retiring to Derry, a relation who had him under his
charge, having no opportunity of conveying him to her,
took him with him to Scotland; by which means he
escaped the hardships he must have suffered at the siege
of Derry, where Mrs Abernethy lost all her other
children. He afterwards studied at the university of
Glasgow, till he took the degree of agregation at Antrim, where he continued
years. About the time of the Bangorian controver-
sy, escaped the hardships he must have
suffered; after his death a second volume was
published of his sermons on the Divine
attributes; after his death a second volume was
published by his friends; and these were succeeded by four
other volumes on different subjects: all of which have
been greatly admired.

ABERNETHY, a town in Strathern, a
district of Perthshire in Scotland. It is seated on the river Tay,
a little above the mouth of the Earn. It is said to have
been the seat of the Pictish kings; and was afterwards
the see of an archbishop, since transferred to St
Andrews. It is now greatly decayed.

ABERRATION, in astronomy, a small apparent
motion of the fixed stars discovered by the late Dr
Bradley. The discovery was made by accident in the
year 1725, when Mr Molyneux and Dr Bradley began
to observe the bright star in the head of Draco, mark-
ed γ by Bayer, as it passed near the zenith, with an
instrument made by Mr Graham, in order to discover the
parallax of the earth's annual orbit; and, after repeated
observations, they found this star, about the beginning
of March 1726, to be 20' more northern than at the
time of the first observation. It now indeed seemed to
have arrived at its utmost limit southward; because, in
several trials made about this time, no sensible difference
was observed in its situation. By the middle of April,
it appeared to be returning back again toward the
north; and, about the beginning of June, it passed at
the same distance from the zenith as it had done in De-
cember, when it was first observed; in September fol-
lowing, it appeared 29' more northerly than it was in
March, just the contrary way to what it ought to
appear by the annual parallax of the stars. This un-
expected phenomenon perplexed the observers very
much; and Mr Molyneux died before the true cause of it
was discovered. After this, Dr Bradley, with another Aberration
instruments more exact and accurately adapted to this
purpose, observed the same appearance not only in that
but in many other stars; and, by the great regularity
that appeared in a series of observations made in all
parts of the year, the Doctor was fully satisfied with re-
gard to the general laws of the phenomenon; and there-
fore endeavored to find out the cause of them. He
was already convinced, that the apparent motion of the
stars was not owing to a motion of the earth's axis.
The next thing that offered itself, was an aberration in
the direction of the plumb line, with which the in-
strument was constantly rectified; but this, upon trial,
proved insufficient. Then he had recourse to what re-
fraction might do; but here also nothing satisfactory
occurred. At last this acute astronomer found, that the
phenomena in question proceeded from the progressive
motion of light, and the earth's annual motion in its
orbit; for he perceived, that if light was propagated in
time, the apparent place of a fixed object would not
be the same when the eye is at rest, as when it is
moving in any other direction than that of the line par-
llel to the object, or moving through the eye and
object; and that, when the eye is moving in different directions, the apparent
place of the object would be different.

ABERRATION in optics, is used to denote that error
or deviation of the rays of light, when intercepted by a
lens or speculum, whereby they are hindered from
meeting or uniting in the same point. There are two
species of the aberrations of rays, distinguished by
their different causes: one arising from the figure of the
glass or speculum, the other from the unequal re-
frangibility of the rays of light. This last species is
sometimes called the Newtonian, from the name of its
discoverer. See Optics, vol. 2. 156, 173.

ABERYSWITH, a market-town of Cardig-
shire, in Wales, seated on the Rheid, near its confluence
with the Trefeth, where it falls into the sea. It is
a populous, rich town, and has a great trade in
lead, and a considerable fisheries of whiting, cod, and
herrings. It was formerly surrounded with walls, and
fortified with a castle; but both are now in ruins. Its
distance from London is 199 miles west-south-west.
W. Long. 4. 15. Lat. 52. 36.

ABESTA, the name of one of the sacred books
of the Persian magi, which they ascribe to their great
founder Zoroaster. The abesta is a commentary on two
of their religious books called Zend and Pazyru,
the three together including the whole system of
the Iganan, or worshippers of fire.

ABETTOR, a law-term, implying one who en-
courages another to the performance of some criminal
action, or who is art and part in the performance it-
self. Tresession is the only crime in which abettors are
excluded by law, every individual concerned being
considered as a principal. It is the same with Act-
and-part in the Scots law.

ABEX, a country in High Ethiopia, in Africa,
bordering on the Red Sea, by which it is bounded on
the east. It has Nobah or Sennar on the north; Senan
and Abyfsoh on the west; and Abyfinsic on the south.
Its principal towns are Suquem and Arkeko. It is
subject to the Turks, and has the name of the Begler-
berg of Habeleth. It is about five hundred miles in
length and one hundred in breadth, and is a wretched
C country;
country; for the heat here is almost insupportable, and the air is so unhealthy, that an European cannot stay long in it without the utmost hazard of his life. It is very mountainous, insomuch that there are many more wild beasts than men. There are forests, in which grow a great number of ebony trees.

ABEYANCE, in law, the expectancy of an estate. Thus if lands be left to one person for life, with reversion to another for years, the remainder for years is an abeyance till the death of the lessee.

ABGARUS, or ABGARUS, a name given to several of the kings of Edessa in Syria. The most celebrated of them is one who, it is said, was contemporary with Jesus Christ, and who having a diftermer in his feet, and hearing of Jesus's miraculous cures, requested him, by letter, to come and cure him. Eusebius*, who believed that his letter was genuine, and also an answer our Saviour is said to have returned to it, has translated them both from the Syriac, and were taken out of the archives of the city of Edessa. The first is as follows:—

"Abgarus, prince of Edessa, to Jesus the holy Saviour, who hath appeared in the flesh in the confines of Jerusalem, greeting. I have heard concerning thee, who art a god, and have returned to it, has translated them both from the Syriac, and were taken out of the archives of the city of Edessa. The first is as follows:—

"Abgarus, prince of Edessa, to Jesus the holy Saviour, who hath appeared in the flesh in the confines of Jerusalem, greeting. I have heard concerning thee, who art a god, and have returned to it, has translated them both from the Syriac, and were taken out of the archives of the city of Edessa. The first is as follows:—

"Abgarus, prince of Edessa, to Jesus the holy Saviour, who hath appeared in the flesh in the confines of Jerusalem, greeting. I have heard concerning thee, who art a god, and have returned to it, has translated them both from the Syriac, and were taken out of the archives of the city of Edessa. The first is as follows:—

"Abgarus, prince of Edessa, to Jesus the holy Saviour, who hath appeared in the flesh in the confines of Jerusalem, greeting. I have heard concerning thee, who art a god, and have returned to it, has translated them both from the Syriac, and were taken out of the archives of the city of Edessa. The first is as follows:—

"Abgarus, prince of Edessa, to Jesus the holy Saviour, who hath appeared in the flesh in the confines of Jerusalem, greeting. SCIRED, bordering on the Thracians and Ban-

SAMS: They were commended by Curtius for their love of justice, and by Ammianus for their concept of earthly things.

ABIMELECH, king of Gerar, a country of the Philistines, was contemporary with Abraham. This patriarch and his family being there, his wife Sarah, though 90 years of age, was not safe in it; for Abimelech carried her off, and was so enamoured of her, that he resolved to marry her. Abraham did not declare him to be Sarah's husband; but gave out she was his sister. But the king being warned in a dream, that she was married to a prophet, and that she should die if he did not restore her to Abraham, the king obeyed; at the same time reproving Abraham for his dissimulation; who thereupon, among other excuses, said she was really his sister, being born of the same father, tho' of a different mother. Abimelech afterwards gave considerable presents to Abraham; and a covenant, that of Beerheba, was entered into between them.——After the death of Abraham, which was caused by a famine in the neighbouring countries, Isaac his son also withdrew into Canaan; but Abimelech afterwards entered into a covenant with him.

ABIMELECH, the natural son of Gideon, by Drusilla, was killed at the age of 30 years by his concubine, her beauty forced her husband to declare her for his wife, who thereupon, among other excuses, said she was really his sister, being born of the same father, tho' of a different mother. Abimelech afterwards gave considerable presents to Abraham; and a covenant, that of Beerheba, was entered into between them.——After the death of Abraham, which was caused by a famine in the neighbouring countries, Isaac his son also withdrew into Canaan; but Abimelech afterwards entered into a covenant with him.

Here Rebekah's beauty forced her husband to declare her for his wife, who thereupon, among other excuses, said she was really his sister, being born of the same father, tho' of a different mother. Abimelech afterwards gave considerable presents to Abraham; and a covenant, that of Beerheba, was entered into between them.——After the death of Abraham, which was caused by a famine in the neighbouring countries, Isaac his son also withdrew into Canaan; but Abimelech afterwards entered into a covenant with him.
ABL [20] ABR

Abjuration renouncing, disinclining, and denying upon oath, the Pretender to have any kind of right to the crown.

Abjuration of Heresy, the public recantation of any doctrine as false and wicked.

Ablation, or wearing a child from the breast. See Wounding.

Ablation, among the ancient gardeners, the name with which is called expelling by approach.

Ablation, a country of Great Tartary, the inhabitants of which, called Bichar or Bicharah, are subject to Ryllia, but that only for protection. It lies eastward of the river Iris, and extends five hundred leagues along the southern frontiers of Siberia.

Ablation, an old term in gardening, signifies the operations of removing the earth and burying the roots of trees in winter, to expose them more freely to the air, rains, snows, &c.

Ablation Court. See Perrot.

Ablative, in Grammar, the sixth case of Latin nouns which is formed from the fifth: "to take away." Frischlin also calls it the "comparative case;" or serving, among the Latins, for comparing, as well as taking away.

The ablative is opposite to the dative; the first expressing the action of taking away, and the latter that of giving.

In English, French, &c. there is no specific mark whereby to distinguish the ablative from other cases; and we only use the term in analogy to the Latin. Thus, in the two phrases, the magnitude of the city, and he spoke much of the city, we say, that of the city in the first is genitive, and in the latter ablative; because it would be so, if the two phrases were expressed in Latin.

The question concerning the Greek ablative has been the subject of a famous literary war between two great grammarians, Frischlin and Cruiis; the former of whom maintained, and the latter opposed the reality of it. The dispute still subsists among their respective followers. The chief reason adduced by the former is, that the Roman writers often joined Greek words with the Latin prepositions, which govern ablutive cases, as well as with nouns of the same case. To which their opponents reply, that the Latins, anciently had no ablative themselves; but instead thereof, made use, like the Greeks, of the dative case: till at length they formed an ablative, governed by prepositions, which were not put before the dative: that, at first, the two cases had always the same termination, as they still have in many instances; but that this was afterwards changed in certain words. It is no wonder then, that the Latins sometimes join prepositions which govern an ablative case, or nouns in the ablative case, with Greek datives, since they were originally the same; and that the Greek datives have the same effect as the Latin ablative.

Able, or ABL. (Thomas), chaplain to Queen Catherine confor to Henry the eighth, distinguished himself by his zeal in opposing the proceedings against that unfortunate princess for a divorce. For this purpose he wrote a piece entitled "Tractatus de non diffolvento Henri et Catharine matrimonio, i.e. A Treatise proving that the marriage of king Henry and queen Catherine ought not to be dissolved." But the title of the book, according to bishop Tanner, was Justitia Veritatis. He took the degree of Bachelor of Arts at Oxford on the 4th of July 1513, and that of Master of Arts on the 27th of July 1516. In 1524 he fell under a prosecution for being concerned in the affair of Elizabeth Barton, called the Holy Maid of Kent. This was an infamous impostor, forborne by the monks of some strange gesticulations, and to pretend to inspiration by the spirit of prophecy; and so well did he act her part, that some people of consequence gave credit to her; but being at last detected, she was condemned and executed, after discovering the names of her principal accomplices and instigators. On her account Able was accused of misprision of treason, by Stat. 25. Hen. VIII.; and being also one of those who denied the king's supremacy over the church, he was apprehended and imprisoned; during which time his confinement was so rigorous, that the keeper of Newgate was committed to Marshalsea prison for suffering him to go out upon bail. He was afterwards hanged, drawn, and quartered, at Smithfield in 1540. Bouchier gives him the character of a very learned man; and says, that he taught to teach the queen music and the learned languages.

Ablative, in Roman antiquity, a select body of soldiers chosen from among those called Extraordinary.

Ablegmina, in Roman antiquity, those choice parts of the entrails of victims which were offered in sacrifice to the gods. They were sprinkled with salt, and burnt upon the altar; the priests pouring some wine on them.

Abluents, in medicine, the same with diluters of Diluents.

Ablution, in a general sense, signifies the washing or purifying something with water.

Ablution, in a religious sense, a ceremony in use among the ancients, and still practised in several parts of the world: it consisted in washing the body, which was always done before sacrificing, or even entering their houses. Ablutions appear to be as old as any ceremonies, and external worship itself. Mosaic enjoined them; the heathens adopted them; and Mahomet and his followers have continued them; thus they have got footing among most nations, and make a considerable part of most established religions. The Egyptian priests had their diurnal and nocturnal ablutions: the Grecians their sprinklings: the Romans their lastrations and lavations: the Jews their washing of hands and feet, besides their baptisms. The ancient Christians had their ablutions before communion; which the Romish church still retain before their masses, sometimes after: the Syrians, Copts, &c. have their solemn washings on Good Friday: the Turks their greater and lighter ablutions; their Ghaft and Wodon, their Aman, Taharat, &c.

Abner, the son of Ner, father-in-law to Saul, and general of all his forces, who served him on all occasions with fidelity and courage. After the death of that prince, Abner set Ishbooth, Saul's son, on the throne. A war breaking out between the tribe of Judah who had elected David king, and Israel, Abner marched against that prince with the flower of his troops, but was defeated. Abner afterward, being disdained, went over to David, and disposed the chiefs of the army and the elders of Israel to declare for him; and was received by David with such testimonies of affection, as gave umbrage to Joab, who killed him traitorously.
ABONOA, now Årno, a long range of mountains in Germany, taking different names according to the different countries they run through. As about the river Maine, called the Odenwald, between Hesse and Frankfort, the Speich; and about the duchy of Wirtemberg, where the Danube takes its rise, called the Baar.

ABO, a maritime town in Sweden: it is the capital of the province of Finland, and lies upon the point where the gulfs of Bothnia and Finland unite. It is a good port; and is the seat of a bishop, suffragan of Upsal. It has an university, founded by queen Christina in 1640, and endowed with the same privileges as that of Upsal. There is also a school here, which was founded by Gustavus Adolphus, for 300 scholars.

The town is tolerably well built, and contains several brick buildings; but the generality are of wood painted red. The inhabitants export linen, corn, and planks. It lies 120 miles north-east from Stockholm.

L. Long. 21. 28. Lat. 60. 50.

ABOARD, the inside of a ship. Hence any person who enters a ship is said to go aboard: but when an enemy enters in the time of battle, he is said to board; a phrase which always implies hostility.—To fall aboard of, is to strike or encounter another ship when one or both are in motion, or to be driven upon a ship by the force of the wind and current.—Aboard main-tack, the order to draw the main-tack, i.e. the lower corner of the main-sail, down to the Chess-tree.

ABOLITION, implies the act of annihilating, destroying, making void, or reducing to nothing. In law, it signifies the repealing any law or statute.

ABOLL, a warm kind of garment, lined or doubled, worn by the Greeks and Romans, chiefly out of oxen, goats, of the fourth quality of this garment. The pallium, or cloak. The abomasus, or abominat.
The term Abortion, though so famous in antiquity, is used in modern geography only occasionally as an apppellative. It is given to the primitive inhabitants of a country, in contradistinction to colonies, or new races of people.

ABORTION, in midwifery, the exclusion of a foetus before it has acquired a sufficient degree of perfection to enable it to perform respiration and the other vital functions. See MIDWIFERY.

The practice of procuring abortions was prohibited by the ancient Greek legislators Solon and Lycurgus. Whether or not it was permitted among the Romans, is used in modern geography only occasionally as an apppellative.

There was a council by them called vifcera, over which was by them called vifcera, over which was by them called ufed in modern geography only occasionally as an apppellative.

Whether or not it was permitted among the Romans, is used in modern geography only occasionally as an apppellative.

Moreover, the negative; and may be observed, that often all the powers of art prove ineffectual, and no less often do the consequences which they occasion, that the crime amounted to little more than the penalty had the same power to leave the ship's crew to prepare for tacking.

ABORTIVE CORN, a distemper of corn mentioned by M. Gillet, and fungicide to be occasioned by insects. It appears long before harvest, and may be known by a deformity of the stalk, the leaves, the ear, and even the grain.

ABORTIVE Vellum is made of the skin of an abortive calf.

ABOUKIR, a small town of Egypt, situate in the desert between Alexandria and Rosetta. It is the ancient Canopus, and is situated, according to Mr Savary, fix leagues from Pharos. Pliny says, from the testimonies of antiquity, that it was formerly an island: and its local appearance makes this credible; for the grounds around it are so low, that the sea still covers a part of them in the days of Strabo. The town is built upon a rock, which forms a handsome road for shipping, and is out of the reach of inundations. See CANOPUS.

ABOUT, the situation of a ship immediately after she has tacked, or changed her course by going about and standing on the other tack.—About ship! the order to the ship's crew to prepare for tacking.

ABOUTIGE, a town in Upper Egypt, on Africa, near the Nile where they make the best opium in all the Levant. It was formerly a large, but now is a mean place. N. Lat. 26° 30'.

ABRA, a silver coin struck in Poland, and worth about one shilling Sterling. It is current in several parts of Germany, Constantinople, Afracan, Smyrna, and Grand Cairo.

ABRABANELS, of ABRABANELS, or ABRAYANEL, (Isaac), a celebrated rabbi, descended from King David, and born at Lisbon A.D. 1437. He became counsellor to Alphonso V. king of Portugal, and afterwards to Ferdinand the Catholic; but in 1492 was obliged to leave Spain with the other Jews. In short, after residing at Naples, Corfu, and several other cities, he died at Venice in 1508, aged 71. Abrabanel passed for one of the most learned of the rabbis; and the Jews gave him the name of the Sage, the Prince, and the Great Politician. We have a commentary of his on all the Old Testament, which is pretty scarce: he there principally adheres to the literal sense; and his style is clear, but a little diffuse. His other works are: A Treatise on the Creation of the World; in which he refutes Aristotle, who imagined that the world was eternal: A Treatise on the explication of the prophecies relating to the Messiah, against the Christian: A book concerning articles of Faith; and some others lefts fought after. Though Abrabanel discourses his implacable a-version to Christianny in all his writings, yet he treats of Christians with politeness and good-manners in the common affairs of life.

ABRACADABRA, a magical word, recommended by Serenus Samonicus as an antidote against agues and several other illnesses. It was to be written upon a piece of paper as many times as the words contain letters, omitting the last letter of the former every time, as in the margin, and repeated in the same order: and then suffused about the neck by a linen thread. Abracadabra was the name of a god worshiped by the Syrians; so wearing his name was a sort of invocation of his aid: a practice which, though not more nefecity, yet was least ir- rationally, that is the equally heathenish practice, among those who call themselves Christians, of wearing various things, in expectation of their operating by a sympathy, whose parents were Ignorance and Superstition.

ABRAHAM, the father and stock whence the faithful sprung, was the son of Terah. He was descended from Noah by Shem, from whom he was nine degrees removed. Some fix his birth in the 130th year of Terah's age, but others place it in his father's 70th year. It is highly probable he was born in the city of Ur, in Chaldea, which he and his father left when they went
Abraham went to Canaan, where they remained till the death of Terah; after which, Abraham returned his first design of going to Palestine. The Scriptures mention the several places he lodged in Canaan, on his journeying into Egypt, where his wife was carried off from him; his going into Gerar, where Sarah was again taken from him, but restored as before; the victory he obtained over the four kings who had plundered Sodom; his compliance with his wife, who intimated that he should make use of her maid Hagar in order to raise up children; the covenant God made with him, sealed with the ceremony of circumcision; his obedience to the command of God, who ordered him to offer up his only son as a sacrifice, and how that bloody act was prevented; his marriage with Keturah; his death at the age of 175 years; and his interment at the cave of Macpelah, near the body of Sarah his first wife. It would be of little use to dwell long upon these particulars, since they are so well known. But tradition has supplied numberless others, the mention of one or two of which may not be unacceptable.

Many extraordinary particulars have been told relating to his conversion from idolatry. It is a pretty general opinion, that he sucked in the poison with his mother, and that his father being gone a journey, left him to fell the flames, excepting the man, brig were 365 heavens between the earth and it. Also no deity but the Geu efin.

Abraham is said to have been well skilled in many sciences, and to have wrote several books. Josephus tells us that he taught the Egyptians arithmetic and geometry; and, according to Eusebius and Aratianus, he instructed the Phoenicians, as well as the Egyptians, in astronomy. A work which treats of the creation has been long ascribed to him; it is mentioned in the Talmud, and the Rabbis Chana, and Hofciba used to read it on the eve before the sabbath. In the first ages of Christianity, according to St Epiphanius, there were sects called Sethinians. Some Jewish authors relate, that Abraham followed the fame trade with Terah for a considerable time. Maimonides says, that he was bred up in the religion of the Sabæans, who acknowledged no deity but the stars; that his reflections on the nature of the planets, his admiration of their motions, beauty, and order, made him conclude there must be a being superior to the machine of the universe, a being who created and governed it.

Looking to an old tradition, he did not renounce paganism till the 50th year of age. It is related, that his father being gone on a journey, left him to fell the flames, excepting the man, who pretended to be a pedlar, asked him how old he was, Abraham answered, "Fifty." "Wretch that thou art, (said the other,) for adoring at such an age, a being which is but a day old!" These words greatly confounded Abraham. Some time afterwards, a woman brought him some flour, that he might give it as food to the flames; "Upon which (said he), the god you see there, being the flousted, bade the others to pieces with that hatchet." Terah told him this was butting; for those idols had not the fene to act in this manner. Abraham retorted these words upon his father against the worshipping of such gods. Terah, hugging with his rafter, delivered up his son to the cognition of Nimrod, the sovereign of the country: who exhorted Abraham to worship the fire; and, upon his refusal, commanded him to be thrown into the midst of the flames: "Now let your God (said he) come and deliver you!" But (adds the tradition) Abraham came safe and sound out of the flames. This tradition is not of modern date, since it is told by St. Jerome; who seems to credit it in general, but disbelives that part of it which makes Terah so cruel as to be the informer against his own son. Perhaps the authority of the words of the tradition is given to the father in the form is mentioned above. It is the proper name of a city, and it also signifies a father. The Heretical son.

Abraham uttered the following words, which God says to Abraham (Gen. xv. 7): "Now the Lord that brought thee out of Ur of the Chaldees, imagine that he saved him from a great perfection, since he employed the very same words in the beginning of the decalogue to denote the deliverance from Egypt.

Abraham has been long ascribed to him; it is mentioned in the Talmud, and the Rabbis Chana, and Hotchiba used to read it on the eve before the sabbath. In the first ages of Christianity, according to St. Epiphanius, there were sects called Sethinians. Some Jewish authors relate, that Abraham followed the same trade with Terah for a considerable time. Maimonides says, that he was bred up in the religion of the Sabæans, who acknowledged no deity but the stars; that his reflections on the nature of the planets, his admiration of their motions, beauty, and order, made him conclude there must be a being superior to the machine of the universe, a being who created and governed it.

Some time afterwards, a woman brought him some flour, that he might give it as food to the flames; "Upon which (said he), the god you see there, being the flousted, bade the others to pieces with that hatchet." Terah told him this was butting; for those idols had not the fene to act in this manner. Abraham retorted these words upon his father against the worshipping of such gods. Terah, hugging with his rafter, delivered up his son to the cognition of Nimrod, the sovereign of the country: who exhorted Abraham to worship the fire; and, upon his refusal, commanded him to be thrown into the midst of the flames: "Now let your God (said he) come and deliver you!" But (adds the tradition) Abraham came safe and sound out of the flames. This tradition is not of modern date, since it is told by St. Jerome; who seems to credit it in general, but disbelives that part of it which makes Terah so cruel as to be the informer against his own son. Perhaps the authority of the words of the tradition is given to the father in the form is mentioned above. It is the proper name of a city, and it also signifies a father. The Heretical son.
ABRASION, is sometimes used among medicinal writers, for the effect of sharp corrosive medicines, or humours in wearing away the natural mucous which covers the membranes, and particularly those of the fo- 
mach and intestines. The word is composed of the Latin ab and rados to shave or scrape off.

ABRAVANNUS (anc. geog.) the name of a pro-
montory and river of Galloway, in Scotland, so called from the Celtic terms Ebor, signifying either the mouth of a river, or the confluence of two rivers, and Aboon, a river.

ABRAUM, in natural history, a name given by some writers to a species of red clay used in England by the cabinet makers, &c. to give a red colour to new mahogany wood. We have it from the file of Wight; but it is also found in Germany and Italy.

ABRASAS, an antique stone with the word abrassat engraven on it. They are of various sizes, and most of them as old as the third century. They are frequent in the cabinets of the curious; and a collection of them, as complete as possible, has been desired by several. There is a fine one in the abbey of St Geneviève, which has occasioned much speculation. Most of them seem to have come from Egypt; whence they are of some use for explaining the antiquities of that country. Sometimes they have no other inscription besides the word: but others have the names of saints, angels, or Jehovah himself annexed; though most usually the name of the Basildian god. Sometimes there is a re- 
presentation of Isis sitting on a liones, or apis, surrounded with stars; sometimes monstrous compositions of animals, obscene images, Phalli and ithyfalli. The graving is rarely good, but the word on the reverse is sometimes said to be in a more modern taste than the other. The characters are usually Greek, Hebrew, Coptic, or Hetnerian, and sometimes of a mongrel kind, invented, as it would seem, to render their meaning the more intractable. It is disputed whether the Vestal Virgins, or other granite obelisk mentioned by Gori, be abrassases.

ABREAST (a sea-term), side by side, or opposite to; a situation in which two or more ships lie, with their sides parallel to each other, and their heads equally advanced. This term more particularly regards the line of battle at sea, where, on different occasions of attack, retreat, or pursuit, the several squadrons or divisions of a fleet are obliged to vary their dispositions, and yet maintain a proper regularity by falling in right or curved lines. When the line is formed abreast, the whole squadron advances uniformly, the ships being equally distant from and parallel to each other, so that the length of each ship forms a right angle with the extent of the squadron or line abreast. The commander in chief is always stationed in the centre, and the second and third in command in the centre of their respective squadrons. Abreast, within the ship, implies on a line with the beam, or by the side of any object aboard; as, the frigate sprang a leak abreast of the main-hatch-way, i.e. on the same line with the main hatch-way, cutting the ship's length at right angles, in opposition to aove or abash the hatch-way. We discovered a fleet abreast of Bexley-head; i.e. off, or abreast, directly opposite to it.

ABRITTE, or Abrettine (anc. geog.), a di-
strict of Syria, in Asia. Hence the epithet Abretnus given to Jupiter (Strabo), whose priest was Ebon, formerly at the head of a gang of robbers, and who received many and great favours at the hands of Augustus, but afterwards went over to Augus. The people were called Abretti: inhabiting the country between Ancya of Phrygia, and the river Rhynidac.

ABRIDGEMENT, in literature, a term signify-
ing the reduction of a book into a smaller compass. The art of conveying much sentiment in few words, is the happiest talent an author can be possessed of. This talent is peculiarly necessary in the present state of literature; for many writers have acquired the dexterity of spreading a few critical thoughts over several hundred pages. When an author hits upon a thought that pleases him, he is apt to dwell upon it, to view it in different lights, to force it in improperly, or upon the lightest relations. Though this may be pleasant to the writers, it tires and vexes the reader. There is another great source of diffusion in composition. It is a capital object with an author, whatever be the sub-
ject, to give vent to all his thoughts. When he finds a proper place for any of them, he is peculiarly happy. But, rather than sacrifice a thought he is fond of, he forces it in by way of digression, or superfluous illuration. If none of these expedients answer his purpose, he has recourse to the margin, a very conven-
ient apartment for all manner of pedantry and imper-
tinenre. There is not an author, however correct, but is more or less faulty in this respect. An abridger, however, is not subject to these temptations. The thoughts are not his own; he views them in a cooler and less affectionate manner; he discovers an impropriety in some, a vanity in others, and a want of utility in many. His butifens, therefore, is to retrench superfluities, digressions, quotations, pedantry, &c. and to lay before the public only what is really useful. This is by no means an easy employment: To abridge some books, requires talents equal, if not superior, to those of the author. The facts, manner, spirit, and reafoning, must be preserved; nothing essential, either in argument or illuration ought to be omitted. The difculty of the task is the principal reason why we have so few good abridgements: Wynne's abridgment of Locke's Essay on the Human Understanding, is, per-
haps, the only unexceptionable one in our language. These observations relate solely to such abridgements as are designed for the public. But,

When a person wants to fet down the substance of any book, a shorter and less laborious method may be followed. It would be foreign to our plan to give ex-
amples of abridgements for the public: But as it may be useful, especially to young people, to know how to abridge books for their own use after giving a few di-
rections, we shall exhibit an example or two, or show what safe it may be done.

Read the book carefully; endeavour to learn the principal view of the author, attend to the arguments employed: When you have done so, you will generally find, that what the author uses as new or additional arguments, are in reality only collateral ones, or exten-
tions of the principal argument. Take a piece of
Abridging is peculiarly useful in taking the substance
Abridgments are brief summaries of texts.

---

...paper or a common-place book, put down what the
author wants to prove, follow the argument or argu-
ments, and you have the substance of the book in a
few lines. For example,

In the Essay on Miracles, Mr Hume's design is to
prove, That miracles which have not been the imme-
diate objects of our senses, cannot reasonably be be-
lieved upon the testimony of others.

Now, his argument (for there happens to be but one)
is,

"That experience, which in some things is variable,
"in others uniform, is our only guide in reaoning
"concerning matters of fact. A variable experience
gives rise to probability only; an uniform experi-
ence amounts to a proof. Our belief of any fact
"from the testimony of eye-witnesses is derived from
"no other principle than our experience in the vera-
city of human testimony. If the fact attested be
"miraculous, here arises a contest of two opposite ex-
periences, or proof against proof. Now, a miracle
"is a violation of the laws of nature; and as a firm and
"unfavorable experience has established these laws, the
"proof against a miracle, from the very nature of the
"fact, is as complete as any argument from experi-
ence can possibly be imagined; and if so, it is an un-
"deniable consequence, that it cannot be furbombed by
"any proof whatever derived from human testimony."

In Dr Campbell's Dissertation on Miracles, the au-
thor's principal aim is to shew the fallacy of Mr Hume's
argument; which he has done most successfly by
another single argument, as follows:

"The evidence arising from human testimony is not
"solely derived from experience: on the contrary, te-
"limony hath a natural influence on belief antece-
dent to experience. The early and unlimited affer-
given to testimony by children gradually con-
as they advance in life: it is, therefore, more con-
fonant to truth, to lay, that our diSference in testimo-
ny is the result of experience, than that our faith in
"it has this foundation. Besides, the uniformity of
"experience, in favour of any fact, is not a proof a-
"gainst its being reversed in a particular instance.
"The evidence arising from the single testimony of a
"man of known veracity will go further to establish a
"belief in its being actually reversed: If his testimo-
"ny be confirmed by a few others of the same charac-
ter, we cannot withhold our assent to the truth of it.
"Now, though the operations of nature are governed
"by uniform laws, and though we have not the testi-
mony of our senses in favour of any violation of
"them; still, if in particular instances we have the
"testimony of thousands of our fellow-creatures, and
"those too, men of strict integrity, swayed by no mo-
tives of ambition or interest, and governed by the
"principles of common-fence, That they were actu-
"ally eye-witnesses of these violations, the constitu-
tion of our nature obliges us to believe them.

These two examples contain the substance of about
400 pages. Making private abridgements of this
kind has many advantages; it engages us to read with
accuracy and attention; it fixes the subject in our minds: and, if we should happen to forget, instead of
reading the book again, by glancing a few lines we are
not only in poifession of the chief arguments, but re-
call in a good measure the author's method and manner.

vL. 1.
and still is, their staple commodity: the flocks, after palling the whole summer in the fine pastures of the mountains, are driven for the winter into the warm plains of Puglia, and a few spots near their own coast, where the snow does not lie; there are no manufactures of woollens in the province, except two small ones where the snow does not lie; there are no of coarse cloth, and the greatest part of the wool is sent out unwrought. No silk is made here, though mulberry-trees would grow well in the low grounds.

Formerly the territory of Aquila furnished Italy almost exclusively with silk; but since the culture of that plant has been so much followed in Lombardy, it has fallen to nothing in Abruzzo. In the maritime tracks of the country the cultivation of liquorice has been increased of late years, but foreigners export the roots in their Sophistic pursuit to a similar climate, came, and disposed of them. The Greeks, who retained almost every other part of the kingdom under their dominion, never had any sway here. For this reason the Abruzzesi still bear a great resemblance to their northern progenitors or mailers: to this day, one may trace in them the same goodness of heart, but great indulgence, and repugnance to lively exertions; a fault that proceeds rather from a want of active virtue, than a disposition to wickedness. Hence it comes that in the provinces, where the proximity of the frontier almost infuses impurity, fewer atrocious and inhuman deeds are heard of than in other parts of the realm. Remnants of ancient northern customs existed here so late as the beginning of this century, and, among the mountaineers, very evident traces of the Frank and Teutonic languages may be discovered.

ABSALOM, the son of David by Maachah, was brother to Thamar, David's daughter, who was ravished by Amnon their eldest brother by another mother. Absalom waited two years for an opportunity of revenging the injury done to his father; and at last procured the assassination of Amnon at a feast which he had prepared for the king's sons. He took refuge with Talmi king of Gethin; and was no sooner restored to favour, but he engaged the Israelites to revolt from his father. Absalom was defeated in the wood of Ephraim: as he was flying, his hair caught hold of an oak, where he hung till Joab came and thrust him through with three darts: David had expressly ordered his life to be spared, and extremely lamented him.

ABSCESS, in surgery; from abscedo, to depart. A cavity containing pus; or, a gathering of matter in a part. So called, because the parts which were joined are now separated; one part recedes from another, to make way for the collected matter. See SURGERY.

ABSCISSA, in conics, a part of the diameter or transverse axis of a conic section intercepted between the vertex or some other fixed point and a semidiameter. See CONIC SECTIONS.

ABSCONSA, a dark lantern used by the monks at the ceremony of burying their dead.

ABSENCE, in Scots law: When a person cited before a court does not appear, and judgment is pronounced, that judgment is said to be in abscence. No person can be tried criminally in abscence.

ABSINTHIATED, any thing tinged or impregnated with absinthium or wormwood. Bartholin mentions a woman whose milk was become abstiniated, and rendered as bitter as gall, by the too liberal use of wormwood. 

Vinum absintinites, or pectorum absinthitium, "wormwood wine," is much spoke of among the ancients as a whole-
wholesome drink, and even an antidote against drunkenness, though some have charged it with being offensive to the head, and liable to cause fevers, cephalalgias, vomitings, uterine fluxes, &c. Ray also makes it a preventative of venery. According to the common opinion, it is made by infusing the leaves of the plant in wine; but, according to Fehr, it ought to be prepared by fermentation, in order to correct the crudities, and call forth a volatile salt; which last, however, does not exist in wormwood. Some prefer the distilled water, but whatever virtues wormwood possesses reside entirely in its essential oil.

ABSINTHIUM, in botany, the trivial name of the common wormwood. See the article ARTEMISIA.

ABSIS, in astronomy, the same with apsis. See APSIS.

ABSOlute, in a general sense, something that stands free or independent.

Absolute is more particularly understood of a being or thing which does not proceed from any cause, or does not subsist by virtue of any other being, considered as its cause; in which sense, God alone is absolute. Absolute, in this sense, is synonymous with independent, and stands opposed to dependent.

Absolute also denotes a thing's being free from conditions or limitations; in which sense, the word is synonymous with unconditional. We say, an absolute decree, absolute promise, absolute obedience.

Absolute Government, that wherein the prince is left solely to his own will, being not limited to the observance of any laws except those of his own direction.

Absolute Equation, in astronomy, is the aggregate of the optic and eccentric equations. The apparent inequality of a planet's motion arising from its not being equally distant from the earth at all times, is called its optic equation, and would subsist even if the planet's real motion were uniform. The eccentric inequality is caused by the planet's motion being uniform. To illustrate which, conceive the sun to move, or to appear to move, in the circumference of a circle, in whose centre the earth is placed. It is manifest, that if the sun moves uniformly in this circle, it must appear to move uniformly to a spectator on the earth, and in this case there will be no optic nor eccentric equation: but suppose the earth to be placed out of the centre of the circle, and then, though the sun's motion should be really uniform, it would not appear to be so, being seen from the earth; and in this case there would be an optic equation, without an eccentric one. Imagine farther, the sun's orbit to be not circular, but elliptic, and the earth in its focus; it will be as evident that the sun cannot appear to have a uniform motion in such ellipse: so that his motion will then be subject to two equations, the optic and the eccentric.

Absolute Number, in algebra, is any pure number standing in any equation without the conjunction of literal characters; as $2x + 5y = 28$; where 36 and 48 are absolute numbers, but 2 is not, as being joined with the letter $x$.

ABSOLUTION, in civil law, is a sentence whereby the party accused is declared innocent of the crime laid to his charge. Among the Romans, the ordinary method of pronouncing judgment was this: after the caufe had been pleaded on both sides, the praecox used the word dixerunt, q.q.d. they said what they had to say; then three ballots were distributed to each judge, marked as mentioned under the article A; and as the majority fell of either mark, the accused was absolved or condemned, &c. If he were absolved, the praecox dismissed him with videtur non esse, or juster est esse.

ABSOLUTION, in the canon law, is a judicial act, whereby the priest declares the sins of such as are present remitted. The Romanists hold absolution a part of the sacrament of penance: the council of Trent, feu. xiv. cap. iii. and that of Florence, in the decree ad Armenos, declare the form or essence of the sacrament to lie in the words of absolution, I absolve thee of thy sins. The formula of absolution, in the Romish church, is absolute: in the Greek church it is deprecatory; and in the churches of the reformed, declarative.

ABSOLUTION is chiefly used among protestants for a sentence whereby a person who stands excommunicated is released or freed from that punishment.

ABSORBENT, in general, any thing possessing the faculty of absorbing, or swallowing up another. ABSORBENT Medicines, tinctures, powders, as chalk, crab-eyes, &c. which are taken inwardly for drying up or absorbing any acid or redundant humours in the stomatch or intestines. They are likewise applied outwardly to ulcers or sores with the same intention.

ABSORPTION Vesels, a name given promiscuously to the lasteal vessels, lymphatics, and inhalent arteries. See Anatomy.

Naturalists speak of the like absorbents in plants, the fibrous or hairy roots of which are as a kind of vas absorbentia, which attract and imbibe the nutritious juices from the earth. See PLANTS.

ABSORBING, the swallowing up, sucking up, or imbibing any thing: thus black bodies are said to absorb the rays of light; luxuriant branches, to absorb or waste the nutritious juices which should feed the fruit of trees, &c.

ABSORPTION, in the animal economy, is the power whereby the absorbent vessels imbibe the juices, &c.

ABSORPTIONS of the Earth, a term used by Kircher and others for the finking in of large tracts of land by means of subterraneous commotions, and many other accidents.

Pliny tells us, that in his time the mountain Cymbotus, with the town of Eurus, which stood on its side, were wholly absorbed into the earth, so that not the least trace of either remained; and he records the like fate of the city Tantalus in Magnesia, and after it of the mountain Syelbus, both thus absorbed by a violent opening of the earth. Galanis and Garnatus, towns once famous in Phocis, are recorded to have met the same fate: and the well promontory, called Phlegethon, in Ethiopia, after a violent earthquake in the night-time, was not to be seen in the morning, the whole having disappeared, and the earth closed over it. These and many other histories, attested by the authors of greatest credit among the ancients, abundantly prove the fact in the earlier ages; and there have been not wanting too many instances of more modern date. Kircher's Mund. Subterr. p. 77. See EARTH and EARTHQUAKE.
Abstemious, properly understood of a person who refrains absolutely from all use of wine.

The history of Mr. Wood, in the Medici. Trans. vol. ii. p. 261. art. 18. is a very remarkable exemplification of the very beneficial alterations which may be effected on the human body by a strict course of abstinence.

The Roman ladies, in the first ages of the republic, were all enjoined to be abstemious; and that it might appear, by their breath, whether or no they kept up themselves the use of such meats as were prohibited by that selection of ancient authors.

Abstemiosus (Laurentius), a native of Macerata, professor of belles lettres in Urbino, and librarian of Duke Guido Ubaldo, under the pontificate of Alexander VI. He wrote, 1. Notes on most difficult passages of ancient authors. 2. Hecatomthyum, i. e. A collection of 100 fables, &c. which have been often printed with those of Aesop, Phaedrus, Gabrias, Avicinus, &c.

Abstergent medicines, those employed for resolving obstructions, concretions, &c. such as soap, &c.

Abstinence, in a general sense, the act or habit of refraining from something which we have a propensity to or find pleasurable. Among the Jews, various kinds of abstinence were ordained by their law.

Among the primitive Christians, some denied themselves the use of such meats as were prohibited by that law, others looked upon this abstinence with contempt; as to which, St. Paul gives his opinion, Rom. xiv. 1 - 3. The council of Jerusalem, which was held by the Apostles, enjoined the Christian converts to abstain from meats strained, from blood, from fornication, and from idolatry. Abstinence, as prescribed by the gospel, is intended to mortify and restrain the passions, to humble our vicious natures, and by that means raise our minds to a due sense of devotion. But there is another sort of abstinence, which may be called ritual, and consists in abstaining from particular meats at certain times and feasts. It was the spiritual monarchy of the western world which first introduced this ritual abstinence; the rules of which were called regulations; but grotesquely abused from the true nature and design of fasting. In England, abstinence from flesh has been enjoined by statute even since the reformation, particularly on Fridays and Saturdays, on vigilis, and on all commonly called fast-days. The like injunctions were renewed under Elizabeth: but at the same time it was declared, that this was done not out of motives of religion, as if there were any difference in meats; but in favour of the consumption of fish, and to multiply the number of fishermen and mariners, as well as spare the flock of the sheep. The great fault, says St. Augustine, is to abstain from sin.

Abstinence is more particularly useful for a spare diet, or a slender parthimonious use of food, below the ordinary standard of nature. The physicians relate wonders of the effects of abstinence in the cure of many disorders, and protracting the term of life. The noble Venetian, Cornaro, after all imaginable means had proved vain, so that his life was despaired of at 40, recovered, and lived to near 100, by mere dint of abstinence; as he himself gives the account. It is indeed surprising to what a great age the primitive Christians of the east, who retired from the persecutions into the deserts of Arabia and Egypt, lived, healthful and cheerful, on a very little food. Cassian affures us, that the common rate for 24 hours was 12 ounces of bread, and mere water; with this St. Anthony lived 105 years; James the Hermit 104; Arsenius, tutor of the Emperor Arcadius, 120; S. Ephraim, 115; Simeon the Stylite, 112; and Rumauld, 120. Buchanan writes, that in Scotland one Laurence preferred himself to 450 by force of temperance and labour; and Spottwood mentions one Kentigern, afterwards called S. Mongah or Mungo, who lived to 185 by the same means. Other instances see under the article Longevity.

Abstinence, however, is to be recommended only as it means a proper regimen; for in general it must have bad consequences when observed without a due regard to constitution, age, strength, &c. According to Dr. Cheyne, most of the chronic diseases, the infirmities of old age, and the short lives of Englishmen, are owing to repletion; and may be either cured, prevented, or remedied by abstinence: but then the kinds of abstinence which ought to obtain, either in sickness or health, are to be deduced from the laws of diet and regimen.

Among the brute creation, we see extraordinary instances of long abstinence. The serpent-kind, in particular, bear abstinence to a wonderful degree. We have seen rattle-shakes that had subsisted many months without any food, yet still retained their vigour and fierceness. Dr. Shaw speaks of a couple of serpents, (a sort of Egyptian serpents,) which had been kept five years in a bottle close corked, without any sort of food, unless a small quantity of sand wherein they coiled themselves up in the bottom of the bottle may be reckoned as such; yet when he fed them, they had newly cast their skins, and were as brisk and lively as if just taken. But it is even natural for divers species to pass four, five, or six months every year, without either eating or drinking. Accordingly, the tortoise, bear, dormouse, serpent, &c. are observed regularly to retire, at these seasons, to their respective cells, and hide themselves, some in the caverns of rocks or ruins; others dig holes under ground; others get into woods, and lay themselves up in the crevices of trees; others bury themselves under water, &c. And these animals are found as fat and fleshy after some months abstinence as before.

Sir G. Ent* weighed his tortoise several years successively, at its going to earth in October, and coming out again in March; and found, that of four pounds, twelve ounces, it only used to lose about one ounce.

*Phil. Trans.
Abstinence months as strictly abstinence as other creatures. In particular, the records of the Tower of London mention a Scotchman imprisoned for felony, and strictly watched in for three weeks: in all which time he took not the least sustenance: for which he had his pardon. Numberless instances of extraordinary abstinence, particularly from morbid causes, are to be found in the different periodical Memoirs, Transactions, Ephemerides, &c. It is to be added, that, in most instances of extraordinary human abstinence related by naturalists, there were said to have been apparent marks of a texture of blood and humours, much like that of the animals abovementioned. Though it is no improbable opinion, that the air itself may furnish something for nutrition. It is certain, there are substances of all kinds, animal, vegetable, &c. floating in the atmosphere, which must be continually taken in by respiration. And that an animal body may be nourished thereby, is evident in the instance of vipers; which if taken when first brought forth, and kept from every thing but air, will yet grow very considerably in a few days. So the eggs of lizards are observed to increase in bulk, after they are produced though there be nothing to furnish the increment but air alone; in like manner as the eggs or spawn of fishes grow and are nourished with the water. And hence, say fome, it is that cooks, turnpits, dogs, &c. though they eat but little, yet are usually fat. See Fasting.

ABSTINENTS, or ABSTINENTS, a set of heretics that appeared in France and Spain about the end of the third century. They are supposed to have borrowed part of their opinions from the Gnostics and Manicheans, because they opposed marriage, condemned the use of flesh meat, and placed the Holy Ghost in the place of created beings. We have, however, no certain account of their peculiar tenets. See ABSTRACTION.

ABSTRACT, in a general sense, any thing separated from something else. ABSTRACT Idea, in metaphysics, is a partial idea of a complex object, limited to one or more of the component parts or properties, laying aside or abstracting from the rest. Thus, in viewing an object with the eye, or recollecting it in the mind, we can easily abstract from some of its parts or properties, and attach ourselves to others: we can attend to the redness of a cherry, without regard to its figure, taste, or consistence. See ABSTRACTION.

ABSTRACT Terms, words that are used to express abstract ideas. Thus beauty, ugliness, whiteness, roundness, life, death, are abstract terms. ABSTRACT Numbers, are assemblages of units, considered in themselves without denoting any particular and determined particulars. Thus 6 is an abstract number, when not applied to anything; but, if we say 6 feet, 6 becomes a concrete number. See the article NUMBERS.

ABSTRACT Mathematics, otherwise called Pure Mathematics, is that which treats of magnitude or quantity, absolutely and generally considered, without restriction to any species of particular magnitude; such are Arithmetic and Geometry. In this sense, abstract mathematics is opposed to mixed mathematics; wherein simple and abstract properties, and the relations of quantities primitively considered in pure mathematics, are applied to sensible objects, and by that means become intermixed with physical considerations; such as Hydrostatics, Optics, Navigation, &c.

ABSTRACT, in literature, a compendious view of any large work; shorter and more superficial than an abridgment.

ABSTRACTION, in general, the act of abstracting, or the state of being abstracted.

ABSTRACTION, in metaphysics, the operation of the mind when occupied by abstract ideas. A large idea fixes our attention, and abstracts us from the troubles that surround it. In the same manner, a beautiful woman in a crowd, abstracts our thoughts, and engrosses our attention solely to herself. These are examples of real abstraction: when thee, or any others of a similar kind, are recalled to the mind after the objects themselves are removed from our sight, they form what are called abstract ideas, or the mind is said to be employed in abstract ideas. But the power of abstraction is not confined to objects that are separable in reality as well as mentally: the figure, the figure, the colour of a tree are inseparably connected, and cannot exist independent of each other; and yet we can mentally confine our observations to one of the properties, neglecting or abstracting from the rest.

Abstraction is chiefly employed these three ways. First, When the mind considers any one part of a thing, in some respect distinct from the whole; as a man's arm, without the consideration of the rest of the body. Secondly, When we consider the mode of any substance, omitting the substance itself; or when we separately consider several modes which subsist together in one object. This abstraction the geometers make use of when they consider the length of a body separately, which they call a line, omitting the consideration of its breadth and thickness. Thirdly, It is by abstraction that the mind forms general or universal ideas; omitting the modes and relations of the particular objects whence they are formed. Thus, when we should understand a thinking being in general, we gather from our self-consciousness what it is to think; and, omitting these things which have a particular relation to our own minds, or to the human mind, we conceive a thinking being in general.

Ideas formed in this manner, which are what we properly call abstract ideas, become general representatives of all objects of the same kind; and their names applicable to whatever exists conformable to such ideas. Thus the idea of colour that we receive from chalk, snow, milk, &c. is a representative of all that kind; and has a name given it, white, which signifies the same quality wherever found or imagined.

ABSTRUSE, something deep, hidden, concealed, or far removed from common apprehensions, and therefore not easily understood; in opposition to what is obvious and palpable. Thus metaphysics is an abstruse science; and the doctrine of fluxions, and the method de maxima et minima, are abstruse points of knowledge.

ABSURD, an epithet applied to anything that opposes the human apprehension and contradicts a manifest truth. Thus, it would be absurd to say that 6 and 6 make only 10, or to deny that twice 6 make 12. When the term absurd is applied to actions, it has the same import as ridiculous. ABSYN-
ABSYNTHIUM. See ABSINTHIUM.

ABSYNTHIUM, in the heathen mythology, the son of Eta and Hypsea, and the brother of Medea. The latter running away with Jason, after her having affinitiated him in carrying off the golden fleece, was perfured by her father; when, to stop his progress, the tears of Abysynius in pieces, and scattered his limbs in his way.

ABTHANES, a title of honour used by the ancient inhabitants of Scotland, who called their nobles thanes, which in the old Saxon signifies king's miniflers, and of thefe the higher rank were styled abithanes, and thole of the lower underthanes.

ABUCCO, Abuco, or Abocchi, a weight used in the kingdom of Pegu. One abucco contains 124, tectcalls; two abuccos make a giro or agire; two giri, half a hiza; and a hiza weighs an hundred tectcalls; that is, two pounds five ounces the heavy weight, or three pounds nine ounces the light weight of Venice.

ABUKESO, in commerce, the fame with ASLAN.

ABULFARAGIUS (Gregory), son to Aaron a physician, born in 1226, in the city of Malatia, near the source of the Euphrates in Armenia. He followed the profession of his father; and practifed with great success, numbers of people coming from the most remote parts to ask his advice. However, he would hardly have been known at this time, had his knowledge been confined to phyfic, but he applied himself to the study of the Hebrew, Syriac, and Arabic languages, as well as philosophy and divinity; and he wrote a hiftry which does honour to his memory. It is written in Arabic, and divided into diñtiftics. It consists of ten parts, being an epitome of universal hiftry from the creation of the world to his own time. Dr Pocock published it with a Latin translation in 1663; and added, by way of supplement, a short continuation relating to the hiftry of the eastern princes.

ABUNA, the title given to the archbishop or metropolis of Abyssinia. See Abyssinia.

ABUNDANT MEMBERS, in arithmetic, is a number, the sum of whose aliquot parts is greater than the number itself. Thus the aliquot parts of 12, being 1, 2, 3, 4, and 6, they make, when added together, 16. An abundant number is oppofed to a deficient number, or that which is greater than all its aliquot parts taken together; as 14, whose aliquot parts are 1, 2, and 7, which make no more than ten: and to a perfect number, or one to which its aliquot parts are equal, as 6, whose aliquot parts are 1, 2, and 3.

ABUNDANTIA, a heathen divinity, repreffented in ancient monuments under the figure of a woman with a pleasing aspect, crowned with garlands of flowers, pouring all sorts of fruit out of a horn which she holds in her right hand, and feating grain with her left, taken poffecively from a sheaf of corn. On a medal of Trajan, she is repreffented with two cornucopias.

ABUSAID, (Ebn Aljapin), Sultan of the Moguls, fucceeded his father anno 717 of the hegira. He was the last monarch of the race of Jenghis Khan, and after his death, which happened the fame year that Tamerlane was born, the empire was made a scene of blood and defolation.

ABUS, (anc. geog.), a river of Britain, formed by the confluence of the Ure, the Derwent, Trent, &c. falling into the German sea, between Yorkshire and Lincolnshire, and forming the mouth of the Humber.

ABY, Abufc.

ABUSE, an irregular use of a thing, or the introducing something contrary to the true intention thereof. In grammar, to apply a word abufively, or in an abuse fene, is to mistake its meaning.

A permutation of benefices, without the consent of the bishop, is termed abufe, and consequently null.

ABUTILON, in botany, the trivial name of several species of the fida. SeeSRa.

ABYDOs, (anc. geog.), anciefly a town built by the Milefians in Asia, on the Hellespont, where it is fcarce a mile over, oppofite to Sefos on the European fide. Now both called the Dardanellae. Abyssos lay midway between Lampacus and Ilium, famous for Xerxes's bridge, (Herodotus, Virgil); and for the loves of Leander and Hero. (Mufaeus, Ovid;) celebrated also for its ruins, (Ennius, Virgil.) The inhabitants were a foil, effeminate people, given much to deftraction; hence the proverb, Ne teneres Abyssos when we would caution againil danger, (Stephanus).

ABYDOS, (anc. geog.), anciefly an inland town of Egypt, between Ptolemais and Diospolis Parva, towards Syene, famous for the palace of Memnon and the temple of Otiiris. A colony of Milefians; (Stephanus.) It was the only one in the country into which the fingers and dancers were forbid to enter.

This city, reduced to a village under the empire of Augufus, now presents to our view only an heap of ruins without inhabitation; but to the fleft of these ruins is still found the celebrated tomb of Isanderes. The entrance is under a portico 60 feet high, and supported by two rows of maffy columns. The immoveable folidity of the edifice, the huge maffes which compose it, the hieroglyphics it is loaded with, flamp it a work of the ancient Egyptians. Beyond it is a temple 300 feet long and 145 wide. Upon entering the monument we meet with an immenfe hall, the roof of which is supported by 28 columns 60 feet high and 19 in circumference at the base. They are 12 feet distant from each other. The enormous fones that form the ceiling, perfectly joined and inerupted, as it were, one in the other, offer to the eye nothing but one folid platform of marble 116 feet long and 26 wide. The walls are covered with hieroglyphics. One fees there a multitude of animals, birds, and human figures with pointed caps on their heads, and a piece of stuff hanging down behind, dressed in loose robes that came down only to the waif. The sculpture, however, is clumsy; the forms of the body, the attitudes and proportions of the members, ill observed. Amongst these we may dilinguish fome women suckling their children, and men presenting offerings to them. Here also we meet with the divinities of India. Monfieur Chevalier, formerly governor of Chandernagore, who refided 20 years in that country, carefully vifited this monument on his return from Bengal. He remarked here the gods Fagus, Grenet, Gomez, and Vechan or Wifnon, fuch as they are repreffented in the temples of Indoftan.—A great gate opens at the bottom of the fift hall, which leads to a apartment 46 feet long by 24 wide. Six square pillars support the roof of it; and at the angles are the doors of four other chambers, but f0choaked up with rubbith that they cannot now be entered. The falt hall, 64 feet long by 24 wide, has fairs by which one descends into the fubterraneous apartments of this grand edifice. The Arabs, in searching after treasure, have piled
ABY

ABY

Abydos

Aby.

piled up heaps of earth and rubbish. In the part we
are able to penetrate, sculpture and hieroglyphics are
discouraged as in the upper story. The natives say that
they correspond exactly with those above ground, and
that the columns are as deep in the earth as they are
lofty above ground. It would be dangerous to go far
into those vaults; for the air of them is so laden with a
nephtic vapour, that a candle can scarce be kept burn­
ing in them. Six lions heads, placed on the two sides
of the temple, serve as spouts to carry off the water.
You mount to the top by a

and

The walls, the roof, and the columns of this edifice,
have suffered nothing from the injuries of time; and
did not the hieroglyphics, by being corroded in some
places, mark its antiquity, it would appear to have been
newly built. The solility is such, that unless people
make a point of destroying it, the building must last
a great number of ages. Except the colossal figures,
whose heads serve as an ornament to the capitals of the
columns, and which are sculptured in relief, the rest
of the hieroglyphics which cover the inside are carved
in stone. To the left of this great building we meet
with another much smaller, at the bottom of which is
a fort of altar. This was probably the sanctuary
of the temple of Osiris.

ABYLA, (Ptolemy, Mela): one of Hercules’ pil­
lars on the African side, called by the Spaniards Sierr­
da de las Monas, over against Calpe in Spain, the other pillar
supposed to have been formerly joined, but dif­
parated by Hercules, and thus to have given entrance
to the sea now called the Mediterraneum: the limits
of the labours of Hercules, (Pline.)

ABYSS, in a general sense, denotes something pro­
found, and, as it were, bottomless. The word is or­
ierally Greek, Αύσσης, compounded of the primitive αυ,
and παρει, q.e.d. without a bottom.

Abyss, in a more particular sense, denotes a deep
mias or fund of waters. In this sense, the word is
particularly used, in the Septuagint, for the water
which God created at the beginning with the earth,
which replenished it round, and which our tran­
fators render by deep. Thus it is that darkness is said
to be upon the face of the abyss.

Abyss is also used for an immense cavern in the
earth, wherein God is supposed to have collected all
those waters on the third day; which, in our version,
is rendered the seas, and elsewhere the great deep. Dr
Woodward, in his Natural History of the Earth, af­
fers, That there is a mighty collection of waters in­
cluded in the bowels of the earth, constituting a huge
orb in the interior or central parts of it; and over the
surface of this water he supposes the terrestial strata to
be expanded. This, according to him, is what Moses
calls the great deep, and what most authors render the
great abyss. The water of this vast abyss, he alleg­
es, does communicate with that of the ocean, by means of
certain interstices or chasms passing betwixt it and
the bottom of the ocean; and this and the abyss he sup­
poses to have one common centre, around which the
water of both is placed; but that, the ordinary sur­
face of the abyss is not level with that of the ocean,
or at a great distance from the centre as the other,
ABY

Abyssinia, or by some called Higher Ethiopia, and by the Arabian Al Habab, is bounded on the north by Nubia; on the east, by the Arabic gulf or Red Sea, and the kingdom of Adel; on the south, by the kingdoms of Ajan, Alabo, and Gingiro; and on the west, by the kingdoms of Goram, and part of Gingiro; and is divided into a great number of provinces. The principal river is the Nile, which has its source in this region when father Lobo visited this country in 1624.

The soil of the country is various. In some places there are nothing but rocks and profound caverns: in others, especially where there are rivers, the lands exceeding luxuriously; and the banks of these streams are bordered with flowers of various kinds, many of which are unknown in Europe. The torrents in the rainy season wash a great deal of gold from the mountains. This country produces a great variety of animals, both tame and wild, such as lions, tigers, rhinoceroses, leopards, elephants, monkeys, flags, deer, horfes, camels, dromedaries, goats, cows, sheep; likewise ostriches, with a vast variety of other birds. In the rivers are crocodiles and the hippopotamus. Travellers mention also a peculiar kind of bees, small, black, and without a stinger, which live in the earth, and make honey and wax that are extremely white. The country is greatly infested with locusts, which devour every thing that is green wherever they come.

The inhabitants are Moors, Pagans, Jews, and Christians. The last was the reigning and established religion when father Lobo visited this country in 1624. This diversity of people and religion is the reason that the kingdom, in different parts, is under different forms of government, and that their laws and customs are extremely various. Some of the people neither sow their crops nor improve them; but live on milk and flesh, and encamp like the Arabs, without any settled habitation. In some places they practice rites of worship, though they believe that there dwells in the regions above a Being who governs the world: This deity they call Oul. In these parts where Christianity is professed, it is so corrupted with superstitions and errors, that they have nothing that is good, unless it be the name of Christ, which little by little is lost among them.

They have two harvests in the year; one in winter, which begins in May, and lasts, with great rigor, through the months of July, August, and September; and the other in spring.

Every man who has a thousand cows saves once a year a day's milk, and makes a bath for his friends; so that to give an idea of a man's wealth, their common expression is, he bathes so many times a-year. Their males marry about ten years old, and their females younger. Their marriage tie is to boole, that they part whenever they find that they cannot live agreeably together.

Besides the large towns, there are a great number of villages, which in some places are so thick, that they look like one continued town: the houses are very mean, being but one story high, and built of straw, earth, and lime. In most of the towns the houses are separated by hedges, which are always green, and mixed with flowers and fruit-trees at a certain distance from each other, which affords an agreeable prospect. The government is monarchical. The sovereign has the title of Negus, and is an absolute prince. When he is in camp, the tents are so regularly disposed as to have the appearance of a city; and there is a captain over every division, to prevent disorders, and to execute justice.

The Abyssinians in general are of an olive complexion, tall, graceful, and well featured. Those who are neither mechanics nor tradesmen (which few of them are) nor tillers of the ground, are inured to bear arms, which are a head-piece, a buckler, a coat of mail, bows and arrows, darts, pikes capped with iron at both ends, a fling, and a sword: they have very few fire-arms, and those were introduced by the Portuguese. The habit of perfons of quality is a fine silken vest, or fine cotton, with a kind of scarf. The citizens have the same habit, only coarser. The common people have nothing but a pair of cotton drawers, and a scarf, which covers the rest of their body. The women are of a healthy constitution, active, and moderately handsome, having neither flat noses nor thick lips like the negroes; and nature is so friendly, that they stand in little need of midwives, which is indeed the case, of most countries in the torrid zone. They appear in public as in Europe, without being forbidden the conversation of the men as among the Mahometans. Princesses of the royal blood are not permitted to marry foreigners: and when they take the air, they go in great state, with 400 or 500 women attendants. Their language is the Ethiopic, which bears a great affinity with the Arabic; but particular provinces have a different dialect.

Manufactures are almost wholly wanting in this country; and the few trades which they have amongst them are always conveyed from the father to the children. They seem indeed by their churches, and other ruined places, to have had a knowledge of architecture. But the workmen were sent for from other countries, and were forced to do all themselves; so that when these fabrics were reared, especially the imperial palace built by Peter Pais, a Portuguese architect, the people flocked from all parts of Ethiopia to view it, and admired it as a new wonder of the world. Gold, silver, copper, and iron, are the principal ores with which their mines abound in this extensive part of Africa; but not above one third part is made use of by way of merchandize, or converted into money, of which they have little or no use in Abyssinia. They cut their gold indeed into small pieces for the pay of their troops, and for expences of the court, which is but a modern custom among them;
Abyllinia, them; the king's gold, before the end of the 17th century, being laid up in his treasury in ingots, with intent to be never carried out, or never used in any thing but vellels and trinkets for the service of the palace.

In the lieu of small money, they make use of rock salt as white as snow and as hard as flone. This is taken out of the mountain of Lafa, and put into the king's warehouses; where it is reduced into tablets of a foot long, and three inches broad, ten of which are worth about a French crown. When they are circulated in trade, they are reduced into still smaller pieces, as occasion requires. This salt is also applied to the same purpofe as common sea-salt. With this mineral salt they purchase pepper, spices, and silk fuffs, which are brought to them by the Indians, in their ports in the Red Sea. Cardamums, ginger, aloes, myrrh, cassia, civet, ebony-wood, ivory, wax, honey, cotton and linnen of various forts and colours, are merchandizes which may be had from Abyllinia; to which may be added sugar, hemp, flax, and excellent wines, if these people had the art of preparing them. It is affirmed there are in this country the finest emeralds that are any where to be found; and, though they are found but in one place, they are there in great quantities, and some so large and so perfect as to be of almost inefitable value. The greatest part of the merchandise abovementioned, are more for foreign than inland trade. Their domestic commerce consists chiefly in salt, honey, buck-wheat, grey peafe, citrons, oranges, lemons, and other provisions, with fruits and herbage necessary for the fupport of life. Thofe places that the Abyssinian merchants frequent the moft, who dare venture to carry their commodities by sea themfelves, are Arabia Felix, and the Indies, particularly Goa, Cambay, Bengal, and Sumatra. With regard to their ports on the Red Sea, to which foreign merchants commonly refort, the moft confiderable are thofe of Mette, Azun, Zajalla, Maja, Dazo, Patea, and Brava. The trade of the Abyssinians by land is inconsiderable. There are, however, bands of them who arrive yearly at Egypt, particularly at Cairo, laden with gold dust, which they bring into trade for merchandise of that country, or of Europe, for which they have occasion. Thofe caffias or caravans, if we may be allowed thus to call a body of 40 or 50 poor wretches who unite together for their mutual affitance in their journey, are commonly three or four months on their route, traversing forests and mountains almost impaffable, in order to exchange their gold for necessaries for their families, and return immediately with the greatest part of the merchandise on their backs. Frequently the Jews or Egyptians give them large credit; which may feem surprising, as they are beyond recourfe if they shou'd fail of payment. But experience has shown, that they have never abus'd the confidence repofed in them; and even in the event of death, their fellow-travellers take care of the effects of the deceafed for the benefit of their families, but in the first place for the discharge of thofe debts contracted at Cairo.—It remains only to be obferved, that one of the principal branches of trade of the Abyssines is that of slaves, who are greatly efteemed in the Indies and Arabia for the beft and moft faithful, of all that the other kingdoms of Africa furnifh. The Indian and Arabian merchants frequently substitute them as their fafeguards; and on account of their good services and integrity, not only often give them their liberty, but liberally reward them.

Into this part of the globe the admiffion of travellers has been fuppos'd extremely difficult, and their return from thence almost impracticable. A Scotch gentleman, however, of family and fortune, James Bruce, Efq; of Kinnaird, is known not only to have entered that country, but to have refided in it feveral years, and returned safe home, bringing with him many great curiosities. Soon after his return, the following notice was given by the Count de Buffon in an advertisement prefixed to the 3d volume of his History of Birds: "A new aid which I have received, and which I am anxious to announce to the public, is the free and generous communication which I had of the drawings and observations of James Bruce, Efq; of Kinnaird, who returning from Abyssinia, and the interior parts of Abyllinia, has made a particular of the knowledge which he had acquired in a tour no less fatiguing than hazardous. It filled me with the utmost aflonishment to view the numerous drawings which he had made and coloured himself. He poliftles the moft perfect representations and descriptions of the birds, flowers, plants, edifices, monuments, arms, &c. of different nations, all of them objects worthy of knowledge. Nothing has escaped his curiosity, and his talents have been proportioned to it. The English government will without doubt take proper measures for the publication of his work. That respectable nation, which has given a lead to all others in discoveries of every kind, will not fail to add to its glory, by speedily communicating to the world at large, those of this excellent traveller, who, not contented with accurate descriptions of nature, has made many important observations on the culture of different kinds of grains; on the navigation of the Red Sea; on the course of the Nile, from its mouth to its source, which he has been the first to discover; and on different particulars which may be of the highest utility to commerce and agriculture, those great arts which are but little known and ill cultivated. Yet, on the whole, the superiority of one nation over another does depend, and for ever will depend." It is much to be regretted, that after fo long an interval, this gentleman's discoveries have not yet made their appearance. The delay has given rise to various speculations. Doubts have even been entertained concerning the credibility of the reports that have tranffpired, or been gathered from his conversation. His honour and abilities, however, are too extensively known to be affected by fuch injurious infinuations. That he has great talents for communicating the information of the regions he has visited, appears by his difcription on the Theban Harp,* See the article Harp in this Dictionary.

Mr Bruce moreover, is said to have given a great facility in leaming languages, and talents for drawing; nor perhaps was any other traveller furnished with fo large and scientific an apparatus of instruments. Add to all this, that he is poliffed of a spirit and enterprife not easily to be equalled. The speedy production, therefore, of fo interesting an account as he is capable of giving, of this almost unfrequented part of Africa, cannot but fill be
Abythnia. carefully wished for. In the mean time, the following authentic anecdotes will not, it is presumed, be unacceptable, nor appear foreign to the present article.

Mr Bruce was appointed consul to Algiers, where he continued till 1764. In June 1764, he requested leave of absence from the secretary of state for the southern department, in order to make some drawings of antiquities near Tunis.

In Mr Bruce's last letter from Algiers to the same secretary (dated December 29th 1764), he alludes to another leave of absence, which he had likewise requested, that he might visit parts of the African continent. He explains himself no farther in this letter; but it is believed that he proceeded considerably to the southward of Algiers, and made those very capital drawings of remains of Roman architecture, which many have seen since his return to Britain. Before he set out for Algiers, he informed some of his friends, that the making such excursions for these interesting purposes was his principal inducement for accepting the consulship.

How long he continued in Africa, the present writer has not had the opportunity of procuring information; but having intentions afterwards of visiting Palmyra, he was shipwrecked on the coast of Tunis, and plundered of every thing by the barbarous inhabitants.

The most delightful part of the loss was probably that of his instruments, so necessary to a scientific traveller; and though he afterwards procured some of these, yet others (particularly a quadrant) could not be recovered. Mr Bruce, however, determining to repair this loss as soon as possible from France, so much nearer to him than England, was so fortunate as to be provided with a time-piece and quadrant from that quarter. Upon this occasion Lewis XV. presented him with an iron quadrant of four feet radius, as he had probably represented to the academy of sciences his want of such an instrument whilst he should be in Abythnia: Mr Bruce brought back with him to England this cumbersome fellow-traveller, and, having put upon it an inscription to the following purport, is said to have presented it to the university of Glasgow:

"With this instrument given by the king of France, Lewis XV. Mr Bruce proceeded to the sources of the Nile, it being carried on foot, upon mens shoulders, over the mountains of Abythnia." This information was received from that eminent maker of instruments Mr Nairne.

Where and when Mr Bruce received the French instruments is not known; but as he was still bent on visiting Abythnia, he gave a commission to Mr W. Ruffel, F. R. S. for a reflecting telescope, made by Bird or Short; a watch with a hand to point seconds, and the newest and completest English astronomical tables; all of which were to be sent to Mr Fremaux, and forwarded to him at Alexandria before August.

On the 29th of March 1768, Mr Bruce was at Sidon on the coast of Syria, and wrote to Mr Ruffel from thence for the following additional instruments, viz. a twelve-feet reflecting telescope, to be divided into pieces of three feet, and joined with screws. This telescope was also accompanied by two thermometers and two portable barometers. Mr Bruce moreover informed Mr Ruffel, that he was going into a country (viz. Abythnia) from which few travellers had returned; and wished Mr Ruffel, or his philosophical friends, would send him their desiderata, as he was entirely at their service. Mr Bruce added, that if he could not obtain admission into Abythnia, he still would do his best in the cause of science on the eastern coast of the Red Sea.

As Mr Bruce had directed the instruments to be ready for him at Alexandria by the beginning of August 1768, it is probable that he reached Cairo about that time; from whence he proceeded to Abythnia, by way of Jeddah, Mazava, and Arbitico.

It is supposed that Mr Bruce did not continue long at Jeddah, as he is said to have explored the coast on the east side as low as Mocha, during which drawings were taken of many curious ship in the Red Sea. Mr Bruce must also have entered Abythnia, either at the latter end of 1768, or the very beginning of 1769, as he made an observation in that part of Africa on the 15th of January of that year.

In this perilous enterprise he was accompanied by a Greek servant (named Michael), and an Italian painter, who probably assisted in the numerous articles which might deserve representation, and who died of a flux before Mr Bruce's return to Cairo in 1773. Mr Bruce must at times also have been assisted by many others, as his instruments, apparatus for drawings, and other necessaries, from their weight and bulk could not be easily transported from place to place, and perhaps required beasts of burden. To these likewise must be added several medicines which enabled him to perform cures on the inhabitants, and probably occasioned the good reception he afterwards met with.

Such other particulars as happened to Mr Bruce, during his long residence in this unfrequented country, must be left to his own superior narrative; and it shall suffice, therefore, only to state, that he made a large number of observations to fix the situations of places, out of which 31 have been examined and computed by the astronomer royal. The first of these observations was made on the 10th of January 1769, and the last on the 5th of October 1772, from 20 to 28 degrees of east longitude from Greenwich, and from 12 to 28 degrees of north latitude. It need scarcely be said therefore, that these observations, which include so large an extent of almost unknown country, must prove a most valuable addition to geography; and the more so, because the Portuguese, who first visited Abythnia, give neither longitude nor latitude of any place in that empire; and Poncet only two latitudes, viz. those of Sennar and Giefun.

As Mr Bruce made the last of his observations on the 5th of October 1772, it is probable that he might then be on his return to Cairo, through Nubia and Upper Egypt, where he arrived on the 15th of January 1773, after an absence of more than four years; bringing back with him his Greek servant, named Michael.

Mr Bruce continued at Cairo four months, during which time, he had daily intercourse with Mr Antes; the substance of a letter from whom will contain the principal confutation of Baron Tott, and others, who have been increasest in regard to Mr Bruce's expected narrative.

Mr Antes was born of German parents, who were possessed of lands in the back settlements of Pennsylvania.
Abyffinia: and having showed early abilities as a mechanic, removed to Europe, where he distinguished himself in the art of watch-making, which he learned without apprenticeship. Being a member of the church known by the name of Unitas Fratrum, and commonly called Mennonites, he wished to be employed in their missions, and more especially of the same persuasion established at Cairo, who always have desired to procure opportunities of instructing the Abyffiniants.

Mr Bruce had left Cairo fifteen months before Mr Antes came there; and the intercourse, therefore, between them first took place on Mr Bruce's return in 1773.

Having given this account of Mr Bruce and Mr Antes's being first known to each other, we shall state the substance of some information received from the latter, who is now established at Fulneck near Leeds, after having resided eleven years at Cairo.

"That Mr Bruce left Cairo in 1768, and proceeded thence by way of Jeddah, Mecca, and Arquico, into Abyssinia."

"That in 1771, a Greek came from Gondar (the capital) in Abyssinia, who had a draught from Mr Bruce on a French Merchant at Cairo (named Roë) for some hundreds of German coins, which were paid immediately. This draught was accompanied by a letter from Mr Bruce, and was the first time that he had been heard of at Cairo since his departure in 1768."

"That after Mr Bruce's return to Cairo in 1773, Mr Antes saw a young Armenian and his father (who came likewise from Gondar) at Mr Pini's, an Italian merchant of Cairo, where they and Mr Bruce conversed in the Abyssinian language, and seemed glad to meet him again."

"That Mr Bruce returned to Cairo from Abyssinia by way of Nubia and Upper Egypt; which can be fully attested by the Franciscan friars who are established at Asyut near Asyuan, which latter is the highest town of Upper Egypt."

"That during Mr Bruce's stay at Cairo, which was not less than four months, no day passed without their seeing each other; which gave Mr Antes frequent opportunities of inquiring with regard to Abyssinia, concerning which he was particularly interested from a reason before stated."

"That Mr Antes likewise frequently conversed with Michael, Mr Bruce's Greek servant; who is flated to have by no means had a lively imagination, and who always agreed with the circumstances mentioned by his master, and more particularly in relation to their having visited the sources of the Nile; which the Baron Tott doubts of, from having had a conversation with this same Greek servant."

Mr Antes adds, "That Baron Tott stated but a few days at Cairo; and, from his short residence in that country, hath given several erroneous accounts relative to Egypt. Mr Antes, on the other hand, had almost daily conversations with Michael for several years, and often in relation to the sources of the Nile."

"Lastly, "That after Mr Bruce left Cairo, Mr Antes had conversed with others who had known Mr Bruce in Abyssinia, and that he was there called Martha Jakobs, or Mr James."

After this state of facts, it is conceived that no one can entertain a reasonable doubt with regard to Mr Bruce's not only having visited, but resided long in Abyssinia; though it is remarkable that the Jesuits expressed the same doubts in relation to Poncet, who had continued there nearly as long as Mr Bruce. Poncet happened to be a layman; and the Jesuits, perhaps, would not approve of any narrative that did not come from father Beneventi, who accompanied Poncet to Abyssinia, but unfortunately died there (a)."

Driven, however, from this hold, the objectors will possibly retain their incredulity as to many particulars to be related.

The first of these is, the having visited the sources of the Nile; which, from classical education, we cannot easily believe, as they were unknown to the ancients, though they had so great a curiosity with regard to this discovery."

Many things, however, have been accomplished by travellers in modern times, which the ancients never could achieve, and which may be attributed to their want of enterprise (as travellers at least), of languages, and lastly the not being able to procure credit when in a distant country. Mr Bruce could not have continued so long as he did in Abyssinia, unless he had drawn from Gondar upon a merchant established at Cairo.

The difficulty, however, with regard to reaching the sources of the Nile, arises principally from the uncivilized state of Abyssinia, unless the traveller hath a proper introduction (b). When once this is procured, all difficulties seem to cease, as we find by Lobo's (c) account of this same discovery, and likewise by Poncet's account of this same discovery (d)."

(a) It must be admitted, however, that we owe to the zeal of the Jesuits the best accounts we have both of China and Paraguay. Few laymen have been actuated so strongly for the promotion of geography and science as Mr Bruce; and we must therefore (upon the order of the Jesuits being abolished) look up chiefly to the missionaries from the church of the Unitas Fratrum, who, though differing so totally in other respects, seem to have an equal ardour with the Jesuits for instructing the inhabitants of countries unfrequented by Europeans. Such missions are already established in West Greenland, the coast of Labrador, N. Lat. 56. the back settlements of Carolina and Pennsylvania, in India, Bengal, and the Nicobar islands. Thoë established on the coast of Labrador send over yearly meteorological journals, which are communicated to the Royal Society. As for the dispute between Poncet and Maillet the French consul at Cairo, see Mod. Univ. Phil. vol. 6.

(b) The professing the knowledge of medicine was Poncet's introduction, and seems to have been that of Mr Bruce. Even in our own civilized country, how are quacks and mountebanks reportd to? And what an impression must Mr Bruce, with his magnificent and scientific apparatus, have made upon the inhabitants of such a country as Abyssinia?

(c) In father Telles's compilation. See also Ludolf, who describes the sources from Gregory, who was a native of Abyssinia. Father Paz was the first who visited them, A.D. 1622. His account of this is laid to be in the archives.
A B Y

Abyssinia, etc.'s narrative, who was prevented by illness from visiting the very spot, but hath given an ample relation from an Abyssinian who had often been there. Poncet, moreover, had obtained leave from the emperor to make this journey, which he states as not being a distant one, and that the emperor hath a palace near the very sources.

If it be doubted whether Mr Bruce hath visited the very source of the Nile, it may be answered, that perhaps no Englishman hath taken this trouble with regard to the sources of the Thames, which, like most other great rivers, is probably derived from many springs and rills in different directions.

The other objection which we have often heard, is, "That Mr Bruce hath mentioned in conversation, that the Abyssinians cut a slice from the living ox, esteemed it one of their greatest delicacies."

This sort of dainty, indeed, is not so considered in other parts of the globe; but every nation almost hath its peculiarities in the choice of their food. Do not we eat raw oysters within a second? Fish seem to equal practice seems to equal that of the Abyssinians! Do not cooks skin oysters whilst alive? And do not epicures crisp fish for the gratification of their appetites?

That the Abyssinians can eat beef in a raw state, is agreed both by Lobo and Poncet; and the former says, "Seeking it in the beast. Mr Atties, moreover, was told by a Franciscan monk, who went with the caravan from Abyssinia to Cairo (d), that he was witness of an ox being killed, and immediately devoured by the band of travellers.

One reason, perhaps, for this usage may be, the great heat of the climate, which will not permit meat to be kept a sufficient time to make it tender (as with us): and it is generally allowed, that a foul, dressed immediately after it is killed, is in better order for eating than if it is kept four and twenty hours.

Is it therefore extraordinary, that an Abyssinian epicure may really find (or perhaps fancy) that a piece cut from the beast whilst alive, may be more tender, or have a better relish, than if it is previously killed by the butcher? To this may be added, that according to the information which has been received on this head, Mr Bruce's account of this practice is much misrepresented by the objectors, who suppose that the ox lives a considerable time after these pieces are cut from it. When these dainty bits, however, have been sent to the great man's table (and which are probably taken from the fleshly parts), the beast soon afterwards expires, when the first artery is cut, in providing slices for the numerous attendants.

Upon the whole, the not giving credit to a traveller, because he mentions an usage which is very different from ours (and is undoubtedly very barbarous), seems rather to argue ignorance than acuteness.

This brings to recollection the incredulity which was shown to another distinguished traveller, Dr Shaw; who having mentioned, in an Oxford common room, that some of the Algerines were fond of lion's flesh, never could obtain any credit afterwards from his brother-fellows of the same college, though many of them were learned men. It is well known, however, that Dr Shaw states this same circumstance in the publication of his travels, that he is cited with the greatest approbation in almost every part of Europe.

Sir William Temple somewhere mentions, that a Dutch governor of Batavia, who lived much with one of the most considerable inhabitants of Java, could never obtain any credit from him after having mentioned, that in Holland water became a solid body. The traveller, who first saw a flying fish, probably told every one of this extraordinary circumstance as soon as he fet his foot on shore, and was probably discredited with regard to the other particulars of his voyage.

The natural cause and progress of the incredulity, which a traveller generally experiences, seems to be the following:

When he returns from a distant and little frequented country, every one is impatient to hear his narrative; from which, of course, he selects the more striking parts, and particularly the usages which differ most from our own. Some of the audience, disbelieving what the traveller hath mentioned, put questions to him which show their distrust. The traveller by this treatment becomes irritated, and answers some of them peevishly, others ironically, of which the interrogators afterwards take advantage to his prejudice. Nothing is more irritating to an ingenuous person than to find his affections are disbelieved. This is commonly experienced in the crofs examinations of almost every witness. To the diftrusts of the traveller on his return, we may add, the being often teasted by very ignorant questions.

ABYSSINIAN, in ecclesiastical history, is used as the name of a sect, or heresy, in the Christian church, established in the empire of Abyssinia. The Abyssinians are a branch of the Copts or Jacobites; with whom they agree in admitting but one nature in Jesus Christ, and rejecting the council of Chalcedon: whence they are also called Eutychians, and stand opposed to the Melchites. They are only distinguished from the Copts, and other sects of Jacobites, by some peculiar national usages. — The Abyssinian sect or church is governed by a bishop or metropolitan styled Abuna, sent them by the Coptic patriarch of Alexandria residing at Cairo, who is the only person that ordains priests. The next dignity is that of Komo, or Hegumenas, who is a kind of arch-prebend. They have canons also, and monks: the former of whom marry; the latter, at their admission, vow celibacy, but with a reservation: theft, is said, make a person scoundrel, before their superior, to keep charity; but add, in a low voice, as you keep it. The emperor has a kind of supremacy in ecclesiastical matters. He alone

archives of the college de propaganda fide at Rome. It is believed that there are many other curious particulars for the illustration of geography to be found in the same depository. Dr Shaw mentions, moreover, some papers of Lippi (who accompanied the French embassy into Abyssinia, A. D. 1704), which are to be found in the botanical library at Oxford.

(d) This points out another channel by which a traveller of enterprise may visit Abyssinia.
Acacia, or Robinia, or Honey-locust. See Gleditsia.

Acacia, in the Materia Medica, the inspissated juice of the unripe fruit of the Mimosa Nigrica.

This juice is brought from Egypt, in roundish masses, wrapped up in thin bladders. It is outwardly of a deep brown colour, inclining to black; inwardly of a reddish or yellowish brown; of a firm consistence, but not very dry. It soon softens in the mouth, and dissolves a rough, not disagreable taste, which is followed by a sweetish relish. This inspissated juice entirely dissolves in watery liquors, but is scarcely sensible acted on by rectified spirit.

Acacia is a mild astringent medicine. The Egyptians give it in spitting of blood, in the quantity of a dram, dissolv'd in any convenient liquor; and repeat this dose occasionally: they likewise employ it in collyria for strengthening the eyes, and in gargarsins for quinsey. Among us, it is little otherwise used than as an ingredient in mitridate and theriac, and is rarely met with in the shops. What is usually sold for the Egyptian acacia, is the inspissated juice of unripe fruits: this is harder, heavier, of a darker colour, and somewhat sharper taste, than the true sort. See the next article.

German Acacia, the juice of unripe fruits inspissated nearly.
nearly to dryness over a gentle fire, care being taken to prevent its burning. It is moderately aromatic, similar to the Egyptian acacia, for which it has been commonly cultivated in the houses. It is given in fluxes, and other disorders where hepatic medicines are indicated, from a scupple to a dram.

Acacia, among antiquaries, something resembling a roll or bag, seen on medals, as in the hands of several consuls and emperors. Some take it to represent a handkerchief rolled up, with which they made signals at the games; others, a roll of petitions or memorials; and some, a purple bag full of earth, to remind them of their mortality.

ACACIANS, in ecclesiastical history, the name of several sects of heretics; some of which maintained, that the Son was only a simile, not the same, substance with the Father; and others, that he was not only a distinct, but a dissimilar, substance. Two of these sects had their denomination from Acacius bishop of Caesarea, who lived in the fourth century, and changed his opinions, so as, at different times, to be head of both. Another was named from Acacius patriarch of Constantinople, who lived in the close of the fifth century.

ACACIUS, surnamed Lusus, because he was blind of one eye, was bishop of Caesarea in Palestine, and succeeded the famous Eusebius; he had a great share in the banishment of Pope Liberius, and bringing Felix to the see of Rome. He gave name to a sect, and died about the year 365. He wrote the life of Eusebius, and several other works.

Acacius (St.), bishop of Amida, in Mesopotamia, in 420, was distinguished by his piety and charity. He sold the plate belonging to his church, to redeem a slave who was delivered over irretrievably to the devil by Pope Felix III.

ACAD, or Acadh, (anc. geog.) the town in which Nimrod reigned, called Archad by the feventy; situated in Babylonia, to the eastward of the Tigris.

ACADEMIAN, or ACADEMIST, a member of an academy. See ACADEMY in a modern sense.

ACADEMICS, or ACADEMISTS, a denomination given to the cultivators of a species of philosophy originally derived from Socrates, and afterwards illustrated and enforced by Plato, who taught in a grove near Athens, consecrated to the memory of Academus, an Athenian hero; from which circumstance this philosophy received the name of academical. Before the days of Plato, philosophy had in a great measure fallen into contempt. The contradictory systems and hypotheses which had successively been urged upon the world were become so numerous, that, from a view of this incongruity and uncertainty of human opinions, many were led to conclude, that truth lay beyond the reach of our comprehension. Absolute and universal scepticism was the natural consequence of this conclusion. In order to remedy this abuse of philosophy and the human faculties, Plato laid hold of the principles of the academical philosophy; and, in his Phaedo, reasons in the following manner. "If we are unable to discover truth, (says he), it must be owing to two circumstances: either there is no truth in the nature of things; or the mind, from a defect in its powers, is not able to apprehend it. Upon the latter supposition, all the uncertainty and fluctuation in the opinions and judgments of mankind admit of an easy solution: Let us therefore be moderate, and ascribe our errors to the real weakness of our own minds, and not to the nature of things themselves. Truth is often difficult of access; in order to come at it, we must proceed with caution and diffidence, carefully examining every step; and after all our labour, we will frequently find our great efforts disappointed, and be obliged to confess our ignorance and weakness."

Labour and caution in their researches, in opposition to rash and hasty decisions, were the distinguishing characteristics of the disciples of the ancient academy. A philosopher, polished by these principles, will be slow in his progress; but will seldom fall into errors, or have occasion to alter his opinion after it is once formed. Vanity and precipitance are the great sources of scepticism. Hurried on by these instead of attending to the cool and deliberate principles recommended by the academy, several modern philosophers have plunged themselves into an absurd and ridiculous kind of scepticism. They pretend to discredit subjects that are plain, simple, and easily comprehended; but give peremptory and decisive judgments upon things that evidently exceed the limits of our capacity. Of these, Berkeley and Hume are the most considerable. Berkley denied the existence of every thing, excepting his own ideas. Mr Hume has gone a step further, and questioned even the existence of ideas; but at the same time has not hesitated to give determined opinions with regard to eternity, providence, and a future state, miraculous interpositions of the Deity, &c. subjects far above the reach of our faculties. In his essay on the academical or sceptical philosophy he has confounded two very opposite species of philosophy. After the days of Plato, indeed, the principles of the first academy were grossly corrupted by Arcesilaus, Carneades, &c. This might lead Mr Hume into the notion that the academical and sceptical philosophy were synonymous terms. But no principles can be of a more opposite nature than those which were inculcated by the old academy of Socrates and Plato, and the sceptical notions which were propagated by Arcesilaus, Carneades, and the other disciples of the succeeding academies.

ACADEMY, in antiquity, a garden, villa, or grove, situated within a mile of Athens, where Plato and his followers held their philosophical conferences. It took its name from one Academus, or Acedemus, who was the original owner of it, and made it a kind of gymnasium; he lived in the time of Thepheus; and, after his death, it retained his name, and was consecrated to his
Academies of his memory. Cimon embellished it with fountains, trees, and walks; but Sylla, during the siege of Athens, employed the very trees in making battering engines against the city. Cicero too had his villa, or place of retirement, near Pauzzolo, which he also named an academy, where he composed his Academical questions, and his book De natura dormum.

Academy, among the moderns, is most commonly used to signify a society of learned men established for the improvement of any art or science, and generally under the protection of a prince.

The first Academy we read of, was established by Charlemagne, at the instigation of Alcuin. It was composed of the chief wits of the court, the emperor himself being a member. In their academical conferences, every person was to give an account of what ancient authors he had read; and each even assumed the name of some ancient author who pleased him most, or some celebrated person of antiquity. Alcuin, from whole letters we learn these particulars, took that of Placens, the surname of Horace; a young lord, named Augulf, took that of Homer; Adelard, bishop of Corbie, was called Augustin; Riculpe, bishop of Mentz, was Dametas; and the king himself, David. This shows the mistake of some modern writers, who relate, that it was in conformity with the genius of the learned men of those times, who were great admirers of Roman names, that Alcuin took the name of Placcus Albinus.

Most nations have now their academies; but Italy has the greatest number.—The French have many flourishing academies, most of which were established by Louis XIV. —There are but few in Britain; and those of chief note go by a different name. See the article Society.

In giving an account of the principal Academies, it seems most proper to arrange them according to their subjects.

I. Medical Academies, as that of the Nature Curiosi in Germany; that founded at Palermo in 1645: another at Venice in 1701, which meets weekly in a hall near the grand hospital; another at Geneva in 1715, in the house of M. Le Clerc. The colleges of physicians at London and Edinburgh are also, by some, ranked in the number of academies.

The Academy of Nature Curiosi, called also the Leopoldine Academy, was founded in 1652, by Jo. Laur. Bauschius, a physician; who, in imitation of the English, published an invitation to all physicians to communicate their extraordinary cafes; and, meeting with success, was elected president. Their works were at first published separately; but in 1670 a new scheme was laid for publishing a volume of observations every year. The first volume appeared in 1684, under the title of Ephemeredes, and the work has been continued with some interruptions and variations of the title, &c. In 1687, the emperor Leopold took the society under his protection, granting the members several privileges, particularly that their presidents should be counts palatine of the holy Roman empire. This academy has no fixed residence, nor regular assemblies; instead of thefe, there is a kind of bureau, or office, first established at Breslaw, and afterwards removed to Nuremberg, where letters, observations, &c. from correspondents or members are taken in. The academy consists of a president, two adjutants or secretaries, and colleagues or Academicians, members without restriction. The colleagues, at their admission, oblige themselves to two things: first, to choose some object out of the animal, vegetable, or mineral kingdom, to handle, provided it had not been treated of by any colleague before: the second, to apply themselves to furnish materials for the annual Ephemerides. Each member to bear a symbol of the academy, in a gold ring; whereon, instead of a mote, is a book open, and, on the back thereof, an eye; on the other side the motto of the academy, Nunciam etiam.

II. Chirurgical Academies; as that instituted some years ago, by public authority, at Paris: the members of which were not only to publish their own and correpondents observations and improvements, but to give an account of all that is published on surgery, and to compose a complete history of the art, by their extracts from all the authors ancient and modern who have written on it. A question in surgery is annually proposed by the academy, and a gold medal of 200 livres value given to him who furnishes the most satisfactory answer.

Academy of Surgery at Vienna, was instituted some years ago by the present emperor, under the direction of the celebrated Brambilla. In this there were at first only two professors; and to their charge the instruction of 150 young men was committed, 30 of whom had formerly been surgeons in the army. But of late the number both of the teachers and pupils has been considerably increased. Gabrielli has been appointed to teach pathology and practice; Boecking, anatomy, physiology, and physics; Streit, medical and pharmaceutical surgery; Hunzowsky, surgical operations, midwifery, and the chirurgia forensica; and Plenk, chemistry and botany. To these has been added, Beindl, as professor and extraordinary professor of surgery and anatomy. Besides this, the emperor, with his usual liberality, has provided a large and splendid edifice in Vienna, which affords habitation both for the teachers, the students, pregnant women, patients for clinical lectures and servants. He has also purchased for the use of this academy a medical library, which is open every day: a complete set of chirurgical instruments; an apparatus for experiments; a collection of preparations in wax brought from Florence; and a variety of other useful articles. Adjoining to the building also there is a good botanical garden.

Among other parts of this institution, three prize medals, each of the value of 40 florins, are to be annually bestowed on those students who return the best answer to questions proposed the year before. These prizes are not entirely founded by the emperor, but are in part owing to the liberality of Brendellius, the protochirurgus at Vienna.

III. Ecclesiastical Academies; as that of Bologna in Italy instituted in 1687; employed in the examination of the doctrine, discipline, and history, of each age of the church.

IV. Cosmographical Academies; as that at Venice, called the Argonauti. This was instituted at the solicitation of F. Coronelli, for the improvement of geographical knowledge. Its design was to publish exact maps, both celestial and terrestrial, as well particular-
A C A

Adventures of the Academies. — Each particular academy, together with geographical, historical, and astronomical descriptions. Each member, in order to defray the expense of such a publication, was to subscribe a proportional sum, for which they were to receive one or more copies of each piece published. For this end three societies are fetted; one under F. Moro, provincial of the minoritics in Hungary; another under the abbot Laurence at Rue Pavenne au Marais; the third under F. Baldigiani, Jefuit, professor of mathematics in the Roman college. The device of this academy is the terraqueous globe, with the motto Plus ultra; and at its expense all the globes, maps, and geographical writings of F. Coronelli have been published.

V. Academies of Sciences. — These comprehend such as are erected for improving natural and mathematical knowledge. They are otherwise called Philosophical and Physical academies.

The first of these was instituted at Naples, about the year 1560, in the house of Baptista Porta. It was called the Academy Scienzarum Naturae; and was succeeded by the Academy of Lyncei founded at Rome by Prince Frederic Cesi, towards the end of that century. Several of the members of this academy rendered it famous by their discoveries; among these was the celebrated Galileo. Several other academies were instituted about that time, which contributed greatly to the advancement of the sciences; but none of them comparable to that of the Lynceum.

Some years after the death of Toricelli, the Academy del Cimento made its appearance, under the protection of Prince Leopold, afterwards Cardinal de Medicis. Redi was one of its chief members; and the studies pursued by the rest may be collected from those curious experiments published in 1667, by their secretary Count Laurence Magulotti, under the title of Saggi di Naturali Esperienze; a copy of which was presented to the Royal Society, translated into English by Mr. Waller, and published at London in 4th.

The Academy degli Isquiti, afterwards incorporated into that of Della Tracia in the same city, followed the example of that of Del Cimento. Some excellent discoveries on physical and mathematical subjects, by Gemiliano Montenari, one of the chief members, were published in 1667, under the title of Perforis Fisico Mathematici.

The Academy of Raffano, in the kingdom of Naples, was originally an academy of Belles Letters; founded in 1540, and transformed into an Academy of Sciences in 1695 at the solicitation of the learned abbot Don Giacinto Gimmia; who being made president, under the title of Promoter General thereof, gave them a new set of regulations. He divided the academists into the following classes: Grammarians, Rhetoricians, Poets, Historians, Philosophers, Physicians, Mathematicians, Lawyers, and Divines, with a class apart for Cardinals and persons of quality. To be admitted a member, a man must have some degrees in the faculty. The members are not allowed to take the title of Academy; in the beginning of their books, a written permission from their president, which is not granted till the work has been examined by the censors of the academy; and the permission is the greatest honour the academy can confer, as they thereby adopt the work, and are answerable for it against all criticisms that may be made upon it. To this law the president or promoter himself is subject; and no academist is allowed to publish any thing against the writings of another without leave from the society.

Several other Academies of Sciences have been founded in Italy; but, for want of being supported by princes, did not continue long. The loss of them, however, was abundantly repaired by the institution of others still subsisting; such as, the Academy of Philosophers at Verona; of Rancini at Pavia, where a learned discourse on the origin of springs was delivered by Sig. Vallisniere, first professor of physics in the university of that city, and which was afterwards printed. To the Academy of the Mastri de Reggio, at Modena, the fame Sig. Vallisniere presented an excellent discourse on the scale of created beings, since inferred in his history of the generation of man and animals printed at Venice in the year 1721. F. Mersenne is said to have given the first idea of a philosophic academy in France, towards the beginning of the 17th century, by the conferences of naturalists and mathematicians occasionally held at his lodgings; at which Gaffendi, Des Cartes, Hobbes, Roberval, Pascal, Blondel, and others assisted. F. Mersenne proposed to each certain problems to examine; or certain experiments to be made. These private assemblies were succeeded by more public ones, formed by Mr Montmort, and Mr Thevenot the celebrated traveller. The French example animated several Englishmen of di&ine learning and erudition to erect a kind of philosophical academy at Oxford, towards the close of Oliver Cromwell’s administration; which, after the restoration, was erected into a Royal Society. See Society. The English example, in its turn, animated the French. Lewis XIV. in 1666, assisted by the counsels of Mr Colbert, founded an academy of sciences at Paris, with a sufficient revenue to defray the charge of experiments, and salaries to the members.

Royal Academy of Sciences. — After the peace of the Pyrenees, Lewis XIV. being desirous of establishing the arts, sciences, and literature, upon a solid foundation, directed M. Colbert to form a society of men of known abilities and experience in the different branches, who should meet together under the king’s protection, and communicate their respective discoveries. Accordingly Mr Colbert, having conferred with those who were at that time most celebrated for their learning, resolved to form a society of such persons as were conversant in natural philosophy and mathematics, to join to them other persons skilled in history and other branches of erudition, along with those who were entirely engaged in what are called the Belles Lettres, grammar, eloquence, and poetry. The geometricians and natural philosophers were ordered to meet on Tuesdays and Saturdays, in a great hall of the king’s library, where the books of mathematics and natural philosophy were contained; the learned in history to assemble on Mondays and Tuesdays, in the hall where the books of history are contained; and the classes of Belles Lettres to assemble on Wednesdays and Fridays. All the different classes were likewise ordered to meet together upon the first Tuesday of every month; and, by their respective secretaries, make a report of the proceedings of the foregoing month.

In a short time, however, the classes of History, Belles
Academies: Belles Lettres, &c. were united to the French Academy, which was originally instituted for the improvement and refining the French language; so that the royal Academy contained only two classes, viz. that of natural philosophy and mathematics.

In the year 1696, the king, by a proclamation dated the 26th of January, gave this Academy a new form, and put it upon a more respectable footing. It was now to be composed of four kinds of members, viz. honorary, penitential, associates, and eleves. Their last were a kind of pupils, or scholars, each of whom was attached to one of the penitentiaries. The first classes to contain ten persons, and each of the rest twenty. The honorary academists to be all inhabitants of France; the penitentiaries all to reside at Paris; eight of the associates allowed to be foreigners; and the eleves all to live at Paris. The officers to be, a president named by the king, out of the classes of honorary academists; and a secretary and treasurer to be perpetual. Of the penitentiaries, three to be geometricians, three astronomers, three mechanics, three anatomists, three chemists, three botanists, and the remaining two to be secretary and treasurer. Of the twelve associates, two to apply themselves to geometry, two to botany, and two to chemistry. The eleves to apply themselves to the same kind of science with the penitentiaries they were attached to; and not to speak except when called by the president. No regular or religious to be admitted, except into the class of honorary academists; nor any person to be admitted either for associate or penitential, unless known by some considerable printed work, some machine, or other discovery. The assemblies were held on Wednesdays and Saturdays, unless either of them happened to be a holiday, and then the assembly was held on the preceding day. To encourage the members to pursue their labours, the king engaged not only to pay the ordinary pensions, but even to give extraordinary gratifications, according to the merit of their respective performances; furnishing with the expense of the experiments and other inquiries necessary to be made. If any member gave in a bill of charges of experiments he had made, or defiring the printing of any book, and brought in the charges of gravelling, the money was immediately paid by the king, upon the president's allowing and signing the bill. So, if an anatomist required live tortoises, for instance, for making experiments about the heart, &c. as many as he pleased were brought him at the king's charge. Their motto was, *invenit et perfect.*

In the year 1716, the duke of Orleans, then regent, made an alteration in their constitution; augmenting the number of honories, and of associates capable of being foreigners, to 12; admitting regulars among such associates; and supposing the classes of eleves, as it appeared to be attended with some inconveniences, particularly that of making too great an inequality among the chemists, and being productive of some misunderstandings and animosities among the members. At the same time he created other two classes; one consisting of 12 adjutants, who, as well as the associates, were allowed a deliberative voice in matters relative to science; and the other six free associates, who were not attached to any particular science, nor obliged to pursue any particular work.

Since its re-establishment in 1696, this academy has been very exact in publishing, every year, a volume containing either the works of its own members, or such memoirs as have been composed and read in the academy during the course of that year. To each volume is prefixed the history of the academy, or an extract of the memoirs, and, in general, of whatever has been read or said in the academy; at the end of the history, are the catalogues of such academists as have died that year.—M. Fouillée et Deslay, counselor to the parliament of Paris, founded two prizes, one of 2500, and the other of 2000 livres, which are alternately distributed by the parliament every year; the subject for the first must relate to physical astronomy, and that for the latter to navigation and commerce.

Notwithstanding the advantages which the members of this academy enjoy over others, in having their expenses defrayed, and even being paid for their time and attendance, they have fallen under some imputations, particularly that of plagiarism, or borrowing their neighbour's inventions; but with what justice we do not say.

The French have also considerable academies in most of their great cities; as, at Montpellier, a royal academy of sciences on the like footing as that at Paris, being as it were a counter part thereof; at Toulouse, an academy under the denomination of Lanternists; others at Nantes, Arles, Lyons, Dijon, Bourdeaux, &c.

The Royal Academy of Sciences at Berlin was founded in 1700, by Frederic II. king of Prussia, on the model of that of England; excepting that, besides natural knowledge, it likewise comprehends the Belles Lettres. In 1716, it was ordained that the president shall be one of the counsellors of state, and nominated by the king. The members were divided into four classes; the first for prosecuting physics, medicine, and chemistry; the second for mathematics, astronomy, and mechanics; the third for the German language and the history of the country; the fourth for oriental learning, particularly as it may concern the propagation of the gospel among infidels. Each class to elect a director for themselves, who shall hold his post for life. The members of any of the classes have free admission into the assemblies of any of the rest.

The great promoter of this institution was the celebrated Mr Leibnitz, who accordingly was named the first director. The first volume of their transactions was published in 1710, under the title of *Miscellanea Berolinensia*; and though they received but few marks of the royal favour for some time, they continued to publish new volumes in 1723, 1725, 1724, and 1740. At last, however, Frederic III. the late king of Prussia, gave new vigour to this academy, by inviting to Berlin such foreigners as were most distinguished for their merit in literature, and encouraged his subjects to prosecute the study and cultivation of the sciences by giving ample rewards; and thinking that the academy, which till that time had had some minifter or opulent nobleman for its president, would find an advantage in having a man of letters at its head, he conferred that honour on M. Maupertuis. At the same time, he gave a new regulation to the academy, and took upon himself the title of its protector.

The academists hold two public assemblies annually; one in January, on the late king's birthday; and the
At the latter of these is given, as a prize, a gold medal of 50 ducats value: the subject for this prize is successively, natural philosophy, mathematics, metaphysics, and erudition.

The Imperial Academy of Sciences at Peterburgh was projected by Czar Peter the Great. That great monarch having, during his travels, observed the advantage of public societies for the encouragement and promotion of literature, formed the design of founding an academy of sciences at St Peterburgh. By the advice of Wolf and Leibnitz, whom he consulted on this occasion, the society was regulated, and several learned foreigners were invited to become members. Peter himself drew the plan, and arranged the details of the academy; and on the 27th of Feb. 1724, but was prevented, by the suddenness of his death, from carrying it into execution. His decease, however, did not prevent its completion: for on the 21st of December 1725, Catherine I. established it according to Peter's plan; and on the 27th of the same month the society was first assembled. On the 1st of August 1726, Catherine honoured the meeting with her presence, when professor Bullinger, a German naturalist of great eminence pronounced an oration upon the advances made by the lodestone and needle for the discovery of the longitude.

The fund which the empress settled a fund of 49821. per annum for the support of the academy; and fifteen members, all eminent for their learning and talents, were admitted and pensioned, under the title of Professors, in the various branches of literature and science. The most distinguished of these professors were Nicholas and Daniel Bernoulli, the two De Liles, Bullinger, and Wolf.

During the short reign of Peter II. the salaries of the members were discontinued, and the academy was utterly neglected by the court; but it was again patronised by the empress Anne, who even added a feminary for the education of youth, under the superintendence of the professors. Both institutions flourished for sometime under the direction of Baron Korff; but upon his death, towards the latter end of Anne's reign, an ignorant person being appointed president, many of the most able members quitted Russia. At the accession of Elizabeth, new life and vigour were again restored to the academy: the original plan was enlarged and improved; some of the most learned foreigners were again drawn to Peterburgh; and, what was considered as a good omen for the literature of Russia, two natives, Lomonosof and Rumovkly, men of genius and abilities, who had prosecuted their studies in foreign universities, were enrolled among its members. The annual income was increased to 10,659l. and soon afterwards the new institution took place.

The present empress Catharine III. with her usual zeal for promoting the diffusion of knowledge, has taken this useful society under her more immediate protection. She has altered the court of directors greatly to the advantage of the whole body; she has corrected many abuses, and has infused a new spirit into their researches. By her majesty's particular recommendation, the most ingenious professors have visited the various provinces of her vast dominions; and as the fund of the academy was not sufficient to supply the whole expense of these several expeditions, the empress be-

Academies. other in May, on the day of his accession to the throne.

Academies. The purpose and intent of these travels will appear from the instructions given by the academy to the several persons who were engaged in them. They were ordered to pursue their inquiries upon the different sorts of earths and waters; upon the best methods of cultivating the barren and desart spots; upon the local disorders incident to men and animals, and the most efficacious means of relieving them; upon the breeding of cattle, and particularly of sheep; on the rearing of bees and silk-worms; on the different places and objects for fishing and hunting; on minerals; on the arts and trades; and on forming a Flora Russica, or collection of indigenous plants: they were particularly instructed to redify the longitude and latitude of the principal towns; to make astronomical, geographical, and meteorological observations; to trace the course of the rivers; to take the most exact charts; and to be very distinct and accurate in remarking and describing the manners and customs of the different people, their dress, languages, antiquities, traditions, history, religion; and, in a word, to gain every information which might tend to illustrate the real state of the whole Russian empire.

In consequence of these expedititions, perhaps no country can boast, within the space of so few years, such a number of excellent publications on its internal state, on its natural productions, on its topography, geography, and history; on the manners, customs, and languages of the different people, as have issued from the press of this academy.

The first transactions of this society were published in 1728, and intitled Commentarii Academiae Scientiarum Imperialis Petropolitanae ad an. 1726, with a dedication to Peter II. The publication was continued under this form until the year 1747, when its transactions were called Novi Commentarii Academiarum, &c. In 1777 the academy again changed the title into Acta Academiae Scientiarum Imperialis Petropolitanae, and likewise made some alteration in the arrangement and plan of the work. The papers, which had been hitherto published in the Latin tongue, are now written either in that language or French; and a preface is added, intitled Partie Historique, which contains an account of its proceedings, meetings, admission of new members, and other remarkable occurrences. Of the Commentaries, 14 volumes were published: the first of the New Commentaries made its appearance in 1750, and the twentieth in 1776. Under the new title of Acta Academiae, several volumes have been given to the public, and two are printed every year. These transactions abound with ingenious and elaborate disquisitions upon various parts of science and natural history, and which reflect the greatest honour upon their authors; and it may not be an exaggeration to assert, that no society in Europe has more distinguished itself for the excellence of its publications, and particularly in the more abstruse parts of the pure and mixed mathematics.

The academy is still composed, as at first, of fifteen professors, besides the president and director. Each of these professors has a house and an annual stipend from 200l. to 600l. Besides the professors, there are four adjutants, who are pensioned, and who are present at the
Academies.

The Academy of Sciences at Bologna, called the Instituto di Bologna, was founded by count Martigelli in 1712, for the cultivating of physics, mathematics, medicine, chemistry, and natural history. Its history is written by M. de Limiers, from memoirs furnished by the founder himself.

The Academy of Sciences at Stockholm, or Royal Swedish Academy, owes its institution to fix persons of distinguished learning, among whom was the celebrated Linnaeus: they originally met on the 2d of June 1739, formed a private society, in which some dissertations were read; and in the latter end of the same year their first publication made its appearance. As the meeting continued and the members increased, the society attracted the notice of the king, and was, on the 31st of March 1741, incorporated under the name of the Royal Swedish Academy. Not receiving any pension from the crown, it is only under the protection of the king, being directed, like the Royal Society, by its own members. It has now a large fund, which has chiefly arisen from legacies and other donations; but a professor of experimental philosophy, and two secretaries, are still the only persons who receive salaries. Each of the members resides at Stockholm becomes president by rotation, and continues in office during three months. There are two species of members, native and foreign: the election of the former is held in April, and of the latter in July; no money is paid at the time of admission. The dissertations read at each meeting are collected and published four times in the year; they are written in the Swedish language, and printed in octavo, and the annual publications make a volume. The first 40 volumes, which were finished in 1779, are called the Old Transactions; for in the following year the title was changed into that of New Transactions. The king is sometimes present at the ordinary meetings, and particularly at the annual assembly in April for the election of members. Any person who sends a treatise which is thought worthy of being printed, receives the transcriptions for that quarter gratis, and a silver medal, which is not esteemed for its value, being worth only three shillings, but for its rarity and the honour conveyed by it. All the papers relating to agriculture are put forth separately under the title of Geonomica. Annual premiums, in money and gold medals, principally for the encouragement of agriculture and inland trade, are also distributed by the academy. The fund for these prizes is supplied from private donations.

The Royal Academy of Sciences at Copenhagen, owes its institution to the zeal of fix literati, whom Christian VI. in 1742, ordered to arrange his cabinet of medals. The count of Holstein was the first president; and the six persons who first formed the design, were John Gram, Joachim Frederic Ramus, Christian Louis Scheid, Mark Wolsdicky, Eric Pontopidan, and Bernt Moehlman. These persons occasionally meeting for that purpose, extended their designs; associated with them others who were eminent in several branches of science; and forming a kind of literary society, employed themselves in searching into, and explaining the history and antiquities of their country. The count of Holstein warmly patronized this society, and recommended it so strongly to Christian VI. that, in 1743, his Danish Majesty took it under his protection, called it the Royal Academy of Sciences, endowed it with a fund, and ordered the members to join to their former pursuits, natural history, physics, and mathematics. In consequence of the royal favour, the members engaged with fresh zeal in their pursuits; and the academy has published 15 volumes in the Danish language, some whereof have been translated into Latin.

American Academy of Sciences, was established in 1760 by the council and house of representatives in the commonwealth of Massachusetts's Bay for promoting the knowledge of the antiquities of America, and of the natural history of the country; for determining the use of which its various natural productions might be applied; for encouraging medicinal discoveries, mathematical disquisitions, philosophical inquiries and experiments, astronomic, meteorological, and geographical observations, and improvements in agriculture, manufactures, and commerce; and in short, for cultivating every art and science which may tend to advance the interest, honour, dignity, and happiness, of a free, independent, and virtuous people. The members of this academy are never to be more than 200, nor less than 40.

VI. Academies or Schools of Arts: as that at Peterburgh, which was established by the empress Elizabeth, at the suggestion of count Shuvalof, and annexed to the academy of sciences: the fund was L. 4000 per annum, and the foundation for 40 scholars. The present empress has formed it into a separate institution, enlarged the annual revenue to L. 12,000, and has augmented the number of scholars to 500; she has also constructed, for the use and accommodation of the members, a large circular building, which fronts the Neva. The scholars are admitted at the age of 18, and continue until they have attained that of 55: they are clothed, fed, and lodged, at the expense of the crown. They are all instructed in reading and writing, arithmetic, the French and German languages and drawing. At the age of 14 they are at liberty to choose any of the following arts, divided into four classes. 1. Painting in all its branches of history, portraits, battles and landscapes; architecture; Mosaic; enamelling; &c. 2. Engraving on copperplates, seal-cutting, &c. 3. Carving in wood, ivory and amber. 4. Watch-making, turning, instrument-making, casting statues in bronze and other metals, imitating gems and medals in paste and other materials.
Academies other compositions, gilding and varnishing. Prizes are annually distributed to those who excel in any particular art; and from those who have obtained four prizes, twelve are selected, who are sent abroad at the charge of the empress. A certain sum is paid to defray their travelling expenses; and when they are settled in any town, they receive an annual salary of £60, which is continued during four years. There is a small assortment of paintings for the use of the scholars; and those who have made great progress are permitted to copy the pictures in the empress's collection. For the purpose of design, there are models in platter of the best antique statues in Italy, all done at Rome, of the same size with the originals, which the artists of the academy were employed to cast in bronze.

The Royal Academy of Arts in London, was instituted for the encouragement of Designing, Painting, Sculpture, &c. &c. in the year 1768. This academy is under the immediate patronage of the king, and under the direction of 40 artists of the first rank in their several professions. It furnishes in winter, living models of different characters to draw after; and, in summer, models of the same kind to paint after. Nine of the ablest academicians are annually elected out of the 40, whose business is to attend by rotation, to set the figures, to examine the performance of the students, and to give them necessary instructions. There are likewise four professors, of Painting, of Architecture, of Anatomy, and of Perspective, who annually read public lectures on the subjects of their several departments; besides a president, a council, and other officers. The admission to this academy is free to all students properly qualified to reap advantage from the studies cultivated in it; and there is an annual exhibition of paintings, sculptures, and designs, open to all artists of distinguished merit.

The Academy of Painting and Sculpture at Paris. This took its rise from the disputes that happened between the master painters and sculptors in that capital; in consequence of which, M. Le Brun, Sarazin Cornelle, and others of the king's painters, formed a design of instituting a particular academy; and having procured a patent to the king, obtained an arrest dated Jan. 20, 1648. In the beginning of 1655, they obtained from cardinal Mazarin a brevet, and letters patent, which were registered in parliament; in gratitude for which favour they chose the cardinal for their protector, and the chancellor for their vice-protector. In 1663, by means of M. Colbert, they obtained a pension of 4000 livres. The academy consists of a protector; vice-protector; a director; a chancellor; four rectors; four treasurers; four professors, one of which is professor of anatomy, and another of geometry; several adjuncts and counsellors, an historiographer, a secretary, and two uffers.

The Academy of Painting holds a public assembly every day for two hours in the afternoon, to which the painters resort either to design or to paint, and where the sculptors model after a naked person. There are 12 professors, each of whom keeps the school for a month; and there are 12 adjuncts to supply them in case of need. The professor upon duty places the naked model, as he thinks proper, and lets him in two different attitudes every week. This is what tlicy call "setting the model." In one week of the month he sets two models together, which is called "setting the group." The paintings and models made after this model, are called "academy" or "academy-figures." They have likewise a woman who stands for a model in the public school. Every three months, three prizes for design are distributed among the eleve or disciples; two others for painting, and two for sculpture every year.

There is also an Academy of Painting, Sculpture, &c. at Rome, established by Lewis XIV. wherein those who have gained the annual prize at Paris are intended to be three years entertained at the king's expense, for their further improvement.

The Academy of Architecture, established by M. Colbert in 1671, consisting of a company of skilful architects, under the direction of the superintendent of the buildings.

The Academy of Dancing, erected by Lewis XIV. with privileges above all the rest.

VII. Academies of Law; as that famous one at Berne, and that of the Sittenes at Bologna.

VIII. Academies of History and Painting, as the Royal Academy of Portuguese History at Lisbon. This academy was established by king John V. in 1720. It consists of a director, four censors, a secretary, and 50 members; to each of whom is assigned some part of the ecclesiastical or civil history of the nation, which he is to treat either in Latin or Portuguese. In the church-history of each diocese, the Prelates, bishops, council, churches, manuscripts, academies, persons illustrious for fagacity or learning, places famous, for miracles or relics, must be distinctly related in twelve chapters. The civil history comprises the transactions of the kingdom from the government of the Romans down to the present time. The members who reside in the country are obliged to make collections and extracts out of all the registers, &c. where they live. Their meetings to be once in 15 days.

A medal was struck by this academy in honour of their prince: the front of which was his effigy, with the inscription Johannes V. Lustororum Rex; and, on the reverse, the same prince is represented standing, and holding History almost prostrate before him, with the legend Historia Restituta. Underneath are the following words in abbreviation: REGia ACADemia Hist. Soria LUSITane, INSTI. Tu 6. Idus December MDCCXX.

Academy of Swedish History at Tubingen, was lately established by some learned men, for publishing the best historical writings, the lives of the chief historians, and compiling new memoirs, on the several points and periods thereof.

IX. Academies of Astronomers; as that at Cortona in Italy, and at Upsal in Sweden. The first is designed for the study of Heturian antiquities; the other for illustrating the northern languages, and the antiquities of Sweden, in which notable discoveries have been made by it. The head of the Heturian academy is called Lucaomon, by which the ancient governors of the country were distinguished. One of their laws is to give audience to poets only one day in the year; another is to fix their fees, and impose a tax of a differentiation on each member in his turn.

The Academy of Medals and Inscriptions at Paris was set on foot by M. Colbert, under the patronage of Lewis XIV. in 1663, for the study and explanation of
Academies of ancient monuments, and perpetuating great and memorable events, especially those of the French monarchy, by coins, reliques, inscriptions, &c. The number of members at first was considered as four or five, chosen out of those of the French academy; who met in the library of Mr. Colbert, from whom they received his majesty's orders. The days of their meetings were not determined; but generally they met on Wednesdays, especially in the winter season: but, in 1691, the king having given the inspection of this academy to M. de Pontchartrain comptroller general, &c. he fixed their meetings on Tuesdays and Saturdays.

By a new regulation, dated the 16th of July 1701, the academy was composed of ten honorary members; ten affiliates, each of whom had two declarative voices; ten penjuniaries; and ten scholars, or pupils. They then met every Tuesday and Wednesday, in one of the halls of the Louvre; and had two public meetings yearly, one the day after Martinmas and the other the 16th after Easter. The clasps of scholar have been suppressed, and united to the associates. The king nominate their president and vice-president yearly; but their secretary and treasurer are perpetual. The rest are chosen by the members themselves, agreeably to the constitutions on that behalf given them.

One of the first undertakings of this academy, was to compose by means of medals, a connected history of the principal events of Lewis XIV's reign; but in this design they met with great difficulties, and of consequence it was interrupted for many years; but at length it was completed down to the advancement of the duke of Anjou to the crown of Spain.

In this celebrated work, the establishment of the academy itself was not forgot. The medal on this subject represents Mercury sitting, and writing with an antique stylus on a table of brass, he leans with his left hand upon an urn full of medals, and at his feet are several others placed upon a card: the legend, Revera geoffarum fide et honora; and on the exergue, Academia regia inscriptiorm et numismatum, infitit in MDC.LXIII., signifying that the Royal Academy of medals and inscriptions, founded in 1663, ought to give to future ages a faithful testimony of all great actions. Besides this work, we have several volumes of their memoirs; and their history, written and continued by their secretaries.

X. Academies of Belles Lettres, are those where, in eloquence and poetry are chiefly cultivated. These are very numerous in Italy, and not uncommon in France.

The Academy of Umidi at Florence has contributed greatly to the progress of the sciences by the excellent Italian translations given, by some of its members, of the ancient Greek and Latin historians. Their chief attention is to the Italian poetry, at the same time that they have applied themselves to the polishing of their language, which produced the Academy del la Crusca.

The Academy of Humanists, Umoristi, had its origin at Rome from the marriage of Lorenzo Marcini, a Roman gentleman; at which several persons of rank were present; and, it being carnival time, to give the ladies some diversion, they took themselves to the executing of verses, sonnets, speeches, extempore, and afterwards premeditatedly; which gave them the denomination of Bili Humorist After some experience, composing more and more into unison, they resolved to form an Academy of Belles Lettres; and changed the title of Bili Humorist for that of Humanists: choosing for their device, a cloud, which, after being formed of exhalations from the salt waters of the ocean, returns in a gentle sweet shower; with this motto from Lucretius, Redi against dali.

In 1690, the Academy of Arcadi was established at Rome, for reviving the study of Poetry and of the Belles Lettres. Besides most of the polite wits of both sexes in Italy, this academy comprehends many princes, cardinals, and other ecclesiastics; and, to avoid disputes about pre-eminence, all appear masked after the manner of Arcadian shepherds. Within ten years from its first establishment, the number of Academys amounted to six hundred. They hold assemblies seven times a year in a mead or grove, or in the gardens of some noblemen of distinction. Six of these meetings are employed in the recitation of poems and verses of the Arcadi residing at Rome; who read their own compositions; except ladies and cardinals, who are allowed to employ others. The seventh meeting is set apart for the compositions of foreign or absent members.

This academy is governed by a Cuffos, who represents the whole society, and is chosen every four years, with a power of electing 12 others yearly for his assistance. Under these are two sub-custodes, one vicar or pro-custos, and four deputies or superintendants, annually chosen. The laws of the society are immutable, and bear a near resemblance to the ancient model.

There are five manners of electing members. The first is by acclamation. This is used when sovereign princes, cardinals, and ambassadors of kings, desire to be admitted; and the votes are then given viva voce. The second is called numeration. This was introduced in favour of ladies and academical colonies, where the votes are taken privately. The third representation, was established in favour of colonies and universities, where the young gentrty are bred; who have each a privilege of recommending one or two members privately to be balloted for. The fourth, suffrage; whereby new members are substituted in the room of those dead or expelled. The last, definition whereby, when there is no vacancy of members, persons of poetical merit have the title of Arcadi conferred upon them till such time as a vacancy shall happen. All the members of this body, at their admission, assume new pastoral names, in imitation of the shepherds of Arcadia. The academy has several colonies of Arcadi in different cities of Italy, who all regulated after the same manner.

XI. Academies of Languages; called, by some, Grammatical Academies.

The Academia della Crusca at Florence, famous for its vocabulary of the Italian tongue, was formed in 1582, but scarce heard of before the year 1585, when it became noted for a dispute between Tasso and several of its members. Many authors confound this with the Florentine academy. The difcourses which Toricelli, the celebrated disciple of Galileo, delivered in the assemblies, concerning levity, the wind, the power of percussion, mathematics, and military architecture, are a proof of...
The Academy of Prussia had its rise in 1617, as an assembly of several princes and nobility of the country, who met with a design to reform and perfect the German tongue. It flourished long under the direction of princes of the empire, who were always chosen presidents. In 1668 the number of members arose to upwards of 900. It was prior in time to the French academy, which only appeared in 1629, and was not established into an academy before the year 1635. Its history is written in the German tongue by George Neumack.

The French Academy, which had its rise from a meeting of men of letters in the house of M. Conrart, in 1629, in 1635, it was erected into an academy, by Cardinal Richilien, for refining and ascertaining the French language and style. The number of its members are limited at 40; out of whom a director, chancellor, and secretary, are to be chosen: the two former hold their post for two months, the latter is perpetual. The members of this academy enjoy several privileges and immunities, among which is that of not being obliged to answer before any court but that of the king's household. They meet three times a week in the Louvre; at breaking up, 40 silver medals are distributed among them, having on one side the king of France's head, and on the reverse, Protecteur de l'Académie, with laurel, and this motto, À l'Innocence. By this distribution, the attendance of the Academiciis is secured, those who are present receiving the surplus otherwise intended for the absent. To elect or expel a member, at least 18 are required; nor can any be chosen unless by petition for it: by this expedient, the affront of refusals from persons elected is avoided. Religious are not admitted; nor can any nobleman, or person of distinction, be admitted on another footing than as a man of letters. None are to be expelled, except for base and dishonest practices; and there are but two instances of such expulsions, the first of M. Granier for refusing to return a deposit, the other of the Abbé Furet for plagiarism. The design of this academy was to give not only rules, but examples, of good writing. They began with making speeches on subjects taken at pleasure, about 20 of which were printed. They met with great opposition from the parliament at their first institution; it being two years before the patents granted by the king were registered. They have been severely satirized, and their style has been ridiculed as everything instead of refining the French language. They are also charged with having forfeited the world by flattery, and having exhausted all the topics of panegyrick in praise of their founder; it being a duty incumbent on every member, at his admission, to make a speech in praise of the king, the cardinal, the chancellor Segnier, and the person in whom place he is elected. The most remarkable work of this academy is a dictionary of the French tongue; which, after 50 years spent in settling the words and phrases to be used in writing, was at last published in 1694.

The foundation of an Academy similar to the above, has been proposed at Peterburgh, by the learned princes Dalsko: it is to consist of 60 members. The plan has been approved by the emperors, who has already given a fund for its support and establishment.

The Royal Spanish Academy at Madrid held its first meeting in July 1713, in the palace of its founder, the duke d'Escalonza. It consisted of eight academicians, including the duke, to which number 14 others were afterwards added, the founder being chosen president or director. In 1714, the king granted them his confirmation and protection. Their device is a crucible in the middle of the fire, with this motto, Lintia, Fyos, y de Efplendor: "it purifies, fixes, and gives brightness." The number of members is limited to 24: the duke d'Escalonza to be director for life, but his successors chosen yearly, and the secretary to be perpetual. Their object, as marked out by the royal declaration, was to cultivate and improve the national language: they were to begin with choosing carefully such words and phrases as have been used by the best Spanish writers, noting the Low, barbarous, or obsolete ones; and composing a dictionary wherein these may be distinguished from the former.

Academy is also a term for schools and other seminaries of learning among the Jews, where their rabbins and doctors instructed their youth in the Hebrew language, and explained to them the Talmud and the secrets of the cabala: Those of Tiberias and Babylon have been the most noted.

The Romans had a kind of military academies, established in all the cities of Italy, under the name of Cami Martis. Here the youth were admitted to be trained for war at the public expense. The Greeks, beside academies of this kind, had military professors called Tactic, who taught all the higher offices of war, &c. &c.

Academy is often used to denote a kind of collegiate seminary, where youth are instructed in arts and sciences. There is one in Portsmouth for teaching navigation, drawing, &c.; another at Woolwich, for fortification, gunnery, &c.—Besides these, there are numerous academies, especially in London, for teaching mathematics, languages, writing, accounts, drawing, and other branches of learning.

The nonconformist ministers, &c. are bred up in private academies; as not approving the common university education. The principal of their academies are those in London, Daventry, and Warrington.

Academy is likewise a name given to a riding-school, where young gentlemen are taught to ride the great hourse, &c. and the ground allotted is usually called the Manege.

Academy Figure, a drawing of a naked man or woman, taken from the life; which is usually done on paper with red or black chalk, and sometimes with pastil or crayons. See Academy, No. VI. par. 4. supra.

ACADIE, or Academy, in geography, a name formerly given to Nova Scotia, or New Scotland. See Nova Scotia.

ACENA, in antiquity, a Grecian measure of length, being a ten feet-rode, used in measuring their lands.
ACANTHA, in botany, a genus of the monogynia order belonging to the tetradria class of plants; the characters of which are these: The calyx is a perianthium consisting of four leaves, which are ovate, concave, equal, and persistent; there is no corolla. The flamina consists of four equal middle-sized filaments opposite to the calyx; the anthers are quadrangular, thin, erect; the pistillum has an inversely-ovate hilped germ; the style is small, and inflected on one side; and the stigma is a small thickish coloured membrane, divided into many segments. The pericarpium is an inversely-ovated dry one-celled berry covered with prickles bent backwards; the seed is single. There is only one species, a native of Mexico.

ACAjou, or Cashew-nut-tree. See Anacardium.

ACALANDRUS, a river falling into the bay of Tarentum, not far from the Metapontum, (Pliny, Strabo); now Finicia de Rofsio.

ACALEPTIC, in ancient proflity, a complete vixte.

ACALYPHA, the three-seeded Mercury, a genus of plants belonging to the monotecta monadepha class. The characters of this genus are the following.—Male flowers crowded above the female ones; The calyx is a three or four-lobed perianthium, the leaves roundish, concave, and equal; The corolla is wanting: The flamina have from 6 to 18 filaments, which are short, crowded, and connected at the base; the anthers are roundish.—Female flowers fewer, placed beneath, and received into a large divided involucre: The calyx is a perianthium, consisting of three leaves, which are concave, converging, small, and persistent: No corolla: The pistillum has a roundish germ; the style is three, branchy, often interrupted, and long; the stigmate are simple: The pericarpium has a roundish trifoliated trilocular capsule, the valvulgate gaping two ways: The seeds are solitary, roundish, and large.—This genus ranks in the 38th natural order, Triococca. There are five species, all natives of Virginia.

ACAMANTIS (the ancient name of the island of Cyprus), taken from one of its promontories situated to the west, and called Acanas. Teos in Ionia was also called thus from Acanus the founder.

ACAMAS, Acamantis (anc. geog.), the west promontory of the island of Cyprus, from whence it took its ancient name: now Cape Paphus or Epiphania, where formerly was a town of the same name, now a village called Crefico.

Acamas, son of Theseus, followed the rest of the Greek princes to the siege of Troy; and was deputed, with Diomedes, to the Trojans, in order to get Helen restored. Laocoon, Priam's daughter, fell in love with him, stole a night with him, and had a son by him called Munitus. He was one of the heroes who concealed themselves in the wooden horse. One of the tribes of Athens was called Acamantides from him, by the appointment of the oracle; and he founded a city in Phrygia Major, called Acamanthus. Homer mentions two other heroes of this name; one a Thracian prince who came to succour Priam, another a son of Antenor.

ACANACEOUS PLANTS, such as are armed with prickles.

ACANGIS, that is, Ravagers or Adventurers; a name which the Turks give their huskars or light troops, who are generally sent out in detachments to procure intelligence, harass the enemy, or ravage the country.

ACANTHA, in botany, the prickie of any plant; in zoology, a term for the spine or prickly fins of fishes.

ACANTHABOLUS, in surgery, an instrument for pulling thorns, or the like, out of the skin.

ACANTHINE, any thing resembling or belonging to the herb acanthus. Acantline garments, among the ancients, are said to be made of the down of thistles; others think they were garments embroidered in imitation of the acanthus.

ACANTHOPTERYGIOUS FISHES, a term used by Linnaeus and others for those fishes whose back-fins are hard, offensive, and prickly.

ACANTHOS, a town of Egypt, near Memphis, (Pliny); now Bifauta. Also a maritime town of Macedonia, to the west of mount Athos, a colony of Andrians, (Thucydides, Ptolemy); now Kritos; near which was shown Xerxes's ditch, of seven fadias, in order to separate mount Athos from the continent, and convey his ships, without doubling Athos, into the Singitic Bay. Acanthus, is also a town of Epirus.

ACANTHUS, bear's-breech, or bract-wrapping, in botany: a genus of the angiosperma order, belonging to the didynamia class of plants; and ranking in the 4th natural order, Perifome. The generic characters are: The calyx is a perianthium with leaflets of three alternate pairs unequal and persistent: The corolla is one-petal'd and unequal; the tubus very short, closed with a beard; no upper-lip, the under-one very large, flat, straight, very broad, three-lobed, and obulate: The flamina have four subulate filaments shorter than the corolla; the two superior rather longer, recurved, and incurved at the top; the antherae are oblong, compressed, obtuse, lateral, parallel, and villous before: the pistillum has a conic germ; a filiform style, the length of the flamina; and two acute lateral stigmata: The perianthium is an acutely-ovate bilocular capful, with a lateral partition: The seeds one or two, fliehy and gibbous.

Species. 1. The mollis, or common bear's-breech, a native of Italy, is the sort that is used in medicine, and is supposed to be the volii acanthus of Virgil; and the leaves are famous for having given rise to the capital of the Corinthian columns. 2. The spinolus, or prickly bear's-breech; the leaves of which are deeply jagged in very regular order, and each segment is terminated with a sharp spine, as are also the toothed edges of the leaves and the embalmen of the flower, which renders it troublesome to handle them. 3. Illifolus, or shrubby bear's-breech, grows naturally in both the Indies. It is an evergreen shrub, which rises about for feet high; and is divided into many branches, garnished with leaves like those of the common holly, and armed with spines in the same manner: the flowers are white, and shaped like those of the common acanthus, but smaller. 4. The nigra, or Portugueal bear's-breech, with smooth flat-ruffled leaves of a vivid green colour, was discovered in Portugal by Dr Jaffrey of the royal garden at Paris. 5. The middle bear's-breech, with entire leaves, having spines on their border, is supposed to be the acanthus of Dioscorides.
ACARNANIA, the first country of Free Greece, or Greece Proper, bounded on the west by the Sinus Ambraeci, or Ambracian Gulf, and separated from Aetolia by the river Achelous on the east, and by the Sinus Ambraeci from Epirus. The people were called Accarniani, denoting persons unhewn; other Eoliots, to the east of the Achelous, being called Curetes (Homer) from being thorn. According to Lucian, they were noted for effeminacy and incontinence; hence the proverb, 

PORELLUS ACARNANIUS. This country was famous for an excellent breed of horses; so that AQAIPZMN, is a proverbial saying for a thing excellent in its kind. It is now called la Garnie et il Disporata.

ACARON, or ACARON, a town of Palestine, called Ekrin in Scripture. It was the boundary of the Philistines to the north; flood at some distance from the sea, near Bethheleth; and was famous for the idol of Baalzephub.

ACARUS, the Tick or Mite, a genus of insects belonging to the order of apsectra, or such as have no wings. The acarus has eight legs; two eyes, one on each side of the head; and two jointed tentaculas. The female is oviparous. Linnaeus enumerates 35 species; of which some are inhabitants of the earth, some of waters; some live on trees, others among stones, and others on the bodies of other animals, and even under their skin. The description of a few of the most remarkable will here suffice.

1. The siro, or cheese-mite, is a very minute species. To the naked eye, these mites appear like moving particles of dust: but the microscope discovers them to be perfect animals, having as regular a figure, and performing all the functions of life as perfectly, as creatures that exceed them many times in bulk. The principal parts of them are the head, the neck, and the body. The head is small in proportion to the body; and has a sharp snout, and a mouth that opens and shuts like a mole's. They have two small eyes, and are extremely quick-fanged; and when they have been once touched with a pin, you may easily perceive how cunningly they avoid a second touch. Their legs are each furnished at the extremity with two little claws, with which the animal very nicely takes hold of any thing. The hinder part of the body is plumy and bulgy; and ends in an oval form, from which there issue out a few exceeding long hairs. Other parts of the body are also beset with thin and long hairs. The males and females are easily distinguished in these little animals. The females are oviparous, as the louse and spider; and from their eggs the young are hatched in their proper form, without having any change to undergo afterwards. They are, however, when first hatched, extremely minute; and, in their growing to their full size, they cast their skins several times. These little creatures may be kept alive many months between two concave glasses, and applied to the microscope with pleasure. They are thus often seen in coitus, conjoined tail to tail; and this is performed by an incredibly swift motion. Their eggs, in warm weather, hatch in 12 or 14 days; but in winter they are much longer. These eggs are so small, that a regular comparison shows, that 90 millions of them are not so large as a common pigeon's egg. They are very voracious animals, and have often been seen to eat one another.
ACA

Acras. jaw forward and the other backward, and in this manner grinding their food; and after they have done feeding, they seem to chew the cud. — There are several varieties of this species found in different substances besides cheese; as in malt-dust, flour, oatmeal, &c. Those in malt-dust and oat-meal are much nimbler than the cheese-mites, and have more and longer hairs. There are also a sort of wandering mites, which range wherever there is anything they can feed on: They are often seen in the form of a white dust, and are not suspected to be living creatures. — The mite is called by authors, simply, Acras. It is an animal very tenacious of life, and will live months without food. Mr Lewenhoek had one which lived 11 weeks on the point of a pin, on which he had fixed it for examining by his microscope.

ACA

2. The fangulatus. The hinder part of the abdomen is crenated, the cutellum is oval and yellowish, and the head is triquet. It is a native of America, and sticks so fast on the legs of travellers, fucking their blood, that they can hardly be extracted.

3. The telarius is of a greenish yellow colour. It has a small sting or weapon, with which it wounds the leaves of plants, and occasions them to fold backward. They are very frequently to be met with in the autumn, inclosed in the folded leaves of the lime-tree.

4. The exulcerans, or itch-acarus, is a very small species: its body is of a figure approaching to oval, and lobated; the head is small and pointed; its colour is whitish, but it has two dusky fimbriar lines on the back. It has long feticaceous legs, but the two first are short. It is found in the pusules of the itch: authors in general have supposed that it caueth that disease; but others observe, that if this were so, it would be found more universally in those pusules. It is more probable that these only make a proper nidus for it. See, however, the article itch.

5. The batatas is of a blood-colour, and a little rough; the fore pair of legs are as long as the body. It inhabits the potatoes of Surinam.

6. The ovinus, or sheep-tick, has a flat body, of a roundish figure, but somewhat approaching to oval, and of a yellowish white colour, and has a single large round spot on the back: the anus is visible in the lower part of the body; the thorax is fcarce confpicuous; the head is very small and black; the mouth is bifid: the antennae are of a elevatet figure, and of the length of the front; the legs are short and black. It is common on sheep, and its excrements stain the wool green: it will live in the wool many months after it is torn from the animal.

7. The coleoptratorum, or acarus of infects, is extremely minute: its body is round, reddish, and covered with a firm and hard skin: the head is very small, the neck scarce visible: the legs are moderately long, the anterior pair longer than the others; it has a white-nets about the anus. It is frequent on the bodies of many insects, with which it infects, as the loafe does others; it runs very swiftly: the humble bee, and many other of the larger insects, are continually infected with it; but none so much as the common black beetle, which has thence been called the loafe beetle.

8. The bacarum, or fcarlet tree-mite, is a small species: its body is roundish, and the back not at all flattened, as it is in many others; the skin is smooth, shining, and glossy; and the whole animal seems distended, and ready to burst; the color is a bright red, but a little duiker on the sides than elsewhere: the head is very small, and the legs short; there is on each side a small dusky spot near the thorax, and a few hairs grow from different parts of the body. It is very common on trees, particularly on the currant, on the fruit of which we frequently see it running.

9. The longiporus, or red foon-acarus, is very small, and of a bright red colour; the body is round, and distended; the head is very small and pointed; the legs are moderately long, and of a paler red than the body; the antennae are much longer than in any other species. It is frequent about old stone-walls and on rocks, and runs very nimbly. See Plate 1.

10. The aquaticus is a small species: the body is of a figure approaching to an oval, and the back appears depressed; it is of a bright and strong fcarlet colour. The head is small; the legs are moderately long, and form, and are of a paler red than the body. It is common in shallow waters, where it runs very quickly along the bottom. Its diminutive size hinders the beauty of its colours from being perceived, as they are not discernible without the microscope.

11. The holosericeus is a small species: its body is roundish, but a little approaching to oval; the back somewhat depressed; it is of a fine fcarlet colour, and covered with a velvety down. The head is very small; the eyes are two, and very small; the legs are short and of a paler red, and there is a small black spot near the inferior of the anterior ones. It is very common under the surface of the earth, and sometimes on herbs and among hay. It is suppos’d to be poisonous if swallowed; but we do not seem to have any certain account of such an effect.

12. The longipipes is the largest of the acarus kind: its body is roundish, of a dusky brown on the back, with a dusky spot of a rhomboidal figure near the middle of it; the belly is whitish; the legs are extremely long and slender. On the back part of the head there stands a little eminence, which has on it a kind of double crest, formed as it were of a number of minute spines: the eyes are small, and black, and are two in number. It is very common in pastures towards the end of summer. Ray and Lister call it acarus crufatus longipes; Moeufet, aracus longipes; and, notwithstanding its having but two eyes, it has been almost universally ranked among the spiders.

ACASTUS, in classic history, the son of Peleus, king of Thetis, and one of the most famous hunters of his time, married Hippolyta, who falling desperately in love with Peleus her son-in-law, and he refusing to gratify her wishes, she accused him to her husband of rape; on which he slew them both.

ACATALECTIC, a term, in the ancient poetry, for such verses as have all their feet or syllables, in contradistinction to those that have a syllable too few.

ACATAPSY, signifies the impossibility of comprehending something. — The distinguishing tenet of the Pyrrhonists was their affecting an absolute acataply in regard to every thing.

ACATERY, or ACATRY, anctiently an officer of the king’s household, designed for a check between the clerks of the kitchen and the purveyors.
Thus, we

ACATHISTUS, the name of a solemn hymn anciently sung in the Greek church on the Saturday of the fifth week of Lent, in honour of the Virgin, for having thrice delivered Constantinople from the invasions of the barbarous nations.

ACCELERATION, in ancient navigation, a kind of boat or pinnace used for military purposes. The 
aeolum was a species of those vessels called naeum ablatum, i.e. such as were wrought with oars. It was sometimes made use of in battle. Strabo describes it as a privateer or private boat.

ACAIULUS, in botany, a term applied to certain plants, the flowers of which have no pedicel or stalk to support them, but rest immediately on the ground, such as the cardine thistle, &c.

ACCA (St.), bishop of Hagufakitis, or Hexham, in Northumberland, succeeded Wilfrid in that see in 769. He ornamented his cathedral in a most magnificent manner: he furnished it also with plate and holy vestments; and erected a noble library, consisting chiefly of ecclesiastical learning, and a large collection of the lives of the saints, which he was at great pains to procure. He was accounted a very able divine, and was famous for his skill in church-music. He wrote several pieces: particularly, Faedone Sanctorum, the Sufferings of the Saints; Pro illud etanu scripturis, ad Be- dena, for explaining the scripture, addrefTed to Bede. He died in 740, having enjoyed the see of Hexham 31 years, under Egbert king of the Northumbrians.

ACCALIA, in Roman antiquity, solemn festivals held in honour of Acca Laurentia, Romulus's nurse: they were otherwise called Laurentalia.

ACCAPITARE, in law, the act of becoming vassal of a lord, or of yielding him homage and obedience.

Hence, ACCAPITUM, signifies the money paid by a vassal upon his admission to a fev.

ACCUSATION, in ancient law, was used also to express the relief due to the chief lord. See RELIEF.

ACCEDAS AD CURIAM, in the English law, a writ lying, where a man has received, or fears, false judgment in an inferior court. It lies also for justice delayed, and is a species of the writ RECORDARE.

ACCELERATION, in mechanics, the increase of velocity in a moving body. Accelerated motion is that which continually receives fresh accelerations of velocity. Acceleration stands directly opposed to retardation, which denotes a diminution of velocity.

ACCELERATION is chiefly used in physics, in respect of falling bodies, i.e. of heavy bodies tending towards the centre of the earth by the force of gravity. That natural bodies are accelerated in their descent, is evident from various considerations, both a priori and posteriori. Thus, we actually find, that the greater height a body falls from, the greater impellion it makes, and the more vehemently does it strike the subject plane, or other obstacle.

Various were the systems and opinions which philosophers produced to account for this acceleration. But the immediate cause of acceleration is now sufficiently obvious; the principle of gravitation, which determines the body to descend, determining it to be accelerated by a necessary consequence.

Suppose a body let fall from on high: the primary cause of its beginning to descend is doubtless the power of gravity; but when once the descent is commenced, that force becomes in some measure natural to the body; so that if left to itself, it would perforce in it for ever, even though the first cause should cease: as we see in a stone cast with the hand, which continues to move after it is left by the cause that gave it motion. But, beside the propensity to descend impressed by the first cause, and which of itself were sufficient to continue the same degree of motion, once begun, in infinitum; there is a constant accession of subsequent efforts of the same principle, gravity, which continues to act on the body already in motion, in the same manner as if it were at rest. Here, then, being a double cause of motion; and both acting in the same direction, viz. directly towards the centre of the earth; the motion they jointly produce must necessarily be greater than that of any one of them. And the velocity thus increased having the same direction of increase full persisting, the descent must necessarily be continually accelerated.

The motion of a body ascending, or impelled upwards, is diminished or retarded from the same principle of gravity, acting in another direction, in the same manner as a falling body is accelerated: See RETA-

RICATION. A body thus projected upwards, rises till it has lost all its motion: which it does in the same time that a body falling would have acquired a velocity equal to that whither the body was thrown up. Hence the same body thrown up, will rise to the same height from which falling it would have acquired the velocity wherewith it was thrown up: And hence the heights which bodies thrown up with different velocities do ascend to, are one to another as the squares of those velocities.

ACCELERATION of Bodies of Inclined Planes. The same general law obtains here as in bodies falling perpendicularly: the effect of the plane is to make the motion slower; but the inclination being everywhere equal, the retardation arising therefrom will proceed equally in all parts, at the beginning and at the ending of the motion. See MECHANICS.

ACCELERATION of the Motion of Pendulums. The motion of pendulous bodies is accelerated in their descent; but in a less ratio than that of bodies falling perpendicularly. See MECHANICS and PENDULUM.

ACCELERATION of the Motion of Projectiles. See PROJECTILE.

ACCELERATION is also applied in the ancient astronomy, in respect of the fixed stars. This acceleration was the difference between the revolution of the primary mobile and the solar revolution; which was computed at three minutes and 56 seconds.

ACCELERATION of the Moon, a term used to express the increase of the moon's mean motion from the sun, compared with the diurnal motion of the earth: so that it is now a little swifter than it was formerly. Dr Halley was the first who made this discovery; and he was led to it by comparing the ancient eclipses observed at Babylon with those observed by Albatennius in the ninth century, and some of his own time. He was not able to ascertain the quantity of this acceleration, because the longitudes of Bagdad, Alexandria, and Aleppo, where the observations were made, had not been
been accurately determined. But since his time, the
longitude of Alexandria has been ascertained by Chas-
uelles; and Babylon, according to Prolemy’s account,
lies 50° east from Alexandria. From these data, Mr
Dunthorne compared several ancient and modern eclip-
es, with the calculations of them, by his own tabular
and thereby verified Mr. Hale’s opinion; for he found that
the former tables represent the moon’s place more back-
ward than her true place in ancient eclipses, and more
forward than her true place in later eclipses; and thence
justly inferred, that her motion in ancient times was
flower; in later times quicker, than the tables give it.
But he did not content himself with merely, ac-

certaining the fact; he proceeded to determine the quan-
tity of the acceleration; and by means of the most ancient
eclipse of which any authentic account remains, ob-
served at Babylon in the year before Christ 721, he
concluded, that the observed beginning of this eclipse
was not above an hour and three-quarters before the
beginning given by the tables; and therefore the moon’s true
place could precede her place by computation but little
more than 50° of a degree at that time. Admitting
the acceleration to be uniform, and the aggregate of
it as a square of the time, it will be at the rate of
about 10° in 100 years.

Dr. Long attributes the acceleration above described to
one or more of these causes: either. 1. The annual
and diurnal motion of the earth continuing the fame,
the moon is really carried round the earth with a
greater velocity than heretofore; or, 2. The diurnal motion
of the earth, and the periodical revolutions of the moon
continuing the same, the annual motion of the earth
round the sun is a little retarded; which makes the
moon’s apparent motion in the ecliptic a little slower
than formerly, and consequently, the moon in passing
‘from any conjunction with the sun, spends less time
before the again overtakes the sun, and forms a sub-
sequent conjunction: in both these cafes, the motion
of the moon from the sun is really accelerated, and
the synodical moon actually shortened. Or; 3. The annual
motion of the earth, and the periodical revolutions, of the
moon continuing the same, the rotation of the earth round its axis is a little retarded: in this case
days, hours, minutes, seconds, &c., by which all periods
of time must be measured, are of a longer duration;
and consequently the synodical moon will appear to
be shortened, though it really contains the same quan-
tity of absolute time as it always did. If the quantity
of matter in the body of the sun be leffened by the
particles of light continually streaming from it, the
motion of the earth round the sun may become slower:
if the earth increases in bulk, the motion of the moon
round the earth may be quickened thereby. See A-
STRONOMY.

ACCELERATOR, in anatomy, the name of two
muscles of the penis, which serve for ejaculating
or semen. See ANATOMY, Table of the Muscles.

ACCELERENTES, a lower order of minifters in the
Romish church, whose office is to light and trim
the candles.

ACCELERONES, in Roman antiquity, a kind of
gladiators, whose office was to excite and animate the
combatants during the engagement. The orthogra-
phy of the word is controverted: the first edition of Ter-
tullian, by Rhenanus, has it accedones; an ancient
manuscript, accendones. Aquinas adheres to the for-
er, Pighius to the latter. The origin of the word, sup-
tposing it accedones, is from accedo, I kindle; sup-
tposing it accedones, from accedo, I accede, am added to.
The former places their distinguishing character in ex-
livening the combat by their exhorations and go-

tions; the latter supposes them to be much the same
with what among us are called seconds, among the Ita-
lians, patroni: excepting that these latter only fend by
to see the laws of the sword duly observed, without in-
termeddling to give advice or instruction.

ACCENSI, in the Roman armies, certain supernu-
merary folders, destined to supply the places of tho-
of an elocution of the voice. The Latins have made the

fame ufe of these three accents.

The Hebrews have a grammatical, a rhetorical, and

musical accent; through the first and last seem, in effect,
to be the fame; both being comprized under the ge-

geral name of tonic accents, because they give the pro-

per tone to syllables; as the rhetorical accents are said
to be euphonic, because they tend to make the

pronunciation more soft and agreeable. There are

dre euphonic accents, and twenty-five tonic; of which some

are placed above, and others below the syllables; the

Hebrew accents serving not only to regulate the risings

and fallings of the voice, but also to distinguish the

phrases, periods, and numbers of periods, in a discourse;

and to answer the same purposes with the points in

other languages. Their accents are divided into

emperors, kings, dukes, &c., each bearing a title an-

swering to our point. Their king answers to our colon;

and their duke to our comma. The king, however, oc-

casionally becomes a duke, and the duke a king; as the

phrases are more or less short.

It must be noted, by the way, that the manage-

ment and combination of these accents differ in Hebrew

poetry from what they are in prose. The use of the to-

nic or grammatical accents has been much controver-

sied: some holding that they distinguish the sen-

fence; while others maintain that they are only intended to

regulate the music, or singing; alleging that the Jews

sing, rather than read, the scriptures in their

scripts; whereas the Academics, or grammarians, uti-

lize them in their syna-

gogues. Be this, however, as it will, it is certain the

ancient Hebrews were not acquainted with these ac-

cents. The opinion which prevails amongst the learn-

ed, is, that they were invented about the fifth century,

by the Jewish doctors of the school of Tiberias, called

the Mafforetes.

As to the Greek accents, now seen both in manu-

scripts and printed books, there has been no lefs dis-

pute about their antiquity and ufe than about those of

the Hebrews. Isaac Volfius endeavours to prove them

of modern invention; alleging, that anciently they had

nothing of the kind, but only a few notes in their po-

etry, which were invented by Arithophanes the gram-

marian, about the time of Ptolemey Philopater; and

that these were of musical, rather than grammatical ufe,

serving as aids in the singing of their poems, and very
different from those introduced afterwards. He also

flows from several ancient grammarians, that the man-

ner of writing the Greek accents in these days was quite

different from that which appears in our books. The

author of Lall:thode Grecq.ep. 546 observes, that the right

pronunciation of the Greek language being natural to

the Greeks, it was needless for them to mark it by ac-

cents in their writings: so that, according to all ap-

pearance, they only began to make ufe of them after-

as the time in which the Romans, being curious to

learn the Greek tongue, sent their children to study at

Athens, thinking thereby to ftrengthen the pronunciation; and

to facilitate it to foreigners; which happened, as the fame

author observes, a little before Cicero's time. Weinfein,

Greek professor at Basil, in a learned dissertation,

deveaurs to prove the Greek accents of an older stand-

ing. He owns that they were not always formed in the

fame manner by the ancients; but thinks that difference

owing to the different pronunciation which obtained in

the different parts of Greece, he brings several reasons,

a priori, for the ufe of accents, even in the earliest days:

as that they then wrote all in capital letters equidistant

from each other, without any distinction either of words

or phrases, which without accents could scarce be in-
telligible; and that accents were neceffary to diftinguish

ambiguous words, and to point out their proper mean-

ing; which he confirms from a dispute on a pallage in

Homer, mentioned by Aristotle in his l DETT, chap. v.

Accordingly, he observes, that the Syrians, who have

tonic, but no distinctive accents, have yet invented cer-

tain points, placed either below or above the words, to

show their mood, tense, perfon, or fence.

The ufe of accents, to prevent ambiguities, is most

remarkably perceived in some eastern languages, par-

icularly the Siamese and Chinese. Among the peo-

ple of China, every word, or (which is the fame thing)

fyllable, admits of five accents, as spoken more accurately

or remifly; and thus stands for many different things.

The fame found ya, according to the accent affixed

to it, signifies God, a wall, excellent, stupidity, and a

goofy. The Chinese have but 320 spoken words in their

language; but these being multiplied by the different

accents or tones, which affect the vowels, furnish a

language tolerably copious. By means hereof, their

330 simple founds come to denote 1650 things; but

this being hardly fufficient, they are encrafed further

by aspirates added to each word to double the number.

The Chinese only reckon four accents: for which the

milifonaries ufe the following marks, a, a, a, a; to

which they have added a fifth, thus, ا. They made a

kind of modulation; wherein, prolonging the duration

of the found of the vowel, they vary the tone, rafing

and finking it by a certain pitch of voice: so that their

talking is a fort of music or finging. Attempts have

been made to determine the quantity of the rife or fall in

each accent by means of musical notes; but this is

effect, as being different in different persons. Hence

the great difficulty of the language to foreigners; they

are forced to sing most scrupulously: if they deviate

ever fo little from the accent, they fay quite a diffe-

rent thing from what was intended. Thus, meaning

to compliment the perfon you are talking to with the

title Sir, you call him a bead with the fame word,

only a little varied in the tone. Magalhon makes the

language the eafier to learn on this account.— The

Siamese are also obfervcd to sing rather than talk.

Their alphabet begins with fix characters, all only

equivalent to a K, but differently accented. For the

in the pronunciation the accents are naturally on the

vowels, yet they have fome to deftrify fuch of their

confonants as are in other refpects the fame.

Accent, in music, is a certain enforcement of par-

ticular founds, whether by the voice or instruments,

generally ufed at the beginning of bars.

Acceptance, in law, a perfon's agreeing to offers

made in bargaining, by which the bargain is con-

cluded. 

Acceptance, in the church of Rome, is put for

receiving the pope's confitutions.

Acceptance, in commerce, is the fubscribing,

signing, and making one's felf debtor for the sum con-
nained in a bill of exchange or other obligation.

Acceptation, in grammar, the fentence or mean-
ing wherein any word is taken.
ACCESSIBLE, something that may be approached, or that access may be had to. Thus we say, Such a place is accessible on one side, &c.

ACCESSION, in law, is a method of acquiring property, by which, in things that have a close connection or dependence upon one another, the property of the principal thing draws after it the property of the accessory: Thus, the owner of a cow becomes likewise the owner of the calf. It is sometimes likewise signifies content or acquiescence.

ACCESSION, among physicians, is used for a paroxysm of a disease; among politicians, it signifies a prince's succeeding to the government upon the death of his predecessor.

ACCESSORY, or Accessory, something that accedes, or is added to another more considerable thing; in which sense the word stands opposed to principal.

Accessory, or Accessory, in common law, is chiefly used for a person guilty of a felonious offence, not principally, but by participation: as, by assistance, or comfort, or concealment.

There are two kinds of accessories: one, before the fact, and after it.—The first is he who commands, or procures another to commit felony, and is not present himself; for if he be present, he is a principal. The second is he who receives, affilits, or comforts any man that has done murder, or felony, whereof he has knowledge. A man may be also accessory to an accessory, by aiding, receiving, &c. an accessory in felony.

An accessory in felony shall have judgment of life and member, as well as the principal who did the felony; but not till the principal be first attainted, and convicted, or outlawed thereon. Where the principal is pardoned without attainer, the accessory cannot be arraigned; it being a maxim in law, Ubi non est principalis, non potest esse accessorius: but if the principal be pardoned, or have his clergy after attainer, the accessory shall be arraigned; 4 and 5 W. et M. cap. 4. And by lat. 1 Anne, cap. 9. it is enacted, that where the principal is convicted of felony, or flands mute, or challenges above 20 of the jury, it shall be lawful to proceed against the accessory in the same manner as if the principal had been attainted; and notwithstanding such principal shall be admitted to his clergy, pardoned, or delivered before attainer. In some cases only, if the principal cannot be taken, then the accessory may be prosecuted for a misdemeanour, and punished by fine, imprisonment, &c. In the lowest and highest offences there are no accessories, but all are principals: as in riots, roasts, forcible entries, and other trespasses, which are the lowest offences. So also in the highest offence, which is, according to the English law, high treason, there are no accessories.

Accessories, in petty treason, murder, and in felonies of several kinds, are not to have their clergy. There can be no accessory before the fact in manslaughter; because that is sudden and unpremeditated.

ACECITY Nerves, in anatomy, a pair of nerves, which, arising from the medulla in the ventricles of the neck, ascend, and enter the skull, and pass out of it a gain with the par vagum, wrapped up in the same common integument, and after quitting them, are distributed into the muscles of the neck and shoulders. See Anatomy.

ACCESSORY, among painters, an epithet given to such parts of an history-piece as serve chiefly for ornament, and might have been wholly left out: such as vases, armour, &c.

ACCIDENT, a town of Tarraconensis, formerly called Acti; supposed to be Aquadis, to the city of Granada, at the foot of a mountain, near the source of the rivulet Guadalantin; now greatly decayed. It is the Colonia Accitania Genella, and was of some repute among the Roman colonies. The people were called Gemellenses, because the colony consisted of colonists from the third and sixth legions.

ACCI AOLOI (Donata), a man famous for his learning and the honourable employments he professed in Florence his native country, in the 15th century. He wrote, A Latin translation of some of Plutarch's Lives; Commentaries on Aristotle's Ethics and Politics; and the life of Charlemagne. He was sent to France by the Florentines, to sue for succour from Lewis XI. against Pope Sextus IV. but on his journey died at Milan; his body was carried to Florence, and buried in the church of the Carthusians. The small fortune he left his children is a proof of his propriety and disinterestedness. His daughters, like those of Arilides, were married at the public expense, as an acknowledgement of his services. His funeral eulogium was spoken by Christopher Landini; and an elegant epitaph, by Poltions, was inscribed on his tomb.

ACCIDENT, in a general sense, denotes any casual accident.

ACCIDENT, among logicians, is used in a threefold sense. 1. Whatever does not essentially belong to a thing; as the clothes a man wears, or the money in his pocket. 2. Such properties in any subject as are not essential to it; thus whiteness in paper. 3. In opposition to essentiality whatever are called accidents; as sweetness, softness, &c.

ACCIDENT, in grammar, implies a property attached to a word, without entering into its essential definition; for every word, notwithstanding its signification, will be either primitive, derivative, simple, or compound, which are the accidents of words. A word is said to be primitive, when it is taken from no other word in the language in which it is used; thus heaven, king, good, are primitive words. It is said to be derivative, when it is taken from some other word; thus heavens, kingdom, goodness, &c. are derivatives. A simple word is easily distinguished from a compound; thus just, justice, are simple words; unjust, injustice, are compound: res is a simple word, as well as public; but republca is a compound. Besides these accidents, which are common to all sorts of words, each particular species has its accidents; thus the accidents of the noun substantive are the gender, declension, and number; and the adjective has another accident, namely, the comparison. See the article Grammar and Language.

ACCIDENT, in heraldry, an additional point or mark in a coat of arms, which may be either omitted or retained without altering the essence of the armour; such as, abatement, difference, and tincture.
ACCIDENTAL, in a general sense, implies something that happens by accident, or that is not essential to its subject. ACCIDENTA, in philosophy, is applied to that effect which flows from some cause intervening by accident, without being subject, or at least without any appearance of its being subject, to general laws or regular returns. In this sense, accident is opposed to constant and principal. Thus the sun's place is, with respect to the earth, the constant and principal cause of the heat in summer, and the cold in winter; whereas winds, snows, and rains, are the accidental causes which often alter and modify the action of the principal cause.

ACCIDENTAL point, in perspective, is that point in the horizontal line which are the projections of twolines, parallel to each other meet the perspective plane.

ACCIDENTAL Colours, are those which depend upon the affections of the eye, in contradistinction to those which belong to the light itself. The impressions made upon the eye by looking steadfastly at a particular colour, are various, according to the single colour or combination of colours in the object; and they continue for some time after the eye is withdrawn, and give a false colouring to other objects. Mr Buffon has endeavoured to trace the connections which these accidental colours have with such as are natural, in a variety of instances. The subject has also been considered by De la Hire, and M. Epences; and M. d’Arcy has contrived a machine for determining the duration of the effects of light, and after several trials, finds that it continues about eight thirds of a minute.

ACCIPENSER, in ichthyology, a genus of fishes belonging to the Amphibia Nantes of Linnaeus. The accipenser has a single linear nodule: the mouth is in the under part of the head, and contains no teeth; the cirri are below the fin, and in front of the mouth. There are three species of this genus, viz.

1. The ruthenus has 4 cirri, and 15 squamous proterubances. It is a native of Russia.
2. The huo has 4 cirri; the body is naked, i.e. has no prickles or proterubances. The skin of the huo is so tough and strong, that it is employed for ropes in carts and other wheel-carriages; and the ichthyocolla, or binglass of the shops, famous as an agglutinant, and used also for the fining of wines, is made from its scale or scales. The ancients were acquainted with the fish that afforded this drug. The huo is the largest of the genus, and grows to 24 feet in length. It inhabits the Danube and the rivers of Russia.
3. The fluoro, or flurgeon, with 4 cirri and 12 squamous proterubances on the back. This fish annually ascends the rivers in Britain, but in no great numbers, and is taken accident in the salmon-nets. It seems a spiritifed fish, making no manner of resistance when entangled, but is drawn out of the water like a lifeless lump. It is seldom taken far out at sea, but frequents such parts as are not remote from the acutions of great rivers. It is admired for the delicacy and firmness of its flesh, which is white as veal, and extremely good when roasted. It is generally pickled. A considerable quantity are annually sent to Britain from America and the Baltic rivers. Great numbers are taken during summer in the lakes Frisehaff and Cunrich-haff near Pillau, in large nets made of small cord. The adjacent shores are formed into districts, and turned out to companies of fishermen, some of which are reured for six thousand guilders, near three hundred pounds per annum. They are found in vast abundance in the American rivers in May, June, and July; at which time they leap some yards out of the water, and, falling on their sides, make a noise to be heard in full weather at a great distance. Caviare is made of the roe of this fish, and also of all the other sorts of flurgeon, dried, salted, and pickled up clofe. Ichthyocolla, or tiglafra, is likewise made of the found of this fish, as well as that of the others; but in very small quantity. The flurgeon grows to a great size, to the length of 18 feet, and to the weight of 500 pounds. In the manner of breeding, this fish is an exception among the cartilaginous kind; being, like the bony fish, oviparous, spawning in water.

ACCIPITER, the name of Linnaeus's first order of Birds. See ZOOLOGY.

Among the Romans, the term accipiter signified a hawk, and which, from its being very carnivorous, they are considered as birds of bad omen.

Ovid. 

Pliny, however, tells us, that in some cafes, particularly in marriage, it was esteemed a bird of good omen, because it never eats the hearts of other birds; intimating thereby, that no differences in a married state ought to reach the heart. The accipiter was worshipped as a divinity by the inhabitants of Tentyra, an island in the Nile, being considered by them as the image of the sun; and hence we find that luminary represented, in hieroglyphics, under the figure of a hawk.

ACCIUS (Lucius), a Latin tragic poet, the son of a freedman, and, according to St Jerome, born in the consilhip of Hoftillius Mainicus and Atilius Serranus, in the year of Rome 593; but there appears somewhat of confusion and perplexity in this chronology. He made himself known before the death of Pacuvius, a dramatic piece of his being exhibited the same year that Pacuvius brought one upon the stage, the latter being then eighty years of age, and Accius only thirty. We do not know the name of this piece of Accius's, but the titles of several of his tragedies are mentioned by various authors. He wrote on the most celebrated stories which had been represented on the Athenian stage: as Andromache, Andromeda, Ateus, Clytemnestra, Medea, Meleager, Philocletes, the
Acclamations were not unknown on the theatres in the earliest ages of the Roman commonwealth; but they were incident then, and little other than confused shouts. Afterwards they became a sort of regular concerts. That mentioned by Phedrus, letus e mediasmos Roma falso princeps, which was made for Augustus, and proved the occasion of a pleasant mixture of a flute-player called Princps, shows that musical acclamations were in use in that emperor's reign. Recepit enim Provincia nobiliss. caroliss. f. regi. quae fpetulat, says Suetonius, who gives another instance in the time of Tibersius: a false report of Germanicus's recovery being spread through Rome, the whole ran in crowds to the Capitol with torches and victims, singing, Salvya Roma, Salto Patria, Saltem off Germaniis.—Nero, passionately fond of music, took special care to improve and perfect the music of acclamations. Charmed with the harmony wherewith the Alexandrians, who came to the games celebrated at Naples, had sung his praises, he brought several over to infract a number of youth, chosen from among the knights and people, in the different kinds of acclamations practised at Alexandria. They continued in use as long as the reign of Theodoric. But the people did not always make a single chorus; sometimes there were two, who answered each other alternately: thus, when Nero played on the theatre, Buthus and Seneca, who were on either hand, giving the signal by clapping, 5000 soldiers called Auluglatis, began to chant his praise, which the spectators were obliged to repeat. The whole was conducted by a music-master called Mefeborus or Panfarius.—The honour of acclamations was chiefly rendered to emperors, their children, and favourites; and to the magistrates who preferved the peace of the times. Persons of distinguished merit also sometimes received them, of which Quintilian gives us instances in Cato and Virgil. The most usual forms were, Feliciter, Loniorem citam, Aunos felicis. The actors themselves, and they who gained the prizes in the games of the circus, were not excluded from the honour of acclamations.

To theatrical acclamations may be added those of the soldiery and people in time of triumph. The victorious army accompanied their general to the Capitol; and, among the verbs they sung in his praise, frequently, to Triumpha, which the people answered in the same strain. It was also in the way of acclamations, that the soldiers gave their general the title of Imperator, after some notable victory; a title which he only kept till the time of his triumph.

The acclamations of the senate were somewhat more serious than the popular ones; but arose from the same principle, viz. a desire of pleasing the prince or his favourites; and aimed likewise at the same end, either to express the general approbation and zeal of the company, or to congratulate him on his victories, or to make him new protests of fidelity. These acclamations were usually given after a report made by some senator, to which the rest all expressed their consent by crying Omnes, Omnes; or else, Equum est, justum est. Sometimes they began with acclamations, and sometimes ended with them without other debates. It was by this manner that all the elections and proclamations of emperors, made by the senate, were conducted; something of which practice is still retained at modern elections of kings and emperors, where Voto.
Acclamations. Rev. Titre de Roy, and Long live the King, are customary forms.

The Greeks borrowed the custom of receiving their emperors in the public places from the Romans. Lutprand relates, that at a procession where he was present, they sung to the emperor Nicephorus, παραστατης; that is, Many years: which Codin explains thus, by τον ἔλεγον τοις παραστατης, or by τος παραστατης; and the wish or salutation by παραστατης. And at dinner, the Greeks then present wished with a loud voice to the emperor and Bradas, Ut Deus anus multiplicant; as he translates the Greek. Plutarch mentions an acclamation so loud, upon occasion of Flamininus's restoring liberty to Greece, that the very birds fell from heaven with the shout. The Turks practise something like this on the right of their emperors and grand viziers to this day.

For the acclamations wherewith authors, poets, &c. were received, who recited their works in public; it is to be observed, the assemblies for this purpose were held with great parade in the most solemn places, as the capital, temples, the Athenaeum, and the houses of great men. Invitations were sent every where, in order to get the greater appearance. The chief care was, that the acclamations might be given with all the order and pomp possible. Men of fortune who pretended to wit, kept able applauders in their service, and lent them to their friends. Others endeavoured to gain them by presents and treaties. Philostratus mentions a young man named Vavus, who lent money to the men of letters, and forgave the interest to such as applauded his exercises. These acclamations were conducted much after the same manner as those on the theatre, both as to the music and the accompaniments; they were to be suited both to the subject and to the person. There were particular ones for the philosophers, for orators, for historians, and for poets. It would be difficult to rehearse all the forms of them; one of the most usual was Sophies, which was to be repeated three times. Martial comprehends several other usual forms in this verse:

Accolation. Cита, Negquiter, Exus, Beate.

Neither the Greeks nor Romans were barren on this head. The names of gods and heroes were given thence whom they would extol. It was not enough to do it after each head of discourse, chiefly after the exordium; but the acclamations were renewed at every fine passage, frequently at every period.

The acclamations wherewith the speclators honoured the victories of the athletes, were a natural consequence of the impetuous motions which attended the gymnastic games. The cries and acclamations of the people, sometimes expressing their compassion and joy, sometimes their horror and disgust, are strongly painted by different poets and orators.

Acclamations made also a part of the ceremony of marriage. They were used for the man's sake; being the Latia Ovina, sometimes spoken of before marriage in Roman writers.

Acclamations, at first practised in the theatre, and palling thence to the senate, &c. was in process of time received into the acts of councils, and the ordinary assemblies of the church. The people expressed their approbation of the preacher variously; the more usual were, Griissant Thard Apothe, &c. There acclamations being sometimes carried to excess, and often miscalculated, were frequently prohibited by the ancient doctors, and at length abrogated; though they appear to have been in some use as low as the time of St. Bernard.

Acclamation M. thus, among antiquaries, such as represent the people expressing their joy in the posture of acclamation.

Accuracy, the rise or ascent of a hill, in opposition to the declivity or descent of it. Some writers in fortification use it for the talus of a rampart.

Accola, among the Romans, signified a person who lived near some place; in which sense it differed from incolla, the inhabitant of such a place.

Accolade, a ceremony anciently used in the conferring of knighthood.

Antiquaries are not agreed wherein the accolade properly consisted. The generality suppose it to be the embrace, or kiss, which princes anciently gave the new knight, as a token of their affection: whence the word accolade; q. d. a clasping, or taking round the neck. Others will rather have it to be a blow on the chine of the neck, given on the same occasion. The Accolade is of some antiquity, in which fewer of the two fenes it be taken. Greg. de Tours writes, that the kings of France, even of the first race, in conferring the girt shoulder-belt, kissed the knights on the left cheek. For the accolade, or blow, John of Salisbury affures us, it was in use among the ancient Normans: by this it was that William the Conqueror conferred the honour of knighthood on his son Henry. At first, it was given with the naked fist; but it was afterwards changed into a blow with the flat of the sword on the shoulder of the knight.

Accolée, sometimes synonymous with Accolade, which is also it is used in various senses in heraldry: sometimes it is applied to two things joined; at other times, to animals with crowns, or collars about their necks, as the lion in the Ogilvy's arms; and, lastly, to kews, battons, maces, swords, &c. placed fullerwise behind the shield.

Accolti (Bernardo), secretary to the republic of Florence, was furnished L'Unico, or the Nonfuch, probably from the great extent of his understanding, the variety of sciences he had acquired, and the excellency of his poetic vein; which not only gained him a feast among the academicians of the court of Urbino, but made that great Mecenas, pope Leo X. in 1520, create him prince of the state of Nepi. He wrote many pieces; among others, a collection of beautiful poems, printed in Venice in 1590 and 1553.

accommodation, the application of one thing, by analogy, to another; or the making two or more things agree with one another.

To know a thing by accommodation, is to know it by the idea of a similar thing referred thereto.

A prophecy of scripture is said to be fulfilled various ways: properly, as when a thing foretold comes to pass: and improperly, or by way of accommodation, when an event happens to any place or people, like to what fell out some time before to another. Thus, the words of Isaiah, spoken to thine of his own time; are said to be fulfilled in those who lived in our Saviour's; and are accommodated to them: "Ye hypocrites, well did Isaiah prophecy of you," &c. which same words St Paul afterwards accommodates to the Jews of his time.

The
The primitive church accommodated multitudes of Jewish, and even heathen ceremonies and practices, to Christian purposes; but the Jews had before done the same by the Gentiles; some will even have circumcision, the tabernacle, brazen serpent, &c. to have been originally of Egyptian use, and only accommodated by Moses to the purposes of Judaism. Spencer maintains, that most of the rites of the old law were an imitation of those of the Gentiles, and particularly of the Egyptians; that God, in order to divert the children of Israel from the worship they paid to the false deities, consecrated the greatest part of the ceremonies performed by those idolaters, and had formed out of them a body of the ceremonial law; that he had indeed made some alterations therein, as barriers against idolatry; and that he thus accommodated his worship to the genius and occasions of his ancient people. To this De lege, condensation of God, according to Spencer, is owing.

ACCOMPANIMENT, something attending or added as a circumstance to another, either by way of ornament, or for the sake of symmetry.

ACCOMPANY, in music, denotes the instruments which accompany a voice, in order to suit it, as well as to make the music more full. The accompaniment is used in recitative, as well as in song; on the stage, as well as in the choir, &c. The ancients had likewise their accompaniments on the theatre; they had even different kinds of instruments to accompany the chorus, from those which accompanied the actors in the recitation. The accompaniment, among the moderns, is frequently a different part or melody from the song it accompanies. It is disputed whether it was so among the ancients. It is generally alleged, that their accompaniments went no farther than the playing in octave, or in antiphony to the voice. The Abbé Frugier, from a passage in Plato, pretends to prove, that they had actual symphony, or music in parts: but his arguments seem far from being conclusive.

ACCOMPANY, in painting, denotes such objects as are added, either by way of ornament, or probability; as dogs, guns, game, &c. in a hunting piece.

ACCOMPANY, in heraldry, any thing added to a shield by way of ornament; as the belt, mantling, supporters, &c. It is also applied to several bearings about a principal one; as a saltier, bend, fess, chevron, &c.

ACCOMPLICE, one that has a hand in a business; or is privy in the same design or crime with another. See ACCESSORY.

By the law of Scotland, the accomplice can only be prosecuted after the conviction of the principal offender, unless the accession of the accomplice is immediate, in esp. airt, so as in effect to render them co-principal. By the general rule, the accomplice suffers the same punishment with the principal offender; yet if he he remarkably less guilty, justice will not permit equal punishment.

The council of Sens, and several other synodical statutes, expressly prohibit the revealing of accomplices. ACCOMPLISHMENT, the entire execution or fulfilling of any thing.

ACCOMPLISHMENT, is principally used in speaking of events foretold by the Jewish prophets in the Old Testament, and fulfilled under the New. We say a literal accomplishment, a mystical or spiritual accomplishment, a single accomplishment, a double accomplishment, a Jewish accomplishment, a Christian accomplishment. The same prophecy is sometimes accomplished in all, or in several of those different ways. Thus, of some of the prophecies of the Old Testament, the Jews find a literal accomplishment in their own history, about the time when the prophecy was given: the Christians find another in Christ, or the earliest times; the heathens another, in some of their emperors; the Mahometans another, in their legislator, &c. There are two principal ways of accomplishing a prophecy; directly, and by accommodation. See ACCOMMODATION, and PROPHECY.

ACCOMPLISHMENT, is also used for any mental or personal endowment.

ACCORD, in painting, is the harmony that reigns among the lights and shades of a picture.

ACCORDS (Stephen Tabourou, seigneur des) advocate in the parliment of Dijon in France, and king's advocate in the bailiwick and chancery of that city, born in the year 1549. He was a man of genius and learning; but too much addicted to trifles, as appears from his piece, intituled, "Les Bigarrures," printed at Paris in 1582. his was not his first production, for he had before printed some sonnets. His work, intituled, "Les Touches," was published at Paris in 1585; which is indeed a collection of witty poems, but worked up rather in too loose a manner, according to the licentious taste of that age. His Bigarrures are written in the same strain. He was cenured for this way of writing, which obliged him to publish an apology. The lordship of Accords is an imaginary fief or title from the device of his ancestors, which was a drum, with the motto, à tous accords, "chiming with all." He had sent a sonnet to a daughter of Mr Be - gat, the great and learned president of Burgundy, who (says he) did me the honour to love me; and inasmuch (continues he), I had inscribed my sonnet with only my device, à tous accords, this lady first nicknamed me, in her answer, Seigneur des Ac cord; by which title her father also called me several times. For this reason I chose this surname, not only in all my writings composed at that time, but even in these books." He died July 24th 1561, in the 40th year of his age.

ACCOUNT, or ACCOMPT, in a general sense, a computation or reckoning of any thing by numbers. Collectively, it is used to express the books which merchants, traders, bankers, &c. use for recording their transactions in business. See BOOK-KEEPING.

Chamber of Accounts, in the French polity, is a sovereign court of great antiquity, which takes cognizance of and registers the accounts of the king's revenue. It is nearly the same with the English Court of Exchequer.

ACCOUNT is taken sometimes, in a particular sense, for the computation of time: thus we say, The Julian Account, the Gregorian Account &c. in which sense it is equivalent to styie.

ACCOUNTANT, or ACCOUMTANT, in the most general sense, is a person skilled in accounts. In a more restricted sense, it is applied to a person, or officer, appointed to keep the accounts of a public company or office; as the South-sea.
ACCOUNTANTSHIP, the art of keeping and balancing accounts. See Book-keeping.

ACCOUNTANT-GENERAL, a new officer in the court of Chancery in Great Britain appointed by act of parliament to receive all moneys lodged in court instead of the masters, and convey the same to the bank of England for security.

ACCOUNTREMENT, an old term, applied to the furniture of a soldier, knight, or gentleman.

ACCRETION, in physics, the increase, or growth of an organical body, by the accession of new parts. See Nutrition, Plants, and Vegetables.

Accretion, among civilians, the property acquired in a vague or unoccupied thing, by its adhering to or adhering by right of accretion. The word comes from the Latin *accretio*, denoting a thing's being added to another already occupied; thus, if a legacy in a vague or unoccupied thing, by its adhering to or adhering to the survivor.

The Romans, during the frugal ages of the republic, were strangers to it: for as to this, it was reputed an indecency in them to place more than one person on each bed; to crowd more, was deemed for this reason.

The Romans, during the frugal ages of the republic, were strangers to this. Before they came to table, the pony stood at the head of the bed, with his feet extended behind the back of the second; the second lay with the back of his head towards the navel of the first, only separated by a pillow, his feet behind the back of the third; and so of the third, or fourth. The middle place was esteemed the most honourable. Before they came to table, they changed their clothes, putting on what they called *sanauria vestis*, the dining-garment; and pulled off their flows, to prevent fouling the couch.

ACCUBITOR, an ancient officer of the emperors of Constatinople, whose business was to lie near the emperor. He was the head of the youth of the bed-chamber, and had the *cubicularesium* and procurator under him.

ACCU MULATION, in a general sense, the act of heaping or piling things together. Among lawyers, it is used in speaking of the concurrence of several titles to the same thing, or of several circumstances to the accumulation of proof.

Accumulation of Degrees, in an university, is the taking several of them together, or at smaller intervals than usual, or than is allowed by the rules of the university.

ACCRUSED, something that lies under a curse, or sentence of excommunication. In the Jewish idiom, *accursed* and *crucified* were synonymous. Among them, every one was accounted *accursed* who died on a tree. This serves to explain the difficult passage in Rom. ix. 3, where the apostle Paul wishes himself *accursed* after the manner of Christ, i.e. crucified, if happily he might by such a death save his countrymen. The proposition is here made use of, is used in the same sense, 2 Tim. 1. 3, where it obviously signifies after the manner of.

ACCRUSIUS, a law-professor in the 13th century, born in Florence. His authority was for some time so great, that he was called the idol of the Lawyers. —Other three lawyers of note had the same name.

Accursius (Mariangelus), a famous critic of the 12th century, born at Aquilon in the kingdom of Naples. His Diatribe, printed at Rome in folio in 1524, on Ovid and Solinus, are a proof of his abilities in this kind of erudition. In his edition of Ammianus Marcellinus there are five books more than in any of the preceding ones; and he affirms he had corrected 5000 errors in that historian. His predominant passion was the searching for and collecting of old manuscripts: yet he made Latin and Italian verses, was complete master of the French, German, and Spanish tongues; and understood optics and music. He purged himself by oath, being charged for being a plagiarist with regard to his Antonius; it being reported, that he had appropriated to himself the labours of Pa- bricio Varana, bishop of Camerino.

ACCUSATION, the charging any person with a criminal action, either in one's own name, or in that of the public. The word is compounded of *ad*, to; and *causeri*, to plead.

Writers on politics treat on the benefit and the inconveniences of public accusations. Various arguments are alleged, both for the encouragement and discouragement of accusations against great men. Nothing, according to Michelet, tends more to the preservation of a state, than frequent accusations of persons trusted with the administration of public affairs. This, accordingly, was strictly observed by the Romans, in the instances of Camillus, accused of corruption by Manlius Capitolinus, &c. Accusations, however, in the judgment of the same author, are not more beneficial than calumnies are pernicious; which is also confirmed by the practice of the Romans. Manlius not being able to make good his charge against Camillus, was cast into prison.

By the Roman law, there was no public accuser for public crimes; every private person, whether interested in the crime or not, might accuse, and prosecute the accused to punishment, or abolishment. Cato, the most innocent person of his age, had been accused 42 times, and as often abolished. But the accusation of private crimes was never received but from the mouths of those who were immediately interested in them; None (e.g.) but the husband could accuse his wife of adultery.

The
The ancient Roman lawyers distinguished between posdatio, delatia, and accusatio. For, acrim, leave was granted to bring a charge against one, which was called posdatio; when he against whom the charge was laid, was brought before the judge: which was called derever, or nonnus delatia: lastly, the charge was drawn up and presented, which was properly the accusatio. The accusation properly commenced, according to Padianus, when the reus or party charged, being interrogated, denied he was guilty of the crime, and subscribed his name to the delatia made by his opponent.

In the French law, none but the Procureur general, or his deputies, can form an accusation, except for high-treason and coinage, where accusation is open to every body. In other crimes, private persons can only act the part of denounced, and demand reparation for the offence, with damages.

In Britain, by Magna Charta, no man shall be imprisoned or condemned on any accusation without trial by his peers, or the law: none shall be vexed with any accusation, but according to the law of the land; and no man may be molested by petition to the king, &c., unless it be by indictment or presentment of lawful men, or by process at common law. Promoters of suggestions, are to find surety to purge them; and if they do not make them good, shall pay damages to the party accused, and also a fine to the king. No person is to be made a party, unless it be by petition to the king, &c.

There are several kinds of birth, from Schenckius, for the offence, with damages. The accused, and also a fine to the king. No person is not make them good, unless it be by petition to the king, &c., unless it be by indictment or presentment of lawful men, or by process at common law. Promoters of suggestions, are to find surety to purge them; and if they do not make them good, shall pay damages to the party accused, and also a fine to the king. No person is to be made a party, unless it be by petition to the king, &c.

The ancient voyagers, viewing certain barbarous people from the coasts, had been impressed by their uncouth dress; for that the Samogitians, being florn of stature, and going in the vicinity of winter with their heads covered in hoods, seem at a distance as if they were headless. P. Laftat says, that by Acephaloi are only meant, people whose heads are sunk below their shoulders. In effect, Hulius, in his epitome of Sir Walter Raleigh's voyage to Guiana, also speaks of a people which that traveller found in the province of Irivipana, between the lakes of Panama and Callipus, who had no head or neck; and Hondius, in his map, marks the place with the figures of three monsters. Yet De Lacta rejects the story; being informed by others, that the inhabitants of the banks Amer.l.7 of the Caora, a river that flows out of the lake of c. 22. Callipus, have their head so far sunk between their shoulders, that many believed they had their eyes in their shoulders and their mouths in their breasts.

But though the existence of a nation of Acephaloi be ill warranted, naturalists furnish several instances of individuals born without heads, by some lufus or aberration of nature. Wepfer gives a catalogue of such accephalous births, from Schenckius, Licetus, Pariss, Wollfs, Mauriceau, &c.

Acephaloi, an obsolete term for the taenia or tape. 

Acephali, a term applied to several sects who refused to follow some noted leader. Thus the perons who refused to follow either John of Antioch, or St Cyril, in a dispute that happened in the council of Ephesus, were termed Acephaloi, without a head or leader. Such bishops, also, were as exempt from the jurisdiction and discipline of their patriarchs, were styled Acephali.

Acephali, the levellers in the reign of Henry I. who acknowledged no head or superior. They were reckoned so poor, that they had not a tenement by which they might acknowledge a superior lord.

Acephalous, or Acephaloi, in a general sense; without a head.

The term is more particularly used in speaking of certain nations, or people, represented by ancient naturalists and cosmographers, as well as by some modern travellers, as formed without heads; their eyes, mouths, &c., being placed in other parts.

Such are the Blemmyes, a nation of Africa near the head of the Niger, represented to be by Pliny and Solinus; Blemmyes traduntur capita abebe, ore et oculis bellentis. Ctesias and Solinus mention others in India near the Ganges, fine cervix, caules in humoris habentem. Mela also speaks of people, quius capitis et velutis in pettere, quarto. And Suidas, Stephanus Byzantius, Vopiscus, and others after them, related the like. Some modern travellers still pretend to find accephalous people in America.

Several opinions have been framed as to the origin of the fable of the Acephali. The first is that of Thomas Bartholin, who turns the whole into a metaphor; being convinced, that the name Acephali was anciently given to such as had loss brain, or conducted themselves as by the rules of prudence, than others. Olearius rather apprehends, that the ancient voyagers, viewing certain barbarous people from the coasts, had been impressed by their uncouth dress; for that the Samogitians, being short of stature, and going in the vicinity of winter with their heads covered in hoods, seem at a distance as if they were headless. P. Laftat says, that by Acephali are only meant, people whose heads are sunk below their shoulders.

In effect, Hulius, in his epitome of Sir Walter Raleigh's voyage to Guiana, also speaks of a people which that traveller found in the province of Irivipana, between the lakes of Panama and Callipus, who had no head or neck; and Hondius, in his map, marks the place with the figures of three monsters. Yet De Lacta rejects the story; being informed by others, that the inhabitants of the banks Amer.l.7 of the Caora, a river that flows out of the lake of c. 22. Callipus, have their head so far sunk between their shoulders, that many believed they had their eyes in their shoulders and their mouths in their breasts.

But though the existence of a nation of Acephali be ill warranted, naturalists furnish several instances of individuals born without heads, by some lufus or aberration of nature. Wepfer gives a catalogue of such accephalous births, from Schenckius, Licetus, Pariss, Wollfs, Mauriceau, &c.
A C E [ 60 ] A C E

Acer, or the Maple-tree, is a genus of the monoeoic order, belonging to the polymagia class of plants; and ranking under the 23d Natural Order Trihitita. — The generic characters, both natural and essential, are: The Hermaprodite calyx is an acute, coloured, one-leaved perianthium, divided into five segments, flat and entire at the base, and persistent: the corolla is five-petal'd, ovate, and expanding; the flamina consist of eight subulate short filaments; the anther is simple, the dust cruriform: The pistillum has a compriised germen, imbeded in the receptacle, which is convex, perforated, and large; the stylos is filiform: the stigma are two, pointed, slender, and reflex: The perianthium consists of two or three capsulars, united at the base, roundish, compriised, each terminated with a large membranous wing: The seeds are solitary and roundish. The Male caty's, corolla, and flamina, are the same as in the hermaphrodite; the pistillum has no germen, nor stylos; the stigma is beaded. [Nota. On the first opening of the flower, the stigma alone appears; a few days after, the stylos. — The hermaphrodite flowers on the same umbel are frequently of two sorts: the inferior ones feminine, the antheres of which do not burst, but the pistillum quickly grows into fruit: the superior ones masculine, of which the antheres scatter their pollen, but the pistillum without increasing fall off.]

Species, with their uses and properties. — 1. The pendif-platanus, or sycamore, is a very large and beautiful tree, with broad leaves, divided into five lobes serrated in their edges; of a dark green colour on the upper side, but paler and somewhat hoary underneath; the flowers are very small, and of a greenish white colour. The corolla of this species is frequently distinguisihable from the other, and the stamina are long. The fruit is large, and beautifully variegated with green and purple. This species is a native of Germany, but thrives very well in Great Britain, where it is frequent in plantations. It is very proper for making plantations near the sea, or sheltering such as are already too near it; because the sycamore-tree refists the spray of the ocean much better than most other trees. But it has this inconvenience, that its leaves are devoured by insects, so as to become full of holes, and very unightly: which has caused the planting of it to be much neglected of late. It has, however, long been considered as a timber tree, having been much used by the turners for wooden bowels, dilies, trenchers, &c.; but since the custom of using earthen ware has become so prevalent, its value for those purposes has greatly decreased. There are two varieties; one with broad leaves and large keys, the other with variegated leaves. By tapping it yields a liquor not unlike that of the birch tree; from which the highlanders of Scotland some times make an agreeable and wholesome wine.

2. The campestris, or common maple, is too well known to need any particular description, as it grows very frequently in hedge-rows in most parts of Britain. The timber of the common maple is far superior to the beech for all the uses of the turner. When it abounds with knots, as it frequently does, it is highly esteemed by joiners for inlaying. It is also frequently employed for making musical instruments, on account of its lightness; and for the whiteness of its wood was formerly esteemed for making tables, &c. But the principal value of the maple is for underwood; it being of a quick growth, and affording good fuel.

3. The negundo, or Virginian ash-leaved maple, is a very strong hoothing tree; and in Virginia, where it is a native, is one of the largest trees of this kind. Its leaves are of a pale green, and well adapted to give a variety of tint: but Hanbury says, that this tree ought not to be planted in exposed situations, the branches being subject to be split off by the wind. Its uses are similar to those of the sycamore.

4. The Platanoids, or Norway-maple, grows naturally in Norway, Sweden, and other northern countries of Europe. It rises to a good height, and is well furnished with branches with smooth leaves, of a shining green colour, and beautifully indented. These have an acid milky juice, which prevents them from being preyed upon by insects as the sycamore is; and as this species refists the spray of the sea equally with the fir, it is preferable in plantations situated near the sea. In summer the leaves dye to a golden yellow colour, which caueth a delightful effect at that season when the different tints of decaying vegetables are displayed. The flowers are also beautiful; they come out early in the spring, are of a fine yellow colour, and show themselves to advantage before the leaves come out. They are frequently succeeded by keys, which sometimes arrive at maturity in Britain. There is a variety with striped leaves.

5. The rubrum, or Virginia scarlet flowering maple, is a native of that country, and never grows to a large size in Britain. It is, however, cultivated in gardens for the beauty of its flowers, which appear in the beginning of April, in roundish bunches, at the bottom of the footstalks of the leaves. The flowers are ripe in five or six weeks after; and ought to be immediately fown, being otherwise very apt to wither. The tree ought to be sheltered, especially whilst young, from the north-east winds; it delights in a moist light soil, where it will thrive much better, as well as produce many more flowers and much better seeds, than in a dry ground. A variety of this tree is known in England by the name of Sir Charles Wager's flowering maple, from its being first sent from America to Sir Charles Wager. The flowers of this kind come out in larger clusters than the other, and surround the small branches, so that the tree appears entirely covered with them, and makes a much more beautiful appearance than the former, which is now not so much esteemed.

6. The saccharinum, or sugar-maple, is a large growing tree; will arrive at the height of 40 feet; and has broad thin leaves, divided into five principal parts; which are again indented or cut at the edges into several acute segments. Their surface is smooth, of a light green colour, whitish underneath; and they grow on pretty long footstalks. The flowers come out in the spring, about the time of the Norway maple; and they are succeeded by long keys, which sometimes ripen in England. In America the inhabitants tap this tree in the spring, boil the liquor, and the feces afford.
ford a useful sugar. The sycomore, the ash-leaved, and the Norway maples, also abound with a saccharinaceous juice, from which there is no doubt but a useful sugar might be prepared.

7. The Penylvanum, or American mountain-maple, resembles the fugar-maple, only its leaves are more pointed.

8. The ocalis, or Italian maple, is very common in most parts of Italy, particularly about Rome; but in Britain is very rarely to be met with, though hardly enough to bear the open air. It is one of the largest species of trees in Italy, and affords a great shade by its numerous and large leaves. On this account it is planted on the road-sides, and near habitations.

9. The monspelulanum, or Montpellier maple, is common in the south of France, and in Italy; but is hardly met with in Britain. The leaves resemble those of the common maple; but are of a much thicker substance, a shining green colour, and not so large. They continue in verdure very late in the autumn, which renders the trees more valuable.

10. The creticum, or Cretan maple, grows naturally in the Levant; it somewhat resembles the last species; but its leaves are of a much thicker texture, and their footstalks covered with a soft hairy down; whereas those of the other are smooth and soft.

Propagation and culture.—1. By seeds. The first two species are easily propagated in this way. The seeds, when ripe in autumn, may be gathered, and in a few days after sown about an inch and an half deep, in beds of common mould. In spring the plants will appear, and make a shoot of about a foot and an half by the autumn following, if the ground of the seminary be tolerably good, and they are kept free from weeds. The spring after they come up they should be planted in the nursery in rows two feet and an half auster, and their distance in the rows must be one foot and an half. Here they may remain till they are big enough to plant out finally, with no further trouble than taking off unliplantly side-branches, and fuch as have a tendency to make the tree forked, except digging between the rows, which must always be done every winter. For the other species, their seeds, as they do not ripen in this country, ought to be procured from the places where they naturally grow, and managed in the following manner: A cool shady part of the seminary should be appropriated for the purpose; the mould should be made fine; beds should be marked out four feet wide, and in length proportionable to the quantity; and in these the seeds should be regularly sown, sifting over them about half an inch of the finest mould. When the plants come up, they must be kept clean from weeds, and frequently watered; and this work must be duly attended to all summer. The next spring, the strongest may be drawn out, and planted in the nursery, in rows two feet auster, and at the distance of a foot from each other in the rows; leaving the others in the seminary to gain strength. The spring following they also must receive the same culture; and in the nursery they may remain with no other trouble than keeping the ground clean from the weeds in summer, digging between the rows in the winter, and taking off all strong and irregular side-shoots till they are planted out. Trees raised from seeds will grow faster, and arrive at greater height, than those raised from layers; but they will not pro-

produce such quantities of flowers; which makes the latter method more eligible for those who want these plants for a low shrubbery. — Seeds of the variegated kinds also, when sown, will produce variegated plants in rows, which renders the propagation of these sorts very expeditious, where either the space or the ground will admit. Where these are not to be obtained, the plants are propagated by budding, as afterwards directed.

2. By layers. All the species may be propagated by this method; though it is never practised for the common maple and the sycomore. The young shoots may be at any time laid down in the autumn, winter, or early in the spring. By the autumn following, they will have struck root, and become good plants; when the strongest may be set out in the places where they are to remain; whilst the weakest may be planted in the nursery, like the seedlings, for a year or two, to acquire strength.

3. By cuttings: which method, however, is chiefly practised on the ash-leaved and Norway maples, which more readily take root this way. The cuttings should be the bottom parts of the last year's shoots: They should be taken off early in October, and planted in rows in a moist shady place. The spring and summer following, they must be duly watered as often as dry weather makes it necessary, and be kept clean from weeds. By the autumn they will be fit to remove into the nursery; though if the cuttings are not planted too close, they may remain in their situation for a year or two longer, and then be set out finally, without the trouble of being previously planted in the nursery.

4. By budding, grafting, and inarching. These methods are only practised for the variegated sorts and the large broad-leaved kind. The latter is to be continued no otherwise than by budding it on italks of the common sycomore; for from the seeds, tho' so large themselves, only the common sycomore is produced.

In order to propagate these varieties by budding, let some plants of the common sycomore, one year old, be taken out of the seminary, and set in the nursery in rows a yard auster, and the plants about a foot and a half distance from each other. Let the ground be kept clean from weeds all summer, and turned in the winter; and the summer following the fodds will be of a proper size to receive the buds, which should be taken from the most beautifully-stripped branches. The best time for this work is the middle or latter end of August. Having then budded your sodds with the eyes or buds fronting the north, early in October take off the half-matting, which before this time will have confined the bark and pinched the bud, but not so as to hurt it much. Then cut off the fodd just above the bud, and dig the ground between the rows. The summer following, keep the ground clean from weeds; cut off all natural side-hours from the fodd as they come out; and by autumn, if the land is good, the buds will have shot forth, and formed themselves into trees five or six feet high. They may be then removed into the places where they are destined to remain; or a few of them only may be drawn out, leaving the others to be trained up for larger standards. The striped Norway maple should be budded on fods of its own kind; for on these they take best, and both kinds are not very liable to run away from their colours. Variegated plants in general must be planted in
poor, hungry, gravelly, or sandy soils, to feed the dif-
cafe which occasions these beautiful strips, and cause it to be more powerful. But these trees show their strips in greater perfection in a good soil: The plant, though in sicknels, has the appearance of health; the shoots are vigorous and strong; the leaves are large, left liable to be hurt by insects; and the strips appear more perfect, natural, and beautiful, than those on flunted trees growing on a poor soil.

ACERB, a four rough astringency of taste, such as that of unripe fruit.

ACERNO, a town of Italy, in the exterior principality of Naples, with a bishop's see. E. Long. 15. 40. N. Lat. 40. 50.

ACERINA, in ichthyology, a name given by Pliny, and other of the old naturalists, to the fish we at this time call the ruffe. See PERCA.

ACERRA, in antiquity, an altar erected, among the Romans, near the bed of a person deceased, on which his friends daily offered incense till his burial.—The real intention probably was to overcome any offensive smell that might arise from the corpse. The Chinese have fill a coffin like this: they erect an altar to the deceased in a room hung with mourning; and place an image of the dead person on the altar, to which every one that approaches it bows four times, and offers oblations and perfumes.

The Acerra also signified a little pot wherein were put the incense and perfumes to be burnt on the altars of the gods and before the dead. It appears to have been the same with what was otherwise called thuris-bulums, and pyxis.

We find mention of Acerra in the ancient church. The Jews had also their Areat, in our version rendered cespers; and the Romanists still retain them under the name of inscepo-pots. In Roman writers, we frequently meet with plena acerra, a full acerra: to understand which, it is to be observed, that people were obliged to offer incense in proportion to their estate and condition; the rich in larger quantities, the poor only a few grains; the former poured out acerras full on the altar, the latter took two or three bits with their fingers.

ACERRA, a town of Italy, in the kingdom of Naples, and in the Terra di Lavoro; seat on the river Agno. E. Long. 15. 10. N. Lat. 40. 55.

ACERRE (anc. geog.), the ancient name of a town on the Clarius, in Campania, not far from Naples, now Acerra.—The name also of another town, now called la Circe in the territory and to the south-east of Lod, where the rivulet Serio falls into the Adda, to the west of Cremona and north of Placentia.

ACESCENT, a word used to denote any thing which is turning four, or which is slightly acid. It is only applied properly to the former of these two meanings. The second may be exprest by either of the two words, acetabulum or sub-acid.

ACETABULUM, in antiquity, a measure used by the ancients, equal to one-eighth of our pint. It seems to have acquired its name from a vessel in which acetum or vinegar was brought to their tables, and which probably contained about this quantity.

ACETABULUM, in anatomy, a cavity in any bone for receiving, the protuberant head of another, and there-

by forming that species of articulation called ENAR-
THROSIS.

ACETABULUM, in botany, the trivial name of a species of the peziza, or cup-peziza, a genus belonging to the cryptogam fungi of Linnaeus. It has got the name of acetabulum, from the resemblance its leaves bear to a cup. See PEZIZA.

ACETUM, VINEGAR, the vegetable acid of the chemists. See VINEGAR.

ACETUM, VINEGAR, the vegetable acid of the chemists. See VINEGAR.

ACHABYTUS (anc. geog.), a high mountain in Rhodes, on the top of which stood a temple of Jupiter.

ACHAIA (anc. geog.), a town of the island of Rhodes, in the district of Japyx, and the first and most ancient of all, fald to be built by the Heliaides, or Grandfons of the Sun.

ACHAEA, a hamlet of Atalid Sarmatia on the Euxine. The inhabitants were called Achai, a colony of the Orchomenians.

ACHAEANS, the inhabitants of ACHIIA Propria, a Peloponnesian state. This republic was not considerable in early times, for the number of its troops, nor for its wealth, nor for the extent of its territories; but it was famed for its probity, its justice, and its love of liberty. Its high reputation for these virtues was very ancient. The Crotonians and Sybarites, to re-establish order in their towns, adopted the laws and customs of the Achaenians. After the famous battle of Leucera, a difference arose betwixt the Lacedemonians and Thebans, who held the virtue of this people in such veneration, that they terminated the dispute by their decision. The government of the Achaenians was democratic. They preferred their liberty till the time of Philip and Alexander: But in the reign of those princes, and afterwards, they were either subject to the Macedonians, who had made themselves masters of Greece, or opprefled by cruel tyrants. The Achaean commonwealth conftituted of twelve inconfiderable towns in Peloponnesus. Its firft annals are not marked by any great action, for they are not graced with one eminent character. After the death of Alexander, this little republic was a prey to all the evils which flow from political discord. A zeal for the good of the community was now extingufhed: Each town was only attentive to its private interest. There was no longer any flability in the state; for it changed its masters with every revolution in Macedonia. Towards the 124th Olympiad, about the time when Ptolemy Soter died, and when Pyrrhus invaded Italy, the republic of the Achaenians recovered its old institutions and unanimity. The inhabitants of Patae and Dymet were the first afferers of ancient liberty. The tyrants were banifhed, and the towns again made one commonwealth. A public council was then held, in which affairs of importance were difcufled and determined. A regifter was
ACHAJE [63]

ACHAJAE, a name taken for that part of Greece which Ptolemy calls Hellas; the younger Pliny, Graecia; now called Livadia; bounded on the north by Thessaly, the river Sperchius, the Sinus Malicus, and mount Oeta; on the west by the river Achelous; on the east, running a little to the north, it is washed by the Archipelago, down to the promontory of Samium; the south, joined to the Peloponnesus, or Morea, by the isthmus of Corinth, five miles broad. Achaia Propria, anciently a small district in the north of Peloponnesus, running westward along the bay of Corinth, and bounded on the west by the Ionian Sea, on the south by Elis and Arcadia, and on the east by Sicyonia: inhabitants, the Achaeni, properly so called; its metropolis, Patra. It is now called Romania Alia, in the Morea. Achaia was also taken for all those countries that joined in the Achaean league, reduced by the Romans to a province. Likewise for Peloponnesus. Achaia Presbyteri, or the Presbyters of Achaia, were those who were present at the martyrdom of St. Andrew the Apostle, A.D. 59; and are said to have written an epistle in relation to it. Bellarmine, and several other eminent writers in the church of Rome, allow it to be genuine, while Du Pin, and some others, expressly reject it. ACHADIUS, son of Echinos, was raised to the crown of Scotland, A.D. 788. The emperor Charlemagne sent an embassy to desire an alliance with him against the English, whose parties so infested the seas, that the merchants could not carry on their trade. This alliance was concluded in France upon conditions so advantageous to the Scots, that Achadius, to perpetuate the memory of it, added to the arms of Scotland a double field fowled with lilies. He died in 810. ACHALALACTLI, in ornithology, a species of king-t-ffiler. See ALCEDO. ACHANE, the son of Carmi, of the tribe of Judah, at the taking of Jericho concealed two hundred shekels of silver, a Babylonish garment, and a wedge of gold, contrary to the express command of God. This sin proved fatal to the Israelites, who were repulsed at the siege of Ai. In this dreadful exigence, Joshua prostrated himself before the Lord, and begged that he would have mercy upon his people. Achian was discovered by calling lots, and he and his children were stoned to death. This expiation being made, Ai was taken by stratagem. John vii. 8, 9. ACHANE, an ancient Persian corn measure, containing 45 Attic medimnii. ACHARACA, anciently a town of Lydia, situate between Trullas and Nysa; in which were the temple of Pluto, and the cave Charonius, where patients slept in order to obtain a cure. ACHAT, in law, implies a purchase or bargain. And hence probably purveyors were called Achators, from their making bargains. ACHATES, the companion of Eneas, and his most faithful friend, celebrated in Virgil... ACHATES, in natural history. See AEGATE. ACHATES (anc. geog.), a river of Sicily, now the Drillo; which runs from north to south, almost parallel with, and at no great distance from, the Gelai, and rives in the north of the territory of Notto. It gave name to the Achates, or Agate, said to be first found there. ACHAZIB, or ACHII, (anc. geog.), a town of Galilee, in the tribe of Abin, nine miles from Potalmas.—Alfo a town in the more southern parts of the tribe of Judah. ACHEN, ACHEN, or ACHEN, a kingdom of Samaria in the East-Indies, situated on the north-western part of the island. The capital is situated on a river which empties itself near the north-west point, or Achen-head, about two miles from the mouth. It lies in a wide valley, formed...
A C H

Acheen, formed like an amphitheatre by two lofty ranges of hills. The river is not large, and by emptying itself fill several Acheens.

The general of Malay bazars, excepting that the superior goods of their country, and receive in return, gold-dust, japa-wood, betel-nut, patch-leaf \( \text{calophyllum} \), a little pepper, sulphur, camphire, and benzoin. The country is supplied with Bengal opium, and also with iron, and many other articles of merchandise, by the European traders.

Acheen is esteemed, comparatively, healthy, being more free from woods and swamps than most other portions of the island; and the fevers and dysenteries to which these are exposed to give occasion, are there said to be uncommon. The soil is light and fertile; and the products, besides those already enumerated as articles of export trade, and a variety of fine fruits, are chiefly rice and cotton. There is likewise some raw silk procured in the country, of very inferior quality. Gold dust is collected in the mountains near Acheen, but the greatest part is brought from the southern ports of Malabar and Sooloo. The sulphur is gathered from a volcano mountain in the neighbourhood, which supplies their own consumption for the manufacture of gun-powder, and admits of a large exportation.

In their persons, the Acheene different from the rest of the Sumatrans, being taller, flunter, and darker complexioned. They appear not to be a genuine people, but are thought, with great appearance of reason, to be a mixture of Batta, Malays, and Moors from the west of India. In their dispositions they are more active and industrious than their neighbours; they possess more penetration and capacity; have more general knowledge; and as merchants, they deal upon a more extensive and liberal footing. Their religion is Mahometanism; and, having a great number of mosques and priests, its forms and ceremonies are strictly observed.

The appearance of the town, and the nature of the buildings, are much the same as are found in the generality of Malay bazars, excepting that the superior wealth of this place has occasioned a great number of public edifices, but without the smallest pretensions to magnificence. The king's palace, if it deserves the appellation, is a vast and uncouth piece of architecture, designed to resist the force of an enemy, and surrounded for that purpose by strong walls, but without any regular plan, or view to the modern system of military attack. The houses in common are built of bamboo and rough timber, and raised some feet from the ground on account of the place being overflowed in the rainy season.

A considerable fabric of a thick species of cotton cloth, and of stuff for the short drawers worn both by Malays and Acheene, is established here, and supplies an extensive demand. They weave also very handsome silk pieces, of a particular form, for that part of the dress which is called by the Malays an \( \text{eysen} \) \( \text{farrang} \).

The Acheene are expert and bold navigators, and employ a variety of vessels, according to the voyages they undertake, and the purposes for which they design them. The river is covered with a multitude of fishing sampans or canoes, which go to sea with the morning breeze, and return in the afternoon, with the sea wind, full laden.

Having no convenient coins, though most species of money will be taken there at a valuation, they commonly make their payments in gold dust, and for that purpose are all provided with scales or small steel yards. They carry their gold about them wrapped up in pieces of bladder, and often purchase to so small an amount, as to make use of grain or seeds for weights.

The monarchy is hereditary; and the king usually maintains a guard of 100 Seapoys about his palace.

According to Mr Marshden, "the grand council of the nation consists of, the King or Sultan, four \( \text{osloballangs} \), and eight of a lower degree, who sit on his right hand, and sixteen \( \text{cajoorangs} \), who sit on his left. At the king's feet sits a woman, to whom he makes known his pleasure; by her it is communicated to an eunuch, who sits next to her, and by him to an officer named \( \text{cajoorang kondong} \), who then proclaims it aloud to the assembly. There are also present two other officers, one of whom has the government of the \( \text{bazar or market} \), and the other the superintending and carrying into execution the punishment of criminals. All matters relative to commerce and the customs of the port come under the jurisdiction of the \( \text{shahander} \), who performs the ceremony of giving the \( \text{chap or licence for trade} \); which is done by lifting a golden handed cresset over the head of the merchant who arrives, and without which he dares not to land his goods. Prefents, the value of which are become very regularly ascertained, are then sent to the king and his officers. If the stranger be in the style of an ambassador, the royal elephants are sent down to carry him and his letters to the monarch's presence; these being first delivered into the hands of an eunuch, who places them in a silver dish, covered with rich silk, on the back of the largest elephant, which is provided with a machine \( \text{hounder} \) for that purpose. Within about an hundred yards of an open hall where the king sits, the cavalcade stops, and the ambassador dismounts, and makes his obeisance by bending his body, and lifting his joined hands to his head. When he enters the palace, if an European, he is obliged to take off his shoes; and having made a second obeisance, is seated upon a carpet on the floor, where \( \text{bostel} \) is brought to him. The throne was some years ago of ivory and tortoiseshell, and when the place was governed by queens, a curtain of gauze was hung behind it, which did not obstruct the audience, but prevented any perfect view. The stranger, after some general discourse, is then conducted to a separate building where he is entertained with the delicacies of the country, by the officers of state, and in the evening returns in the manner he came, surrounded by a prodigious number of lights. On high days \( \text{arcs rhab} \) the king goes in great state mounted on an elephant richly caparisoned, to the great mosque, preceded by his \( \text{osloballangs} \); who are armed nearly in the European manner.

The country under the immediate jurisdiction of Acheen, is divided into three districts, named \( \text{Duo peclos} \).
ACHEOLOUS, in fabulous history, wrestled with Hercules, for no less a prize than Deianira, daughter to king Oeneus: but as Acheclus had the power of assuming all shapes, the contest was long doubtful: at last, as he took that of a bull, Hercules tore off one of his horns; so that he was forced to stoop, and to redeem it by giving the conqueror the horn of Amalthea, the same as our quarter, or eight bushels. The name Acheloë, a river of Acarnania; which rises in the mountains, and falls from north to south into the sea near the promontory of Chimerium, to the west of the Sinus Ambraeisus, in a course from north to south. Acheron, a river of Epirus. The poets feigned it to have been the son of Ceres, whom the hero in hell for fear of the Titans, and turned into a river, over which fown departed were ferried in their way to Elyium. Acheron, a river of the Bruttii in Italy, running from east to west: Where Alexander king of Epirus was slain by the Lynci, being deceived by the oracle of Dodona, which bid him beware of Acheron. Acherus, an ancient measure of corn, conjectured to be the same as our quarter, or eight bushels. Acherusia Pelus, a lake between Cumæ and the promontory Misenum, now il Lago Della Collucia, (Cluerius.) Some confound it with the Laci Lucrinus, and others with the Lacus Avernus. But Strabo and Pliny distinguish them. The former takes it to be an effusion, an exudation, or washes of the sea, and therefore called by Lycothron, Acherusa spad. Also a lake of Epirus, through which the Acheron runs. There is also an Acherusa, a peninsula of Bithynia on the Exuniae, near Heraclea; and a cave there of the same name, through which Hercules is said to have descended to hell to drag forth Cerberus. Achiar, is a Malay word, which signifies all sorts of fruits and roots pickled with vinegar and spice. The Dutch import from Batavia all sorts of achiar, but particularly that of Bamboo (see Arundo), a kind of cane, extremely thick, which grows in the East Indies. It is preferred there, whilst it is still green, with a very strong vinegar and spice; and is called bakoos-achiar. The name changes according to the fruit with which the achiar is made. Achicolum, is used to express the fornicis, tholos.
ACHILLÆA, YARROW, MILFOIL, NOSEBLEED, or SNEEZEWORT; a genus of the order of the polygamous superfamily, belonging to the syngepenia class of plants. The natural order to which it belongs is the 49th, Composite dicoidae.

The characters are: The common calyx is ovate and imbricated; the hermaphrodite corollas are tubular in the discus, the feminine linear and from 5 to 10 in the rays. The proper corolla of the hermaphrodites is funnel-shaped, expanded, and divided into 5 segments; that of the females, tongue-shaped, inversely corollated, expanding, and of 3 segments. The flamine in the hermaphrodites consists of 5 very short capillary filaments; the anthers is cylindrical and tubular. The Achillea in the hermaphrodites has a small germen; the stamen is filiform in the length of the flamine; the stigma is obtuse and emarginated; in the females, the germen is small; the stamen is filiform; the stigmata are 3, obtuse and reflexed. The pericarpium is wanting; the calyx scarcely changed; the receptacle filiform, elongated at the disc of the seeds, ovate, and twice as long as the calyx. The seeds are solitary, ovate, and furnished with a lock of wool; no pappus. The receptacle is chaffy and elevated.

Species and properties. There are 20 species, of which the following are the principal: 1. The milfoil, or common yarrow, is found naturally on banks, and by the sides of foot-paths, in most parts of England. It most commonly bears white flowers, though a variety of it is found which bears purple ones. Thefe, however, do not long continue to bear flowers of this colour, if transplanted into gardens. It was formerly used in medicine; but though it may still have a place in some dispensatories, no physician of any note expects any virtue from it, or even prescribes it. It creeps greatly by its roots, and also multiplies by the seeds, so that it becomes a troublesome weed where it is once allowed to get a footing. The cultivation of it is recommended by Mr Anderson, in his Essays on Agriculture, as a proper food for cattle. This species was the proper achillea of the ancients, so named from Achilles; who, having been the disciple of Chiron, first brought it into use for the cure of wounds and ulcers.

2. The fantolina, or eastern sneezewort, is sometimes cultivated in gardens; it has large yellow flowers, which hand upon pretty long footstalks placed singly, not in bunches as in the common kind. It has leaves like lavender-cotton, which, when rubbed, emit a strong oily odour. The flowers appear in June and July.

3. The tomentosa, or woolly yarrow, is a native of the south of France and Spain, but lives in the open air in England. The flowers are of a bright yellow, and continue long in beauty, growing in clusters at the top of the footstalks, which seldom rise above a foot high. The leaves are finely cut, and very hoary.

4. The abrotanifolia, or tall eastern yarrow, is a native of the islands in the Archipelago; it grows to the height of two feet and a half, with large umbels of yellow flowers on the top; the leaves resemble those of the common wormwood, and are cut into long narrow segments.

5. The clava, or Alpine umbelliferous wormwood, takes its name from the mountains of which it is a native. It seldom grows above 3 or 4 feet in height; it supports umbels of white flowers, like those of the common sneezewort, which appear in April and May. The leaves are hoary, and shaped like those of wormwood, which often decay in the autumn and winter.

6. The tanacetifolia, or eastern sneezewort, with tansey leaves, is a very handsome plant, seldom rising above 5 to 6 feet in height. The flowers are nearly as large as those of the common sneezewort, white, and growing in flat umbels. They appear in June and July.

7. The ageratum, or sweet achillea, is a native of the Alps. It is a plant that is often used in medicine; it is said to have a very pleasant smell; it was formerly much used in medicine and for culinary purposes, but has now fallen so much into neglect as to be totally unknown in the markets; so that when it is demanded, the white maudlin is substituted in its stead. The reason of this substitution was, that the latter is more hardy and easily propagated than the sweet maudlin, which is apt to rot in wet winters. The common maudlin flowers in June and July, and the seeds are ripe in September.

8. The Egyptiaca, or hoary sneezewort, is a native of the Archipelago. It hath very hoary leaves, which remain all the year; and the plants growing close together, make a beautiful appearance at all seasons. The flowers are yellow, and are produced in umbels on the top of the stalks; they appear in June, and continue till the end of September.

9. The ptarmica, or common sneezewort, is a native of the Alps. It is a plant that is often used in medicine; it is said to have a very pleasant smell; it was formerly much used in medicine and for culinary purposes, but has now fallen so much into neglect as to be totally unknown in the markets; so that when it is demanded, the white maudlin is substituted in its stead. The reason of this substitution was, that the latter is more hardy and easily propagated than the sweet maudlin, which is apt to rot in wet winters. The common maudlin flowers in June and July, and the seeds are ripe in September.

10. The macrophylla, or Alpine sneezewort, with fewer leaves, is a native of the Alps. It produces many stalks rising near three feet high; having loose branching umbels of white flowers on their top, resembling those of the common sneezewort, but larger.

11. The nana, or hoary Alpine milfoil, is likewise a native of the Alps; the leaves are hoary, and the umbels of its flowers are more compact than the former; the stalks do not rise more than a foot high.

12. The nobilis, or sweet milfoil, approaches to the nature of the common milfoil; but its leaves are of a paler green, and are neither so long nor so much cut off as those of the common milfoil: they have a strong sweet scent when bruised.

13. The alpina, or white maudlin, bears some resemblance to the common sneezewort; but the leaves are longer, of a deeper green colour, and deeply indented in their edges; the flowers are white, and the roots creep far under ground. The plant will rise, in good land, to the height of four feet.

Culture. All the sorts of yarrow are easily propagated by seeds, which may be sown either in the spring or
ACHILLINI (Alexander), born at Bologna, and doctor of philosophy in that university. He flourished in the 15th and 16th centuries, and by way of eminence was styled the Great Philosopher. He was a flated follower and accurate interpreter of Averroes upon Aristotle, but most admired for his acuteness and strength of arguing in public and private disputations. He made a surprising quick progress in his studies, and was very early promoted to a professorship in the university; in which he acquitted himself so much that his name became famous throughout all Italy. He continued at Bologna till the year 1506; when the university of Padua made choice of him to succeed Antonio Francatiano in the first chair of philosophy, and his fame brought vast numbers of students to his lectures at Padua: but the war, wherein the republic of Venice was engaged against the league of Cambrai, putting a stop to the lectures of that university, he withdrew to his native country; where he was received with the same marks of honour and distinction as before, and again appointed professor of philosophy in Bologna. He spent the remainder of his life in this city, where he died, and was interred with great pomp in the church of St. Martin the Great, which belongs to the Carmelite Friars. Jovius, who knew Achillini, and heard his lectures, says, that he was a man of such exceeding simplicity, and so unacquainted with address and flattery, that he was a laughing-stock to the pert and fancy young scholars, although esteemed on account of his learning. He wrote several pieces on philosophical subjects, which he published, and dedicated to John Bentivoglio.

Achillini (Clodius), grandson of the former, read lectures at Bologna, Ferrara, and Parma; where he was reputed a great philosopher, a learned divine, an excellent lawyer, an eloquent orator, a good mathematician, and an elegant poet. He accompanied Cardinal Ludovico, who went as legate into Piedmont, but being afterward neglected by this cardinal, when he became pope under the name of Gregory XV. he left Rome in distress, and retired to Parma; where the duke appointed him professor of law, with a good salary. He published a volume of Latin Letters, and another of Italian poems, which gained him great reputation: he died in 1640, aged 66.

Achiotte, or Achiot, a foreign drug, used in dying, and in the preparation of chocolate. It is the same with the substance more usually known by the name anonto; which see.

Achiropoetos, a name given by ancient writers to certain miraculous pictures of Christ and the Virgin, supposed to have been made without hands. The most celebrated of these is a picture of Christ, preferred in the church of St. John Lateran at Rome; said to have been begun by St. Luke; but finished by the ministry of angels.

Achmet, son of Seirim, has left a book concerning the interpretation of dreams according to the doctrine of the Indians, Persians, and Egyptians, which was translated out of the Greek into Latin by Leo Tuscus in 1160. He lived in the 9th century.

Achmet-Gedec, a famous general under Mahomet II. and Bajazet II. in the 15th century. When Mahomet II. died, Bajazet and Zezan both claimed the throne: Achmet sided with the former, and by his brave...
bravery and conduct fixed the crown on his head. But
Bajazet took away his life; shining virtue being always
an unpardonable crime in the eyes of a tyrant.

ACHMETSCHET, a town of the peninsula of
the Crimea, the residence of the sultan Galga, who is
called son of the Khan of Tartary. Long. 51. 20. Lat.
45° 40′.

ACHMIM, a large town of Upper Egypt, situated
on the eastern bank of the Nile. "One admires there
(says Abulfeda, as quoted by Mr Savary), a temple,
which is comparable to the most celebrated monuments
of antiquity. It is constructed with stones of a surpris-
ing size, on which are sculptured innumerable figures."  
Though this town be fallen from its ancient splendor,
it is still one of the most beautiful of Upper Egypt.
According to Mr Savary, an Arab prince commands
there, and the police is well attended to. The streets
are wide and clean, and commerce and agriculture
flourish. It has a manufactory of cotton, stuffs, and pot-
ttery, which are conveyed over all Egypt. It is the
same that Herodotus calls Chasmos, and Strabo
Pasopolis, or the city of Pan, who was worshipped there.
Herodotus says, that Perseus was a native of this city,
and that his descendants had established festivals there
in his honour. It has lost its ancient edifices, and much
of its extent; the ruins of the temple, defcribed by
Abulfeda, being without its limits, to the north. No-
thing remains of it but some stones, of such magnitude
that the Turks have not been able to move them.
They are covered with hieroglyphics. On one of them are
traced four concentric circles, in a square. The inner-
most of these contains a fun. The two succeeding ones,
divided into 12 parts, contain, one, 12 birds, the other,
12 animals almost effaced, which appear to be the
signs of the zodiac. The fourth has no divisions, and
presents 12 human figures, which Mr Savary imagines
to represent the 12 gods, the 12 months of the year,
and the 12 signs of the zodiac. The Egyptians, says
Herodotus, are the first who divided the year into 12
months, and employed the names of the 12 gods. The
four seasons occupy the angles of the square, on the
side of which may be distinguished a globe with wings.
Mr Savary thinks it probable that this stone belonged
to a temple dedicated to the sun, that the whole of
these hieroglyphics mark his passage into the signs of
the zodiac, and his course, whose revolution forms the
year. The columns of this temple have been partly
broken to make lime and millstones. Some of them
have been transported into one of the mosques of
Achmim, where they are placed without taste; others are
heaped up in the squares of the town.

Mr Savary tells us of a serpent which is wor-
shipped here, and is the wonder of the country.
"Upwards of a century ago (says he), a religious
Turk called Scheilk Habidi died here. He pased
for a saint among the Mahometans; who raised a
monument to him, covered with a cupola, at the
foot of the mountain. The people flocked from all
parts to offer up their prayers to him. One of their
priests, profiting by their credulity, persuaded them
that God had made the foul of Scheilk Habidi pass in
the body of a serpent. Many of these are found in
the Thebais, which are harmless; and he had
taught one to obey his voice. He appeared with his
serpent, dazzled the vulgar by his surprizing tricks,
and pretended to cure all disorders. Some lucky in-
stances of success, due to nature alone, and sometimes
to the imagination of the patients, gave him great ce-
lebrity. He soon confined his serpent Habidi to the
tomb, producing him only to oblige princes and per-
fons capable of giving him a handsom recompense.
The successor of this priest, brought up in the fame
principles, found no difficulty in giving fuch a
fame, and concluded to inatent an advantageous an error. They added to the general
persuasion of his virtue that of his immortality. They
had the boldnes even to make a public proof of it.
The serpent was cut in pieces in presence of the Emir,
and placed for two hours under a vase. At the infant
of lifting up the vase, the priests, no doubt, had the
address to substitute one exactly resembling it. A mir-
cle was proclaimed, and the immortal Habidi acquired a
fneen degree of confideration. This knavery procures
them great advantages. The people flock from all quar-
ters to pray at this tomb; and if the serpent crawls
out from under the stone, and approaches the fuppliant,
it is a sign that his malady will be cured. It may be
imagined, that he does not appear till an offering has
been made proportioned to the quality, and riches of
the different persons. In extraordinary cafes, where
the fick person cannot be cured without the presence
of the serpent, a pure virgin must come to solicit him.
To avoid inconveniences on this head, they take care
to shew a very young girl indeed. She is decked out
in her best clothes, and crowned with flowers. She
puts herfeif in a praying attitude; and as the priests
are inclined, the serpent comes out, makes circles
round the young fuppliant, and goes and repofes on
her. The virgin, accompanied by a vaft multitude,
carries him in triumph amidst the general acclama-
tion. No human reafoning would perfuade these igno-
rant and credulous Egyptians that they are the dupes
of a few impostors: they believe in the serpent Ha-
ridi as firmly as in the prophet."

ACHONRY, a small town of Ireland, in the
province of Connaught and county of Sligo, feated on
the river Shannon.

ACHOR, a valley of Jericho, lying along the river
Jordan, not far from Gilgal, so called from Achan,
the troubler of Israel, being there ftoned to death.

Achor, in medicine, a species of Herpes.

Achor, in mythology, the god of flies; to whom,
according to Pliny, the inhabitants of Cyrene sacrificed,
in order to obtain deliverance from the insects and the
disorders occasioned by them.

ACHRASINA (anc. geog.), one of the four
cities or divisions of Syrakus, and the strongest, largest,
and most beautiful part of it; separated by a very strong
wall from the outer town, Typha and Neapolis. It was
adorned with a very large forum, with beautiful por-
ticos, a moft elegant pyraneum, a fparious famine-
house, and a fuperb temple of Jupiter Olympus.

ACHRAS, or SAPOTA PLUM: a genus of the mo-
negynia order, belonging to the hesandria clafs of
plants; and ranking in the 43d Natural Order, Du-
nojia.

The characters are: The calyx is a perianthium,
consisting of six ovate concave eréct leaflets, the ex-
terior ones broader and shorter, the interior ones co-
oured. The corolla is composed of one ovate petal,
the height of the calyx; the border divided into six
segments,
ACH [69] ACI

ACANTHERA, in botany, the trivial name of a species of Rhexia.

ACICULAR, the small pikes or prickles of the hedge-hog, echinus-marinus, &c.

ACIDALUS (Valens) would, in all probability, have been one of the greatest critics in these latter ages, had he lived longer to perfect those talents which nature had given him. He was born at Witstock, in Brandenburg; and having visited several academies in Germany, Italy, and other countries, where he was greatly esteemed, he afterwards took up his residence at Bredlaw, the metropolis of Sicilea. Here he remained a considerable time; in expectation of some employment; but nothing offering, he turned Roman-Catholic, and was chosen rector of a school at Niefla. It is related, that about four months after, as he was following a procession of the hoft, he was feized with a sudden phrenzy, and being carried home, expired in a very short time. But Thuanus tells us, that his excessive application to study was the occasion of his untimely death: and that his sitting up a-nights in composing his conjectures on Plautus, brought upon him a distemper which carried him off in three days, on the 25th of May 1593, being just turned of 28. He wrote a Commentary on Quintus Curtius; also, Notes on Tacitus, on the twelve Panegyrics; besides speeches, letters, and poems. His poetical pieces are inferred in the Delicia of the German poets; and consist of epistles, odes, and epigrams. A little piece, printed in 1595, under the title of Maters non esse hominis, "That women were not of the human species," was falsely ascribed to him. But the fact was, that Acidalus, happening to meet with the manuscript, and thinking it very whimsical, transcribed it, and gave it to the bookfeller, who printed it. The performance was highly exclaim'd against, insomuch that the bookfeller being feized, he discovered the person who gave him the manuscript, and a terrible outcry was made against Acidalus. A story goes, that being one day to dine at a friend's house, there happened to be several ladies at tale; who, supposing him to be the author, were moved with so much indignation, that they threatened to throw their plates at his head. Acidalus, however, ingeniously diverted their wrath. In his opinion, he said, the author was a judicious person, the ladies being certainly more of the species of angels than of men. Mr. Bailllet has given him a place among his Enfans Celebrés; and says, that he wrote a comment upon Plautus when he was but 17 or 18 years old, and that he composed several Latin poems at the same age.

ACIDALUS, a fountain in Orchomenus, a city of Boeotia, in which the Graces, who are sacred to Venus, bathed. Hence the epithet Acidalius, given to Venus, (Virgil.)

ACIDITY, that quality which renders bodies acid.
ACIDOTON, in botany, the trivial name of a species of ADELIA.

ACIDS, in chemistry, the name by which one of the general classes of fluids are distinguished. The characteristic marks of them are, 1. The peculiar taste which we call sour; though this does not hold universally: for the acid of arsenic, which in other respects manifests a strong acid power, has not this sour taste; nor are the volatile sulphurous acid, or those of tungslen and molybdæna, lately discovered by Mr Scheele, very distinguishable in this way. On the other hand, the strong acids of vitriol, nitre, and even sea-salt, are altogether caustic, and cannot be tasted until they have been largely diluted with water. 2. With water they combine into a fluid, the specific gravity of which is not a medium between the water and acid separately taken. This holds good with the strong acids, which grow hot with water, and shrink into less bulk by reason of their emitting a quantity of the fire they contain: but whether it also takes place in the weaker acids, has not yet been ascertained; though the probability is, that it will take place in them also. 3. With spirit of wine, they unite into a very volatile and inflammable substance called ether. This must also be understood of the strong mineral acids, or of the acetic when very much concentrated; for the acetic of tartar, borax, arsenic, lapis ponderosus (tungslen), and molybdæna, do not produce any. 4. They change the blue colour of vegetables to red, and heighten the colour of those which are already red. This property is more universal than those we have yet mentioned; though the probability is, that it will take place in them also. 5. They unite with all kinds of earths excepting the siliceous (though the fluoric acid dissolves this also), with fixed and volatile alkalies, and with metals, in such a manner as to form compounds considerably permanent, and whose ingredients cannot be separated without some difficulty. This is the most universal and distinguishing mark; and there is not any acid but what phlegmatized with water, and shrinks. 6. With sugar it forms the acid of sugar.

The opinion of Mr Lavoyer concerning the composition of acids has in part been adopted by Mr Kirwan; who, in his treatise on Phlogiston, published in 1757, informs us that he is now of opinion "that dephlogificated air becomes an essential constituent part of acids. All acids (he adds) consist of two principles: one peculiar to each, which, in the opinion of the antiphlogists, has not as yet been decomposed, and consequently must be looked upon, relative to the present state of our knowledge, as a simple substance: the other, pure air, in a concrete state; that is, deprived of the greater part of its specific heat, and condensed into a small volume. The first they call the acid basis; the last, the oxygenous principle: thus the vitriolic acid, according to them, consists of sulphur as its basis, and pure air in a concrete state as its acidifying or oxygenous principle. This doctrine of the composition of acids has been admitted by some of the ablest defenders of phlogiston, and particularly by that distinguished philospher M. de Morveau, with this single modification, that the bases of acids contain phlogiston, which they lose on uniting to pure air: yet it seems very difficult to conceive how pure air can unite to phlogiston, a substance to which it has the greatest affinity, without forming a new compound endowed with very different properties from those which it possessed before such union. It seems therefore more reasonable to conclude, either that it forms water, as Mr Cavendish thinks; or fixed air, as I shall afterwards endeavour to prove."
Kirwan first states the opinion of the antiphlogiarians, viz. That the vitriolic acid, when considered abstractedly from the water it contains, always consists of sulphur (which they consider as a simple substance) united to a large portion of the oxygenous principle. "In my opinion (says he), it consists of a basis or radical principle, which, when saturated with phlogiston, constitutes sulphur; when saturated with fixed air, becomes common fixed vitriolic acid, and, when combined partly with the one and partly with the other, becomes volatile vitriolic acid. That sulphur, during its conversion into vitriolic acid, unites to air of some sort or other, is evident from the quantity of air which it absorbs, in whatever way that conversion is brought about. Thus, first, during combustion in respirable air, 100 grains of sulphur absorb 246 cubic inches of pure air, or about 2.43 grains; but the proportion of this pure air united with a given quantity of sulphur is not easily determined, because it is vitriolic air that is conflagrably formed; and this air essentially contains fixed air of sulphur in solution, to which portion is variable. Secondly, Pyrites, during their decomposition, absorb a considerable proportion of pure air, as Mr Lavoisier has observed; for also does liver of sulphur exposed to the atmosphere, for after some time it is converted into tatar vitriolate."

Mr Kirwan next proceeds to inquire, whether the air absorbed during the combustion of sulphur continues to be pure air; or whether it be converted into water or fixed air? He inclines to the latter opinions, for various reasons, which he specifies.

With regard to the nitrous acid, the experiments of Mr Cavendish, as well as of the French chemists, leave no room to doubt that it is produced during the distillation of dephlogisticated and inflammable air. Mr Cavendish has shown that the nitrous acid may be formed by taking the electric spark in a mixture of three measures of phlogisticated air and seven of dephlogisticated air, or, in weight, one part of the former and about 2/6 of the latter. Mr Lavoisier, as has been already mentioned, supposes the nitrous acid to be composed of nitrous air united to the oxygenous principle, or basis of pure air; and 100 grains of dry nitrous acid consist of 64 grains of nitrous air united to 36 of pure air deprived of its specific fire; or, according to Mr Kirwan's calculation, 173 cubic inches of nitrous air and 105 of pure air. But nitrous air, as Mr Lavoisier himself has observed, is a compound; 100 grains of it, according to him, containing 32 of phlogisticated and 68 of pure air; consequently 64 grains of it contain 20.5 of phlogisticated air, and 43.5 of pure air. Hence, according to him, 100 grains of dry nitrous acid contain 79 of pure air and 20 of phlogisticated air. Mr Kirwan is of opinion that 100 grains of pure, dry, and colourless nitrous acid contain 38.17 grains of fixed air as its acidifying principle, 57.06 of nitrous basis, and 4.77 of phlogiston united to the nitrous basis. With regard to the nitrous basis itself, he says that one third of its weight is phlogisticated and two thirds dephlogisticated air, both in a concrete state.

"Nitrous basis (says Mr Kirwan), saturated with phlogiston, constitutes nitrous air; 100 grains of this basis take up nearly 22 of phlogiston. Hence the constant principles of nitrous acid are fixed air, dephlogisticated air, phlogisticated air, and inflammable air, all in their concrete state.

"Red, yellow, green, and blue nitrous acids, when those colours are intense, owe their origin to the absorption of nitrous air; and consequently the proportion of their principles is variable, though all have the dephlogisticated acid for their ground. Thus Dr Pritchley, having exposed strong pale-yellow nitrous acid to the sun, has shewn that the gravity of the solution could not be less than 1,400 to nitrous air, found that 100 grains of this acid absorbed, in two days, 247 cubic inches of nitrous air: now, 100 grains of this spirit must have contained, by my calculation, about 21 grains of dry acid, and these 21 grains took up 91.29 grains of nitrous air. When about 20 cubic inches of nitrous air were absorbed (that is, about seven grains), the acid became of an orange colour; and when 30 cubic inches were absorbed (about 9 grains) it became green; and when nearly the whole was absorbed, it evaporated in the form of nitrous vapour, carrying off part of the water with it. Hence we see, that nitrous vapour consists of nitric acid united to three or four times its weight of nitrous air and a little water."

Mr Kirwan next proceeds to contest Mr Lavoisier's opinion, that nitric acid is a constituent principle of the nitrous acid. "The following experiments (says he) show that nitrous acid is not a constituent principle of the nitrous acid, but that fixed air is. 1. There is not a doubt but that pure nitrous acid enters entire, and without decomposition, into fixed alkalis, and forms nitrite. Now if nitre be distilled in a good earthen retort, it will be wholly decomposed; and so also will the acid itself, except a few drops which pass in the beginning of the distillation, and nothing but dephlogisticated air, more or less pure, and consequently intermixed with phlogisticated air and a slight proportion of fixed air, will be found in these, therefore, are its true constituent parts when digested from substances that cannot communicate phlogiston to it in any remarkable quantity, such as alkalies and earths, but if it be separated from substances that contain phlogiston, such as metals, it will then indeed be resolved into nitrous air and dephlogisticated air more or less pure, the phlogiston of the fixed air being detained by the metal. Mr Berthollet, who seems to have made the experiment with the greatest exactness, produced 714 cubic inches of dephlogisticated air from a troy ounce of nitre. This, however, was far from being of the purest kind; and Dr Pritchley, Mr Berthollet, and Mr Suckow, observ'd, that the air which first passes contains fixed air and renders lime-water turbid. Here then we have three of the constituent parts of the nitrous acid, with scarce any nitrous acid; which the antiphlogiarians suppose to be one of the constituent parts of the acid, and to make two thirds of its bulk when exhibited in an aerial form.

To obviate an objection that the quantity of fixed air thus obtained is too small to deserve to be ranked among the constituent parts of the nitrous acid, Mr Kirwan first inquires in what proportion it ought to exist there; and though this is variable, according to the different states of the nitrous acid with respect to phlogistication, he reckons it at one-third of the acid as existing in the nitre; and, from the decomposition of this..."
Acids. 

This fixed air, and the phlogiston emitted by it of consequence, he attributes the phlogification and reduction of the nitrous acid when exposed to more heat. As a proof that fixed air may be decomposed in this manner, he adds two experiments of Dr Priestley. In one of these, dephlogisticated air was obtained by means of acetic acid in that concentrated state in which it is called radical vinegar. Having mixed half an ounce of the acid with two ounces of calcined whiting, he obtained from it 350 ounce-measures of air; of which about one third was fixed more in the first portion, and left in the last. The standard of the residuum in the first portion was 1.66, in the second, 1.42, and in the third, 1.28; which is very near the goodness of common air. The whiting then weighed 760 grains. On adding a quarter of an ounce more of radical vinegar, and repeating the operation, 120 ounce-measures of air were obtained, and the whiting was reduced to 730 grains. A third operation, in which another quarter of an ounce of vinegar was added, reduced the matter to 459 grains: but the last portion of air extracted had no fixed air, and was considerably better than that of the atmosphere.—The other experiment was made with lime-stone alone; from four ounces of the white crysall, of which 830 ounce-measures of air were obtained, the first portion of which had only one-fourth of fixed air, and the standard of the residuum was never better than 1.56, nor worse than 1.66; so that it was nearly of the goodness of common air.

Our author then proceeds to relate several other experiments in which the nitrous acid was decomposed; but a particular relation of them would swell this article beyond its due bounds. At last, however, he concludes in the following manner. "If spirit of nitre be made to boil, and its vapour received through a red-hot earthen tube, it will be converted into dephlogisticated air, in which a portion both of phlogisticated and fixed air is found, as Dr Priestley has discovered: the water through which this air passes will also contain fixed air. Here then are several ways of decomposing the nitrous acid; and in one only it is resolved into nitrous and dephlogisticated air; and in this way it may, at least, be strongly suspected to receive an addition of another principle. Why then should these be regarded as its constituent principles? And as in the two different methods of decomposition, in which the re-acid of no foreign substance can be fixed, it appears in the form of dephlogisticated, phlogisticated, and fixed air (the former always containing a portion of the two last), why then should not the air be accounted its true constituent parts?—This theory is further confirmed by reflecting on the manner in which nitrous acid is generated by nature. Mr Thouvenel found that this acid is constantly produced when chalk is exposed to a mixture of nitrid and common air, or purified and dephlogisticated air; but if the purified air be passed through lime-waters, it is never generated; and that it is rarely produced by the exposure of quick lime or fixed alkalis to these airs. The reason that alkalis, though aërated, are not so proper, is, that they do not combine with phlogisticated air as calcareous earths do. Mr Cavendish, indeed, produced nitrous acid without any apparent mixture of fixed air; but the atom of it necessary for the formation of the small quantity of nitrous acid he produced (about one-third of a grain), might well be contained in the phlogisticated air he employed, or perhaps formed in the operation."

Having thus far stated the different opinions of the most celebrated French and English philosophers concerning the composition of acids, it is necessary to take notice of some experiments made by Mr. Watt, in order to determine whether the dephlogisticated air produced from nitre really proceeds from a decomposition of the acid, or what quantity of the latter is required to constitute a determinate quantity of the former. To ascertain this, 240 grains of mercury were put into a glais retort with 480 grains of diluted dephlogisticated nitrous acid, which was the * dephlogisticated air of Kirwan's doctrine. A quantity necessary to dissolve the whole of the mercury; and as soon as the common air was expelled, a proper vessel was applied to receive the air produced in the operation. Sixteen ounce-measures of nitrous air came over during the solution, and on changing the receiver, a quantity of dilute, but highly phlogisticated nitrous acid, was obtained. The air receiver being again applied, four ounce-measures of strong and pure nitrous air were obtained, which, by the dephlogisticated air that arose immediately after, were reduced to half an ounce-measure. The production of dephlogisticated air continued very rapid, the mercury being all the while received, until the distillation or sublimation of the whole of the mercury. Two hundred and eighty grains of the metal were obtained in its running form, and 22 remained in the form of an orange-coloured sublimate in the upper part of the retort.—The 16 ounce-measures of nitrous air, first obtained, were then converted into nitrous acid by the gradual admission of common air, and then added to the water in the bason in which the receiver had been inverted; the whole quantity being about two quarts, and very acid to the taste, sparkling at the same time with nitrous air. To determine the quantity of acid thus recovered, as well as that which remained in the sublimate, a solution of alkali of tartar was made; and by experiment it was found, that 120 grains of the acid, originally employed in dissolving the mercury, saturated 325 grains of this solution; the orange-coloured sublimate and all the acid liquor recovered being saturated by 1395 grains of the same. Hence it appears, by the rule of proportion, that out of 480 grains of nitrous acid originally employed, only five were lost: "a smaller quantity (as Mr Watt justly observes) than what might reasonably be supposed to be lost in the processes by the extreme volatility of the nitrous acid." His conclusion therefore is, that "the nitrous acid does not enter into the composition of dephlogisticated air: it seems only to serve to absorb phlogiston from the watery part of the mercurial nitre."

This experiment was repeated with cubic nitre, and only 50 ounce-measures of air distilled from an ounce of the mineral alkali exactly saturated with nitrous acid. The water through which the air passed was acid, and the residuum in the retort alkaline; but on mixing the two together, the solution was found to be exactly neutral by every possible test.

Not satisfied with these experiments, Mr. Watt distilled an ounce (430 grains) of common nitre, dropping the whole process when 50 ounce-measures of air had been produced. This air had a strong smell of the nitrous
Acids.

Nitrous acid, from which it could not be freed by washing with the water in the basin. The residue in the retort was alkaline as before, and the water slightly acid; nor was the saturation completed by mixing the two together. Ten grains of weak nitrous acid, 105 grains of which contained the acid of 60 of nitre, completed the saturation. These ten grains contained the acid of 57 grains of nitre; which, by Mr Kirwan's experiments, is equal to two grains of real nitrous acid.

We have therefore (says Mr Watt) 34 grains weight of dephlogisticated air produced, and only two grains of real air produced; and it is not certain that even this quantity was destroyed, because some portion of the glass of the retort was dissolved by the nitre, and some part of the materials employed in making the glass being alkaline, we may conclude, that the alkali of the nitre would be augmented by the alkali of that part of the glass it had dissolved; but as the glass cracked into small pieces on cooling, and some part of the coating adhered firmly to it, the quantity of the glass that was dissolved could not be ascertained.

To avoid the force of objections drawn from these experiments, and which seem ready to overthrow his hypothesis, as well as that of Mr Lavoisier entirely, Mr Kirwan makes the following reply: "My ingenious friend Mr Watt, as well as Mr Cavendish, are of opinion, that the whole quantity of dephlogisticated air, produced from the distillation of glass, arises from the dephlogistication of the water it contains, it being decomposed by the nitrous acid, which then becomes phlogisticated. This opinion is exposed to insurmountable difficulties. For, in the first place, nitre affords dephlogisticated air at the rate of 146.125 cubic inches for every hundred grains of nitre, which, by the proper allowances for phlogisticated air, should weigh 46.77 grains; but then dephlogisticated air is only one of the constituent parts of water, for it contains 13 per cent. of inflammable air, that is to say, 87 grains of dephlogisticated air; to form 100 grains of water requires an addition of 13 grains of inflammable air; consequentiy 46.77 grains of dephlogisticated air require nearly 7 of inflammable air, and would then form 53.77 grains of water, which exceeds half the weight of the nitre; a quantity of water, as Mr Watt owns, certainly inadmissible. Mr Watt found, that the water over which the air passing from the decomposition of 960 grains of nitre had been received, contained only the acid belonging to 120 grains of nitre; and even this small quantity he inferred only from my experiments. But my experiments are totally inapplicable in this case; for I used only the dephlogisticated nitrous acid: and alkalis are saturable by a much smaller quantity of phlogisticated than of dephlogisticated acids, as is evident in the case of the dephlogisticated muriatic acid, as Stahl long ago observed; for he says, that the volatile acid of sulphur faturates 10 times as much alkali as the fixed. Mr Bergman and Mr Scheele observed, that melted nitre is still neutral, though it be phlogisticated; therefore it is air, and not water, which it wants. Accordingly Dr Priestley found it to injure common air by attracting its dephlogisticated part; but if it be kept in fusion for some time, it loses its acid, and becomes alkaline, and the air it receives must surely be deemed rather to recompose the acid than to form water; of whose formation, in the temperature of the atmosphere, we have no sort of proof. On the contrary, the impossibility of accounting for the loss of acid in this case is an evident proof of the fallacy of that hypothesis. — Mr Lavoisier's analysis, 100 grains of nitre contain 57 of car­
cil alkali; by Mr Bergman's, 59; by Mr Wenzel's, 52; by Mr Wiegleb's, 45; by mine, 63; the mean of all which, is 53; which leaves 4.5 for acid and water, which is very nearly the weight of the air expelled. The different quantity of acid affixed by different peroxis to nitre, is in part owing to its degree of phlogistication in nitre. I believe at present that 100 grains of nitre contain 34 of acid, and about 12 of water, including the water in the acid and that of crystallization."

Mr Kirwan next proceeds to consider, in a manner similar to that above related, the composition of the other acids. — The marine acid, according to him, consists of a peculiar basis united to phlogiston, and a certain quantity of fixed air; to both of which the basis seems to have a strong affinity. On depriving it of this phlogiston, the affinity of the acid to fixed air becomes much stronger, and it fatuates itself to a large extent with it, the attractions for other substances, containing little or no phlogiston, become nearly as weak as those of fixed air itself when equally condensed; but with respect to bodies that contain a considerable quantity of phlogiston, its affinities are much stronger, as its basis attracts the phlogiston, while those bodies attract its excess of fixed air. In this state it does not expel fixed air from the fixed alkalies or earths until it is heated; and then dephlogisticated air separates from it, and it becomes, in all respects, common marine acid. For as it contains an excess of fixed air, it acts nearly as an acid of the same nature; but when heat is applied, its basis dephlogisticates its own fixed air, which then becomes dephlogisticated air, at the same time that the acid becomes common marine acid, and acts as such.

Mr Lavoisier, and other philosophes, who deny the existence of phlogiston, are of opinion, that the common marine acid consists of a peculiar basis united to a small proportion of pure air, or oxygenous principle, and the dephlogisticated marine acid differs from it only by containing an excess of this principle. — This opinion they are chiefly induced to maintain, because the acid in its dephlogisticated state is procured by distilling common marine acid from manganite; and the manganite, if distilled by itself, before the acid is distilled from it, affords dephlogisticated air; but after the acid is distilled from it, it yields none. — "This experiment, however, (says Mr Kirwan) proves no more by Mr Kirwan but that the manganite contains some air which is dephlogisticated during the calcination. And that this air is fixed air, appears from the following considerations: The black cals of manganite always gives out fixed air at first, before any dephlogisticated air appears: whence it is natural to think, that the dephlogisticated air proceeds from the dephlogistication of the fixed. And hence, if it be distilled with filings of iron, or in a gun-barrel, it first gives out any other than fixed air; if at any time it gives out dephlogisticated air, with little or no mixture of fixed air, this transduces to a very perfect dephlogistication of the cals, and to its containing very little moisture. Thus Dr Priestley, having
Decisive experiment in his favour.

Several other experiments are related by Mr. Kirwan, which the limits of this article will not allow us to insert; but the following, he is of opinion, fully confirms your experiment which the limits of this article will not allow us to discuss.

Phosphoric acid.

The other acids particularly treated of by Mr. Kirwan are the phosphoric and saccharine. In his treatise on the former, he adopts the analysis of Mr. Lavoisier, changing only his acid principle of dephlogisticated fixed air. From this it appears, that the phosphoric acid consists of a peculiar basis united to 2.265 of its weight of the acid principle; or, in other words, 100 grains of dry phosphoric acid contains about 69 of fixed air and 31 of its peculiar basis; 100 grains of the phosphoric basis take up 226.5 of fixed air, or 32.6 of phlogiston when it becomes phosphoric acid; and 100 grains of phosphorus contain 75.24 of basis and 24.76 of phlogiston.

Fixed air.

The acid of sugar be distilled, it is wholly converted into the acid principle, according to Mr. Kirwan, which is far from being the case, that it is universally agreed to be much less; Bergman making it only.

Saccharine acid.

If the saccharine acid be distilled of fixed acid, or converted of that substance undecomposed, and barely united to the oxigenous principle, it ought to be formed by treating sugar with the black calx of manganese, or with dephlogisticated marine acid; both of which, according to him, have less attraction for the oxigenous principle than sugar. Lastly, (says Mr. Kirwan), if the acid of sugar be distilled, it is wholly converted into the acid principle, and not a particle of coal, or dephlogisticated air is found in it. It is not therefore reasonable to look on either of them as constituting principles; but as fixed air alone can be extracted from all vegetable acids, it seems to be the true acidifiable principle.

Having given a view of the present opinions relative to the original formation of acids, it remains to treat a little more particularly of each of the different kinds.

(a) On mixing these, a dense white cloud appears; one half the bulk of both disappears, and the residuum explodes like a mixture of inflammable and dephlogisticated air.
kinds. They are divided into three different classes, expressive of their origin, viz. the Mineral, Vegetable, and Animal. The mineral acids are those of vitriol, nitre, fessa-falt, borax, amber, flour, arctic, tungsten, molybdæna, &c. The vegetable are, those of vinegar, tartar, figar, benzoin, apples, citrons, lemons, tamarinds, forcell, cork, &c. The animal acids are, the microscopic or acid of urine, and that of bones, both of which are also called the phosphenous, though this might be accounted a vegetable acid, as it is procured by diffilting mustard and some other vegetables by a violent fire. Besides these, there are the acids of ants, wasps, bees, flick-worms, milk, &c. It has also been discovered, that the human calculus is formed for the most part of a peculiar acid, which has received the name of lithius acid. Lastly, As an acid distinct from all these, we may now add fixed air, by some called the aerial, and by others the cretesous acid; the latter appellation it derives from create, chalk, because it is found in that substance in great quantity. See AEREOLOGY.

The general properties of acids have already been enumerated; the most remarkable of which is their attraction for alkaline fads, earths, and metals. Though this is common to all, yet very considerable differences are observed among them in this respect, and on those differences depend almost all the phenomena of that part of chemistry which treats of fads. As these phenomena are particularly considered under that article, we shall here only in general take notice, that the three acids named the vitriolic, nitrous, and marine, are the strongest of them all; that is, if any other acid be united to an alkalii, earth, or metal, the union will be broken by adding to that compound any of the three acids just mentioned. Neither are these equal in power among themselves; for the vitriolic is stronger than the nitrous, and the nitrous stronger than the marine. The rule, however, is liable to certain exceptions and variations, depending chiefly on the circumstances of heat or cold, moisture or dryness, and particularly on the state of the marine acid with regard to its being in the form of an aqueous fuid or reduced to a dry vapour. In this last cafe it seems stronger than either the vitriolic or nitrous; and even when in an aqueous fiate, both the nitrous and marine fads, when added in great quantity, seem to oppose and overwhelm the stronger vitriolic acid, fo that they will partly expel it from an alkaline falt. This does not depend on the mere quantity of acidity they pollute: for the acceous acid may be concentrated to a degree as to become stronger in this respect than spirit of fad; yet it will always be inferior in point of real strength, when tried with an alkalii in competition with the latter. The aerial acid is the weakest of all; and may be expelled not only by vinegar, but by the acid jui'es of fruits, tartar, and the acids of tungsten and molybdæna.

Some acids have the property of refilling the fire, and melting into a kind of glass, such as that of borax and phosphorus. This circumstance gives them an advantage over the stronger acids which are volatile; and thus the two just mentioned, as well as those of arctic and tungsten, will, in a very strong heat, expel the acid of vitriol itself, though the latter will, in the cold, expel any one of them with great ease.

Both the vitriolic and nitrous acids have a very strong attraction for phlogition; and unite with certain oily and inflammable matter so vehemently as to occasion great heat, and sometimes even violent and unextinguifiable flame. This is particularly the case with the nitrous acid, or with a mixture of the two; and indeed the nitrous acid, though weaker than the vitriolic, flows itself in every instance to be far more active, and to perform all its operations with vastly greater rapidity, than the other. All these particular, however, as they properly fall under the article CHEMISTRY, are here explained at length: together with the origin and peculiar methods of preparing each of the acids, and the various uses to which they may be applied in arts and manufactures. See also their different titles as they occur in the order of the alphabet; as, Nitre, Vinegar, Vitriol, &c.

ACIDULOUS denotes a thing that is slightly acid; it is synonymous with the word but-acid.

ACIDULÆ. Mineral waters that contain a brisk spirit, when unaccompamed with heat, are thus named; but if they are hot also they are called THERMAE. See MINERAL WATERS.

ACIDULATED, a name given to medicines that have an acid in their composition.

ACIDUM AERÆUM, the same with Fixed Air. Acidum pingue, an imaginary acid, which some German chemists suppos'd to be contained in fire, and by combining with alkalies, lime, &c. to give them their caustic properties; an effect which is found certainly to depend on the fof of their fixed air.

ACILA, OCILA, or OCELIS (anc. geog.), a flape or mart town in Arabia Felix, on the Arabic gulf, from which, according to Pliny, they fett fai for India. Now Ziden.

ACILIUS GLABRIO (Marcus), conful in the year of Rome 562, and 211 years before the Christian era, di.stinguished himself by his bravery and conduct in gaining a complete vitory over Antiochus the Great, king of Syria, at the ftreights of Thermopylae in Thellafy, and on feveral other occasions. He built the Temple of piety at Rome, in confquence of a vow he made before the abovementioned battle: and the reafon of his giving it that name is very remarkable. The story is mentioned by Pliny, Valetiius Maximus, and others. See the article PIETY.

ACINIPPO (anc. geog.), a town of Boetiae; its ruins, called Ronda la Vega, are to be feen near Arunda, in the kingdom of Granada.

ACINODENDRUM, in botany, the trivial name of a species of MELASTOMA.

ACINOS, in botany, the trivial name of a species of THYMUS.

ACINS, or ACINI, the small protuberances of mulberries, strawberries, &c. and by some applied to grapes. Generally it is used for those small grains growing in bunches, after the manner of grapes, as LIGUSTRUM, &c.

ACIS, in fabulous hisory, the fon of Faunus and Simethes, was a beautiful shepherd of Sicily, who being beloved by Galatea, Polyphemus the giant was so enraged, that he daifed out his brains against a rock; after which Galatea turned him into a river, which was called by his name.

ACIS, (Ovid, Theocritus); a river of Sicily, running from a very cold spring, in the woody and shady foot
foot of mount Aetna, eastward into, and not much above a mile from the sea, along green and pleasant banks, with the iped of an arrow, from which it takes its name. It is now called Acit Lambi, or Ghirli, according to the different Sicilian dialects: Antonine calls it Acis. Also the name of a hamlet at the mouth of the Aci.

ACKNOWLEDGMENT, in a general sense, is a person's owning or confessing a thing; but, more particularly, is the expression of gratitude for a favour.

ACKNOWLEDGMENT-MONEY, a certain sum paid by tenants, in several parts of England, on the death of their landlords, as an acknowledgment of their new lords.

ACLIDES, in Roman antiquity, a kind of missile weapon, with a thong affixed to it, whereby to draw it back. Most authors describe it as a kind of dart or javelin; but Scaliger makes it roundish or globular, and full of spikes, with a slender wooden stem to point it by.

ACLOWA, in botany, a barbarous name of a species of Colutea. It is used by the natives of Guiana to cure the itch: They rub it on the body as we do unguents.

ACME, the top or height of anything. It is usually applied to the maturity of an animal just before it begins to decline; and physicians have used it to express the utmost violence or crisis of a disease.

ACMELLA, in botany, the trivial name of a species of Spilanthes.

ACMONIA, and ACAMONIA, in Peutinger's map, a town of Phrygia Major, now in ruins. The inhabitants are called Acumonenses by Cicero, and the city Civitas Aemontis. Also a city of Dacia (Philomcy), on the Danube, near the ruins of Trajan's bridge, built by Severus, and called Severianum; distant 12 German miles from Temeswar, to the south-east.

ACNIDA, VIRGINIAN HEMP, in botany, a genus of the dioecia order, belonging to the pentandria class of plants; and, in the Natural Order, associating with the Scabridae (53). The characters are: In the male, the calyx is a perianthium consisting of five leaves, ovate, concave, acute, and membranous on the margin. No corolla. The stamina consist of five very short capillary filaments; the anthers are versatile, two-celled, and forked at both ends. Female on a separate plant; of which the calyx consists of an involucre many-leaved, linear, and deciduous; and a perianthium two-leaved, very small, and perfect. No corolla. The pistillum has an ovate germen; the stigmas are five, long, reflexed, and downy; the filaments are simple. The pericarpium is an egg-shaped fruit, compressed, many-angled, fulcated, and covered with a succulent calyx. The seed is solitary, round, and compressed. There is only one species of it, viz. the acnida cannabida. It's a native of Virginia; but rarely cultivated in Europe, except for the sake of variety. It has little beauty, and at present is applied to no useful purpose.

ACNUEA, in Roman antiquity, signified a certain measure of land, near about the English rood, or fourth part of an acre.

ACOEMETÆ, or ACOEMETI, in church-history; or, Men who lived without sleep: A fret of monks who chanted the divine service night and day in their places of worship. They divided themselves into three bodies, who alternately succeeded each other, so that their churches were never silent. This practice they founded upon the precept, Pray without ceasing. They flourished in the east about the middle of the 5th century. There are a kind of acoemeti still subsisting in the Roman church, viz. the religious of the holy facrament, who keep up a perpetual adoration, some one or other of them praying before the holy sacrament day and night.

ACOLUTHI, or ACOLUTHISTS, in antiquity, was an appellation given to those persons who were steady and immovable in their resolutions: and hence the title of those, because they would not forfake their principles, nor alter their resolutions, acquired the title of Acoluthi. The word is Greek, and compounded of α, priv. and κολυθω, away; as never turning from the original course.

ACOLUTHI, among the ancient Christians, implied a peculiar order of the inferior clergy in the Latin church; for they were unknown to the Greeks for above 400 years. They were next to the sub-deacon; and we learn from the fourth council of Carthage, that the archdeacon, at their ordination, put into their hands a candlestick with a taper, giving them thereby to understand that they were appointed to light the candles of the church, as also an empty pitcher, to imply that they were to furnish wine for the eucharist. Some think they had another office, that of attending the bishop wherever he went. The word is Greek, and compounded of α, priv. and κολυθω, to hinder or disturb.

ACOLYTHIA, in the Greek church, denotes the office or order of divine service; or the prayers, ceremonies, hymns, &c. whereas the Greek service is composed.

ACOMAC, a town of North America, in New Mexico, seated on a hill, with a good cattle. To go into the town, you must walk up 50 steps cut out of the rock. It is the capital of that province, and was taken by the Spaniards in 1599. W. Long. 104. 15. L. 35. 0.

ACOMAC or ACOMACK, the name of a county in Virginia. It is on the eastern side of the Chesapeake bay, on a slip of land, called the eastern shore.

ACOMINATUS (Niceria), was secretary to Alexius Comnenus and to Isaacas Angelus successively: he wrote an history from the death of Alexius Comnenus 1118, where Zonaras ends his, to the year 1209, which has undergone many impressions, and is much applauded by the best critics.

ACONITI, See ACONITUM.

ACONITUS, See ACONITUM.

ACONITO, See HELEDOURUS.

ACONCROBA, in botany, the indigenous name of a plant which grows wild in Guinea, and is in great esteem among the natives for its virtues in the small-pox. They give an infusion of it in wine. The leaves of this plant are opaque, and as flat as those of the phile; they grow in pairs, and stand on short foot-stalks; they are small at each end, and broad in the middle; and the largest of them are about three inches in length, and an inch and quarter in breadth in the middle. They are of a dusky colour on the upper side, and of a pale green underneath.
ACONITI, in antiquity, an appellation given to some of the Atules, but differently interpreted. Mercantilists understand it of those who only anointed their bodies with oil, but did not flexure themselves over with dust, as was the usual practice.

ACONITUM, Aconite, Wolfsbane, or Monkhood; a genus of the trigyna order, belonging to the polyandria clafs of plants. In the natural order, it associates with the Multiflora, 26. The characters are: There is no calyx. The corolla consists of five unequal petals opposite in pairs; the highest helmet-tube, inverted, and obtuse; the twolateral ones, broad, roundish, opposite, and converging; the two lowest, oblong, and looking downwards: The sepalia are two, piped, nodding, and sitting on long subulate peduncles, and concealed under the highest petal: The scales are six, very short, coloured, and in an orb with the sepalia. The flamina consists of numerous small subulate filaments; the anthers are creft and small. The pistillum has three [five] oblong germen, ending in filii the length of the flamina; the stigmata are simple and reflected. The pericarpium has three or five univalve capsules gaping inward. The seeds are numerous, angular, and wrinkled.

Species. 1. The lycoceum, or yellow wolfsbane, grows in hedges of three feet high, flowers about the middle of June, and if the seafon is not warm will continue in flower till August. 2. The atlimum, or greatest yellow wolfsbane, grows upwards of four feet high, and the spikes of its flower are much longer in this sort than the former. 3. The variegatum, or leifer wolfsbane, seldom grows more than two feet high, it carries blue flowers, and the spikes of them are much shorter than either of the two last. 4. The anthes, or wholefome wolfsbane, flowers in the middle of August, and often continues in beauty till the dear of September; its flowers are not large, but are of a beautiful phosphor-yellow colour. 5. The napellus, bears large blue flowers, which appear in August, and make a pretty appearance. There are two or three varieties of this kind; one with white, another with rofe-coloured, and a third with variegated flowers: but these are only varieties which often change. 6. The Pyramidal, or common monkhood, bears a long spike of blue flowers, which appear sooner than any of the other forms, being fo early as June, or sometimes even May. The spikes of flowers are upwards of two feet long, so that it makes a pretty appearance; the seeds are ripe in September. 7. The alpinum, or large-flowered monkhood, flowers in August, and will grow to the height of five feet in good ground; the flowers are very large, of a deep blue colour, but not many upon each spike. 8. The pyreniacum, or Pyrenean monkhood, flowers in July. It grows about four feet high, and carries a long spike of yellow flowers. 9. The cammarum, grows about four feet high, and flowers in the beginning of July. 10. The orientale, or eastern monkhood, grows sometimes more than fix feet high, and bears a white flower.

Culture. All thefe species, except the laft, are natives of the Alps, the mountains of Germany, Austria, and Tartary; so require a cool shady situation, except the wholefome wolfsbane, which must have an open exposure. They thrive better in a moift than dry soil: but the ground muft not be so wet as to have the water flanding near their roots in the winter-time. Aconitum. They may all be propagated by leaving their seeds in autumn, upon a north border, where they are freced from the rain. The plants will come up in the spring, when they must be kept clean from weeds during the summer-months: and in very dry feasons, if they are frequently refted with water, their growth will be greatly promoted. The following autumn they should be transplanted into shady borders, in rows a foot aunder, and the plants fix inches distant from one another. In this situation they may remain two years, when they will carry flowers, and so may be transplanted to fole places where they are to remain. The eastern monkhood is a native of the Levant, from whence the seeds of it were first sent by Dr Tournfort to the royal garden at Paris, from whence fome other gardens have been furnished with feeds. It is very rare in Europe at present.

Qualities. Since the time of Theophrastus, moft of the species of monkhood have been reckoned a deadly poifon both to men and brutes. Diocorides, however, recommends the external application of common monkhood for pains of the eyes. The flowers of a great many species communicate their noxious quality by being smelted; and some of the species called noxialis being placed on the head, occasion a violent megrim. Of the bad qualities of thefe plants we sometimes avail ourselves to get rid of vermin. A decoction of the roots destroys bugs; the fame part being powdered, and administered in bread or fome other palatable vehicle to rats and mice, corrodcs and infames their intestines, and foon proves mortal. The juice of the plant is used to poifon flih with, for the destruction of wolves, foxes, and other ravenous brutes. The beft antidote to the poifon of the different monkheads is said to be the root of the anthes, a species of the fame genus, hence termed beneficial or wholefome monkhood. The fame plant is regarded as efficacious against bites of ferpents and other venomous creatures. The roots have a bitter acrid taste; the leaves are only bitter: the former are chiefly used in medicine; and, besides the excellent quality just mentioned, are ftoflictic, and promote perforation. The peasants, who gather the plants on the Alps and Pyrenees, are faid to use it with forcefs againft the biting of mad dogs, and to cure the cholical It is remarkable, that the monkheads with blue flowers are much more virulent than the yellow or white-flowered kinds. Miller afferts that the huntsmen of the wolves and other wild beasts on the Alps, dip their arrows into the juice of those plants, which renders the wounds made by them deadly.

That the anthes is an antidote to the poifon of the reft of the species, is not considered as a fact sufficiently established. Of the effects of the above, indeed, and other vegetable poifons, medical writers give but a confused account. In general, thofe which are not of the narcotic kind, nor excite violent vomiting and purgings, produce their pernicious effects by irritating the nervous coats of the fomach and intestines, as to occasion violent convulsions, not only in them, but, through the whole body. The proper cure is evacuation by vomit: but this is not to be obtained without some difficulty; because there is usually such a contraction about the upper orifice of the fomach, that nothing;
A C O N T I A S, in zoology, an obsoletene name of the anguis jugularis, or dart-snake, belonging to the order of amphibia serpentes. See ANGUIS.

A C O N T I U M, or contumacy, in Grecian antiquity, a kind of dart or javelin, resembling the Roman pilaum.

A C O N T U S (James), a philosopher, civilian, and divine, born at Trelton the 16th century; he embraced the reformed religion; and, coming into England in the reign of queen Elizabeth, which he acknowledges in a book dedicated to that queen. This work is his celebrated Collection of the Stratagemas of Satan, which has been so often translated, and borne so many editions.

A C O S T A N, a mountainous island in the north seas between Asia and America, observed by captain Cook.

A C O R N, the fruit of the oak-tree. See QUERCUS.

A C O R N, (in sea-language), a little ornamental piece of wood, fashioned like a cone, and fixed on the uppermost point of the spindle, above the vase, on the masthead. It is used to keep the vase from being blown off from the spindle in a whirlwind, or when the ship leans much to one side under sail.

A C O R U S, CALAMUS AROMATICUS, SWEETFLAG, or SWEET RUSH: a genus of the monocotylous order, belonging to the xantharia class of plants, and ranking in the second natural order, Piparieae. The characters are: The calyx is a cylindrical simple spadix covered with florets; there is no stamens, nor perianthium. The corolla is composed of six obtuse, concave, loose petals. The filaments consist of six thickish filaments, somewhat longer than the corolla; the anthers are thick and dicydous. The pistillum has a gibbon oblong germen the length of the filaments; no styles; the stigma a prominent point. The pericarpium is a short triangular, obtuse, three-celled capsule, attenuated at both ends.

The seeds are numerous, and of an oblong egg-shape.

There is but one species, the acorus calamus. It grows naturally in shallow standing waters, and is found wild in some parts of Britain. It grows plentifully in rivulets and marshy places about Norwich and other parts of the island, in the canals of Holland, in Switzerland, and in other countries of Europe. The shops have been usually supplied from the Levant with dried roots, which do not appear to be superior to those of other parts. The leaves are sometimes two feet long, narrow, compressed, smooth, and of a bright green, terminating in a point; the root is pretty long, of a whitish, reddish, and partly greenish colour. Among the leaves there arises a single one, thicker and more robust than the rest, furred on the surface, and of a paler green. On this grow frequently two spikes of flowers, by many writers called futili. These are of a brown colour, having a chequered surface. The root of this plant has a very agreeable flavour, which is greatly improved by drying. It is reckoned carminative and stomachic, having a warm, pungent, bitterish taste; it is frequently used as an ingredient in bitters. It has been complained of, however, as communicating a nauseous flavour to those bitters in which it was infused; and Neumann observes, that its agreeable flavour, as well as its distinguishing taste, resides entirely in a volatile essential oil; the residuum after distillation having a nauseous flavour, not at all resembling that of the calamus. It is an ingredient in the mithridate and theriac of the London pharmacopoeia; and in the aromatic and stomachic tinctures, and compound arum powder, of the Edinburgh. The fresh root candied is said to be employed at Constantinople as a preservative against epidemic diseases. The leaves of this plant have a sweet fragrant smell, more agreeable, though weaker than that of the roots. Neither horses, cows, goats, sheep, nor fwine, will eat the herb, or its root.

Culture. The acorus being a perennial plant, may be transplanted into a garden, where it will thrive very well if the ground is moist; but never flowers unless it grows in water. It loves an open situation, and will not thrive well under the shade of trees. The flowers appear the latter end of June, and continue till August.

A C O R U S, in the materia medica, a name sometimes given to the great galangal. See KEMPERIA.

A C O R U S, in natural history, blue coral. The true form is very scarce; some, however, is filled on the coasts of Africa, particularly from Rio del Re to the river of the Camarones. This coral is part of the merchandise which the Dutch trade for with the Camarones; that of the kingdom of Benin is also very much esteemed. It grows in form of a tree on a rocky bottom.

A C O U S M A T I C I, sometimes also called Acoustic, in Grecian antiquity, such of the disciples of Pythagoras as had not completed their five years probation.

A C O U S T I C, in general, denotes any thing that relates to the ear, the sense of hearing, or the doctrine of sounds.

A C O U S T I C D u d, in anatomy, the fame with meatus auditorius, or the external passage of the ear. See ANATOMY.

A C O U S T I C I n s t r u m e n t , or auricular tube. See A C O U S T I C S, n° 26.

A C O U S T I C V e s s e l s, in the ancient theatres, were a kind of vessels made of brass, shaped in the bell fashion, which being of all tones within the pitch of the voice or even of instruments, rendered the sounds more audible, so that the actors could be heard through all parts of theaters, which were even feet in diameter.

ACOUSTICS

Dialectics

INSTRUCTS us in the nature of sound. It is divided by some writers into Dialectics, which explains the properties of those sounds that come directly from the sonorous body to the ear; and Catacogistics, which treats of reflected sounds: but such distinction does not appear to be of any real utility.

Chap. I. Different theories of Sound.

Of the vehicles of sound.

Most sounds, we all know, are conveyed to us on the bosom of the air. In whatever manner they either float upon it, or are propelled forward in it, certain it is, that, without the vehicle of this or some other fluid, we should have no sounds at all. Let the air be exhausted from a receiver, and a bell shall emit no sound when rung in the void; for, as the air continues to grow less dense, the sound dies away in proportion, so that at last its strongest vibrations are almost totally silent.

Thus air is a vehicle for sound. However, we must not, with some philosophers, assert, that it is the only vehicle; that, if there were no air, we should have no sounds whatsoever: for it is found by trial, that sounds are conveyed through water almost with the same facility with which they move through air. A bell rung in water returns a tone as distinct as if rung in air. This was observed by Derham, who also remarked that the tone came a quarter deeper. Some naturalists affirme also, that fishes have a strong perception of sounds, even at the bottom of deep rivers (A). From hence, it would seem to be not very material in the propagation of sounds, whether the fluid which conveys them be elastic or otherwise. Water, which, of all substances that we know, has the least elasticity, yet serves to carry them forward; and if we make allowance for the difference of its density, perhaps the sounds move in it with a proportional rapidity to what they are found to do in the elastic fluid of air.

One thing however is certain, that whether the fluid which conveys the note be elastic or non-elastic, whatever sound we hear is produced by a stroke, which the founding body makes against the fluid, whether air or water. The fluid being struck upon, carries the impression forward to the ear, and there produces its sensation. Philosophers are so far agreed, that they all allow that sound is nothing more than the impression sound is made by an elastic body upon the air or water (B), and how this impression carried along by either fluid to the organ of hearing. But the manner in which this conveyance is made, is still disputed: Whether the sound is diffused into the air, in circle beyond circle, like the waves of water when we disturb the smoothness of its surface by dropping in a stone; or whether it travels along, like rays diffused from a centre, somewhat in the swift manner that electricity runs along a rod of iron; these are the questions which have divided the learned.

Newton was of the first opinion. He has explained Newton's theory of sound by an undulatory, or rather a theory vermicular, motion in the parts of the air. If we have an exact idea of the crawling of some insects, we shall have a tolerable notion of the progression of sound upon this hypothesis. The insect, for instance, in its motion, first carries its contractions from the hinder part, in order to throw its fore-part to the proper distance; then it carries its contractions from the fore-part to the hinder to bring that forward. Something similar to this is

(A) Dr. Hunter has proved this, and demonstrated the auricular organ in these animals. See Fish, and Comparative Anatomy.

(b) Though air and water are both vehicles of sound, yet neither of them seems to be so by itself, but only as it contains an exceedingly subtle fluid capable of penetrating the most solid bodies. Hence, by the medium of that fluid, sounds can be propagated through wood, or metals, even more readily than through the open air. By the same means, deaf people may be made sensible of sounds, if they hold a piece of metal in their mouth, one end of which is applied to the founding body. As it is certain, therefore, that air cannot penetrate metals, we must acknowledge the medium of sound to be of a more subtle nature; and thus the electrical fluid will naturally occur as the proper one. But why then is found no longer heard in an exhausted receiver, if the air is not the fluid by which it is conveyed, seeing the electrical matter cannot be excluded? The reply to this is obvious: The electrical fluid is so exceedingly subtle, and pervades solid bodies with so much ease, that any motion of a solid body in a quantity of electrical matter by itself, can never excite a degree of agitation in it sufficient for producing a sound; but if the electrical fluid is entangled among the particles of air, water, wood, metal, &c. whatever affects their particles will also affect this fluid, and produce an audible noise. In the experiment of the air-pump, however, there may be an ambiguity, as the gradual exhausting of the air creates an increasing difference of pressure on the outside, and may occasion in the glass a difficulty of vibrating, so as to render it less fit to communicate to the air without the vibrations that strike it from within. From this cause the diminution of found in an exhausted receiver may be supposed to proceed, as well as from the diminution of the air. But if any internal agitation of its parts should happen to the electrical fluid, exceeding loud noises might be propagated through it, as has been the case when large meteors have kindled a great distance of the earth. It is also difficult to account for the exceeding great swiftness of found, upon the supposition that it is propagated by means of air alone; for nothing is more certain, than that the strongest and most violent gale is, in its course, inert and sluggish, compared with the motion of found.
in the motion of the air when struck upon by a sounding body. To be a little more precise, suppose ABC, the string of a harpichord drawn to a proper pitch, and drawn out of the right line by the finger at B. We shall have occasion elsewhere to observe, that such a string would, if let go, vibrate to E; and from E to D, and back again; that it would continue thus to vibrate like a pendulum for ever, if not externally resisted, and like a pendulum, all its little vibrations would be performed in equal times, the leaf and the first being equally long in performing; also, that, like a pendulum, its greatest swiftness would always be when it arrived at E, the middle part of its motion. Now then, if this string be supposed to fly from the finger at B, it is obvious, that whatever be its own motion, such also will be the motion of the parts of air that fly before it. Its motion, as is obvious, is first uniformly accelerated forward from B to E, then retarded as it goes from E to D, accelerated back again as it returns from D to E, and retarded from E to B. This motion being therefore sent in succession through a range of elastic air, it must happen, that the parts of one range of air must be first forward with accelerated motion, and then with a retarded motion. This accelerated motion reaching the remotest end of the first range will be communicated to a second range, while the nearest parts of the first range being retarded in their motion, and falling back with the reception of the string, retire first with an accelerated, then with a retarded motion, and the remotest parts will soon follow. In the mean time, while the parts of the first range are thus falling back, the parts of the second range are going forward with an accelerated motion. Thus there will be an alternate condensation and relaxation of the air, during the time of one vibration; and as the air going forward strikes any opposing body with greater force than upon retreating, so each of these accelerated progressions have been called by Newton a pulse of sound.

Thus will the air be driven forward in the direction of the string. But now we must observe, that these pulses will move every way; for all motion impressed upon fluids in any direction whatsoever, operates all around in a sphere: so that sounds will be driven in all directions backwards, forwards, upwards, downwards, and on every side. They will go on succeeding each other, one on the outside of the other, like circles in disturbed water; or rather, they will lie one without the other, in concentric shells, shell above shell, as we see in the coats of an onion. All who have remarked the tone of a bell, while its sounds are decaying away, must have an idea of the pulses of sound, which, according to Newton, are formed by the air's alternate progression and reception. And it must be observed, that as each of these pulses is formed by a single vibration of the string, they must be equal to each other; for the vibrations of the string are known to be so.

Again, as to the velocity with which sounds travel, this Newton determines, by the most difficult calculation that can be imagined, to be in proportion to the thickness of the parts of the air, and the dilance of these parts from each other. From hence he goes on to prove, that each little part moves backward and forward like a pendulum; and from hence he proceeds to demonstrate, that if the atmosphere were of the same density every where as at the surface of the earth, in such a case, a pendulum, that reached from its highest surface down to the surface of the earth, would by its vibrations discover to us the proportion of its velocity with which sounds travel. The velocity with which each pulse would move, he shows, would be as much greater than the velocity of such a pendulum swinging with one complete vibration, as the circumference of a circle is greater than the diameter. From hence he calculates, that the motion of sound will be 979 feet in one second. But this not being conformable to experience, he takes in another consideration, which destroys entirely the vigour of his former demonstration, namely, vapours in the air; and then finds the motion of sound to be 1142 feet in one second, or near 13 miles in a minute: a proportion which experience had established nearly before.

Thus much will serve to give an obscure idea of a preceding theory which has met with numbers of opposers. Even Theory of John Bernouilli, Newton's greatest disciple, moderately famed. He owned that he did not pretend to understand this part of the Principia. He attempted therefore to give a more perspicuous demonstration of his own, that might confirm and illustrate the Newtonian theory. The subject seems to reject elucidation; his theory is obviously wrong, as D'Alembert has proved in his Theory of Fluids.

Various have been the objections that have been made to the Newtonian system of sounds. It is urged, that this theory can only agree with the motion of sound in an elastic fluid, whereas sounds are known to move forward through water that is not elastic. To explain their progress therefore through water, a second theory must be formed: so that two theories must be made to explain a similar effect; which is contrary to the simplicity of true philosophy, for it is contrary to the simplicity of nature. It is farther urged, that this slow vermicular motion but ill represents the velocity with which sounds travel, as we know by experience that it is almost 13 miles in a minute. In short, it is urged, that such undulations as have been described, when coming from several sonorous bodies at once, would crowd, obstruct, and confound each other; so that, if they were conveyed to the ear by this means, we should hear nothing but a medley of discordant and broken articulations. But this is equally with the rest contradictory to experience, since we hear the fullest concert, not only without confusion, but with the highest pleasure. These objections, whether well founded or not, have given rise to another theory: which we shall likewise lay before the reader; though it too appears liable to objections, which shall be afterwards mentioned.

Every sound may be considered as driven off from another the sounding body in straight lines, and impressed upon Theory, the air in one direction only: but whatever impression is made upon a fluid in one direction, is diffused upon its surface into all directions; so that the sound first driven directly forward does fill up a wide sphere, and is heard on every side. Thus, as it is impressed, it instantaneously travels forward with a very swift motion, resembling the velocity with which we know electricity flies from one end of a line to another.

Now, as to the pulses, or close shocks, as the musicians express it, which a sounding body is known to make
Chap. 1. ACOUSTICS

Theories of Sound.

Different

make, each pulse (say the supporters of this theory,) is itself a distinct and perfect sound and the interval between every two pulses is profoundly silent. Continuity of sound from the same body is only a deception of the hearing; for as each distinct sound succeeds at very small intervals, the organ has no time to transmit its images with equal swiftness to the mind, and the interval is thus lost to sense; just as in facing a flaming torch, if flared round in a circle, it appears as a ring of fire. In this manner a beaten drum, at some small distance, presents us with the idea of continuing sound. When children run with their sticks along a rail, a continuing sound is thus represented, though it need scarce be observed that the stick is not always returned in the same body. All bodies whatever that are struck return more or less a sound; but some, wanting elasticity, give back no repetition of the sound; the noise is at once begotten and dies; while other bodies, however, there are, which being more elastic and capable of vibration, give back a sound, and repeat the same several times successively. These last are said to have a tone; the others are not allowed to have any.

This tone of the elastic string, or bell, is notwithstanding nothing more than a similar sound to what the former bodies produced, but with the difference of being many times repeated while their note is but single. So that, if we would give the former bodies a tone, it will be necessary to make them return their sound, by repeating our blows swiftly upon them. This will effectually give them a tone; and even an unmusical instrument has often had a fine effect by its tone in our concerts.

Let us now go on then to suppose, that by swift and equally continued strokes we give any non-elastic body its tone: it is very obvious, that no alterations will be made in this tone by the quickness of the strokes, though repeated ever so fast. Thence will only render the tone more equal and continuous, but make no alteration in the tone it gives. On the contrary, if we make an alteration in the force of each blow, a different tone will then undeniably be excised. The difference will be fatal; it must be confessed; for the tones of these inelastic bodies are capable but of small variation; however, there will certainly be a difference. The table on which we write, for instance, will return a different sound when struck with a club, from what it did when struck only with a twitch. Thus non-elastic bodies return a difference of tone, not in proportion to the swiftness with which their sound is repeated, but in proportion to the greatness of the blow which produces it; for in two equal non-elastic bodies, the body produced the deepest tone which was struck by the greatest blow.

We now then come to a critical question. What is it that produces the difference of tone in two elastic sounding bells or strings? Or what makes one deep and the other shrill? This question has always been hitherto answered by saying, that the depth or height of the note proceeded from the slowness or swiftness of the times of the vibrations. The slowest vibrations, it has been said, are qualified for producing the deepest tones, while the swiftest vibrations produce the highest tones.

In this case, an effect has been given for a cause. It is in fact the force with which the sounding string strikes the air when struck, that makes the true distinction in the tones of sounds. It is this force, with greater or less impression, resembling the greater or less force of the blows upon a non-elastic body, which produces correspondent affections of sound. The greatest forces produce the deepest sounds: the high notes are the effect of small efforts. In the same manner a bell, wide at the mouth, gives a grave sound; but if it be very mally withal, that will render it still graver; but if mally, wide, and long or high, that will make the tone deepest of all.

Thus, then, will elastic bodies give the deepest sound, in proportion to the force with which they strike the air: but if we should attempt to increase their force by giving them a stronger blow, this will be in vain; they will still return the same tone, for such is their formation, that they are numerous only because they are elastic, and the force of this elasticity is not increased by our strength or the greatness of a pendulum's vibration will not be increased by falling from a greater height.

Thus far of the length of chords. Now as to the frequency with which they vibrate the deepest tones, it has been found, from the nature of elastic strings, that the longest strings have the widest vibrations, and consequently go backward and forward slowest; while, on the contrary, the shortest strings vibrate the quickest, or come and go in the shortest intervals. From hence those who have treated of sounds, have inferred, as was said before, that the tone of the string depended upon the length or the shortness of the vibrations. This, however, is not the case. One and the same string, when struck, must always, like the fame pendulum, return precisely similar vibrations; but it is well known, that one and the same string, when struck, does not always return precisely the same tone: so that in this case the vibrations follow one rule, and the tone another. The vibrations must be invariably the same in the same string, which does not return the same tone invariably, as is well known to musicians in general. In the violin, for instance, they can easily alter the tone of the string an octave or eight notes higher, by a better method of drawing the bow; and some are known thus to bring out the most charming airs imaginable. These peculiar tones are by the English fiddlers called faltieter. The only reason, it has been alleged, that can be assigned for the same string thus returning different tones, must certainly be the different force of its strokes upon the air. In one case, it has double the tone of the other; because upon the soft touches of the bow, only half its elasticity is put into vibration.

This being understood (continue the authors of this theory,) we shall be able clearly to account for many things relating to sounds that have hitherto been inexplicable. Thus, for instance, if it be asked, When two strings are stretched together of equal lengths, tensions, and thickness, how does it happen, that one of them being struck, and made to vibrate
Acoustics.

Chap. I.

Different Theories of Sound.

Throughout, the other shall vibrate throughout also? the answer is obvious: The force that the string struck receives is communicated to the air, and the air communicates the fame to the similar string: which therefore receives all the force of the former; and the force being equal, the vibrations must be so too. Again, put the question, If one string be but half the length of the other, and be struck, how will the vibrations be? The answer is, The longest string will receive all the force of the string half as long as itself, and therefore it will vibrate in proportion, that is, through half its length. In the same manner, if the longest string were three times as long as the other, it would only vibrate in a third of its length; or if four times, in a fourth of its length. In short, whatever force the smaller string imparts upon the air, the air will imparts a similar force upon the longer string, and partially excite its vibrations.

From hence also we may account for the cause of those charming, melancholy gradations of sound in the Eolian lyre: an instrument (says Sir John Hawkins) late arrested upon the public as a new invention, though described above a century ago by Kircher.*

This instrument is easily made, being nothing more than a long narrow box of thin dale, about 30 inches long, 5 inches broad, and 1 inch diameter, pierced with small holes. On this side are seven, ten, or (according to Kircher) fifteen or more strings of very fine gut, stretched over bridges at each end, like the bridge of a fiddle, and screwed up or relaxed with screw-pins (a). The strings are all tuned to one and the same note; and the instrument is placed in some current of air, where the wind can blow over its strings with freedom. A window with the sash fastened to give the air admission, will answer this purpose exactly. Now when the entering air blows upon the strings with different degrees of force, there will be excited different tones of sound; sometimes the blast brings out all the tones in full concert; sometimes it sinks them to the softest murmurs; it feels for every tone, and by its gradations of strength solicits those gradations of sound which art has taken different methods to produce.

It remains, in the last place, to consider (by this theory) the loudness and softness, or, as the musicians speak, the strength and softness of sound. In vibrating strings, the loudness of the tone is in proportion to the depth of the note; that is, in two strings, all things in other circumstances alike, the deepest tone will be loudest. In musical instruments upon a different principle, as in the violin, it is otherwise; the tones are made in such instruments, by a number of small vibrations crowded into one stroke. The refined bow, for instance, being drawn along a string, its roughnesses catch the striking at very small intervals, and excite its vibrations. In this instrument, therefore, to excite loud tones, the bow must be drawn quick, and this will produce the greatest number of vibrations. But it must be observed, that the more quick the bow passes over the string, the less apt will the roughness of its surface be to touch the string at every instant; to remedy this, therefore, the bow must be drawn as its drawn quicker, and thus its fullest sound will be brought from the instrument.

If the swiftness of the vibrations in an instrument thus rubbed upon, exceed the force of the deeper found in another, then the swift vibrations will be heard at a greater distance, and as much farther off as the swiftness in them exceeds the force in the other.

By the same theory (it is alleged) may all the phenomena of musical sounds be easily explained.—The fables of the ancients pretend, that music was first found out by the beating of different hammers upon the smith’s anvil. Without purifying the fable, let us endeavour to explain the nature of musical sounds by a similar method. Let us suppose an anvil, or several similar anvils, to be struck upon by several hammers of different weights or forces. The hammer, which is double that of another, upon striking the anvil will produce a sound double that of the other: this double found musicians have agreed to call an Octave.

The ear can judge of the difference of resemblance of these sounds with great ease, the numbers being as one and two, and therefore, very readily compared. Suppose that an hammer, three times less than the first, strikes the anvil, the sound produced by this will be three times less than the first: so that the ear, in judging the similitude of these sounds, will find something more difficulty; because it is not so easy to tell how often one is contained in three, as it is to tell how often it is contained in two. Again, suppose that an hammer four times less than the first strikes the anvil, the ear will find greater difficulty still in judging precisely the difference of the sounds; for the difference of the numbers four and one cannot so easily be determined with precision as three and one. If the hammer be five times less the difficulty of judging will be still greater. If the hammer be six times less, the difficulty still increases, and so also of the seventh, inasmuch that the ear cannot always readily and at once determine the precise gradation. Now, of all comparisons, those which the mind makes most easily, and with least labour, are the most pleasing. There is a certain regularity in the human soul, by which it finds happiness in exact and striking, and easily-made comparisons. As the ear is but an instrument of the mind, it is therefore most pleased with the combination of any two sounds, the differences of which it can most dily distinguish. It is more pleased with the concord of two sounds which are to each other as one and two, than of two sounds which are as one and three, or one and four, or one and five, or one and six or seven. Upon this pleasure, which the mind takes in comparison, all harmony depends. The variety of sounds is infinite; but because the ear cannot compare two sounds as readily to distinguish their differences when they exceed the proportion of one and seven, musicians have been content to confine all harmony within that compass, and allowed but seven notes in musical composition.

Let us now then suppose a stringed instrument fitted up

(a) The figure represents the instrument with ten chords; of which some direct only eight to be tuned unison, and the two outermost octaves below them. But this seems not to be material.
Chap. 1.

ACOUSTICS.

Of musical sounds. For instance: Let the first string be twice as long as the second; let the third string be three times shorter than the first; let the fourth be four times, the fifth five times, and the sixth six times as short as the first. Such an instrument would probably give us a representation of the lyre, as it came first from the hand of the inventor. This instrument will give us all the seven notes following each other, in the order in which any two of them will accord together most pleasingly; but yet it will be very inconvenient and a very disagreeable instrument: inconvenient, for in a compass of seven strings only, the first must be seven times as long as the last; and disagreeable, because this first string will be seven times as loud as the others, so that when the tones are to be played in a different order, loud and soft sounds would be intermixed with most disgusting alternations. In order to improve the first instrument, therefore, succeeding musicians very judiciously threw in all the other strings between the two first; or, in other words, between the two octaves, giving to each, however, the same proportion to what it would have had in the first natural instrument. This made the instrument more portable, and the sounds more even and pleasing. They therefore disposed the sounds between the octaves in their natural order, and gave each its own proportional dimensions. Of these sounds, where the proportion between any two of them is most obvious, the concord between them will be most pleasing. Thus octaves, which are as two to one, have a most harmonious effect; the fourth and fifth also sound sweetly together, and they will be found, upon calculation, to bear the same proportion to each other that octaves do. "Let it not be supposed (says Mr. Savare), that the musical scale is merely an arbitrary combination of sounds; it is made up from the confluence and differences of the parts which compose it. Those who have often heard a fourth and fifth accord together, will be naturally led to discover their difference at once; and the mind unites itself to their resemblance. Let us then cease to assign the coincidences of vibrations as the cause of harmony, since these coincidences in two strings vibrating at different intervals, must at first be but fortuitous; whereas concord is a most pleasing. The true cause why concord is pleasing, must arise from our power, in such a case, of measuring more easily the differences of the tones. In proportion as the note can be measured with its fundamental tone by large and obvious dilations, then the concord is most pleasing; on the contrary, when the ear measures the disjunctions of two tones by very small parts, or cannot measure them at all, it looses the beauty of their resemblance; the whole is discord and pain (c).

But there is another property in the vibration of a musical string not yet taken notice of, and which is alleged to confirm the foregoing theory. If we strike the string of an harpsichord, or any other elastic sounding chord whatever, it returns a continuing sound. This till of late was considered as one simple uniform tone; but all musicians now confess, that instead of one tone it actually returns four tones, and that constantly. The notes are, besides the fundamental one, an octave above, a twelfth above, and a fourteenth. One of the bass notes of an harpsichord has been dissected in this manner by Ramond, and the actual existence of these notes proved beyond a possibility of being incontroverted. In fact, the experiment is easily tried; for if we firmly strike one of the lower keys of an harpsichord, and then take the finger briskly away, a tolerable ear will be able to distinguish, that, after the fundamental tone has ceased, three other thriller tones will be distinctly heard; first the octave above, then the twelfth, and lastly the fourteenth: the octave above is in general almost mixed with the fundamental tone, so as not to be easily perceived, except by an ear long habituated to the minute discrimination of sounds. So that we may observe, that the smallest tone is heard last, and the deepest and largest one first: the two others in order.

In the whole theory of sounds, nothing has given greater room for speculation, conjecture, and disapprobation, than this amazing property in elastic strings. The whole string is universally acknowledged to be in vibration in all its parts, yet this single vibration returns no less than four different sounds. They who account for the tones of strings by the number of their vibrations, are here at the greatest loss. Daniel Bernoulli supposes, that a vibrating string divides itself into a number of curves, each of which has a peculiar vibration; and though they all swing together in the common vibration, yet each vibrates within itself. This opinion, which was supported, as most geometrical speculations are, with the parade of demonstration, was only born soon after to die. Others have ascribed this to an elastic difference in the parts of the air, each of which, at different intervals, thus received different impressions from the string, in proportion to their elasticity. This is absurd. If we allow the difference of tone to proceed from the force, and not the frequency, of the vibrations, this difficulty will admit of an easy solution. These sounds, though they seem to exist together in the string, actually follow each other in succession; while the vibration has greater force, the fundamental tone is brought forward: the force of the vibration decaying, the octave is produced, but almost only instantaneously; to this succeeds, with diminished force, the twelfth; and, lastly, the fourteenth is heard to vibrate with great diminuendo, while the three other tones are always silent. These sounds, thus excited, are all of them the harmonic tones, whose differences from the fundamental tone are, as was said, strong, and distinct. On the other hand, the discordant tones cannot be heard. Their differences being but very small, they are overpowered, and in a manner drowned in the tones of superior difference yet not always neither; for Daniel Bernoulli has been able, from the same stroke, to make the same string bring out its harmonics and its discordant tones also (d). So that from hence we may justly infer, that every note whatsoever

(c) It is certain, that in proportion to the simplicity of relations in sound, the ear is pleas'd with its combinations; but this is not to be admitted as the cause why musicians have confined all harmony to an octave. Discriminated sounds, whose vibrations either never coincide, or at least very rarely, do not only cease to please, but violently grate the ear. Harmony and discord, therefore, are neither discriminated by the judgment of hearers, nor the institution of musicians, but by their own essential and immutable nature.

Chap. I.

Of Musical Sounds.

12. Objections to the preceding theory.

The same battery, in conjunction with another of thirty-one jars, founded C sharp. So that a greater quantity of coated glass always gave a deeper note. Differences in the degree of a charge in the same jar made little or no difference in the tone of the explosion: if any, a higher charge gave rather a deeper note.

These experiments show us how much the gravity of different substances depends upon the quantity of air put in agitation by the founding body. We know that the noise of the electric explosion arises from the return of the air into the vacuum produced by the electric flash. The larger the vacuum, the deeper was the note; for the reason, the discharge of a musket produces a more acute note than that of a cannon, and thunder is deeper than either.

Besides this, however, other circumstances concur to produce different degrees of gravity or acuteness in sounds. The sound of a table struck upon with a piece of wood, will not be the same with that produced from a plate of iron struck by the same piece of wood, even if the blows should be exactly equal, and the iron perfectly kept from vibrating. Here the sounds are generally said to differ in their degrees of acuteness, according to the specific gravities or densities of the substances which emit them. Thus gold, which is the most dense of all metals, returns a much graver sound than silver; and metallic wires, which are more dense than them, return a proportionally greater sound. But neither does this appear to be a general rule in which we can put confidence. Bell-metal is denser than copper, but it by no means appears to yield a graver sound; on the contrary, it seems very probable, that copper will give a graver sound than bell-metal, if both are struck upon in their non-elastic state; and we can by no means think that a bell of pure tin, the least dense of all the metals, will give a more acute sound than one of bell-metal, which is greatly more dense. In some bodies hardness seems to have a considerable effect. Glass, which is considerably harder than any metal, gives a more acute sound; bell-metal is harder than gold, lead, or tin; and therefore sounds much more acutely; though how far this holds with regard to different substances, there are not a sufficient number of experiments for us to judge.

In bodies musically elastic, the whole substance vibrates with the lightest stroke, and therefore they always give the same note whether they are struck with a large or with a small instrument; so that striking a part of the surface of any body musically elastic is equivalent, in it, to striking the whole surface of a non-elastic one. If the whole surface of a table was struck with another table, the note produced would be neither more or less acute whatever force was employed; because the whole surface would then yield a sound, and so force could increase the surface: the sound would indeed be louder in proportion to the force employed, but the gravity would remain the same. In like manner, when a bell, or musical string, is struck, the whole substance vibrates, and a greater stroke cannot increase the substance. Hence we see the fallacy of what is said concerning the Pythagorean anvils. An anvil is a body musically elastic, and no difference in the tone can...
Chap. I. ACOUSTICS.

can be perceived whether it is struck with a large, or with a small hammer; because either of them are sufficient to make the whole substance vibrate, provided nothing but the anvil is struck upon: smiths, however, do not strike their anvils, but red-hot iron laid upon their anvils; and thus the vibrations of the anvil are stopped, so that it becomes a non-elastic body, and the differences of tone in the strokes of different hammers proceed only from the surface of the large hammers covering the whole surface of the iron, or at least a greater part of it than the small ones. If the small hammer is sufficient to cover the whole surface of the iron as well as the large one, the note produced will be the same, whether the large or the small hammer is used.

Lastly, the argument for the preceding theory, grounded on the production of what are called flute-notes on the violin, is built on a false foundation; for the bow being lightly drawn on an open string, produces no flute-notes, but only the harmonics of the note to which the string is tuned. The flute-notes are produced by the motion of the bow, quick and near the bridge, and by fingering very gently. By this management, the same sounds are produced, tho' at certain intervals only, as if the vibrations were transferred to the space between the end of the finger-board and the finger, instead of that between the finger and the bridge. Why this small part of the string should vibrate in such a case, and not that which is under the immediate action of the bow, we must own ourselves ignorant: nor dare we affirm that the vibrations really are transferred in this manner, only the same sounds are produced as if they were.

Though these objections seem sufficiently to overturn the foregoing theory, with regard to acute sounds being the effects of weak strokes, and grave ones of stronger impulsi, we cannot admit that longer or shorter vibrations are the occasion of gravity or acuteness in sound. A musical sound, however lengthened, either by striking or bending, is only a repetition of a single stroke, whose duration by itself is but for a moment, and is therefore termed inappreciable, like the instant of a particular motion of an electrical battery. The continuation of the sound is nothing more than a repetition of this instantaneous inappreciable noise after the manner of an echo, and it is only this echo that makes the sound agreeable. For this reason, music is much more agreeable when played in a large hall where the sound is reverberated, than in a small room where there is no such reverberation. For the same reason, the sound of a singing voice is more agreeable when it is heard in a large church than in a small room, as it is here the reverberating echo gives the voice that peculiar sonority which distinguishes one singer from another. The sound appears to be made up of different pulses, or repetitions of the sound produced by the strike of the hammer. It can by no means be allowed, that the note would be more acute though these pulses were to succeed one another more rapidly; the sound would indeed become more simple, but would still preserve the same tone. In musical strings the reverberations are vastly more quick than in bells; and therefore their sound is more uniform or simple, and consequently more agreeable than that of bells. In musical glasses*, the vibrations must be inconceivably quicker than in any bell, or stringed instrument: and hence they are of all others the most simple and the most agreeable, though neither the most acute nor the loudest. —As far as we can judge, quickness of vibration contributes to the uniformity, or simplicity, but not to the acuteness, nor to the loudness of a musical note.

It may here be objected, that each of the different pulses, of which we observe the sound of a bell to be composed, is of a very perceptible length, and far from being inappreciable; so that it is not fair to infer that the sound of a bell is only a repetition of a single instantaneous stroke, seeing it is evidently the repetition of a lengthened note. —To this it may be replied, that the inappreciable sound which is produced by striking a bell in a non-elastic state, is the very same which, being first propagated round the bell, forms one of those short pulses that is afterwards re-echoed as long as the vibrations of the metal continue, and it is impossible that the quickness of repetition of any sound can either increase or diminish its gravity.

Chap. II. Of the propagation of Sound. Newton's Doctrine explained and vindicated.

The writers on sound have been betrayed into the difficulties and obscurities, by rejecting the 47th proposition, B. ii. of Newton, as inconclusive reasoning. Of this proposition, however, the ingenious Mr. Young of Trinity college, Dublin, has lately given a clear, explanatory, and able defence. He candidly owns that the demonstration is obliquely stated, and takes the liberty of varying, in some degree, from the method of Newton.

1. The parts of all sounding bodies, (he observes), vibrate according to the law of a cycloidal pendulum: for they may be considered as composed of an indefinite number of elastic fibres; but these fibres vibrate according to that law. Vide Halstead, p. 270.

2. Sounding bodies propagate their motions on all sides in directam, by successive condensations and rarefactions, and successive going forward and returnings backward of the particles. Vide prop. 43. B. 2. Newton.

3. The pulses are the whole parts of the air which vibrate backwards and forwards; and which, by going forward, strike (pulsam) against obstacles. The latitude of pulse is the rectilinear space through which the motion of the air is propagated during one vibration of the sounding body.

4. All pulses move equally fast. This is proved by experiment; and it is found that they describe 1070 Paris feet, or 1142 London feet in a second, whether the sound be loud or low, grave or acute.

5. To determine the latitude of a pulse. Divide the space which the pulse describes in a given time (4) by the number of vibrations performed in the same time by the sounding body, (cor. 1. prop. 24. Smith's Harmonics), the quotient is the latitude.

M. Sauvage, by some experiments on organ-pipes, found that a body, which gives the gravest harmonic sound, vibrates 12 times and a half in a second, and that the grivelst bounding body vibrates 51.100 times in a second. At a medium, let us take the body which gives what Sauvage calls his fixed sound: it performs 100 vibrations in a second, and in the same time the pulses describe 1070 Parisian feet; therefore the space described by the pulses whilst the body vibrates once, that

* See Harmonics.
ACOUSTICS.

Plate I.

fig. 7.

that is, the latitude or interval of the pulse, will be 10.7 feet.

6. Prob. To find the Proportion which the greatest space, through which the particles of the air vibrate, bears to the radius of a circle, whose perimter is equal to the latitude of the pulse.

During the first half of the progress of the elastic fibre, or founding body, it is continually getting nearer to the next particle; and during the latter half of its progress, that particle is getting farther from the fibre, and these portions of time are equal (Helmham): therefore we may conclude, that at the end of the progress of the fibre, the first particle of air will be nearly as far distant from the fibre as when it began to move; and in the same manner we may infer, that all the particles vibrate through spaces nearly equal to that run over by the fibre.

Now, M. Sauveur (Acad. Sciences, an. 1700, p. 141) has found by experiment, that the middle point of a cord which produces his fixed sound, and whose diameter is 4/6 of a line, runs over in its smallest sensible vibrations 72 times that space; that is 72 + 1/4th of a line, or 4 lines, that is, 1/4 of an inch.

The latitude of the pulses of this fixed sound is 10.7 feet (4); and since the circumference of a circle is to its radius as 710 is to 113, the greatest space described by the particles will be to the radius of a circle, whose periphery is equal to the latitude of the pulse as 3/4 of an inch is to 1.7029 feet, or 20.4348 inches, that is, as 1 to 61.3044.

If the length of the string be increased or diminished in any proportion, ceteris paribus, the greatest space described by its middle point will vary in the same proportion. For the inflecting force is to the tending force as the distance of the string from the middle point of vibration to half the length of the string (see Helmham and Martin); and therefore the inflecting and tending forces being given, the string will vibrate through spaces proportional to its length; but the latitude of the pulse is inversely as the number of vibrations performed by the string in a given time, (5) that is, directly as the time of one vibration, or directly as the length of the string (prop. 24. of "Smith's Harmonics"); therefore the greatest space through which the middle point of the string vibrate, will vary in the direct ratio of the latitude of the pulse, or of the radius of a circle whose circumference is equal to the latitude, that is, it will be to that radius as 1 to 61.3044.

7. If the particles of the aerial pulses, during any part of their vibration, be successively agitated according to the law of a cycloidal pendulum, the comparative elastic forces arising from their mutual action, by which they will afterwards continue to be agitated.

In the same manner the arc of the cycloid for any given time is equal to the square of the arc, the radius of which is the distance of the point from the centre, and of which the radius is the perpendicular fall on the vertical axis; and if ES be taken equal to PL or PR, the particle E shall be found in. Thus will the particle P perform its vibrations according to the law of a cycloidal pendulum. Prop. 5b. B. 1. Principia.

Let us suppose now, that the particles have been successively agitated, according to this law, for a certain time, by any cause whatsoever, and let us examine what will be the comparative elastic forces arising from their mutual action, by which they will afterwards continue to be agitated.

Prop. 52. B. 1. Principia.

In the same manner the arc of the cycloid for any given time is equal to the square of the arc, the radius of which is the distance of the point from the centre, and of which the radius is the perpendicular fall on the vertical axis; and if ES be taken equal to PL or PR, the particle E shall be found in. Thus will the particle P perform its vibrations according to the law of a cycloidal pendulum. Prop. 5b. B. 1. Principia.

Draw the right line PS equal to EC, bisected in O, and from the centre O, with the radius OP, draw a circle, and let the whole time of the vibration of a particle and its parts be denoted by the circumference of this circle and its proportional parts. And since the particles are supposed to be at first agitated according to the law of a cycloidal pendulum, if at any time PH, or PFS, the pendicular HL or FH, be let fall on PS, and if ES be taken equal to PE or EY, the particle E shall be found in. Thus will the particle P perform its vibrations according to the law of a cycloidal pendulum. Prop. 5b. B. 1. Principia.

Draw the right line PS equal to EC, bisected in O, and from the centre O, with the radius OP, draw a circle, and let the whole time of the vibration of a particle and its parts be denoted by the circumference of this circle and its proportional parts. And since the particles are supposed to be at first agitated according to the law of a cycloidal pendulum, if at any time PH, or PFS, the pendicular HL or FH, be let fall on PS, and if ES be taken equal to PE or EY, the particle E shall be found in. Thus will the particle P perform its vibrations according to the law of a cycloidal pendulum. Prop. 5b. B. 1. Principia.
the motion of G; and that the expansion of EF in the place φ is to its mean expansion as $EF^2/F_2 = E\varepsilon$, or as $E^2+\varepsilon\varphi$ is to $EF$, or as $V+h\varepsilon$ is to $V$ in its regress, and its elastic force to the mean elastic force as $1$ is to $\varphi$; and that the difference of the elastic forces existing between $E$ and $F$, and between $F$ and $G$, is the comparative elastic force by which the physical point $φ$ is agitated: and therefore the comparative accelerating force, by which every physical point in the medium will continue to be agitated both in progress and regress, will be directly as its distance from the middle point of its vibration; and consequently, will be such as will cause the particles to continue their motion, undissipated, according to the law of a cycloidal pendulum. Prop. 38. B. I. Newton.

Newton rejects the quantity $VxIM+KN+IMxKN$ on supposition that IM and KN are indefinitely less than $V$. Now, although this may be a reasonable hypothesis, yet, that this quantity may be safely rejected, will, I think, appear in a more satisfactory manner from the following considerations derived from experiment: PS, in its greatest possible state, is to $V$ as $1$ is to $61.3044$ (6); and therefore $IM$ or $KN$, in its greatest possible state, (that is, when the vibrations of the body are as great as possible, and the particle in the middle point of its vibration) is to $V$ as one is to 122.6. Hence $V'=15030.76$; $VxIM+KN=245.2$ and $1MxKN=992$; therefore $V'$ is to $V$ as $VxIM+KN+IMxKN$ as 15.03076 to 14.73656; that is, as 61 is to 60 nearly.

Hence it appears, that the greatest possible error in the accelerating force, in the middle point, is the 1st part of the whole. In other points it is much less; and in the extreme points the error entirely vanishes.

We should also observe, that the ordinary sounds we hear are not produced by the greatest possible vibration of which the founding body is capable; and that in general IM and KN are nearly evanescent with respect to $V$. And very probably the disagreeable sensations we feel in very loud sounds, arise not only from IM or KN bearing a tolerable proportion to $V$, by which means the cycloidal law of the pulses may be in some measure disturbed, but also from the very law of the motion of the founding body itself being disturbed. For, the proof of this law's being observed by an elastic fibre is founded on the hypothesis that the space, through which it vibrates, is infinitely little with respect to the length of the string. See Smith's Harmonics, p. 237, Helff's Harmonies, p. 270.

8. If a particle of the medium be agitated, according to the law of a cycloidal pendulum, the comparative elastic force, acting on the adjacent particle, from the instant in which it begins to move, will be such as will cause it to continue its motion according to the same law.

For let us suppose, that three particles of the medium had continued to move for times denoted by the arches PK, PL, PH, the comparative elastic force, acting on the second during the time of its motion, would have been denoted by $H\varepsilon - 1M$, that is, would have been directly at $M0$ (7). And if this time be diminished till it becomes coincident with $P$, that is, if you take the particles in that state when the second is just beginning to move, and before the third particle has yet been set in motion; then the point $M$ will fall on $P$, and $MO$ become $PO$; that is, the comparative elastic force of the second particle, at the instant in which it begins to move, will be the force with which it is agitated in any other moment of time, before the subsequeint particle has yet been set in motion, directly as its distance from the middle point of vibration. Now this comparative elastic force, with which the second particle is agitated in the very moment in which it begins to move, arises from the preceding particle's approaching it according to the law of a pendulum; and therefore, if the preceding particle approaches it in this manner, the force by which it will be agitated, in the very moment it begins to move, will be exactly such as should take place in order to move it according to the law of a pendulum. It therefore sets out according to that law, and consequently the subsequeint elastic forces, generated in every successive moment, will also continue to be of the just magnitude which should take place, in order to produce such a motion.

9. The pulses of the air are propagated from founding bodies, according to the law of a cycloidal pendulum. The point $E$ of any elastic fibre proceeding a found, may be considered as a particle of air vibrating according to the law of a pendulum (1). This point $E$ will therefore move according to this law for a certain time, denoted by the arch $IH$, before the second particle begins to move; for found is propagated in time through the successive particles of air (4). Now from that instant, the comparative elastic force which agitates $P$, is (8) directly as its distance from the middle point of vibration. $F$ therefore sets out with a motion according to the law of a pendulum: and therefore the comparative elastic force by which it will be agitated until $G$ begins to move, will continue that law (8). Consequently $F$ will approach $G$ in the same manner as $E$ approached $F$, and the comparative elastic force of $G$, from the instant in which it begins to move, will be directly as its distance from the middle point of vibration; and so on in succession: Therefore all the particles of air in the pulses successively set out from their proper places according to the law of a pendulum, and therefore (7) will finish their entire vibrations according to the same law.

Cor. 1. The number of pulses propagated is the same with the number of vibrations of the tremulous body, nor is it multiplied in their progress; because the little physical line $r$, (fig. 7) as soon as it returns to its proper place, will there quiesce; for its velocity, which is denoted by the sine $IM$, then vanishes, and its density becomes the same with that of the ambient medium. This line, therefore, will no longer move, unless it be again driven forwards by the impulse of the founding body, or of the pulses propagated from it. Cor. 2. In the extreme points of the little space through which the particle vibrates, the expansion of the air is in its natural state; for the expansion of the physical line is to its natural expansion as $V+1M$ is
Propagation of Sound.

Plate III.

to V; but IM is then equal to nothing. In the middle point of the progress the condensation is greatest; for IM is then greatest; and consequently the expansion V—IM least. In the middle of the regres, the rarefaction is greatest; for IM, and consequently V+IM, is then greatest.

10. To find the velocity of the pulses, the density and elastic force of the medium being given.

This is the 46th prop. B. 2. Newton, in which he shows, that whilst a pendulum, whose length is equal to the height of the homogeneous atmosphere, vibrates once forward and backwards, the pulse will describe a space equal to the periphery of a circle described with that altitude as its radius.

Cor. 1. He thence shows, that the velocity of the pulses is equal to that which a heavy body would acquire in falling down half the altitude of that homogeneous atmosphere; and therefore, that all pulses move equally fast, whatever be the magnitude of PS, or the time of its being described; that is, whether the tone be loud or low, grave or acute. See Hales de Sonis, § 49.

Cor. 2. And also, that the velocity of the pulses is in a ratio compounded of the direct subduplicate ratio of the elastic force of the medium, and the inverse subduplicate of its density. Hence sounds move somewhat faster in summer than in winter. See Hales de Sonis, p. 141.

11. The strength of a tone is as the moment of the particles of air. The moment of these particles, (the medium being given) is as their velocity; and the velocity of these particles is as the velocity of the firing which sets them in motion (9). The velocities of two strings are equal when the spaces which they describe in their vibrations are to each other as the times of these vibrations; therefore, two different tones are of equal strength, when the spaces, through which the strings producing them vibrate, are directly as their vibration.

12. Let the strength of the tones of the two strings AB, CD, which differ in tension only (fig. 1, 2.) be equal. Quere the ratio of the inflecting forces F and f. From the hypothesis of the equality of the strength of the tones, it follows (11), that the space GE must be to the space HP as f to F. (Smith's Harm. Prop. 24. Cor. 4.) Now the forces inflecting AB, CD through the equal spaces GE, HP are to each other as the tending forces, that is, as F to f. (Malcolm's Treatise on Music, p. 52.) But the force inflecting CD through HP is to the force inflecting it through HP as HP or GE to HP, (ib. p. 47.) that is, by the hyp. as f to F. Therefore, ex aequo, the forces inflecting AB and CD, when the tones are equally strong, are to each other as F+2f to f+2F, or as F to f. That is, the forces necessary to produce tones of equal strength in various strings which differ only in tension, are to each other in the subduplicate ratio of the tending forces, that is, inversely as the time of one vibration, or directly as the number of vibrations performed in a given time. Thus, if CD be the acute octave to AB, its tending force will be quadruple that of AB, (Malcolm's Treatise on Music, p. 52) and therefore to produce tones of equal strength in these strings, the force impelling CD must be double that impelling AB: and so in other cases.

"Suppose, now, that the strings AB, CD, (fig. 4, 3.) differ in length only. The force inflecting AB through GE is to the tending force, which is given, as GE to AG; and this tending force is to the force inflecting CD through the space HP equal to GE, as HD to HP. Therefore, ex aequo, the forces inflecting AB and CD through the equal spaces GE and HP, are to each other as HD to AG, or as CD to AB. But the force inflecting CD through HP is to the force inflecting it through HP, as HP or GE to HP, that is, because these spaces are as the times (11), as AB to CD. Therefore, ex aequo, the forces inflecting AB and CD, when the tones are equally strong, are to each other in a ratio of equality. Hence we should suppose, that in this case, an equal number of equal impulses would generate equally powerful tones in these strings. But we are to observe, that the longer the string, the greater, ceteris paribus, is the space through which a given force inflects it (Malcolm); and therefore whatever diminution is produced in the spaces thro' which the strings move in their successive vibrations, arising either from the want of perfect elasticity in the strings or from the resiliency of the air, this diminution will bear a greater proportion to the left space, through which the shorter string vibrates. And this is confirmed by experience; for we find that the duration of the tone and motion of the whole string exceeds that of any of its subordinate parts. Therefore, after a given interval of time, a greater quantity of motion will remain in the longer string; and consequently, after the successive equal impulses have been made, a greater degree of motion will fall unfinished in it. That is, a given number of equal impulses being made on various strings differing in length only, a stronger sound will be produced in that which is the longer."

Chap. III. Of the Velocity, &c. of Sound. Anomis.

Experience has taught us, that sound travels at about Velocity of the rate of 1142 feet in a second, or near 13 miles in a found minute; nor do any obstacles hinder its progress, contrary wind only a small matter diminishing its velocity. The method of calculating its progress is easily made known. When a gun is discharged at a distance, we see the fire long before we hear the sound. If then we know the distance of the place, and know the time of the interval between our first seeing the fire and then hearing the report, this will show us exactly the time calculated. The sound has been travelling to us. For instance, if the gun is discharged a mile off, the moment the flash is seen, you take a watch and count the seconds till you hear the sound; the number of seconds is the time the sound has been travelling a mile. Again, by the above axiom, we are enabled to find the distance between objects that would be otherwise immeasurable. For ex: Distautes ample, suppose you see the flash of a gun in the night as calculated sea, and tell seven seconds before you hear the report, by means it follows therefore, that the distance is seven times of sound. 1142 feet, that is, 24 yards more than a mile and a half. In like manner, if you observe the number of seconds between the lightning and the report of the thunder, you know the distance of the cloud from whence it proceeds.

Derham has proved by experience, that all sounds all sounds whatever travel at the same rate. The sound of a gun, travels the same rate.
and the striking of a hammer, are equally swift in their motions: the softest whisper flies as swiftly, as far as it goes, as the loudest thunder.

To these axioms we may add the following. Smooth and clear sounds proceed from bodies that are homogeneous, and of a uniform figure; and harsh or obtuse sounds, from such as are of a mixed matter and irregular figure.

The velocity of sound is to that of a brisk wind as fifty to one.

The strength of sounds is greatest in cold and dense air, and least in that which is warm and rarefied.

Every point against which the pulses of sound strike, become a centre from which a new series of pulses are propagated in every direction.

Sound describes equal spaces in equal times.

**Chap. IV. Of Reverberated Sounds.**

Sound, like light, after it has been reflected from several places may be collected in one point, as into a focus; and it will be there more audible than in any other part, even than at the place from whence it proceeded. On this principle it is that a whispering gallery is constructed.

The form of this gallery must be that of a concave hemisphere (a), as ABC; and if a low sound or whisper be uttered at A, the vibrations expanding themselves every way will impinge on the points DDD, &c. and from thence be reflected to EEE, and from thence to the points F and G, till at last they all meet in C, where, as we have said, the sound will be the most distinctly heard.

The augmentation of sound by means of speaking-trumpets, is usually illustrated in the following manner: Let ABC be the tube, BD the axis, and B the mouth-piece for conveying the voice to the tube. Then it is evident, when a person speaks at B, without the tube, will have the force of his voice spent in exciting concentric superficies of air all around the point B; and when those superficies or pulses of air are diffused as far as D every way, it is plain the force of the voice will there be diffused through the whole superficies of a sphere whose radius is BD; but in the trumpet it will be so confined, that at its exit it will be diffused through so much of that spherical surface of air as corresponds to the orifice of the tube. But since the force is given, its intensity will be always inversely as the number of particles it has to move; and therefore in the tube it will be to that without, as the superficies of such a sphere to the area of the large end of the tube nearly.

But it is obvious, Mr Young observes, that the confinement of the voice can have little effect in increasing the strength of the sound, as this strength depend on the velocity with which the particles move. Were this reasoning conclusive, the sound should issue through the smallest possible orifice; cylindrical tubes would be preferable to any that increased in diameter; and the less the diameter, the greater would be the effect of the instrument; because the plate or mass of air to be moved, would, in that case, be less, and consequently the effect of the voice the greater; all which is contradicted by experience.

The cause of the increase of sound in these tubes must therefore be derived from some other principles: and amongst these we shall probably find, that what the ingenious Kircher has suggested in his Phaenomina is the most deserving of our attention. He tells us, if the augmentation of the sound depends on its reflection from the tremulous sides of the tube; which reflections, conspiring in propagating the pulses in the same direction, must increase its intensity. Newton also seems to have considered this as a principal cause, in the scholium of prop. 50. B. 2. Princip. when he says, "we hence see why sounds are so much increased in flentorophonic tubes, for every reciprocal motion is, in each return, increased by the generating cause."

Further, when we speak in the open air, the effect on the tympanum of a distant auditor is produced merely by a single pulse. But when we use a tube, all the pulses propagated from the mouth, except those in the direction of the axis, strike against the sides of the tube, and every point of impulse becoming a new centre, from whence the pulses are propagated in all directions, a pulse will arrive at the ear from each of those points; thus, by the use of a tube, a greater number of pulses are propagated to the ear, and consequently the sound increased. The confinement too of the voice may have some effect, though not such as is ascribed to it by some; for the confined pulses produced by the naked voice, freely expand every way; but in tubes, the lateral expansion being diminished, the direct expansion will be increased, and consequently the velocity of the particles, and the intensity of the sound. The sub stance also of the tube has its effect; for it is found by experiment, that the more elastic the substance of the tube, and consequent ly the more susceptible it is of those tremulous motions, the stronger is the sound.

If the tube be laid on any non-elastic substance, it de celerates the sound, because it prevents the vibratory motion of the parts. The sound is increased in speaking trumpets, if the tube be suspended in the air; because the agitations are then carried on without interruption. These tubes should increase in diameter from the mouth piece, because the parts, vibrating in directions perpendicular to the surface, will confpire in impelling forward the particles of air, and consequently, by increasing their velocity, will increase the intensity of the sound: and the surface also increasing, the number of points of impulse and of new propagations will increase.

(e) A cylindric or elliptic arch will answer still better than one that is circular.
As echo is a reflection of sound striking against some object, as an image is reflected in a glass: but it has been disputed what are the proper qualities in a body for thus reflecting sounds. It is in general known, that caverns, grottoes, mountains, and ruined buildings, return this image of found. We have heard of a very extraordinary echo, at a ruined fortrefs near Louvain, in Flanders. If you enter the cave, and continue your voice for some time, you will hear a reflection of your voice at a distance of 127 feet or more, and no other sound will be heard at the same instant. Thus a person, who has entered the cave, may hear his own voice after a second or a third echo, though the echo which the voice of another produces, will return it at the rate of 9 or 10 times a second.

As (by n° 21 and 22) every point against which the pulses of sounds strike becomes the centre of a new series of pulses, and sound describes equal distances in equal times; therefore, when any found is propagated from a centre, and its pulses strike a variety of obstacles, if the sum of the right lines drawn from that point to each of the obstacles, and from each obstacle to a second point, be equal, then will the latter be a point in which an echo will be heard. Thus let A be the point from which the sound is propagated in all directions, and let the pulses strike against the obstacles C, D, E, F, G, H, I, &c. each of these points becomes a new centre of pulses by the first principle, and therefore from each of them one series of pulses will pass through the point B. Now if the several sums of the right lines AC+CB, AD+DB, AE+EB, AG+GB, AH+HB, AI+IB, &c. be all equal to each other, it is obvious that the pulses propagated from A to these points, and again from these points to B, will all arrive at B at the same instant, according to the second principle; and therefore, if the hearer be in that point, his ear will at the same instant be struck by all these pulses. Now it appears from experiment (see Maffchenbroek, V. ii. p. 210), that the ear of an exercised musician can only distinguish such sounds as follow one another at the rate of 9 or 10 in a second, or any slower rate: and therefore, for a distinct perception of the direct and reflected sound, there should intervene the interval of 4th of a second; but in this time sound describes 222 or 127 feet nearly. And therefore, unless the sum of the lines drawn from each of the obstacles to the points A and B exceed the interval AB by 127 feet, no echo will be heard at B. Since the several sums of the lines drawn from the obstacle to the points A and B are of the same magnitude, it appears that the curve passing through all the points C, D, E, F, G, H, I, &c. will be an ellipse. (prop. 4. B. 2. Ham. Cons.) Hence all the points of the obstacles which produce an echo, must lie in the surface of the oblong spheroid, generated by the revolution of the ellipse round its major axis.

As there may be several spheroids of different magnitudes, so there may be several different echoes of the same original found. And as there may happen to be a greater number of reflecting points in the surface of an exterior spheroid than in that of an interior, a second or a third echo may be much more powerful than the first, provided that the superior number of reflecting points, that is, the superior number of reflected pulses propagated to the ear, be more than sufficient to compensate for the decay of found which arises from its being propagated through a greater space. This is finely illustrated in the celebrated echoes at the lake of Killarney in Kerry, where the first return of the found is much inferior in strength to those which immediately succeed it.

From what has been laid down it appears, that for the most powerful echo, the founding body should be in one focus of the ellipse which is the section of the echoing spheroid, and the hearer in the other. However, an echo may be heard in other situations, though not so favourably; as such a number of reflected pulses may arrive at the same time at the ear as may be sufficient to excite a distinct perception. Thus a person often hears the echo of his own voice; but for this purpose he should stand at least 6 or 64 feet from the reflecting obstacle, according to what has been said before. At the common rate of speaking, we pronounce not above three syllables and a half, that is, seven half syllables in a second; therefore, that the echo may return just as soon as three syllables are expressed, twice the distance of the speaker from the reflecting object must be equal to 1000 feet; for, as found describes 1142 feet in a second, this of that space, that is, 1000 feet nearly, will be described while fix half or three whole syllables are pronounced: that is, the speaker must stand near 500 feet from the obstacle. And in general, the distance of the speaker from the echoing surface, for any number of syllables, must be equal to the seventh part of the product of 1142 feet multiplied by that number.

In churches we never hear a distinct echo of the voice, but a confused sound when the speaker utters his words too rapidly; because the greatest difference of distance between the direct and reflected courses of such a number of pulses as would produce a distinct found, is never in any church equal to 127 feet, the limit of echoes.

But though the first reflected pulses may produce no echo, both on account of their being too few in number, and too rapid in their return to the ear; yet it is evident, that the reflecting surface may be so formed, that the pulses which come to the ear after two reflections or more may, after having described 127 feet or more, arrive at the ear in sufficient numbers, and also so nearly at the same instant, as to produce an echo, though the distance of the reflecting surface from the ear be less than the limit of echoes. This is confirmed by a singular echo in a grotto on the banks of the little brook called the Dianan, about two miles from Castlecomer, in the county of Kilkenny. As you enter the cave, and continue speaking loud, no return of the voice is perceived: but on your arriving at
Chap. IV.  

ACoustics.

Entertaining Experiments and Conver-  

ting Experiments,  

1. Place a concave mirror of about two feet diameter, as AB (c), in a perpendicular direction. The focus of this mirror may be at 15 or 18 inches distance from its surface. At the distance of about five or six feet let there be a partition, in which there is an opening EF, equal to the size of the mirror; against this opening must be placed a picture, painted in water-colours, on a thin cloth, that the sound may easily pass through it (H).

Behind the partition, at the distance of two or three feet, place another mirror GH, of the same size as the former, and let it be diametrically opposite to it.

At the point C let there be placed the figure of a man seated on a pedestal, and let his ear be placed exactly in the focus of the first mirror; his lower jaw must be made to open by a wire, and shut by a spring; and there may be another wire to move the eyes; these wires must pass through the figure, go under the floor, and come up behind the partition.

Let a person, properly instructed, be placed behind the partition near the mirror. You then propose to any one to speak softly to the statue, by putting his mouth to the ear of it, affuring him that it will answer instantly. You then give the signal to the person behind the partition, who, by placing his ear to the focus I, of the mirror GH, will hear distinctly what the other said; and, moving the jaw and eyes of the statue by the wires, will return an answer directly, which will in like manner be distinctly heard by the first speaker.

This experiment appears to be taken from the Century of Inventions of the Marquis of Worcester; whose designs, at the time they were published, were treated with ridicule and neglect as being impracticable, but are now known to be generally, if not universally practicable. The words of the Marquis are these:—"How to make a bronz or stone head in the midst of a great field or garden, so artificial and natural, that though a man speak ever so softly, and even whisper into the ear thereof, it will pretend to answer the inquiry, whether in French, Latin, Greek, Irish, or English in good terms, uttering it out of its mouth, and then shut it until the next question be asked."—The two following, of a similar nature, appear to have been inventions of Kircher, by means of which (as he informs us*) he used to "utter designed and ingenious confutations, with a view to give Nov., 1701, open the fallacy and impotence of ancient oracles."

II. Let there be two heads of plaster of Paris, placed on pedestals, on the opposite sides of a room. Here the commode must be a tube of an inch diameter, that must pass through the head of one, and be placed in the other; and at the middle of the chamber, between the heads, will not hear any part of their conversation.

III. Place a bust on a pedestal in the corner of a room, and let there be two tubes, as in the foregoing case. One of which must go from the mouth of the bust, and the other from the ear of the bust, through the pedestal, and the floor, to an under apartment. There may be likewise wires that go from the under jaw and the eyes of the bust, by which they may be easily moved.

A person being placed in the under room, and at a signal given applying his ear to one of the tubes, will hear any question that is asked, and immediately reply; moving at the same time, by means of the wires, the mouth and the eyes of the bust, as if the reply came from it.

IV. In a large room, such as is used for dial and spring A Solar clocks, the front of which, or at least the lower part of it, must be of glass, covered with the inside with guaze, but there must be placed a barrel organ, which, when wound up, is prevented from playing, by a catch that takes a toothed wheel at the end of the barrel. To one end of this catch must be joined a wire, at the end of which there is a flat circle of cork, of the same dimension with the inside of a glass tube, in which it is to rise and fall. This tube must communicate with a reservoir that goes across the front part of the bottom of the room, which is to be filled with spirits, such as is used in their

(c) Both the mirrors here used may be of tin or gilt pasteboard, this experiment not requiring such as are very accurate.

(H) The more effectually to conceal the cause of this allusion, the mirror AB may be fixed in the window, and a guaze or any other thin covering thrown over it, as that will not in the least prevent the sound from being reflected. An experiment of this kind may be performed in a field or garden, between two hedges, in one of which the mirror AB may be placed, and in the other an opening artfully contrived.
thermometers, but not coloured, that it may be the better concealed by the gauze.

This case being placed in the fun, the spirits will be rared by the heat; and rising in the tube, will lift up the catch or trigger, and let the organ in play: which it will continue to do as long as it is kept in the fun; for the spirits cannot run out of the tube, that likely be more complex, but could scarce answer the calls.

When the machine is placed against the side of a room on which the fun shines strong, it may constantly remain in the same place, if you inclose it in a second case, made of thick wood, and placed at a little distance from the other. When you want it to perform, it will be only necessary to throw open the door of the outer case, and expose it to the fun.

But if the machine be movable, it will perform in all seasons by being placed before the fire; and in the winter it will more readily fill when removed into the cold.

A machine of this sort is said to have been invented by Cornelius Dreble, in the last century. What the construction of that was, we know not; it might very likely be more complex, but could scarce answer the intention more readily.

V. UNDER the keys of a common harpichord let there be fixed a barrel, something like that in a chamber organ, with stops or pins corresponding to the tunes you would have it play. These stops must be moveable, so that the tunes may be varied at pleasure. From each of the keys let there go a wire perpendicular down: the ends of these wires must be turned up for about one-fourth of an inch. Behind these wires let there be an iron bar, to prevent them from going too far back. Now, as the barrel turns round, its pins take the ends of the wires, which pull down the keys, and play the harpichord. The barrel and wires are to be all inclosed in a case.

In the chimney of the same room where the harpichord stands, or at least in one adjacent, there must be a smoke jack, from whence comes down a wire, or cord, that, passing behind the wainscot adjoining the chimney, goes under the floor, and up one of the legs of the harpichord, into the case, and round a small ing experiment wheel fixed on the axis of that first mentioned. There should be pulleys at different distances, behind the wainscot and under the floor, to facilitate the motion of the chord.

This machinery may be applied to any other keyed instrument as well as to chimes, and to many other purposes where a regular continued motion is required.

An instrument of this sort may be considered as a perpetual motion, according to the vulgar acceptance of the term; for it will never cease going till the fire be extinguished, or some parts of the machinery be worn out.

VI. At the top of a summer-house, or other building, a Ventofal may be the wind-wheel B (of which A is an horizontal Symphony, section,) be on the upper end of the perpendicular axis F; on the lower end of which is fixed the pin on C that takes the toothed wheel D on the axis of the great wheel E. The perpendicular axis F goes down very near the wall of the room, and may be covered after the same manner as are bell-wires.

In the great wheel there must be placed a number of stops, corresponding to the tunes it is to play. These stops are to be moveable, that the tunes may be altered at pleasure. Against this wheel there must hang 12 small bells, answering to the notes of the gamut. Therefore, as the wheel turns round, the stops striking against the bells, play the several tunes. There should be a fly to the great wheel, to regulate its motion when the wind is strong. The wheel E, and the bells, are to be inclosed in a case.

There may be several sets of bells, one of which may answer to the tenor, another to the treble, and a third to the bass; or they may play different tunes, according to the size of the wheel. As the bells are small, if they are of silver, their tone will be the more pleasing.

Instead of bells, glasses may be here used, so disposed as to move freely at the stroke of the stops. This machinery may likewise be applied to a barrel-organ, and to many other uses.

ACQ., a town at the foot of the Pyrenean mountains, in the government of Foix in France. It takes its name from the hot waters in these parts. E. long. 1. 40. lat. 43. 0.

ACQUAPENDENTE, a pretty large town of Italy, in the territory of the church, and patrimony of St Peter, with a bishop's see. It is seated on a mountain, near the river Paglia, ten miles W. of Orvieto, and 57 N. by W. of Rome. E. long. 11. 53. Lat. 42. 43.

ACQUARIA, a small town of Italy, in Frigana, a district of Modena, which is remarkable for its medicinal waters. It is 12 miles south of the city of Modena. E. long. 11. 17. lat. 44. 24.

ACQUEST, or ACQUIST, in law, signifies goods got by purchase or donation. See Conquest.

ACQUI, a town of Italy, in the duchy of Monteferrat, with a bishop's see, and commodious baths. It was taken by the Spaniards in 1745, and retaken by the Piedmontese in 1746; but after this, it was taken again and dismantled by the French, who afterwards fortook it. It is seated on the river Bormis, 23 miles N. W. of Genoa, and 30 S. of Casal. E. long. B. 30. Lat. 44. 40.

ACQUISITION, in general, denotes the obtaining or procuring something. Among lawyers, it is used for the right or title to an estate got by purchase or donation.

ACQUITTAL, a discharge, deliverance, or freeing of a per son free from the guilt or suspicion of an offence.

ACQUITTANCE, a release or discharge in writing for a sum of money, witnessing that the party has paid the said sum. No man is obliged to pay a sum of
money if the demandant refuses to give an acquittance, which is a full discharge, and bars all actions, &c. An acquittance given by a servant for a sum of money received for the use of his master, shall be a good discharge for that sum, provided the servant used to receive his master's rents, debts, &c.

ACRA, a town of Africa, on the coast of Guinea, where the English, Dutch, and Danes, have strong forts, and each for its particular village. W. Long. 0. 2. Lat. 5. 0.

ACRA, one of the hills of Jerusalem, on which stood the town of Jerusalem, and was afterwards named Zion, or the city of David. Probably called Acre, from the fortresses which Antiochus built there in order to annoy the temple, and which Simon Maccabeus took and razed to the ground.

ACRA Tappia, called Selentia by Ptolemy; now Cape of San Maria de Leuca. A promontory in the kingdom of Naples, to the south-east of Otranto, where formerly was a town, now lying in ruins, on the Ionian sea, over against the Montes Acroceraunii of Epirus.

ACRA, a town of Sicily, where the inhabitants are called Acerani. They were called the Acreans, and their town, Acras, had for its boundary the river Acra, now called Fiume di Gergenti, near the port of Trapani, where formerly was a town, now called配有 the same name. The town was famous for the Phalarides, and his brazen bull. They were a people luxurious in their tables, and magnificent in their dwellings; of whom Empedocles, in Diogenes Laertius, says, that they lived to-day as if they were to die to-morrow, and built as if they were to live forever. The country round the city was laid out in vine and olive yards, in the produce of which they carried on a great and profitable commerce with Carthage. E. Long. 13. 30. Lat. 37. 20.

ACRASIA, among physicians, implies the predominancy of one quality above another, either with regard to artificial mixtures, or the humours of the human body. The word is Greek, and compounded of 

ACRATH, a place in Mauritania Tingitana, now supposed to be Felez de Gomara. A fortified town in the kingdom of Fez, with a capital and commodious harbour on the Mediterranean, scarce a league distant from Penon de Velez, a Spanish fort. W. Long. 5. Lat. 34. 45.

ACRE, or Acre, a sea-port town in Syria. It was formerly called Ptolemais, and is a bishop's see. It was very famous in the time of the crusaders, and underwent several sieges both by the Christians and Saracens. It is situated at the north angle of a bay, which extends in a semicircle of three leagues, as far as the point of Carmel.

During the Crusades, the possession of this town was long disputed by the Christians and Saracens. In 1192 it was taken from the latter by Richard I. of England and Philip of France, who gave it to the knights of St John of Jerusalem, who kept possession of it 100 years, when it was retaken by the Saracens, and almost entirely destroyed. This event is rendered memorable by an act of singular resolution with which it was accompanied. A number of beautiful young nuns, terrified at the prospect of being exposed to the brutal lust of the infidels, determined to avoid the violation of their chastity, by rendering themselves objects of aversion. With this view they cut off their noyes and mangled their faces. The Saracens, inflamed with resentment at such a spectacle which prevented the gratification of their appetites, immediately put them all to the sword. After the expulsion of the crusaders, it remained almost deserted, but in our time has again revived by the industry of Daher; and the works erected by Djezzar, within the last ten years, have rendered it one of the principal towns upon the coast. The mosque of this Pacha is boasted as a masterpiece of eastern taste. The bazaar, or covered market, is not inferior even to those of Aleppo, and its public fountain surpasses in elegance those of Damascus, though the water is of a very indifferent quality. The Pacha has derived the more honour from these works, as he was himself both the engineer and architect: he formed the plans, drew the designs, and superintended the execution.

The port of Acre is one of the best situated on the coast, as it is sheltered from the north and north-west winds by the town itself; but it is greatly spoiled since the time of Fakr-el-din. Djezzar has contented himself with making a landing-place for boats. The fortifications, though more frequently repaired than any other in all Syria, are of no importance: there are only a few wretched low towers, near the port, on which cannon are mounted; and the rusty iron pieces are so bad, that some of them burst every time they are fired. Its defence on the land side is merely a garden-wall, without any ditch.

Corn and cotton form the basis of the commerce of Acre, which is becoming more flourishing every day. Of late, the Pacha, by an abuse common throughout all the Turkish empire, has monopolized all the trade in his own hands; no cotton can be sold but to him, and from him every purchase must be made. In vain have the European merchants claimed the privileges granted
granted them by the Sultan; Djezzar replied, that he was the Sultan in his country, and continued his monopoly. Theb's merchants in general are French, and have six houses at Acre, with a consul; an imperial agent too is lately settled there; also a resident for Ruffia.

That part of the bay of Acre, in which ships anchor with the greatest security lies to the north of Mount Carmel, below the village of Haifa (commonly called Callifa). The bottom is good holding ground, and does not chafe the boats; but the harbour is open to the north-west wind, which blows violently along open fields, about half a square mile, thickly studded with brambles' wild vines and olive trees, which prove that the ancient Israelites called this place Mount Carmel, because the prophet Elias, which affords an extensive plain, is said to have divided the cart into 39.25 acres; the pound (or rupee) is of the value of the French crown in Indostan, or about 16 French c partitions of land, but any open ground, especially the waste lands, is open on lands of the deferts, and to have fed on locusts. Their food was extremely miserable; for in their houses, where they were meagre, and extremely black. In the spring, high wind could not keep the locusts from destroying their crops. The smoke which arose from this immense fire was so thick, that the sky was filled with it, and fell in heaps on the ground. The passage of the locusts being thus intercepted for many days, they made a large provision of locusts and other insects. As their country produced great quantities of salt, they salted them, to render them more palatable, and to make them keep till the next season. This peculiar supply was their sole food: they had neither herds nor flocks. They were unacquainted with fishing; for they lived at a distance from the sea. They were very active, and ran with great swiftness. Their life was not of long duration; it exceeded not forty years. The close of their life was extremely miserable; for in their old age, they were feeble, and their eyesight failed; and in their bodies. This malady, which began in the breast and ended in the heart, was so violent that it was not possible to bear it. For when those lice, which had bred in their heart, forced their way out, they caused effusions of corrup blood, with exccruting pains in the skin. The unhappy man, with lamentable cries, was indwelling himself to make off those for them with his nails. In short, these lice rushed forth successively from the wounds made by the hands of the combatants, between the frontiers of their kingdoms, with sword and lance; it was also called cake of the field being the stage of trial. Acre-Tax, a tax laid on land at $1,000 per acre. In some places this is also called acre-fold. Impostions on lands in the great level are to be raised by a proportionable acre-tax, 20 Car. ii. cap. 8. — An acre-tax of 25 sh. per acre, for draining Hadenden-level, 13 Geo. i. cap. 18.

ACRIBEIA, a term purely Greek, literally denoting an exquisite or delicate accuracy; sometimes used in our language, for want of a word of equal signification. ACRID, a name for any thing that is of a sharp or pungent taste. See MATERIA MEDICA.

ACRIDOPHAGI, in the ancient geography, an Ethiopian people, represented as inhabiting near the deferts, and to have fed on locusts. This latter circumstance their name imports; the word being compounded of the Greek *axiops locusti, and προκαταφιλιμον. We have the following account of them by Diodorus Siculus. Their stature was lower than that of other men; they were meagre, and extremely black. In the spring, high wind could not keep the locusts from their quarter of the earth, and remarkable for the equal colour of their wings. So great was the number of these insects, that they were the only sustenance of the barbarians, who took them in the following manner: At the distance of some fadis from their habitations there was a wide and deep valley. They filled this valley with wood and wild herbs, with which they kept their animals of prey. When the clouds of locusts appeared, which were driven on by the wind, they set fire to the fuel which they had collected. The smoke which arose from this immense fire was so thick, that the locusts, crossing the valley, were killed by it, and fell in heaps on the ground. The passage of the locusts being thus intercepted for many days, they made a large provision of locusts and other insects. As their country produced great quantities of salt, they salted them, to render them more palatable, and to make them keep till the next season. This peculiar supply was their sole food: they had neither herds nor flocks. They were unacquainted with fishing; for they lived at a distance from the sea. They were very active, and ran with great swiftness. But their life was not of long duration; it exceeded not forty years. ACRIBEIA, a term purely Greek, literally denoting an exquisite or delicate accuracy; sometimes used in our language, for want of a word of equal signification. ACRID, a name for any thing that is of a sharp or pungent taste. See MATERIA MEDICA.
hands of the patient, as from a vessel full of holes, and in such numbers that it was impossible to exterminate them. Whether this extraordinary and dreadful distemper was occasioned by the food of the inhabitants of this country, or by a pestilential quality of their climate, it is difficult to determine. Indeed, as to the credibility of the whole account, we must leave the reader to judge.

But though the circumstances of these people should be deemed fabulous, yet may the acridophagia be true. It is well known, that to this day the inhabitants of Ethiopia, Arabia, &c. frequently use locusts as food. The reader will not be displeased if we lay before him the result of Dr Hallequin’s inquiries as to this particular, who travelled in Syria and Egypt so late as the year 1752. This ingenious gentleman, who travelled with a view to improve natural history, informs us, that he asked Franks, and many other people who had lived long in these countries, whether they had ever heard that the inhabitants of Arabia, Ethiopia, &c. used locusts as food. They answered that they had. He likewise asked the same question of Armenians, Copts, and Syrians, who lived in Arabia, and had travelled in Syria and near the Red Sea; some of whom said they heard of such a practice, and others that they had often seen the people eat these insects. He at last obtained complete satisfaction on this head from a learned cheek at Cairo, who had lived six years in Mecca. This gentleman told him, in presence of M. le Grand the principal French interpreter at Cairo, and others, that a famine frequently rages at Mecca when there is a scarcity of corn in Egypt, which obliges the inhabitants to live upon coarser food than ordinary. That when corn is scarce, the Arabs grind the locusts in hand-mills, or stone-mortars, and bake them into cakes, and use these cakes in place of bread: That he has frequently seen locusts used by the Arabs, even when there was no scarcity of corn; but then they boil them, chew them with butter, and make them into a kind of frieace; which he says is not disagreeably tasted, for he had sometimes tasted these locusts themselves out of curiosity.

A later traveller, Dr Spartman, informs us, that locusts sometimes afford a high treat to the inhabitants, more unpolluted and remote hordes of the Hottentots; when, as sometimes happens, after an interval of 8, 10, 15, or 20 years, they make their appearance in incredible numbers. At these times they come from the north, migrating to the southward, and do not suffer themselves to be impeded by any obstacles, but fly boldly on, and are drowned in the sea whenever they come to it. The females of this race of insects, which are most apt to migrate, and are chiefly eaten, are not said to be able to fly; partly by reason of the shortness of their wings, and partly on account of their being heavy and distended with eggs; and shortly after they have laid these in the sand, they are said to die. It is particularly of these that the Hottentots make a brown coffee-coloured soup, which, at the same time, acquires from the eggs a fat and greasy appearance. The Hottentots are highly rejoiced at the arrival of these locusts, though they are sure to destroy every bit of verdure on the ground: but the Hottentots make themselves ample amends for this loss, by falling foul on the animals themselves, eating them in such quantities as in the space of a few days to get visibly fatter and in better condition than before.

The abbé Poiret, also, in his Memoir on the Insects of Barbary and Numidia, informs us, “That the Moors make locusts a part of their food; that they go to hunt them; fry them in oil and butter; and sell them publicly at Tunis, at Bonne.”

From these accounts, we may see the folly of that dispute among divines about the nature of St John’s food in the wilderness: some maintaining the original word to signify the fruits of certain trees; others, a kind of birds, &c.: but those who adhered to the literal meaning of the text were at least the most orthodox, although their arguments were perhaps not so strong as they might have been, had they had an opportunity of quoting such authors as the above.

ACRISIUS, king of Argos (Fab. hist.), being told by the oracle that he should be killed by his grandchild, that up his only daughter Danae in a brazen tower: but Jupiter coming down in a golden flower, beget Perseus upon her: after Perseus had slain the Gorgons, he carried Medusa’s head to Argos; which Acritis seeing, was turned into a flute.

ACRITAS (anc. geog.), a promontory of Messenia, running into the sea, and forming the beginning of the bay of Melfene. Now called Capo di Catto, between Methone to the west, and Corone to the east, where the Sinus Coronensis begins.

ACROAMATIC, or ACROATIC, in general, denotes a thing sublime, profound, or abstruse.

ACROSTIC; a denomination given the discipulæ or followers of Aristotle, &c. who were admitted into the secrets of the inner or acroatic philosophy.

ACROATIC. Aristotles lectures to his discipulæ were of two kinds, exoteric and acroatic. The acroatic were those to which only his own disciples and intimate friends were admitted; whereas the exoteric were public, and open to all. But there are other differences. The acroatic were kept apart for the higher and more abstruse subjects; the exoteric were employed in rhetorical and civil speculations. Again, the acroatics were more subtle and exact, evidence and demonstration being here aimed at; the exoterics chiefly aimed at the probable and plausible. The former were the subjects of the mornings exercises in the Lyceum, and the latter of the evenings. Add, that the exoterics were published: whereas the acroatics were kept secret; being either entirely concealed; or, if they were published, it was in such obscure terms, that few but his own disciples could be the wiser for them. Hence, when Alexander complained of his preceptor for publishing his acroatics, and thus revealing what should have been reserved to his disciples, Aristotle answered that they were made public and not public; for that none who had not heard them explained by the author sicut voca, would understand them.

ACROATHOUM, or ACROTHOUM (anc. geog.), a town situated on the top of mount Athos, where the inhabitants, according to Mela, were longer lived by half than in any other country: called by the modern Greeks, Αγρακτοι by the Italians, La Cima di Monte Santo.

ACROBATIC, or ACROBATICUM, from ακροβατικός, akrobatisikos, high, and πατω, or πατο I go; an ancient engine, whereby
whereby people were raised aloft, that they might see more conveniently about them. The **acrobatia** among the Greeks amounted to the fame with what they call **scanatorium** among the Latins. Authors are divided as to the office of this engine. Turmescus and Barbara take it to have been of the military kind, raised by besiegers, high enough to overlook the walls, and to discover the state of things on the other side. Baldus rather supposes it a kind of moveable scaffold, or cradle, contrived for raising painters, plasterers, and other workmen, to the tops of houses, trees, &c. Some suspect that it might have been used for both purposes; which is the opinion of Vitruvius and Aquinas.

**ACROCERANIA**, or **Montes Ceranii** (anc. geog.), mountains running out into the sea (to called from their being often thunderstruck), separating the Ionian sea from the Adriatic; which is the opinion of Vitruvius and Aquinas.

**ACROCHERISMUS**, among the Greeks, a fort of gymnastic exercise, in which the two combatants contended with their hands and fingers only, without closing or engaging the other parts of the body.

**ACROCORINTHUS** (anc. geog.), a high and steep hill, hanging over the city of Corinth, which was taken within the walls, as an acropolis, or citadel. On its top stood a temple of Venus; and lower down issued the fountain Pyrene.

**ACROMION**, in anatomy, the upper part of the scapula or shoulder-blade. See Anatomy.

**ACROMONOGRAMMATICUM**, in poetry, a kind of poem, wherein every subsequent verse begins with the letter where with the immediately preceding one terminated.

**ACRON**, a celebrated physician of Agrigentum, who first thought of lighting large fires, and purifying the air with perfumes, to put a spell on the pestilence that ravaged Athens, and which was attended with success. He lived about 473 years before the Christian era.

**ACRON**, a territory on the gold-coast of Guinea, in Africa, bordering on the Fannyan country. The Dutch have a fort here called Fort Patience; and under it is a village, inhabited only by fishermen. The other inhabitants are addicted to bushbandy, and fell their corn to other countries. There is plenty of game, which is very commodious for the Dutch factory. The people are very ignorant, and go naked like the rest of the negroes. This is called Little Acron; for Great Acron is farther inland, and is a kind of a republic.

**ACRONICAL**, **ACRONYCHAL**, or **ACRONICAL**, in astronomy, is a term applied to the rising of a star, when the sun is set in the evening; but has been promiscuously used to express a star's rising at sunrise, or setting at sunset.

**ACRONIUS LACUS** (Mela); a small lake formed by the Rhine, soon after its rise out of the Alps, and after passing the greater lake at Constance, called Venetia, and now the Bodensee, or lake of Constance.

**ACROPOLIS** (anc. geog.), the citadel, and one of the divisions of Athens; called Polis, because constituting the first and original city; and the Upper Polis, to distinguish it from the Lower, which was afterwards built round it in a large open plain, the Acropolis standing on a rock or eminence in the heart of this plain; and hence its name: To the north it had a wall, built by the Pelagii, and therefore called Pelagia; and to the south a wall, by Cymon the son of Miltiades, out of the Persian ipolis, many ages after the building of the north wall. It had nine gates, and was therefore called Enneastyle; yet but one principal gate or entrance, the ascent to which was by a flight of steps of white marble, built by Pericles with great magnificence, (Plutarch).

**ACROPOLITA** (George), one of the writers in the Byzantine history, was born at Constantine, in the year 1220, and brought up at the court of the emperor John Ducas at Nice. He was employed in the most important affairs of the empire; being sent ambassador to Larissa, to establish a peace with Michael of Epirus; and was confulated judge to try Michael Comnenus, suspected of engaging in a conspiracy. Theodosius Laercius, the son of John, whom he had taught logic, appointed him governor of all the western provinces in his empire. In 1225, he was taken prisoner in a war with Michael Angelus: but gaining his liberty in 1260, by means of the emperor Palæologus, he was sent by him ambassador to Constance, prince of Bulgaria; and was employed in several other negotiations. He wrote, A Continuation of the Greek History, from the taking of Constantinople by the Latins till it was recovered by Michael Palæologus in 1261, which makes part of the Byzantine history; A Treatise concerning Faith, Virtue, and the Soul; An Epistle of the Sermons of St Gregory Nazianzen and other pieces. Gregory Cyprian, patriarch of Constantinople, in his eulogium upon him, prefixed to Acropolita's history, is perhaps somewhat extravagant in his praise, when he says he was equal to Aritotele in philosophy, and to Plato in the knowledge of divine things and Attic eloquence.

**ACROSPIRE**, a vulgar term for what botanists call the **plume**. See the article Plantes.

**ACROSPURED**, in malt-making, is the grain's floating both at the root and blade end.

**ACROSTIC**, in poetry, a kind of poetical composition, disposed in such a manner, that the initials of the verses form the name of some person, kingdom, place, motto, &c. The word is compounded of the Greek, **ακρις**, **επιτραμμενη**, and **στροφη**. The acrostic is considered by the critics as a species of false wit, and is therefore very little regarded by the moderns.

**ACROSTICUM**, **RUSTICUM**, **WALL-RUE**, or **FORK-FERN**, in botany, a genus of the cryptogamia filices. The fructifications are accumulated on the whole inferior surface of the frond, so that they everywhere cover it. There are upwards of 30 species; but only three of them (according to others, two) are natives of Britain, viz. the septentrionale, or horned fern, which grows on walls or cliffs of rocks; the ilvensis, or hairy fern, growing in cliffs of rocks; and the thelypris, or marsh fern, in tusby bogs.

**ACROSTOLIUM**, in ancient naval architecture, the extreme part of the ornament used on the prows of their ships, which was sometimes in the shape of a backler, helmet, animal, &c.; but more frequently circular, or spiral. It was usual to tear them from the prows of vanquished vessels, and fix them to the conquerors, as a signal of victory.

ACRO-
ACROTELEPTIC, among ecclesiastical writers, an appellation given to any thing added to the end of a plain; as the Gloria Patri, or Doxology.

ACROTERIA, in architecture, small pedestals, usually without bases, placed either at the middle or two extremities of the pediments or frontispieces, serving to support the statues, &c. It also signifies the figures placed as ornaments on the tops of churches, and the sharp pinacles that stand ranges about flat buildings with rails and balusters.

Among ancient physicians, it signifies the larger extremities of the body, as the head, hands, and feet. It has also been used for the tips of the fingers, and sometimes for the eminences or processes of bones.

ACROTHYMION, from ακρό, extreme, and τυμη, thyme. A fort of wart described by Celsus as hard, rough, with a narrow basis and broad top; the top is of the colour of thyme, it easily splits and bleeds. This tumour is also called thymus.

ACT, in general, denotes the exertion of power; and differs from power, as the effect from the cause.

ACT, in logic, is particularly understood of an operation of the human mind. Thus to discern and examine, are acts of the understanding; to judge and affirm, are acts of the will. There are voluntary and spontaneous acts: the former are produced by the operation of the soul, the latter without its privity or participation.

ACT, in the universities, signifies a thesis maintained in public by a candidate for a degree, or to show the capacity and proficiency of a student. The candidates for a degree of bachelor and master of arts are to hold philosophical acts; and those for bachelor of divinity, theological acts, &c. At Oxford, the time when masters or doctors complete their degrees is also called the act; which is held with great solemnity. At Cambridge, they call it the commencement.

ACT of Faith, Auto da Fe, in the Romish church, is a solemn day held by the inquisition, for the punishment of heretics, and the abolition of the innocent accused. They usually contrive the Auto to fall on some great day, when the execution may pass with the more awe and regard; at least it is always on a Sunday.

The Auto da Fe may be called the last act of the inquisitorial tragedy; it is a kind of goal-delivery, appointed as oft as a competent number of prisoners in the inquisition are convicted of heresy, either by their own voluntary, or exterior confession, or on the evidence of certain witnesses. The process is thus: in the morning they are brought into a great hall, where they have certain habits put on, which they are to wear in the procession. The procession is led up by dominican friars; after which come the penitents, some with fan-bones, and some without, according to the nature of their crimes; being all in black coats without sleeves, and bare-footed, with a wax-candle in their hands. These are followed by the penitents who have narrowly escaped being burnt, who over their black coats have flames painted with their points turned downwards, Fuego redundo. Next come the negative, and released, who are to be burnt, having flames on their habits pointing upwards. After these come such as profess doctrines contrary to the faith of Rome, who, besides flames pointing upwards, have their picture painted on their breasts, with dogs, serpents, and devils, all open-mouthed, about it. Each prisoner is attended with a familiar of the inquisition; and those to be burnt have also a Jesuit on each hand, who are continually preaching to them to abjure. After the procession of penitents comes a troop of familiars on horseback; and after them the inquisitors, and other officers of the court, on mules; last of all, the inquisitor-general on a white horse, led by two men with black hats and green hat bands. A scaffold is erected in the Terriero de Paua, big enough for two or three thousand people; at one end of which are the prisoners, at the other the inquisitors. After a sermon made up of encomiums on the inquisition, and inveigles against heretics, a priest ascends a dais near the middle of the scaffold, and having taken the abjuration of the penitents, recites the final sentence of those who are to be put to death; and delivers them to the secular arm, earnestly beseeching at the same time the secular power not to touch their blood, or put their lives in danger. The prisoners being thus in the hands of the civil magistrate, are presently loaded with chains, and carried first to the secular goal, and from thence in an hour or two brought before the civil judge; who, after asking in what religion they intend to die, pronounces sentence, on such as declare they die in the communion of the church of Rome, that they shall be first strangled, and then burnt to ashes; on such as die in any other faith, that they be burnt alive.' Both are immediately carried to the Ribera, the place of execution; where there are as many stakes set up as there are prisoners to be burnt, with a quantity of dry furze about them. The stakes of the professed, that is, such as perist in their heresy, are about four yards high, having a small board towards the top of the prisoner to be foasted on. The negative and relapsed being first strangled and burnt, the professed mount their stakes by a ladder; and the Jesuits, after several repeated exhortations to be reconciled to the church, part with them, telling them they leave them to the devil, who is standing at their elbow to receive their souls, and carry them with him into the flames of hell. On this a great shout is raised; and the cry is, Let the dogs boards be made; which is done by thrusting flaming furze fastened to long poles against the stakes. till their faces are burnt to a coal, which is accompanied with the loudest acclamations of joy. At last, fire is let to the furz at the bottom of the stake, over which the professed are chained so high, that the top of the flame seldom reaches higher than the seat they sit on, so that they rather seem roasted than burnt. There cannot be a more lamentable spectacle; the sufferers continually cry out while they are able, Misericordia por amor de Dios, "Pity for the love of God!" yecit is beheld by all fexes, and ages, with transports of joy and satisfaction.

ACT, in dramatic poetry, signifies a certain division, or part, of a play, designed to give some refpite both to the actors and spectators. The Romans were the first who divided their theatrical pieces into acts; for no such divisions appear in the works of the first dramatic poets. Their pieces indeed consisted of several parts or divisions, which they called protasis, epitasis, catastasis, and catastrophe; but these divisions were not marked by any real interruptions on the theatre. Nor does Aristotle mention any thing of acts in his Art of Poetry. But, in the time of Horace, all regular and finished pieces were divided into five acts.
The first act, according to some critics, besides introducing upon the stage the principal characters of the play, ought to propose the argument or subject of the piece; the second, to exhibit this to the audience, by carrying the fable into execution; the third, to raise obstacles and difficulties: the fourth, to remove these, or raise new ones in the attempt; and the fifth, to conclude the piece, by introducing some accident that may unravel the whole affair. This division, however, is not essentially necessary; but may be varied according to the humour of the author, or the nature of the subject. See Poetry, Part II. Sect. 1.

Act of Poetry. See Grace.

Act, among lawyers, is an instrument in writing for declaring or justifying the truth of any thing. In which sense, records, decrees, fentences, reports, certificates, &c. are called acts.

Acts, also denote the deliberations and resolutions of an assembly, senate, or convention: as acts of parliament, &c. Likewise matters of fact transmitted to posterity in certain authentic books and memoirs.

**Acta Consiliori** are the edicts or declarations of the council of state of the emperors. These edicts were generally expressed in such terms as these: "The august emperors, Diocletian and Maximian, in council declared, That the children of Decurions should not be exposed to wild beasts in the amphitheatre."

The senate and soldiery often swore, either through subject flattery or by compulsion, upon the edicts of the emperor, as we do upon the bible. And the name of Apelles Merula was erased by Nero out of the register of senators, because he refused to swear upon the edicts of the emperor Augustus.

**Acta Diurna** was a sort of Roman gazette, containing an authorized narrative of the transactions worthy of notice which happened at Rome. Petronius has given us a specimen of the acta diurna in his account of Trimalchius; and as it may not perhaps be uninteresting to see how exactly a Roman newspaper runs in the style of an American one, the following is an article or two out of it:

"On the 26th of July, 30 boys and 40 girls were born at Trimalchi's estate at Cuma."

"At the same time a slave was put to death for uttering detestable words against his lord."

"The same day a fire broke out in Pompey's gardens, which began in the night, in the steward's apartment."

**Acta Populi**, among the Romans, were journals or registers of the daily occurrences; as assemblies, trials, executions, buildings, births, marriages, deaths, &c. of illustrious persons, and the like. These were otherwise called **Acta Publica**, and **Acta Diurna**, or simply **Acta**. The **Acta** differed from **Annales**, in that only the greater and more important matters were in the latter, and those of less note were in the former. Their origin is attributed to Julius Caesar, who first ordered the keeping and making public the acts of the people. Some trace them higher, to Servius Tullius; who, to discover the number of persons born, dead, and alive, ordered that the next of kin, upon a birth, should put a certain piece of money into the treasury of Juno Lucina; upon a death, into that of Venus Libitina: the like was also to be done upon affirming the toga virilis, &c. Under Marcus Antoninus, this was carried further: persons were obliged to notify the births of their children, with their names and surnames, the day, consul, and whether legitimate or spurious, to the prefects of the **Aerarium Saturni**, to be entered in the public acts; though before this time the births of persons of quality appear thus to have been registered.

**Acta Senatus**, among the Romans, were minutes of what passed and was debated in the senate-house. These were also called **Commentarii**, and by a Greek name **εὐγένετα**. They had their origin in the consulship of Julius Caesar, who ordered them both to be kept and published. The keeping them was continued under Augustus, but the publication was abrogated. Afterwards all writings, relating to the decrees or sentences of the judges, or what passed and was done before them, or by their authority, in any cause, were also called by the name **Acts**: in which sense we read of civil acts, criminal acts, interdict acts; **agii civila, criminalia, intercessiva**, &c.

**Public Acts**. The knowledge of public acts forms part of a peculiar science, called the **Diplomatic**, of great importance to an historian, statesman, chronicler, and even critic. The preservation of them was the first occasion of erecting libraries. The style of acts is generally barbarous Latin. Authors are divided as to the rules of judging of their genuineness, and even whether there be any certain rule at all. F. Germain will have the greater part of the acts of former ages to be spurious. Fontaini afferts, that the number of forged acts now extant is very small. It is certain there were severe punishments inflicted on the forgers and falsifiers of acts. The chief of the English acts, or public records, are published by Rymer, under the title of **Eadem**, and continued by Saunders; an extract whereof has been given in French by Rapin, and translated into English under the title of **Acta Regia**. Great commendations have been given this work; also some exceptions made to it; as that there are many spurious acts, as well as errors, in it; some have even charged it with falsifications. The public acts of France fell into the hands of the English after the battle of Poitiers, and are commonly said to have been carried by them out of the country. But the tradition is not supported by any sufficient testimony.

**Acts of the Apostles**, one of the sacred books of the New Testament, containing the history of the infant-church, during the space of 29 or 30 years from the ascension of our Lord to the year of Christ 63. It was written by St. Luke; and addressed to Theophilus, the peron to whom the evangelist had before dedicated his gospel. We here find the accomplishment of several of the promises made by our Saviour; his ascension; the defeat of the Holy Ghost; the first preaching of the apostles, and the miracles whereby their doctrines were confirmed; an admirable picture of the manners of the primitive Christians; and, in short, every thing that passed in the church till the dispersion of the apostles, who separated themselves in order to propagate the gospel throughout the world. From the period of that separation, St. Luke quits the history of the other apostles, who were then at too great a distance from him, and confines himself more particularly to that of St. Paul, who had chosen him for the companion of his labours. He follows that apostle in all his missions, and

Act of Parliament of Great Britain, is a positive law, consisting of two parts, the words of the act, and its true sense and meaning; which being joined, make the law. The words of acts of parliament should be taken in a lawful sense. Cases of the same nature are within the intention, though without the letter, of the act; and some acts extant by equity to things not mentioned therein. See Parliament.

ACT 4., were meadows of remarkable verdure and luxuriance near the sea-shore, where the Romans used to indulge themselves to a great degree in fruits and delicacy of living. The word is used in this sense by Cicero and Virgil; but Voilius thinks it can only be used in speaking of Sicily, as these two authors did. ACT 8. A, A C O N I T U M R A C E M O S U M, Herb Christopher, or Bane-berries, a genus of the monogynia order, belonging to the polyanthera class of plants. The characters are: the calyx is a perianthium consisting of four roundish, obtuse, concave leaves, which fall off. The corolla consists of four petals, larger than the calyx, pointet at both ends, and falling off. The filament consists of numerous capillary filaments; the anthers are roundish, erect, and didymous. The pellitum has an ovate germ; no stamens; the stigma thickened and obliquely depressed. The poecipetalum is an oval smooth one-furrow'd one-cell'd berry. The seeds are very numerous, semiorbiculare, and inconstant in a double order. This genus is associated with the Multifolium, the 26th natural order. There are four species and properties. 1. The piciata, or common herb-christopher, is a native in several parts of Britain. It grows to the height of about two feet and a half; the foot-flakes of the leaves arise from the root; these divide into three smaller foot-flakes, each of which are again divided into three, and these have each three lobes, so that each leaf is composed of 27 lobes or smaller leaves. The flowers grow in ramous spires, and are of a pure white; they are borne upon a slender, jointed, furrowed stem; appear in May; and are succeeded by black, shining, pulpy berries, about the size of peas, which ripen in the autumn. This plant is a powerful repellant, and the root has been used internally in some nervous cases, but must be administered with caution. The berries are, highly poisonous. It is said toads resorted to this plant, on account of its fetid smell. Sheep and goats eat it; cows, horses, and swine refuse it. 2. The alba, or American herb-christopher, is a native of North America. The leaves of this species are somewhat like the former, but not so deeply indented in the edges. The flowers grow in ramous spires, and are of a pure white; they are borne upon a slender, jointed, furrowed stem; appear in May; and are succeeded by black, shining, pulpy berries, about the size of peas, which ripen in the autumn. This plant is a powerful repellant, and the root has been used internally in some nervous cases, but must be administered with caution. The berries are, highly poisonous. It is said toads resorted to this plant, on account of its fetid smell. Sheep and goats eat it; cows, horses, and swine refuse it.

and even Rome itself; for it appears that the Acts were published in the second year of St Paul's residence in that city, or the 26th year of the Christian era, and in the 9th or 10th year of Nero's reign. The style of this work, which was originally comprised in the canonical books, and it is observable, that St Luke, who was much better acquainted with the Greek than with the Hebrew language, always, in his quotations from the Old Testament, makes use of the Septuagint version. The council of Laodicea places the Acts of the Apostles among the canonical books, and all the churches have acknowledged it as such without any controversy.

\* See Abdias.
ACT

Acmon

Culture. The first species hath a perennial root, but the stalks annually decay. It may be propagated either by seeds, or parting the roots, which should be transplanted in autumn. The seeds should be sown soon after they are ripe, or they will lie a whole year in the ground before they vegetate. They should be sown in a shady border: and as all the plants do not come up at the same time, the border should not be disturbed till the following autumn, when they should be transplanted into a shady border, where they may be allowed to remain and flower.—The second species may be propagated in the same manner: only the plants should be allowed three feet every way, on account of their wide-spreading leaves. This species delights in a light soil, and shady situation.—The third is usually propagated by seeds sent annually from North America: it thrives in the same kind of soil as the former; and is very hardy, requiring no other culture than the common flowering-thrubs. The plants should not be often removed for that will prevent their flowering strongly.—The fourth requires a moist loamy soil, and shady situation. It may be propagated in the same manner as the others.

ACTEON, in Roman antiquities, was a great hunter. He was turned by Diana into a stag, for looking on her while bathing; and died by his own dogs.

ACTANIA, an island, according to Pliny, in the North sea. 'It lies to the west of Holstein and Dithmarsch, not far from the mouth of the Eyder and Elbe, and is now called Heystland.'

ACTE. See Samucus.

ACTIAN GAMES, in Roman antiquity, were solemn games instituted by Augustus, in memory of his victory over Marc Anthony at Actium, held every fifth year, and celebrated in honour of Apollo, since called Actius. Hence Actian Years, an area commencing from the battle of Actium, called the Era of Augustus. Virgil infinuates them to have been instituted by Aeneas; from that passage Aen. iii. v. 280.

Aen. iii. 280.

Adiages Ilacia celebramus litora ludi.

But this he only does by way of compliment to Augustus; attributing that to the hero from whom he descended, which was done by the emperor himself: as is observed by Servius.

ACTINIA, in zoology, a genus belonging to the order of vermes mollusces. The body is elongate and smooth, attacking itself firmly by its basis to rocks or other solid substances, having a dilatable apex hooked within. The mouth is furnished with crooked teeth, the rostrum cylindrical and radiated. There are five species, some of which make a beautiful appearance, and are called Animal Flowers. See Actinaria, and Urtica Martia. See Animal Flowers.

Progressive motion in these creatures is so slow, that it is difficult to perceive any, as they scarce advance the length of one inch in an hour. It would seem they do not all produce, when handled, the painful sensation which had acquired them the name of sea-nettle—They are viviparous, feed on shell-fish, open their mouth more or less according to the size of the prey they have to deal with, and then reject the shell through the same aperture. When the mouth is open, all the tentacula of the adelisins may be seen, resembling in that situation a full-blown flower, which has given it the denomination of the flower-fish.

ACTIO, in Roman antiquities, an action at law in a court of justice. The formalities used by the Romans, in judicial actions, were these: If the difference failed to be made up by friends, the injured persons proceeded in jure rem vocare, to summon the offending party to the court, who was obliged to go and give bond for his appearance.

The offending party might be summoned into court in suo voces, by the plaintiff himself meeting the defendant, declaring his intention to him, and commanding him to go before the magistrate and make his defence. If he would not go willingly, he might drag and force him along, unless he gave security for his appearance on some appointed day. If he failed to appear on the day agreed on, then the plaintiff, whenever he met him, might take him along with him by force, calling any bystanders to bear witness, by asking them uti se anteferunt; the bystanders upon this turned their ear towards him in token of their consent: To this Horace alludes in his Sat. against the impertinent, Lib. 1. Sat. 9. See this further explained under the article Atestarum.

Both parties being met before the praetor, or other supreme magistrate presiding in the court, the plaintiff proposed the action to the defendant; in which he designed to protract him. This they termed edere actionem; and was commonly performed by writing it in a tablet; and offering it to the defendant, that he might see whether he had better stand the suit or compound.

In the next place came the postulatio actionis, or the plaintiff's petition to the praetor, for leave to prosecute the defendant in such an action. The petition was granted by writing at the bottom of it aliudem, or refraining by writing in the same manner aliudem non.

The petition being granted, the plaintiff videbat reum, i.e. obliged him to give security for his appearance on such a day in the court; and this was all that was done in public, before the day fixed upon for the trial.

In the mean time, the difference was often made up, either transtulitiones, by letting the cause fall as dubious; or pactiones, by composition for damages among friends.

On the day appointed for hearing, the praetor ordered the several bills to be read, and the parties summoned by an accensus, or head. See Accensus.

Upon the non-appearance of either party, the defaultor lost his cause:—if they both appeared, they were said se metisse; and the plaintiff proceeded sumem jure aliudem intenderem, i.e. to prefer his suit, which was done in a set form of words, varying according to the difference of the actions. After this the plaintiff desired judgment of the praetor, that is, to be allowed a judicium or arbitrum, or else the recuperatores or contemnitori. These he requested for the hearing and deciding the business; but none of them could be denied but by the consent of both parties.

The praetor having assigned them their judges, defined and determined the number of witnesses to be admitted, to hinder the protrasting of the suit; and then the parties proceeded to give their caution, that the
ACTION, in general sense, implies nearly the same thing with Act. — Grammarians, however, observe a distinction between acts and act, the former being generally restricted to the common or ordinary transactions, whereas the latter is used to express those which are remarkable. Thus, we say it is a good action to comfort the unhappy; it is a generous act to deprive ourselves of what is necessary for their fake. The wife man propoees to himself an honest end in all his actions; a prince ought to mark every day of his life with some act of greatness. The abbe Girard makes a further distinction between the words action and act. The former, according to him, has more relation to the power that acts than the latter; whereas the latter has more relation to the effect produced than the former: and hence the latter is properly the attribute of the other.

Thus we may properly say, "Be sure to preserve a preference of mind in all your actions; and take care that they all be acts of equity."

ACTION, in mechanics, implies either the effort which a body or power makes against another body or power, or the effect itself of that effort.

As it is necessary in works of this kind to have a particular regard to the common language of mechanics and philosophers, we have given this double definition: but the proper signification of the term is the motion which a body really produces, or tends to produce, in another; that is, such is the motion it would have produced, had nothing hindered its effect.

All power is nothing more than a body actually in motion, or which tends to move itself; that is, a body which would move itself if nothing opposed it. The action therefore of a body is rendered evident to us by its motion only; and consequently we must not fix any other idea to the word action, than that of actual motion, or a simple tendency to motion. The famous question relating to vis viva, and vis mortua, owes, in all probability, its existence to an inadequate idea of the word action; for had Leibnitz and his followers observed, that the only precise and definite idea we can give to the word force or action, reduces it to its effect, that is, to the motion it actually produces or tends to produce, they would never have made that curious distinction.

Quantity of Action, a name given by M. de Maupertuis, in the Memoirs of the Parisian Academy of Sciences for 1744, and those of Berlin for 1746, to the product of the mass of a body by the space which it runs through, and by its celerity. He lays it down as a general law, "that, in the changes made in the state of abody, the quantity of action necessary to produce such a change is the least possible." This principle he applies to the investigation of the laws of refraction, of equilibrium, &c. and even to the ways of acting employed by the Supreme Being. In this manner M. de Maupertuis attempts to connect the metaphysics of final causes with the fundamental truths of mechanics, to show the dependence of the collision of both elastic and hard bodies upon one and the same law, which before had always been referred to separate laws; and to reduce the laws of motion, and those of equilibrium, to one and the same principle.

ACTION, in ethics, denotes the external signs or expressions of the sentiments of a moral agent. See Acts of Love, infra.

ACTION, in poetry, the same with fable or fable. Critics generally distinguish two kinds, the principal and the incidental. The principal action is what is generally called the fable; and the incidental an epistle. See Poetry, Part II.

ACTION, in oratory, is the outward department of the orator, or the accommodation of his countenance, voice, and gesture, to the subject of which he is treating. See Oratory, Part IV.

ACTION, in a theatrical sense. See Declaration, Art. IV.

ACTION for the Pulpit. See Declaration, Art. I.

ACTION, in painting and sculpture, is the attitude or position of the several parts of the face, body, and limbs of such figures as are represented, and whereby they seem to be really actuated by passions. Thus we say, the action of such a figure finely expresses the passions with which it is agitated; we also use the same expression with regard to animals.

ACTION, in physiology, is applied to the functions of the body, whether vital, animal, or natural.

The vital functions, or actions, are those which are absolutely necessary to life, and without which there is no life, as the action of the heart, lungs, and arteries. On the action and reaction of the fluids and fluids on each other, depend the vital functions. The pulse and respiration are the external signs of life. Vital diseases are all those which hinder the influx of the venous blood into the cavities of the heart, and the expulsion of the arterial blood from the same. — The natural functions are those which are instrumental in repairing the several losses which the body sustains; for life is destructive of itself, its very offices occasioning a perpetual waste. The manutacuation of food, the deplutition and digestion thereof, also the separation and distribution of the chyle and excrements parts, &c. are under the head of natural functions, as by their ordnance is converted into our nature. They are necessary to the continuance of our bodies. — The animal functions are those which we perform at will, as muscular motion, and all the voluntary actions of the body, they are those which constitute the senses of touch, taste, smell, sight, hearing; perception, reasoning, imagination, memory, judgment, affections of the mind. Without any, or all of them, a man may live, but not so comfortably as with them.

ACTION, in commerce, is a term used abroad for a certain part or share of a public company's capital stock. Thus, if a company has 400,000 livres capital stock, this may be divided into 400 actions, each confiting of 1000 livres. Hence a man is said to have two, four, &c. actions, according as he has the property of two, four, &c. 1000 livres capital stock. The transferring of actions abroad is performed much in the same manner as stocks are in England. See Stocks.

ACTION, in law, is a demand made before a judge for obtaining what we are legally intitled to demand, and is more commonly known by the name of law-suit or proces. See Suit.
ACTIONARY, or Actionist, a proprietor of a fleet in a trading company.

ACTIONS, among merchants, sometimes signify moveable effects; and we say the merchant's creditors have feized on all his actions, when we mean that they have taken possession of all his active debts.

ACTIVE, denotes something that communicates action or motion to another; in which acceptance it stands opposed to passive.

Active, in grammar, is applied to such words as express action; and is therefore opposed to passive. The active performs the action, as the passive receives it. Thus we say, a verb active, a conjugation active, &c. or an active participle.

Active Verbs, are such as do not only signify doing, or acting; but have also nouns following them, to be the subject of the action or impression: thus, To love, to teach, are verbs active; because we can say, To love a thing, to teach a man. Neuter verbs also denote an action, but are distinguished from active verbs, in that they cannot have a noun following them: such are To fly, to go, &c. — Some grammarians, however, make three kinds of active verbs: the transitive, where the action passes into a subject different from the agent: reflected, where the action returns upon the agent; and reciprocal, where the action turns mutually upon the two agents who produced it.

Active Power, in metaphysics, the power of executing any work or labour: in contradistinction to passive powers, or the powers of being, hearing, remembering, judging reasoning, &c.

The exertion of active power we call action; and as every action produces some change, so every change must be caused by some effect, or by the cessation of some exertion of power. That which produces a change by the exertion of its power, we call the cause of that change; and the change produced, the effect of that cause. See Metaphysics.

Active Principles, in chemistry, such as are supposed to act without any assistance from others; as mercury, sulphur, &c.

Activity, in general, denotes the power of acting, or the active faculty. See Active.

Sphere of Activity, the whole space in which the virtue, power, or influence, of any object, is exerted.

ACTIUM (anc. geog.), a town situated on the coast of Acarnania, in itself inconsiderable, but famous for a temple of Apollo, a safe harbour, and an adjoining promontory of the same name, in the mouth of the Sinus Ambracius, over against Nicopolis, on the other side of the bay: it afterwards became more famous on account of Augustus's victory over Anthony and Cleopatra; and for quinquennial games instituted there, called Attica or Ludi Atticæ. Hence the epithet Atticus, given to Apollo (Virgil). Attica era, a computation of time from the battle of Actium. The promontory is now called Capo di Fago.

ACTIU.S, in mythology, a surname of Apollo, from Actium, where he was worshipped.

ACTON, a town near London, where is a well that affords a purging water, which is noted for the pungency of its salt. This water is whitish, to the taste it is sweethith, with a mixture of the same bitter which is in the Epion water. The salt of this water is not quite so soft as that of Epion; and is more calcareous than it, being more of the nature of the salt of lime: for a quantity of the Acton water being boiled high, on being mixed with a solution of sublimate in pure water, threw down a yellow sediment. The salt of the Acton water is more nitrous than that of Epion; it strikes a deep red, or purple, with the tincture of logwood in brandy, as is usual with nitrous salts; it does not precipitate silver out of the spirit of nitre, as common salt does: 1 lb of this water yields 48 grains of salt.

ACTOR, in general, signifies a person who acts or performs something.

Actor, among civilians, the proctor or advocate in civil courts or causes: as, Actor ecclesiae has been sometimes used for the advocate of the church; actor dominicus for the lord's attorney; actor villa, the herald or head bailiff of a village.

Actor, in the drama, is a person who represents some part or character upon the theatre. The drama confided originally of nothing more than a simple chorus, who sung hymns in honour of Bacchus; so that the primitive actors were only singers and musicians. Thespis was the first that, in order to ease this unformed chorus, introduced a declaimer, who repeated some heroic or comic adventure. Eschylus, finding a single person tiresome, attempted to introduce a second, and changed the ancient recitals into dialogues. He also demiied his actors in a more majestic manner, and introduced the cithernus or luscinian. Sophocles added a third, in order to represent the various incidents in a more natural manner; and here the Greeks stopped, at least we do not find in any of their tragedies above three persons in the same scene. Perhaps they looked upon it as a rule of the dramatic poem, never to admit more than three speakers at a time on the stage; a rule which Horace has expressed in the following verse:

Nec quarta loci persona laboret.

This, however, does not prevent their increasing the number of actors in comedy. Before the opening of a play, they named their actors in full theatre, together with the parts they were to perform. The ancient actors were marked, and obliged to raise their voice extremely, in order to make themselves heard by the innumerable crowd of people who filled the amphitheatres: they were accompanied with a player on the flute, who played a prelude, gave them the tone, and played while they declaimed. Horace speaks of a kind of secondary actors, in his time, whose business was to imitate the first; and lessen themselves, to become better foils to their principals.

The moderns have introduced an infinite number of actors upon the stage. This heightens the trouble and distress that should reign there, and makes a diversity, in which the spectator is sure to be interested.

Actors were highly honoured at Athens. At Rome they were despised, and not only denied all rank among the citizens, but even when any citizen appeared upon the stage he was expelled his tribe and deprived of the right of suffrage by censors. Cicero, indeed, esteems the talents of Roscius: but he values his virtues still more; virtues which distinguished him so remarkably above all others of his profession, that they seemed to have exalted him from the theatre. The French have, in this respect, adopted the ideas of the Romans; and the English those of the Greeks.

Actor, the name of several persons in fabulous

A C T [ 1 0 2 ]
ACTUARIUS, a celebrated Greek physician, of the 13th century, and the Greek author who has treated of mild purgatives, such as castor oil, safflower, &c.

His works were printed in one volume folio, by Henry Stephens, in 1567.

ACTUARIUS, or ACTRESS, a notary or officer appointed to write the acts or proceedings of a court, or the like. In the Eastern Empire, the aktarri were properly officers who kept the military accounts, received the corn from the fuccepers or store-keepers, and delivered it to the soldiers.

ACTUARE, to bring into act, or put a thing in action. Thus an agent is said, by the schoolmen, to affume a power, when it produces an act in a subject. And thus the mind may be said to affume the body.

ACTUS, in ancient architecture, a measure in length equal to 120 Roman feet. In ancient agriculture, the word signified the length of one furrow or the distance a plough goes before it finishes.

ACTUS MINIMUS, was a quantity of land 120 feet in length, and four in breadth.

ACTUS MAJOR, or ACTUS Quadratus, a piece of ground in a square form, whose side was equal to 120 feet, equal to half the jugerum.

ACTUS INTEGIMENTALIS, a space of ground four feet in breadth, left between the lands as a path or way.

ACUANITES, in ecclesiastical history, the name of those called more frequently MANICURERS. They took the name from Acus, a disciple of Thomas one of the twelve apostles.

ACULEATS, or ACULEATI, a term applied to any plant or animal armed with prickles.

ACULEI, the prickles of animals or of plants.

ACULER, in the manage, is used for the motion of a horse, when, in working upon volts, he does not go far enough forward at every time or motion, so that his shoulders embrace or take in too little ground, and hisroupe comes too near the centre of the volt. Horses are naturally inclined to this fault in making demi-volts.

ACUMINA, in antiquity, a kind of military omen, most generally supposed to have been taken from the points or edges of darts, swords, or other weapons.

ACUNA (Christopher de), a Spanish Jesuit, born at Burgos. He was admitted into the society in 1612, being then but 15 years of age. After having devoted some years to study, he went to America, where he assisted in making converts in Chili and Peru. In 1640, he returned to Spain, and gave the king an account of how far he had succeeded in the commission he had received to make discoveries on the river of the Amazons; and the year following he published a description of this river, at Madrid. Acuna was sent to Rome, as procurator of his province. He returned to Spain with the title of Qualificador of the Inquisition; but soon after embarked again for the West Indies, and was at Lima in 1675, when father Southwell published at Rome the Bibliotheca of the Jesuit writers. Acuna's work is intitled, Nuevo descubrimiento del gran rio de las Amazonas; i.e. "a new discovery of the great river of the Amazons." He was ten months together upon this river, having had instructions to inquire into everything with the greatest exactness, that his majesty might thereby be enabled to render the navigation more
ACUPUNCTURE, the name of a surgical operation among the Chinese and Japanese, which is performed by pricking the part affected with a silver needle. They employ this operation in headaches, lethergies, convulsions, colics, &c.

ACUSA, in ichthyology, the trivial name of a species of synagathus. See SYNGATHUS.

ACUSIO COLONIA, now Ancone, according to Holstenius, between Orange and Valence, near Montelimart, on the banks of the Rhone.

ACUTE, an epithet applied to such things as terminate in a sharp point or edge. And in this sense it stands opposed to obtuse.

ACUTE ANGLE, in geometry, is that which is less than a right angle, or which does not subtend 90 degrees.

ACUTE-ANGLED TRIANGLE, is a triangle whose three angles are all acute.

ACUTE, in music, is applied to a sound or tone that is sharp or high, in comparison of some other tone. In this sense, acute stands opposed to grave.

ACUTE ACCENT. See ACCENT.

ACUTE DISORDER, such as come suddenly to a crisis. This term is used for all diseases which do not fall under the head of chronic.

ACUTATOR, in writers of the barbarous ages, denotes a person that whets or grinds cutting instruments; called also in ancient glossaries, acutor, acunvus, famarius, cobarius, &c. In the ancient armies there were acutators, a kind of smiths, retained for whetting or keeping the arms sharp.

AD, a Latin preposition, originally signifying to, and frequently used in composition both with and without the d, to express the relation of one thing to another.

AD BEASIS, in antiquity, is the punishment of criminals condemned to be thrown to wild beasts.

ADEM, in logic, a kind of argument drawn from the principles or prejudices of those with whom we argue.

ADA LUDUS, in antiquity, a sentence upon criminals among the Romans, whereby they were condemned to entertain the people by fighting either with wild beasts, or with one another, and thus executing justice upon themselves.

ADA METALLA, in antiquity, the punishment of such criminals as were condemned to the mines, among the Romans; and therefore called Metalliae.

ADA VALOREM, a term chiefly used in speaking of the duties or customs paid for certain goods: The duties on some articles are paid by the number, weight, measure, tale, &c.; and others are paid ad valorem, that is, according to their value.

ADAGE, a proverb, or short sentence, containing some wise observation or popular saying. Erasmus has made a very large and valuable collection of the Greek and Roman adages; and Mr Ray has done the same with regard to the English. We have also Kelly's collection of Scots Proverbs.

ADAGIO, in music. Adverbially, it signifies softly, leisurely; and is used to denote the slowest of all times. Used substantively, it signifies a slow movement. Sometimes this word is repeated, as adagio, adagio, to denote a still greater retardation in the time of the music.

ADALIDES, in the Spanish policy, are officers of justice, for matters touching the military forces. In the laws of king Alphonse, the adalides are spoken of as officers appointed to guide and direct the marching of the forces in time of war. Lopez represents them as a sort of judges, who take cognizance of the difference arising upon excursions, the distribution of plunder, &c.

ADAM, the first of the human race, was formed by the Almighty on the sixth day of the creation. His body was made of the dust of the earth; after which, God animated or gave it life, and Adam then became a rational creature.—His heavenly parent did not leave his offspring in a destitute state to shift for himself: but planted a garden, in which he caused to grow not only every tree that was proper for producing food, but likewise such as were agreeable to the eye, or merely ornamental. In this garden were assembled all the brute creation; and, by their Maker, caused to pass before Adam, who gave all of them names, which were judged proper by the Deity himself.—In this review, Adam found none for a companion to himself. This solitary state was seen by the Deity to be attended with some degree of unhappiness; and therefore he took Adam into a deep sleep, in which condition he took a rib from his side, and healing up the wound formed a woman of the rib he had taken out. On Adam's waking, the woman was brought to him; and he immediately knew her to be one of his own species, called his bone and his flesh, giving her the name of woman because she was taken out of man.

The first pair being thus created, God gave them authority over the inferior creation, commanding them to subdue the earth, also to increase and multiply and fill it. They were informed of the proper food for the beasts and for them; the grafs, or green herbs, being appointed for beasts; and fruits or seeds, for man. Their proper employment also was assigned them; namely, to dress the garden, and to keep it.

Though Adam was thus highly favoured and instruc-
ticed, the Tree of the Knowledge of Good and Evil. This prohibition, however, they soon broke through. The woman having entered into conversation with the Serpent, was by him persuaded, that by eating of the tree she should become as wise as God himslef; and accordingly, being invited by the beauty of the fruit, and its desirable property of imparting wisdom, she plucked and eat; giving her husband of it at the same time, who did likewise eat.

Before this transgression of the divine command, Adam and his wife had no occasion for clothes, neither had they any sense of shame; but immediately on eating the forbidden fruit, they were ashamed of being naked, and made aprons of fig-leaves for themselves. On hearing the voice of God in the garden, they were terrified, and hid themselves: but being questioned by the Deity, they confessed what they had done, and received sentence accordingly; the man being condemn- ed to labour; the woman to subjection to her husband, and to pain in childbearing. They were now driven out of the garden, and their access to it prevented by a terrible apparition. They had clothes given them by the Deity made of the skins of beasts. In this state Adam had several children; the names of only three of whom we are acquainted with, viz. Cain, Abel, and Seth. He died at the age of 930 years. These are all the particulars concerning Adam's life, that we have on divine authority: but a great number of stories are added by the Jews, Mahometans, and others; which indeed appear downright falsehoods or absurdities. That he was a handsome man is probable; but some writers, not content with this, affirm, that God, intending to create a perfect body, was either pleasing or power of producing his like, without the concur- rent assistance of woman. The division into two sexes, he imagined, was a consequeuce of man's sin; and now, the observers, mankind are become so many monsters in nature, being much less perfect in this respect than plants or trees, who are capable of producing their like alone, and without pain or misery. She even imagined, that, being in an ecstacy, we saw the figure of Adam before he fell, with the manner how, by himself, he was capable of procreating other men. "God," says she, "reprented to my mind the beauty of the first world, and the manner how he had drawn it from the chaos: every thing was bright, transparent, and darted forth light and ineffable glory. The body of Adam was purer and more transparent than crystal, and vailly fleet; through this body were seen vessels and rivuletts of light, which penetrated from the inward to the outward parts, through all his pores. In some vessels ran fluids of all kinds and colours, vailly bright, and quite diaphanous. The most ravishing harmony arose from every motion; and nothing resisted, or could annoy, him. His figure was taller than the preference of men: his hair was short, curled, and of a colour inclining to black; his upper lip covered with short hair: and instead of the beshial parts which modesty will not allow us to name, he was fashioned as our bodies will be in the life eternal, which I know not whether I dare reveal. In that region his nose was formed after the manner of a face, which diffused the most delicious fragrancy and perfumes; whence all men were to issue, all whose principles were inherent in him; there being in his belly a vail, where little eggs were formed; and a second vail filled with a fluid, which impregnated those eggs: and when man heated himself in the love of God, the desire he had that other creatures should exist besides himself, to praise and love God, caused the fluid abovementioned (by means of the fire of the love of God) to drop on one or more of these eggs, with inexpressible delight; which being thus impregnated, issued, some time after, out of man, by this canal, in the shape of an egg, whence a perfect man + i. e. the first man was hatched by inintensible degrees. Woman was formed by taking out of Adam's side the vessels that contained the eggs; which she still possesses, as is discovered by anatomists."

Many others have believed, that Adam at his first creation was both male and female: others, that he had two bodies joining together at the shoulders, and their faces looking opposite ways like those of Janus. Hence, say they, when God created Eve, he had no more to do than to separate the two bodies from one another.† Of all others, however, the opinion of Paracelsus seems the most ridiculous. Negatio primi parvis auctus lap- sum habiti partes generationis hominis necessariae; credit us parvulis accessisse, ut reservam gottifari. Extravagant things are asserted concerning Adam's knowledge. It is very probable that he was taught by the Deity how to accomplish the work appointed him, viz. to dress the garden, and keep it from being destroyed by the brute creatures; and it is also probable that he had likewise every piece of knowledge communicated to him that was either necessary or pleasing: but that he was acquainted with geometry, mathematics, rhetoric, poetry, painting, sculpture, &c. is too ridiculous to be credited by any sober person. Some rabbis,
...rabbis, indeed, have contented themselves with equaling Adam's knowledge to that of Moses and Solomon; while others, again, have maintained that he excelled the angels themselves. Several Christianists seem to be little behind the Jews in the degree of knowledge they ascribe to Adam; nothing being hid from him, according to them, except contingent events relating to futurity. One writer indeed (Pinedo) excepts politics; but a Carthusian friar, having exhausted, in favour of Aristotle, every image and comparison he could think of, at last affirms that Aristotle's knowledge was as extensive as that of Adam. —In consequence of this surprising knowledge with which Adam was endued, he is supposed to have been a confiderable author. The Jews pretend that he wrote a book on the creation, and another on the Deity. Some rabbis ascribe the 92d psalm to Adam; and in some manuscripts the Chaldee title of this psalm expressly declares that this is the song of praise which the first man repeated for the Sabbath-day.

Various conjectures have been formed concerning the place where man was first created, and where the garden of Eden was situated; but none of these have any solid foundation. The Jews tell us, that Eden was separated from the rest of the world by the ocean; and that Adam, being banished therefrom, walked across the sea, which he found every way fordable, by reason of his enormous stature. The Arabians imagined paradise to have been in the air; and that our first parents were thrown down from it on their transgression, as Vulcan is said to have been thrown down headlong from heaven by Jupiter. Strange stories are told concerning Adam's children. That he had none in the state of innocence, is certain from scripture; but that his marriage with Eve was not consummated till after the fall, cannot be proved from thence. Some imagine, that for many years after the fall, Adam denied himself the connubial joys by way of penance; others, that he cohabited with another woman, whose name was LILITH. The Mahometans tell us, that our first parents having been thrown headlong from the celestial paradise, Adam fell upon the isle of Serendib, or Ceylon, in the East Indies; and Eve on Iodda, a port of the Red Sea, not far from Mecca. After a separation of upwards of 200 years, they met in Ceylon, where they multiplied; according to some Eve had twenty, according to others only eight, deliveries; bringing forth at each time twins, a male and female, who afterwards married. The Rabbins imagine that Eve brought forth Cain and Abel at a birth; that Adam wept for Abel an hundred years in the valley of tears near Hebron, during which time he did not cohabit with his wife; and that this separation would probably have continued longer, had it not been forbid by the angel Gabriel. The inhabitants of Ceylon affirm, that the salt lake on the mountain of Colombo consists wholly of the tears which Eve for one hundred years together shed because of Abel's death.

Some of the Arabians tell us, that Adam was buried near Mecca on Mount Abukobes: others, that Noah, having laid his body in the ark, caused it to be carried after the deluge to Jerusalem by Melchisedek the son of Shem: of this opinion are the eastern Christianists; but the Persians assert that he was interred in the isle of Serendib, where his corps was guarded by lions at the time the giants warred upon one another. —St. Jerom imagined that Adam was buried at Hebron; others, on Mount Calvary. Some are of opinion that he died on the very spot where Jerusalem was afterwards built; and was buried on the place where Christ suffered, that so his bones might be sprinkled with the Saviour's blood!!

Adam (Melchior) lived in the 17th century. He was born in the territory of Grotkaw in Silesia, and educated in the college of Brégu, where the dukes of that name, to the utmost of their power, encouraged learning and the reformed religion as professed by Calvin. Here he became a firm Protestant; and was enabled to pursue his studies by the liberality of a person of quality, who had left several exhibitions for young students. He was appointed rector of a college at Heidelberg, where he published his first volume of ill-fated men in the year 1615. This volume, which consisted of philosophers, poets, writers on polite literature, and historians, was followed by three others; that which treated of divines was printed in 1619; that of the lawyers came next; and, finally, that of the physicians: the two last were published in 1620. All the learned men, whose lives are contained in these four volumes, lived in the 16th, or beginning of the 17th century, and are either Germans or Flemings; but he published in 1618 the lives of twenty divines of other countries in a separate volume. All his divines are Protestants. The Lutherans were not pleased with him, for they thought him partial; nor will they allow his work to be a proper standard whereby to judge of the learning of Germany. He wrote other works besides his lives, and died in 1622.

Adam's Apple, a name given to a species of Citrus. Adam's Needle. See Yucca.

Adam's Peak, a high mountain of the East Indies, in the isle of Ceylon, on the top of which they believe that the first man was created. See Adam.

Adam, or Adom, a town in the Peraea, or on the other side the Jordan, over-against Jericho, where the Jordan began to be dried up on the passage of the Israelites; (Joln.)

Adam, or Admah, one of the towns that were involved in the destruction of Sodom; (Moses.)

Adamant, a name sometimes given to the diamond. (See Diamond.) It is likewise applied to the sioras of gold, the magnet, &c.

Adamic Earth, a name given to common red clay, alluding to that species of earth of which the first man is supposed to have been made.

Adam's Poison, in anatomy, a protuberance in the fore-part of the throat, formed by the os hyoides. It is thought to be so called upon a strange conceit, that a piece of the forbidden apple which Adam eat, stuck by the way, and occasioned it.

Adamites, in ecclesiastical history, the name of a sect of ancient heretics, supposed to have been a branch of the Basilidians and Carpocratians.

Epiphanius tells us, that they were called Adamites from their pretending to be re-established in the state of innocence, and to be such as Adam was at the moment of his creation, whence they ought to imitate him in his nakedness. They detested marriage; maintaining that the conjugal union would never have taken place upon earth had it been unknown.
This obscure and ridiculous feat did not at first last long; but it was revived, with additional absurdities, in the twelfth century, by one Tanchelin, since known by the name of Tanchelin, who propagated his errors at Antwerp, in the reign of the emperor Henry V. He maintained, that there ought to be no distinction between priests and laitymen, and that fornication and adultery were meritorious actions. Tanchelin had a great number of followers, and was constantly attended by 3000 of these profligates in arms. His deed did not, however, continue long after his death; but another appeared under the name of Tartarinus, in Savoy and Dauphiny, where they committed the most brutal actions in open day.

About the beginning of the fifteenth century, one Picard, a native of Flanders, spread these errors in Germany and Bohemia, particularly in the army of the famous Zica, notwithstanding the severe discipline he maintained. Picard pretended that he was sent into the world as a new Adam, to re-establish the law of nature; and which, according to him, consisted in exposing every part of the body, and having all the women in common. This fact found also some partisans in Poland, Holland, and England: they assembled in the night; and it is asserted, that one of the fundamental maxims of their society was contained in the following verse:

furo, perjura, secretum prodere nos.

ADAMUS, the philosopher's stone is so called by alchemists; they say it is an animal, and that it has carried its invisible Eos in its body, since the moment they were united by the Creator.

ADAMSHIDE, a district of the circle of Ralfenborg, belonging to the king of Prussia, which, with Dombroaken, was bought, in 1737, for 42,000 dollars.

ADAMSON (Patrick), a Scottish prelate, archbishop of St Andrews. He was born in the year 1543 in the town of Perth, where he received the rudiments of his education; and afterwards studied philosophy, and took his degree of master of arts at the university of St Andrews. In the year 1566, he left for Paris, as tutor to a young gentleman. In the month of June of the same year, Mary queen of Scots being delivered of a son, afterwards James VI. of Scotland and First of England, Mr Adamson wrote a Latin poem on the occasion. This proof of his loyalty involved him in some difficulties, having been confined in France for six months; nor would he have easily got off, had not Queen Mary, and some of the principal nobility, interested themselves in his behalf. As soon as he recovered his liberty, he retired with his pupil to Bourges. He was in this city during the massacre at Paris; and the fame prevailing spirit prevailing among the catholics at Bourges as at the metropolis, he lived concealed for seven months in a public house, the master of which, upwards of 70 years of age, was thrown from the top thereof, and had his brains dashed out, for his charity to heretics. Whilst Mr Adamson lay thus in his sepulchre, as he called it, he wrote his Latin poetical version of the Book of Job, and his Tragedy of Herod in the same language. In the year 1575, he returned to Scotland; and, having entered into holy orders, became minister of Paisley. In the year 1575, he was appointed one of the commissioners, by the general assembly, to settle the jurisdiction and polity of the church; and the following year he was named, with Mr. David Lindsay, to report their proceedings to the earl of Morton, then regent. About this time the earl made him one of his chaplains; and on the death of bishop Douglas, promoted him to the archiepiscopal see of St Andrew's, a dignity which brought upon him great trouble and uneasiness: for now the clamour of the presbyterian party rose very high against him, and many inconsequent absurd stories were propagated concerning him. Soon after his promotion, he published his catechism in Latin verse, a work highly approved even by his enemies; but nevertheless, they still continued to persecute him with great violence. In 1578, he submitted himself to the general assembly, which procured him peace but for a very little time; for, the year following, they brought fresh accusations against him. In the year 1582, being attacked with a grievous disease, in which the physicians could give him no relief, he happened to take a simple medicine from an old woman, which did him service. The woman whose name was Alison Pearson, was thereupon charged with witchcraft, and committed to prison, but escaped out of confinement; however, about four years afterwards, she was again found and burnt for a witch. In 1583, King James came to St Andrews; and the Archibishop, being much recovered, preached before him, and disputed with Mr Andrew Melvil, in presence of his Majesty, with great reputation, which drew upon him fresh calumny and persecution. The king, however, was so well pleased with him, that he sent him ambassador to Queen Elizabeth, at whose court he resided for some years. His conduct, during his embassy, has been variously reported by different authors. Two things he principally laboured, viz. the recommending the king his master to the nobility and gentry of England, and the procuring some support for the episcopal party in Scotland. By his eloquent preaching, he drew after him fuch crowds of people, and raised in their minds such a high idea of the young king his master, that queen Elizabeth forbade him to enter the pulpit during his stay in her dominions. In 1584, he was recalled, and sat in the parliament held in August at Edinburgh. The Presbyterian party was still very violent against the archbishop. A provincial synod was held at St Andrew's in April 1586; the Archbishops was here accused and excommunicated; he appealed to the king and the states, but this availed him little; for the mob being excited against him, he durst scarce appear in public. At the next general assembly, a paper being produced containing the archbishop's submission, he was absolved from the excommunication. In 1588, fresh accusations were brought against him. The year following, he published the Lamentations of the prophet Jeremiah in Latin verse; which he dedicated to the king, complaining of his hard usage. In the latter end of the same year, he published a translation of the Apocalypse, in Latin verse; and a copy of Latin verses, addressed also to his Majesty, when he was in great distress. The king, however, was so far from having him affiance, that he granted the revenue of his fee to the duke of Lennox; so that the remaining part of this prelate's life was very wretched, he having hardly subsistence for his family. He died in 1591.

ADANA, a town of Asia, in Natalia, and in the province
ADA

Adanonia, province of Carmania. It is seated on the river Choquer; on the banks of which stands a strong little castle built on a rock. It has great number of beautiful fountains brought from the river by means of water-works. Over the river there is a flately bridge of fifteen arches, which leads to the water-works. The climate is very pleasant and healthy, and the winter mild and serene: but the summer is so hot as to oblige the principal inhabitants to retire into the neighbouring mountains, where they spend six months among shady trees and groves, in a moist delicious manner. The adjacent country is rich and fertile, and produces melons, cucumbers, pomegranates, pulse, and herbs of all sorts, all the year round; and in Jully, and the fruits ripen in October and November. It is very common in Senegal and the Cape de Verde islands; and is found 100 leagues up the country at Golum, and upon the sea-coast as far as Sierra-leona.

The age of this tree is perhaps no less remarkable than its enormous size. Mr. Adanson relates, that, in a botanical excursion to the Magdalene islands, in the neighbourhood of Goree, he discovered some calabash-trees from five to six feet diameter, on the bark of which were engraved or cut to a considerable depth a number of European names. Two of these names, which he was at the trouble to repair, were dated one the 14th, the other the 15th century. The letters were about six inches long, but in breadth they occupied a very small part only of the circumference of the trunk: from whence he concluded they had not been cut when these trees were young. These inscriptions, however, he thinks sufficient to determine pretty nearly the age which these calabash-trees may attain; for even supposing that those in question were cut in their early years, and that trees grew to the diameter of six feet in two centuries, as the engraved letters evince, how many centuries must be requisite to give them a diameter of 25 feet which perhaps is not the last term of their growth! The inscribed trees mentioned by this ingenious Frenchman had been seen in 1555, almost two centuries before, by Thetev, who mentions them in the relation of his voyage to Terra Antarctica or Australia. Adanson saw them in 1749.

The virtues and uses of this tree and its fruit are various. The negroes of Senegal dry the bark and leaves in the shaded air; and then reduce them to powder, which is of a pretty good green colour. This powder they preferve in bags of linen, and call it tillo. They use it every day, putting two or three pinches of it into a mea, whatever it happens to be, as we do pepper and salt: but their view is, not to give a relish to their food, but to preserve a perpetual and plentiful perspiration, and to attemper the too great heat of the blood; purposes which it certainly answers, as several Europeans have proved by repeated experiments, preferring themselves from the epidemic fever, which, in that country, destroys Europeans like the plague, and generally rages during the months of September and October, when, the rains having suddenly ceased, the fun exhales the water left by them upon the ground, and fills the air with a noxious vapour. M. Adanson, in that critical season, made a light pilfan of the leaves of the baobab, which he had gathered in the August of the preceding year, and had dried in the shade; and drank constantly about a pint of it every morning, either before or after breakfast, and the fame quantity of it every evening after the heat of the fun began to abate: he also sometimes took the same quantity in the middle of the day, but this was only when he felt some symptoms of an approaching fever. By this precaution he preserved himself, during the five years he resided at Senegal, from the diarrhoea and fever, which are so fatal there and,
Adansonia and which are, however, the only dangerous diseases of the place; and other officers suffered very severely, only one excepted, upon whom M. Adanson prevailed to use this remedy, which for its simplicity was defined by the text. This ptisan alone also prevents that heat of urine which is common in these parts, from the month of July to November, provided the person abstains from wine.

The fruit is not less useful than the leaves and the bark. The pulp that envelopes the seeds has an agreeable acid taste, and is eaten for pleasure: it is also dried and powdered, and thus used medicinally in febrile fevers, the dysentery, and bloody discharges, which are eaten with palm-oil that begins to be rancid.

The trunks of such of these trees as are decayed, the negroes hollow out into burying places for their poets, musicians, buffoons: persons of these characters they esteem greatly while they live, supposing them to derive their superior talents from forcery or a commerce with demons; but they regard their bodies with a kind of horror when dead, and will not give them burial in the usual manner, neither suffering them to be put into the ground, nor thrown into the sea or any river, because they imagine that the water would not then nourish the fiilh, nor the earth produce its fruits. The bodies shunt up in these trunks become perfectly dry without rotting, and forming a kind of mummies without the help of embalment.

The baobab is very distinct from the calabash-tree of America, with which it has been confounded by father Labat. See Crescentia.

Culture. This tree is propagated from seeds, which are brought from the countries where they grow naturally. Being natives only of hot climates, the plants will not thrive in the open air in Britain, even in summer. The seeds are therefore to be sown in pots, and plunged into a hot-bed, where they will appear in about six weeks, and in a short time after be fit to transplant. They must then be planted each in a separate pot, in light sandy earth, and plunged into a hot-bed, shading them until they have taken root: after which they should have fresh air admitted every day in warm weather; but must be sparingly watered, as being apt to rot. They grow quickly for two or three years, but afterwards make little progress; the lower part of the stem then begins to swell, and put out lateral branches, inclining to a horizontal position, and covered with a light grey bark. — Some of this kind of plants were raised from seeds obtained from Grand Cairo by Dr William Sherard, in 1724, and were grown to the height of 18 feet; but were all destroyed by the fever which in 1740; after which they were unknown in Britain till the return of Mr Adanson to Paris in 1754.

ADAPTORS, or Adopters. See Chemistry, (India).

ADAR, the name of a Hebrew month, answering to the end of February and beginning of March, the 12th of their sacred, and 6th of their civil year. On the 7th day of it, the Jews keep a fast for the death of Moses; on the 13th, they have the fast of Esther; and on the 14th, they celebrate the fast of Purim, for the deliverance from Haman's conspiracy. — At the lunar year, which the Jews followed in their calculations, is shorter than the solar by about 11 days, which at the end of three years make a month, they then intercalate a 13th month, which they call Veadar, or the fecond Adar.

ADARCE, a kind of concreted salts found on reeds and other vegetables, and applied by the ancients as a remedy in several cutaneous diseases.

ADARCON, in Jewish antiquity, a gold coin mentioned in scripture, worth about 13s. sterling.

ADARME, in commerce, a small weight in Spain, which is also used at Buenos-Aires, and in all Spanish America. It is the 16th part of an ounce, which at Paris is called the demi-gros. But the Spanish ounce is seven per cent. lighter than that of Paris. Stephens renders it in English by a dram.

ADATAIS, ADATIS, or ADATYS, in commerce, a mufin or cotton-cloth, very fine and clear, of which the piece is ten French ells long, and three quarters broad. It comes from the East-Indies; and the finest is made at Bengal.

ACCORDABILIS DECANT, in old law books, signify money paid by the valid to his lord, upon the selling or exchanging of a feud.

ADCRESCENTES, among the Romans, a kind of foildiery, entered in the army, but not yet put on duty; from these the flanging forces were recruited. See Accensi.

ADDA, in geography, a river of Switzerland and Italy, which rises in mount Brusio, in the country of the Grifons, and, passing through the Valteline, traverses the lake Como and the Milanene, and falls into the Po, near Cremona.

ADDEPHAGIA, in medicine, a term used by some physicians, for gluttony, or a voracious appetite. ADDER, in zoology, a name for the Viper. See Coluber.

Adder's-Bolts, or Adder's-bites. See Libellula.

Sea-Adder, the English name of a species of Sphenus. See Lata.

Water-Adder, a name given to the Coluber Naatrix.

Adder's-flung, is used in respect of cattle, when flung with any kind of venomous reptiles, as adders, scorpions, &c. or bit by a hedgehog or shrew. — For the cure of such bites, some use an ointment made of dragon's blood, with a little barley-meal, and the whites of eggs. See Varia-Wart, or Snake-wood. See Polygænum.

ADDEXTOROI, in the court of Rome, the pope's mitre-bearers, focalled, according to Ducange, because they walk at the Pope's right-hand when he rides to visit the churches.

ADDICE, or ADIZE, a kind of crooked ax used by shipwrights, carpenters coopers, &c.

ADJECTI, in antiquity, a kind of slaves, among the Romans, adjudged to serve some creditor whom they could not otherwise satisfy; and whose slaves they became till they could pay or work out of the debt.

ADDICTION, among the Romans, was the making,
Mr Addison's, reported to have up his abroad, particularly by the celebrated Boileau, who is. said to have it, that he would not have written to Mr Dryden, which procured him great reputation from the best judges. This was soon followed by a translation of the Fourth of Virgil, (omitting the fary of Arilidus), much commended by Mr Dryden. He wrote also the Essay on the Geogies, prefixed to Mr Dryden's translation. There are several other pieces written by him about this time; among the rest, one dated the 3rd of April 1694, addrefled to H. S. that is, Dr Sacheverel, who became afterwards fo famous, and with whom Mr Addison lived once in the greatest friendship; but their intimacy was some time after broken off by their disagreement in political principles. In the year 1695, he wrote a poem to king William on one of his campaigns, addrefdel to Sir John Somers lord keeper of the great seal. This gentleman received it with great approbation, took the author into the number of his friends, and bestowed on him many marks of his favour.

Mr Addison had been closely pressed, while at the university, to enter into holy orders; and had once resolved upon it: but his great modesty, his natural diffidence, and an uncommonly delicate sense of the importance of the sacred function, made him afterwards alter his resolution; and having expressed an inclination to travel, he was encouraged thereto by his patron abovementioned, who by his interest procured him from the crown a pension of L.300 per annum to support him in his travels. He accordingly made a tour to Italy in the year 1699; and, in 1701, he wrote a poetical epistle from Italy to the earl of Halifax, which has been universally esteemed as a most excellent performance. It was translated into Italian verse by the abbot Antonio Maria Salvinii, Greek professor at Florence. In the year 1705, he published an account of his travels, dedicated to lord Somers; which, though at first indifferently received, yet in a little time met with its deserved applause.

In the year 1702, he was about to return to England, when he received advice of his being appointed to attend prince Eugene, who then commanded for the emperor in Italy: but the death of king William happening soon after, put an end to this affair as well as his pension; and he remained for a considerable time unemployed. But an unexpected incident at once raised him, and gave him an opportunity of exerting his fine talents to advantage: for in the year 1704, the lord treasurer Godolphin happened to complain to lord Halifax, that the duke of Marlborough's victory at Blenheim had not been celebrated in verse in the manner it deserved; and intimated, that he would take it kindly, if his lordship, who was the known patron of the poets, would name a gentleman capable of doing justice to so elevated a subject. Lord Halifax replied, somewhat hastily, that he did know such a person, but would not mention him; adding, that long had he seen, with indignation, men of no merit maintained in luxury at the public expense, whilst those of real worth and modesty were suffered to languish in obscurity. The treasurer answered very coolly, that he was sorry there should be occasion for such an observation, but that he would do his endeavour to wipe off such reproaches for the
ADD[III]  

Addison.  

the future; and he engaged his honour, that whoever his lordship named, as a person capable of celebrating this victory, should meet with a suitable recompence. Lord Halifax thereupon named Mr Addison; insisting, however, that the treasurer himself should send to him; which he promised. Accordingly he prevailed on Mr Boyle (afterwards Lord Carlton) then chancellor of the exchequer, to make the proposal to Mr Addison; which he did in so polite a manner, that our author readily undertook the task. The lord-treasurer had a sight of the piece, when it was carried no farther than the celebrated fimile of the angel; and was so pleased with it, that he immediately appointed Mr Addison a commissioner of appeals, vacant by the promotion of Mr Locke, chosen one of the lords commissioners for trade. The Campaign is addressed to the Duke of Marlborough; it gives a short view of the military transactions in 1704, and contains a noble description of the two great actions at Schellemberg and Blenheim. In 1705, he attended Lord Halifax to Hanover; and the year following was appointed under-secretary to Sir Charles Hedges, secretary of state; in which office he acquired himself so well, that the earl of Sunderland, who succeeded Sir Charles in December, continued Mr Addison in his employment. 

A taste for opera begins at this time to prevail in England, and many persons having solicited Mr Addison to write one, he complied with their request, and composed his Rosamond. This, however, whether from the defect of the music, or from the prejudices in favour of the Italian taste, did not succeed upon the stage; but the poetry of it has, and always will, justly abound. About this time, Sir Richard Steele composed his comedy of the Tender Husband, to which Mr Addison wrote a prologue. Sir Richard surprized him with a dedication of this play, and acquainted the public, that he was indebted to him for some of the most excellent strokes in the performance. The marquis of Wharton, being appointed lord lieutenant of Ireland in 1709, took Mr Addison with him as his secretary. Her majesty also made him keeper of the records of Ireland, and, as a father mark of her favour, considerably augmented the salary annexed to that place. Whilst he was in this kingdom, the Tatler was first published; and he discovered his friend Sir Richard Steele to be the author, by an observation on Virgil, which he had communicated to him. He afterwards affiicted considerably in carrying on this paper, which the author acknowledges. The Tatler being laid down, the Spectator was left on foot. Mr Addison furnished great part of the most admired papers. The Spectator made its first appearance in March 1711, and was brought to a conclusion in September 1712. 

His celebrated Cato appeared in 1713. He formed the design of a tragedy upon his subject when he was very young, and wrote it when on his travels; he retouched it in England, without any intention of bringing it on the stage; but his friends being persuaded it would serve the cause of liberty, he was prevailed on by their solicitations, and it was accordingly exhibited on the theatre, with a prologue by Mr Pope, and an epilogue by Dr Garth. It was received with the most uncommon applause, having run thirty-five nights without interruption. The Whigs applauded every line in which liberty was mentioned, as a satire on the Tories; and the Tories echoed every clap, to show that the satire was unfelt. When it was printed, notice was given that the Queen would be pleased if it was dedicated to her; "but as he had designed that compliment elsewhere, he found himself obliged," says Tickell, "by his duty on the one hand, and his honour on the other, to send it into the world without any dedication." It was no less esteemed abroad, having been translated into French, Italian, and German; and it was acted at Leghorn, and several other places, with vast applause. The Jefuits of St Omers made a Latin version of it, and the students acted it with great magnificence.

About this time, another paper called the Guardian was published by Steele, to which Addison was a principal contributor. It was a continuation of the Spectator, and was distinguished by the same elegance and the same variety; but, in consequence of Steele's propensity to politics, was abruptly discontinued in order to write the Englishman.

The papers of Addison are marked in the Spectator by one of the letters in the name of Gite, and in the Guardian by a Hand. Many of these papers were written with powers truly comic, with nice discrimination of characters, and accurate observation of natural or accidental deviations from propriety; but it was not supposed that he had tried a comedy on the stage, till Steele, after his death, declared him the author of "The Drummer." This, however, he did not know to be true by any cogent testimony; for when Addison put the play into his hands, he only told him it was the work of a gentleman in the company; and when it was received, as is confessed, with cold disapprobation, he was probably less willing to claim it. Tickell omitted it in his collection; but the testimony of Steele, and the total silence of any other claimant, has determined the public to ascribe it to Addison, and it is now printed with his other poetry. Steele carried "The Drummer" to the playhouse, and afterwards to the press, and sold the copy for 50 guineas. To Steele's opinion may be added the proof supplied by the play itself, of which the characters are such as Addison would have delineated, and the tendency such as Addison would have promoted.

It is said that Mr Addison intended to have composed an English dictionary upon the plan of the Italian (Della Crusca); but, upon, the death of the queen being appointed secretary to the lords justices, he had not leisure to carry on such a work. When the earl of Sunderland was appointed lord lieutenant of Ireland, Mr Addison was again made secretary for the affairs of that kingdom; and upon the earl's being removed from the lieutenantcy, he was chosen one of the lords of trade.

Not long afterwards an attempt was made to revive the Spectator, at a time indeed by no means favourable to literature, when the succession of a new family to the throne filled the nation with anxiety, discord, and confusion; and either the turbulence of the times or the fatigue of the readers put a stop to the publication, after an experiment of 80 numbers, which were afterwards collected into an eighth volume, perhaps more valuable than any of those that went before it: Addison produced more than a fourth part.
In 1715, he began the Freetholder, a political paper, which was much admired, and proved of great use at that juncture. He published also, about this time, verses to Sir Godfrey Kneller upon the king's picture, and some to the princess of Wales with the tragedy of Cato.

Before the arrival of king George he was made secretary to the regency, and was required by his office to send notice to Hanover that the queen was dead, and that the throne was vacant. To do this would not have been difficult to any man but Addison, who was so overwhelmed with the greatness of the event, and so distracted by choice of expression, that the lords, who could not wait for the niceties of criticism, called Mr Southwell, a clerk in the house, and ordered him to dispatch the message. Southwell readily told what was necessary, in the common style of business, and valued himself upon having done what was too hard for Addison.

In 1716, he married the countess dowager of Warwick, whom he had solicited by a very long and anxious courtship. He is said to have first known her by becoming tutor to her son. The marriage, if uncontradicted report can be credited, made no addition to his happiness; it neither found them nor made them equal. She always remembered her own rank, and thought herself entitled to treat with very little ceremony the tutor of her son. It is certain that Addison has left behind him no encouragement for ambitious love. The year after, 1717, he rose to his highest elevation, being made secretary of state; but is represented as having proved unequal to the duties of his place. In the house of commons he could not speak, and therefore was useless to the defence of the government. In the office he could not infuse an order without losing his time in quelling of fine expressions. At last, finding by experience his own inability for public business, he was forced to solicit his discharge, with a pension of 1500l. a-year. Such was the account of those who were inclined to detract from his abilities; but by others his relinquishment was attributed to declining health, and the necessity of reces and quiet.

In his retirement, he applied himself to a religious work*, which he had begun long before; part of which, scarce finished, has been printed in his works.

He intended also to have given an English paraphrase of some of David's psalms. But his ailments increased, and cut short his designs. He had for some time been oppressed by an arithmetical disorder, which was now aggravated by a dropsey, and he prepared to die conformably to his precepts and professions. He sent, as Pope relates, a message by the earl of Warwick to Mr Gay, desiring to see him: Gay, who had not visited him for some time before, obeyed the summons, and found himself received with great kindnefs. The purpose for which the interview had been solicited was then discovered: Addison told him, that he had injured him; but that if he recovered, he would recom pense him. What the injury was he did not explain, nor did Gay ever know; but supposed that some preference design ed for him had by Addison's intervention been withheld. Another death-bed interview, of a more solemn nature, is recorded: Lord Warwick was a young man of very irregular life, and perhaps of loose opinions. Addison, for whom he did not want respect, had very diligently endeavoured to reclaim him; but his arguments and expostulations had no effect: One experiment, however, remained to be tried. When he found his life near its end, he directed the young lord to be called: and when he desired, with great tendernefs, to hear his last injunctions, told him, "I have sent for you that 'you may see how a Christian can die.' What effect this awful scene had on the earl's behaviour is not known: he died himself in a short time. Having given directions to Mr Tickell for the publication of his works, and dedicated them on his death-bed to his friend Mr Craggs, he died June 17, 1719, at Holland-house, leaving no child but a daughter who is still living.

Addison's course of life before his marriage has been detailed by Pope. He had in the house with him Budgell, and perhaps Philips. His chief companions were Steele, Budgell, Philips, Carey, Davenant, and Colonel Brett. With one or other of these he always breakfasted. He studied all morning; then dined at a tavern, and went afterwards to Button's. From the coffeehoufe he went again to the tavern, where he often sat late, and drank too much wine.

Dr Johnfon, in delineating the charactcr of Addison, observes that Tickell, that he employed wit on the side of virtue and religion. He not only made the proper use of wit himself, but taught it to others; and from his time it has been generally subservient to the cause of reason and truth. He has dissipated the prejudice that had long connected gaiety with vice, and easiness of manners with laxity of principles. He has restored virtue to its dignity, and taught innocence not to be ashamed. This is an elevation of literary character, "above all Greek, above all Roman fame." No greater felicity can genius attain than that of having purified intellectual pleasure, separated mirth from indecency, and wit from licentiousness; of having taught a succession of writers to bring elegance and gaiety to the aid of goodnefs; and, to use expressions yet more awful, of having "turned many to righteousness, ore outf chromium nature," or rafters merriment or wonder by the violation of truth. His figures neither divert by distortion, nor amaze by aggravation. He copies life with so much fidelity, that he can be hardly said to invent; yet his exhibitions have an air so much original, that it is difficult to suppose them not merely the product of imagination. As a teacher of wisdom he may be confidently followed. His religion has nothing in it enthusiastic or supercilious; he appears neither weakly credulous nor wantonly sceptical; his morality is neither dangerously lax nor impractically rigid. All the enchantment of fancy and all the cogency of argument are employed to recommend to the reader his real interest, the care of pleasing the Author of his being. Truth is shown sometimes as the phantom of a vision, sometimes as the allegory of an attribute; sometimes it attracts regard in the robes of fancy, and sometimes it is the only foundation in the confidence of reason: She wears a thousand dresses, and in all is pleasing.
The Doctor, however, has related the following anecdote, which every admirer of Addison, every man of feeling, must be reluctant to believe. — Steele (says the Doctor), whose imprudence of generosity, kept him almost invariably некедитов, upon some preling exigence, in an evil hour, borrowed an hundred pounds of his friend, probably without much purpose of repayment; but Addison, who seems to have had other notions of a hundred pounds, grew impatient of delay, and reclaimed his loan by an execution. Steele felt, with great sensibility, the obduracy of his creditor; but with emotions of sorrow rather than of anger. It is much to be wished, says Dr Kippis, that Dr Johnson had produced his authority for this narration. It is very possible, that it may be only a story the Doctor had somewhere heard in conversation, and which is entirely groundless: "and this I am the rather inclined to believe, as I have been assured by one of the most respectable characters in the kingdom; that the fact hath no foundation in truth." Mr Potter, in a late publication, hath informed us, that he is told by the best authority, that the story is an absolute falsehood.

Mr Tycers, in "An historical Essay on Mr Addison," printed, but not published, has mentioned some facts concerning him, with which we were not before acquainted. These are, That he was laid out for dead as soon as he was born: that, when he addressed his verses on the English poets to Henry Sacheverell, he courted that gentleman's sister; that, whenever Jacob Tonson came to him for the Spectator, Bayle's French Historical and Critical Dictionary lay always open before him; that, upon his return to England, after his travels, he discharged some old debts he had contracted at Oxford, with the generosity of good interest; that he was put into pleasant circumstances by the death of a brother in the East Indies; that, having received encouragement from a married lady, he had the industry to refill the temptation: that he refused a gratification of a three hundred pounds bank-note, and afterwards of a diamond ring of the same value, from a Major Dunbar, whom he had endeavoured to serve in Ireland by his interest with Lord Sunderland; and that his daughter by lady Warwick is still alive and unmarried, residing at Bilton near Rugby, and poffelling an income of more than twelve hundred a-year.

The following letter, which probably relates to the cafe of Major Dunbar, reflects great honour on Mr Addison's integrity. "June 26. 1715. Sir, I find there is a very strong opposition formed against you; but I shall wait on my lord lieutenant this morning, and lay your cause before him as advantageously as I can, if he is not engaged in other company. I am afraid what you say of his grace does not portend you any good. And now, Sir, believe me, when I affure you I never did, nor ever will, on any pretence whatsoever, take more than the flated and customary fees of my office. I might keep the contrary practice concealed from the world, were I capable of it, but I could not from myself; and I hope I shall always fear the reproaches of my own heart more than those of all mankind. In the mean time, if I can serve a gentleman of merit, and such a character as you have in the world, the satisfaction I meet with on such an occasion is always sufficient, and the only reward to, Sir, your most obedient, humble servant, ADDISON." — The following was told by the late Dr Birch. Addison and Mr Temple Stan­ yan were very intimate. "In the familiar conversations which passed between them, they were accustomed freely to dispute each other's opinions. Upon some occasion, Mr Addison lent Stanyan five hundred pounds. After this, Mr Stanyan behaved with a timid reserve, deference, and respect; not conversing with the same freedom as formerly, or canvassing his friend's sentiments. This gave great uneasiness to Mr Addison. One day, they happened to fall upon a subject on which Mr Stanyan had always been used strenuously to oppose his opinion. But, even upon this occasion, he gave way to what his friend advanced, without interposing his own view of the matter. This hurt Mr Addison so much, that he said to Mr Stanyan, "Either contradict me, or pay me the money.""

In Tickell's edition of Mr Addison's works there are several pieces hitherto unmentioned, viz. The Diff­ eration on Medals; which, though not published till after his death, yet he had collected the materials, and began to put them in order, at Vienna, in 1702. A pamphlet, intitled, The present State of the War, and the Necessity of an Augmentation, considered. The late Trial and Conviction of Count Tariff. The Whig Examiner came out on the 14th of September 1716; there were five of these papers attributed to Mr Addison, and they are the several pieces he ever wrote. He is said also to have been the author of a performance intitled Diferentiae de inexpectis Romanorum Poesis, and of a Discourse on Ancient and Modern learning.

ADDITIONAL, something added to another. Thus physicians call the ingredients added to a medicine already compounded, *additaments*. ADDITION, is the joining together or uniting two or more things, or augmenting a thing by the accession of others thereto. ADDITIONS, in ARITHMETIC, ALGEBRA, &c. See these articles.

ADDITION, in music, a dot marked on the right side of a note, signifying that it is to be founded or lengthened half as much more as it would have been without such mark.

ADDITION, in law, is that name or title which is given to a man over and above his proper name and surname, to shew what estate, degree, or mystery he is of and of what town, village, or country.

ADDITONS of Estate, of Quality, are, Yeoman, Gentle­man, Esquire, and such like.

ADDITONS of Degree, are those we call names of dignity; as Knight, Lord, Earl, Marquis, and Duke.

ADDITONS of Place, are, of Thorn, of Dale, of Woodstock. — Where a man hath household in two places, he shall be said to dwell in both; so that his addition in either may suffice. Knave was a locally a regular addition. By Stat. 1. Hen. V. cap. 5. it was ordained, that in such suits or actions where proofs of outlawry lies, such addition should be made to the name of the defendant, to show his estate, mystery, and place where he dwells; and that the writ not havi
ADELME, or ALDHEL, son to Kenred, nephew to Ina king of the West Saxons: after having been educated abroad, was abbot of Malmby 30 years. He was the first Englishman who wrote in Latin, the first who brought poetry into England, and the first bishop of Sherburn. He lived in great esteem till his death, which happened in 709. He was canonized, and many miracles were told of him. He is mentioned with great honour by Camden and Bayle, and his life was written by William of Malmbury.

ADELPHIANI, in church-history, a sect of ancient heretics, who fasted always on Sundays.

ADELSCALC, in ancient customs, denotes a servant of the king. The word is also written adeliscalchu, and adelascalchu. It is compounded of the German adel, noble, and scal, a servent, a slave, a servant. Among the Bavarians, adelascales appear to have been the name with royal thanes among the Saxons, and those called miniatri regis in ancient charters.

ADEMPTION, in the civil law, implies the revocation of a grant, donation, or the like.

ADEN, formerly a rich and considerable town of Arabia the Happy. It is seated by the sea-side, a little eastward of the straits of Babelmandel.

ADENANTHERA, BASTARD FLOWER-FENCE, a genus of the monogyne order, belonging to the candelaria class of plants. In the natural method, it belongs to the 31st order. Lomentoeae. The characters are: The calyx is a perianthium consisting of one very small five-toothed leaf. The corolla consists of five bell-shaped lanceolate sessile petals, convex within and concave under. The flamina has ten erect filaments shorter than the corolla; the antherae are roundish, incumbent, bearing a globular gland on the exterior top. The pistillum has a long gibbous stem, the stylus filibrated the length of the flamina; the stigma simple. The pericarpium is a long compressed membranaceous legumen. The seeds are very numerous, roundish, and remote. Only one species of this plant is known in Britain: but there is a variety, with scarlet seeds; which, however, is rare, and grows very slowly. It is a native of India, and rife to a considerable height. It is as large as the tamarind tree; spreads its branches wide on every side, and makes a fine shade; for which reason, it is frequently planted by the inhabitants in their gardens, or near their habitations. The leaves of this tree are doubly winged, the flowers of a yellow colour, and dispoised in a long bunch. These are succeeded by long twisted membranaceous pods, including several hard compressed seeds, of a beautiful scarlet, or shining black colour. This plant must be raised in a hot-bed, and kept during the winter in a close. 

ADENBURG, or ADENSBURG, a town of Westphalia, and in the duchy of Burg, subject to the Elector Palatine. It is 12 miles N. E. of Cologne, and 17 W. of Bonn: E. Long. 7. 25. Lat. 51. 2.

ADENOGRAPHY, that part of anatomy which treats of the glandular parts. See Anatomy.
ADHESION, in a general sense, implies the sticking or adhering of bodies together.

ADHSION, in philosophy. See Cohesion.

ADHESION, in anatomy, a term for one part sticking to another, which in a natural state are separate. For the most part, if any of those parts in the thorax or belly lie in contact, and inflame, they grow together. The lungs very frequently adhere to the pleura.

ADHIL, in astronomy, a star of the sixth magnitude, upon the garment of Andromeda, under the last star in her foot.

ADHOA, in ancient customs, denotes what we other wise call relief. In which sense we sometimes also find the word written adoba, admissions, adhognement.

ADIANTHUM, maiden-hair; a genus of the order of filices, belonging to the cryptogamia class of plants. The fructifications are collected in oval spots under the reflected tops of the fronds.

Species. Of this genus botanical writers enumerate fifteen species; the most remarkable are the following.

1. The capillus veneris, or true maiden-hair, is a native of the southern parts of France, from whence it is brought to Britain; though it is likewise said to grow plentifully in Cornwall, and the Trichomanes has been almost universally substituted for it. 2. The pedatum, or American maiden-hair, is a native of Canada; and grows in such quantities, that the French send it from thence in package for other goods, and the apothecaries of Paris use it for maiden-hair in the compositions wherein that is ordered. 3. The trapeziforme, or black American maiden-hair, is a native of Jamaica; and has shining black stalks, and leaves of an odd shape, which make an agreeable variety among other plants, so is sometimes cultivated in gardens.

Culture. The first species grows naturally out of the joints of walls, and fissures of rocks. It ought therefore to be planted in pots filled with gravel and lime-rubbish; where it will thrive much better than in good earth. It must also be sheltered under a frame during the winter.—The second is to be treated in the same manner; but the third will not thrive in Britain, unless kept in a stove during the winter.

Properties. The true maiden-hair has been greatly celebrated in disorders of the breast proceeding from a thinness and acrimony of the juices; and likewise for opening obstructions of the viscera, and promoting the expectoration of tough phlegm. But modern practice pays little regard to it; the asplenium trichomanes, or English maiden-hair, supplying its place. See Asplenium.

ADIAPHORISTS, in church-history, a name importing lukewarmness, given, in the 16th century, to the moderate Lutherans, who embraced the opinions of Melanthon, whose disposition to cloisterism was vastly more pacific than that of Luther.

ADIAPHOROUS, Adiaphorus, a name given by Mr Boyle to a kind of spirit distilled from tartar and some other vegetable bodies; and which is neither acid, vinous, nor urinary; but in many respects different from any other sort of spirit.

ADJAZZO, Adrazzo, or Ajaccio, in geography,
A D J  [116] A D J

debt; or that action by which the holder of an heritage right, labouring under any defect in point of form, may apply that defect. ADJUNCT, among philosophers, signifies something added to another, without being any necessary part of it. Thus water absorbed by cloth or a sponge, is an adjunct, but no necessary part of either of those substances.

ADJUNCT, in metaphysics, some quality belonging to either the body or mind, whether natural or acquired. Thus thinking is an adjunct of the mind, and growth an adjunct of the body.

ADJUNCT, in music, a word which is employed to denominate the connection or relation between the principal mode and the modes of its two-fifths, which, from the intervals that constitute the relation between them and it, are called its adjuncts.

ADJUNCT is also used to signify a colleague, or some person associated with another as an assistant.

ADJUNCTS, or Adjuncts of the Gods, among the Romans, were a kind of inferior deities, added as assistants to the principal ones, to cave them in their functions. Thus, to Mars was adjointed Bellona and Nemesis; to Neptune, Salacia; to Vulcan, the Cabi- ri; to the Good Genius, the Lares; to the Evil, the Lemures, &c.

ADJUNCTS, in rhetoric and grammar, signify certain words or things added to others, to amplify or augment the force of the discourse.

ADJUNCTS, or Adjoints, in the royal academy of sciences at Paris, denote a class of members, attached to the pursuit of particular sciences. The class of Adjuncts was created in 1716, in lieu of the Eleves; they are twelve in number; two for geometry, two for mechanics, two for astronomy, two for anatomy, two for chemistry, and two for botany. The Eleves not taken into this establishment were admitted on the foot of supernumerary Adjuncts.

ADJUTANT, in the military art, is an officer whose business it is to assist the major. Each battalion of foot and regiment of horse has an adjutant, who receives the orders every night from the brigade-major; which, after carrying them to the colonel, he delivers out to the serjeants. When detachments are to be made, he gives the number to be furnished by each company or troop, andassigns the hour, and place of rendezvous. He also places the guards; receives, and distributes the ammunition to the companies, &c.; and, by the major's orders, regulates the prices of bread, beer, and other provisions. The word is sometimes used by the French for an aide-du-camp.

ADJUTANTS-general, among the Jeluits, a select number of fathers, who resided with the general of the order, each of whom had a province or country assigned him, as England, Holland, &c. and their business was to inform the father-general of state-occurrences in such countries. To this end they had their correspondents delegated, emissaries, visitors, regents, provincials, &c.

ADJUTORIUM, a term used by physicians for any medicine in a prescription but the capital one.

ADLE-EGGS, such as have not received an impregnation from the semen of the cock.

ADLEGATION, in the public law of the German empire, a right claimed by the states of the empire of
ADMIRABILIS SAT, the same with GLAUBER'S. See CHEMISTRY, No. 124.

ADMIRAL, a great officer or magistrate, who has the government of a navy, and the hearing of all marine causes.

Authors are divided with regard to the origin and denomination of this important officer, whom we find established in most kingdoms that border on the sea. But the most probable opinion is that of Sir Henry Spelman, who thinks, that both the name and dignity were derived from the Saracens, and, by reason of the holy wars, brought into Europe; for admiral, in the Arabian language, signifies a prince, or chief ruler, and was the ordinary title of the governors of cities, provinces, &c. and therefore they called the commander of the navy by that name, as a name of dignity and honour. And indeed there are no instances of admirals in any part of Europe before the year 1284, when Philip of France, who had attended St. Lewis in the wars against the Saracens, created an admiral. Du Cange affirms us, that the Sicilians were the first, and the Genoese the next, who gave the denomination of Admiral to the commanders of their naval armaments; and that they took it from the Saracen or Arabic Emir, a general name for every commanding officer. As for the exact time when the word was introduced in England, it is uncertain; some think it was in the reign of Edward I.,

which have leave to trade along that coast, are obliged to unload here, paying 13 per cent. of the price they sell for, if the cargo be entire, and even 16 per cent. if otherwise; besides which, they pay 3 per 1000, duty, for consulship and some other small royal rights and claims.

ADMINISTRATOR, in law, he to whom the ordinary commits the administration of the goods of a person deceased, in default of an executor. An action lies for, or against an administrator, as for, or against an executor; and he shall be accountable to the value of the goods of the deceased, and no farther—unless there be waste, or other abuse chargeable on him. If the administrator die, his executors are not administrators; but the court is to grant a new administration.

If a stranger, who is neither administrator nor executor, takes the goods of the deceased, and administers, he shall be charged, and sued as an executor, nor as an administrator. The origin of administrators is derived from the civil law. Their establishment in England is owing to a statute made in the 31st year of Edw. III. Till then, no office of this kind was known beside that of executor; in case of a want of which, the ordinary had the disposal of goods of persons intestate, &c.

ADMINISTRATOR, in Scots law, a person legally empowered to act for another whom the law presumes incapable of acting for himself. Thus tutors or curators are sometimes styled administrators in law to pupils, minors, or fatusous persons. But more generally the term is used to imply that power which is conferred by the law upon a father over the persons and estates of his children during their minority. See LAW, No. 124.

ADMINISTRATOR is sometimes used for the president of a province; for a person appointed to receive, manage, and distribute, the revenues of an hospital or religious house; for a prince who enjoys the revenues of a secularized bishopric; and for the regent of a kingdom during a minority of the prince, or a vacancy of the throne.

ADMINISTRATOR, in law, the right of offending or being offended, in matters of direction, which relate to the empire in general. In which sense adilegation differs from legation, which is the right of sending ambassadors on a person's own account. Several princes and states of the empire enjoy the right of legation, who have not that of adilegation, and vice versa. The bishops, for instance, have the right of adilegation in the treaties which concern the common interest, but no right of legation for their own private affairs. The like had the duke of Mantua.

The emperor allows the princes of Germany the privilege of legation, but disputes that of adilegation. They challenge it as belonging to them juris regis, which they enjoy in common with the emperor himself.

ADLOCUTION, adlocutio, in antiquity, is chiefly understood of speeches made by Roman generals to their armies, to encourage them before a battle. We frequently find these adlocutions expressed on medals by the abbreviation adlocut. coh. —This general is sometimes represented as seated on a tribunal, often on a hill or mount of turf, with the cohorts ranged orderly round him, in manipuli et turmae. The usual formula in adlocutions was, Fortis eft et fideli.

ADMANUENSES, in ancient law books, denote persons who swore by laying their hands on the book.

—in which sense, admanuentis is the same to the law with laymen; and stands opposed to clerks, who were forbidden to swear on the book, their word being to be reputed as their oath; whereas they were also denominated fideli digni.

ADMEASUREMENT, admeasureatio, in law, a writ which lies for the bringing thofe to reason, or multifcription, as they usurp more of any thing than their share. This writ lies in two cases; termed

ADMEASUREMENT of Dower. Admeasureatio dotis, where the widow of the deceased holds more from the heir, or his guardian, on account of her dower, than of right belongs to her. And,

ADMEASUREMENT of Pasture, Admeasureatio pasturae; this lies between thoé who have common of pastures appendant to their freehold, or common by vicinage, in case any of them forcharge the common with more cattle than they ought.

ADMINICLLE, a term used chiefly in old law-books, to imply an aid, help, alidance, or support. The word is Latin, adinicionem; and derived from ad minister, to prop or support.

ADMINICLLE, in Scots law, signifies any writing or deed referred to by a party in an action of law, for proving his allegations.

ADMINICULATOR, an ancient officer of the church, whose business it was to attend to and defend the cause of the widows, orphans, and others deficient of help.

ADMINISTRATION, in general, the government, direction, or management of affairs, and particularly the exercise of distributive justice; among ecclesiastics, it is often used to express the giving or dispensing of the tithes, &c.

ADMINISTRATION, is also the name given by the Spaniards in Peru to the flape magazine, or warehouse, established at Callao, a small town on the S. Sea, which is the port of Lima, the capital of that part of South America, and particularly of Peru. The foreign ships,
Admiral. Edward I. Sir Henry Spelman is of opinion that it was first used in the reign of Henry III., because neither the laws of Oleron made in 1266, nor bracton, who wrote about that time, make any mention of it; and that the term "admiral" was not used in a charter in the eighth of Henry III., wherein he granted this office to Richard de Lacey, by these words Maritimum Angliae; but in the 56th year of the same reign, not only the historians, but the charters themselves, very frequently use the word "admiral.

Anciently there were generally three or four admirals appointed in the English seas, all of them holding the office durante bene placito: and each of them having particular limits under their charge and government: as admirals of the fleet of ships, from the mouth of the Thames northward, southward, and westward. Besides these, there were admirals of the Cinque Ports, as in the reign of Edward III. when one William Latimer was styled admirals quinque portuum; and we sometimes find that one person has been admiral of the fleet to the southward, northward, and westward: but the title of admiral of England was not frequent till the reign of Henry IV. when the king's brother had that title given him, which in all commissions afterwards was granted to the succeeding admirals. It may be observed, that there was a title above that of admiral of England, which was locum-tenens regis super mare, the king's lieutenant general of the seas; this title we find mentioned in the reign of Richard II. Before the use of the word "admiral" was known, the title of etatis maris was made use of.

Lord High Admiral of England, in some ancient records called capitenus maritimorum, an officer of great antiquity and trust, as appears by the laws of Oleron, so denominated from the place they were made at by Richard I. The first title of Admiral of England, expressly conferred upon a subject, was given by patent of Richard II. to Richard Fitz-Allen, jun., earl of Arundel and Surrey; for those who before enjoyed this office were simply termed admirals, though their jurisdiction seems as large, especially in the reign of Edward III. when the court of admiralty was first erected.

This great officer has the management of all maritime affairs, and the government of the royal navy, with power of decision in all maritime cases both civil and criminal: he judges of all things done upon or beyond the seas, in any part of the world; upon the sea-coasts, in all ports and havens, and upon all rivers below the first bridge from the sea. By him, vice-admirals, rear-admirals, and all sea-captains are commissioned: all deputies for particular coasts, and coroners to view dead bodies found on the sea-coasts, or at sea; he also appoints the judges for his court of admiralty, and may imprison, release, &c. All ports and havens are infra corpus comitatus, and the admiral hath no jurisdiction of any thing done in them. Between high and low water mark, the common-law and the high-admiral have jurisdiction by turns, one upon the water, and the other upon the land.

The lord-admiral has power, not only over the seamen serving in his ships of war, but over all other seamen, to arrest them for the service of the state: and if any of them run away, without leave of the admiral, he hath power to make a record thereof, and certify the same to the sheriffs, mayors, bailiffs, &c. who shall cause them to be apprehended and imprisoned.

To the lord high-admiral belong all penalties and amerceements of all transgressions at sea, on the sea-floreat, and ports and havens, and all rivers below the first bridge from the sea; the goods of pirates and felons condemned or enslaved, sea-wrecks, goods floating on the sea, or cast on the shore (not granted to lords of manors adjoining to the sea), and a share of lawful prizes, also great fishes, commonly called royal fishes, except whales and sturgeons: to which add, a salary of 7000l. a year.

In short, this is so great an office, in point of trust, honour, and profit, that it has been usually given to princes of the blood, or the most eminent persons among the nobility. There has been no high admiral for some years; the office being put in commission, or under the administration of the lords commissioners of the admiralty, who by statute have the same power and authority as the lord high admiral.

Lord High Admiral of Scotland, one of the great officers of the crown, and supreme judge in all maritime cases within that part of Britain. See Law, Part III. of Civil.

Admiral, also implies the commander in chief of any single fleet or squadron, or, in general, any flag-officer whatever. The commander of a fleet carries his flag at the main-top-mast head.

Vice Admiral, is the commander of the second squadron, and carries his flag at the fore-top-mast head.

Rear Admiral, is the commander of the third squadron, and carries his flag at the mizen-top-mast head.

Vice Admiral, is also an officer appointed by the lords commissioners of the admiralty. There are several of these officers established in different parts of Great Britain, with judges and martials under them, for executing jurisdiction within their respective limits. Their decrees, however, are not final, an appeal lying to the court of admiralty in London.

Admiral is also an appellation given to the most considerable ships of a fleet of merchant-men, or of the vessels employed in the cod-fishery of Newfoundland. This last has the privilege of choosing what place he pleases on the shore to dry his fish; gives proper orders, and appoints the fishing places to those who come after him; and as long as the fishing season continues, he carries a flag on his main-mast. Admiral, in zoology, the English name of a species of the voluta, a shell-fish belonging to the order of Vermes testacea. See Voluta.

Admiralty properly signifies the office of lord high-admiral, whether discharged by one single person, or by joint commissioners called lords of the admiralty.

Court of Admiralty, is a sovereign court, held by the lord high-admiral, or lords of the admiralty, where cognizance is taken in all maritime affairs, whether civil or criminal. All crimes committed on the high-seas, or on the great rivers below the first bridge next the sea, are cognizable in this court only, and before which they must be tried by judge and jury. But in civil causes the mode is different, the decisions being all made according to the civil law. From the sentences of the admiralty-judge an appeal always lay, in ordinary course, to the king in chancery, as might be collected from statute 25 Hen. VIII. c. 19. which directs the appeal from the archbishop's courts to be determined by persons named in the king's commission, like as in
Admiration "cafe of appeal from the admirals-court." But this is also expressly declared by statute 8 Eliz. ed 5, which enacts, that upon an appeal made to the chancery, the sentence definitive of the delegates appointed by commission shall be final.

Appeals from the vice-admiralty courts in America, and other plantations and settlements, may be brought before the courts of admiralty in England, as being a branch of the admiral's jurisdiction, tho' they may also be brought before the king in council. But in case of prize vessels, taken in time of war, in any part of the world, and condemned in any courts of admiralty or vice-admiralty as lawful prize, the appeal lies to certain commissioners of appeals constituting chiefly of the privy council, and not to judges delegates. And this by virtue of divers treaties with foreign nations, by which particular courts are established in all the maritime countries of Europe for the decision of this question, whether lawful prize or not? for this being a question of subjects of different states, it belongs entirely to the law of nations, and not to the municipal laws of either country, to determine it.

Court of Admiration in Scotland. See Law, Part III. No. 15.

Admiration Islands, lie in about 2° 18'. S. Lat. and 16° 44'. E. long. There are between 20 and 30 islands said to be scattered about here, one of which alone would make a large kingdom. Captain Carteret, who first discovered them, was prevented touching at them, although their appearance was very inviting, on account of the condition of his ship, and of his being entirely unprovided with the articles of barter which suit an Indian trade. He describes them as clothed with a beautiful vegetation of woods, lofty and luxuriant, interspersed with spots that have been cleared for plantations, groves of cocoa nut-trees, and houfes of the natives, who seem to be very numerous. The largest of these islands is 18 leagues long in the direction of east and west. The discoverer thinks it highly probable that these islands produce several valuable articles of trade, particularly spices, as they lie in the same climate and latitude as the Moluccas.

Admonition, in ecclesiastical affairs, a part of discipline much used in the ancient church. It was the first act or step towards the punishment or expiation of delinquents. In case of public offences, it was performed according to the evangelical rule, privately, in case of public offence, openly, before the church. If either of those sufficed for the recovery of the fallen person, all further proceedings in the way of confession ceased: if they did not, recourse was had to excommunication.

Adonitio Filiation, among the Romans, a military punishment, not unlike our whipping, only it was performed with viole-branches.

Adorations, in the feudal customs, the reduction of the property of lands or tenements to mortmain. See Mostmain.

Adnata, in anatomy, one of the costs of the eye, which is also called conjunctiva and albuginea.

Adnata, is also used for any hair, wool, or the like, which grows upon animals or vegetables.

Adnata, or insecuta, among gardeners, denote those off-sents, which, by a new germination under the earth, proceed from the lily, narcissus, hyacinth, and, other flowers, and afterwards grow to true roots. The French call them caudex, "stalks."

ADNOUN, is used by some grammarians to express what we more usually call an Adjective. The word is formed by way of analogy to adverb; in regard adjectives have much the same office and relation to nouns as adverbs have to verbs. Bishop Wilkins uses the word adnans in another sense, viz. for what we otherwise call a preposition.

ADOLESCENCE, the state of growing youth; or that period of a person's age commencing from his infancy, and terminating at his full stature or manhood. The word is formed of the Latin adolescent, to grow. — The state of adolescence lasts so long as the fibres continue to grow, either in magnitude or firmness. The fibres being arrived at the degree of firmness and tension sufficient to sustain the parts, no longer yield or give way to the efforts of the nutritious matter to extend them; so that their further accretion is stopped, from the very law of their nutrition. Adolescence is commonly computed to be between 15 and 25, or even 30 years of age; though in different constitutions its terms are very different. — The Romans usually reckoned it from 12 to 25 in boys; and to 21 in girls, &c. And yet, among their writers, juvenis and adolecentis are frequently used indifferently for any person under 45 years.

ADOLLAM, or ODOLLAM (anc. geog.), a town in the tribe of Judah, to the east of Eleutheropolis. David is said to have hid himself in a cave near this town. (Bible.)

ADON, a populous village in the province of Stuhl-Weiltemberg, belonging to Hungary. It lies in a fruitful country, towards the river Danube. Long. 49° 20'. Lat. 47° 30'.

ADONIA, one of the names of the Supreme Being, in the scriptures. The proper meaning of the word is my lord, in the plural number; as Adon in my lord, in the singular. The Jews, who either out of respect or superstition, do not pronounce the name of Jehovah, read Adonai in the room of it, as often as they meet with Jehovah in the Hebrew text. But the ancient Jews were not so superstitious; nor is there any law which forbids them to pronounce the name of God. Calmet.

ADONIA, in antiquity, solemn feasts in honour of Venus, and in memory of her beloved Adonis. The Adonia were observed with great solemnity by most nations; Greeks, Phoenicians, Lyceans, Syrians, Egyptians, &c. From Syria, they are supposed to have passed into India. The prophet Ezekiel is understood to speak of them. They were still observed at Alexandria in the time of St Cyril; and at Antioch in that of Julian the apostate, who happened to enter that city during the solemnity, which was taken for an ill omen. The Adonia lasted two days: on the first of which certain images of Venus and Adonis were carried, with all the pomp and ceremonies practised at funerals; the women wept, tore their hair, beat their breasts, &c. imitating the cries and lamentations of Venus for the death of her paramour. This lamentation they called Adonias. The Syrians were not contented with weeping, but gave themselves discipline, shaved their heads, &c. Among the Egyptians, the queen herself used to carry the image of Adonis in procession. St. Cyril mentions an extraordinary ceremony practised by the Alexandrians: A letter was written to the women of Byblus, to inform them that...
Adonids. Adonis was found again: this letter was thrown into the sea, which (it was pretended) did not fail punctually to convey it to Byblus in seven days; upon the receipt of it by a train of anniversaries, consisting for pleasure than profit.

Adonis, son to Cinyras king of Cyprus, the darling of the god Venus: being killed by a wild boar in the Idaian woods, he was turned into a flower. Venus was inconsolable; and no grief was ever more celebrated than this, most nations having perpetuated the memory of it by a train of anniversaries. Among Shakespeare's poems, is a long one on the subject of Venus's affection for Adonis.

The text of the vulgate in Ezekiel, viii. 14. says, that this prophet saw women sitting in the temple, and weeping for Adonis; but according to the reading of the Hebrew text, they are said to weep for Tammuz, or the hidden one. Among the Egyptians, Adonis was adored under the name of Osiris the husband of Isis. But he was sometimes called by the name of Ammuz, or Tammuz, the concealed, to denote probably his death or burial. The Hebrews, in derision, call him sometimes the dead. Psal. civ. 28. and Lev. xix. 28. because they wept for him, and represented him as one dead in his coffin: and at other times, they called him the image of jealousy, Ezek. viii. 3. 5. because he was the object of the god Mars's jealousy. The Syrians, Phoenicians, and Cyprians called him Adonis, and P. Calmet is of opinion, that the Ammonites and Moabites gave him the name of Baal-peor. See Baal-peor.

Adonis, Adonis, (anc. geog.): a river of Phoenicia, rising in Mount Lebanon, and falling into the sea, after a north-west course, at Byblus: famous in fable, as a beautiful shepherds youth, (Virgil;) son of Cynaras, king of the Cyprians, loved by Venus, slain by a boar, and turned into a river. Theoricius lamented him dead in an idyllion, or rather ode, as did the women yearly, when in flood time, the river rolled down a red earth, which tinged its waters, deemed to be his wound bleeding afresh. In the Phcenician language Adan signifies a willow, and Adon lord, with the same radical letters. Hence teares Adonis, Salignus, and Adonios, or Adonis, for Adon. Adonis's horti, are gardens beautifully arranged, but more adapted for pleasure than profit.

Adonis, Birds-eye, or Phasianus-eye: a genus of the polyandria order, belonging to the polygynia class of plants. It is allied with the Multiflorae, or 26th Nat. Order. The characters are: The calyx is a perianthium, consisting of five oblong concave leaves, somewhat coloured, and deciduous. The corolla has from five to fifteen oblong petals obtuse and glossy. The pistillum consists of very numerous, short, tabulated filaments; the antherae are oblong and intus-serrulata. The Acontium has a long, straight, pointed head; no o; li; the dimidiate acute and reticulata. There is no pericarpium; the receptacle is oblong and spiked. The seeds are numerous, irregular, angular, gibbous at the base, reticulate at the top, somewhat prominent, and awl-shaped.

Species. The most remarkable species are the following: 1. The annus, or common adonis, is a native of Kent, where it is found in great plenty in the fields sown with wheat. Its flowers are of a beautiful scarlet colour, and appear in the beginning of June; the seeds ripening in August and September. Great quantities of these flowers are sold in London, under the name of Red Morocco. 2. The calcis, or annual adonis, with yellow flowers, grows much taller than the first, has its leaves thinner set, and of a lighter colour. 3. The vermis, or perennial adonis, grows naturally on the mountains of Bohemia, Prussia, and other parts of Germany. It flowers the latter end of March, or beginning of April; the stalks rise about a foot and a half high; and when the roots are large, and have flower unremoverd for some years, they will put out a great number of stalks from each root; on the top of each of these grows one large yellow flower. 4. The acontium, is a native of Siberia and the Appenines. Culture. The first two species, being annual, must be propagated from seeds, which ought to be sown in autumn, soon after they are ripe, or they will be in danger of not growing up that year. They thrive best in a light soil. The third and fourth species are likewise to be propagated from seeds, which must be sown in autumn, or they seldom succeed. When the plants come up, they must be carefully kept clear of weeds; and in very dry weather their growth will be promoted by being now and then watered. They should remain in the place where they are sown till the second year; and be transplanted thence in autumn, to the place where they are to remain.

Adonists, a sect or party, among Divines and Critics, who maintain, that the Hebrew points ordinarily annexed to the consonants of the word Jehovah, are not the natural points belonging to that word, nor express the true pronunciation of it; but are the vowel-points, belonging to the words Adonai and Elohim, applied to the consonants of the ineffable name Jehovah; to warn the readers, that instead of the word Jehovah, which the Jews were forbid to pronounce, and the true pronunciation of which had been long unknown to them, they are always to read Adonai. They are opposed to Jehovah: of whom the principal are Drufuris, Capellus, Buexfor, Alting, and Reland, who has published a collection of their writings on this subject.

Adoptianism, in church history, a sect of ancient heretics, followers of Felix of Urgel, and Elipand of Toledo, who, towards the end of the eighth century, advanced the notion, that Jesus Christ, in his human nature, is the Son of God, not by nature, but by adoption. Adoption, an act by which any one takes another into his family, owns him for his son, and appoints him for his heir.

The custom of adoption was very common among the ancient Greeks and Romans: yet it was not practiced.
Adoption was a sort of imitation of nature, intended for the comfort of those who had no children; wherefore he that was to adopt was to have no children of his own, and to be past the age of getting any; nor were enunuchs allowed to adopt, as being under an actual impotency of begetting children: neither was it lawful for a young man to adopt an elder, because that would have been contrary to the order of nature; nay, it was even required that the person who adopted should be eighteen years older than his adopted son, that there might at least appear a probability of his being the natural father.

Among the Greeks it was called φιλότητα, filiation. It was allowed to such as had no issue of their own; excepting those who were not κοινογενείοι, their own near kinsmen, e.g. slaves, women, madmen, infants, or persons under twenty years of age; who being incapable of making wills, or managing their own estates, were not allowed to adopt heirs to them. foreigners being incapable of inheriting in Athens, if any such were adopted, it was necessary first to make them free of the city. The ceremony of adoption being over, the adopted had his name enrolled in the tribe and ward of the Lacedemonians, and was allowed to do, unless they had first begotten children, to bear the name of the person who had adopted them: thus providing against the ruin of families, which would otherwise have been extinguished by the defection of those who had been adopted to preserve them. If the children adopted happened to die without children, the inheritance could not be alienated from the family into which they had been adopted, but returned to the relations of the adopter. It should seem, that by the Athenian law, a person, after having adopted another, was not allowed to marry without permission from the magistrate: in effect, there were instances of persons, who being illused by their adoptive children, petitioned for such leave. However this be, it is certain some men married after they had adopted sons; in which case, if they begat legitimate children, their estates were equally shared between the begotten and adopted.

The Romans had two forms of adoption; one before the praetor; the other at an assembly of the people, in the times of the commonwealth, and afterwards by a referment of the emperor. In the former, the natural father addressed himself to the praetor, declaring that he emancipated his son, resigned all his authority over him, and contented he should be translated into the family of the adopter. The latter was practised, where the party to be adopted was already free; and this was called adrogation. The person adopted changed all his names; assuming the surname, name, and forename of the person who adopted him.

Adoption by baptism, is that spiritual affinity which is contracted by god-fathers and god-children, in the ceremony of baptism. This kind of adoption was introduced into the Greek church, and came afterwards into use among the ancient Franks, as appears by the Capitulums of Charlemagne.

In reality, the god-father was so far considered as adoptive father, that his god-children were supposed to be intitled to a share in the inheritance of his estate.

Adoption by marriage, is the taking the children of a wife or husband, by a former marriage, into the condition of proper or natural children; and admitting them to inherit on the same footing with those of the present marriage. This is a practice peculiar to the Germans; among whom, it is more particularly known by the name of einkindschaft; among their writers in Latin, by that of utroque parentum, or union of effects. But the more accurate writers observe, that this is no adoption. See AFFILIATION.

Adoption by testament, that performed by appointing a person heir by will, on condition of his assuming the name, arms, &c. of the adopter. Of which kind we meet with several instances in the Roman history.

Among the Turks, the ceremony of adoption is performed by obliging the person adopted to pass through the skirt of the adopter. Hence, among that people, to adopt, is expressed by the phrase, to draw another through my skirt. It is said, that something like this has also been observed among the Hebrews; where the prophet Elijah adopted Elisha for his son and successor, and communicated to him the gift of prophecy, by letting fall his cloak or mantle on him. But adoption, properly so called, does not appear to have been practised among the ancient Jews: Moses says nothing of it in his laws: and Jacob's adoption of his two grandsons, Ephraim and Manasseh, is not so properly an adoption, as a kind of substitution, whereby these two sons of Joseph were allotted an equal portion in Israel with his own sons.

Adoption is allowed, in theology, for a federal act of God's free grace; whereby those who are regenerated by faith, are admitted into his household, and intitled
ADOPTION is sometimes also used, in speaking of the admission of persons into certain hospitals, particularly that of Lyons; the administrators whereof have all the power and rights of parents over the children admitted.

ADOPTION is also used for the reception of a new academy into the body of an old one. — Thus the French academy of Marseilles was adopted by that of Paris; on which account we find a volume of speeches extant, made by several members of the academy of Marseilles, deputed to return thanks to that of Paris for the honour.

In a similar sense, adoption is also applied by the Greeks, to the admitting a monk, or brother, into a monastery of Mars. It is also used among Romans, for ordinarily they paid to their gods, taken chiefly from the Egyptians: — The ceremony of adoption among the Romans was thus: The emperor published adoptive books; and adds it to his other works. — M. Menage has published a book of eulogies, or Uber Adoptivus, which he calls Liber Adoptivus; an adoptive book; and adds it to his other works. — Heinus, and Furtenburg of Munster, have likewise published adoptive books.

In ecclesiastical writers we find adoptive women, or sisters, (adoptivae feminae, or forores, used by those mandmaids of the ancient clergy, otherwise called sub-intrudite.

Adoptive arma are those which a person enjoys by the gift or concession of another, and to which he was not otherwise entitled. They stand contradistinguished from arms of alliance.

We sometimes meet with adoptive hair, by way of opposition to natural hair: and adoptive gods, by way of contradistinguished to domestic ones. The Romans, notwithstanding the number of their domestic, had their adoptive gods, taken chiefly from the Egyptians: such were Isis, Osiris, Anubis, Apis, Harpocrates, and Canopus.

ADORATION, the act of rendering divine honours; or of addressing a being, as supposing it a god. The word is compounded of ad (to); and oris, "mouth," and literally signifies, to apply the hand to the mouth; Manum ad or admoventer, q.d. "to kiss the hand;" this being, in the eastern countries, one of the great marks of respect and subMission. — The Romans professed adoption at sacrifices, and other solemnities; in passing by temples, altars, groves, &c. at the sight of statues, images, or the like, whether of stone or wood, wherein any thing of divinity was supposed to reside. Usually there were images of the gods placed at the gates of cities, for those who went in or out, to pay their respects to. — The ceremony of adoption among the ancient Romans was thus: The devotee having his head covered, applied his right hand to his lips, the fore-finger resting on his thumb, which was erect, and thus bowing his head, turned himself round from left to right. The kiss thus given was called salutum labraturum; for ordinarily they were afraid to touch the images of their gods themselves with their profane lips. Sometimes, however, they would kiss their feet, or even knees, it being held an incivility to touch their mouths; so that the affair paused at some distance. Saturn, however, and Hercules, were adored with the beard bare; whence the worship of the last was called infiristum peregrinatum, and Hylas Grammat- 

ADORATION, or the act of rendering divine honours to, or out, to a being, in supposing it a god. The word is compounded of ad (to); and oris, "mouth," and literally signifies, to apply the hand to the mouth; Manum ad or admoventer, q.d. "to kiss the hand;" this being, in the eastern countries, one of the great marks of respect and submission. — The Romans professed adoption at sacrifices, and other solemnities; in passing by temples, altars, groves, &c.; at the sight of statues, images, or the like, whether of stone or wood, wherein any thing of divinity was supposed to reside. Usually there were images of the gods placed at the gates of cities, for those who went in or out, to pay their respects to. — The ceremony of adoption among the ancient Romans was thus: The devotee having his head covered, applied his right hand to his lips, the fore-finger resting on his thumb, which was erect, and thus bowing his head, turned himself round from left to right. The kiss thus given was called salutum labraturum; for ordinarily they were afraid to touch the images of their gods themselves with their profane lips. Sometimes, however, they would kiss their feet, or even knees, it being held an incivility to touch their mouths; so that the affair paused at some distance. Saturn, however, and Hercules, were adored with the beard bare; whence the worship of the last was called infiristum peregrinatum, and Hylas Grammati-
than with his head covered, turning himself round, and then falling on his face. Heliodorus restored the practice, and Alexander Severus again prohibited it. Diocletian redemanded it; and it was, in some measure, continued under the succeeding princes, even after the establishment of Christianity, as Constantine, Constantius, &c. It is particularly said of Diocletian, that he had gems fastened to his feet, that divine honours might be more willingly paid him, by killing his feet. The like usage was afterwards adopted by the popes, and is observed to this day. These prelates, finding a vehement disposition in the people to fall down before them and kiss their feet, procured crucifixes to be fastened on their gippers; by which stratagem, the adoration intended for the pope's person is supposed to be transferred to Christ. Divers acts of this adoration we find offered even by princes to the pope.

Adoration is also used for a method of elevating a pope. The election of popes is performed two ways; by adoration and by feruting. In election by adoration, the cardinals rush hastily, as if agitated by some spirit, to the adoration of some one among them, to proclaim him pope. When the election is carried by feruting, they do not adopt the new pope till he is placed on the altar.

Barbarous adoration is a term used, in the laws of King Canute, for that performed after the manner of the heathens who adored idols. The Romish church is charged with the adoration of saints, martyrs, images, crucifixes, relics, the virgin, and the host; all which by Protestantists are generally aggravated into idolatry, on a supposition, that the honour thus paid to them is absolute and supreme, called by way of distinction Latria, which is due only to God. Roman catholics, on the contrary, explain them as only a relative or subordinate worship, called Dulia and Hyperdulia, which terminates ultimately in God alone. But may not the fame be paid of the idol-worship of the heathens? The Phecinians adored the winds, on account of the terrible effects produced by them; the same was adopted by most of the other nations, Persians, Greeks, Romans, &c. The Persians chiefly paid their adorations to the sun and fire; some pay also to rivers, the wind, &c. The motive of adoring the sun was the benefits they received from that glorious luminary, which of all creatures has doubtless the best pretensions to such high regard.

Adorea, in Roman antiquity, a word used in different senses; sometimes for all manner of grain, sometimes for a kind of cakes made of fine flour, and offered in sacrifice; and finally for a dole or distribution of corn, as a reward for some service; whence by metonymy it is put for praife or rewards in general.

Adosculatio, a term used by Dr Grew, to imply a kind of impregnation, without intromission; and in this manner he supposes the impregnation of plants is affected by the falling of the farina on the pistil.

Adosee, in heraldry, signifies two figures or bearings being placed back to back.

Adour, the name of a river in France, which rises in the mountains of Bigorre, and running N. by Tarbes through Gascony, afterwards turns E., and, passing by Dax, falls into the bay of Biscey, below Bayonne.

Adoxa, Tuberous MoschateL, Hollow-root, Incongruous; a genus of the tetragnia or. Order, belonging to the octandra class of plants. In the natural method it belongs to the 13th order, or Succulents.—The characters of this genus are: The calyx is a perianthium beneath, divided into two segments, flat, perifent. The corolla is composed of one flat petal, divided into four ovate acute segments longer than the calyx. The flaminia consists of eight subulate filaments the length of the calyx; with roundish antherae. The pistillum has a germin beneath the receptacle of the corolla; four simple, erect, perifent styli, the length of the flaminia; and simple stigma. The pericarpium is a globular four-celled berry between the calyx and the corolla. The seeds are foliary and compressed.

There is but one species, which is a native of the woods in Britain, and several parts of Europe: it is a very low plant, seldom rising more than four or five inches high; the leaves resemble those of bulbous omitory; the flower-stalk arises immediately from the root, on the top of which grow four or five small flowers of an herbaceous white colour; which appear in the beginning of April, and the berries ripen in May, soon after which, the leaves decay. The herb may be procured by transplanting the roots any time after the leaves decay, till winter. They must be planted in the shade, under shrubs; for they will not thrive if exposed to the sun. The leaves and flowers smell like musk, from whence it has by some been called musk-crowfoot.

Adounus omnium, among physicians, on a prescription in their prescriptions, signifying that the last mentioned ingredient is to weigh as much as all the rest together.

Ad Quod Damnun, in the English law, a writ directed to the sheriff, commanding him to inquire into the damage which may befall from granting certain privileges to a place, as a fair, a market, or the like.

Adrachne, in botany, a species of the strawberry-tree. See Arbutus.

Adramelech, one of the gods of the inhabitants of Sepharvaim, who were settled in the country of Samaria, in the room of those Israelites who were carried beyond the Euphrates. The Sepharvaites made their children pass through the fire, in honour of this idol and another called Anamelch. It is suppofed, that Adramelech meant the sun, and Anamelch the moon: the first signifies the magnificent king; the second the gentle king.

Adramyttium (anc. geog.), now Adramiti; a town of Myfia Major, at the foot of mount Ida, an Athenian colony, with a harbour and dock near the Caicus. Adramyttius the epithet; as Adramyttius Sinus, a part of the Egean Sea, on the coast of Myfia; Adramyttius Commenus, feilions affiles. The eighth in order of the nine Conventus Juridici of the province of Alia.

Adran, a river of Germany, (Polybius); now the Eder, rising on the borders of the county of Nassau, to the North-east of, and not far from Dillenburg, running through the landgrave of Halle, the county of Waldeck, by Fritzlar, and then again through the landgrave's, and, together with the Fulda, falling into the Weser, to the south of, and not far from Caffel.

Adranum, or Hadranum, (anc. geog.), now Aderno; a town of Sicily, built by the elder Dionysius,
ADRASTEA, in antiquity, an epithet given to the goddess Nemesis, or Revenge. It was taken from king Adræus, who first erected a temple to that deity.

ADRASTIA (Gorgoneia), in antiquity, a kind of Pythian games, instituted by Adræus, king of Argos, in the year of the world 2700, in honour of Apollo, at Sicyon. These are to be distinguished from the Pythian games celebrated at Delphi.

ADRASTUS, king of Argos, son of Talaus and Lybia, daughter of Polybius, king of Sicyon, acquired great honour in the famous war of Thebes, in support of Polynices his son-in-law, who had been excluded the sovereignty of Thebes by Eteocles his brother, notwithstanding their reciprocal agreement. Adræus, followed by Polynices and Tydeus his other son-in-law, by Cephenus and Hippomenon his foster's sons, by Amphiarus his brother-in-law, and by Parnassus, marched against the city of Thebes; and this is the expedition of the Seven Worthies, which the poets have so often sung. They all lost their lives in this war, except Adræus, who was saved by his horse called Arion. This war was revived ten years after by the sons of these deified warriors, which was called the war of the Epigonés, and ended with the taking of Thebes. None of them lost their lives except Egealus son of Adræus; which afflicted him so much that he died of grief in Megara, as he was leading back his victorious army.

ADRAZZO, or AJACCIO. The name with Adræus.

ADRIA, or HADRIEN (anc. geog.), the name of two towns in Italy. One in the country of the Veneti, on the river Tartarus, between the Padus and the Athris, called Aricia by Pliny and Prolemy, but Adria by Strabo. Another on the river Vomanaus, in the territory of the Piceni, (to which Antonine's Itinerary from Rome is directed,) the country of the ancestors of the emperor Adrian. From which of these the Adriatic sea is denominated, is matter of doubt. A third opinion is, that it is so called from Adrias the son of Joan, of Italian origin; (Bukathias in Dionysius.)

ADRIAN (or ADRIATICUM) MARE (anc. geog.), now the gulf of Venice, a large bay in the Mediterranean, between Dalmatia, Scilavonia, Greece, and Italy. It is called by the Greeks, Adriatic Ocean; and Adriaco by the Romans, (as Arbitre, Adria Notus, Hor.) Cicero calls it Hadrianum Mare; Virgil has Hadriaticas Undas. It is commonly called Mare Adriaticum, without an aspiration; but whether it ought to have one, is a dispute: if the appellation is from Hadria, the town of the Piceni, it must be written Hadriaticum, because the emperor's name, which thence derives his origin, is on coins and stones Hadriaticus; but if it from the town in the territory of Venice, as the more ancient, and of which that of the Piceni is a colony, this will justify the common appellation Adriaticum.

ADRIAN, or HADRIAN, (Publius Aelius), the Roman emperor. He was born at Rome, the 24th of January, in the 76th year of Christ. His father left him an orphan, at ten years of age, under the guardianship of Trajan, and Ecelus Attianus a Roman knight. He began to serve very early in the armies, having been tribune of a legion before the death of Domitian. He was the person chosen by the army of Lower Media, to carry the news of Nerva's death to Trajan, successor to the empire. He accompanied Trajan in most of his expeditions, and particularly distinguished himself in the second war against the Daci; and having before been quaestor, as well as tribune of the people, he was now successively praetor, governor of Pannonia, and consul. After the siege of Atra in Arabia was raised, Trajan, who had already given him the government of Syria, left him the command of the army; and at length, when he found death approaching, it is said he adopted him. Adrian, who was then in Antiochia, as soon as he received the news thereof, and of Trajan's death, declared himself emperor, on the 11th of August, 117. No sooner had he arrived at the imperial dignity, than he made peace with the Persians, to whom he yielded up a great part of the conquests of his predecessors; and from generosity, or policy, he remitted the debts of the Roman people, which, according to the calculation of those who have reduced them to modern money, amounted to 22,500,000 gold crowns; and he burnt all the bonds and obligations relating to those debts, that the people might be under no apprehensions of being called to an account for them afterwards. There are medals in commemoration of this fact, in which he is represented holding a flambeau in his hand, to set fire to all those bonds which he had made void. He went to visit all the provinces; and did not return to Rome till the year 118, when the senate decreed him a triumph, and honoured him with the title of Father of his country; but he refused both, and desired that Trajan's image might triumph. No prince travelled more than Adrian; there being hardly one province in the empire which he did not visit. In 120 he went into Gaul; from thence he went over to Britain, in order to subdue the Caledonians, who were making continual inroads into the provinces. Upon his arrival they retired towards the north: he advanced however as far as York, where he was diverted from his intended conquest by the description some old soldiers he found there, who had served under Agricola, gave him of the country. In hopes, therefore, of keeping them quiet by enlarging their bounds, he delivered up to the Caledonians all the lands lying between the two Fritias and the Tyne; and at the same time, to secure the Roman provinces from their future incursions, built the famous wall which still bears his name (A). Having thus settled...
Adrian was honoured with the title of Reformer of Britain, as appears by some medals. He soon after went into Spain, to Mauritania, and at length into the East, where he quitted the communities held by the Parthians. After having visited all the provinces of Asia, he returned to Athens in 127, where he passed the winter, and was initiated in the mysteries of Eleusinian Ceres. He went from thence to Sicily, chiefly to view Mount Aetna, contemplate its phenomena, and enjoy the beautiful and extensive prospect afforded from its top. He returned to Rome the beginning of the year 129; and, according to some, he went again, the same year, to Africa; and, after his return from thence, to the East. He was in Egypt in the year 132, revisited Syria the year following, returned to Athens in 134, and to Rome in 135. The persecution against the Christians was very violent under his reign; but it was at length suspended, in consequence of the remonstrances of Quadrat bishop of Athens, and Ariatides, two Christian philosophers, who represented the emperor with some books in favour of the Christian religion. He conquered the Jews; and, by way of insult, erected a temple to Jupiter on Calvary, and placed a statue of Adonis in the manger of Bethlehem; he caused also the images of swine to be engraven on the gates of Jerusalem. At last he was seized with a droopy, which vexed him to such a degree, that he became almost raving mad. A great number of physicians were sent for, and to the multitude of them he ascribed his death. He died at Baia in the 69th year of his age, having reigned 21 years. The Latin verses (A) he addressed to his soul have been much criticized and variously interpreted. There are some fragments of his Latin poems extant, and there are Greek verses of his in the Anthology. He also wrote the history of his own life: to which, however, he did not chuse to put his name; but that of Phegon, one of his freed-men, a very learned person, was prefixed to it. He had great wit, and an extensive memory. He understood the sciences perfectly well; but he was very jealous of others who excelled in them. He was also cruel, envious, and lascivious. Antoninus his predecessor obtained his apotheosis; and prevented the reflection of his acts, which the senate once intended.

ADRIAN IV. (Pope), the only Englishman who had the honour of sitting in the papal chair. His name was Nicholas Brekefere; and he was born at Langley, near St Alban's, in Hertfordshire. His father having left his family, and taken the habit of the monastery of St Alban's, Nicholas was obliged to submit to the lowest offices in that house for daily support. After some time, he desired to take the habit in that monastery, but was rejected by the abbot Richard. Upon this he resolved to try his fortune in another country, and accordingly went to Paris; where, though in very poor circumstances, he applied himself to his studies with great industry, and made a wonderful proficiency. But having still a strong inclination to a religious life, he left Paris, and removed to Provence, where he became a regular clerk in the monastery of St Rufus. He was not immediately allowed to take the habit; but passed some time, by way of trial, in recommending himself to the monks by a strict attention to all their commands. This behaviour, together with the beauty of his person, and prudent conversation, rendered him so acceptable to those religious, that after some time they intreated him to take the habit of the canonical order. Here he distinguished himself so much by his learning and strict observance of the monastic discipline, that, upon the death of the abbot, he was chosen superior of that house; and we are told that he rebuilt that convent. Pope Eugenius III. being apprised of the great merit of Nicholas, and thinking he might be serviceable to the church in a higher station, created him cardinal-bishop of Alba in 1146. In 1148, his Holiness sent him legate to Denmark and Norway; where, by his fervent preaching and diligent instructions, he converted those barbarous nations to the Christian faith; and erected Up

the town of Newcastle now stands; so that it must have been above 60 English, and near 70 Roman miles in length. It consisted of four parts: 1. The principal agger, mound of earth, or rampart, on the brink of the ditch. 2. The ditch on the north side of the rampart. 3. Another rampart on the south side of the principal one, about five paces distant from it. 4. A large rampart on the north side of the ditch. This last was probably the military way to the line of forts on this work: it was so to those formerly built by Agricola; and if it did not serve the same purpose in this, there must have been no military way attending it. — The south rampart might serve for an inner defence in case the enemy should beat them from any part of the principal rampart, or it might be designed to protect the soldiers from any sudden attack of the provincial Britons. — For many ages, this work hath been in so ruinous a condition, that it is impossible to discover its original dimensions with certainty. From their appearance, it seems probable that the principal rampart was at least 10 or 12 feet high, and the south one not much lefs; but the north one was considerably lower. From the dimensions of the ditch taken as it passes through a lime-flone quarry near Harlow-hill, it appears to have been 9 feet deep, and 11 wide at the top, but somewhat narrower at the bottom. The north rampart was about 20 feet distant from the ditch.

(A) The verses are these:

Animula vagula, blandula,
Hospes, consilium corporis,
Quae nunc, abhis in loca
Pallidula, rigida, nudula,
Nec ut foles, dasbis jocos?

Thus translated by Mr Pope:

Ah! fleeting spirit! wandering fire,
That long had warm'd my tender breast,
Must thou so more this transing fire?

No more a pleasing cheerful guest?
Whither, ah whither art thou flying?
To what dark unlook'd for shore?

Thou seem'st all trembling, shivering, dying.

And wit and humour are no more!
Romulus, he was received by the pope and cardinals with great marks of honour; and Pope Anastasius, who succeeded Eugenius, happening to die at this time, Nicholas was unanimously chosen to the holy see, in November 1554, and he took the name of Adrian. When the news of his promotion reached England, King Henry II. sent Robert abbot of St Albans', and three bishops, to Rome, to congratulate him on his election; upon which occasion Adrian granted very considerable privileges to the monastery of St Albans, particularly an exemption from all episcopal jurisdiction, excepting to the fee of Rome. Adrian, in the beginning of his pontificate, boldly withstood the attempts of the Roman people to recover their ancient liberty under the confuls, and obliged those magistrates to abdicate their authority, and leave the government of the city to the pope. In 1555, he drove the heretic Arnaud de Brete, and his followers, out of Rome. The fame year he communicated William, king of Sicily whorsaged the territories of the church, and abdolicted that prince's subjedts from their allegiance. About the fame time, Frederic king of the Romans, having entered Italy with a powerful army, Adrian met him near Sutriam, and concluded a peace with him. At this interview, Frederic confented to hold the pope's right whilst he mounted on horseback. After which, his holiness conducted that prince to Rome, and in St Peter's church placed the imperial crown on his head, to the great mortification of the people of Rome. Then next year a reconciliation was brought about between the pope and the Sicilian king, that prince taking an oath and profession of obedience. At this interview, Frederic conformed to the pope and the Sicilian king, that prince taking an oath and profession of obedience.

After this, his holiness proceeded to hold a council at Mantua, with a powerful army, and in every thing he showed a great dislike for all of his followers, out of date. He was very partial to his own countryman John of Corneto, his father was not able to maintain him at school, but he got a place at Louvain, in a college in which a certain number of scholars were maintained gratis. It is reported that he ufed to read in the night-time by the light of the lamps in the churches or streets. He made a considerable progress in all the sciences; led an exemplary life; and there never was a man less intriguing and forward than he was. He took his degree of doctor of divinity at Louvain; was soon after made canon of St Peters, and professor of divinity at Utrecht, and then dean of St Peters and vice-chancellor of the university. He was obliged to leave an academic life, to be tutor to the archduke Charles. This young prince made no great progress under him: however, never was a tutor more considerately rewarded; for it was by Charles V.'s credit he was raised to the papal throne. Leo X. had given him the cardinal's hat in 1517. After this pope's death, several cabals in the conclave ended in the election of Adrian, with which the people of Rome were very much displeased. He would not change his name, and in every thing he showed a great dislike for all inconvenient and f념ial pleasures, though such an aversion had been long ago out of date. He was very partial to Charles V. and did not enjoy much tranquillity under the triple crown. He lamented much the wicked morals of the clergy, and wished to establish a reformation of manners among them. He died Sept. 14. 1523.

ADRIANI (Joanni Batista), was born of a patrician family at Florence, in 1511. He wrote a History of his own Times in Italian; which is a continuation of Guicciardini, beginning at the year 1536; to which Thanatus acknowledges himself greatly indebted: besides which, he compiled six funeral orations, on the emperor Charles V. and other noble personages; and is thought to have been the author of a long letter on ancient painters and sculptors, prefixed to the third volume of Vafari. He died at Florence in 1579.

ADRIANISTS, in ecclesiastical history, a sect of heretics divided into two branches; the first were disciples of Simon Magus, and flourished about the year 34. Theodoret is the only person who has preserved their name and memory; but he gives us no account of their origin. Probably this sect, and the six others which sprang from the Simonians, took their name from the particular disciples of Simon. The second were the followers of Adrian Hamstead, the anabaptists; and held some particular errors concerning Christ.

ADRIANOPELE, a city of Turkey in Europe, in the province of Romania, and the see of an archbishop under the patriarch of Constantinople. It is about seven or eight miles in circumference, including the old city and some gardens. The mosques and other public buildings are built of stone, and are very elegant; but...
Advanced Guard, or Vanguiard, in the art of war, the first line or division of an army, ranged or marshaling in order of battle or, it is that part which is next the enemy, and marches first towards them.

Advanced Guard, is more particularly used for a small party of horse stationed before the main-guard.

ADVANCER, among sportsmen, one of the flarts or branches of a buck's antler, between the back antler and the palm.

ADUAR, in the Arabian and Moorish customs, a kind of ambulatory village, consisting of tents, which these people remove from one place to another, as suits their convenience.

ADVENT, in the calendar, properly signifies the approach of the feast of the nativity. It includes four Sundays, which begin on St Andrew's day, or on the Sunday before or after it. During advent, and to the end of the octaves of epiphany, the solemnizing of marriage is forbidden without a special licence. It is appointed to employ the thoughts of Christians on the first advent or coming of Christ in the flesh, and his second advent or coming to judge the world. The primitive Christians practiced great austerity during this season.

ADVENTURÉ, in a general sense, some extraordinary or accidental event. It also denotes a hazardous or difficult undertaking.

Bill of Adventure, among merchants, a writing signed by a merchant, testifying the goods mentioned in it to be shipped on board a certain vessel belonging to another person, who is to run all hazards; the merchant only obliging himself to account to him for the produce.

ADVENTURE-Bay, in Van Diemen's land. There is a beautiful sandy beach, about two miles long, at the point of the bottom of Adventure Bay, formed to all appearance, by the particles which the sea washes from a fine white sandstone. This beach is very well adapted for hauling a seine. Behind it is a plain, with a brackish lake, out of which we caught, by angling, some bream and trout. The parts adjoining the bay are mostly hilly, and are an entire forest of tall trees, rendered almost impassable by breaks of fern, shrubs, &c. The soil on the flat land, and on the lower part of the hills, is sandy, or consists of a yellow with earth, and in some parts of a reddish clay; but further up the hills, it is of a grey tough clay. This country, upon the whole, bears many marks of being very dry, and the heat appears to be great. No mineral soil, nor stones of any other kind but the white sandstone, were observed by us; nor could we find any vegetables that afforded subsistence for man. The forest-trees are all of one kind, and generally quite straight; they bear clusters of small white flowers. The principal plants observed, are wood-forrel, milk-wort, cudweed, bell-flower, gladioris, falphaire, and several kinds of fern: the only quadruped, a species of opossum, about twice the size of a large rat. The kangaroo, found further northward in New Holland, may also be supposed to inhabit there, as some of the inhabitants had pieces of the skin of that animal.
ADVERTISER, in antiquity, a servant who attended the rich in returning from foppers, to give them notice of any obstacles in the way, at which they might be apt to stumble.

ADVERTISEMENT, in a general sense, denotes any information given to persons interested in an affair; and is more particularly used for a brief account of an affair inserted in the public papers, for the information of all concerned.

ADULA (anc. geog.), a mountain in Phœnicia, or the country of the Cilions, part of the Alps, in which are the fountains of the Rhine, now St Godahard.

ADULE, or ADULIS, (anc. geog.) a town of Egypt built by fugitive slaves, distant from its port on the Red Sea 25 stadia. Pliny calls the inhabitants Aduliacs. The epithet is either Adulianus; as, Monumentum Adulianum, on the pompous inscription of the statue of Ptolemy Euergetes, published by Leo Alatus at Rome in 1631, and to be found in Spot and Thevenot: Or, Adulius; as Adulius Sinus, a part of the Red Sea.

ADULT, an appellation given to any thing that is arrived at maturity: Thus we say, an adult person, an adult plant, &c. Among civilians, it denotes a youth between 14 and 25 years of age.

ADULTERER, a man who commits adultery. See ADULTERY.

ADULTRESS, a woman guilty of ADULTERY. An adulterer, by the English law, undergoes no temporal punishment whatever, except the loss of her dower; and she does not lose even that, if her husband is weak enough to be reconciled to her, and cohabit with her after the offence committed. 13 Ed. I. cap. 34.

But it is to be observed, that adulteresses are fequefterd either by the canon or civil law. According to the former, a woman is an adulteress who, either being herself married, converses carnally with another man; or being single herself, converses with a man that is married. According to the latter, she is not an adulteress, if she be not herself in the married state, though she converses with a man that is. The crime, in this case, was more properly called superstruens than adulterium. Hence, among the Romans, the word adultereia "a-dulteries," differed from pellex, which denoted a single woman who cohabited with a married man, and pellex differed from concludens which signified her who had only intercourse with an unmarried man. The former was repelled infamously, and the latter innocent.

ADULTERATION, the act of debaseing, by an improper mixture, something that was pure and genuine.

The word is Latin, formed of the verb adultereare, "to corrupt," by mingling something foreign to any substance. There are in England laws against the adulteration of coffee, tea, tobacco, fluff, wine, beer, bread, wax, hair-powder, &c.

ADULTERATION OF COIN, properly imports the making, or casting of a wrong metal, or with too base or too much alloy.

Adulterations of coins are effected divers ways: as, by forging another stamp or inscription; by mixing impure metals with the gold or silver: most properly, by making use of a wrong metal, or an undue alloy, or too great an admixture of the bater metals with gold or silver. Counterfeiting the flamp, or clipping and...
ADULTERINE and lenifying the weight, donot inproperly come under
ADULTERY. the denomination of adulterating.—Evelyn gives rules and
methods, both of adulterating and detecting adulterated metals, &c.
Adulterating is somewhat less extensive than debasing, which includes diminishing, clipping, &c.
To adulterate or debase the current coin, is a capital crime in all nations.—The ancients punished it with
great severity: among the Egyptians both hands were
cut off; and by the civil law, the offender was thrown to
wild beasts. The emperor Titus enacted, that
counterfeiting the coin should be capital; and under
Constantine it was made treason, as it is also among us.
The adulterating of gems is a curious art, and the
methods of detecting it are lesuseful. Nichols Lapid. p. 18.

ADULTERINE, in the civil law, is particularly
excepted from the crime of adulterating a married person and another, or between a married and
an unmarried person. This was an awkward form of
impalement, permitted only to take her back again; if he refused,
not receive alms among the
Greeks. Adulterous children are more odious than
the illegitimate offspring of single perfons. The
Romans had a particular law in favour of the wife, who
was permitted to kill both parties, when
caught in the fact, provided he did it immediately, killed both together, and as it were with one blow. The
same power ordinarily was not indulged the husband, but rather banishment, or deportation, being interdicted fire and water; though Octavius,
appears, in several instances, to have gone beyond his own law, and to have put adulterers to death. Under
Macrinus, many were burnt at a stake. Constantine
first law made the crime capital. Under Constan-
tius and Constans, adulterers were burnt, or fewed in
sacks and thrown into the sea. Under Leo and Mar-
cian, the penalty was abated to perpetual banishment,
or cutting off the nose. Under Justinian, a further
mitigation was granted, at least in favour of the wife, who
was only to be scourged, lofe her dowery, and be
shut up in a monastery: after two years, the husband was at liberty
to take her back again; if he refused, she was shaven,
and made a nun for life: But it still remained death
for the husband. The reason alleged for this difference
is, that the woman is the weaker vessel. Mathæus de-
claims against the empress Theodora, who is supposed
to have been the caufe of this law, as well as of others
procured in favour of that sex from the emperor.
Under Theodosius, women convicted of this crime
were punished after a very singular manner, viz. by a
public confuption; being locked up in a narrow cell,
and forced to admit to their embraces all the men that
would offer themselves. To this end the gallants were
to drefs themselves on purpose, having several little bells
fastened to their clothes, the tinkling of which
gave notice to those without of every motion. The
custom was again abolished by the future emperors.

By the Jewish law, adultery was punished by death
in both parties, where they were both married, or only
the woman. The Jews had a particular method of
trying, or rather purging, an adulterer, or a woman
fufpected of the crime, by making her drink the bitter waters of jealousy; which, if she were guilty, made
her swell.

Among the Mingrelians, according to Chardin, ad-
ultery is punished with the forfeiture of a hog, which
is usually eaten in good friendship between the gallant,
the adulterers, and the cuckold. In some parts of the
Indies, it is said any man's wife is permitted to pro-
stitute herself to him who will give an elephant for the
use of her; and it is reputed no small glory to her to
have
Adultery have been rated so high. Adultery is said to be so frequent at Ceylon, that not a woman but practises it, notwithstanding its being punishable with death. Among the Japanese, and divers other nations, adultery is only penal in the woman. Among the Abyssinians, the crime of the husband is said to be only punished on the innocent wife. In the Marian islands, on the contrary, the woman is not punishable for adultery: but if the man go astray he pays severally: the wife and her relations waste his lands, turn him out of his house, &c. Among the Chinese, there is reason to conclude that adultery is not capital; for it is said that fond parents will make a contract for their daughters future husbands to allow them the indulgence of a gallant.

In Spain, they punished adultery in men by cutting off that part which had been the instrument of the crime. In Poland, before Christianity was established, they punished adultery and fornication in a very particular manner: the criminal they carried to the market-place, and there fastened him by the testicles with a nail; laying a razor within his reach, and leaving him under the necessity, either of doing justice upon himself or of perishing in that condition.

The Saxons formerly burnt the adulterers, and over her affes erected a gibbet, whereon the adulterer was hanged. In England, likewise, adultery, by the ancient laws, was severely punished. King Edmund of the Saxons ordered adultery to be punished in the same manner as homicide; and Canute the Dane ordered that a man who committed adultery should be banished, and that the woman should have her nose and ears cut off. In the time of Henry I. it was punished with the loss of eyes and genitals.

In Britain, adultery is reckoned a spiritual offence, that is, cognizable by the spiritual courts, where it is punished by fine and penance. The common law takes no further notice of it, than to allow the party guilty of an action and damages. This practice is often cen sured by foreigners, as making too light of a crime, the bad consequences of which, public as well as private, are so great. It has been answered, that perhaps this penalty, by civil action, is more wisely calculated to prevent the frequency of the offence, which ought to be the end of all laws, than a severer punishment. He that by a judgment of law is, according to circumstances, stripped of great part of his fortune, thrown into prison till he can pay it, or forced to fly his country, will, no doubt, in most cases, own that he pays dearly for his amiss.

As to the moral turpitude of this offence, some have mainly endeavoured to deny or explain it away by various arguments, and even by an appeal to scripture. On the part of the man who solicits the chastity of a married woman, it certainly includes the crime of seduction, and is attended with mischief still more complicated and extensive. It creates a new sufferer, the injured husband, upon whose simplicity and affection is inflicted a wound the most painful and inexcusable that human nature knows. The infidelity of the woman is aggravated by cruelty to her children, who are generally involved in their parents flame, and always made unhappy by their quarrel.

It has been argued, that these consequences ought to be attributed to the crime than to the discovery. But, in the first place, the crime could not be discovered unless it were committed, and the commission is never secure from discovery. 

The marriage-vow is "witnessed before God," and accompanied with circumstances of solemnity and religion which approach to the nature of an oath. The married offender, therefore, incurs a crime little short of perjury, and the seduction of a married woman is little less than subornation of perjury:—and this guilt is independent of the discovery.

But the usual apology for adultery is the prior transgression of the other party; and so far, indeed, as the bad effects of adultery are anticipated by the conduct of the husband or wife who offends first, the guilt of the second offender is extenuated. But this can never amount to a justification; unless it could be shown that the obligation of the marriage-vow depends upon the condition of reciprocal fidelity; a construction which appears founded neither in expediency, nor in the terms of the vow, nor in the design of the legislature which prescribed the marriage-rite. The way of considering the offence upon the footing of "prosecution and retaliation," is a childish trifling with words.

"Thou shalt not commit adultery," was an interdict delivered by God himself; yet scripture has been adduced as giving countenance to the crime. As Christ told the woman taken in adultery, "Neither do I condemn thee," we must believe, it is said, that he deemed her conduct either not criminal, or at least not a crime of the heinous nature we represent it to be. But from a more attentive examination of the case, it will be evident that nothing can be concluded from it favourable to such an opinion. The transaction is thus related: "Early in the morning Jesus came again into the temple, and all the people came unto him; and he sat down and taught them; and the scribes and Pharisees brought unto him a woman taken in adultery; and when they had set her in the midst, they said unto him, Master, this woman was taken in adultery; and in the law which Moses in the law commanded that such should be stoned, but what sayest thou? This they said tempting him, that they might have to accuse him: but Jesus stooped down, and with his finger wrote on the ground as though he heard them not. So when they continued asking him, he lift up himself, and said unto them, He that is without sin among you, let him first cast a stone at her; and again he stooped down and wrote on the ground; and they which heard it, being convicted by their own conscience, went out one by one, beginning at the eldest, even unto the last; and Jesus was left alone, and the woman standing in the midst. When Jesus had lifted up himself, and saw none but the woman, he said unto her, Woman, where are those thine accusers? Hath no man condemned thee? She said unto him, No man, Lord: and he said unto her, Neither do I condemn thee; go and sin no more."
This they said tempting him, that they might have to accuse him; that is, to draw him into an exercise of judicial authority, that they might have the power to accuse him before the Roman governor of usurping or intermeddling with the civil government.

This was their design; and Christ's behaviour throughout the whole affair proceeded from a knowledge of this design, and a determination to defeat it. He gives them at first a cold and full denial, well suited to the insidious intention with which they came: he stooped down, and with his finger wrote on the ground as though he heard them not.

When they continued asking him, when they teased him to speak, he dismissed them with a rebuke, without reproving them, with the reproof, to speak, he dismissed them with a rebuke.

Neither do I condemn thee; go and sin no more. And then follows the conversation, which is the part of the narrative most material to our present subject. Jesus saith unto her, Woman, where are those that accused thee? hath no man condemned thee?

She said, No man, Lord. And Jesus said unto her, Neither do I condemn thee: go and sin no more.

Now, when Christ asked the woman, Hath no man condemned thee? he certainly spoke, and was understood by the woman to speak, of a legal and judicial condemnation; otherwise her answer, No man, Lord, was not true. In every other sense of condemnation, as blame, cenfure, reproof, private, judgment, and the like, many had condemned her; all these, indeed, who brought her to Jesus. If then a judicial sentence was what Christ meant by condemning in the question, the common use of language requires us to suppose that he meant the same in his reply, Neither do I condemn thee: i.e. I pretend to no judicial character or authority over thee; it is no office or business of mine to pronounce or execute the sentence of the law. When Christ adds, Go and sin no more, the effect of that sentence is to inform her that she had sinned already; but as to the degree or quality of the sin, or Christ's opinion concerning it, nothing is declared, or can be inferred, either way.

It has been controverted, whether adultery may be lawfully committed in war, with the enemies wives? The answer is in the negative, and the authorized practice of civilized nations is agreeable to this. It has also been a famous question, whether it be lawful for a woman to commit adultery with the consent of her husband, and for the procuring some good great to him? St. Austin apparently allows of it; at least does not condemn it.

It has likewise been a dispute, whether it be lawful for one of the parties married to commit adultery, with the consent of the other, for the sake of having children? of which we have instances in Abraham, who, on this account, converted with Hagar; and likewise among the Greeks and Romans. Pollian, a German professor, has a dissertation on the husband's right to alienate his wife's body to another's use.

It is much disputed whether adultery dissolves the bond of matrimony, and be a sufficient cause of divorce, so that the parties may marry again. This was allowed in the ancient church, and is still continued in the Greek, as well as the Lutherans and Calvinists in the churches. Romanists, however, dissent from it, and the council of Trent even anathematized those who maintain it: though the canon of anathematization was mitigated in deference to the republic of Venice, in foon of whose dominions, as Zant, Cephalonia, &c., the contrary usage obtains. These ecclesiastical courts in England do agree with those of Rome, that they only grant a divorce à mensa et thoro, in case of adultery; so that a complete divorce, to enable the parties to marry again, cannot be had without an act of parliament.

Adultery is also used in ancient customs, for the punishment or fine imposed for that offence, or the privilege of prosecuting for it. In which sense adultery amounts to the same with what the Saxons call legerus.

Adultery is sometimes used in a more extensive sense, for any species of impurity or crime, against the virtue of chastity; and in this sense divines understand the seventh commandment.

Adultery is also used, especially in scripture, for idolatry, or departing from the true God, to the worship of a false one.

Adultery is also used, in ecclesiastical writers, for a pernicious invading or intruding into a bishop's diocese during the former bishop's life. The reason of the appellation, that a bishop is supposed to exact a kind of spiritual marriage with his church. The translation of a bishop from one see to another was also reputed a species of adultery on the supposition of its being a kind of second marriage, which, in those days, was esteemed a degree of adultery. This conclusion was founded on that text of St. Paul, Let a bishop be the husband of one wife, by a forced contraction of church for wife, and bishop for husband. Di-Cange.

Adultery is also used, in ancient naturalists, for the act of ingrafting one plant upon another. In which sense, Pliny speaks of the adulteries of trees, arborum adulteria, which he represents as contrary to nature, and a piece of luxury, or needless refinement.

Advocate, among the Romans, a person skilled in their law, who undertook the defence of causes at the bar. The Roman advocates answered to one part of the office of a barrister in England, viz. the pleading part; for they never gave council, that being the business of the turfes. The Romans, in the first ages of their state, held the profession of an advocate in great honour; and the fees of their bar were crowded with senatoris and confuls; they, whose voices commanded the people, thinking it an honour to be employed in defending them. They were styled comites, honorati, clarissimi, and even patroni; as if their clients were not left obliged to them than freed men to their masters. The bar was not at that time venal. Those who afforded to honours and offices took this way of gaining an interest in the people, and always pleaded gratis. But no sooner were luxury and corruption introduced into the commonwealth, than the senators became a dars in them. Then it was the senators let out their voices for pay, and zeal and eloquence were sold to the highest bidder. To put a stop to this abuse, the
Ad
defendants.

Advocates} tribune Cinigas procured a law to be passed, called from him Lex Cinius, whereby the advocates were forbidden to take any money of their clients. It had before this been prohibited the advocates to take any presents or gratuities for their pleading. The emperor Augustus added a penalty to it: notwithstanding which, the advocates played their part so well, that the emperor Claudius thought it an extraordinary circumstance, when he obliged them not to take above eight great fereces, which are equivalent to about 641 Sterling, for pleading each cause.

Advocates} are still used, in countries and courts where the civil law obtains, for those who plead and defend the cause of clients trusted to them.

Advocates} of a City, in the German polity, a magistrate appointed in the emperor's name to administer justice.

Advocates} is more particularly used, in church history, for a person appointed to defend the rights and revenues of a church or religious house. The word 

Advocatus, or 

Advovus, is still retained for what we usually call the patron, or he who has the advowson, or right of presentation, in his own name.

Confessional Advocates; officers of the confistory at Rome, who plead in all oppositions to the disposal of benefices in that court: they are ten in number.

Elective Advocates, those chosen by the abbot, bishop, or chapter; a particular licence being had from the king, or prince, for that purpose. The elections were originally made in the presence of the count of the province.

Feudal Advocates. These were of the military kind, who, to make them more zealous for the interest of the church, had lands granted them in fee, which they held of the church, and did homage, and took an oath of fidelity to the bishop or abbot. These were to lead the vassals of the church to war, not only in private quarrels of the church itself, but in military expeditions for the King's service, in which they were the standard-bearers of their churches.

Fiscal Advocates, fiscal advocatus, in Roman antiquity, an officer of state under the Roman emperors, who pleaded in all causes wherein the fiscus, or private treasury, was concerned.

Juridical Advocates, in the middle age, were those who from attending causes in the court of the comice, or count of the province, became judges themselves, and held courts of their vassals thrice a-year, under the name of the tria placita generis. In consideration of this further service, they had a particular allowance of one third part of all fines, or mullets, imposed on defaulters, &c. besides a proportion of diet for themselves and servants.

Matricular Advocates, were the advocates of the mother or cathedral churches.

Military Advocates, those appointed for the defense of the church, rather by arms and authority than by pleading and eloquence. They were introduced in the times of confusion, when every person was obliged to maintain their own property by force; bishops and abbots not being permitted to bear arms, and the scholastic or gowned advocates being equally unacquainted with them, recourse was had to knights, noblemen, holders, or even to princes.

Nominate Advocates, those appointed by a king or pope. Sometimes the churches petitioned kings, Advocates, &c. to appoint them an advocate; at other times this was done of their own accord. By some regulations, no person was capable of being elected advocate, unless he had an estate in land in the same county.

Regular Advocates, those duly formed and qualified for their profession, by a proper course of study, the requisite oath, subscription, licence, &c.

Subordinate Advocates, those appointed by other superior ones, acting under them, and accountable to them. There were various reasons for the creation of these subordinate advocates; as, the superior quality of the principal advocate, his being detained in war, or being involved in other affairs; but chiefly the too great distance of some of the church-lands, and their lying in the dominions of foreign princes.

Supreme or Sovereign Advocates, were those who had the authority in chief; but acted by deputies or subordinates. These were called also principali, greater, and sometimes general advocates. Such in many cases were kings, &c. when either they had been chosen advocates, or became such by being founders or endowers of churches. Princes had also another title to advocatehip; some of them pretending to be advocati nati of the churches within their dominions.

Advocates, in the English courts, are more generally called counsel. See Counsel.

Faculty of Advocates, in Scotland, a respectable body of lawyers, who plead in all causes before the Court of Session, Judiciary, and Exchequer. They are also entitled to plead in the house of peers, and other supreme courts in England.

In the year 1660, the faculty founded a library upon a very extensive plan, suggested by that learned and eminent lawyer Sir George M'Kenzie of Rofhaugh, advocate to king Charles II. and king James VII. who enriched it with many valuable books. It has been daily increasing since that time, and now contains not only the best collection of law-books in Europe, but a very large and select collection of books on all subjects. Besides, this library contains a great number of original manuscripts, and a vast variety of Jewish, Grecian, Roman, Scots, and English coins and medals.

A candidate for the office of an advocate undergoes three several trials: The first is in Latin, upon the civil law and Greek and Roman antiquities; the second, in English, upon the municipal law of Scotland; and, in the third, he is obliged to defend a Latin thesis, which is impugned by three members of the faculty. Immediately before putting on the gown, the candidate makes a short Latin speech to the lords, and then takes the oaths to the government and de jure.

The faculty at present consists of above 200 members. As an advocate or lawyer is esteemed the gentlest profession in Scotland, many gentlemen of fortune take the degree of advocate, without having any intention of practicing at the bar. The circumstance greatly increases their number, gives dignity to the profession, and enriches their library and public fund. It is from this respectable body that all vacancies on the bench are generally supplied.

Lord Advocate, or King's Advocate, one of the eight great officers of state in Scotland, who as such...
Advowee, in ancient customs and law books, denotes the advocate of a church, religious house, or the like. There were advowees of cathedrals, abbeys, monasteries, &c. Thus, Charlemagne had the title of advowee of St Peter's; King Hugh, of St Riquier; and Bolandus mentions some letters of pope Nicholas, by which he constituted Edward the Confessor, and his successors, advowees of the monastery at Westminster, and of all the churches in England. These advowees were the guardians, protectors, and administrators of the temporal concerns of the churches, &c. and under their authority were passed all contracts which related to them. It appears also, from the most ancient charters, that the donations made to churches were confirmed on the persons of the advowes. They always pleaded the causes of the churches in court, and distributed justice for them, in the places under their jurisdiction. They also commanded the forces furnished by their monasteries, &c. for the war; and even were their champions, and sometimes maintained duels for them.

This office is said to have been first introduced in the fourth century, in the time of Stillicco; though the Benedictines do not fix its origin before the eighth century. By degrees, men of the first rank were brought into it, as it was found necessary either to defend with arms or to protect with power and authority. In some monasteries they were only called confessors; but these, without the name, had all the functions of advowees. There were also sometimes several sub-advowees, or sub-advocates, in each monastery, who officiated instead of the advowees themselves; which, however, proved the ruin of monasteries; those inferior officers running into great abuses.

Hence also, husbands, tutors, and every person in general, who took upon him the defence of another, were denominated advowes, or advocates. Hence several cities had their advowees; which were established long after the ecclesiastical ones, and dwindled from their example. Thus we read in history of the advowees of Augsburg, of Arras, &c.

The vidamis assumed the quality of advowees; and hence it is, that several historians of the eighth century confound the two functions together. Hence also, that several secular lords in Germany bear mitres for their crests, as having anciently been advowees of the great churches.

Spcman distinguishes two kinds of ecclesiastical advowees.—The one, of causes or processins advocati consistorii; the other, of territory or lands, advocati positae. The former were nominated by the king, and were usually lawyers, who undertook to plead the causes of the monasteries. The other, which still subsist, and are sometimes called by their primitive name, advowes, though more usually patrons, were hereditary; as being the founders and endowers of churches, &c. or their heirs.

Women were sometimes advowees, advocatrices. And, in effect, the canon law mentions some who had this title, and who had the same right of presentation, &c. in their churches which the advowees themselves had. In a flat 25 Edw. III. we meet with advowes paramount for the highest patron; that is, the king.

Advowsen, or advowzen, in common law, signifies a right to present to a vacant benefice. Advowson is so called, because the right of presenting to the church was first gained by such as were founders, benefactors, or maintainers of the church. Though the nomination of fit persons to officiate in every diocese was originally in the bishop, yet they were content to let the founders of churches have the nomination of the persons to the churches so founded, referring to themselves a right to judge of the fitness of the persons so nominated.

Advowsons formerly were most of them appendant to manors, and the patrons were parochial barons: the lordship of the manor and patronage of the church were seldom in different hands, until advowsons were given to religious houses. But of late times the lordship of the manor and advowson of the church have been divided.

Advowsons are presentative, collative, or donative: presentative, where the patron presents or offers his clerk to the bishop of the diocese, to be instituted in his church; collative, where the benefice is given by the bishop, as original patron thereof, or by means of a right he has acquired by lapse; donative, as where the king or other patron does, by a single donation in writing, put the clerk into possession, without presentation, institution, or induction.

Sometimes, anciently, the patron had the sole nomination of the prelate, abbots, or prior: either by in-velliture (i.e. delivery of a pastoral staff), or by direct presentation to the diocesan; and if a free election was left to the religious, yet a voce d'alter, or licence of election, was first to be obtained of the patron, and the person elected was confirmed by him. If the founder's family became extinct, the patronage of the convent went to the lord of the manor. Unless the several colleges in the universities be restrained in the number of advowsons they may receive, it is argued, they will in time acquire such a flock as to frustrate the designs of their foundation (which is the education of youth, by creating too quick a succession of fellows);
Adz. and Adze, or Adibre, a cutting-tool of the ax kind; having its blade made thin and arching, and its edge at right angles to the handle; chiefly used for taking off thin chips of timber or boards, and for paring away certain irregularities which the ax cannot come at. The adze is used by carpenters, but more by coopers, as being convenient for cutting the hollow sides of boards, &c. It is ground from a base on its inside to its outer edge; so that, when it is blunt, they cannot conveniently grind it without taking its helve out of the eye.

Æ, or Æ, a diphthong compounded of A and E. Authors are by no means agreed as to the use of the æ in English words. Some, out of regard to etymology, insist on its being retained in all words, particularly technical ones, borrowed from the Greek and Latin; while others, from a consideration that it is no proper diphthong in our language, its sound being no other than that of the simple e, contend that it ought to be entirely diñed; and, in fact, the simple e has of late been adopted instead of the Roman æ, as in the word equator, &c.

ÆC, in Grecian antiquity, solemn festivals and games celebrated at Ægina, in honour of Æacus. Æacus, the son of Jupiter by Ægina. When the Ægean was depopulated by a plague, his father, in compassion to his grief, changed all the ants upon it into men and women, who were called Myrmidons, from μυρμύδων, an ant. The foundation of the fable is said to be, that when the country had been depopulated by pirates, who forced the few that remained to take shelter in caves, Æacus encouraged them to come out, and by commerce and industry recover what they had lost. His character for justice was such, that, in a time of universal drought, he was nominated by the Delphic oracle to intercede for Greece, and his prayer was answered. See the article ÆGINA. The Pagans also imagined that Æacus, on account of his impartial justice, was chosen by Pluto one of the three judges of the dead; and that it was his province to judge the Europeans.

ÆBURA, an ancient town of Spain, in Estremadura, on the river Guadiana, to the west of Merida, now called Talavera. W. Long. 7. 15. Lat. 38. 40.

ÆCHMALOTARCHA, in Jewish antiquity, a title given to the principal leader or governor of the Hebrew captives residing in Chaldea, Assyria, and the neighbouring countries. This magistrate was called by the Jews rosh-galah, i. e. the chief of the captives; but the above term, of like import in the Greek, is that used by Origen and others who wrote in the Greek tongue. The Jewish writers assure us, that the echebalotarche were only to be chosen out of the tribe of Judah. The eastern Jews had their princes of the captivity, as the western Jews their patriarchs. The Jews are still said to have an echebalotarcha at Babylon, but without the authority of the ancient ones. Bainage Hist. Jews, and Prideaux's ConneCtion.

ÆCULANUM (anc. geog.), a town of the Hirpini in Italy, at the foot of the Appenine, to the east of Abellium, contracted Eclanum, situate between Beneventum and Tarentum. The inhabitants are called Eclanum, Pliny; and Ecilenes, in an ancient inscription (Gruter). The town is now called Fricon by the people of Naples. E. Long. 15. 36. Lat. 41. 15.

ÆDES, in Roman antiquity, besides its more ordinary signification of a houle, likewise signifies an inferior kind of temple, consecrated to some deity.

ÆDICULA, a term used to denote the inner part of
of the temple, where the altar and statue of the deity stood.

ÆDILE, the office of ædile, sometimes called ædilitus. See the next article.

ÆDILE (ædītus), in Roman antiquity, a magistrate whose chief business was to superintend buildings of all kinds, but more especially public ones, as temples, aqueducts, bridges, &c. To the ædiles like wife belonged the care of the highways, public places, weights and measures, &c. They also fixed the prices of provisions, took cognizance of delinquent, punished law-breakers, and enforced the observance of the laws. The ædiles of the plebeians, on matters of business, for the tribunes, finding themselves oppressed by the actions of the patricians, in the first instance, was called ædiles curule, and were elected every year at Rome. This office required numbers by its expensiveness; so that, in Augustus's time, even many senators declined it on that account.

All these functions which rendered the ædiles so considerable belonged at first to the ædiles of the people, ædiles plebei, or minoræ: these were only two in number, and were first created in the same year as the tribunes: for the tribunes, finding themselves oppressed with the multiplicity of affairs, demanded of the senate to have officers, with whom they might intrust matters of less importance; and accordingly two ædiles were created, and hence it was that the ædiles were elected every year at the same assembly as the tribunes. But these plebeian ædiles having refused, on a signal occasion, to treat the people with shows, as pleading themselves unable to support the expense thereof, the patricians made an offer to do it, provided they would admit them to the honours of the ædiles. On this occasion there were two ædiles created, of the number of the patricians, in the year of Rome 388: they were called ædiles curule, or minoræ; as having a right to sit on a curule chair, enriched with ivory, when they gave audience; whereas the plebeian ædiles only sat on benches. Besides that the curule ædiles shared all the ordinary functions with the plebeian, their chief employ was to procure the celebration of the great Roman games, and to exhibit comedies, shows of gladiators, &c. to the people; and they were also appointed judges in all cases relating to the selling or exchanging of slaves.

To cense these four first ædiles, Caesar created a new kind, called ædiles cereales, as being deputed chiefly to take care of the corn, which was called dominæ cerealis; for the Hestians honoured Ceres as the goddess who presided over corn, and attributed to her the invention of agriculture. These ædiles cereales were also taken out of the order of patricians. In the municipal cities there were ædiles, and with the same authority as at Rome.

We also read of an ædiles alimentariæ, expressed in abbreviation by ædil. alim. whose business seems to have been to provide diet for those who were maintained at the public charge, though others assign him a different office. In an ancient inscription we also meet with ædile of the camp, ædilis exercitus.ÆDILITUM ædicum, among the Romans, was that whereby a remedy was given a buyer, in case a vicious or unlawful feast, or slave, was sold him. It was called ædilicum, because the prevention of frauds in sales and contracts belonged especially to the curule ædiles.

ÆDITUS, in Roman antiquity, an officer belonging to the temple, who had the charge of the offerings, treasure, and sacred utensils. The female deities had a woman officer of this kind called ædita.

ÆGAGROPLA, a ball composed of a substance resembling hair, generated in the stomach, of the chamois-goat. This ball is of the same nature with those found in cows, hogs, &c.

ÆGE, or ÆGIA (anc. geog.), the name of Ægina, so called from the following adventure: Caranus, the first king of Macedonia, being ordered by the oracle to seek a settlement in Macedonia, under the conduct of a flock of goats, surpried the town of Ægina, and sacked it. Hence probably, in the prophet Daniel, the he-goat is the symbol of the king of Macedon.

ÆGEAN SEA (anc. geog.), a part of the Mediterranean, separating Europe from Asia and Africa: washing, on the one hand, Greece and Macedonia; on the other, Caria and Ionia. The origin of the name is greatly disputed. Festus advances three opinions: one, that it is so called from the many islands therein, at a distance appearing like so many goats; another, because Ægina queen of the Amazons perished in it: a third opinion is, because Ægeus, the father of Theseus, threw himself headlong into it.

ÆGEUS, in fabulous history, was king of Athens, and the father of Theseus. The Athenians having财力 killed the son of Minos king of Crete, for carrying away the prize from them, Minos made war upon the Athenians; and being victorious, imposed this severe condition on Ægeus, that he should annually send into Crete a he-goat to be devoured by the Minotaur. On the fourth year of this tribute, the choice fell on Theseus; or, as others say, he himself interceded to be sent. The king, at his son's departure, gave orders, that as the ship failed with black sails, it should return with the same in case it perished; but, if he became victorious, he should change them into white. When Theseus returned to Crete, after killing the Minotaur, and for forgot to change the sails in token of his victory, according to the agreement with his father; the latter, who watched the return of the vessel, supposing by the black sails that his son was dead, called himself headlong into the sea, which afterwards obtained the name of the Ægean Sea. The Athenians decreed Ægeus divine honours; and sacrificed to him as a marine deity, the adopted son of Neptune.

ÆGIAS, among physicians, a white speck on the pupil of the eye, which occasions a dimness of sight.

ÆGIDA (Pihus); now Cape d’Ifiria, the principal
AEGI [ 136 ] AEGI

AEGILops

AEginetan

town on the north of the territory of Istria, situated in a little island, joined to the land by a bridge. In an inscription, (Gruter), it is called *Aegi-lops* Inferna. E. Long. 14. 20. Lat. 43. 50. It was afterwards called *Talos*, after the emperor Julianus. 

**AEGILOPS**, the name of a tumor in the great angle of the eye; either with, or without, an inflammation. The word is compounded of *aε*, goat, and *αωε*, eye; as goats are suppos'd extremely liable to this distemper.

Authors frequently use the words *aegilops*, *anchilops*, and *flfula lacrymalitis*, promiscuously; but the more accurate, after *Aeginetan*, make a difference. —The tumor, before it becomes ulcerous, is properly called *anchilops*; and after it is got into the lacrymal pafages, and has rendered the os lacrymalis carinate, *flsula lacrymalitis*.

If the *aegilops* be accompanied with an inflammation, it is suppos'd to take its rise from the abundance of blood which a plethoric habit discharges on the corner of the eye. If it be without an inflammation, it is suppos'd to proceed from a viscous pustulous humour, thrown upon this part.

The method of cure is the same as that of the ophthalmia. But before it has reached the lacrymal pafages, it is managed like other ulcers. If the *aegilops* be neglected, it bruizes, and degenerates into a *flsula*, which eats into the bone.

**AEGILOPS, *Wild Ficus***, a genus of the monoecea order, belonging to the polygama class of plants, and ranking under the 4th natural order, *Cramina*. —The characters are: The *hermaproditic calyx* is a two-valved glume, triflorous; the corolla a two-valved glume, the exterior valvata terminated by three arilites or awns, the interior anwklefs: *Stamina*, three capillary filamenta; style, two: *Seed*, one, oblong. *Male calyx* and *corolla*, each a glume as in the former; *flsula*, the same number. —There are seven species, natives of Italy and some other parts of Europe; one of them, the incurvata, a native of Britain, grows by the sea-shore, and is vulgarly called *sea-bard grapes*.

**AEGILOPS** is also the trivial name of a species of *Quercus*.

**ÆGINUMUS** (anc. geog.), an island on the bay of Carthage, about 30 miles distant from that city, (Livy); now the *Galeta*: This island being afterwards sunk in the sea, two of its rocks remained above water, which were called *Arce*, and mentioned by Virgil, because the Romans and Carthaginians entered into an agreement or league to settle their mutual boundries at these rocks.

**ÆGINA**, in fabulous history, the daughter of *Æacus*, king of *Bœotia*, was beloved by Jupiter, who debauched her in the similitude of a lambent flame, and then carried her from Epidaurus to a desert island called *Oenope*, which afterwards obtained her own name.

**ÆGINA** (anc. geog.), an island on the Saronic Bay, or bay of Engia, 20 miles distant from the Piraeus, formerly vying with Athens for naval power, and at the sea-fight of Salamin disputing the palm of victory with the Athenians. It was the country and kingdom of *Æacus*, who called it *Ægina* from his mother's name, it being before called *Oenopia*, (Ovid). The inhabitants were called *Æginetan*, and *Æginensis*. The Greeks had a common temple dedicated to Jupiter in *Ægina*. The *Æginetan* applied to commerce: and were the first who coined money, called *numerus* *Æginum*: hence *Ægineum at*, formerly in great repute. The inhabitants were called *Brynydones*, or a nation of ants, from their great application to agriculture. (See *Æacus*.)

This island was surrounded by Attica, the territory of Megara, and the Peloponnesus, each distant about 100 stadia, or 12 miles and a half. In circumference it was reckoned 180 stadia, or 22 miles and a half. It was washed on the east andsouth by the Myrtoan and Cretan seas.

It is now called *Ejina*, or *Ægina*, the g-foth and the i short. The temple abovementioned is situated upon the summit of a mountain called *Panbellenus*, about an hour distant from the shore. The *Æginetans* affirmed it was erected by *Æacus*; in whole time Hellas being terrified by drought, the Delphic oracle was consulted; and the response was, That Jupiter must be rendered propitious by *Æacu*s. The cities interceded to be their mediator: He sacrificed and prayed to Jupiter Panbellenus, and procured rain.

The temple was of the Doric order, and had six columns in front. Twenty-one of the exterior columns are yet standing, with two in the front of the pronaoos and of the polisca, and five of the number which formed the range of the cell. The entablature, except the architrave, is fallen. The fome is of a light brown colour, much eaten in many places, and indicating a very great age. Some of the columns have been injured by boring to their centres for the metal. In several, the juncture of the parts is so exact, that each seems to confist of one piece. This ruin Mr. Chandler considers as scarcely to be paralleled in its claim to a remote antiquity. The situation on a lonely mountain, at a distance from the sea, has preserved it from total demolition, amid all the changes and accidents of numerous centuries.

Near the shore is a barrow, raised, it is related, for Phocis, upon the following occasion. Telamon and Pelcus, sons of *Æacus*, challenged their half-brother Phocus to contend in the Pentathlum. In throwing the stone, which served as a quoit, Pelcus hit Phocus, who was killed; when both of them fled. Afterwards, Telamon sent a herald to affer his innocence. *Æacus* would not suffer him to land, or to apologize, except from the vessel; or, if he chose rather, from a heap cast up in the water. Telamon, entering the private port by night, raised a barrow, as a token, it is likely, of a pious regard for the deceased. He was afterwards condemned, as not free from guilt; and failed away again to Salamis. The barrow in the second century, when seen by Pausanias, was surrounded with a fence, and had on it a rough stone. The terror of some dreadful judgment to be inflicted from heaven had preserv'd it entire and unaltered to his time; and in a country depopulated and neglected, it may still endure for many ages.

The foid of this island is, as described by Strabo, very floy, especially the bittoms, but in some places not unfertile in grain. Besides corn, it produces olives, grapes, and almonds; and abound in pigeons and partridges. It has been related, that the *Æginetans* annually wage war with the feathered race, carefully
ÆGIS, after the loss of his lamented wife, is supposed to have passed the remainder of his days in religious retirement, and to have died soon after the year 840. His life of Charlemagne, his annals from 741 to 829, and his letters, are all included in the 2d volume of Duchefne's Scriptures Francorum. But there is an improved edition of this valuable historian, with the annotations of Hermann Schmincke, in 440, 1744.

ÆGIS, in heathen mythology, a denomination given to the god Pan, because he was represented with the horns, legs, feet, &c. of a goat.

ÆGIS, the ancient mythology, a name given to the shield or buckler of Jupiter and Pallas.

The goat Amalthea, which suckled Jove, being dead, that god is said to have covered his buckler with the skin thereof; whence the appellation ægis, from ophis, a serpentine,掀起物. Jupiter, afterwards resting the beetle to life again, covered it with a new skin, and placed it among the stars. As to his buckler, he made a present of it to Minerva; whence that goddeß's buckler is also called ægis.

Minerva, having killed the Gorgon Medusa, nailed her head in the middle of the ægis, which henceforth had the faculty of converting into stone all those who looked thereon; as Medusa herself had done during her life.

Others take the ægis not to have been a buckler, but a cuirass, or breast-plate, and it is certain the ægis of Pallas, described by Virgil, Æn. lib. viii. ver. 435, must have been a cuirass; since that poet says expressly, that Medusa's head was on the breast of the goddeß. But the ægis of Jupiter, mentioned a little higher, ver. 354, seems to have been a buckler: the words Cum sage migratæ ægidæ concubint ægis concurrent

Ægis concurrent dextræ,
agreeing very well to a buckler; but not at all to a cuirass or breast-plate.

Servius makes the same distinction on the two passages of Virgil: for on ver. 354, he takes the ægis for the buckler of Jupiter, made, as above mentioned, of the skin of the goat Amalthea; and on ver. 455 he describes the ægis as the armour which covers the breast, which in speaking of men is called cuirass, and ægis in speaking of the gods. Many authors have overlooked these distinctions for want of going to the sources.

ÆGIS, in ancient history, was the son of Tyndale by his own daughter Pilopela, who, to conceal her shame, exposed him in the woods: some say he was taken up by a shepherd, and suckled by a goat, whence he was called Ægillis. He corrupted Cly-
AEGO [138] AEGO

ÆGITHALUS tenuifera the wife of Agamemnon; and with her affiance flew her husband, and reigned seven years in Mycenæ. He was, together with Clytemnestra, slain by Orestes. Pompey used to call Julius Caesar Ægithus, on account of his having corrupted his wife Mutia, whom he afterwards put away, though he had three children by her.

ÆGITHALUS (anc. geog.), a promontory and citadel of Sicily, between Drypanum and the Empori-um Aegismanum, afterwards called Aelius; corruptly written Ægitharfish, in Ptolemy; situated near mount Eryx, and now called Copo di Santo Teodoro.

ÆGIUM, (anc. geog.) a town of Achaea Propria, five miles from the place where Helice flood, and famous for the council of the Acheans, which usually met there on account either of the dignity or commodious situation of the place. It was also famous for the worship of Ægigiane, Conventual Jupiter, and of Panthæan Ceres. The territory of Ægium was watered by two rivers, viz. the Phoenix and Meganitas. The epithet is Ægiumis. There is a coin in the cabinet of the king of Prussia, with the inscription Art, and the figure of a tortoise, which is the symbol of Peloponnesus, and leaves no doubt as to the place where it was struck.

ÆGOBOULUM, in antiquity, the sacrifice of a goat offered to Cybele. The ægobolum was an expiatory sacrifice, which bore a near resemblance to the taurusbolium andcribolium, and seems to have sometimes joined with them.

ÆGOPODIUM, SMALL WILD ANGELICA, GOAT-WORT, GOATSFOOT, HERB GERARD, or ASH WEEDE; a genus of the digynia order, belonging to the pentandria class of plants; the characters of which are: The universal calyx is a manifold convex umbel; the partial one, coniflaral and flat; there is no involucrum; and the proper perianthium is scarcely discernible: The universal corolla is uniform, the florets all fertile; the proper one has five inverte-ovate, concave, equal petals, inflected at the top: The stamina confift of five simple filaments twice the length of the corolla; the antheræ roundish: The pistillum has a germen beneath; two purple erect styli the length of the corollett; the stigmate are headed: No pericarpium: The fruit is ovate, fricated, and bipartite: The seeds are two, ovate, on one side convex and fricated, and flat on the other. There is but one species, a native of Britain and other parts of Europe. It is very common under hedges and about gardens; the leaves resemble those of Angelica, and it carries small white flowers. Its roots run so faft, as to render it a very troublesome weed.

ÆGOPRICORN, a genus of the monoecea order, belonging to the diandria class of plants; the characters of which are: The calyx both of the male and female is tubular perianthium of one leaf divided into three segments: Corolla wanting in both: The stamina consist of a single erect filament longer than the calyx, with an ovate anthera: The pistillum has an ovate germem, three divaricated styli, and simple perifent stigma: The pericarpium is a globular berry, three-grained within, and three-celled: The seeds are solitary, and angular on one side.—There is but one species, a native of Surinam.

ÆGOSPOTAMOS, (anc. geog.), a river in the Thracian Cheroneus, falling with a south-east course into the Hellepont, to the north of Cefнос; also a town, station, or road for ships, at its mouth. Here the Athenians, under Conon, through the fault of his colleague Isocrates, received a signal overthrow from the Lacedemonians under Lyfander, which was followed by the taking of Athens, and put an end to the Peloponnesian war. The Athenian fleet having followed the Lacedemonians, anchored in the road, over against the enemy, who lay before Lampèacus. The Hellepont is not above two thousand paces broad in that place. The two armies facing themselves so near each other, expected only to rest that day, and were in hopes of coming to a battle on the next.

But Lyfander had another design in his view. He commanded the seamen and pilots to go on board their galleys, as if they were in reality to fight the next morning at break of day, to hold themselves in readiness, and to wait his orders with profound silence. He commanded the land-army in like manner to draw up in battle upon the coast, and to wait the day without noise. On the morrow, as soon as the sun was risen, the Athenians began to row towards them with their whole fleet in one line, and to bid them defiance. Lyfander, though his ships were ranged in order of battle, with their heads towards the enemy, lay still without making any movement. In the evening, when the Athenians withdrew, he did not suffer his folders to go ahoare, till two or three galleys, which he had before to observe them, were returned with advice that they had seen the enemy land. The next day paffed in the same manner, as did the third and fourth. Such a conduct, which argued reserve and apprehension, extremely augmented the security and boldness of the Athenians, and inspired them with an extreme contempt for an army, which, fear, in their sense, prevented from showing themselves, and attempting anything.

Whilest this paffed, Alcibiades, who was near the fleet, took horse, and came to the Athenian generals; to whom he represented, that they kept upon a very disadvantageous coast, where there were neither ports nor cities in the neighbourhood; that they were obliged to bring their provisions from Céfнос with great danger and difficulty; and that they were very much in the wrong to suffer the folders and mariners of the fleet, as soon as they were ahoare, to straggle and disperse themselves at their own pleasure, whilst they were faced in view by the enemy's fleet, accustomed to execute the orders of their general with the deadlest obedience, and upon the slightest signal. He offered also to attack the enemy by land with a strong body of Thracian troops, and to force them to a battle. The generals, especially Tydeus and Menander, jealous of their command, did not content themselves with refusing his offers, from the opinion, that if the event proved unfortunate, the whole blame would fall on them, and if favourable, that Alcibiades alone would have the honour of it; but rejected also with insult his wife and sultanary council, as if a man in disgrace lost his sense and abilities with the favour of the commonwealth. Alcibiades withdrew.

The fifth day the Athenians presented themselves again, and offered battle; returning in the evening according to custom with more infulting airs than the days before. Lyfander, as usual, detached some galleys to observe them, with orders to return with the utmost
EGYPTIAN artificers, when they saw the Athenians land;
ed, and to put up a brazen buckler at each ship's head as
soon as they reached the middle of the channel.

Himself in the mean time ran through the whole line in
his galley, exhorting the pilots the feamen and soldiers in readiness to row and fight
on the first signal.

As soon as the bucklers were put up in the ships' heads, and the admiral galley had given the signal by
the sound of trumpet, the whole fleet set forward in
good order. The land-army at the same time made all
possible haste to the top of the promontory to see the
battle. The strait that separates the two continents
poisible as soon as they reached the middle of the
good order.

AEGYPTIUS, (fab. hist.) was the son of Belens, and
brother of Danans. See BEIDES.

ELINATÆ, in antiquity, a denomination given to
the senators of Milectus, because they held their delibera-
tions on board a ship, and never returned to land,
till matters had been agreed on.

ELIAN (Claudius), born at Prænesta in Italy. He
taught rhetoric at Rome, according to Perizonius,
under the Emperor Alexander Severus. He was famed
for his works on Natural History and Animals. He com-
posed likewise a book on Providence, mentioned by
Pliny, and another on divine Appearances, or The
Histories of Providence. There have been several editions of
his various Histories.

ELIUS PONS (anc. geog.) one of the fortresses near
the wall or rampart, or, in the words of the Notitia,
through the line of the hither wall; built, as is thought,
by Adrian*. Now Portland, (Camden), in North-
umberland, between Newcastle and Morpeth.

ELIUS PONS, now il Ponte S. Angelo, a stone-
bridge at Rome, over the Tiber, which leads to the
Burgo and Vatican from the city, along Adrian's mole,
built by the Emperor Adrian.

ELFRED. See ALFRED.

ELURUS, in Egyptian mythology, the deity or
god of cats: sometimes personified as a cat, and
sometimes like a man with a cat's head. The Egyp-
tians had it superstitious a regard for this animal, that
the killing it, whether by accident or design, was
punished with death: and Didorus relates, that, in the
time of extreme famine, they chose rather to eat one
another than to touch these sacred animals.

AEM, AM, or AME, a liquid measure used in most
parts of Germany; but different in different towns;
the aem commonly contains 20 versili, or 80 ma-
fes; that of Heidelberg is equal to 48 maizes; and that of
Wtmerbergh to 160 maizes. See AM.

EMILUS (Paulus), the son of Lucius Paulus,
who was killed at the battle of Canne, was twice con-
ful. In his first consulship he triumphed over the Lib-
garians; and in the second subdued Perieus king of
Macedonia, and reduced that country to a Roman pro-
vince, on which he obtained the surname of Macedoni-
cus. He returned to Rome loaded with glory, and
triumphed for three days. He died 168 years before
Christ.

EMILUS (Paulus), a celebrated historian, born at
Verona, who obtained such reputation in Italy, that he
was invited into France by the cardinal of Bourbon, in
the
The reign of Lewis XII. in order to write the history of the kings of France in Latin, and was given a cameo in the cathedral of Paris. He was near 30 years in writing that history, which has been greatly admired; and died at Paris on the 5th of May 1529.

MOBOLIUM, in antiquity, the blood of a bull or ram offer'd in the sacrifices, called taurobolia and erichnia; in which sense the word occurs in ancient inscriptions.

ÆNARIA (anc. geog.), an island on the bay of Cumae, or over-against Cumae in Italy, (Pliny.) It is also called Cerinthus, (Virgil;), and now Ischia: scarce three miles distant from the coast, and the promontory Milenuis to the west; 20 miles in compass; called Pitha by the Greeks. It is one of the Oenotrides, and fenced round by very high rocks, so as to be inaccessible but on one side; it was formerly famous for its carthare. See ISCIA.

ÆNEAS (fab. hist.), a famous Trojan prince, the son of Anchises and Venus. At the destruction of Troy, he bore his aged father on his back, and saved him from the Greeks; but being too solicitous about his son and house-gods, lost his wife Creuca in the escape. Landing in Africa, he was kindly received by Queen Dido: but quitting her coast, he arrived in Italy, where he married Livinia the daughter of king Latinus, and defeated Turnus, to whom the name of his prince immortal, by making him the martyr, and defeated Turnus, to whom the name of this prince immortal, by making him the hero of his poem. See ÆNEID.

Æneas Sylvius, (Pope.) See PIUS II.

ÆNEATORES, in antiquity, the musicians in an army, including those who played drums, horns, &c. The word is formed from æneas, on account of the brazen instruments used by them.

ÆNEID, the name of Virgil's celebrated epic poem.

Blair's Latin.

The subject of the Æneid, which is the establishment of Æneas in Italy, is extremely happy. Nothing could be more interesting to the Romans than to look back to their origin from so famous a hero. While the object was splendid itself, the traditionary history of his country opened interesting fields to the poet; and he could glance at all the future great exploits of the Romans, in its ancient and fabulous state.

As to the unity of action, it is perfectly well preserved in the Æneid. The settlement of Æneas, by the order of the gods, is constantly kept in view. The schemes are linked properly with the main subject. The nodus, or intrigue of the poem, is happily managed. The wrath of Juno, who opposes Æneas, gives rise to all his difficulties, and connects the human with the celestial operations throughout the whole poem.

One great imperfection of the Æneid, however, is, that there are almost no marked characters in it. Achaæs, Cloanthes, Gyas, and other Trojan heroes who accompanied Æneas into Italy, are inoffensive figures. Even Æneas himself is without interest. The character of Dido is the best supported in the whole Æneid. The principal excellence of Virgil is tenderness. His song was full of sensibility. He must have felt himself all the affecting circumstances in the scenes he describes; and he knew how to touch the heart by a single stroke. In an epic poem this merit is the next to sublimity. The second book of the Æneid is one of the greatest master pieces that ever was executed. The death of old Priam, and the family-pieces of Æneas, Anchises, and Creuca, are as tender as can be conceived. In the fourth book, the unhappy passion and death of Dido are admirable. The episodes of Pallis and Evander, of Nifus and Euryalus, of Lausus and Mezentius, are all superlatively fine.

In his battles, Virgil is far inferior to Homer. But in the important episode, the descent into hell, he has outdone Homer by many degrees. There is nothing in antiquity to equal the sixth book of the Æneid.

ÆNGINA, one of the islands of the Archipelago. It lies in the bay of Engia, and the town of that name contains about 500 houres and a castle; and near it are the ruins of a magnificent structure, which was probably a temple.

ÆNIGMA, denotes any dark saying, wherein some well-known thing is concealed under obscure language. The word is Greek, Ανιγμα, formed of ανιγμα, obscure insinuate, to hint a thing darkly, and of αιγμα, an obscure speech or discourse. The popular name is riddle; from the Sylisac rædsyn, or the Saxon rædstan, to interpret. Fa. Bouhuris, in the memoirs of Teverus, defines an ænigma, A discourse, or painting, including some hidden meaning, which is proposed to be guessed. Painted ænimas are representations of the works of nature, or art, concealed under human figures, drawn from history, or fable.

A verbal ænimà is a witty, artful, and abstruse description of any thing.—In a general sense, every dark saying, every difficult question, every parable, may pass for an ænigma. Hence obscure laws are called ænimata juris. The alchemists are great dealers in the ænimatic language, their proceeds for the philosophers' stone being generally wrapped up in riddles: c. e. Fac ex mare et fæmina circulum, inæ quadratum, hinc triangulum, fac circulum, et habebis lapidem philosophorum.—F. Menestrier has attempted to reduce the composition and resolution of ænimas to a kind of art, with fixed rules and principles, which he calls the philosophy of ænimatic images.

The Subject of an ænimà, or the thing to be concealed and made a mystery of, he justly observes, ought not to be such in itself; but, on the contrary, common, obvious, and easy to be conceived. It is to be taken, either from nature, as the heavens, or stars; or from art, as painting, the compas, a mirror, or the like.

The Form of ænimas consists in the words, which, whether they be in prose or verse, contain either some description, a question, or a proverbiation. The last kind are the most pleasing, inasmuch as they give life and action to things which otherwise have them not. To make an ænimà, therefore, two things are to be pitched on, which bear some resemblance to each other; as the sun and a monarch; or a ship and a house; and on this resemblance is to be raised a superfature of contrarieties to amuse and perplex. It is easier to find great subjects for ænimas in figures than in words, inasmuch as painting attracts the eyes and excites the attention to discover the sense. The subjects of ænimas in painting, are to be taken either from history or fable: the composition here is a kind of metamorhosis,
Enigmas, in which human figures are changed into trees, and rivers into metals. It is essential to any picture, it may be known to every body; otherwise it will be two enigmas instead of one; the first of the history or fable, the second or fable in which it is to be taken. Another essential rule of the enigma is, that it only admits of one feme. Every enigma which is susceptible of different interpretations, all equally natural is far imperfect. What gives a kind of crucifixion to an enigma, is an invention of figures in situations, gestures, colours, &c. authorized by passages of the poets, the customs of artificers in statues, bas-relievo, inscriptions, and foreign languages.

The explanation of ENIGMAS makes a considerable exercise; and that one of the most difficult and amusing, where wit and penetration have the largest field.

—By explaining an enigma, is meant the finding a motto corresponding to the action and persons represented in a picture, taken either from history or mythology. The great art of this exercise consists in the choice of a motto, which either by itself, or the circumstances of time, place, person who speaks, or those before whom he is speaking, may divert the spectators, and furnish occasion for strokes of wit; all the more to advantage the conformities between the figure and thing figured; giving ingenious turns to the reasons employed to support what is advanced, and in artfully introducing pieces of poetry to illustrate the sujet de and awaken the attention of the audience.

As to the solution of enigmas, it may be observed, that those expressed by figures are more difficult to explain than those consisting of words, by reason images may signify more things than words can; so that to fix them in a particular sense, we must apply every situation, symbol, and without omitting a circumstance. As there are few persons in history, or mythology, but have some particular character of vice or virtue, we are, before all things, to attend to this character, in order to divine what the figure of a person represented in a painting signifies, and to find what agreement this may have with the subject whereof we would explain it. Thus, if Proteus be represented in a figure, it may be taken to denote insensibility, and applied either to a physical or moral subject, whose character is to be changeable; e.g. an almanack, which expresses the weather, the feasons, heat, cold, storms, and the like. The colours of figures may also help to unriddle what they mean: white, for instance, is a mark of innocence, red of modesty, green of hope, black of sorrow, &c. When figures are accompanied with symbols, they are less precarious; these being, as it were, the soul of enigmas, and the key that opens the mystery of them. Of all the kinds of symbols which may be met with in those who have treated professedly on the subject, the only truly enigmatical are those of Pythagoras, which, under dark proverbs, hold forth effons of morality: as when he says, Statere in se tranquillas, to signify, Do no injustice. But it must be added, that we meet with some enigmas in history, complicated to a degree, which much transcends all rules, and has given great perplexity to the interpreters of them. Such is that celebrated ancient one, Enilda Crispis, about which many of the learned have puzzled their heads. There are two exemplars of it: one found 140 years ago, on a marble near Bologna: the other in an ancient MS. written in Gothic letters, at Milan. It is controverted between the two cities, which is to be reputed the more authentic.

The Bononian Enigma.

D. M.

Ælia Lelia Crispis,

Nec vir, nec mulier,

Nec androgyne;

Nec puella, nec juvenis,

Nec anus;

Nec caulis, nec materrix,

Nec indicia;

Sed omnia:

Subhata

Necque fane, necque ferro,

Necque veneno;

Sed omnibus:

Neculo, nec terris,

Nec aquat,

Sed ubiue iacet.

Lucius Agatho Prisnus,

Nec maritus, nec amator,

Nec necessarius;

Necque marcius, necque be advert,

Necque fogs;

Hanc,

Nec molem, nec pyramidem

Nec sepulchrum,

Sed omnia,

Seit et nefcit, eas pofuerit.

That is to say, To the god: Land, Ælia Lelia Crispis, neither man, nor woman, nor hermaphrodite; neither girl, nor young woman, nor old, neither chaste, nor a whore; but all these: killed neither by hunger, nor fleat, nor pain; but by all these: repels neither in heaven, nor on earth nor in the waters; but every where. Lucius Agatho Prisnus, neither her husband, nor lover, nor friend; neither forsworn, nor joyful, nor weeping, certain or uncertain, to whom he rears this monument, neither erects her a temple, nor a pyramid, nor a tomb, but all these. In the MS. at Milan. Instead of D. M. we find A. M. P. P. D. and at the end the following addition:

Hoc eft sepulchrum inus cadaver non baletis,

Hoc eft cadaver sepulchrum extru non baletis,

Sed cadaver idem eft et sepulchrum

We find near 50 several solutions of this enigma, advanced by learned men. Marius Michael Angelus maintains Ælia Lelia Crispis to signify rain-water falling into the sea. R. Vitus first explained it of Niobe turned to a stone, afterwards of the rational soul, and afterwards of the Platonic idea: Jo. Turrisius, of the materia prima: Fr. Schottius, of an encauch; Nic. Bernardis, of the philosophia-terrene, in which he is followed by Boschius; Zach. Pontinus, of three human bodies in the same situation, and buried by three different men at the same time; Nelfiandus, of a law-suit; Jo. Graf. Gerarium, of love; Zu. Boxhornius, of a shadow; P. Terronius, of matter, Fort Libenius, of generation, friendship, and privation: M. Cv. Montalbanus, of hemp; Car. af. Malvafia, of an abortive girl promised in marriage; Pet. Mengius, of the rule of chafity, prescribed by the founder of the military
ÆOL, a military religion of St Mary; M. de Ciconia, of pope Joan; Heumannus, of Lor’s wife; and lastly, J. C. S. an anonymous writer in the Leipic Acts, of the Christian church.

ÆGMATOGRAPHY, or ÆGMATOGRAPHY, the art of resolving or making enigmas.

ÆNONA (anc. geog.), a city of Liburnia, called by Pliny Civitas i s. lajina, the reason of which is unknown; also Ænona, and is now called Nona; on the Adriatic, by which it is for the greater part surrounded; over against the island Gilfa, from which it is distant four miles to the west. E. Long. 160, Lat. 28°.

ÆNUS (anc. geog.), now the Inn, a river of Germany, which, rising in the country of the Grifons, out of the Alps, in the district called Gottes-haus-punt, runs through the Grifons, the country of Tyrol, the duchy of Bavaria, and through Passau into the Danube.

ÆNUS, Ænis, or Ænum (anc. geog.), a town of Thrace, situate on the east-end mouth of the Hebrus, which has two mouths, and said to be built by the Cumeans. It was a free town, in which flood the tomb of Polydorus, (Pliny) Ænis is the epithet. Here the brother of Catu Uticensis died, and was honoured with a monument of marble in the forum of the Ænus, (Plutarch) called Ænetis, (Stephanus) Livy says that the town was otherwise called Æthynus. Now Æna.

ÆNITIOLOGIUS, in poetry, a verse of two dactyls and three trochees; as, Pradlia diva placenta truci juventus.

ÆOLIE INSULÆ, now Isola di Lipari, (anc. geog.) feven islands, situated between Sicily and Italy, so called from Æolus, who reigned there about the time of the Trojan war. The Greeks call them Hephaestias; and the Romans Pyliasia, from their fiery eruptions. They are also called Liparaverum Insulae, from their principal island Lipara. Dionysius Periegetes calls them Æneas because circum navigable.

ÆOLIC, in a general sense, denotes something belonging to Æolus.

ÆOLIC, or Æolian, in grammar, denotes one of the five dialects of the Greek tongue. It was first used in Boeotia; whence it passed into Ἐλλαδα, and was that which Sappho and Alcaeus wrote in. The Æolic dialect generally throws out the aspirate or sharp spirit, and agrees in so many things with the Doric dialect that the two are usually confounded together.

Æolic Onoma, a name given to the letter ο, which the Æolians used to prefix to words beginning with vowels as φοινικα, for φοινικα, also to infer between vowels, as ειρετικ, for ειρετικα.

Æolic Verse, in profody, a verse consisting of an iambus, or spondee; then of two anapaests, separated by a long syllable; and, lastly, of another syllable. Such as, ὁ δεινοστρεμθηδων ορθος. This is otherwise called enotic verse; and, from the chief poets who used it, Archibius and Pindar.

ÆOLIPILE, in hydraulics, is a hollow bowl of metal, generally used in courses of experimental philosophy, in order to demonstrate the possibility of converting water into an elastic steam or vapour by heat. The instrument therefore, consists of a slender neck, or pipe, having a narrow orifice inserted into the ball by means of a hollowed screw. This pipe being taken out, the ball is filled almost full of water, and the pipe being again screwed in, the ball is placed on a pan of kindled charcoal, where it is well heated, and there issues from the orifice a vapour, with prodigious violence and great noise, which continues till all the included water is discharged. The stronger the fire, the more elastic and violent will be the steam; but care must be taken that the small orifice of the pipe be not, by any accident, stopped up; because the instrument would in that case infallibly burst in pieces, with such violence as may greatly endanger the lives of the persons near it. Another way of introducing the water is to heat the ball red-hot when empty, which will drive out almost all the air; and then by suddenly merging it in water, the pressure of the atmosphere will force it in, till it is nearly full. Des Cartes and others have used this instrument to account for the natural cause and generation of the wind; and hence it was called Æolophus q.d. pia Æolis, the ball of Æolus or of the god of the winds.

ÆOLIS, or ÆOLIA (anc. geog.), a country of the Hither Asia, settled by colonies of Æolian Greeks. Taken at large, it comprehends all Troas, and the coast of the Hellepont to the Propontis, because in those parts there were several Æolian colonies: more briefly, it is situated between Troas to the north, and Ionia to the south. The people are called Æolites, or Æolii.

ÆOLIA MARÉ (anc. geog.), a part of the Egean sea, walking Æolus; called also Myfium, from Myfia, now called, Cofo di Smyrna.

ÆOLUS in heathen mythology, the god of the winds, was said to be the son of Jupiter by Acasta, or Sigeia, the daughter of Hippotus; or, according to others the son of Hippotus by Meneclea, daughter of Hyllus king of Lipara. He dwelt in the island Strongyle, now called Stromboli, one of the seven islands called Æolian from their being under the dominion of Æolus. Others say, that his residence was at Regium, in Italy; and others again place him in the island Lipara. He is represented as having authority over the winds, which he held enchaîned in a vast cavern to prevent their continuing the devastations they had been guilty of before they were put under his direction. Mythologists explain the original of these fables, by saying, that he was a wife and good prince; and, being skilled in astronomy, was able, by the flux and reflux of the tides, and the nature of the volcano in the island Strongyle, to foretell storms and tempests.

Æolus, or Æolus, or the Æolian lyre. See Acoustics, no. 10.

ÆON, a Greek word, properly signifying the age or duration of anything.

Æon, among the followers of Plato, was used to signify any virtue, attribute, or perfection; hence they represented the deity as an assemblage of all possible aeons; and called him περεμα, a Greek term signifying πνεύμα. The Valentinians, who, in the first ages of the church, blended the conceits of the Jewish cabalists, the Platonists, and the Chaldean philosophers, with the simplicity of the Christian doctrine, invented a kind of Theogony, or Genealogy of Gods (not unlike that of Hefiod), whom they called by several glorious names, and all by the general appellation of άεόνας; among which they reckoned θανώς, Life; ζωή, Word; θειοπάθεια, Only-begotten; παράσιτος, Fugitive; and many other divine powers and emanations, amounting in
The idea of an era comprehends also a certain succession of years proceeding from a fixed point of time, and the epoch is that point itself. Thus the Christian era began at the epoch of the birth of Jesus Christ. See Chronology, where the different eras, &c. are enumerated and explained.

ÆRARIUM, the treasury or place where the public money was deposited amongst the Romans.

ÆRARIUM Victorum, the place where the money arising from the taxes levied from foreign countries was laid up, so called because it most commonly consisted of a twentieth part of all legacies: this was kept for the extreme necessities of the state.

ÆRARIUM Privatum was the emperor's private purse, or the place where the money arising from his private patrimony was deposited.

ÆRARIUM Victorum, the place where the money arising from the taxes levied from foreign countries was laid up, so called because it most commonly consisted of a twentieth part of all legacies: this was kept for the extreme necessities of the state.

ÆRARIUM Privatum was the emperor’s private purse, or the place where the money arising from his private patrimony was deposited.

ÆRARIUM Victorum, the place where the money arising from the taxes levied from foreign countries was laid up, so called because it most commonly consisted of a twentieth part of all legacies: this was kept for the extreme necessities of the state.

ÆRARIUM Privatum was the emperor’s private purse, or the place where the money arising from his private patrimony was deposited.

ÆRARIUM Victorum, the place where the money arising from the taxes levied from foreign countries was laid up, so called because it most commonly consisted of a twentieth part of all legacies: this was kept for the extreme necessities of the state.

AERIAL, in a general sense, denotes something pertaining to nature of air; thus, aerial substance, aerial particles, &c. - Aerial Perspective: See Perspective and Painting.

AERIANS, in church history, a branch of Arians, who, to the doctrines of that sect, added some peculiar dogmas of their own; as, that there is no difference between bishops and priests; a doctrine maintained by many modern divines, particularly of the presbyterian and reformed churches. The sect received its denomination from Aærius an Armenian priest of the fourth century. He founded his doctrine chiefly upon some passages in St Paul; and, among others, upon that in 1 Tim. iv. 14, where the apostle exhorts him not to neglect the gift he had received by the laying on of the hands of the Presbytery. Here, observes Ac-

AEROROLOGY,

The doctrine or science of air, its nature and different species, with their ingredients, properties, phenomena, and uses.

Air, in a general sense, is that invisible fluid everywhere surrounding the globe; on which depends not only animal but vegetable life; and which, in short, to be one of the great agents employed by nature in carrying on her operations throughout the world.

Though the attention of philosophers has in all ages been engaged in some measure by inquiries concerning the nature of the atmosphere, yet till within these last 30 years, little more than the mere mechanical action of this fluid was discovered, with the existence of some anomalous and permanently elastic vapours, whose properties and relation to the air we breathe are almost entirely unknown. Within the above-mentioned period, however, the discoveries concerning the constituent parts of the atmosphere itself, as well as the nature of the different permanently elastic fluids which go under the general name of air, have been so numerous and rapid, that they have at once raised this subject to the dignity of a Science, and now form a very considerable, as well as important, part of the modern system of natural philosophy.

These discoveries, indeed, have not been more interesting to philosophers, than useful to science and beneficial to society. Many perplexing processes in chemistry have been explained in consequence of them, several have been facilitated, and a number of new and useful ones have been introduced. The phenomena attending metallic calcinations and reductions have been greatly elucidated. The knowledge of the use of the air in respiration; the method of ascertaining its purity and times for that function; the investigation of dephlogisticated air; the method of impregnating water with fixed air; are all calculated to answer purposes of the highest utility. The medicinal properties of fixed air have been in great measure ascertained, and its antiplectic qualities in certain respects promise to be of considerable advantage. The method of ascertaining the purity of the air of a place, and the manner of ventilating an apartment, are of great use for those concerned in public buildings. In short, there is perhaps no station in life where some knowledge of this subject may not be of use.

Sect. I. Of the general Constitution, Mechanical Properties, and Operations of the Air.

§ 1. The general Constitution of the Air we breathe.

For many ages this fluid was supposed to be simple, and homogeneous; its common operations to depend on its heat, cold, moisture, or dryness; and any effects concerning which could not be explained by these (such as the appearance of pestilential diseases), were reckoned to be entirely supernatual, and the immediate effects of Divine power. But, however simple and homogeneous this fluid may have been thought in former times, it is far from posseing the simplicity of an element, that it is the receptacle of all kinds of effluvia produced from terrestrial substances, both naturally or artificially. Hence whatever maybe the nature of the aerial fluid when absolutely pure, that which we breathe, and commonly goes under the name of air, must be considered as an exceedingly heterogeneous mixture, various at various times, and which it is by no means possible to analyse with accuracy.

Though, in this view, air seems to be a kind of sink in what or common sewer, where all the poisonous effluvia arising from putrid and corrupted matters are deposited; yet it has a wonderful facility of purifying itself, and one way or other of deposing those vapours contained in it; so that it never becomes noxious except in particular places, and for a short time; the general mass remaining upon all occasions pretty much the same. The way in which this purification is effected is different, according to the nature of the vapour with which the air is loaded. That which most universally prevails is water; and from experiments it appears, that the quantity of aqueous vapour contained in the atmosphere is immense. Dr Halley, from an experiment on the evaporation from a fluid surface heated to the same degree with that given by our meridian sun, has calculated, that the evaporation from the Mediterranean sea is alone sufficient to yield all the water of the
Section I. AEROLOGY.

Of Air in general.

The rivers which run into it. Dr. Watson, in his Chemical Experiments, has given an account of some experiments made with a view to determine the quantity of the water raised from the earth itself in time of drought. He informs us, that when there had been no rain for above a month, and the grass was become quite brown and parched, the evaporation from an acre was not less than 1600 gallons in 24 hours. Making afterwards two experiments, when the ground had been wetted by a thunder-shower the day before, the one gave 1795, the other 1905, gallons in 24 hours. From this the air is every moment purified by the ascent of the vapour, which flying off into the clouds, thus leaves room for the exhalation of fresh quantities; so that as the vapour is considerably lighter than the common atmosphere, and of consequence ascends with greater velocity, the air during all this time is said to be dry, notwithstanding the vast quantity of aqueous fluid that passes through it.

Nor is it only from the aqueous vapour that the air is purified at this time. Much of that vapour arising from decayed and putrid animal and vegetable substances, and which by some modern philosophers is called phlogiston, attaches itself to the aqueous vapour, and ascends along with it. Another part is absorbed by vegetables; for the phlogistic vapour, as is shewn under Agriculture, no. 5, is probably the food of plants. The phlogistic vapours which ascend along with the water, probably continue there and descend along with the rain; whence the fertilizing qualities of rain-water above those of any other. Thus we may see why a dry air, whether cold or hot, must always be wholesome; but as the atmosphere cannot always receive vapours, it is obvious, that when great rains come on, especially if attended with heat, the lower regions of the air must be overloaded with vapours both of the aqueous and phlogistic kind, and of consequence be very unwholesome.

But besides the aqueous and phlogistic vapours, both of which are specifically lighter than common air, there are others, which, being specifically heavier, cannot be carried off in this manner. Hence these gross vapours contaminate certain places of the atmosphere, rendering them not only unhealthy, but absolutely poisonous. Of these are, 1. Sulphureous, acid, and metallic exhalations. These are produced principally by volcanoes; and as they descend, in consequence of their specific gravity, they suffocate and spread destruction all around them, poisoning not only animals, but vegetables also. 2. The vapours arising from hooves where lead and other metals are melted, have the same pernicious qualities; insomuch that the men who breathe them, the cattle who eat the graps, and the fitches who inhabit the waters on which they fall, are poisoned by them if taken into the body in a certain proportion. 3. Of the same kind are the nocent, or emanations of fixed air, which sometimes proceed from old lavas, or perhaps from some other places even of the surface. From all these the air seems not capable of purifying itself, otherwise than by either dispersing them by winds, or by letting them subside by their superior gravity, till they are absorbed either by the earth or water, according as it is their nature to unite with one or other of these elements. 4. Of this kind also seem to be the vapours which are called properly specific. The contagion of the plague itself seems to be of an heavy digested nature, incapable in general of arising in the air, but attaching itself to the sides of houses, bed-cloths, and wearing apparel. Hence scarce any confutation of the atmosphere can dispel these noxious effluvia; nor does it seem probable that pestilential distempers ever cease until the contagion has operated so long, and been so frequently communicated from one to another, that, like a ferment much exposed to the atmosphere, it becomes rapid, communicates a milder infection, and at last loses its strength altogether.

§ 2. Mechanical Properties of the Air.—In common with water, the air we breathe possesses gravity, and specific conseqentiy will perform everything in that way which water can do, making allowance for the great difference between the specific gravity of water and of air. This difference indeed is exceedingly great, and has been variously calculated. Ricciolus estimates the gravity of air to be to that of water as 1 to 1000; Mercurius, as 1 to 1300, or 1 to 1356; Lana, as 1 to 649; and Galileo, only as 1 to 400. Mr. Boyle, by more accurate experiments makes the air at London to be 1 to 983; and thinks, that, all things considered, the proportion of 1 to 1000 may be taken as a medium. But by three experiments made since that time before the Royal Society, the specific gravity of the air was determined to be to that of water as 1 to 840, 872, and 860. By a very accurate experiment, Mr. Hauksbee fixed the proportion as 1 to 885. But as all these experiments were made when the barometer was at 293 inches, Dr. Jurin supposes, that, at a medium between heat and cold, when the barometer is 30 inches high, the proportion between the two fluids may be taken as one to 800; and this agrees with the observations of the Hon. Mr. Cavendish, made when the barometer was 291 inches, and the thermometer at 50.

By means of its gravity, the air presses with great effects of force upon all bodies, according to the extent of their gravity. M. Pascal has computed the quantity of this preasure to be no less than 2232 pounds upon every square foot of surface, or upwards of 15 pounds on every square inch. According to some experiments made by M. Amontons and de la Hire, a column of air on the surface of the earth, and 36 fathoms high, is equal in weight to three lines depth of mercury. From the barometer, however we know that the whole preasure of the atmosphere is very different; sometimes being equal only to a column of 28 inches, and varying from thence to 31 inches. The whole quantity of preasure must thus be immense, and has been computed equal to a globe of lead 60 miles in diameter.

By means of its gravity, the atmosphere accomplishes many useful purposes in nature. It prevents the aerial vessels of animals and the sap-vessels of plants from being too much diffused by the expansive power (whatever it is), which has a perpetual tendency to swell them out. Thus we see, that, in the operation of cupping, where the preasure of the air is taken off from a particular part, the expansive force instantly acts, and swells out the vessels to a great degree. Hence also, when animals are put into an air-pump, their whole bodies swell.

By
AEROLOGY.

Sect. I.

Of Air in general.

8. Elascity of the air.

By its gravity, the air promotes the union of fluid bodies, which would instantly cease in vacuo. Thus oils and salts, which remain united in air, separate as soon as that fluid is extracted. Hence also, when hot water is put under an exhausted receiver, it boils violently; because the pressure of the air being now taken of, the particles of steam, which existed invisibly among the water, and which the gravity of the atmosphere prevented from flying off so soon, are now hurried up with great velocity, by means of the excessive comparative gravity of the aqueous fluid.

On the gravity of the air depend the ascent of water in pumps, syphons, & c. and likewise all the phenomena of the barometer.

Besides its gravity, which the air has in common with water and other fluids, there is another which it has only in common with steam or vapour. This is called its elasticity; by which, like a spring it allows itself to be compressed into a smaller bulk, and then returns again to its original size upon removing the preasure.

The elasticity of the air was first ascertained by some experiments of lord Bacon, who, upon this principle, constructed the first thermometer, which he called his instrument calculare. Of this power we have numerous proofs. Thus a blown bladder being squeezed in the hand, we find the included air sensibly resist; so that, upon ceasing to compress, the cavities or impressions made in its surface are readily expanded again and filled up.

The structure and office of the Air-Pump depend on this elastic property. Every particle of air always exerts a resist or endeavour to expand, and thus strives against an equal endeavour of the ambient particles; whose resistance happening by any means to be weakened, it immediately diffuses itself into an immense extent. Hence it is that thin glass bubbles, or bladders filled with air, and exactly closed, being included in the exhausted receiver of an air-pump, burst by the force of the air they contain; and a bladder almost quite flaccid, swells in the receiver and appears full. The same effect also takes place, though in a smaller degree, on carrying the flaccid bladder to the top of an high mountain.

It has been questioned among philosophers, whether this elastic power of the air is capable of being destroyed or diminished. Desaguliers found, that air, after having been inclosed for half a year in a wind-gun, had lost none of its elascity; and Roberval, after preserving it in the same manner for 16 years, observed, that its expansive projectile force was the same as if it had been recently condensed. Nevertheless, Mr Haukbee concludes, from a later experiment, that the sprying of the air may be disturbed by a violent preasure, in such a manner as to require some time to return to its natural tone. Dr Hales inferred, from a number of experiments, that the elascity of the air is capable of being impaired and diminished by a variety of causes.

The weight or preasure of the air has no dependence on its elascity; but would be the same whether it had such a property or not. The air, however, being elascic, is necessarily affected by the preasure, which reduces it into such a space, that the elascity, which reacts against the compressing weight, is equal to that weight. In effect, the law of this elascity is, that it increases as the density of the air increases; and the density increases as the force increases by which it is preressed. Now there must necessarily be a balance between the action and re-action: i.e. the gravity of the air which tends to comprcss it, and the elascity by which it endeavour to expand, must be equal. Hence the elascity increasing, or diminishing universally, as the density increaseth or diminishes, it is no matter whether the air be compressed and retained in such a space by the weight of the atmosphere, or by any other means; it must endeavour in either case to expand with the same force. And hence, if air near the earth be pent up in a vessel, and all communication with the external fluid cut off, the preasure of the inclosed air will be equal to the weight of the atmosphere at the time the quantity was confined. Accordingly, we find mercury sustained at the same height, by the elascic force of air inclosed in a glafs vessel, as by the whole atmospheric preasure. On the same principle air may be artificially condensed; and hence the structure of the Air-Gun.

The utmost limits to which air, of the density which it polysifes at the surface of the earth, is capable of being comprressed, have not been ascertained. Mr Boyle conjectured, it was 12 times more dense; Dr Halley says that he has seen it comprressed so as to be 60 times denser than in its natural state, which is farther confirmed by Mr Papin and M. Guygens. Dr Hales, by means of a press, condensed it 38 times; and by forcing water in an iron bell or globe, into 1551 times less space than it naturally occupies. However, Dr Halley has ascertained, in the Philosophical Transactions, Abr. vol. ii. p. 17, that from the experiments made at London, and by the academy del Cimento at Florence, it might be safely concluded, that no force whatever is able to reduce air into 8000 times less space than that which it naturally polysifes on the surface of our earth. In answer to this, M. Amontons, in the Memoirs of the French Academy, maintains, that there is no fixing any bounds to its condensation; that greater and greater weights will still reduce it into less and less compacts; that it is only elascic in virtue of the fire which it contains; and that as it is impossible ever to drive all the fire out of it, it is impossible ever to make the utmost condensation.

The dilatation of the air, by virtue of its elascic force, is found to be very surprizing; and yet Dr Wallis suggests, that we are far from knowing the utmost of which it is capable. Several experiments made by Mr Boyle, it dilated first into nine times its former space; then into 31 times; than into 60; then into 150. Afterwards it was brought to dilate into 8000 times its space, then into 10,000, and even at last into 13,679 times its space, and this altogether by its own expansive force, without the help of fire. On this depend the structure and use of the MANOMETER.

Hence it appears, that the air we breathe near the surface of the earth is comprressed by its own weight into at least the 13,679th part of the space it would polysife in vacuo. But if the same air be condensed by art,
A E R O L O G Y.

§ 3. Effects of the different Ingredients of Air.—

This fluid acts not only by its common properties of gravity and elasticity, but produces numerous other effects arising from the peculiar ingredients of which it consists.

Thus, 1. It not only dissolves and attenuates bodies by its prehension and attrition, but as a chaos containing power of all kinds of menstrua, and consequently possesting power for dissolving all bodies. It is known that iron and copper readily dissolve and become rusty in air, unless well defended with oil. Boerhaave affirms us, that he has seen pillars of iron soon dissolve by air, that they might be crumbled to dust between the fingers; and as for copper, it is converted by the air into a substance much like the verdigris produced by vinegar.

Mr Boyle relates, that in the southern English colonies the great guns rust so fast, that after lying in the air a few years, large cakes of rust or cinders may be separated from them. Acosta adds, that in Peru the air dissolves lead, and consideribly increases its weight. Yet gold is generally esteemed indissoluble by air, being never found to contract rust, though exposed to it ever so long. In the laboratories of chemists, however, where aqua regia is prepared, the air becoming impregnated with a quantity of the vapour of this menstrum, gold contracts a rust like other bodies.

Stones also undergo the changes incident to metals. On bones. Thus Purbeck stone, of which Salisbury cathedral contains, is observed gradually to become softer, and to moulder away in the air; and Mr Boyle gives the same account of Blackington stone. He adds, that air may have a considerable operation on vitriol, even when a strong fire could act no farther upon it. And he has found, that the fumes of a corrosive liquor work more suddenly and manifestly on a certain metal when sustained in the air, than the menstruum itself did, which emitted fumes on those parts of the metal which it covered; referring to the effects of the effluvia of vinegar on copper.

The dissolving power of air is increased by heat, and by other causes. It combines with water; and by access of cold, deposits part of the matter which was kept dissolved in it by a greater degree of heat. Hence the water, by being deposited and condensed upon any cold body, such as glass, &c. in windows, forms fog, and becomes visible.

In the various operations of chemistry, air is a very necessary and important agent; the result of particular chemical processes depending on its presence or absence, on its effects of being open or indlosed. Thus, the parts of animals and vegetables can only be calcined in open air; in close vessels they never become any other than black coals. And these operations are affected by the changes to which the air is liable. Many infusions might be added to this purpose. Let it suffice to observe, that it is very difficult to procure oil of vitriol, per campaurnum, in a clear dry atmosphere; but in a thick moist air it may be obtained with greater ease, and in larger quantities. So, pure well-fermented wine, if it be carried to a place where the air is rendered with

91

147
The changes in the air arise from various causes, and are observable, not only in its mechanical properties, such as gravity, density, &c. But in the ingredients that compose it. Thus, as pitch in Sweden, noted for copper-mines, the mineral exhalations affect the air in such a manner as to discolour the silver coin in purses; and the same effluvia change the colour of brides. In Carniola, Campania, &c., where are mines of sulphur, the air becomes sometimes very unwholesome, which occasions frequent epidemic diseases, &c.

The effluvia of animals also have their effect in varying the air; as is evident in contagious diseases, plagues, murrains, and other mortals, which are spread by an infected air.

For the vivifying principle of air, see the article Blood.

Sect. II. Historical Account of the principal Discoveries concerning the Composition of Atmospheric Air, and other Aerial Fluids.

While the preceding discoveries were making concerning the mechanical and other properties of the air, little notice seems to have been taken of the elementary parts of the air itself, or of the different kinds of fluid which go under that name. It was known, indeed, that air was separable from terrestrial bodies by means of fire, fermentation, &c. But this was commonly reckoned to be the same with what we breathe. Van Helmont, a disciple of Paraeus, was the first who undertook to make inquiries concerning this species of air. He gave it the name of gas fylveyfi, from the Dutch word gheu, significating spirit; and observes, that some bodies resolve themselves almost entirely into it. "Not (says he) that it had been actually contained in that form in bodies from which it was separated; but it was contained under a concrete form, as if fixed, or coagulated." According to this author, the gas sylveyfi is the same with what is separated from all substances by fermentation; from vegetables by the action of fire; from gun-powder when it explodes; and from charcoal when burning. On this occasion he affirms, that 62 pounds of charcoal contain 61 pounds of gas and only one pound of earth. To the effluvium of gas he also attributes the fatal effects of the grotto del Canti in Italy, and the suffocation of workmen in mines. He affirms, that it is to the corruption of the aliment, and the gas discharged from it, that we are to attribute wind, and the discharges of it from the bowels. Upon the same principles he accounts for the swelling of dead bodies which have remained for a time under water, and for the tumours which arise on some parts of the body in certain diseases. He also determines, that this gas is different from the air we breathe; that it has a greater affinity with water; and he imagined it might consist of water reduced to vapours, or a very subtle acid combined with volatile alkali.

My Boyle repeated all Van Helmont's experiments to a more advantage than he himself had performed them, but seems not to have proceeded further in his discoveries than Van Helmont did: only he found some bodies, such as sulphur, amber, camphor, &c., diminish the volume of air in which they burn.

Dr Hales first attempted to determine the quantity of air produced from different bodies; for which purpose he made experiments on almost every known substance in nature, examining them by distillation, fermentation, combustion, combinations, &c. He also first suspected, that the brilliancy and sparkling of the waters called acdious, were owing to the air they contained. But notwithstanding all his discoveries concerning the quantity of elastic fluid obtained from different bodies, he did not imagine there was any essential difference between this fluid and the air we breathe; only that the former was loaded with noxious vapours, foreign to its nature. His suspicion concerning this impregnation was confirmed by M. Venel, professor of confirmed chemistry at Montpelier, in a memoir read before the Royal Academy of sciences in 1750. This gentleman was able to difengage the air from the Seltzer waters, and to measure its quantity; which he constantly found to amount to about one-fifth of its bulk. The water thus deprived of its air became flat, and ceased to sparkle; the only difference then between it and common water was, that the former contained a small quantity of sea-fall. Upon these principles he attempted to recompose Seltzer water, by dissolving in a pint of common water two drachms of soluble alkali, and then adding an equal quantity of marine acid. The quantity of sea-fall produced by the union of these two, he knew would prove equal to that contained in a pint of Seltzer water; and the effervescence produced by the action of the acid and alkali upon each other, he imagined, would produce air sufficient for the impregnation of the water. In this he was not deceived; the water thus produced was not only analogous to Seltzer, but much more strongly impregnated with air.

Dr Black first discovered, that chalk, and the other earths reducible to quicklime by calcination, consist of an alkaline earth, which is soluble in water, but which, when combined with a large quantity of fixed air, becomes insoluble; losing the properties of quicklime, and assuming the natural appearance we observe those earths to have when not reduced into lime. The same thing he discovered in magnesia alba, and in alkalis both fixed and volatile. On the fixed air contained in these bodies, he found not only their property of effervescing with acids to depend, but likewise their mildness; both the alkalis and calcareous earth being highly cautious when deprived of their fixed air. He also found, that this fluid, which he called fixed air, had different degrees of affinity with different substances; that it was stronger with calcareous earth than with fixed alkali; with fixed alkali, than magnesia; and with magnesia, than volatile alkali. He also suspected, that the fixed air of alkaline falls unites itself with the precipitates of metals, when thrown down from acids; and that the increase of weight observable in these precipitates was owing to this cause. But he was of opinion, that the fluid which he called fixed air was very different from the common air we breathe; and therefore adopted the name of air, merely as one already established, whatever impropriety there might be in the term.

It was not long before the discovery of this species of air suggested new theories in physiology and natural philosophy. Mr Haller had inferred, from Dr Hales's experiments,
Of Air in general. Experiments that air is the real cement of bodies; which, fix'd itself in the solids and fluids, unites them to each other, and serves as a bond by which they are kept from dissolution. In 1764, Dr. Macbride of Dublin published a number of experiments in support of this doctrine. From his work it appears, that fixed air is separated, not only from all substances in fermentation, but also from all animal substances as they begin to putrefy; and that this air is capable of uniting itself to all calcareous earths, as well as to all fixed and volatile, and referring to them the property of extinguishing with acids when they have by any means been deprived of it. But though these opinions have since been found erroneous, the conclusions drawn by him from his numerous experiments still hold good, viz. that fixed air is an elastic fluid, very different from the common air we breathe: that it is possessed of a strong antifeptic quality, and may be introduced with safety into the intestinal canal and other parts of the animal economy, where common air would have fatal effects; but is mortal if breathed into the lungs, &c.

In 1766 and 1767, Mr. Cavendish communicated some new experiments to the Royal Society at London, wherein he determines the quantity of air contained in fixed air, when fully saturated with it, to be five-twelfths of its weight, and seven-twelfths in volatile air: that water is capable of absorbing more than its own bulk of this air, that it has then an agreeable, spirituous, and acidulous taste; and that it has the property of dissolving calcareous earths and magnesia, as well as almost all the metals, especially iron and zinc: that the vapour of burning charcoal occasioned a remarkable diminution of common air, at the same time that a considerable quantity of fixed air is produced in the operation. He also found, that solution of copper in spirit of salt, instead of producing inflammable air, like that of iron or zinc, afforded a species of air which lost its effusiveness as soon as it came into contact with water.

The discoveries of Dr Black concerning fixed air had not been long published, when they were violently attacked by some foreign chemists, while his caule was as eagerly espoused by others. The principal opponents were Mr. Meyer apothecary at Ofonbruck, Mr. Crans physician to his Russian Majesty, and Mr. de Smeth at Utrecht. Their arguments, however, were effectually answered at the time by Mr. Jacquin, botanical professor at Vienna; and the numerous discoveries made since that time have given such additional confirmation to his doctrine, that it is now universally adopted by chemists both in Britain and other countries. It was referred, however, for Dr. Priestley to make the great discovery concerning the nature of our atmosphere; and to inform the world, that it is composed of two fluids; the one absolutely noxious, and incapable of supporting animal life for a moment; the other extremely salutary, and capable of preserving animals alive and healthy for a much longer time than the purest air we can meet with. This may be considered as the ultimate period of our history: for since that time the discoveries of philosophers still living, in many different countries, have been so rapid, that it is difficult to obtain the dates of them by any authentic documents; especially as, by reason of such numerous experiments, the same things have not unfrequently been discovered by different persons, known to each Dephlogisticated other. We must therefore proceed to give an account of the different kinds of fixed fluids, beginning with those which are known, or supposed, to constitute a part of our atmosphere.

§ I. Discovery and Methods of procuring this Kind of Air. Dephlogisticated air was first obtained by Dr. Priestley on the 11th of August 1774. The circumstances which led him to the discovery, were his having procured inflammable air from spirit of salt, by adding to it spirit of wine, oil of olives, oil of turpentine, charcoal, phosphorus, bees wax, and even sulphur. Hence he supposed, that the common air we breathe might be composed of some kind of acid united with phlogiston. On this supposition he extracted air from whence mercurycalculates per se, by exposing it to the focus of extractions of a burning-glass 12 inches in diameter; and, having repeated the experiment with red precipitate and muriate, he found, that though a quantity of fixed air was always produced, yet after that was separated, the remainder supported flame much more vigorously than common air; for a candle burned in it with a flame very much enlarged, and with a crackling noise, at the same time that it appeared fully as much diminished by the tepid of nitrous air. Whence he concluded, that it was respirable; and, on making the experiment, found that it actually was so, for a mouse lived a half hour in a quantity of this fluid; which, had it been common air, would only have kept it alive half that time. Nor did the animal seem to be otherwise injured than by the cold; as it presently revived on bringing it near the fire, and the remainder of the air still appeared better than that of the atmosphere, when the tepid of nitrous air was applied to it.

This pure kind of air being discovered, the Doctor why not next proceeded to name it dephlogisticated, from his most deplorable opinion that common air, in the act of burning, absorbed phlogiston; of consequence, he deduced, which absorbed the most, or which most vigorously and for the greatest length of time supported flame, was supposed to contain the smallest quantity of this phlogiston. In the course of his inquiries why this kind of air comes to be so much dephlogisticated, he fell upon a method of extracting it from a great variety of substances, viz. by moistening them with spirit of niter, and then distilling them with a strong heat. Thus he obtained it from flowers of zinc, chalk, quicklime, slaked from a lime, tobacco-pipe clay, flint, Mufcovy tallow, and even great varieties. He then found, that by simply dissolving any piece of sulphur in the nitrous acid, and then distilling the solution, he could obtain very pure air; and Mr. Withraille found even the trouble of distillation unnecessary; nothing more being requisite than to moisten red lead with the spirit of niter, and then pour upon it the oil of vitriol, which instantly dengaged the dephlogisticsed air without applying any more heat than was generated by the mixture.

While discoveries of this kind engaged Dr. Priestley in England, Mr. Scheele was employed in a similar manner in Sweden; and had actually obtained the same kind of air, without knowing anything of what Dr. Priestley had done. The latter had the merit of the prior
AEROLOGY

Dephlogisticated Air

Prior discovery: but Mr. Scheele's method was more simple, consisting only in the distillation of nitre with a strong heat; by which means it is now found that dephlogisticated air may be obtained in very considerable quantity, and in as great purity, as by the more expensive processes. The pure air from nitre had indeed partly been obtained by Dr. Hales long before this time; since he informs us, that half a cubic inch of nitre yielded 90 cubic inches of air, which was undoubtedly the fluid we speak of; but as he neglected to practice this discovery, nothing farther was known at that time.

As the nitrous acid was universally concerned in the first processes for obtaining this kind of air, it was for some time generally believed to be a peculiar property of that acid alone to produce it; but the indefatigable genius of Dr. Priestley soon found, that it might not only be procured where no nitrous acid was employed, but where the substances were treated with vitriolic acid. It was indeed evident, from the very first experiment, that nitrous acid was not essentially necessary; since pure air was procured from precipitate per fe, in the preparation of which no nitrous acid is employed. The Abbé Fontana found, that 192 grains of this substance yielded 65½ cubic inches of dephlogisticated air, at the same time that the weight of it was reduced to 788 grains, which is nearly the weight of that quantity of air. It had formerly been observed, that the weight of mercury is augmented during its conversion into precipitate per fe, as that of lead is by its conversion into minium. The experiments just now mentioned, therefore, show, that during this process the air is decomposed; the pure dephlogisticated part of it being absorbed by the metal, and appearing again on the application of heat; and the same appears to be the case with red lead, from the experiment of Mr. Warthire already mentioned. With regard to this last substance, however, a very great irregularity is observed; viz. that when newly prepared it yields none at all, and even for some time after the produce is much smaller than when it has been long kept. The reason of this seems to be, that the minium still contains a considerable quantity of phlogiston, which flies off into the atmosphere by long keeping, a larger quantity of the dephlogisticated part of the atmosphere being imbibed at the same time. The mode of applying heat has also a very considerable effect on the quantity of air produced. Thus, Dr. Priestley remarks, "that from equal quantities of red lead, without any mixture of spirit of nitre, and using the same apparatus for distilling it, he obtained, by means of heat applied suddenly, more air than when slowly applied, in the proportion of ten to one. The proportion of fixed air was the same in both cases, and the remainder equally dephlogisticated." By heat alone, the Doctor found, that sedative falt, manganese, lapis calaminaris, and the mineral called lapis pendulum, silex, or tungsten, would yield dephlogisticated air; the first indeed in very small quantity, and sometimes even of a quality very little inferior to common air. In these experiments, he made use of small-bellied retorts of green glass, which can stand the fire best, containing about an ounce of water, and having narrow necks 18 or 20 inches long. The substance to be examined was put into a retort of this kind, and then exposed to a red heat, either in sand or dephlogisticated air over a melted fire, while the neck of the vessel was plunged in water or mercury.

Having dissolved six pennyweights of very clean iron in oil of vitriol, and then distilled the solution to dryness in a long-necked retort, he received the common air a little phlogisticated, some fixed air, much vitriolic acid air, and lastly 18 ounce measures of dephlogisticated air. The iron that remained undissolved weighed 23 grains, so that the air was yielded by five pennyweights one grain of iron. The ochre weighed seven pennyweights thirteen grains; that is, he there probably remained a quantity of oil of vitriol in it; and consequently, had the heat been greater, more air would have been obtained.

In his experiments with the nitrous acid, as it had constantly been found, that by pouring on more nitrous acid on the residuum, and repeating the operation, more dephlogisticated air might be obtained, the Doctor determined to try whether the fame would not hold good with vitriolic acid also. For this purpose, he added more oil of vitriol to the residuum of the last-mentioned experiment. When in a red heat with a glass retort, it yielded a quantity of vitriolic air, no fixed air, but about 24 ounce measures of dephlogisticated air; when, the retort being melted, a good deal of the air was necessarily lost; but on retaining the procefs in a gun-barrel, he procured as much air as had been got before. Pursuing these experiments, he obtained with common crust of iron and oil of vitriol, dephlogisticated air at the first distillation, and a great deal more from the residuum, by pouring fresh oil of vitriol upon it. The same produce he obtained from blue vitriol, solution of copper in the vitriolic acid, and from a solution of mercury in that acid. On this substance he remarks, that "either by means of oil of vitriol or spirit of nitre, it yields a great quantity of dephlogisticated air; but with this difference, that in the procefs with spirit of nitre, almost the whole of the air was recovered, but not more than a twentieth part of it being lost, if the procefs be conducted with care, in that with vitriolic acid, almost the whole is lost."

From the later experiments of Mr. Lavoisier, however, it appears that the Doctor's processes had not been conducted with sufficient care; as from two ounces of the dry salt formed by a combination of vitriolic acid with mercury, the former obtained 6 drachms 12 grains of running mercury, besides 3 drachms 58 grains of mercurial sublimate of two different colours. Dephlogisticated air was likewise obtained from pure calx of tin, or putty, mixed with oil of vitriol; but none in any trial with the marine acid, excepting when it was mixed with minium, in which case the air obtained was probably that which the minium would have yielded without any addition.

That all thee, and innumerable other experiments made by philosophers in different countries, was, that dephlogisticated air may be obtained from a vast variety of mineral and metallic substances by means of the vitriolic and nitrous acids. It now remains only How to discover in what manner this fluid, so essentially necessary to the support of animal life, is naturally produced.
AEROLOGY.

Deplagnoticated Air.

Deplagnoticated air itself was known. Dr Priestley, after having tried various methods of purifying contaminated air, found that, if some kinds of vegetables answered this purpose very effectually; for which discovery he received the thanks of the Royal Society. Among the vegetables employed on this occasion, he found mint answer the purpose very effectually. "When air," says he, "has been rendered perfectly clear by means of mint, so as to smell through the water, seeds of mint have frequently died upon being put into it, their leaves turning black; but if they do not die presently, they thrive in a most surprising manner. In no other circumstances have I seen vegetation so vigorous as in this kind of air, which is immediately fatal to animal life. Though these plants have been crowded in jars filled with this kind of air, every leaf has been full of life; fresh shoots have branched out in various directions, and grown much faster than other similar plants growing in the same exposed in common air."—Having in consequence of this observation rendered a quantity of air thoroughly phlogisticated, by means of mint breathing and dying in it, he divided it into two receivers inverted in water, introducing a sprig of mint into one of them, and keeping the other receiver unsealed. About eight or nine days after, he found that the air of the receiver into which he had introduced the sprig had become resipile; for a mouse lived very well in this, whereas it died the moment it was put into the other.

From these experiments the Doctor at first concluded, that in all cases the air was ameliorated by the vegetation of plants; but even in his first volume he observes, that some experiments of this kind did not answer so well towards the end of the year as they had done in the hot season; and a second instance, which he had so well towards the end of the year as they had done in the hot season; and a second instance, which he had

Noxious air improved by vegetation mint.

Experiments seemingly contradictory.

Noxious air, which he had supposed to be an essential requisite in conducting such a process.

At the time that Dr Priestley made these experiments, he supposed that the air was ameliorated merely by the absorption of phlogiston from that which had been tainted; but the experiments of Dr Ingenhousz, made in 1779, showed that this was accomplished, not only by the absorption just mentioned, but by the e-Deplagnoticenation of deplagnoticated air. He observed in general that plants have power of correcting bad air, and even of improving common air in a few hours, when exposed to the light of the sun; but, in the night-time, or when they are not induced by the solar rays, they contaminate the air. This property, however, does not belong in an equal degree to all kinds of plants: nor is it possible to discover by the external properties of a plant, whether it be fit for this purpose or not; as some which have a bad smell, and are entirely unfit for food, show themselves much superior to others whose external appearance would seem preferable. His method of making the experiment was, to fill a vial with air, fouled either by respiration or combustion; after which a sprig of any plant was introduced, by pulling it through the water in which the vial was immersed. The vial was then stopped; or it was removed into a small basin of full of water, and exposed to the sun, or situated in some other proper place as occasion required. Air phlogisticated by breathing, and in which a candle could not burn, after being exposed to the sun for three hours, with a sprig of peppermint in it, was so far corrected, as to be again capable of supporting flame.

The following experiment, however, made with a mustard plant, may be looked upon as decisive: A plant of this kind was put into a glass receiver containing common air, and its stem cut off even with the mouth of the receiver. The vessel was then inverted in an earthen pan, containing some water to keep the plant alive, and the whole apparatus was set over-night in a room. Next morning the air was found so much contaminated, that it extinguished the flame of a wax taper. On exposing the apparatus to the sun for a quarter of an hour, the air was found to be somewhat corrected; and after an hour and a half it was so far improved, that by the test of nitrous air it appeared considerably better than common air.

Before we proceed farther in the account of Dr Ingenhousz's experiments, it will be necessary to relate some observations made by Dr Priestley; from which it appears, that dephlogisticated air, in very considerable quantity, may, in certain circumstances, be procured from water alone. The substance of these is, that water, especially pump-water, when exposed to the light of the sun, emits air slowly; but after some time a green matter appears on the bottom and sides of the glass; after which it emits very pure air in great quantity, and continues to do so for a very long time, even after the green matter has shown some symptoms of decay by becoming yellow. He observed, that the water which naturally contained the greatest quantity of fixed air, yielded also the greatest quantity of that which was dephlogisticated; but that the quantity of the latter much exceeded that of the fixed air contained even in any water. The light of the sun was found to be an essential requisite in the formation of this air, as very little, and that of a much worse quality, was produced in the dark.

As the green matter produced in Dr Priestley's glass was by himself, as well as others, considered as belonging to the vegetable kingdom, Dr Ingenhousz improved upon his process, by putting the leaves of plants into water, and exposing them to the sun. All plants from the leaves of
A E R O L O G Y.

Sect. III.

After the publication of Dr Ingenhouz's experiments, it became generally believed, that the atmosphere was mitigated by the common process of vegetation, and that plants absorbed the phlogistic part as means.

Sir Benjamin Thompson, in his founder's experiment, they found that the pure dephlogisticated air was an excrement, which is just the reverse of what happens to animals, who absorb the pure part in respiration, and reject the phlogistic.

In the Philosophical Transactions for 1787, however, we find a number of experiments related by Benjamin Thompson, which seem to render this matter dubious. One very considerable objection is, that the green matter, already mentioned in Dr Priestley's experiments, when carefully observed by a good microscope, appears not to be a vegetable, but of an animal nature.

The colouring matter of the water, says he, is evidently of an animal nature; being nothing more than the affumblage of an infinite number of very small, active, oval-formed animalcules, without any thing resembling tremella, or that kind of green matter or water-moss which forms upon the bottom and sides of the vessel when this water is suffered to remain on it for a considerable time, and into which Dr Ingenhouz supposes the animalcules above mentioned to be actually transformed.

This gentleman has also found, that several animal substances, as well as vegetables, have a power of separating dephlogisticated air from water when exposed to the light of the sun, and that for a very great length of time. Not that the same quantity of water will always continue to furnish air; but the same substance being taken out, washed, and again put into fresh water, seems to yield dephlogisticated air, without any kind of limitation.

Raw silk possesses a remarkable power of this kind. To determine it, Sir Benjamin introduced 30 grains of this substance, previously washed in water, into a thin glass globe 4 inches in diameter, having a cylindrical neck 3 inches of an inch wide, and twelve inches long, inverting the globe into a jar filled with the same kind of water, and exposing it to the action of the sun in the window. It had not been ten minutes in this situation, when the silk became covered with an infinite number of air-bubbles, gradually increasing in size till, at the end of two hours, the silk was boiled up, by their means, to the top of the water. By degrees they began to separate themselves, and form a collection of air in the upper part of the globe; which, when examined by the test of nitrates air, appeared to be very pure. In three days she had collected 3 cubic inches of air, into which a wax-taper being introduced, that had just been blown out, the wick only remaining red, it instantly took fire, and burned with a bright and enlarged flame. The water in the globe appeared to have lost something of its transparency, and had changed its color to a very faint greenish cast, having at this time a very pungent flavor to me.
AEROLOGY.

153

DEPHLOGISTICATION.

Sect. III.

Dephlogisticated air, at the same time acquired the fonnell of raw silk. This was several times repeated with fresh water, retaining the same silk, and always with a smaller result; but with this difference, that when the fun's rays were very bright, the quantity of air produced was not only greater, but its quality superior to that yielded when the fun's rays were feeble, or when they were frequently intercepted by flying clouds. "The air, however, (says he), was always not only much better than common air, but even than that produced by the fresh leaves, plants exposed in water to the fun's rays, in the experiments of Dr. Ingenhousz; and, under the most favourable circumstances, it was to good, that one measure of it required four of nitrous air to saturate it, and the whole five measures were reduced to 0.35.'

An experiment was next made in order to determine the effect of darkenss upon the production of air: and in this case only a few considerable bubbles were formed, which remained attached to the silk; nor was the cafe altered by removing the globe into a German stove. Some single bubbles, indeed, had detached themselves from the silk and ascended to the top, but the fun's rays were too small to be measured or proved. — The medium heat of the globe, when exposed to the fun's rays, was about 90° of Fahrenheit, though sometimes it would rise as high as 96°; but air was frequently produced, when the heat did not exceed 65 and 70°. On reverting this experiment, in order to try the effect of light without heat, it was found that by plunging the globe into a mixture of ice and water, which brought it to the temperature of about 30° of Fahrenheit, the produce of air was diminished, though it still continued in considerable quantity.

The effect of artificial light, instead of that of the fun, was next tried. For this purpose all the air was removed from the globe; and its place being supplied with a quantity of fresh water, so as to render it quite full, it was again inverted in the jar, and removed into a dark room surrounded with fix lamps and reflectors; fix was candles were also placed at different distances from three to six inches from it, and disposed in such a manner as to throw the greatest quantity of light possible upon the silk, taking care at the same time that the water should not acquire a greater heat than 90°.

In this situation the fun began to be covered with air bubbles in about ten minutes; and in six hours as much was collected as could be proved by nitrous air, when it was found to be very pure. A fresh-gathered, healthy leaf of a peach-tree, and a stem of the pea-plant with three leaves upon it, furnished air by exposure to the fun's rays; but in smaller quantities than by the action of the fun's rays. The air produced in the dark, in whatever manner procured, was always in too small a quantity to be measured.

In making these experiments, it was found somewhat troublesome to invert the globes in water, they were at last only kept in an inclined posture on the table, as represented in Pl. X. fig. 1, the air collecting itself in the upper part of the bottle. Having provided himself with a number of globes of different sizes, he then proceeded in his experiments in the following manner.

Finding that raw silk, exposed to the action of light, produced a great quantity of air, he was induced to try whether some other substances might not be found out capable of doing the same. Having therefore provided six globes of 47 inches in diameter, and filled them with dephlogisticated air, he introduced into each of them 15 grains of one of the following substances, viz. sheep's wool, cider-down, fur of a Ruman hare, cotton wool, lint, or the ravelings of linen yarn, and human hair.

The results of these experiments were, 1. The globe containing the sheep's wool began to yield air in three days; but several days of cloudy weather intervening, he did not remove it for some time, when only 1 part of an inch of air was collected, which proved very pure when tried with nitrous air: but the wool, even in the most favourable circumstances, never afforded more than one third of the quantity which would have been yielded by silk. 2. The water with the cider-down began to furnish air almost immediately, and continued to do so in quantities little less than had been furnished by the silk, and nearly of the same quality.

One cubic inch and three quarters of this air, furnished the eighth day from the beginning of the experiment, with three measures of nitrous air, was reduced to 1.34. 3. The fur of the hare produced more air than the wool, but less than the cider-down. Two cubic inches of air were collected in four days; which made its appearance in a different manner from that of the other substances, the air-bubbles being at considerable distances from one another, and growing to an uncommon size before they detached themselves from the fur. The cotton yielded a considerable quantity of air of a better quality than any of the former. The ravelings of linen were very slow in furnishing air, and produced but a small quantity; only two cubic inches being collected in the space of a fortnight. This substance appeared to be the very reverse of the hare's fur, for the air, instead of attaching and collecting itself about the substance in large bubbles, scarce ever made its appearance in sufficient quantity to raise it to the top of the water. The human hair furnished still less than the linen, and the produce was of inferior quality, though still superior to the common atmosphere.

In order to discover the comparative fineness of air produced from vegetables and from raw silk, a small quantity of air from the stem of a pea-plant, which had four healthy leaves upon it, was proved with nitrous air, and found greatly inferior to that from raw silk and several of the substances already mentioned. An entire plant of housewort, of a moderate size, furnished only 5ths of a cubic inch of air in seven hours, and that greatly inferior to common air; but the leaves alone afforded a much greater quantity, and of a quality greatly superior.

Having proceeded thus far, it was next determined of the to ascertain how much air a given quantity of water quantity would yield by exposure to the sun's rays. For this purpose, a globe of fine white, clear, and very thin glass, containing 266 inches, being filled with fresh spring water, and 30 grains of raw silk immersed in it, was exposed to the air for three days in the month of May, but for the most part cold and cloudy. During this time only 95 inches of air were produced; but next day, by exposure to the sun from nine in the morning till five in the afternoon, the weather being very fine, 8.46 inches more were produced. The water had now assumed a light greenish colour. Next day, the produce of air was nine cubic inches, of a better quality; and the day following, six inches still more.
to be nearly equivalent to that of water; and, by a
comparative view of the two through a microsco-
pic, the surfaces appeared to be as 1000 to 3468. By
proceeding in this calculation, it appeared that the surface
of 30 grains of the cotton could not be less than 6600
square inches, while that of a like quantity of the silk
amounted to no more than 476. Hence it evidently
appeared, that the produce of air from the two sub-
fances was neither in proportion to their weights nor
their surfaces. It appeared also, that the quality of
the air produced at first was considerably inferior to that
yielded sometime afterwards. In order to ascertain
the times at which air of the best quality was produ-
ced, &c. the following experiments were made: 1. At
what times air of the best quality is produced.

(A) In all these experiments, the quality of the atmospheric air is supposit to be 100.
bodies, used in the foregoing experiments, actually did not contribute any thing, considered as chemical substances, in the process of the production of pure air yielded by water; but if, on the contrary, they acted merely as a mechanical aid in its separation from the water, by affording them a convenient surface for air to attach itself to; in this case, any other body having a large surface, and attracting air in water, might be made use of instead of the silk in the experiment, and pure air should be furnished, though the body should be totally incapable of communicating anything whatever to the water.

With a view to ascertain this, the large globe being made perfectly clean, and filled with spring-water, he introduced into it a quantity of the fine thread of glass commonly called sfum, glafis, such as is used for making a brush for cleaning jewels, and an artificial feather fold by Jew pedlars. The result of the experiment was, that the globe being exposed to the sun, air-bubbles began almost instantly to make their appearance on the surface, and in four hours 0.77 of a cubic inch of air was produced, which, with nitrous air, showed a quality of 88; after which, not a single globe more was procured, though the globe was exposed for a whole week in fine sunshine weather. Hence it appears, that something more than mere surface was wanted to produce dephlogisticated air from water by means of the sun’s light.

The following experiments were made with a view to determine the quantity and quality of air produced by means of the heat and light of the fun from water alone. A large jar of clear glass, containing 455 cubic inches, being washed very clean, was filled with fresh spring-water, inverted in a glass basin of the same, and exposed to the weather for 28 days. At the same time, another similar jar was filled with water taken from a pond in a garden in which many aquatic plants were growing, and exposed in the same place, and during the same period. The latter began to yield air in pretty large quantities on the third day, and continued to do so till the 14th; the former yielded little or none till the 14th; when it began to emit air, and continued to do so till the 22d. On removing the air produced, that from the spring-water was 14 inches in quantity, and 138 in quality; but from the pond water, 51 in quantity, and 252 in quality. The colour of the water was not changed; but both of them had deposited a considerable quantity of earth, which was found adhering to the surfaces of the glasses basins in which the jars were inverted. As these basins, however, were very thick, and consequently had but little transparency, the sediment of the water was in a great measure deprived of the benefit of the sun’s light; the experiment was therefore repeated with the following variation: In a large cylindrical jar of very fine transparent glass, 10 inches in diameter and 12 inches high, filled with spring-water, a conical jar, 91 inches in diameter at the bottom, and containing 244 inches, was inverted, and the whole exposed to the sun for 21 days. Little air was furnished till the 7th day, when the liquor assumed a greenish cast, and a fine filmy sediment of the same colour, the green matter of Dr Priestley, beginning to be formed on the bottom, air was generated in abundance, and was furnished in pretty large quantities till the 18th, when it entirely ceased. The whole amounted to 40 cubic inches, and dephlogisticated the quality 213.

The air of the following experiments was contained in Sir Benjamin Thompson’s letter to Sir Joseph Banks. In his postscript he observes, that as he never was thoroughly satisfied with the opinion of Dr Ingenhousz, that the dephlogisticated air was elaborated in the vessels of the plant, he found his doubts rather confirmed than diminished by the experiments above related. That the fresh leaves of certain vegetables (fays he) exposed to water to the action of the sun’s rays, cause a certain quantity of pure air to be produced, is a fact which has been put beyond all doubt: but it does not appear to me by any means so clearly proved, that this air is ‘elaborated in the plant by the powers of vegetation’—dephlogisticated or fixed air being received by the plant as food, and the dephlogisticated air rejected as an excrement: for besides that many other substances, and in which no elaboration or circulation can possibly be supposed to take place, cause the water in which they are exposed to the action of the light to yield dephlogisticated air as well as plants, and even in much greater quantities, and of a more eminent quality, the circumstances of the air, the vegetable, which, accustomed to grow in air, are separated from its stem and confined in water, are so unnatural, that I cannot conceive that they can perform the same functions in such different situations.

Among many facts which have been brought in support of the received opinion of the elaboration of air in the vessels of plants, there is one upon which great stress is laid, which, I think, requires further examination. The fresh healthy leaves of vegetables, separated from the plant, and exposed to water in the action of the sun’s rays, appear, by all the experiments which have hitherto been made, to furnish air only for a short time. After a day or two, the leaves, changing colour, cease to yield air. This has been conceived to arise from the powers of vegetation being destroyed, or, in other words, the death of the plant: and from hence it has been inferred, with some degree of plausibility, not only that the leaves actually retained their vegetative powers for some time after they were separated from their stalk; but that it was in consequence of the exertion of those powers, that the air yielded in the experiment was produced.

"But I have found, that although the leaves, exposed in water to the action of the light, actually do cause fresh air after a certain time, yet that they retain their property of emitting air, after the sun; and it is not the supposition that the air is elaborated in the vessels of the plant that is the matter in question.”

In confirmation of this doctrine, the globe of 46 inches was filled with fresh spring-water, and two peach-leaves were exposed for 10 days to the sun. In four days the water seemed to be entirely exhausted; but, next day, the water acquired a greenish colour, and again produced air pretty plentifully, which appeared in bubbles on the leaves; and on the 6th day, 0.34 of a cubic inch of air was produced, of the quality 222. Next day it yielded 1.5 cubic inches, of the quality 291. The three succeeding days it yielded 1.8 cubic inches, of the quality 307; after which an end was put to the experiment.
AEROLOGY.

Sect. III.

All phlogistic processes are promoted much better by dephlogisticated than common air. Dr Priestley tincted air, put a quantity of pyrophorus into one of the small jars used for making experiments upon air in quinoline; he then filled up the tube of the jar, inverted it in a basin of the same, and threw in dephlogisticated common air at different times. It always occasioned a sudden with pyrotechnic and vehement action, like the flashing of gun-powder. Phosphorus, and the air was greatly diminished.

It has been, almost throughout all ages, believed that combustion in every instance diminished common air is not air, or reduced it to a smaller volume: but the late experiments of Mr Lavoisier have shown, that this is a mistake; and that in ordinary processes attended with the production of fixed and phlogisticated air, the quantity of vapour produced is equivalent to that absorbed, or otherwise made to disappear during the operation. With dephlogisticated air the candle is very different. Mr Lavoisier having introduced a burning candle into a glass jar filled with very pure air obtained from calcinated mercury, a great heat took place, and the air was extinguished, which at first expelled a small quantity of the air; but afterwards, when the candle was extinguished, it was found that two-thirds of the bulk of air employed had been converted into fixed air, or a quantity of this kind of air equivalent to the former had been produced. The remainder, after taking up the fixed air by caustic alkali, was still as pure as before. In the common processes, he observes, that not more than one-tenth of the air employed is converted into fixed air. In this experiment, the superior gravity of fixed air is, and the consequent condensation of the other, must undoubtedly have produced some diminution in the volume of air, though Mr Lavoisier does not take notice of it. In other cases, however, the diminution is much more perceptible. Mr Scheele having introduced some live coals into a mattrass filled with dephlogisticated air, found that it was diminished by one-fourth of its quantity. Repeating the experiment with sulphur, the flame became larger and more vivid than in common air, and three-fourths of its quantity were lost. Putting a piece of phosphorus into seven ounce-measures of this kind of air, stopping the mouth of the bottle with a cork, and setting fire to the phosphorus within it, the phial broke to pieces, as soon as the flame was extinguished, by the pressure of the external air. Repeating the experiment with a stronger vial, and opening it afterwards under water, the fluid rushed into it in such a manner as almost to fill it entirely. This extraordinary diminution was also perceived on setting fire to inflammable air in the dephlogisticated kind. The way in which he accomplished this was, by filling a vessel with that fluid, dephlogisticated, and inverting it over a phial containing an effervescent mixture of vitriolic acid and iron-fillings plunged into a vessel of hot water, and furnished with a flinten tube reaching above the surface of the vessel, as represented Plate X. fig. 2. The inflammable air issuing from the orifice of the small tube, was set on fire previous to the inversion of the mattrass, and the mouth of the latter immerged in the water; on which that fluid soon began to rise, and continued to do till seven-eighths of the vessel were full. In cases of slow combustion, where common air is diminished and phlogisticated, the dephlogisticated kind was found to be almost entirely
Deephlogified air.

61 Phenomena of deephlogificated air.

The purity of deephlogificated air is ascertain'd by its degree of diminution with nitrous acid; which, like that of the diminution by liver of sulphur, or otherwise, is to be considered as a phlogistic process, or kind of burning, especially as a considerible degree of heat is thereby generated. Very great differences are perceived in this respect; and according to the quantity of diminution, the air is said to be two, three, or four times better than common air. It is not yet accurately determin'd how far this proportionable purity extends. Dr Prieſley mentions some extracted from red lead five times as pure as common air. Another quantity, produced from a solution of mercury in nitrous acid, was so pure, that one measure of it mixed with two of nitrous air, which had been obtained in the first part of the same process, occupied only 0.02 of a measure. Repeating the experiment (says he), I found, that two measures of nitrous air were rather more than sufficient to saturate one measure of the deephlogificated air; so that possibly, had the former experiment been made with more circumſpection, the diminution, extraordinary as it was, would have been somewhat greater. Indeed it cannot be fuppofed, that exactly two measures of nitrous air should be the precise quantity that would afford the greatest diminution. It should also be consider'd, that a small portion of air might be yielded by the water in which the experiments were made. Upon the whole, therefore, I am inclin'd to think, that, were it poſsible to make both the deephlogificated and nitrous air in the greatest purity, and then to mix them in some exact proportion, the aerial form of them both would be deftroy'd, the whole quantity seeming to disappear, as in the mixture of alkaline and acid air.

Notwithstanding this great degree of purity, the best deephlogificated air is capable of being contaminat'd by some of the procefses which affect the common air of our atmosphere. Dr Prieſley having introduc'd a quantity of very dry, clean nails, into a receiver fill'd with deephlogificated air, and invert'd it in quickſilver, found, that about nine months after, one tenth of the whole quantity had disappear'd, tho' he could not perceive any luft upon the nails. The effects of combination have already been relate'd, viz. as producing a great quantity of pure fix'd air; but putrefaction and animal respiration probably contaminate it in a manner similar to that of atmospheric air, though few or no experiments seem to have been made on this subje&. Mr Cavallo, however, informs us, that "when an animal is confin'd in a quantity of deephlogificated air, and is kept therein till it dies, that air is not render'd so bad but that it will still be capable of considerable diminution by nitrous air. This seems to show, that deephlogificated air is somewhat different from pure common air; or that common air is originally different from deephlogificated air, lower'd by the addition of phlogiston. The phenomenon is certainly very remarkable; and sometimes a quantity of deephlogificated air, after having been breath'd by an animal till it died, will appear by the nitrous efl to be even better than common air. When the expe-

Dr Prieſley's first hypothesis.

§ 3. Of the Composition of Deephlogificated Air. — When Dr Prieſley firſt discover'd the eſtistence of this fluid, having found that it was always procur'd by means of earthy subſtances; and that as it came over, the bubbles appeared full of white powder; he conclude'd, that it is compoſed of the nitrous acid and earth, with as much phlogiston as is necessary to its elafiſcity; and that the common atmosphere has as much more as is necessary to bring it into the mean condition in which we find it. It was not long, however, before this theory met with opposition. Dr Prieſley himself, though induc'd, from the waft of the foil matter used in his experiments, to conclude that the air contained some quantity of earth, was nevertheless unable, by any method he could think of to ascertain that quantity. His experiments were oppoſed by others made by Lavoifier; who infift'd, that when solution of mercury was carefully distilled, the metal was obtained in full quantity, or with scarce any loss, notwithstanding the deephlogificated air produc'd. This gentleman having put two ounces and one drachm of mercury into red precipitate, and afterwards reduc'd it, left a very few grains of the metal; which, he says, might be the weight of a little red matter that was found adhering to the neck of the vessel. The same thing was observ'd by Mr Fontana, who repeated the experiment often with less than a grain
Earth cannot be proved to exist in dephlogisticated air.

Whether the nitrous acid enters its composition.

AEROLOGY. Sect. III.

Dephlogisticated air.

grain weight of loss. The vessel he used had a neck of about two feet long; and he particularly remarks, that, in order to succeed in this experiment, the fire should be managed with very great dexterity; for if it be too strong, part of the precipitate will be volatilized, and then the result of the experiment is precarious.

These experiments were opposed by others made by Dr Priestley, who, in several trials found that a considerable quantity of the metal was always lost; in one of these experiments, out of 11 pennighty weights 10 grains of mercury, the loss amounted to one pennyweight two grains. In another experiment, 88 grains were lost, out of a quantity of red precipitate, in the preparation of which half an ounce of mercury had been employed. The quantity of mercury lost in his experiments, or rather the proportion of it to that of the metal employed, was always various, and the difference not very small; whence Mr Cavallo and others, with great appearance of reason, conclude, that the true reason of any perceptible loss was the strong heat made use of in the distillation, and consequently that there is no reason to suppose that any earth exists in dephlogisticated air.

The next question was, Whether any of the nitrous acid existed in dephlogisticated air! That it contains none in a proper state of acidity, is indeed evident from many decisive experiments; but an idea was naturally entertained, that in the formation of dephlogisticated air the nitrous acid was decomposed, and part of it entered into the composition of the aerial fluid. This gave rise to the theories of Mr Lavosier and Mr Kirwan, which are noticed under the article Acid; as also the experiments of Mr Watt, which tended to show that no nitrous acid was destroyed in the composition of dephlogisticated air. To these Mr Kirwan replied in the manner related in that article. We shall here, however, give a quotation from Dr Priestley as a kind of addition to Mr Watt's testimony on this head, so that the reader may be the better able to determine the weight of the evidence on both sides.

"At Mr Watt's request (says he), I endeavoured to ascertain the quantity of acid that was expelled from nitre, in procuring the dephlogisticated air from it. To do this, I put two ounces of purified nitre into a glas retort, and receiving the air in 300 ounce measures of water, only filled each recipient half full, and agitated the air very much in the water, in order to make the fluid imbibe as much as possible of the acid it contained. Notwithstanding this agitation, however, every vessel of the air retained a strong smell of the acid. The moment the air ceased to come, I filled a large phial with the water, and carried it to Mr Watt, who carefully examined it; and in a paper which he presented to the Royal Society, and which is published in the Philosophical transactions, he has given an account of the quantity of acid that was contained in all the 300 ounces of water: whence it may be fairly inferred, that there was no occasion to suppose that any of the acid entered into the composition of the air; but that it was all either rendered volatile or retained in the water. On the other hand, the Abbé Fontinana informs us, that, in distilling an ounce of nitre with a strong heat, in order to expel dephlogisticated air from it, only a few grains of weak nitrous acid are obtained, more or less as the fire applied is weak or strong; but that the quantity of dephlogisticated air extracted from it follows the contrary rule, being greatest when the heat is most violent and suddenly applied, and less when the fire is gradually applied.

On calcining metals in dephlogisticated air, very singular phenomena are observed, which seem to throw great light upon the composition of this fluid. "One of the most simple of all phlogistic processes (says Dr Priestley), is that in which metals are melted in dephlogisticated air. I therefore began with this, with a view to ascertain whether any water be produced when the air is made to disappear in it. Accordingly, into a glas vessel, containing seven ounce-measures of pure dephlogisticated air, I introduced a quantity of iron turnings, which is iron in thin small pieces, exceedingly convenient for these and many other experiments, having previously made them, together with the vessel, the air, and the mercury by which it was confined, as dry as I possibly could. Also to prevent the air from imbibing any moisture, I received it immediately in the vessel in which the experiment was made, from the proces of procuring it from red precipitate, so that it had never been in contact with any water. I then fixed the iron by means of a burning lens, and presently reduced the seven ounce-measures of iron air to 0.65 of a measure; but I found no more water after this process than I imagined it had not been possible for me to exclude, as it bore no proportion to the metals. Examining the precipitate, I found one-fifth of it to be fixed air; and when I tried the purity of that which remained by the test with nitrous air, in the proportions which one-fifth was fixed air, and the residuum was made use of in the distillation, and consequently that there is no reason to suppose that any earth exists in dephlogisticated air. For though it was more impure than I suppose the air with which I began the experiment must have been, it was not more so than the phlogistic processes of the seven ounce-measures, which had not been affected by the process, and which must have been contained in the residuum, would necessarily make it. In this case, one measure of this residuum, and two of nitrous air, occupied the space of 0.32 of a measure. In another experiment of this kind, ten ounce-measures of dephlogisticated air were reduced to 0.8 of a measure, and by washing in lime-water to 0.38 of a measure. In another experiment, 7/9 ounce-measures of dephlogisticated air were reduced to half an ounce-measure, of which one-fifth was fixed air, and the residuum was quite as pure as the air with which I began the experiment; the test with nitrous air, in the proportions abovementioned, giving 0.4 in both cases.

"In these experiments the fixed air must, I presume, have been formed by the union of the phlogiston from the iron and dephlogisticated air in which it was ignited; but the quantity of it was very small in proportion to the air which had disappeared; and at that time I had no suspicion that the iron, which had been melted and gathered into round balls, could have imbied it; a melting heat having been sufficient, as I had imagined, to expel every thing that was capable of affaining the form of air from any substance whatever. Serpentine, however, that such a quantity of air must have been imbied by something, to which I have given a very perceptible addition of weight, and

Seeing...
Dephlogisticated Air.

When this cast iron was melted in the bottom of a deep glass receiver, in order to collect all the particles that were dispersed, they firmly adhered to the glass, melting it superficially, though without making it crack, so that it was still impossible to collect and weigh them. However, I generally found, that, notwithstanding the copious dispersion, what remained after the experiment rather exceeded than fell short of the original weight of the iron.

Formation of water from dephlogisticated and inflammable air.

On attempting to revive this calx of iron in inflammable air, a very new and unexpected appearance took place. Having put a piece of iron saturated with pure air into a vessel filled with inflammable air confined by water, the inflammable air disappeared and the metal was revived; but on weighing it, he found that 2.7 ounces of inflammable air which had vanished. Considering all these circumstances, the Doctor had now no doubt that the two kinds of air had united and formed either fixed air or water; and with a view to determine this point, he repeated the experiment in a vessel where the inflammable was confined by mercury, both the vessel and mercury having been previously made as dry as possible. In these circumstances he had no sooner begun to heat the iron, than the air was perceived to diminish, and at the same time the inside of the vessel to become cloudy, with particles of dew that covered almost the whole of it. These particles by degrees gathered into drops, and ran down in all places, excepting those which were heated by the sunbeams. On collecting the water produced in this experiment, by means of a piece of filtering paper carefully introduced to absorb it, he found it to be as nearly as possible of the same weight with that which had been lost by the iron; and also in every experiment of this kind, in which he attended to the circumstance, he found that the quantity of inflammable air which had disappeared was about double that of the dephlogisticated air set loose in the operation, supposing that weight to have been reduced into air. Thus, at one time, a piece of this flag absorbed 5.4 ounces of inflammable air, while it lost the weight of about 3 ounces of dephlogisticated air, and the water collected weighed two grains. Another time a piece of flag lost 1.5 grains, and the water produced was 1.7 grains. In a third case, where 61 ounces of inflammable air were reduced to 0.92 of a measure, the iron had lost the weight of 3.2 ounces of dephlogisticated air, or nearly two grains.

The Doctor having succeeded so well with iron, next experimented the calx of copper, or those scales which fly off in tens with it by hammering whilst it is red-hot; and found copper, water produced in the inflammable air in the same manner as when the scales of iron were used. On putting precipitate *per fe*, he imagined at first that water was obtained from this substance also; but on repeating the experiment to more advantage he found no more water than might be supposed to have been contained as an extraneous substance either in the inflammable air or in the red precipitate. With iron, however, the case was vastly different. As the Doctor had formerly satisfied himself that inflammable air always contains a portion of water, and also that when it has been some time confined by water it imbibes more, as so to be increased in its specific gravity by that means, he repeated the experiment with inflammable air which had not been confined by that fluid, but was received in vessel of dry mercury from the vessel in which it had been generated; and in this case the water was produced, appearance, composition as in the former experiment. Indeed (says he), the quantity of water produced, so greatly exceeding the weight of all the inflammable air, is sufficient to prove that it must have had some other source than any confluent part of that air, or the whole of it, together with the water contained in it, without taking into consideration the corresponding loss of weight in the iron.

71 Formation of water from dephlogisticated and inflammable air.
AEROLOGY.

Sect. III.

About two grains, though the vessel was stopped in deplogisticated air, in a manner that no air could escape by the explosion. It is also related, that on repeating the experiment, in glass vessels, the inside of the glass, though clean and dry before, immediately became dewy, which confirmed an opinion he had long entertained, that common air deposits its moisture by phlogistication. The experiment, however, did not succeed with Mr. Cavendish, at least with regard to the loss of weight, which never exceeded the fifth part of a grain, and commonly was nothing at all. In these experiments the greatest care was taken to observe with accuracy the diminution of air by the explosion, and quality of the remainder; from which it appeared, that 423 measures of inflammable air were nearly sufficient to phlogisticate 1000 of common air, and that the bulk of air remaining after the explosion is very little more than four-fifths of the common air employed, whence it is concluded, that when they are mixed in this proportion, almost all the inflammable, and about one-fifth of the common air, lose their effusiveness, and are condensed into the dew which lines the glas.

To examine more exactly the nature of this dew, 500,000 grain-measures of inflammable air were burnt with about 20 times the quantity of common air, and the burnt air was made to pass through a glass cylinder eight feet long and three-fourths of an inch in diameter, in order to deposit the dew. The two airs were conveyed slowly into this cylinder by separate copper pipes, passing through a brass plate which stopped up one end of the cylinder; and as neither inflammable nor common air can burn by themselves, there was no danger of the flame spreading to the magazines from which they were conveyed. Each of these magazines consisted of a large tin vessel inverted into another just big enough to receive it. The inner vessel communicated with the copper pipe, and the air was forced out of it by pouring water into the outer vessel, and in order that the quantity of common air expelled should be 25 times that of the inflammable air, the water was let into the outer vessels by two holes in the bottom of the same tin pan; the whole which conveyed the water into that vessel in which a piece of copper pipe, about 25 feet as big as the other. In trying the experiments the magazines being first filled with their respective airs, the glass cylinder was taken off, and water let by the two holes into the outer vessels, till the air began to issue from the ends of the copper pipes; they were then set on fire by a candle, and the cylinder put on again in its place. By this means upwards of 135 grains of water were left in the cylinder, which had no taste nor smell, and which left no perceptible sediment on being evaporated to dryness; neither did it yield any pungent smell, during the evaporation; in short, it seemed pure water. In one of his experiments a little foamy matter was perceived, but it was found to proceed from the luting. On repeating the experiment with deplogisticated, instead of common air, the produce was nitrous acid.

The following conclusion is drawn by Mr. Cavendish from all these experiments: 'There seem two ways by which the production of the nitrous acid, in the manner above-mentioned, may be explained first, by supposing that deplogisticated air contains a little nitrous acid, which enters into it as one of the component parts;
II

Deplhlogi-

ticated Air.

79 Conclu-
sions from
the expe-

iments.

... when this acid, when the inflammable air is in sufficient proportion, unites to the phlogiston, and is turned into phlogificated air, but does not when the inflammable air is in too small proportion: and, secondly, by supposing that there is no nitrous acid mixed with or entering into the composition of dephlogificated air; but that, when the air is in sufficient proportion, part of the dephlogificated air with which it is debased is, by the strong affinity of phlogiston to dephlogificated air, deprived of its phlogiston, and turned into nitrous acid; whereas, when the dephlogificated air is not more than sufficient to consume the inflammable air, none then remains to deprive the phlogificated air of its phlogiston, and turn it into acid.—If the latter explanation be true, I think we must allow that dephlogificated air is in reality nothing but dephlogificated water, or water deprived of its phlogiston; or, in other words, that water consists of dephlogificated air united to phlogiston. On the other hand, if the former explanation be true, we must suppose, that dephlogificated air consists of water united to a little nitrous acid, and deprived of its phlogiston; but still the nitrous acid in it must only make a very small part of the whole, as it is found that the phlogificated air into which it is converted is very small in comparison of the dephlogificated air. I think the second of these explanations seems much the more likely; as it was found that the acid in the condensed liquor was of the nitrous kind, not only when the dephlogificated air was prepared from nitrous acid, but when procured from plants or turbit mineral. Another strong argument in favour of this opinion is, that dephlogificated air yields no nitrous acid when phlogificated by liver of sulphur; for if this air contains nitrous acid, and yields it when phlogificated by explosion with inflammable air, it is very extraordinary that it should not do so by other means. But what forms a stronger, and, I think, almost decisive argument in favour of this explanation, is, that when the dephlogificated air is very pure, the condensed liquor is made much more strongly acid by mixing the air to be exploded with a little phlogificated air. The experiments of Dr Priestley adduced were to shew in which inflammable air was supposed by Mr Lavosier to be procured from water by passing its steam through ret-hot iron tubes. It was soon discovered, however, by Dr Priestley, that this inflammable air did not proceed from the water, but from the iron of the tube: and might be obtained by transmitting aqueous vapour through charcoal or iron placed in tubes of copper, glass, or earthen ware, made red-hot, but not through those tubes by themselves. In this case, the loss of the water employed exceeded that of the inflammable air produced in the proportion of 1.3 to 2; and the iron which had thus absorbed the water, appeared exactly similar to that which had been burned in dephlogificated air in the manner already related. His conclusion from thence are these: Since iron gains the same addition of weight by being melted in dephlogificated air, and also by the addition of water when red-hot, and becomes, as I have already observed, dephlogificated, the same substance in all respects, it is evident that this air or water, as existing in the iron, is the very same thing; and this can hardly be explained but on the supposition that water consists of two kinds of air, viz. inflammable and dephlogificated.

Of these proceed, he gives the following explanation: "When iron is heated in dephlogificated air, we may suppose that, though part of its phlogiston escapes, enters into the composition of the small quantity of fixed air which is then procured, yet remains to form water with the dephlogificated air which it has imbibed, so that this calx consists of the intimate union of the pure earth of iron and of water; and therefore, when the same calx, thus satureted with water, is exposed to heat in inflammable air, this air enters into it, destroys the attraction between the water and the earth, and revives the iron, while the water is expelled in its proper form."

The whole of the Doctor's opinions on the component parts of this kind of air, however, are summed up in the following sentence in his Observations relating to Observ. and Theory.—"The only kind of air that is now thought to be properly elementary, and to consist of a simple substance, is dephlogificated air; with the addition at least of the principle of heat, concerning which we know very little; and as it is not probable that this adds any thing to the weight of bodies, it can hardly be called an element in their composition. Dephlogificated air appears to be one of the elements of water, of fixed air, of all the acids, and many other substances, which, till lately, have been thought to be simple."

The experiments of the French philosophers were of the same nature with those of Mr Cavendish, but conducted on a larger scale. The inference drawn from them was the same with that already mentioned, viz. that dephlogificated and inflammable air in all cases are the two constituent parts of water. This opinion is adopted by Mr Kirwan in his Treatise on Phlogiston. "The experiments of Mr Cavendish, and Mr Kirwan," says he, "appear to me to leave no room for doubt, that when very pure dephlogificated and inflammable air are inflamed, the product is more wat- ter (a); for when these airs are employed in the proper proportion, only 0.02 of the mixture of both airs retains its aerial form. Now it is impossible to suppute that all the water obtained pre-existent in these airs; that is, that 49 parts in 50 were mere water."

Norwithstanding these positive conclusions, however, by some of the most respectable names in England, the evidences adduced have been unsatisfactory to some French chemists; who maintain, that Mefrs Cavendish, Priestley, and Kirwan, are totally mistaken with regard to the production of water from dephlogificated and inflammable air; contending, that the water obtained had previously existed in the air, and was not originally produced in the operation. The fact, indeed, becomes somewhat dubious from some experiments related by Dr Priestley himself, and of which we shall now proceed to give an account.

X

One

(a) The experiments of Mr Cavendish shew that nitrous is the product of this case. He takes notice of the difference between the result of the French experiments and his, but ascribes it to their using inflammable air prepared from charcoal: His was from zinc.
One consequence of the hypothesis in question is evident, that if water really be produced by the dephlogistication of either dephlogisticated or common air with inflammable air, the quantity of liquid obtained ought to increase in proportion to the quantity of the two airs combined, and that without any limitation. This, however, is not the case, as Dr Prieëley has observed. He had succeeded indeed with scales of iron and copper, as has already been related; and in the experiment with the latter, the production of water was so copious, that when only 1 ounce-measures of air were absorbed, the water fell in drops on the inside of the vessel, and some of these ran down it. Water was also procured by firing dephlogisticated and inflammable air from iron by the electric spark in a close vessel, an experiment similar to those made by Mr Lavoisier at Paris. In his first experiment he put 2.75 ounce-measures of a mixture of air, of which one-third was dephlogisticated and two-thirds inflammable air from iron, in a close vessel, and, after the explosion, found in it one-tenth of a pound of moisture; but on repeating the experiment with half as much dephlogisticated as inflammable air, he could perceive no sign of moisture. The greatest difficulty, however, which he says he ever met with respecting the preceding theory, arose from his never having been able to procure any water when he revived red precipitate in inflammable air, or at least no more than might have been supposed to be contained in the inflammable air as an extraneous substance. In order to make the experiment with the scales of iron and that with the red precipitate as much alike as possible, and compare them both to the greatest advantage, he made them one immediately after the other with every circumstance as nearly the same he could. The inflammable air was the same in both experiments, and both the scales of iron and red precipitate were made as dry as possible. They were heated in vessels of the same size and form, and equally confined by dry mercury; and yet with the former, water was produced as copiously as before, viz. running down the inside of the vessel in drops, when only four ounce-measures of inflammable air were absorbed; but though he heated the red precipitate till eight ounce-measures of the inflammable air were absorbed, and only one-twentieth of an ounce-measure remained, there was hardly any sensible quantity of water produced, "certainly," says he, "not one-tenth of what appeared in the experiment with the scales of iron. In this experiment there can be no doubt but that the dephlogisticated air produced from the red precipitate mixed with the inflammable air in the vessel; and as no water equal to the weight of the two kinds of air was produced, they must have formed some more solid substance, which, in the small quantities I was obliged to use, could not be found.

The difficulty, with respect to what becomes of the two kinds of air, was not lessened by the attempts which I made to collect all that I could from repeated decompositions of inflammable and dephlogisticated air in a close vessel. As I had produced water in this process when no more than a single explosion was made at a time, I thought that by continuing to make explosions in the same vessel, the water would not fail to accumulate till any quantity might be collected; and I intended to have collected a considerable part of an ounce. And as I would know exactly what quantity of air I decomposed, I had no doubt of being able to Dephlogisticate so as to ascertain the proportion that the water and air bore to each other. With this view a mixture was made of a large quantity of air, one-third dephlogisticated and two-thirds inflammable, from iron and oil of vitriol. But though I had a sensible quantity of water at the first explosion (in each of which between four and five ounce-measures of the mixture of air were used), I was surprised to perceive no very sensible increase of the quantity of water on repeating the explosions. Having therefore expended 40 ounce-measures of the mixture, the process was discontinued; and, collecting the water with all the care that I could, I found no more than three grains, when there ought to have been eleven.

"In this process the inside of the vessel was always very black after each explosion; and when I poured in the mercury after the explosion, though there was nothing visible in the air within the vessel, there filled from the month of it a dense vapour. This was the only clue I had to continue the experiments, before I proceeded to put in more mercury in order to make another; which, if the vapour had been steam, would have been time more than sufficient to permit it to condense into water. I even perceived this vapour when I had a quantity of water in the vessel, and the explosion was consequently made over it, as well as in contact with the sides of the vessel which were wetted with it; so that, as this vapour had passed through the whole body of water when the vessel was inverted, it is probable that it must have consisted of something else than mere water. But I was never able to collect any quantity of it, though it must have been something produced by the union of the two kinds of air."

In order to collect a quantity of this vapour, he contrived an apparatus, which, by diffusing it through a thin glass vessel, he supposed would condense all the contents whether fluid or solid; but after repeating the experiment as carefully as possible, by taking 20 explosions, and repeating the whole several times over, he could find nothing in the vessel besides a small quantity of water, which, added to that in the strong vessel, came far short of the weight of the air that was decomposed.

"All the conjectures," he says, "that I can advance, Prëley's in order to explain this phenomenon is, that since foot conjectures yields pure air, part of the foot is formed by the union concerning the dephlogisticated air in the atmosphere, and the this vapour, inflammable air of the fuel; but smoke, which contains much foot, is soon diffused, and becomes invisible in the open air. Such, therefore, may be the case. The foot formed by the union of the two kinds of air, may be diffused through the air, in the vessel in which they are exploded, and be carried invisibly into the common atmosphere; which may account for my not being able to collect any quantity of it in this apparatus."

Not discouraged by this bad success, the Doctor at first attempted to collect this volatile matter by means of a funnel, quantity of water incumbent upon the mercury in the to collect it, strong glass vessel in which the explosions were made, though he had found that part of it could escape through the water. He decomposed a great quantity of the two kinds of air in these circumstances; and presently
fently found that the water became very cloudy, and
collected, and found that it remained perfectly black
upon the earthen vessel in which the water containing
it was evaporated; which would not have been the
case if the blackish matter in the water had been that
powder of mercury which is produced by agitating it
in pure water: For that black mass always became
white running mercury the moment the water was
vaporated from it. 

Air was also supposed to have the power of being
decomposed, not by the calcination of metals and many other che-

canical products, but by the mere absorbption of phlogiston.

That water in great quantities (pails) is some-
times produced from burning inflammable and dephlogi-
ficating air, is evident from the experiments of Mefirs
Cavendish and Lavoisier. I have also frequently collec-
ted considerable quantities of water in this way, though
never quite so much as the weight of the two kinds of
air decomposed. My apparatus for this purpose was the
following: Into the mouth of a large glass balloon, I
introduced a tube, from the orifice of which there
continually issued inflammable air from a vessel con-
taining iron and vitriol. This being lighted, and
fusilgated, continued to burn like a candle. Presently after
the lighting of it, the inside of the balloon always became
cloudy, and the moisture soon gathered in drops, and
settled in the lower part of the balloon. To catch
what might issue in the form of vapour, in the cur-
rent of air through the balloon, I placed the glass tube
b, in which I always found some water condensed.

It is very possible, however, that in both these modes of
experimenting, the water may be converted into
a kind of vapour, which is very different from steam,
and capable of being conveyed a great way through
air, or even water, without condensation along with
the air with which it is mixed; and on this account
it may not be possible, in either of these modes of
experimenting, to collect all the water into which
the two kinds of air may be converted. The nature
of this kind of vapour into which water may be chan-
ged, and which is not readily condensed by cold, is very
little understood, but well deserves the attention of
philosophers.

That the water collected in the balloon comes
from the decomposition of the air, and not from the
fresh air circulating through it, was evident from pla-
ning balls of hot iron in the place of the flame, and
finding that, though the balloon was as much heated
by them as by the flame of the burning of the inflam-
nable air, and consequently there must have been the
same current of the external air through it, no mois-
iture was found in the balloon."

Sect. IV. Of Phlogificated Air.

The universal prejudice in favour of the existence
of that principal named Phlogiston, first suggested by
Stahl, gave rise, on the first appearance of Dr Prie-
ffley's discoveries, to a theory, concerning the action
of this substance upon air and other bodies. As
it had been observed, that air was diminished, in
certain cases at least, by burning, universally by re-
piration, and by some other processes, it was imagi-
nated that phlogiston was a body of such a singular na-
ture, that when mixed with air, it always diminished
its bulk, instead of enlarging it, which might have been
more naturally expected from the mixture of any va-
pour whatever. It was also supposed, by some, that the
phlogiston was not only entirely devoid of gravity, but
that it was a principle of positive gravity; so that the ab-
solute weight of bodies was diminished by an union with it,
and augmented when it was expelled, though their
specific gravity was diminished. Various other surprising
properties were attributed to phlogiston: such as that of
giving elasticity to air, of constituting flame by a
chemical combination with air, &c. Its emission to the
atmosphere was supposed to be always attended with
phlogiston; a diminution of air; and therefore, all proceses
in which air was diminished and became noxious, such as
that by liver of sulphur, a mixture of iron filings and
brimstone, &c. were called phlogistic processes. Respi-
ration of animals was taken in the same account; but
neither in this, nor in combustion, was it allowed that
any kind of vital spirit was absorbed by the blood, or
separated from the air by the burning body. On the
contrary, it was strenuously argued, that all this was
performed by the emission of phlogiston from the lungs
or the inflamed substance, which deprived the air, and
diminished it in bulk; and as all air was supposed
to contain phlogiston, it was likewise imagined, that in all
cases where air was mended, as by the growing of ve-
getables, or agitation in water, the emendation was
accomplished, not by the emission of any thing into the
atmosphere, but by the mere absorption of phlogiston.

In other respects this substance was thought to be an
exceedingly powerful principle in nature; the light of
the sun itself and the electric fluid being liable to be modi-
fications of it, the different kinds of airs to be phlo-
gistic vapours, &c.; so that the whole system of nature
seemed ready to be absorbed by it at once.

The formidable powers of this principle were first
shown by the discoveries of Mr Lavoisier, though the
latter erred equally on the contrary side; and not con-
tent with keeping the phlogistic principle within due
bounds, would needs deny its existence altogether. *

In a treatise published in the year 1782, he first im-
pugns Dr Prieffley's theory of respiration, and denies that
"the resurrection of animals has the property of
phlogisticating air in a manner similar to what is effec-
ted by the calcination of metals and many other che-

Phlogificated air.

93 Compositions of atmospheric air.

94 Effects of respiration on air.

95 Scheele's experiments.

96 Composition of atmospheric air-dephlogificated.

Phlogificated air.

97 How air is purified by agitating it in water.

98 Properties of phlogificated air.

That common air is compounded of two kinds of elastic fluids, Mr Scheele has proved by the following experiment:—I dissolved (says he) one ounce of alkaline liver of sulphur in eight ounces of water; of this solution I poured four ounces into an empty bottle, whose capacity was 24 ounces, and worked it well; then I turned the bottle, immersed its neck into a small vessel with water, and kept it in this position a fortnight; the solution had partly lost its red colour, and some sulphur had been precipitated from it during this time. After this I put the bottle in the same position in a larger vessel with water, keeping the mouth and neck under water, and the bottom of the bottle above water, and thus I drew the cork under water, which immediately rushed with violence into the bottle. On examining the quantity of water in the bottle, it was found, that during this fortnight, six parts out of 20 of air were lost. On repeating the experiment with the same materials, and in the same bottle, only four parts out of 20 were lost by standing 4 weeks, and no more than six parts after 4 months.

From these experiments, and many others similar, it appears that the doctrine of phlogiston has been carried too far by Dr Priestley and other British philosophers, and that the air consists of two kinds of fluids; one perfectly satyry, and friendly in the highest degree to animal life; the other altogether unfit for it. These two appear incapable of being converted directly into one another by any process, natural or artificial: for though both are destructible, yet they are always converted into other substances; from which indeed, either the one or the other may be extracted at pleasure by employing the proper methods. The strongest arguments in favor of the trituration of phlogificated air into that of a pure kind, were drawn from the purification of noxious air by vegetation, and by agitation in water. In the former case, however, it has been observed in the last section, that this seeming purification is no other than an exchange of the one air for the other; the vegetables absorbing the phlogificated, and emitting the dephlogificated air in its stead. With respect to the agitation in water, the matter remained more dubious; and it is only in the last volume of Dr Priestley's treatise that we have any account of this being accomplished by an emission of purer air from the water. —"In the infancy of my experiments," says he, "I concluded, that all kinds of air were brought by agitation to the same state; the purer air being partially phlogificated, and air completely phlogificated being thereby made purer; inflammable air also losing its inflammability, and all of them brought into such a state as that a candle would just go out in them. This inference I made from all the kinds of air with which I was then acquainted, and which did not require to be confined by mercury, being brought to that state by agitation in a trough of water, the surface of which was exposed to the open air; never imagining that when the air in my jar was separated from the common air by a body of water, generally about twelve inches in depth (adding that within that without the jar), they could have any influence on each other. I have, however, been long convinced, that, improbable as it then appeared to me, this is actually the case."

This remarkable fact is illustrated by the following experiments:—1. About three ounce-measures of air, phlogificated by nitrous air, was agitated for a quarter of an hour in a vessel containing 20 ounces of water, which had been boiled for several hours, and which was still very warm. By this process it became diminished one-sixth, and considerably improved in quality. The next day the remainder was agitated for another quarter of an hour, and the water which had been boiled at the same time, when it was also diminished in quantity and improved in quality. 2. An equal quantity of air, phlogificated by means of iron-filings and brimstone, being agitated for 20 minutes, was diminished one-seventh, and improved so far that a candle would burn in it. 3. After expelling all the air he could from a quantity of water by boiling, he put to it, in separate phials, air that had been phlogificated with iron-filings and brimstone, as well as that which the heat had expelled, leaving them with their mouths in water, and agitating them occasionally. On examining the phials in about two months, he found both the air that was confined by water and that which had been expelled by heat completely phlogificated. 4. That water does imbibe the purer part of the atmosphere, in preference to that which is impure, is evident, he says, from any examination of it: For if the water be clear, and free from any thing that is putrefactive, the air expelled from it by heat is generally of the standard of 1; whereas that of the atmosphere, when the nitrous air is the purest, is about 1.2. Phlogificated air is equally invisible with common air, and something more elastic. Mr Kirwan proved it by expelling air from a vessel, through a long tube, into the main air; and, by carefully placing a stop-plate upon the stem of the tube, no perceptible diminution of the atmosphere in the room could be observed.
AEROLOGY.

Phlogificated Air.

Sec. IV.

Phlogificated Air.

Nitrous acid procured from phlogificated air.

Mr. Cavendish’s experiments on the production of nitrous acid.

Nitrous acid procured from phlogificated air.

cured some perfectly phlogificated, so that it was not in the least diminished by nitrous air, from a mixture of iron-filings and brimstone. Having dried it by frequently introducing dry filtering paper under the jar that contained it, he found its weight to be that of the common air as 683 to 1000, the barometer standing at 20.44 and the thermometer at 60°. The other properties of it are, that it is extremely fatal to animal life, and friendly to that of vegetables, insomuch that it is now generally believed to be the true and proper nourishment of the latter. It seems to exist originally, in very large quantity, in our atmosphere. It may be separated from the common mafs of air by combustion, by respiration, by putrefaction, and in short by every species of phlogistic process; neither is there any other species of air but what may be converted into this by means of fire, dephlogificated air alone excepted.

Phlogificated air is now generally believed to be a combination of the nitrous acid with phlogiston; and, in its gradual progress towards this, which is its ultimate stage, it first assumes the character of phlogificated nitrous acid; then of nitrous acid, in which it is readily parts with its phlogiston to the atmosphere, or rather to the dephlogificated part of it; and lastly, it becomes phlogificated air, in which the union between the principles in so strong, that it cannot be broken by simple exposure to dephlogificated air without heat; though the experiments of Mr Cavendish show, that this may be done by means of the electrical spark, which produces the most violent heat we can imagine.

It had been frequently observed, that common atmospheric air was always diminished by taking the electrical spark in it; and this diminution was fastened to be occasioned by the phlogification of the air, and separation of its fixed part; in consequence of which it was urged, that lime-water is precipitated by taking the spark, which is its phlogiston, and that, when the part of the air contained in the exhausted vessel is again admitted to the common air, the precipitated lime-water is dissolved. Now, Mr Cavendish, however, who has carefully examined this subject, denies that any fixed air is produced in this manner; and by a set of very curious experiments, published in the 75th volume of the Philosophical Transactions, has clearly shown that nitrous acid, and not fixed air, is the product of this operation.

The apparatus used in these experiments, was that represented Plate X., fig. 4, and consists only of a crooked glass tube, whose ends are plunged into quicksilver contained in two glasses, in the middle part of which the air is confined between the two portions of quicksilver. The air was introduced by means of a smaller tube, fig. 5, the tube M of the former figure being filled with quicksilver, the bent end of which was introduced into a jar DEF, filled with the proper kind of air, and inverted in water. The end C being stopped by the finger, the quicksilver was thus prevented from falling out, let the tube be placed in what position it would, until this pressure was removed. Upon introducing the crooked tube into the jar in the position represented in the figure, and removing the finger from the orifice at C, the quicksilver would descend; and by stopping this orifice again, any quantity of the fluid may be allowed to run out, and the empty space of the tube will be filled with the air desired. Having thus got the proper quantity of air into the tube ABC, it was held with the end C uppermost, and stopped with the finger; and the end A, made smaller for that purpose, being introduced into the end of the bent tube M, the air, on removing the finger from C, was forced into that tube by the pressure of the quicksilver in the leg BC. Thus he was enabled to inflate any quantity he pleased of any kind of air into the tube M; and by the same means it was in his power to set up any quantity of soap-leys, or other liquor which he wished to be in contact with it. In one case, however, in which he wished to introduce air into the glass tube many times in the same experiment, he made use of the apparatus represented fig. 6, consisting of a tube AB, of a smaller bore, a ball C, and a tube DE of a larger bore. This apparatus was first filled with quicksilver, and then the ball C and the tube AD were filled with air, by introducing the end A under a glass inverted into water, which contained the proper kind of air, and drawing out the quicksilver from the leg ED by a syphon. A ter being thus furnished with air, the apparatus was weighed, and the end A introduced into one end of the tube M, and kept there during the experiment; the way of forcing air out of this apparatus into the tube being by thrusting down the tube ED, a wooden cylinder of such a size as almost to fill up the whole bore, and by occasionally pouring quicksilver into the same tube, to apply the place of that pulled into the ball C. After the experiment was finished, the apparatus was weighed again, which showed exactly how much air had been forced into the tube M during the whole experiment; it being equal in bulk to a quantity of quicksilver, whose weight was equal to the increase of weight of the apparatus. The bore of the tube M, used in these experiments, was about the tenth of an inch in diameter, and the length of the column of air occupying the upper part of the tube was in general from 3 ½ inches to 1 inch. In order to force an electrical spark through the tube M, it was necessary to place an inflated ball at such a distance from the conductor as to receive a spark from it, and to make a communication between that ball and the quicksilver in one of the glasses, while the quicksilver in the other glass communicated with the ground.

When the electric spark was made to pass through common air included between short columns of a solution of litmus, the solution acquired a red colour, and the air was diminished, as had been observed by Dr Priestley. When lime-water was used instead of the solution of litmus, and the spark was continued till the air could be no further diminished; but not the smallest cloud could be perceived in the water, though the air was reduced to two thirds of its original bulk; which is a greater diminution than it could have suffered by any phlogistic process, that being little more than one-fifth of the whole. The experiment being repeated with impure dephlogificated air, a great diminution took place, but without any cloud in the lime-water. Neither was any cloud produced when fixed air was let up into it; but, on the addition of a little caustic volatile alkali, a brown sediment immediately appeared.

It being thus evident that the lime was saturated by some acid produced in the operation, the experiment was repeated with soap-leys to discover the nature of it. A previous experiment had been made in order to know what degree of purity the air ought to be of to produce the greatest diminution; and thus it was found,
AEROLOGY.

Sect. IV.

Phlogfificated air.

102

103

Proportions of the different airs necessary for the production of nitrous acid.

...found, that when good deep phlogfificated air was used, the diminution was but small; where perfectly phlogifificated air was made use of, no sensible diminution took place; but when five parts of pure phlogifificated air were mixed with three of common air, almost the whole was made to disappear.—It must be remembered, that common air consists of one part of phlogifificated and four of phlogifificated air; so that a mixture of five parts of pure phlogifificated air and three of common air, is the same thing as a mixture of seven parts of phlogifificated air with three of phlogifificated.

Mr Cavenish, having made these previous trials, he introduced into the tube a little soap-leys, and then let up some phlogifificated and common air mixed in the above-mentioned proportions, which, rising in the tube M, divided the soap-leys into its two legs. As fast as the air was diminished by the electrical spark, he continued to add more of the same kind till no further diminution took place. The soap-leys being then poured out of the tube, and separated from the quicksilver, seemed to be perfectly neutralized, as they did not at all discolour paper tinged with blue flowers. On evaporating the liquor to dryness, a small quantity of salt was left, which was evidently nitre, from the manner in which a paper impregnated with the solution of it burned. On repeating the experiment on a larger scale, with five times the quantity of materials, pure nitre was obtained in proportion, and was found by the test of terra pondersa falsa, to contain no more vitriolic acid than what might have been expected in the soap-leys itself, and which is exceedingly small.

As, in some former experiments of Mr Cavenish, it had been found, that by deflagrating nitre with charcoal, the whole of the acid was converted into phlogifificated, he concluded that this kind of air is nothing else than nitrous acid united to phlogifificated; according to which, it ought to be converted into nitrous acid by being deprived of its phlogifificated. "But (says he) as dephlogifificated air is only water deprived of phlogifificated, it is plain, that adding dephlogifificated air to a body, is equivalent to depriving it of phlogifificated, and adding water to it; and therefore dephlogifificated air ought also to be reduced to nitrous acid, by being made to unite or form a chemical combination with dephlogifificated air; only the acid thus formed will be more dilute than if the phlogifificated air was simply deprived of phlogifificated.

"This being premised, we may safely conclude, that in the present experiments, the phlogifificated air was enabled, by means of the electrical spark, to unite to, or form a chemical combination with, the dephlogifificated, and was thereby reduced to nitrous acid, which united to the soap-leys, and formed a solution of nitre; for in these experiments the two airs actually disappeared, and nitrous acid was formed in their room: and as it has been shown, from other circumstances, that phlogifificated air must form nitrous acid when combined with dephlogifificated air, the above-mentioned opinion seems to be sufficiently established. And a further confirmation is, that no diminution of air is perceived when the electric spark is passed either through pure dephlogifificated or through perfectly phlogifificated air; which indicates a necessity for the combination of the two in order to produce nitrous acid. It was also found by the last experiment, that the quantity of nitre produced was the same that would Phlogifificated air have been obtained from the soap-leys, had they been caked Air, fatured with nitrous acid; which shows, that the production of the nitre was not owing to any decomposition of the soap-leys.

"The soap-leys used in the foregoing experiments were made from salt of tartar prepared without nitre, and were of such a strength as to yield one-twentieth of their weight of nitre when satured with nitrous acid. The dephlogifificated air was also produced without nitre; that used in the first experiment with the soap-leys being procured from the black powder formed by the agitation of quicksilver mixed with lead, and that used in the latter from turbit mineral. In the first experiment, the quantity of soap-leys used was 33 measures, each of which was equal in bulk to one grain of quicksilver; and that of the air absorbed was 416 such measures of phlogifificated air and 914 of dephlogifificated. In the second experiment, 178 measures of soap-leys were used; which absorbed 1920 of phlogifificated air and 4860 of dephlogifificated.

It must be observed, however, that in both experiments some air remained in the tube undecomposed, which was of the purest degree of purity I had means of trying; so that the proportion of each species of air absorbed cannot be known with much exactness.

"As far as the experiments hitherto published extend, we scarcely know more of the nature of the phlogifificated part of the atmosphere, than that it is not diminished by lime-water, caustic-alcalies, or nitrous air; that it is unfit to support fire or maintain life in animals; and that its specific gravity is not much less than that of common air; so that though the nitrous acid, by being united to phlogifificated, is converted into air poiffed of these properties; and, consequently, that the proportion of each species of air absorbed cannot be known with much exactness.

I therefore made an experiment to determine whether the whole of a given portion of the atmosphere could be reduced to nitrous acid, or whether there there was not a part of a different nature from the rest, which would refuse to undergo that change. For this purpose, I diminished a similar mixture of dephlogifificated and common air in the same manner as before, until it was reduced to a small part of its original bulk; after which some dephlogifificated air was added, and the spark continued until no further diminution took place. Having by these means condensed as much as I could of the phlogifificated air, I let up some solution of liver of sulphur to absorb the dephlogifificated air; after which only a small bubble of air remained unaborsed, which certainly was not more than one-tenth of the bulk of the phlogifificated air let up into the tube; so that if there is any part of the phlogifificated air of our atmosphere which differs from the rest, and cannot be reduced to nitrous acid, we may safely conclude, that it is not more than one-tenth part of the whole.

Though these experiments had shown that the chief cause of this diminution of airs is the conversion of the phlogifificated kind into nitrous acid, it seemed
sect. V. aeroLogy.

PhlogiLicated Air.

not unlikely, that when any liquor containing inflammable matter was in contact with the air in the tube, some of this matter might be burnt by the spark, and thereby diminish the air. In order to determine this, the electric spark was passed through phlogiLicated air included between different liquors; and the result of the experiments was, that when phlogiLicated air, containing only $\frac{1}{4}$ part of its bulk of phlogiLicated air, was confined between short columns of soap-leys, and the spark passed through it till no further diminution could be perceived, the air lost $\frac{1}{4}$ of its bulk; which is not a greater diminution than might very likely proceed from the decomposition of the small quantity of phlogiLicated air contained in it, as the phlogiLicated air might easily be mixed with a small quantity of common air while putting into the tube. When the same phlogiLicated air was confined between columns of distilled water, the diminution was rather greater than before, and a white powder was formed on the surface of the quicksilver beneath; the reason of which, in all probability, was, that the acid produced in the operation corroded the quicksilver, and formed the powder; and that the nitrous air produced by that corrosion united to the dephlogiLicated air, and caused a greater diminution than would otherwise have taken place. When a solution of litmus was used instead of distilled water, the solution soon acquired a red colour; which grew paler and paler as the spark was continued, till it became quite colourless and transparent. The air was diminished by almost one-half, and might perhaps have been further diminished had the spark been continued. When lime-water was let up into the tube, a cloud was formed, and the air was further diminished by about one-fifth; the remainder was good dephlogiLicated air. In this experiment, therefore, the litmus was, if not burnt, at least decomposed, so as to lose entirely its purple colour, and to yield fixed air; so that, though soap-leys cannot be decomposed by this process, yet the solution of litmus can, and so very likely might the solutions of many other substances be. But there is nothing in any of these experiments which favours the opinion of the air being at all diminished by means of phlogiLiton communicated to it by the electric spark.

sect. V. of fixed air.

The discovery of this kind of air is as old as Van Helmont; who gave it the name of gas fixus, from its being emitted in great quantity by burning charcoal. Subsequent discoveries showed, that a fluid of the same kind was plentifully produced by fermenting marrows; in almost every kind of combustion, and naturally generated in vast quantity in mines and coal-pits, where it is known by the name of chok-damp; that it exists in a concrete state in alkaline salts, chalk, limestone, the shells of marine animals, magnesia alba, &c. in a very large proportion, confining one-half, and sometimes more of their weights; and that it might always be extracted from the atmosphere, in unlimited quantity, by expelling certain substances to it.—On examining the nature of this fluid, it was found so manifastly acid, that it has now obtained a place among these substances under the name of aërial acid; or, more improperly, cretaceous acid, from its being Fixed Air. The fixed air is the heaviest of all permanently elastic fluids, excepting those derived from the mineral acids.

Mr Kirwan determines it to be to common air as 1000 to 10000, the barometer being at 20.85, the thermometer at 64, and the fixed air being extracted from calcareous spar by MARINE, whose specific gravity was 1.045. He observes, however, that though this air was obtained in the driest manner possible, and that the globe which contained it appeared perfectly free from moisture; yet, when carried into a room 27 degrees colder, the inside of the globe was covered with dew, which soon formed visible drops.—In its concrete state, fixed air is one of the heaviest bodies in nature.

Mr Kirwan, in the 7th volume of the Philosophical Transactions, gives an account of his ingenious method of finding the specific gravity of fixed air in its fixed state, when combined with calcareous earth, from which it appears, that fixed air, in that state, is prodigiously concentrated, and, were it possible to extract it by itself in that concentrated state, it would be the heaviest body known, gold and platinum excepted.

Mr Kirwan first ascertained the specific gravity of a piece of white marble, and then expelled the fixed air from a known weight of it finely powdered, by means of diluted vitriolic acid; the bulk and weight of the obtained fixed air being ascertained. Next, he calcined a known quantity of the same sort of marble, by keeping it in a white heat for the space of 14 hours; after which, being weighed again, and from the weight lost by this calcination, the weight of the fixed air, which must have escaped from it according to the abovementioned experiment, being subtracted, the remainder is the weight of water contained in the marble; from which experiments it appears, that 100 grains of the marble contained 32.42 grains of fixed air, 11.66 grains of water, and 55.92 grains of pure calcareous earth.

I next (says he) proceeded to discover the specific gravity of the lime. Into a brass box, which weighed 607.65 grains, and in the bottom of which a small hole was drilled, I stuffed as much as possible of the finely-powdered lime, and then screwed the cover on, and weighed it both in air and in water. When immersed in this latter, a considerable quantity of common air was expelled; when this ceased, I weighed it. The result of this experiment was as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>Grains</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight of the box in air</td>
<td>607.65</td>
</tr>
<tr>
<td>Its loss of weight in water</td>
<td>72.75</td>
</tr>
<tr>
<td>Weight of the box and lime in air</td>
<td>1047.5</td>
</tr>
<tr>
<td>Weight of the lime finely in air</td>
<td>435.85</td>
</tr>
<tr>
<td>Loss of weight of the box and lime in water</td>
<td>256.5</td>
</tr>
<tr>
<td>Loss of weight of the lime finely</td>
<td>182.3</td>
</tr>
</tbody>
</table>

Hence, dividing the absolute weight of the lime by its loss in water, its specific gravity was found to be 2.3968.

From these data I deduced the specific gravity of fixed air in its fixed state; for 100 grains of marble contained 55.92 of earth, 32.42 of fixed air, and 11.66 of water; and the specific gravity of the marble is 2.717. Now the specific gravity of the fixed air, in its fixed state, is as its absolute weight, divided by its loss of weight in water; and its loss of weight in water is as
165

A E R O L O G Y.

Sect. V.

Fixed Air.

the loss of 100 grains of marble, minus the loss of the pure calcareous earth and the water.

Loses of 100 grs. of marble = 100 = 36.8 grs. 2.717

Loses of 55.92 grs. of calcareous earth = 55.92 = 23.39 grs. 2.39

Loses of 11.66 grs. of water = - 11.66

“Then the loss of the fixed air 36.8 - 23.39 = 1.75; consequently its specific gravity is $\frac{32.42}{18.52} = 1.75$.

108

Fixed air differs considerably in its properties from the airs already mentioned. Its acidity is manifest to the taste, and still more from its neutralising both fixed and volatile alkalies; which it will do in such a manner as not only to destroy their causticity, but to give them a manifestly acid taste, and will moreover enable them to form crystals of a neutral or acridulous salt. It has a considerable antiseptic power, and will even check the putrefaction of animal substances; tho' it has been observed, that in this case it acts only by absorbing the putrid effluvia already emitted from the body, and becomes itself very offensive, while it sweetens the other.

When taken into the lungs, it is equally poisonous with phlogisticated or any other noxious air, and extinguishes flame as effectually; but, when mixed with phlogisticated air, may be inspired without any danger, and even in its pure state may be swallowed in large quantities, not only without danger, but with the most favourable effects in some diseases, whence it has now become an article of the Materia Medica. As an acid it finds in the lowest rank, being expelled from alkalies by every other; though it is capable of separating oils, sulphur, and the colouring matter of Prussian blue, from the substances with which they are combined.

The origin of this acid was for a long time as much unknown as that of the others; and while the general prejudice remained that acids were a kind of primary elements unchangeable in their nature, it was supposed that fixed air was some modification of the others, probably the nitrous. But the discoveries made of late years, have abundantly shewn, that the chemical principles are by no means so indestructible as they were imagined; and that the vegetable acids particularly, may be at least totally resolved into fixed air. Hence it was naturally suggested, that fixed air itself might be a compound of some other principles; and it was suggested by Dr Black, that it was a combination of atmospheric air with phlogiston. As the air of our atmosphere, however, is compounded of two substances, one of which naturally contains no phlogiston, and the other as much as it can hold; it seemed unlikely that there should be any possibility of adding to the quantity of phlogiston contained in a portion of the atmosphere, without decomposing it in some manner or other. Succeeding experiments evinced, that it was by a decomposition of the pure part of atmospheric air, and a combination of the phlogiston and the fuel with its balsas, that fixed air was produced; and this fact was evinced by numerous experiments made by Mr Kirwan, Mr Lavosier, and Dr Priestley, so that it is now looked upon to be generally established; and as the experiments made by Dr Priestley appear fully as convincing as fixed air, any, we shall here content ourselves with giving an account of them.

The compound nature of fixed air, and the principles from which it is formed, were first discovered by Mr Loy's experiments; but Dr Priestley was not convinced by the rimes and proofs he adduced, till after making some experiments of his own. The first was, by firing thavgings of iron in dephlogisticated air; when he observed a considerable residuum of fixed air, though that in the receiver had been of the purest dephlogisticated kind, and iron could only have yielded inflammable air. The hypothesis of Mr Kirwan was still further confirmed by an experiment in which iron-filings, which could only have yielded inflammable air, were mixed with red precipitate, which is known to yield only pure dephlogisticated air. On heating these in a glass retort, they gave a great quantity of fixed air, in some portions of which nineteen-twentieths were absorbed by lime-water, and the residuum was inflammable; but when the red precipitate was mixed with powdered charcoal, which had been found to yield only inflammable air, the fixed air produced from it was so pure that only one-fourth part remained unabsorbed by water, which is as pure as that generally prepared from chalk and oil of vitriol. In some of these experiments it appeared, that three ounce-measures of dephlogisticated air went to the composition of two of fixed air: for one ounce of red precipitate gave 60 ounce-measures of dephlogisticated air; and, when mixed with two ounces of iron-filings, it gave about 40 ounce-measures of fixed air that were actually absorbed by water, besides a residuum that was inflammable. The fame proportion was obtained when half the quantity of materials were made use of; but on putting an ounce of each, only 20 ounce-measures of fixed air, including the residuum, could be got.

In considering this subject farther, it occurred to Dr Priestley, that his experiments, in which charcoal was used, lay open to an objection, that since dry wood, and imperfectly made charcoal, yield fixed air, it might be said, that all the elements of fixed air are contained in charcoal; and though this substance alone, even with the affinities of water, will not yield fixed air, this might be effected by treating it with other substances without their imparting anything to it; especially as the inflammable air procured by means of water, appears to contain fixed air when decomposed with the dephlogisticated kind. In order to expel all the fixed air from charcoal, he made a quantity of it from dry oak, and pounding it while hot, instantly mixed four measures of it with one of red precipitate, and, putting them into an earthen retort, got, with a heat no greater than what was sufficient to revive the mercury, a large quantity of air, half of which was fixed. Afterwards the proportion of fixed air was less, and at last no fixed air at all was obtained; but as the residuum was worse than the common atmosphere, he was inclined to believe, notwithstanding Mr Cavendish's experiments, that phlogisticated air may be composed of phlogiston and dephlogisticated air. In another experiment he found a better proportion of charcoal and red precipitate. This was by mixing one ounce of precipitate with the same quantity of perfect char-
AEROLOGY.

Fixed Air. — Charcoal hot from the retort in which it was made, putting these into a coated retort, he expelled from them, by a strong heat, about 30 ounce-measures of air, the whole of which was the purest fixed air, leaving only about one-fourth part unabsorbed by water, and this almost perfectly phlogilicated.

Having recollected, that in some former experiments he had obtained fixed air from nitrous acid and charcoal, he therefore repeated the experiment with some of the same charcoal which had then been made use of; when fixed air was obtained, in the quantity sometimes only of one-fifth, and sometimes of one-half; to the formation of which he supposed the phlogilicated air produced by heating the nitrous acid must have contributed. On account of the objections, however, which might be made to the use of charcoal, he next employed iron, which was liable to nothing of this kind; and on mixing an ounce of iron-fillings with as much charcoal, and then heating them in a glass retort, he obtained 20 ounce-measures of air, of which one-fifteenth remained unabsorbed by water. The residuum was the standard of 1.12, but slightly inflammable. Repeating the experiment with half an ounce of iron fillings, he got 26 ounce-measures of air, of which the first part was pretty pure, but afterwards one-tenth remained unabsorbed by water; but on mixing one ounce of precipitate with two ounces of filings, he got about 40 ounce-measures of air, of the first portions of which only one-twentieth was unabsorbed by water, though towards the conclusion the residuum was greater. In this process he got in all 30 ounce-measures of pure fixed air, completely absorbed by water, besides about four ounce-measures, which, he supposes, might have been absorbed in receiving the air and transferring it into other vessels.

Fixed air was also produced from red precipitate mixed with brass filings, with zinc, from tubercine mineral with iron filings, and from the black powder into which mercury mixed with lead is easily converted. In this latter case the Doctor supposes that the fixed air was produced from the phlogiiliated kind absorbed by the metals and the phlogiston of the lead; and this is confirmed by an observation that the fixed air always comes first in the process, when the phlogiston is most readily separated, but afterwards the produce becomes quite pure and phlogiiliated. In attempting, however, to increase the quantity of fixed air by heating this black powder in phlogiiliated air, he found only an augmentation of the quantity of phlogiiliated air, and of that pure kind.

"Perhaps," says he, "as decisive a proof as any of the real production of fixed air from phlogiston and phlogiiliated air, may be drawn from the experiments in which I always found a quantity of it when I burned sulphur in phlogiiliated air. In one of these experiments, to which I gave particular attention, six ounce-measures and an half of the phlogiiliated air were reduced to about two ounce-measures; and one-fifth of this was fixed air. When both the vitriolic acid and fixed air produced by this operation were absorbed by water, the remainder was very pure dephlogiiliated air.

I had always concluded, that no fixed air could be procured by the decomposition of inflammable air which had been produced by mineral acids, because I had not been able to do it with that which I had got by means of vitriolic acid; but I learned from Mr. Neumann, that this is peculiar to the vitriolic acid, the remainder of which, diluted through the inflammable, procured by it, he conjectures, may actually decompose the fixed air produced in the process. For, as I have hinted before, when the inflammable air is produced from iron by means of fipis of sulphur, there is a very perceivable quantity of fixed air when it is united with dephlogiiliated air. When I decomposed these kinds of air in equal quantities, they were reduced to about 0.5 of a measure, and of this not more than about one fourteenth was fixed air. This experiment, ought, however, to be added to the other proofs of fixed air being produced by the union of dephlogiiliated air and phlogiston.

"The last instance, which I shall mention, of the general production of fixed air from phlogiston and dephlogiiliated air, is of a much more striking nature than any that I have yet recited. Having made what I call charcoal of copper, by passing the vapour of spirit of wine over copper when it was red-hot, I heated a piece of it in different kinds of air. In common air, observing neither increase nor decrease in the quantity, it concluded, perhaps inaccurately, that no change was made in it: for when I repeated the experiment in dephlogiiliated air, the charcoal burned very intently, and when a part of it was consumed, which (like common charcoal in the same process, was done without leaving any sensible residuum) I found that no heat which I could apply afterwards, had any further effect on what was left of the charcoal. Concluding, therefore, that some change must be made in the quality of the air, I examined it, and found about nine-tenths to be the pure fixed air; and the residuum was such as would have been made by separating the absolutely pure part of the dephlogiiliated air, leaving all the impurities behind. — Having ascertained this fact, I repeated the experiment, weighing the piece of charcoal very carefully before and after the process; and then found, that by the loss of one grain of charcoal, I reduced four ounce-measures of dephlogiiliated air till one-ninth only remained unabsorbed by water; and again, with the loss of one grain and a half of the charcoal, I reduced six and an half-measures of dephlogiiliated air till five and an half-measures were pure fixed air. In this process there was a diminution of bulk after the experiment, as might have been expected from the change of the air into one of a heavier kind by means of a substance or principle that could not add much to the weight of it. In one of the experiments, 4.3 ounce-measures of dephlogiiliated air were reduced about one-thirtieth part of the whole; and in this case, when the fixed air was separated by water, there was a residuum of 0.75 of a measure of the standard of 1.0, whereas the dephlogiiliated air, before the experiment, had been of the standard of 0.2.

"That dephlogiiliated air actually enters into the composition of the fixed air, in this experiment, is evident from the weight of the latter, which far exceeds that of the charcoal dispersed in the process. For, in this last experiment, the weight of the fixed air produced was 4.95 grains. Consequendy, supposing the charcoal to be wholly phlogiston, it is very nearly 60 fixed air may be said to consist of 5.45 parts of dephlogiiliated air.
Fixed Air.

\[ \text{phlogisticated air, and } 1.5 \text{ of phlogiston; so that the dephlogisticated air is more than three times the proportion of phlogiston in it.} \]

Phlogisticated air, he observed that fixed air, he found that the quality of the residuum was evidently better than that of the original fixed air.

In order to discover whether the heat or light of the electric spark were the circumstances which effected the change, the Doctor threw a strong light, by means of a lens, for some hours, on a quantity of pounded glafs confined in some fixed air; but though the volume of residuum was thus somewhat increased, yet as it was of the same quality with common air he suspected that it might be only that portion which had been introduced among the particles of the glafs. The quantity of air was increased after the operation.

With glafs-hone sand made very hot, the quantity of air was likewise increased; but the experiment was not more satisfactory than the former. Heated burnt crucibles increased the quantity of residuum in the proportion of 10 to 6.6; but the quality was injured either directly by a comparison with nitrous air or by producing a larger quantity of residuum equally bad. By heating iron, however, in fixed air, part of it was evidently converted into phlogisticated air. On heating turnings of malleable iron for some time in fixed air, one-tenth part of it was rendered immissible with water; and on repeating the process with the remainder, there was a residuum of one-fourth of the whole.

There was also a small addition to the quantity of air after the first part of the process, but none after the second; nor could he, after a third and fourth process, render more than one-fourth immisible with water. In two experiments, the residuum was inflammable, and burned with a blue flame.

With regard to the quantity of fixed air which may be expelled from different substances, Dr Priestley observes, that from seven ounces of whiting, the purest calcareous substance we are acquainted with, he expelled by heat 630 ounce-measures of air; by which means the whiting was reduced to four ounces. One fourth of this was phlogisticated; the standard being 1.36 and 1.28. Repeating the experiment, he obtained 440 ounce-measures of air from six ounces of whiting; about one-half of which was fixed air, and the remainder of the standard of 1.4. On moistening some calcined whiting with water impregnated with vitriolic acid, he obtained 90 ounce-measures; of which the first portions were three-fourths fixed air, and the standard of the residuum 1.5; the latter had less fixed air and the standard of the residuum was 1.44. The whiting was rendered black and hard, but became soft and white with spirit of salt. Three ounces and a quarter of lime fallen in the air, yielded 275 ounce-measures; of which about one-fifth was fixed air, and the residuum of the standard 1.4. Four ounces of white lead had yielded 240 ounce-measures of air when the retort melted. The residuum of the first process was one-third, the standard 1.36; and of the last the standard was 1.28, that with the common atmosphere being 1.22. Two ounces and three quarters of wood-ashes yielded, in a very strong heat, 450 ounce-measures of air; of the first portion of which one-tenth, of the second one-third, and of the third one-half, was fixed air.

Phlogisticated air is more than three times the proportion of phlogiston in it. I must not conclude, however, without observing, that in one experiment, I never failed to produce fixed air; though it is not easy to form a view of its supposed elements, viz. dephlogisticated air, could enter into it. This is by heating iron in vitriolic acid air. In one of these experiments, four ounce-measures of the vitriolic acid were reduced to 0.65 of an ounce-measure; and of the quantity lost three and an half meares were fixed air absorbed by lime-water; and the remainder was inflammable."

Fixed air, even when pure and unmixed, is remarkably altered by the electric spark, part of it being thus rendered immiscible in water. Dr Priestley, having taken the electric spark for about two hours in a small quantity of fixed air confined by mercury, found, that after the operation, one-fourth of it remained immiscible with water; though, before it, only one-thirtieth part had remained unabsorbed. The inside of the tube had become very black; which, in other experiments of a similar kind with vitriolic acid air, he had observed to arise from the adhesion of a small quantity of mercury super saturated with phlogiston. In another experiment, in which the spark was taken an hour and ten minutes in about half an ounce-measure of fixed air; one-fifth remained unabsorbed, and the standard of the residuum was 0.9; though, before the operation, only one-thirtieth part had been absorbed, and the standard of the residuum was 1.0. In this experiment, also, he observed, that the air was increased about a twentieth part. On taking the electric spark an hour in half an ounce-measure of fixed air, as much residuum was left as had remained in five times the quantity of the same fixed air in which no spark had been taken. This residuum was also much purer than that of the original fixed air, the standard being 0.8; whereas that of the original fixed air had been, as before, 1.0. On repeating the experiment, he found the residuum still greater, but equally pure; and, in this case, a good quantity of black matter was observed adhering to the tube. Having taken the spark in a small tube containing 1/8 of an ounce-measure of fixed air, the inside of the tube was clotted with black matter, and in the bottom was a small quantity of yellowish matter resembling sulphur; the residuum was between one-fourth and one-fifth of the whole, and less pure than formerly. This circumstance he also supposes to be a proof that fixed air may be composed of phlogiston and dephlogisticated air. Pursuing this experiment, by taking the electric spark three hours in a small quantity of fixed air, he observed that it was first increased, and then diminished about one-eighth of the whole; the inside of the tube being very black on the upper part, and below the mercury very yellow, for the space of a quarter of an inch all round the tube; but this space had been above the mercury in the beginning of the operation. One-third of the air remained unabsorbed by water; but so impure, that the standard of it was 1.8, or almost completely phlogisticated. Varying the process by using water impregnated with fixed air instead of mercury, the quantity of air was much augmented by that which came from the water; but thus the far greater part of it was incapable of being absorbed by lime-water; and on this occasion he observed, that water impregnated with fixed air is a much worse conductor of electricity than the same fluid impregnated with mineral acids. On still varying the circumstances of the experiment, by using common water instead of that which had absorbed fixed air, he found that the quality of the residuum was evidently better than that of the original fixed air.

Phlogisticated air is more than three times the proportion of phlogiston in it. I must not conclude, however, without observing, that in one experiment, I never failed to produce fixed air; though it is not easy to form a view of its supposed elements, viz. dephlogisticated air, could enter into it. This is by heating iron in vitriolic acid air. In one of these experiments, four ounce-measures of the vitriolic acid were reduced to 0.65 of an ounce-measure; and of the quantity lost three and an half meares were fixed air absorbed by lime-water; and the remainder was inflammable."
SECT. VI.

AEROLOGY.

Fixed Air. The standard of the residuum of the first portion was 1.6, and of the second 1.7. It extinguished a candle; so that the air came properly from the ashes, and not from any remaining particles of the charcoal mixed with them. After the process, the ashes weighed 839 grains; but by exposure to the air for one day, the weight was increased to 843 grains; and, perhaps, with more heat than before, yielded 50 ounce-measures of air; of which about one-eighth was fixed air, and the standard of the residuum 1.38 and 1.41. A candle burned in this residuum, and the ashes were reduced to 739 grains. Two ounce-measures of Homburg's pyrophorus burned in the open air, and then distilled in a retort, yielded 144 ounce-measures of air; of which one-half at first was fixed air, and the standard of the residuum 1.8. The pyrophorus was then kept two days in the retort, with the mouth immersed in mercury; after which, on being taken out, it burned as strongly as ever. Immediately before the burning, it weighed 428 grains; immediately after it, 449; but it had spread thin and exposed to the atmosphere for a night, the weight was increased to 828 grains; though, on being well dried, it was again reduced to 486. Subjecting it to a greater heat than before, the matter yielded 110 ounce-measures of air; the first portions of which were half fixed air, but the last contained very little, and burned with a blue lambent flame. It was then reduced to 296 grains. The experiment was then repeated with a quantity of pyrophorus, which would not take fire in the open air; and on heating this substance in an earthen retort, five-sevenths of the first part of the produce was fixed air: but this proportion gradually diminished; till at last nine-tenths of the whole was inflammable air, burning with a lambent blue flame. This inflammable air being decomposed with an equal quantity of dephlogisticated air, yielded 0.86 of a measure of fixed air. Another quantity of pyrophorus, which burned very well, and which by exposure to the atmosphere had gained 132 grains, being again exposed to heat in an earthen retort, gave 180 ounce-measures of air; three-sevenths of the first portion of which was fixed, and the rest phlogisticated air; but afterwards only one-half was fixed and the rest inflammable, burning with a lambent blue flame; and at last it was wholly inflammable. This pyrophorus took fire again after being poured out of the retort, but not without the assistance of external heat. It had been red-hot through the whole mass at the first burning, and the surface was covered with white ashes; but all the inside was as black as ever it had been. Four ounces of dry ox-blood yielded 1200 ounce-measures of air, and it was conjectured that not less than 200 measures had escaped. It contained no fixed air. The first portion burned with a large lambent white flame, the middle portion fainter, and the last was hardly inflammable at all. The remaining coal weighed 255 grains, and was a good conductor of electricity.

SECT. VI. INFLAMMABLE AIR.

We owe the knowledge of the existence, and of some remarkable properties of this air, to Mr Cavendish, by whom they were first published in 1767. Its effects, inflammable air, however, had long before been lamentably experienced by miners; in whose subterraneous habitations it is often collected in such quantities as to produce the most frightful effects. It is produced in abundance from the air putrid animal and vegetable substances; and, in general, by all those which part with phlogisticated air. Being much lighter than common air, it always rises to the top of those places where it is generated; so that it cannot be confined except in some vaulted place, but always strives to ascend and mix with the atmosphere. By itself it is very noxious, and will instantly put an end to animal life; but when mixed with atmospheric air, may be breathed in much greater quantity than fixed air. Its great inflammability in this state, however, renders it very dangerous to bring any lights, or even to strike a flint with it, in those places where it abounds. But this only takes place when the inflammable air is mixed with common phlogisticated air; in which case, the explosion is much more violent than the former; for pure inflammable air extinguishes flame as effectually as fixed or phlogisticated air.

Besides the subterraneous places already mentioned, this kind of air is found in ditches; over the surface of putrid waters, out of which it escapes; in burying-places; in houses of office where putrid animal and vegetable matters are accumulated; and may, by flogging or boiling, be extracted from the waters of most lakes and rivers, especially those in which great quantities of fermenting and putrefying matters are thrown; and as putrefaction thus seems to be the principal source of inflammable air, it thence happens, that much more of it is produced in warm than in cold climates. In Great Britain, in those countries, we are informed by Dr Franklin, that if the mud at the bottom of a pond be well strained, and a lighted candle brought near to the surface of the water immediately after, a flame will instantly spread a considerable way over the water, from the accession of the inflammable air, affording a very curious spectacle in the night-time. In colder climates, the generation of inflammable air is not so plentiful as to produce this phenomenon; nevertheless Mr Cavendish informs us, that it may be plentifully procured in the following manner: in all the ponds about London. "Fill a wide-mouthed bottle with the water of the pond, and keep it inverted therein; then, with a flick, stir the mud at the bottom of the pond, just under the inverted bottle, so as to let the bubbles of air which come out of it enter into the bottle; which air is inflammable. When by thus stirring the mud in various places, and catching the air in the bottle until this is filled, a cork or glass stopper must be put over it while standing in water, and then the bottle may be taken home, in order to examine the contained inflammable fluid at leisure." The great quantity of inflammable air produced in warm climates has given occasion to some philosophers to suppose, that it may possibly have formed the air produced in producing certain atmospheric meteors. The weak lightnings without any explosion, which are sometimes perceived near the horizon in serene weather, are by them conjectured to proceed from inflammable air fired by electric explosions in the atmosphere. Mr Volta supposes that the ignes fulgur are occasioned by the inflammable air which proceeds from marshy grounds.
Inflammable Air.

This kind of air is more common than any of the other noxious airs; for there is hardly any inflammable substance on earth, out of which it may not be extracted by one means or other. The fluids, however, which go by the general name of inflammable air, have scarce any other property in common to them all, besides those of inflammability, and being specifically lighter than the common atmospheric air. In other respects, the differences between them are very considerable. The smell, weight, power of burning, of preserving their properties, and the phenomena attending their combustion, are by no means the same in them all; some burning in an explosive manner; others quietly, and with a lambent flame of a white or blue colour. It is, however, necessary to make a proper distinction between an inflammable elastic fluid or inflammable gas, which may be properly called so, and that which is evidently made by combining an inflammable substance with common air; which being easily separable from the air, leaves that fluid in the state it was before. Thus a drop of ether, put into a quantity of common air, mixes itself with it, and takes fire on the approach of flame, like a mixture of inflammable and common air; but if the air to which ether is added be walled in water, the latter is soon separated from it. Common air becomes also inflammable by being transmitted through several essential oils; and thus, the air contiguous to the plant called 

Extracted from various substances by heat.

More air procured by a sudden than gradual heat.

The inflammable air produced in this way came only from the metal, without attending to the share which water had in the production. Some late experiments of Mr Lavoisier, however, showed, that water had a great share in the production of inflammable air; and it is much that it gave occasion to a supposition, that the water was the only source from whence it was derived. This mistake, however, was detected by Dr Priestley, who, by his numerous and accurate experiments, seems to have exhausted the subject. The method which Mr Lavoisier had followed, was to send the steam of boiling water through a red-hot iron tube; in doing which, the intense heat acquired by the water occasioned the production of a great quantity of inflammable air. Dr Priestley repeated his experiments not only with water, but with other fluids. Sending the vapour of two ounces of spirit of wine through a red-hot earthen tube, he obtained 900 ounce-measures of inflammable air, which burned with a white lambent flame. It contained no fixed air; and 50 ounce-measures of it weighed eight grains less than an equal quantity of common air. He collected also 0.35 of an ounce-measure of water. In this experiment, the weight of the water collected was 168 grains, of the inflammable air 633 grains, and that of the spirit of wine originally was 821 grains, so that as little was lost in the process as could be expected. Repeating the experiment with vitriolic ether, an ounce of it treated in the same manner in an earthen tube almost filled with pieces of broken earthen retorts and crucibles, one-tenth part of an ounce of water was collected, and 740 ounce-measures of inflammable air were procured, without any mixture of fixed air, burning with a white lambent flame like that of wood, and not exploding with dephlogisticated air. Twenty-nine ounce-measures of this weighed five grains less than an equal quantity of common air. Vapour of spirit of turpentine yielded inflammable air mixed with much black smoke, which soon collected on the surface of the water in the receiver. The smell of this air was exceedingly offensive, and its flame was much less luminous than that of the former. Its specific gravity was the same with that of the air procured from spirit of wine. Olive oil yielded a considerable quantity of air on being mixed with calcined whiting; the first portions burning with a large white flame, and the last with a lambent blue one.

In extracting air from solid substances, the steam of water was always necessary; and thus inflammable air was produced from a great number of different ones. From sulphur treated in this manner in an earthen tube, inflammable air was obtained of a nature similar to that from oil of vitriol and iron. From arsenic, the produce was one-fourth of fixed air; but all the red strongly inflammable, with a smell faintly distinguishable from that of phosphorus. Twenty ounce-measures of this air weighed 47 grains less than an equal quantity of common air. Both these experiments, however, were very troublesome, on account of the volatility of the matters, which suffused and choked up the tubes. From two ounces of the scales of iron or fining cinder, which he has found to be the same thing, Dr Priestley obtained 580 ounce-measures of air; one-tenth of the first part of which was fixed air, but afterwards it was all inflammable. Forty
AEROLOGY.

Air produced in this manner (says he) is of the lightest kind, and free from that very offensive smell which is generally occasioned by the rapid solution of metals in oil of vitriol; and it is extricated in as little time in this way as it is possible to do it by any mode of solution. The following experiment was made with a view to ascertain the quantity of inflammable air that may be procured in this manner from any given quantity of iron. A little hundred and sixty grains of iron, when distilled in acids, will yield about 800 ounce-measures of air; but, treated in this manner, it yielded 1044 measures, and then the iron had gained 329 grains in weight (A).

Inflammable air having been at first produced only from metals by means of acids, it was then supposed that part of the acid necessarily enters into its composition; but this hypothesis is now found to be ill grounded. That no acid (says Dr Priestley) is necessarily contained, or at least in any sensible quantity, is shown by the following experiments. No acid being contained in the two kinds of air, without perceiving the least variation than those with iron, however, were the bones to blacken, the weight of water expended, as it is possible to do it by any mode of solution in inflammable air, though produced by means of acids, or in the dephlogisticated air of the atmosphere, is evident from the following experiment, which I made with the greatest care: Taking a basin which contained a small quantity of water tinged blue with the juice of turnip, I placed it in a bent tube of glass, which came from a vessel containing iron and diluted oil of vitriol; and lighting the current of inflammable air as it issued from this tube, so that it burned exactly like a candle, I placed over it an inverted glass jar, so that the mouth of it was plunged in the liquor. Under this jar the inflammable air burned as long as it could; and when extinguished for want of more pure air, I suffered the liquor to rise as high as it could within the jar, that it might imbibe whatever should be deposited from the decomposition of either of the two kinds of air. I then took off the jar, changed the air in it, and lighting the flame of inflammable air, replaced the jar as before. This I did till I had decomposed a very great quantity of the two kinds of air, without perceiving the least change in the colour of the liquor, which must have been the case if any acid had entered as a necessary constituent part into either of the two kinds of air. I also found no acid whatever in the water, which was procured by keeping a stream of inflammable air constantly burning in a large glass balloon, through which the air could circulate, so that the flame did not go out. Neither was there any acid produced in the decomposition of inflammable and dephlogisticated air in a strong close glass vessel.

With respect to inflammable air, I have observed, that when sufficient care is taken to free it from any acid vapour that may be accidentally contained in it, it is not in the smallest degree affected by a mixture of alkaline air. On the whole, therefore, I have at present no doubt, but that pure inflammable air, though it certainly contains water, does not necessarily contain any

(A) In these experiments, the Doctor seems not to have supposed that any particular kind of water was necessary for this production of inflammable air; but in the Memoirs of the Philosophical Society at Haerlem, it is ascertained by Dr. Deiman and M. Paets Van Troostwyk, that the experiment will not succeed when boiled or distilled water, or any other than that containing fixed air, is made use of; and to this air they attribute the calcination of the iron, and production of inflammable air. This assertion, however, is contrary to what we find related by Mr Kirwan. See n. 138.
AEROLOGY.

Sect. VI.

Inflammable Air.

Early experiments convinced me that inflammable air is capable of a variety of impregnations as inflammable air is.

Mr Cavendish first perceived the necessity of moisture to the production of inflammable air; but it was not until after making several experiments that Dr Priestley could adopt the same idea. He had observed some very remarkable circumstances relating to the production of inflammable air from charcoal, by which he was induced to suppose that the former was pure phlogiston in a volatile state without any moisture whatever.

The Doctor observes, that "charcoal is generally said to be indestructible, except by a red heat in contact with air. But I find (says he), that it is perfectly destructible, or decomposed, in vacuo, and, by the heat of a burning lens, almost convertible into inflammable air, so that nothing remains besides an exceedingly small quantity of white ashes, which are seldom visible, except when in very small particles they happen to cross the fun-beams as they fly about the receiver. It would be impossible to collect or weigh them; but according to appearance, the ashes thus produced, from many pounds of wood, could not be supposed to weigh a grain. The great weight of ashes produced by burning wood in open air arises from what is attracted by them from the air. The air which I get in this manner is wholly inflammable, without the least particle of fixed air in it. But in order to this, the charcoal must be perfectly well made, or with such a heat as would expel all the fixed air which the wood contains; and it must be continued till it yields inflammable air only, which in an earthen retort, is soon produced.

"Wood or charcoal is even perfectly destructible, that is, resolvable into inflammable air, in a good earthen retort, and a fire that would melt iron. In these circumstances, after all the fixed air had come over, I several times continued the process during a whole day; in all which time inflammable air has been produced equally, and without any appearance of a termination. Nor did I wonder at this, after seeing it wholly vanish into inflammable air in vacuo. A quantity of charcoal made from oak, and weighing about an ounce, generally gave me about five ounce-measures of inflammable air in twelve minutes."

Although from these experiments it did not appear that water was in any ways essentially necessary to the production of this kind of inflammable air, it appeared manifestly to be so in the following: "At the time (says he) when I dispersed any quantity of charcoal with a burning lens in vacuo, and thereby filled my receiver with nothing but inflammable air, I had no suspicion that the wet leather on which my receiver stood could have any influence in the cafe, while the piece of charcoal was subject to the intense heat of the lens, and placed several inches above the leather. I had also procured inflammable air from charcoal in a glazed earthen retort for two whole days successively, during which it continued to yield it without intermission. Also iron-filings in a gun-barrel, and a gun-barrel itself, had always given inflammable air whenever I tried the experiment. These circumstances, however, decided me, and perhaps would have decided any other person; for I did not know, and could not have believed, the powerful attraction between water and charcoal or iron, when the latter are intensely hot. They repel, and attract it, in the midst of compounds, even charcoal or iron and water.

Inflammable air is not pure phlogiston. I then repeated the experiment with the charcoal, making the receiver, the stand on which I placed the charcoal, and the charcoal itself, as dry and hot as possible, and using cement instead of wet leather, in order to exclude the air. In these circumstances I was not able, with the advantage of a good fun and an excellent burning lens, to decompose so much as two grains of the piece of charcoal which gave me ten ounce-measures of inflammable air; and this, I imagine, was effected by means of so much moisture which was deposited from the air in its state of rarfaction, and before it could be drawn from the receiver. To the production of this kind of inflammable air, therefore, I was now convinced that water is as essential as to that from iron."

In his analysis of different kinds of inflammable air, Priestley's analysis of different kinds of inflammable air shows that the Doctor observes, that the difference most commonly perceived is, that some of them burn with a lambent flame, sometimes white, sometimes yellow, and sometimes blue; while another kind always burns with an explosion, making more or less of a report when a lighted candle is dipped into a jar filled with it. The inflammable air extracted from metals by means of acids is of this last kind; and that from wood, coal, or other inflammable substances by means of heat, belongs to the former. It has also been observed, that the kinds of inflammable air have different specific gravities; the purest, or that which is extracted from iron, &c., being about ten times as light as common air; but some of the other kinds not more than twice as light (A).

This difference was for some time attributed to a quantity

(A) Here the Doctor's calculation differs somewhat from that of Mr Kirwan; who, in his Treatise on Phlogiston,
quantity of fixed air intimately combined with the heavier kinds, so that it could not be discovered by lime-water, while the lightest contained no fixed air at all. In order to ascertain this point, he had recourse to decomposition; which was performed by mixing with the inflammable air to be tried an equal quantity of common or dephlogisticated air, and then confining them in a strong glass vessel previously filled either with water or mercury; making afterwards an electric spark in some part of the mixture by means of wires inserted through the sides of the vessel, and nearly meeting within it. Thus he supposed that he might be able to determine the quantity of combined fixed air, and likewise the relative quantity of phlogiston contained in each of them. The former appeared by washing the air with lime-water after the explosion, and observing how much of them was absorbed; and the latter by examining the residuum with the test of nitrous air, and observing the purity of it. Finding, however, that, in some cases, more fixed air was found after the explosion than could have been contained in the inflammable air, he was led to observe the generation of fixed air from the principles mentioned in the last section.

In prosecuting this subject, it was found, that one measure of inflammable air produced by steam from metals, and one of dephlogisticated air, such as by mixture with two measures of nitrous air was reduced to 0.72 of a measure, were reduced by explosion to 0.6 of a measure; the residuum, by an equal quantity of nitrous air, was reduced to 0.87. With the same dephlogisticated air, the inflammable air from fining-cinder and charcoal was reduced only to 1.85 of a measure; but by washing in lime-water, to 1.2. The residuum examined by nitrous air appeared to be of the standard of 0.9. In another process, the diminution after the explosion was to 1.55, and that after washing in lime-water to 0.65, of a measure; in a third, by explosion to 1.6, and by washing to 0.66; and in a fourth, the first diminution was to 1.6, and the second to 0.9. In this last experiment there was a generation of an entire measure of fixed air; and that this had not been contained originally in any latent state in the original fluid, was evident from the specific gravity of the inflammable air made use of. This, indeed, was one of the heaviest kinds of the fluid: but 40 ounce-measures of it weighed only two grains more than an equal bulk of common air; whereas, had all the fixed air found in the residuum been contained in the original air, it must have been at least one half heavier. "Indeed (says the Doctor) if any quantity of inflammable air, of about the same specific gravity with common air (which is the case with that species of it I am now considering), yield so much as seven-tenths of its bulk of fixed air in consequence of its explosion with dephlogisticated air, it is a proof that at least part of that fixed air was generated in the process, because seven-tenths of such fixed air would weigh more than the whole measure of inflammable air."
Inflammable Air.

Proportions already mentioned, the diminution was the same as with inflammable air produced from the malleable kind, viz. 1:36.

In the experiments it seemed evident, that at least part of the fixed air found after the explosion was produced by its means; but the following seem no less convincing proofs, that fixed air may be converted into the inflammable kind, or at least that the elements of fixed air may remain in inflammable air in such a manner as to be imperceptible. On heating in an earthen retort a quantity of flaked lime, which had long been kept close corked in a bottle, it gave air, of which one-fifth was generally fixed air; but in the gun-barrel the same lime yielded no fixed air at all, but a great quantity of inflammable air of the explosive kind, like that which is got from iron alone by means of water. As this total disappearance of the fixed air appeared extraordinary, the Doctor was induced to repeat it several times with all possible care; and the following was the result of his experiments: Three ounces of flaked lime, which had for some time been exposed to the open air, heated in an earthen tube, yielded 14 ounce-measures of air, of which only two and an half remained unab sorbed by water; the residuum was slightly inflammable, but not perfectly phlogisticated. Three ounces of the same lime, heated in a gun-barrel, gave 20 ounce-measures of air, all of which was inflammable, and no part fixed. It was expected, however, that the fixed air would have appeared in the decomposition of this inflammable air with the phlogisticated kind; but after this process, it appeared to be exactly such inflammable air as is procured from metals by the mineral acids, or by steam; the diminution of the two kinds of air being exactly the same: and thus some fixed air was found in the residuum, it was no more than is usually met with in the decomposition of inflammable air procured by means of spirit of salt.

Supposing that the two kinds of air might incorporate, when one of them was generated within the other, a gun-barrel was filled with fixed air, and the closed end of it put into a hot fire. Inflammable air was instantly produced; but when the fixed air was separated from it, it burned like inflammable air with which no other kind had ever been mixed.

On heating iron-turnings in five ounce-measures of fixed air, the quantity of it was increased about one ounce-measure, and there remained one and three-fourths unab sorbed by water. The experiment was repeated with the same result; and it was further observed, that though the inflammable air procured in this manner did not appear by the test of lime-water to contain any fixed air, yet when it was decomposed by heating it with an equal quantity of phlogisticated air, the residuum contained one-third of fixed air. The diminution was to 1:45. Hence the Doctor conjectures, that in some cases, the fixed air appears to be generated by the decomposition of phlogisticated and inflammable air, yet that inflammable air, when thus produced in contact with fixed air, may combine with it, so as to be properly contained in it, and in such a manner that it cannot be discovered by lime water.

Inflammable air, when produced in the driest way possible, is exceedingly light, as has been already observed: but Dr Priestley has found, that by standing on water, a very considerable increase is made in its specific gravity; so that from being ten or twelve times lighter than atmospheric air, it becomes only four or five times lighter. This great propensity of inflammable air with water is also taken notice of by Mr Kirwan; who tells us, that the bulk of inflammable air obtained over water with the assistance of heat towards the end, was one-eight greater than when produced over mercury, but that the weight of it in the former case was only eight or nine times less than common air.

"From 85 cubic inches of inflammable air obtained over water, I extracted," says he, "by oil of vitriol exposed to it for 35 hours, two grains of water; and, though undoubtedly there is an error in all these experiments, yet there can be little doubt but this inflammable air contained one-half its weight of water. The inflammable air, by the subfraction of its water, lost its smell, but continued as inflammable as ever; and therefore there is no reason to think that it was decomposed, or that water is any way essential to it."

The conclusion is directly contrary to that of Dr Priestley, that water is an essential ingredient in the composition of inflammable air; nor do the experiments of the latter, already recited, seem to have had any weight with him, as he concludes his Treatise on Phlogiston in these words. "To the proofs I have heretofore given, that inflammable air and phlogiston are the same substance, just as ice and the vapour of water, or the same essence, no objection of any weight has since been made. Some have thought, that I should have included the matter of heat or elementary fire in the definition of inflammable air; but fire is contained in all corporeal substances, it is perfectly needless, except where bodies differ in the quantity of it they contain; and in this respect I expressly mentioned its difference with phlogiston to confit."

Others, attending to the quantity of water contained in inflammable air, have supposed it to be an essential ingredient in the composition of this air, and have called it phlogisticated water; but they may as well suppose silver water to be an essential ingredient in common air, or fixed air, and call this last acidulated water; for inflammable air, equally as other airs, may be deprived of its water without any limitation, and yet preserve all its properties unaltered, which shows the presence of water to be no way essential to it. Lastly, others have thought, that it essentially requires an acid or an alkali, or some saline substance, for its basis; as if there were any more repugnance in the nature of things that phlogiston should exist in an aerial state without any basis, than marine air, alkaline air, or phlogisticated air; when it is evident, than an aerial state requires no more than a certain proportion of latent heat; but the production of inflammable air from iron by means of distilled water, without any acid or salt, has effectually done away any suspicion of that sort.

On the other hand, Dr Priestley informs us, that inflammable air seems now to consist of water and in keys constituting inflammable air; which, however, seems extraordinary, as the two substanccs are hereby made to involve each other; one of the constituent parts of water being inflammable air, and one of the constituent parts of inflammable air being water; and therefore, if the experiments would favour it (but I do not see that they do so.)
log. 177

Sect. VI. Aerology.

Inflammable Air.

Inflammable Air, like fixed air, consists of phlogiston and dephlogisticated air, in some different mode of combination.

"There is an astonishing variety in the different kinds of inflammable air, the cause of which is very imperfectly known. The lighted, and therefore probably the purest kind, seems to consist of phlogiston and water only. But it is probable that air, and that of different kinds, may be held in solution in several of them, and be the reason of their burning with a lambent flame, and also of their being so readily resolved into fixed air when they are decomposed by dephlogisticated air; though why this should be, I cannot imagine.

"When inflammable and dephlogisticated air are burned together, the weight of the water produced is never, I believe, found quite equal to that of both kinds of air. May not the light, therefore, emitted, from the flame, be part of the phlogiston of the inflammable air united to the principle of heat? And as light accompanies the electric spark, may not this also be the real evidence of some phlogistic matter, though it is not easy to find the source of it."

The French chemists, who deny the existence of phlogiston, are of opinion, that inflammable air is a simple uncombined element; but for a more full discussion of this subject, see the article PHLOGISTON.

Inflammable air is absorbed by water in considerable quantity, but by the application of heat may be expelled against equal quantity. By agitation in water Dr Priestley was formerly of opinion that this kind of air might be rendered as good as common air; but this undoubtedly proceeds from the atmospheric air transmitted by the water, as the air with phlogisticated air mentioned in the last section. After a quantity of water, which had absorbed as much inflammable air as it could, had been suffered to stand a month, it was expelled by heat, and found to be as strongly inflammable as ever. The water after the process, deposited a kind of fliny matter; which he supposed to be the earth of the metal that had been employed in producing it.

Plants in general grow tolerably well in inflammable air, and the willow plant has been observed to absorb great quantities of it. Its inflammability is not diminished by the putrefaction of animal substances, nor do their putrefaction seem to be retarded by it. Animals confined in it are killed almost as soon as in fixed air; but insects, which can live a considerable time in phlogisticated air, live also a considerable time in this kind of air; but at last they become torpid, and appear to be dead, though they will still recover if removed into the open air. Mr Cavallo relates, that the Abbe Fontana, having filled a large bladder with inflammable air, began to breathe it in his presence; after having made a very violent expiration, in which cafe the effects are most powerful. The first inspiration produced a great opprobrium in his lungs, the second made him look very pale, the third was scarce accomplished when he fell on his knees through weakness. Birds and small quadrupeds, inclosed in small vellums of this air, died after very few inspirations. Lastly, inflammable air appears to have a smaller power of refractive power than common air; for Mr Wattlire informs us, that having placed an hollow triangular prism, of which the angle was 72 degrees, so as to half cover a large object inflammable glases in one of Mr Dollond's spectacles, and so turned round as to make the frame of a window, the distance of 1280 feet, fixed partly through the prism and partly through common air, appear undivided. The inflammable air was then blown out of the prism, but no part of the apparatus was moved; when the frame of the window seen through the object glases and the prism as before, seemed to separate about four inches.

The inflammability of this species of air has given occasion to various projects concerning it; such as that of employing it to give light and heat; and lamps have been described, which may be lighted by the electric spark in the night time. By its means also very pretty artificial fires are made, with glases tubes bent in various directions, and pierced with a great number of small apertures. The inflammable gas is introduced into these tubes, from a bladder filled with that fluid, and fitted with a copper cock. When the bladder is prefixed, the inflammable air, being made to pass into the tube, fills up all the small apertures, and is set on fire by a lighted taper. None of these contrivances, however, have ever been applied to any use; and the scheme of Mr Volta, who proposed to substitute its explosive force instead of gun-powder, is found insufficient, on account of the weakness of the explosion, except when the two airs are fixed in very great quantity, which would be incompatible with the small bulk necessary for warlike engines.

Sect. VII. Sulphurated Inflammable Air.

This was discovered by Dr Priestley at the time when he was engaged in the experiment of which some account has been given in the last section, of transmitting the steam of water and other fluids through red-hot mortars containing some solid material. Having, at first produced other kinds, treated manganese in this manner, by burning them, it was received forty ounces of this air, one-seventh of which was fixed, and the rest of the standard of 1.7, lambently inflammable. Having then opened the other end of the tube in order to admit the steam, air was procured more copiously than before. Of 50 ounces of this air, one-seventh was fixed, and the rest of the standard of 1.8, explosively inflammable. The last portions were very turbid; and the smell, especially that of the last portion, was very sulphureous, tingeing the water of a very dark colour, by depositing in it a quantity of black glassy matter. However, the air itself became perfectly transparent, and had no other appearance than that of any other kind of air. On looking at the jar in about ten minutes after, it was quite black and opaque; so that nothing could be seen on the inside of it. Filling afterwards another jar with the same kind of air, in order to observe the progress of this uncommon phenomenon, he found, that when the water was well fufphed, black specks began to appear in different places, and, extending themselves in all directions, at length joined each other, till the whole jar became perfectly black, and the glass opaque. When this was done, he transferred the air into another jar; and it soon produced a similar effect upon this, though it never became...
This kind of air, when pure, is instantly fatal to animal life, and extinguishes flame; though, when mixed with common atmospheric air, it is slightly inflammable, and also medicinal in fumings and other cafes of debility. A candle dipped into a jar of this air is extinguished; but just before the flame goes out, it is enlarged by the addition of another flame of a pale yellow colour, and sometimes a weak flame spreads for a considerable way, or even through the whole body of the alkaline air. The electric spark, taken in it appears of a red colour. Every spark taken in it augments its bulk, and by degrees turns the whole into inflammable air. It is readily absorbed by water, as has been already observed, and dissolves ice almost as fast as an hot fire. On confining some water impregnated with alkaline air in a glass tube, and thus expelling it to a strong heat in a sand-furnace for some days, he observed that a white sediment or ashes formed on the surface. The Dr remarked, that his being the same thing, he had got before. On burning a quantity of it, this kind of air appeared to contain some vitriolic acid, the balloon being filled with a very dense white fume, which rendered the water febibly acid to the taste. On decomposing it with dephlogisticated air, however, he found the diminution exact; the same as when common inflammable and dephlogisticated air were used; and that it appeared to contain neither more nor less phlogiston than the other; only there was a small quantity of fixed air produced, which is never the case with common inflammable air from vitriolic acid and iron.

When the sulphurated inflammable air is received over mercury, very little black matter is produced on the glass; the colour presently disappeared, and a yellow matter collected on them, when the air is taken through water, soon grows yellow upon exposing it to the air, it is not the cafe with that, which remains in the water; it adheres to the evaporating vessel in form of a black incrustation, which does not burn blue until it has been digested in the nitrous acid, which deprives it of its pungent phlogiston, and leaves it both of the colour and smell of sulphur.

**SECT. VIII. OF ALKALINE AIR.**

This was procured by Dr Priestley, in the begin-ning of his experiments, from common spirit of sal-ammoniac with quicklime, or the materials from which it is made. He did not at that time procure the discovery farther than by impregnating water with it, which means he could make a much stronger alkaline spirit than any to be met with in the shops. His method of procuring it was by mixing one part of pounded sal-ammoniac with three parts of flaked lime, and for common experiments the same quantity of materials would last a considerable time.
In examining the phenomena which attend the conversion of alkaline air into inflammable air, the Doctor was induced to believe that it was occasioned by heat alone, without the concurrence of light. The effects of the former were first perceived on heating one ochre of iron in alkaline air; when, though the matter turned black, as in an incipient reduction of the metal, he found a considerable increase of quantity instead of decrease in the air, as he had expected; and, on examining the quality of it, he found that it contained no fixed air, but was entirely inflammable. With scales of iron a similar enlargement was perceived; but in this way he could never increase the quantity to more than double that which had been originally employed, and even after this the whole emitted strongly of volatile alkali; and the iron had undergone no change.

The Doctor, now, concluding from these experiments that the change of alkaline into inflammable air was produced by this cause alone, proceeded to repeat the experiment, by heating in the alkaline air bits of dry crucibles, or of earthen retorts, which had been just before exposed to very great heats, so that they could not be supposed to give out any air themselves, and therefore could only serve to communicate a strong heat to the alkaline air; and in these experiments the result was the same as when ochre or iron were made use of. The bits of white earthen ware were always turned black; but finding the same effect of augmenting the air and giving it an inflammable quality, though he used the bit of crucible over and over again, he was thoroughly convinced that the change was effected by heat alone.

In all these experiments, however, with a burning-glass, as a strong light was also concerned, he heated a quantity of alkaline air in a glass glas retort, receiving in a glass tube, filled with water, all the air that could be expelled from it by heat. At first it was all absorbed by the water, being merely alkaline air expelled by the rarefaction; but when the bulb of the retort became red-hot, he found that the bubbles driven out were not wholly absorbed, and at last none of them were so. These were altogether inflammable; so that no doubt remained of the change being produced by heat alone, without any intervention of light.

It was farther observed, that whenever the alkaline air was changed into inflammable by means of bits of retorts or crucibles containing clay, they always became black during the process. He inclined therefore to suppose, that something might be deposited from the air which might attach itself to the clay. "Indeed, (says he) if this was not the case, I do not see why the clay should become black; though, perhaps, part of the fame phlogiston which forms the inflammable air may be attracted by the red-hot clay, with-
Nitrous Air.

Properties of nitrous air.

In common experiments no other degree of heat is necessary than that produced by the effervescence itself, except mercury be used, which requires the application of some degree of heat; but when the metal escapes a very great surface to the acid, as is the case when the filings of the metal are used, the effervescence and production of nitrous air are often much quicker than can be conveniently managed. The most proper method of producing nitrous air, however, is explained in the last section of this treatise.

Nitrous air by itself is equally transparent and invisible with common air, excepting at its first production, when it is somewhat coloured, owing to a little superficial nitrous acid, or to some earthy particles which are carried up with it. Its smell resembles that of nitrous acid, or indeed is the very same; because, in passing through the common air to our nostrils, it is decomposed, and converted into nitrous acid. The same is to be said of its taste; though Mr Fontana, who tasted it without any contact of external air, affirmed that it has no taste whatever. The method in which he ascertained this fact was as follows. Having first introduced the nitrous air into a bottle of elastic gum in water, as is done with glass bottles, he brought his mouth, shut, while the neck of the elastic gum bottle was under water, near the neck of it; and then, by pressing the bottle, introduced the nitrous air into his mouth. The experiment, however, is by no means void of danger; for if the person happens to draw any quantity of this air into the lungs, he may be nearly suffocated, as nitrous air is exceedingly noxious. In performing it, he recommends to exhaust the mouth entirely of common air, though he does not inform us how this can be done; nor indeed is it easy to conceive the possibility of doing so.

Though nitrous air extinguishes flame, it may by certain processes be brought into such a state that a candle will burn in it with an enlarged flame; and it becomes what Dr Priestley calls dephlogisticated nitrous air, which is treated of in the next section. It is remarkable, however, that when a candle is extinguished, as it never fails to be in common air, the flame seems to be a little enlarged about its edges by the addition of another bluish flame before the former goes out.

Nitrous air seems to be the most fatal to animal life of any. Even insects, which can bear phlogisticated and inflammable air, generally die the moment they are put into it. Frogs, snails, and other animals which do not respire very frequently, die in a few minutes, and generally do not recover even when taken out of this noxious fluid before they are dead. Plants perish very soon in nitrous air, and even in common air saturated with nitrous air; but Dr Priestley informs us, that "though in general plants die almost immediately in water impregnated with nitrous air, yet in one case of this kind, when the superfusious nitrous air was let out under water, so that no part of it was decomposed in contact with the water, the plant grew in it remarkably well."

Water, by agitation in nitrous air, may be made to imbibe one-tenth part of its bulk; and afterwards the nitrous air may be expelled again by boiling, though not in the same quantity as it was absorbed; but for this purpose the water should be previously deprived of its air. Dr Priestley informs us, that having carefully pumped all the air out of a quantity of rain-water, letting it stand 24 hours in a good vacuum, and then impregnating it with nitrous air, he instantly expelled it again by boiling, when he obtained only about one quarter of it, though sufficiently pure, and without any mixture of fixed air. Water may also be deprived of the nitrous air it contains, though it does not freeze quite so readily when impregnated with this air as in its natural state.

Nitrous air is absorbed by strong oil of vitriol nearly in the same quantity as by water; the acid acquiring a purple colour, by reason of the phlogiston contained in the nitrous air. The strong nitrous acid absorbs it in great quantity; and becomes smoking, orange coloured, and afterwards green, on account of the phlogiston contained in it. Marine acid imbibles but a small quantity, and very slowly, acquiring at the same time a light-blue colour. Both nitrous air and common air phlogisticated by it are mellowed by agitation in nitrous acid.

Nitrous air is absorbed in considerable quantity by radical vinegar, and the concentrated vegetable acid.—Solution of green vitriol imbibes it in much greater quantity than water, and acquires a black colour; which, however, soon goes off by exposure to the common air. Its taste also becomes acid.—Very little is absorbed by caustic alkalis. Oil-olive slowly absorbs a considerable quantity, but oil of turpentine absorbs much more. By a little agitation, it will imbibe more than ten times its quantity of nitrous air; acquiring at the same time a yellowish or orange colour, and becoming a little glutinous. The part which is not absorbed appears to be converted into phlogisticated air.—Ether and spirit of wine absorb it very quickly, but no nitrous air is obtained by the application of heat after they have absorbed it. It is greatly diminished by oil of turpentine, liver of sulphur, and pyrophorous; all of which leave it in a phlogisticated state. It is also diminished and phlogisticated by being kept in a bladder, alternately exposed to moisture and dryness. Nitrous acid air has the same effect.

One of the most remarkable properties of nitrous air is its diminution with phlogisticated air; by phlogisticated air which means it becomes a tenth of the quantity of that kind of air contained in the atmosphere. With pure phlogisticated air, the diminution is almost to nothing, at the same time that some quantity of nitrous acid is reproduced by the decomposition of the nitrous air; but as our atmosphere is always mixed with a considerable quantity of phlogisticated air, on which nitrous
Nitrous air has no effect, the diminution in this case is never so considerable. Upon this principle the Euphrometer is constructed.

Another very remarkable property of nitrous air is its strong antifeptic power; in so much that animal matters may, by its means, be preserved for many months without corruption. This property, it was thought, might have been extremely useful on many occasions; but Dr Prieslely, after a number of experiments on the subject, concludes in the following manner. " Nitrous air will indeed preserve meat from putrefaction; but after long keeping, it becomes very offensive both to the nostrils and palate, though the smell is not altogether that of putrefaction; and indeed the substance containing quite firm, it could not be properly putrid. Having formerly experienced the remarkable antifeptic power of nitrous air, I proposed an attempt to preserve anatomical preparations, &c. by means of it; but Mr Key, who made the trial, found, that, after some months, various animal substances were shrivelled, and did not preserve their forms in this kind of air."

The specific gravity of nitrous air, as well as of other kinds, has been ascertained by Mr Kirwan. As it corrodes metals, he endeavoured to find its weight by comparing the lost weight of the metals involved with the materials which produce it. Thus he found, that 14 grains of the materials produced 38.74 inches of nitrous air; and, consequently, by proper calculation, that the specific gravity of nitrous air is to that of atmospheric air as 1955 to 1000. "If this air (says he) had been obtained over water, or in strong heat, its weight would probably have been very different; as it is liable to be mixed with phlogisticated air, nitrous vapour, and a variable quantity of water. Nitrous vapour would render it heavier, and phlogisticated air or water probably lighter."

With regard to the constituent principles, or elements of nitrous air, all those who look upon phlogiston to be a distinct substance, have believed that the former is a compound of nitrous acid and phlogiston. By the opposite party, it is supposed to be a substance entirely simple, and one of the constituent parts of the nitrous acid. This opinion seems in part now to be entertained by Dr Prieslely himself, notwithstanding his former sentiments on the subject. "I had no doubt on the subject (says he) until I read the work of Mr Metherie, who afferts, that nitrous air contains no proper nitrous acid, but only one of the elements of it; the other being phlogisticated air, which had before been confidered by Mr Lavoisier as the principle of all acidity. Among other observations in support of his affection, Mr Metherie has the following. 1. Nitrous air burnt together with inflammable air, produces no nitrous acid. 2. Though nitrous air be obtained from a solution of mercury in the nitrous acid, almost all the acid is found in the solution. 3. Nitrous air, absorbed by marine air, does not make aqua regia. 4. He is of opinion, that a small portion of the nitrous acid being decomposed, furnishes a pure air, so altered, that, uniting with inflammable air, it changes it into nitrous air."

"In reviewing the experiments I had formerly made on this kind of air, I could not recollect any of them in which the pure nitrous acid was produced, excepting that with phlogisticated air, besides the experiment in which it was decomposed by the electric spark; which furnishes a strong objection to this hypothesis." To ascertain the matter more fully, the following experiments were made.

"When nitrous air is decomposed by iron, or by a mixture of iron and sulphur, the water, over which the process is conducted, acquires no acidity; but I had supposed that all the acid was absorbed by the iron. Having by me a quantity of this iron which had been reduced to perfect rust in nitrous air, and which, I knew, must have imbibed more than its weight of the air, I thought that the acid might be obtained from it by distillation; but a quantity of this rust of iron, distilled in an earthen retort, yielded neither nitrous air nor nitrous acid, at least in any quantity that could favour the common hypothesis."

"I then endeavoured to decompose nitrous air by heating iron in it with a burning lens; and in this process I succeeded far beyond my expectation: for the air was perfectly diminished in quantity, while the iron became of a darker colour, was sometimes melted into balls, and gathered considerable weight, though it had no appearance of containing any nitrous acid."

In the first experiment, the original quantity of nitrous air was diminished to about one-third; and after this, it was increased. "The increase was found to arise from a production of inflammable and phlogisticated nitrous air."

The Doctor proceeded to try various other experiments on the decomposition of nitrous air, particularly that of burning Homberg's pyrophorus; but without any success, or obtaining the smallest particle of nitrous acid. His conclusions from the whole are the following.

"Water seems to be a necessary ingredient in nitrous as well as inflammable air; at least without a quantity of water, nitrous air cannot be formed. For example, copper will be dissolved in strong nitrous acid without producing any nitrous air, just as iron may be dissolved in concentrated vitriolic acid without producing inflammable air."

"That nothing is necessary to the formation of nitrous air besides phlogisticated nitrous acid and water, is evident from the production of it by the impregnation of pure water with phlogisticated nitrous vapour formed by the rapid solution of bismuth; an experiment which I mentioned before. However, to make it in a more unexceptionable manner, I interpolated a glass vessel between that in which the solution was made and that in which the water to be impregnated with the phlogisticated vapour was contained, that whatever was distilled over by the heat of the process might be prevented from reaching the water. In these circumstances, however, when nothing but the dry phlogisticated vapour could enter the water, it began to sparkle and yield nitrous air very copiously as soon as it had received a bluer tinge from the impregnation. Nitrous air is also produced by pouring a highly coloured or phlogisticated nitrous acid into pure water, in which no metal or earthy matter is in any way concerned."

"I have formerly observed, how readily nitrous air is diminished by taking the electric spark in it. This the electric experiment I have frequently repeated, in order more particularly..."
particularly to ascertain the quantity and quality of the residuum. In one experiment half an ounce of nitrous air was reduced, in less than half an hour, to one-quarter of its bulk. One-fourth of the residuum was still nitrous, and the rest phlogificated. Taking the electric spark in a quantity of nitrous air till it was diminished to one-third, the whole was completely phlogificated, not affecting common air at all, and extinguishing a candle. A white matter was formed with the mercury over which the spark was taken, which made the water admitted to it extremely turbid. In another process, the electric spark was taken in a quantity of nitrous air till it could no more be diminished, when it was reduced in bulk in the proportion of 10 to 24. Letting it stand all night upon the mercury, it was increased in the proportion of 11 to 24; seemingly by the acid uniting to the mercury and generating more nitrous air, since it had that smell. No water appeared after the process; and the water admitted to it acquired no acid taste, but an astringent one like that of water impregnated with nitrous air. There was a white powder formed, as in the former experiments. To try if it were possible to make water imbibe the acid from the nitrous air, the electric spark was taken in it, with a small quantity of water over the mercury. But even this water did not acquire any acid taste, but only an astringent one.

The Doctor concludes his experiments on this subject with a conjecture, that the phlogiston, and neither the heat nor light of the electric, contributes to the decomposition of nitrous air. As his final conclusions on the matter, however, are merely conjecture, without any certain experiments to confirm them, we shall here refer the reader to his Section on Theory, at the end of his sixth volume of experiments, &c.

Section X. Phlogificated Nitrous Air.

This species differs from common nitrous air in being able to support flame, though it still continues fatal to animal life. Common nitrous air may be converted into the phlogificated kind by particular processes; though, when zinc is dissolved in the nitrous acid, if the air be taken at different times, that which comes about the middle, or rather the latter end of the process, will be of this kind; in which it not only supports the burning of a candle, but the flame is enlarged (sometimes to four or five times its original bulk) by the addition of a weaker and bluish flame round the former; and this burning is sometimes accompanied with a crackling noise, as if the candle was burning in dephtogificated air. It may also be obtained in some part of the process of procuring nitrous air from iron, though with this metal the success is uncertain; but it yields a considerable quantity of it. By expelling iron to nitrous air, it may be so far dephtogificated as to admit a candle to burn in it. Dr Priestley filled an eight-ounce phial with nails, and then with mercury; and displacing the mercury with nitrous air, left the phial inverted in a quantity of the same fluid. Two months after, the nitrous air was found to be changed in such a manner as to admit a candle to burn in it with its natural flame; and by continuing still longer in contact with the iron, a candle would burn in it with an enlarged flame. These changes, however, are very irregular, so that they seldom produce the like Dephtogificated effects with the regularity one might expect. Dr. Priestley once found, that by the contact of iron in quicksilver, it was so changed as to be fired with an explosion like a weak inflammable air; whilst another quantity of nitrous air, which had been treated in like manner for about the same length of time, only admitted a candle to burn in it with an enlarged flame.

In that section of his last volume in which the Doctor treats of this kind of air, he observes, that water is not parts absolutely necessary to its composition, or rather to the decomposition of the common nitrous air by iron. He had decomposed it before, either by previously filling the vessels that were to contain the nitrous air with water or with mercury; though it had always required a much longer time when the latter was made use of. The reason of its being formed at all in this last way, was a small quantity of moisture adhering to the inside of the vessel containing the mercury.

To try the influence of water in this case, he now Effects of procured a number of very clean small needles; and water on having made a phial, and likewise a proper quantity of mercury, quite clean and dry, he put the needles into the phial, and, filling it up with mercury, introduced the nitrous air: but it continued in this way for six or eight months without the smallest alteration. Introducing a few drops of water, a diminution of about one-third of the air took place, and the remainder appeared to be phlogificated. On the 26th of May 1782, he examined a quantity of nitrous air, which had been confined with iron-flavings from the 27th of August preceding, when he found one-half of it absorbed; the remainder supported the flame of a candle better than common air; though a mouse died in it; and yet this air had continued several months in the same state with regard to quantity, nor was it at all probable that its quality would have been altered by any length of time.

Though this kind of air is produced by the contact of iron and nitrous air, the Doctor has never been able to ascertain the quantity of nitrous air which a given quantity of iron can decompose; and though iron soon becomes so much affected by this process that it crumbles into powder, it still seems equally capable of decomposing a fresh quantity. Having made a comparative experiment, by putting together one quantity of nitrous air with fresh iron and another with rust, he found that in both the air was diminished to about one-third, and a candle burned in both equally well; but neither of them had the properties of fresh nitrous air in any degree.

As the process for obtaining dephtogificated nitrous air by means of iron is very tedious, the Doctor endeavoured to find another which might be attended with less inconvenience. This he accomplished by dissolving turnings of iron in a dilute solution of copper in nitrous acid (the same that remains after the production of nitrous air), mixing it again with an equal quantity of water. Without this precaution, he tells us, that though the iron will at first be acted upon very slowly, yet the mixture will at length grow so hot as actually to boil, and the process will be exceedingly troublesome; however it will be necessary previous to any attempt to dissolve the iron, to heat the solution of copper, in order to expel all the nitrous air and superfluos
AEROLOGY.

§ 1. Vitriolic acid Air.—This is always a combination of vitriolic acid with phlogiston, and consequently may be procured from any mixture of that acid in its highly-concentrated state with phlogistic matters. Hence it is obtained from all the metals, gold and platinum excepted, by boiling them with vitriolic acid. It is also procurable from the same acid rendered black by any phlogistic matter. No greater heat is required to expel this kind of air than that produced by the flame of a candle. It is the heaviest of all aerial fluids, next to fluor acid, being to common air as $2265 : 1000$. Dr Priestley informs us, that a quantity of vitriolic acid thus impregnated with phlogiston, will yield many times more air than an equal quantity of the strongest spirit of salt. —When the vitriolic acid is produced in great plenty, the top of the phial in which it is generated is commonly filled with white vapours. The air has also the same appearance as it is transmitted through the glass tube; and it is sometimes discoverable in the Nitrous Air.

Diphlogisticated Nitrous Air. Without this precaution a quantity of common nitrous air will be produced. Diphlogisticated nitrous air is absorbed by water almost as readily as fixed air, and in considerable quantity; the liquid taking up about one-half its bulk of air. After being thus saturated, the whole quantity of diphlogisticated nitrous air may be expelled pure by heat, and is easily received in vessels containing mercury. It was likewise observed, that as this kind of air much resembles fixed air in its properties of being imbibed by water, and expelled again by heat, it resembles it also in this further property, that all the air which has been actually incorporated with the water will not be imbibed by water again. But the proportion of this part is three or four times greater than the corresponding part of fixed air; it is also considerably more phlogisticated. Water impregnated with it very soon parts with it again on being exposed to the atmosphere. —It discovers not the smallest trace of containing either acid or alkali. Its specific gravity is less than that of common air. On heating red precipitate in this kind of air, pure phlogisticated air was produced without affecting, or being affected by, the nitrous air. Repeating the experiment with malleable iron, the quantity of it was enlarged, and the whole phlogisticated, without any mixture of fixed air. By heating bits of clean crucibles or retorts in this kind of air, it seemed to approach in quality to common atmospheric air; and the effects were always found to be the more considerable the longer the process was continued. On attempting, however, to determine whether this change in the constitution of diphlogisticated nitrous air was occasioned by means of heat or light, he heated it in earthen tubes; but, found, that though these were glazed both on the outside and inside, and seemed perfectly air-tight both before and after the experiment, the air had escaped. By the electric spark it was rendered wholly immiscible with water, and brought to the standard of 1.45; so that the Doctor had no doubt of its being resipirable. Yet this kind of air, though admitted a candle in it, will not kindle pyrophorus, though the nitrous air from which it is produced would instantly set it on fire.

§ 2. Of Nitrous Acid Air.—This is the pure nitrous acid obtained by itself, without any addition of phlogiston. It is procured by heating the strong spirit of nitre in a phial, and then receiving the vapour in glass vials filled with quicksilver. It is, however, extremely difficult, or rather impossible, to preserve it for a length of time by means of any fluid hitherto known. Water absorbs it immediately, and quicksilver is corroded, and prefered duces nitrous air. "But (says Dr Priestley) tho' the acid vapour very soon unites with the quicksilver, yet of all fluids."

The most remarkable property of this vapour is, that its colour may be made more or less intense by the red colour more circumstance of heat. It may be confined in being glass vials with ground-hoppers, or in tubes hermetically sealed, and thus exposed to the action of heat: in which case it will be found, that the colour of the vapour becomes considerably more intense in proportion as the glass vial containing it is more or less heated; and that, on the contrary, the intensity of the colour diminishing as it is cooled. "It seems probable (says Dr Priestley), that if this vapour was not confined, but had room to expand itself, it would become colourless with heat. This at least is the case when it is combined with water. The phenomena I refer to are very common in the process for making diphlogisticated air, in which I first observed them. But the same things are observable in the process for producing any other kind of air in which much spirit of nitre is made use of: and likewise constantly in the common process for making spirit of nitre itself. It is, that when the heat is moderate, the vapour within the
AEROLOGY.

§ 4. Of Fluor Acid Air.—The discovery of fluor acid air was made by Mr Scheele, who obtained it by distilling the spar called fluor with vitriolic acid. Dr Priestley, who made several experiments upon the subject, was of opinion that this new acid was only the Dysfunction from vitriolic disguised by its connection with the fluor. He even supposed that he had produced it by pouring vitriolic acid on other phosphoric spars: both these opinions, however, he has now retracted, and believes the fluor acid to be one of a peculiar kind. Its most remarkable property is the great attraction it has for fleshy earth, so that it even corrodes and makes holes in the retorts in which it is distilled. See Chemistry, \( \text{Index} \).

§ 5. Of the Vegetable and other Acid Air.—By means of heat alone, the concentrated vegetable acid emits a permanently elastic and aerial fluid. This has the properties of the acid of vinegar; but, like it, is weaker than the rest of the mineral acids, though it agrees with them in its general characters. Water immingles it as readily as any of the other acid airs; olive, olive readily absorbs it, and in considerable quantity, losing at the same time its yellowish colour, and becoming quite transparent. Common air is phlogisitcated by it, as it is by the liquid vegetable acid. As the vegetable acid, however, from which this air was obtained, was distilled by oil of vitriol, the Doctor suspected that what he had examined might derive most of its properties from the oil of vitriol, and rather be vitriolic than vegetable acid air.

An acid air, somewhat different from any hitherto Air from descibed, was obtained by Dr Priestley from the solution of pour ariling on distilling to dryness a solution of gold oxide in marine acid impregnated with nitrous acid vapour, which makes the best kind of aqua regia. "The produce (says he) was an acid air of a very peculiar kind, partaking both of the nature of the nitrous and marine acids; but more of the latter than of the former, as it extinguished a candle; but it was both extinguished and lighted again with a most beautiful deep blue flame. A candle dipped into the same jar with this kind of air went out more than 20 times successively, making a very pleasing experiment. The quantity of this acid air is very great; and the residuum I have sometimes found to be phlogisitcated, sometimes phlogisitcated, and at other times nitrous air."

Sect. XII. Of Hepatic Air.

This species of air, first particularly taken notice of by Mr Bergman, who obtained it from an ore of zinc as to sink in water; and its smell is in great measure altered. Ether absorbs it very fast, and has its colour altered by the impregnation, becoming first turbid, then yellow, and at last brown. The air over the ether is strongly inflammable. A small bit of phlogorius smoked and gave light in this acid air; and the elastic into fluid was but little diminished in twelve hours. On the admission of water, about four-fifths of the gas were absorbed, and the rest was inflammable. This change was also effected by a great number of other substances: some of which, however, require a considerable time to produce their effect; such as cruts of bread not burned, dry wood, dry flesh, roasted pieces of beef, ivory, and even flints. See Chemistry, \( \text{Index} \).
Atmospheric Air.

Produced from an ounce of zinc.

The two component parts of our atmosphere, viz., dephlogisticated and phlogisticated air, have been so fully treated of under their respective sections, that little remains to be said in this place, excepting to determine the proportion in which they are usually met with in the common air. The only regular fact of experiments which have been made on this subject are those of M. Scheele. He constructed an eudiometer, consisting of a glass receiver, which could contain 34 ounces of water, and a glass cup containing a mixture of one pound of iron-filings, and an equal weight of flowers of sulphur moistened; which cup, standing upon a glass stopper, was inserted in the former receiver, which, when this was in it, could contain 33 ounces of water. To the outside of the glass tube or receiver, was affixed a flip of paper, to the height of a third of the tube, containing 11 divisions, each corresponding to one ounce of water. This paper was varnished over with oil varnish, to prevent its being spoilt by water. The whole then was placed in water, which gradually rose as the air was diminished. This mixture would serve four times before the power of diminishing air was lost. He carefully compared the height of the air therein with the barometer and thermometer, both before and after the experiment; in eight hours the experiment was completed. With this instrument he examined the goodness of the common air in Stockholm even during the winter; and found the diminution never to exceed \( \frac{1}{4} \), nor to fall short of \( \frac{1}{5} \); so that upon a medium it may be estimated at \( \frac{1}{4} \). During the months of January and February it was \( \frac{1}{4} \). The 23d of March it was \( \frac{1}{3} \), though the Atmospheric air was cold increased, and the barometer stood higher than usual before. The 19 of April in the year \( 11 \), the barometer and thermometer did not vary, and stood till the 21st. In May and June it stood between \( \frac{1}{2} \) and \( \frac{1}{3} \). The 26th of July it stood at \( \frac{1}{3} \), from the 26th to the 13th of September at \( \frac{1}{4} \), the 15th of October at \( \frac{1}{5} \), during a high flood, but after it fell between \( \frac{1}{3} \) and \( \frac{1}{4} \), till the 4th of November, when it fell to \( \frac{1}{5} \) and continued between \( \frac{1}{5} \) and \( \frac{1}{4} \), to the 20th, when it fell to \( \frac{1}{6} \) and from thence to the 31st it fell between \( \frac{1}{6} \) and \( \frac{1}{5} \).

As it has already been shown that the pure dephlogisticated part of the atmosphere is entirely contained by phlogistic procedures, such as that of fermenting brandy and iron-filings, this eudiometer must be considered as an exact test of the proportion of dephlogisticated air contained in the atmosphere. The small variation in the quantity shows that the processes in nature which destroy this air, are nearly balanced by those which produce it; though, at certain times, fermentation, by heat, and by acids, produce at all seasons of the year in a proportion nearly equal; nor is it left surprising that two fluids of unequal specific gravity should remain incorporated together without any tendency to separate, which it is certain they never do, either in the atmosphere itself, or when confined in vessels in any quantity whatever.—As phlogisticated air is somewhat lighter than dephlogisticated, it might be supposed that the former would occupy the higher regions of the atmosphere in such a manner as to render them considerably more unhealthy than the lower parts; but this seems not to be the case: On the contrary, it appears from experiments with the eudiometer, that the upper parts of the air contain a greater proportion of dephlogisticated air than those near the earth. See EUDIOMETER.

Proportion of the two ingredients of which it is composed.

Sec. XIII. Of Atmospheric Air.

Sect. XIV. Of the artificial Production of Airs of different Kinds.

§ 1. Fixed Air, or Aerial Acid. The artificial methods of producing this are principally three, viz., by fermentation, by heat, and by acids.

(1) By Fermentation. When vegetable or animal substances, especially the former, are fermented, they yield a great quantity of fixed air. In breweries, on the surface of the fermenting liquor, there is always a stratum of fixed air reaching as high as the edge of the vats; so that if these vessels are deep, and the fermenting liquor much below their edges, the abovementioned stratum may be some feet in thickness. The same phenomenon is observable in the fermentation of wines in general; and it is owing to the production and elasticity of fixed air, that fermenting liquors, which put into close vessels, often burst them with great violence. The cause is the same whatever substance it is that undergoes the vinous fermentation, though the quantity of fixed air produced is not the same in all substances, nor even in the same substance at different times. From 42 cubic inches of beer Dr. Hales obtained 58 cubic inches of air in 13 days. From a quantity of sugar...
undergoing the vinous fermentation, Mr Cavendish obtained so much fixed air, that out of 100 parts of the former 57 appeared to have been volatilized and converted into fixed air.

But though a vast quantity of fixed air escapes during this process of fermentation, a very considerable portion still remains united with the fermented liquor, and to this it owes all its briskness and agreeable pungent acidulous taste; for when the fixed air is totally evaporated, the liquor becomes entirely vivid and flat. Hence also we are furnished with a method of restoring the briskness to these liquors after they have lost it in consequence of being exposed to the atmosphere, viz. by impragnating them again with fixed air, either naturally or artificially produced.

Dr Priestley has made several experiments in order to determine the quantity of fixed air contained in several sorts of wine. His method was to take a glass phial (fitted with a ground stopple and tube), capable of containing 1 ounce-measure. This he filled with wine, plunged it into a proper temperature, and then put over the fire, and the water, into the quicksilver, into the top, pulling out part of the metal and taking its place. The result of his experiments was as follows:

During the acetous fermentation also, liquors emit a vapour, great part of which is fixed air, though the nature of its other component parts has not yet been thoroughly ascertained.

Fixed air is likewise produced, though in no great quantity, by putrefaction. In this case, however, a great part of the elastic fluid consists of inflammable and phlogificated air, and the fixed air itself seems to be intimately connected with a putrid offensive effluvium. It seemed to Dr Priestley to "depend in some measure upon the time and other circumstances in the distillation of animal or vegetable substances, whether they yield the proper putrid effluvium, or fixed or inflammable air."

The elastic fluid produced by putrefying vegetables, when kept in a moderate degree of heat, is almost all fixed air; while that from animal substances contains several times more inflammable than fixed air. Vegetable substances yield almost all the permanently elastic fluid in a few days, but animal bodies continue to emit it for several weeks. When the elastic fluid yielded by animal substances is absorbed by water, and that water boiled, the fixed air may then be obtained without any mixture of the putrid effluvium. It is also to be observed, that the quantity of elastic fluid producible from animal substances is various according to the nature of the parts of the animal employed. Thus the muscular parts will yield less elastic fluid, and also

lefs mixed with any putrid or offensive effluvium, than a whole animal, or than the liver, &c. The proportion of inflammable and of fixed air is also various, according to the various parts employed.

(2.) By heat. In every combustion, except that of sulphur or of metals, a quantity of fixed air is generated. This may be observed by fixing a lighted candle in an inverted receiver over a basin of lime-water, for a precipitation of the lime will presently ensue; and the same precipitation is one of the characteristics of fixed air will always ensue, whether a candle, a burning piece of wood, or, in short, any other combustible substance, except sulphur or metals, be made use of.

During this production or extraction of fixed from atmospheric air, the latter is commonly supposed to be considerably diminished, though M. Lavoisier and Mr Scheele have now rendered that opinion doubtful. If a piece of charcoal be burned by throwing the focus of a lens upon it when contained in a glass-receiver inverted in water, after the apparatus is cooled, the water will have mounted a small way into the receiver. The diminution, however, is limited, and depends on several circumstances. Dr Hales has observed, that, in equal receivers, the air suffers a greater diminution by burning larger candles than small ones; and likewise, that, when equal candles are made use of, the diminution is greater in small than in large receivers.

The cause of this phenomenon probably is, that the air contained in the receiver cannot all come into contact with the flame of the candle; whence, as soon as the air which is nearest the flame becomes contaminated, the candle is extinguished. Thus the author of a Concise Treatise on the Various kinds of Permanently Elastic fluids, has diminished the air of an inverted receiver one sixth part, by moving the candle whilst it burned through the different parts of the vessel, so that the flame was brought into contact with a greater quantity of the confined air than if it had remained in one situation all the time. It became extinct, Dr Mayow observed, that by the burning of a candle the air was diminished of one thirtieth only; Dr Hales found it to be diminished of one twenty-fifth part; and Dr Priestley found it to be diminished of one fifteenth or sixteenth. Mr Cavendish observed, that air suffered a diminution of one-tenth of the whole quantity, by passing through an iron-tube filled with red-hot powder of charcoal. A candle, or any other combustible body, will cease to burn by itself, and consequently to contaminate a quantity of confined air much sooner than it is, in some manner, forced to burn by the external application of heat. "The focus of a burning mirror," says Dr Priestley, "thrown for a sufficient time either upon brimstone or wood, after it has ceased to burn of its own accord, and has become charcoal, will have a much greater effect of the same kind, diminishing the air to its utmost extent, and making it thoroughly noxious." The combustion of the phosphorus of urine diminishes air in a great degree. Mr Lavoisier has observed, that by the combustion of phosphorus, air may be diminished of about one-fifth or one-sixth. This accurate philosopher has also observed, that the acid of phosporus thus formed, acquires the weight lost by the diminished air; finding that about three inches of air were absorbed by every
AEROLOGY.

Of Artificial Airs.

...one grain of phosphorus, when the experiment was tried with a receiver inverted in water, upon the surface of which a small quantity of oil had been introduced; but when the receiver was inverted in quicksilver, the absorption was constantly between two and three grains for each grain. Mr Capello mentions having often repeated the experiment of burning phosphorus in a glass tube inverted in water, by applying the closed part of the tube, wherein the phosphorus was contained, to a pretty strong fire, when he always observed that the utmost diminution of the inclosed air effected by this means was full one-fifth.

Dr Hales remarked, that after the extinction of candles in a receiver, the air continued to diminish for several days after. This may be owing to the gradual absorption of part of it by the water; it having been remarked by Dr Priestley, "that this diminution of air by burning is not always immediately apparent, till the air has passed several times through water; and that when the experiment was made with vessels flanding in quicksilver instead of water, the diminution was general, inconvenient to the air had passed through water."

In these experiments of burning combustible bodies in a quantity of air, and measuring the diminution, we should always remark two cauages of mistake, viz. the absorption of air by the coaly residuum of the burnt matter, which sometimes is very considerable, or by the fluid in which the receiver is inverted, and the production of elastic fluid from the burning substances; thus gunpowder generates a great quantity of elastic fluid when inflamed, &c.

Even the electric spark separates fixed air from common atmospheric air; for when a number of these sparks are taken in a small quantity of common air over lime-water, a diminution will take place, the lime will be precipitated, and if we put a blue vegetable juice instead of the lime-water, it will be turned red by the acidity of the fixed air deposited upon it. Dr Priestley having cemented a wire into one end of a glass tube, the diameter of which was about one-tenth of an inch, and having fixed a brass ball to that extremity of the wire which was out of the tube, filled the lower part of it with the juice of turpentine or archil, so that a quantity of common air was contained in the tube between the extremity of the wire and the surface of the liquor. Then taking the electric spark between the said wire and liquor for about one minute, the upper part of the liquor began to look red, and in about two minutes it was manifestly so. The air at the same time, was diminished in proportion as the liquor became red; but when the diminution arrived to be one-fifth of the quantity of the air contained, then a longer electrification produced no sensible effect. "To determine," says the doctor, "whether the cause of the change of colour was in the air or in the elastic matter, I expanded the air which had been diminished in the tube by means of an air-pump. till it expelled all the liquor, and admitted fresh blue liquor in its place; but after that, electricity produced no sensible effect, either on the air or on the liquor; so that it was evident that the elastic matter had decomposed the air, and had made it deposit something that was of an acid nature."

The calculation of metals, as already observed, phlogisticates, and consequently diminishes common air; but does not produce any fixed air, since the lime-water, over which the calcination is made, does not become turbid; and when metallic calxes are exposed to a sufficiently strong heat, they in general yield some fixed air, so that it seems that the fixed air produced in the calcination of metals is absorbed by the calx. Some fixed air may be obtained from red lead, by no greater degree of heat than that of the flame of a candle applied to the phial that contains it.

The calcareous earths, which, when acted on by acids, yield a vast quantity of fixed air, produce a very small quantity of it when exposed to a strong heat by themselves, in a proper vessel, even when exposed to the focus of a lens. Dr Priestley, in his experiments relating to the production of dephlogisticated air from various substances, when moistened with nitrous acid, and afterwards exposed to a sufficient degree of heat, generally found that some fixed air was produced together with the dephlogisticated air; but often obtained fixed air only, without any dephlogisticated air being mixed with it, or fixed and nitrous air together. From half an ounce of rust of iron, moistened with spirit of nitre, and dried, he obtained about a quart of elastic fluid, about one-third of which was fixed and the rest nitrous air. From ashes of pit-coal, treated in the same manner, he obtained nearly the like result. But in those experiments, the Doctor mostly used a gun-barrel, into which he introduced the substances to be tried; so that it is very probable, as he judiciously observes, that the iron might have contributed to the formation of the fixed air. In fact, when he tried substances of the same sort, first in a gun-barrel and then in glass vessels, he obtained much more fixed air in the former than in the latter case. One of these experiments he made with tobacco-pipe clay, which, after being moistened with spirit of nitre, was when dry exposed to the fire in a gun-barrel, and yielded some elastic fluid, which appeared to be wholly fixed air; but repeating the experiment in a glass phial with a ground stopple, and taking the produced elastic fluid at eight different times, found that on the beginning some fixed air was produced, but afterwards the produce was dephlogisticated air. He made a similar experiment with flints carefully calcined in clove vessels, and obtained a similar result.

Most minerals contain fixed air, which may be extracted to a certain degree by means of heat. Most minerals, Krenger, distilling a greenish flufible spar, which was raluminous in the dark, obtained from it some permanently elastic fluid, which, like fixed air, crystallized a solution of fixed alkali. Mr Fontana in his analysis of the malachite, finds that that mineral contains a vast quantity of fixed air, as pure as that which is extracted from chalk by means of vitriolic acid.

From almost every metallic ore and earthy mineral some fixed air may be obtained, as well as from chalk, lime-dense, marble, marine shells, fixed and volatile alkali, and from magnesia alba, by means of a violent fire, or of acids.

In Mr Boyle’s, Dr Boerhaave’s and Dr Hales’s works, and in other books, the quantities of elastic fluid generated in various processes, and by divers substances, are mentioned with distinction, but as those writers are not acquainted with the characteristic properties of fixed air, we do not know whether the elastic fluid mentioned by them was pure fixed air or not.
From animal substances, mixed with spirit of nitre, and sometimes heated a little, in order to facilitate the production of elastic fluid, Dr Priestley obtained, in general, fixed air; but whereas the fixed air produced by a similar process with vegetable substances is mostly mixed with nitrous air, this is mixed with an elastic fluid, which is seldom nitrous in a very slight degree, but is often phlogisticated air, viz. in such a state as extinguishes a candle, does not dim nitrous common air, nor is itself diminished by nitrous air. Towards the end of the process, the Doctor remarks, that when by means of a strong heat, the produce of air is very rapid, and the air full of clouds, it is, like air, produced from vegetable substances in the same circumstances, slightly inflammable; burning with a lambent, greenish, or bluish flame.

(3.) By acids. Calcareous substances in general produce abundance of fixed air when acted upon by any acid, only the strongest acids will expel from them more fixed air than the weakest; and it happens to be particularly advantageous for those who want to produce a great quantity of fixed air, that the vitriolic acid is both the cheapest and strongest, and, upon the whole, the fittest for this purpose. The phenomena attending the production of fixed air from calcareous substances, &c. are themselves very remarkable, and furnish the subject of much speculation in philosophy.

—The principal facts are the following. 1. When calcareous earths, alkalis, and magnetia, in their usual state, are mixed with acids, they cause an effervescence; and consequently the production of a permanently elastic fluid, namely, fixed air. 2. These substances retain the fixed air very obstinately; so that a strong fire is necessary to expel it from magnesia, and the strongest is not sufficient to expel it entirely from fixed alkalis, and especially from calcareous earths (a). When these substances are treated with acids, they yield the fixed air, because they have a stronger attraction to those acids than the fixed air.

3. The calcareous earths which are insoluble in water, when deprived of the fixed air become soluble in it. Thus lime-stone is not soluble in water, but lime (viz. lime-stone deprived of its fixed air) is soluble in water. And if those substances, deprived of their fixed air, are put in a situation proper to recover their lost fixed air, they lose the property of being soluble in water. Thus, when lime-water is exposed to fixed air, the lime absorbs the fixed air; and, losing at the same time its property of being soluble in water, is precipitated from it in the state it was before calcination, viz. of a calcareous earth in soluble in water, and capable of effervescing with acids. 4. Alkalis, both fixed and volatile, when deprived of their fixed air, become more caustic, and more powerful solvents, incapable of crystallisation, and of effervescing with acids. But if those alkalis, and also earths rendered more caustic, their fixed air be restored, they acquire at once all the properties they had before they were deprived of the fixed air, viz. they become more mild, effervescence with acids, recover their weight, &c.

Those properties of calcareous earths and alkalis were ascertained by the learned Dr Black, who performed a variety of decisive and well-contrived experiments, upon which he formed a just theory, viz. that the causticity, sharpness, solubility, &c. of those substances, was owing to the fixed air being expelled from them; and that when they were combined with a proper quantity of fixed air, they were mild, &c. The Doctor gives the epithet of nitile to those substances when they are combined with air, and of calcarie when deprived of it; as calcareous earth, calcatic fixed alkali, &c. Among the other experiments, he connected two phials by means of a bent tube; in one of which he put some caustic spirit of Paris ammonia; and in the other, some mild alkali, or mild calcareous earth; then pouring, through a hole made in the side of the latter phial, some acid upon the mild alkali, so as to produce some fixed air, which, passing through the tube into the other phial, combined with the spirit of Paris ammonia, and rendered it mild.

Early methods of obtaining Fixed Air for occasional Experiments, &c.

1. By Fermentation. Mix together equal parts of brown sugar and good yeast of beer, to which add about twice the bulk of water. This mixture, being put into a phial, to which a bent tube with a cork may be adapted, will yield a considerable quantity of fixed air, which may be received into a phial filled with quicksilver, or water, as in the following process.

(a) Chalk, lime-stone, &c. after being kept in a very strong fire for many hours, if they are put into acids, yield a considerable quantity of fixed air; which shows that the purest quick-lime contains some fixed air.
fing through the water, ascend to the top of the inverted bottle. In proportion as the elasic fluid fills the bottle \( K \), the water gradually descends, and at last is quite expelled from it; the bottle \( K \) then is filled with fixed air, and being corked under water, may be removed from the basin, and kept for use. Another bottle may then be filled with water, and may be inverted over the extremity of the bent tube in the place of \( K \), which other bottle may be filled in a similar manner, and so on till the mixture in \( F \) has finallized to yield any fixed air.

If one of these bottles filled with fixed air be un­ corked, and, holding it with the mouth upwards, a lighted wax taper, bent like \( L \), or a small piece of it affixed to the extremity of a wire, be immediately let down in it, the flame will be instantly extinguished. The same thing will happen if a lighted piece of wood is let down in it.

Take a clean bowl, and putting the mouth of a bottle, filled with fixed air, in it, uncook it, and keep it in that situation for about a minute. The fixed air being specifically heavier than common air, will come out of the bottle, and will remain at the bottom of the bowl, whilst common air enters into the bottle; which bottle may now be removed; and, in order to show the real existence of the fixed air, which will immediately show its being heavier than common air, put a lighted wax-taper into the bowl, pretty near its bottom, which taper will be extinguished immediately. The air in this experiment must be agitated as little as it is possible. That the flame of the wax taper was really ex­ tinguished by the fixed air, may be easily proved in the following manner:— Blow once or twice into the bowl, by which means the fixed air will be expelled from it; and then, on letting down a lighted wax-taper in it as before, it will be found that it is no longer extinguished, but will burn very well, the bowl being now filled with common air. This experiment never fails of sur­ prising the speculators, as it clearly exhibits two remark­ able properties of a fluid, which they can neither see nor distinguish by the feeling.

When the bottle \( K \) is about half filled with fixed air, put a mark with a bit of soft wax on the outside of it, just coinciding with the level of the water in it, and immediately after shake the bottle; but taking care that its mouth be not lifted above the surface of the water in the basin. After having shaken it for about a minute, on intermittently the agitation, it will be found that the water is above the mark; which shows that some of the fixed air has been absorbed by it. Let this abstraction be carried on as far as possible, by agitating the bottle repeatedly, and allowing time to let more fixed air be produced and enter into the bottle in proportion as the water absorbs it. Then apply the hand, or a finger, to the mouth of the bottle whilst under water; bring the bottle out, and turn it with the mouth upwards. The water then will be found to have acquired a pleasan acidulous taste. The water thus impregnated with fixed air changes the blue infusion of some vegetable substances into red; so that if a few drops of heliotrope be mixed with it, or indeed if it is simply exposed to fixed air, the liquor acquires a reddish appearance. It also corrodes iron, and some other metals, much more easily than common water.

But the greatest and most useful property of this acidulated water, or water impregnated with fixed air, is its being a powerful antiseptic. As the most used mineral waters are medicinal principally on ac­ count of their being impregnated with fixed air, besides which they generally contain some small portion of metal or salt dissolved; they may be imitated by impreg­ nating water with fixed air and then adding that quantity of salt or of metal, that by analysis the original mineral waters are found to contain.

It is for this great property of hindering putrefaction, that fixed air by itself, or incorporated with various fluids, especially with water, and that vegetables, sugar, and other substances which abound with fixed air, are very powerful remedies in putrid diseases. Sir John Pringle supposes, with great probability, that the frequent use of sugar and vegetables, which at this time make up a considerable part of the diet of the European nations, prevents these putrid diseases and plagues which formerly were rather frequent.—Dr Macbride, showing experimentally that fixed air is discharged by such substances as form our common food, ascribes the preservation of the body from putre­ faction in great measure to the fixed air, which in the ordinary process of digestion is disengaged from the aliment, and incorporates with the fluids of the body.

From the same property it may be also usefully ap­ plied to several economical purposes. Mr Henry found, that fixed air can preserve fruit for a consider­ able time. He tried a bunch of Italian grapes, which being suspended in the middle part of Dr Nooth’s apparatus, and being supplied with plentiful streams of fixed air every day, was prepared without any signs of decay for about one month longer than a similar bunch suspended in a decanter containing common air. Straw­ berries and cherries he also found to be preserved without decay some days longer in fixed than in common air. Indeed fixed air preserves not only fruit, but refits putrefaction in general. Dr Macbride, in his elegant essays on Medical and Philosophical Subjects, has published various experiments which demon­ strate this property of fixed air. He found, that not only good meat was preserved incorrupt for a con­ siderable time, when exposed to fixed air; but that the putrefaction of substances actually putrid was im­ peded by this means, and even that these substances were restored from the putrefaction to a found state. That putrefaction was checked by fermentation, was sub­ duced by Sir John Pringle; and Dr Macbride ob­ served, that this effect was owing to the fixed air pro­ duced in the act of fermentation. But it must be ob­ served, that when the found, or even putrid sub­ stances, expose a very great surface to the fixed air, as is the case with milk, bile, and other fluids impreg­ nated with fixed air, and also with small bits of meat, then they are preserved for a considerable time: but large pieces of solid animal substances, as for instance roundish pieces of flesh of about half a pound weight, do not seem to remain incorrupt much longer in fixed than in common air; at least the difference is inconsiderable. Sir William Lee, baronet, in two of his letters to Dr Priestley, informs him of his having found, that flesh-meat, even in the hot season, could be pre­ served wholesome for several days, by only walking it two or three times a-day in water impregnated with fixed
AEROLOGY.

Sect. XIV.

Of Artificial Airs.

fixed air. "We have been enabled," says he, "to preferve meat as perfectly sweet and good to the extent of ten days, as at the first killing; and there seems no doubt it might be preferred much longer." He has even recovered some meat that had begun to change. This useful discovery, Sir William Jolly observes, may be very beneficial to the public, espe- cially to butchers. "Particularly a butcher," says he, "who deals pretty largely, affures me he found the greatest success from it, and only objects that the veal was a little discoloured though kept perfectly sweet."

Fixed air, as it combines with water, fo it may be combined with other liquors. Beer, wine, and other fermented liquors, may be impregnated with fixed air, and by this means their flavour may be restored, when they are become vapid, or as it is commonly said, dead. The acridulous tafte communicated by the impregnation of fixed air, cannot be discovered in beer, wines, and, in short, in fuch liquors which have much tafte of their own. Milk acquires an acridulous tafte by being impregnated with fixed air, and is thereby preserved incorrupt for fome days; which affords a very easy expedient of preferving milk in thofe places where it cannot be had new often.

§ 2. To produce inflammable air.—The procefs for making this fort of gas is the fame as that for making fixed air: one of the materials only must be different, viz. iron-filings, or grofsly powdered zinc, must be used infted of chalk; to which fhalings some oil of vitriol and water muft be added, in the fame proportion as in the fixed air, or rather a little more of oil of vitriol.

N. B. Instead of the filings of iron, fmal nails, or small bits of iron-wire, answer equally well. The inflammable elastic fluid produced by this mixture has a displeasing fmall, even when mixed with a very large quantity of common air: fo that if any coniderable quantity of it comes out of the bottle, before the cork with the bent tube be applied to it, &c. its fmall may be perceived all over the room in which the experiment is made, but this fmall is not particularly offensive.

When a bottle has been filled with this elatic fluid, flop the mouth of it with your thumb, or any flopper, and taking it out of the baflon, bring it near the flame of a candle; and when the mouth of the bottle is very near it, remove the flopper, and the elatic fluid contained in the bottle will be immediately inflamed; and if the capacity of the bottle is nearly equal to four ounce-meafures, it will continue burning quietly for about half a minute, the flame gradually decending lower and lower, as far as about the middle of the bottle, in proportion as the inflammable gas is consumed.

In this experiment we fee, that inflammable air follows the general rule of all other combustible substances, namely, that of burning only when in contact with common air: thus the flame of this gas, whilst burning, is obfervable only on that face of it which is contiguous to the common air; fo that if the bottle be closed, the flame is put out immediately, because the air is intercepted from it. But if the inflammable air were put in fuch a situation as to expose a very great surface to the common air, it is plain, that by this means its combustion would be accelerated, fo as to let it burn infinitely, and go off with an explosion, caufed by the sudden rarefaction of the air. In fact, this effect may be easily obferved in the following maner: When the bottle is to be inverted into the baflon, in order to let it be filled with the inflammable gas, instead of filling it entirely with water, let half of it remain filled with common air; then invert it, and let the other half, which is now filled with water, be filled with inflammable air after the usual maner; and when the bottle is full, remove it in the manner shewn above, and approach it to the flame of the candle, by which means the inflammable air takes fire; but now it explodes all at once with a large flame and a confiderable report, sometimes breaking the bottle in which it is contained. In this cafe, the bottle being filled with equal parts of inflammable and common air, thefe two elatic fluids were mixed together, fo that almoft every particle of the one touched every particle of the other, and hence the sudden combustion was occafioned. The force of this explosion is fo very confiderable, that fome piitols have been contrived, which are charged with a mixture of air and inflammable gas; and being fired by means of an electric spark, are capable to drive a leaden bullet with great violence. Sometimes fome piitols are made of glafs (but in this cafe they are not charged with a bullet), and it is very diverting to fee that piitols are charged and exploded by the combustion of an invisible fubfance.

When a flender pipe is tied to the neck of a bladder, and the bladder is filled with inflammable air, after the manner defcribed in the preceding experi- ment (viz. when the bladder was required to be filled with fixed air), two very pleasing experiments may be performed with it. First, the inflammable gas may be inflamed by applying the flame of the candle to the extremity of the pipe; and fqueezing at the fame time the bladder, a stream of fire will be formed in the air, which will last as long as the bladder contains any inflammable air; for this gas coming out of the pipe with violence, will continue inflamed for a confiderable way in the air. Secondly, the extremity of the pipe may be dipped into a folution of foap, then removing it from the folution, and fqueezing the bladder very gently, a ball of foap-water may be formed, including inflammable air; which ball, on account of the inflammable gas being much lighter than common air, as far as it is detached from the pipe will ascend upwards, and will break by dashing against the ceiling, contrary to thofe commonly made by children, which in still air go downwards.—Whilft the ball is ascending, if the flame of the candle be approched to it, the film of foap-water will be infinitely broke, and the inflammable air will take fire; thus a flame may be shown to be feemingly produced from a foap-ball. By taking electric fparkes in any kind of oil, spirit of wine, ether, or spirit of falk ammoniac, Dr Prieftley obtained inflammable air. The oil, or other liquid, was confined in a glafs tube by quickfiver, and a wire was cemented in the upper part of the tube, through which the fparks being tent, went to the quickfiver through the oil; but after that a few fparks had been taken, a quantity of inflammable air was generated, &c. Left the production of inflammable air should be attributed to the cement which fastened the
Sect. XIV.

A E R O L O G Y.

By means of nitrous acid, inflammable air may be obtained from various substances containing phlogiston, but it is always mixed with nitrous air, and sometimes also with fixed and common or phlogisticated air. If two parts of spirit of wine, mixed with one part of nitrous acid, are put into a phial with a ground-funnel and tube, and the flame of a candle be applied to it, so as to heat it gradually, the inflammable air will be produced very readily; the inflammability of which is, however, not very permanent, for by a little washing in water it may be annihilated. In the solution of most substances in nitrous acid, it generally happens, that the elastic fluid, which is obtained towards the latter end of the process, posesses the property of being inflammable: thus iron, dissolved in nitrous acid, yields nitrous air; but when the nitrous air ceases to be produced, if the heat of a candle be applied to the solution, more elastic fluid will be produced which is inflammable. “The nitrous acid (says Dr Ingenhouz) when mixed with iron-fillings in a very diluted state, gives, by the assistance of a moderate degree of heat, a mixture of different airs, partly fixed, partly common air, and partly phlogisticated air. See further the article AEROSTATION.

§ 3. To produce Nitrous Air.—This permanently elastic fluid is never found naturally, like fixed or inflammable air, but is entirely artificial.

Either silver, copper, brass, iron mercury, bismuth, Nitrous air or nickel, when mixed with nitrous acid, yield nitrous air entirely in great quantities. Some of them, especially mercu- ry, require the aid of heat in order to produce the elastic fluid; the flame of a candle applied to the phial is sufficient: but others, especially copper and iron, do not want the application of any heat. Gold platina, and the regulars of antimony, when put in aqua regia, yield nitrous air pretty readily. Among the metals, lead yields nitrous air in the smallest quantity. “I poured (says Dr Priestley) smoking spirit of nitre into a phial with a ground-funnel and tube, containing 1/2 ounce-measure filled with small leaden shot, so as to leave no common air at all, either in the phial or in the tube; and I placed it so as to receive the air that might come from it in water. After waiting an hour, in which little or no air was produced, I applied the flame of a candle, though not very near, to it: and in these circumstances I got about an ounce-measure of air: but upon some water running into the phial while the candle was withdrawn, air was produced very plentifully. I collected in all about a quarter of a pint, and might probably have got much more, but that the falt formed by the solution of the lead had so nearly closed up the tube, that I thought proper to discontinue the process. The air, both of the first and of the last produce, was of the same quantity; and so far nitrous, that two measures of common air, and one of this, occupied the place of two measures only; excepting that the very first and very last produce, mixed with common air, took up a little more room than that which I got in the middle of the process. When the air was produced very fast, it was exceedingly turbid, as if it had been filled with a white powder.”

Among the semi-metals, zinc gives the weakest nitrous air, when dissolved in nitrous acid. The elastic fluid
of artificial Air.

From four pennyweights and 17 grains of zinc, dissolved in spirit of nitre diluted with an equal quantity of water, Dr Priestley obtained about 12 ounce-measures of very weak nitrous air. It occasioned a very slight effervescence when mixed with common air. The Doctor obtained nitrous air even from some flowers of zinc (as he) mixed a quantity of blue spirit of nitre with flowers of zinc, which were of a dull colour, and appeared from several experiments to contain a portion of phlogiston, it yielded, with the heat of a candle applied to the phial which contained it, strong nitrous air; when the common spirit of nitre, applied in the same manner, gave only phlogificated air; the phlogiston of which came probably from the caulk itself, though a small portion of it might have been in the nitrous acid, which I believe is never entirely free from it.

The quantity of nitrous air that may be obtained from various metals, is difficult to be ascertained, on account of the diversity occasioned by the strength of the acid, the various nature of the metallic substance, and the method of performing the experiments. The following is a table of the produce of nitrous air from various metals, extracted from Dr Priestley's first volume of Experiments and Observations; but which, as the author himself intimates, is far from being very accurate.

dwt. grs.

6 0 of silver yielded 17 ounce-measures.
5 19 of quicksilver, 44
1 24 of copper, 144
2 0 of brass, 21
0 20 of iron, 20
1 5 of bismuth, 6
0 12 of nickel, 4

The various strength of the nitrous acid produces great diversity in the production of nitrous air. Thus, if copper is dissolved in strong nitric acid, it will not produce the least quantity of nitrous air; but when dissolved in diluted nitric acid, it produces a great quantity of that elastic fluid. The strong and pale-coloured nitrous acid should be diluted with at least two or three parts of water to one of the acid, for the easy production of nitrous air from copper and mercury.

The briskness of the effervescence, and the production of nitrous air, are promoted by heat, and also by letting the metallic substance present a great quantity of surface to the acids.

For the generality of experiments, no other degree of heat is required than that produced by the effervescence itself, except mercury be used, which requires the application of some heat. When the metal exhibits a very great surface to the acid, as is the case when filings are used, the effervescence and production of nitrous air are often much quicker than can be conveniently managed.

Copper or brass, when clipped into flat bits, each about two or three grains in weight, and about a quarter of an inch in surface, and when dissolved in nitrous acid properly diluted, yield nitrous air very equably; but if they be used, the pieces of it should be much larger and fewer; in short, it should present a much larger surface to the diluted acid; otherwise the increase of heat in the process, and the rapid production of elastic fluid, render the operation both difficult and dangerous for the operator.

As the nitrous air is mostly necessary to try the goodness of respirable air, it is of great consequence to make it always of one constant degree of goodness; pure mercury yields a very homogenous nature in the nitrous acid; therefore it is plain, that the metals whole nature is more uniform must be preferred for this purpose. Accordingly, brass yields nitrous air of a more uniform nature than iron: copper is superior to brass; but pure mercury is still superior to copper: and indeed this is the metal which, considering its nature, uniformity of substance, and easy solution, is upon the whole the most useful for this purpose.

It has been generally observed, that solid vegetable substances, when dissolved in nitrous acid, yield more nitrous air than the animal substances, though this nitrous air is not so pure as that obtained from metals.

Sometimes it contains some fixed air, and a good deal of inflammable air which is mostly produced towards the end of the process. On the other hand, the nitrous air, extracted from animal substances generally contains a good deal of phlogificated air, and sometimes some fixed air. In order to obtain nitrous air from the solution of animal and vegetable substances in nitrous acid, often some degree of heat must be applied to the phial. The acid also sometimes must be very concentrated, and in other cases it must be diluted; but it is hardly worth while, or practicable, to determine with exactness all those particular cases.

To make Nitrous Air.—The metal, viz. copper, brass or mercury, is first put into the bottle (which, as well as the whole process, is the same as that described for fixed Air), so as to fill about one-third of the same; then some water is poured into the bottle, so as just to cover the metal-filings; and lastly, the nitrous acid is added, the quantity of which, when strong, should be about one-third or half the quantity of the water. The smell of the nitrous gas is very penetrating and offensive, and occasions a red smoke as soon as it comes into contact with the common air; hence whenever any of it escapes from the bottle, it may be observed not only by the smell, but also by the slight red colour.

In order to observe the principal property of this elastic fluid, which is that of diminishing the bulk of common air, let a glass tube, closed at one end, and about nine inches long, and half or three quarters of an inch in diameter, be filled with water, and inverted in water; then take a small phial, of about half an ounce-measure, filled with common air, and plunging it under the water contained in the same basin where the inverted tube is kept, let that quantity of air enter into the tube, which will go to the top of it, the water subsiding accordingly. Let a mark be made, either with a file or by sticking soft wax on the tube, just opposite to the surface of the water in it, which will mark how much the tube is filled by that given measure of air. After the same manner, fill the same small phial (which we shall call the measure) again with air, throw that air into the tube, and put a mark on the tube coinciding with the level of the water in it. In this manner, let four or five measures be marked on the tube. Now, if three measures of common air are put
AEROLOGY.

§ 4. To procure Dephlogisticated Air.—This is no other than exceedingly pure atmospheric air, entirely free from those heterogeneous vapours which contaminate the air we commonly breathe. The easiest method of procuring this air is to put the red-lead into the bottle, together with some good strong oil of vitriol, but without any water. Let the red-lead fill up a quarter of the bottle, and the vitriolic acid be about the same quantity or very little less; then apply the bent tube to the bottle, and proceed in the same manner as above. But it must be remarked, that without heat this mixture of red-lead and vitriolic acid will not give any dephlogisticated air, or it yields an inconsiderable quantity of it; for which reason the flame of a candle (that of a wax taper is sufficient) must be applied under the bottom of the bottle; which for this purpose must be rather thin, otherwise it will be easily cracked. In this manner the red-lead will yield a good quantity of elastic fluid, the greatest part of which is dephlogisticated air; but not the whole quantity of it, for a good portion of fixed air comes out with it. In order to separate the fixed air from the dephlogisticated air, the inverted bottle, when filled with the compound of both, as it is emitted from the red-lead, must be shook in the basin for impregnating water with fixed air; by which means the water will absorb the whole quantity of fixed air, and leave the dephlogisticated air by itself.

From every experiment it appears, that dephlogisticated air, if it could readily be obtained, and at a cheap rate, would be a most valuable manufacture. The heat communicated by means of it to burning fuel is incredible.

These are not the only advantages which might be expected from dephlogisticated air. It has been found by experience, that animals will live much longer in this kind of air than in an equal quantity of common air; whence it is supposed, that the breathing of it must be much more healthy, and contribute to longevity much more than the common atmosphere. Nay, there are not wanting some who attribute the longevity of the Antediluvians to the great purity of the atmosphere at that time; the whole mass being afterwards tainted by the déglutine, in such a manner that it could never regain its former purity and salubrity. But all this as yet is mere conjecture; and excepting the single fact, that animals live much longer in a quantity of dephlogisticated than of common air, there is no evidence that the former contributes more to longevity than the latter.

Dr Priestley even throws out a conjecture, that the use of dephlogisticated air might perhaps wear out the system much sooner than common air, in the same manner as it consumes fuel much faster than common air. The great quantity, however, even of the purest air, which is requisite to support animal life, and the expense and trouble of the most ready methods of procuring it, have hitherto prevented any fair trial from being made. Yet philosophers, considering the probability there is of this kind of air being salutary in many diseases, having bestowed some pains in attempting to find out methods of procuring it easily and in large quantity, we may remark, which we have the following observations in Cavallo's Treatise on Air.

"A man makes in general about 15 inspirations in a minute, and takes in about 30 cubic inches of aerial fluid. But the air which has been once inspired is not thereby much injured, and it may be respired again and again; so that upon a very moderate calculation, and as appears from actual experiments often repeated, we may safely assert, that a person can breathe 300 cubic inches of good ordinary atmospheric air, at least 30 times, without any inconvenience, i. e. it would serve for two minutes; after which that air, though much depraved, is still in a state of being breathed, but then it would occasion some uneasiness. Now, supposing the dephlogisticated air employed to be four times more pure than common air, 400 cubic inches of dephlogisticated air would serve for at least 120 respirations or eight minutes."

"But supposing that 30 inches of common air are completely phlogisticated by a single inspiration, and changed for such as is quite fresh, which indeed is the case in common respiration, then 450 cubic inches of common air will be requisite for one minute's respiration, and 27,000 for one hour; and as dephlogisticated air is supposed to be four times as good, the same quantity of it will serve for four hours. Indeed, if we could depend on the assertions of Mr Fontana, that by adding lime-water to absorb the fixed air produced by respiration, an animal can live 30 times as long as without it, no doubt a much smaller quantity would serve."

But it is certain such assertions cannot be true; because, though the fixed air should be absorbed as soon as produced, the remaining quantity would still be contaminated by phlogiston. Nay, we are informed by Dr Priestley, who repeated Fontana's experiments, that

(A) In this operation the flame of the candle, when once applied, must be kept continually near it; and when the mixture does not produce any more elastic fluid, or the operation is required to be intermittent, care should be taken to remove the extremity of the bent tube from the water first, and then to take off the flame of the candle from under the bottle; otherwise, if the flame of the candle be first removed, the materials within the bottle condensing by cold, the water immediately enters, which in an instant fills the bottle, and generally breaks it.
that animals will not live longer in a quantity of dephlogisticated air when it stands in contact with lime-
water, than they will when no lime-water is used.

In what manner a difference so enormous can take
place, between philosophers in other respects so accu-
rate, we can by no means determine. It is plain,
however, that if 27,000 inches of common air are ne-
cessary for a person in one hour, the same quantity of
dephlogisticated air cannot be breathed longer than
four hours, nor even for a single hour.

Mr Cavallo indeed allows only 12,000 inches for four
hours; but though this might no doubt sustain life for
that time, the person must at best expect nothing from
it superior to the common atmosphere, if he was not
materially injured by it.

A very ready method of procuring dephlogisticated air
in large quantity, is by means of nitre; and on the sup-
position that 12,000 inches are sufficient for four hours,
(or for 40 hours, as he limits the Abbé Pontana's suppo-
sition), Mr Cavallo proceeds in the following manner:

"The instruments necessary for the production of
dephlogisticated air from nitre are the following; viz.
earth retorts, or earthen vessels with a straight neck,
several in the shape of Florence flasks, but with a
longer neck, these being cheaper than the retorts; and
answering as well, viz. a small furnace, in which the
earthen retort must be kept red-hot; a common
chimney fire is not sufficient. These furnaces may be
very easily made out of large black lead crucibles.
The nitre must be put into the retort or other vessel,
so as to fill half or nearly three quarters of its belly;
then a bent glass tube is luted to the neck of the ear-
then vessel, in such a manner as not to let any elastic
fluid escape into the open air. The bent tube or ce-
ment for this or similar purposes is made by mixing to-
gether whitening and drying oil. The retort being put
into the furnace, must be surrounded with lighted
charcoal, which is to be supplied according as it wa-
tes; in short, the belly of the retort must be kept quite
red-hot, or rather white-hot, for about three hours at
least. If, instead of the retort, the other described
earthen vessel be used, care should be had to place it
with the neck as little inclined to the horizon as pos-
fible, lest the nitre should drop the neck and break it."
The air is then to be received into large glass jars, as
is usual in other experiments on air.

"The retort or other earthen vessel that is used for
this purpose cannot serve for more than once, because
it generally breaks in cooling; and besides, the de-
composed nitre cannot easily be taken out of it. The
retort capable of holding a pound of nitre (the quan-
tity necessary for producing 12,000 cubic inches of
dephlogisticated air) for this operation, costs at least
half-a-crown; the other earthen vessels in the shape of
Florence flasks, but with longer necks, cost about
1s. 6d. a-piece, or 2s.; so that the price of these ve-

sels far exceeds the usual price of the apparatus. If
such vessels are employed, the nitre will not yield near
as much air, though of a purer sort, because the glass
vessels cannot endure such a great fire as the earthen
ones. The retorts of metal, or at least of those metals
which are most usually employed for this purpose, viz.
iron, copper, plughisticate in a great measure the
air as soon as produced. Considering, then, all these
circumstances, it appears, that when a person has all the
usual apparatus and furnace, the expenses at present
of Artifi-
cial Airs.

of Artificial Airs.

Sec. XIV.

Another method of preparing dephlogisticated air
is, by blowing that of the common atmosphere thro'
melted nitre. In this process the phlogiston contained
in the atmosphere is gradually consumed, by detoning
with the acid of the nitre, and therefore issues much
more pure than before. This method has the appear-
ance at first of being much easier and more commodious
than the former; but as it is impossible to mix the
atmospheric air exactly with the melted nitre that every
particle of the one may come in contact with every
particle of the other, it is plain that the former me-

thod must be preferable; not to mention that it will
be found exceedingly troublesome to blow the air
through the nitre, as the latter will be perpetually apt
to cool and concret into lumps by the cold blast.

§ 5. To procure Vitriolic Acid Air.—This consists of
the vitriolic acid united with some phlogiston, which vo-
latilizes and renders it capable of assuming the form of
a permanently elastic fluid. To obtain it, some strong
concentrated vitriolic acid must be put into the usual
bottle, together with some substance capable of fur-

nishing phlogiston. Olive oil answers very well. The
oil of vitriol should be about three or four times as
much as the sweet oil, and both together should fill
about one-third or half the bottle. A gentle degree of
heat is then required, in order to let these materials
yield any elastic fluid; which may be done by apply-
ing the flame of a wax taper, as directed above for the
production of dephlogisticated air.

§ 6. To procure Marine Acid Air, which is no oth-
er than the marine acid itself, and which without any
addition becomes a permanently elastic fluid; put some
sea-felt, or common kitchen felt, into the usual bottle
in which the materials for producing elastic fluids are
generally put, fo as to fill about a fourth part of it;
and upon this felt pour a small quantity of good con-
centrated vitriolic acid; then apply the bent tube to
the bottle, and introduce it through the quicksilver
into the receiver, filled with and inverted in quicksilver
after the usual method, and the elastic fluid is copi-
ously produced.

§ 7. To procure Nitrous Acid Air.—This may be ob-
ained from heated nitrous acid, the vapour of which
acquires a permanent elasticity, and it has been found
to remain uncondensed into a visible fluid by any cold
to which it has been hitherto exposed. The great dif-
ficulty is to find a fluid capable of confining this acid
air; because it is easily and abundantly absorbed by
water, which is one of its properties by which it differs
from nitrous air. It acts upon quicksilver, and also on
oils; hence its examination cannot be made very
imperfectly; for substances must be exposed to it,
or mixing with it, whilst it is actually changing its
nature by acting on the mercury or other fluid that con-

fines it.

When water has absorbed a good quantity of this
elastic fluid, it acquires the properties of nitrous acid;
and when heated, it yields a large quantity of nitrous
AEROLOGY.

Of Artificial Air.

Air, viz. a quantity many times greater than that which water is wont to imbibe of it by agitation, or by any known means.

When the nitrous acid air is combined with essential oils, a considerable effervescence and heat are produced, nearly in the same manner as when the nitrous acid itself is poured upon those oils.

§ 8. Fluor Acid Air.—Put some of those minerals called flours, or fusible flars, pulverized into the usual bottle, and upon it pour some concentrated oil of vitriol; then adapt the bent tube, &c. The fluor acid air is at first produced without the help of heat; but in a short time it will be necessary to apply the flame of a candle to the bottle, by which means a considerable quantity of this elastic fluid is obtained.

§ 9. Alkaline Air.—Let the usual bottle be about half filled with volatile spirit of sal ammoniac; and after applying the bent tube, &c. let the flame of a candle be brought under the bottle, by which means the alkaline air will be produced copiously.

INDEX.

AEROMANCY, a species of divination performed by means of air, wind, &c. See DIVINATION, No. 5.

AEROMETRY, the science of measuring the air. It comprehends not only the doctrine of the air itself, confidered as a fluid body; but also its preffure, efflance, rarefaction, and condensation. But the term is at present not much in ufe, this branch of natural philosophy being more frequently called Pneumatics. See PNEUMATICS.

AERONAUT, a person who attends and guides an air-balloon. See AEROSTATION and AIR-BALLOON.

AERONAUTICA, from ÅN and AVIUS, derived from SAE, ship; the art of falling in a vesfl or machine through the atmosphere, sustained as a ship in the sea. Aerophylacea.

AERONYMPHA, from ÅR and NYMPH, a water nymph. See AEROSTATION.

AEROPHYTE, a term used by naturalists for caverns or referrers of air, supposed to exist in the bowels of the earth. Kircher speaks much of aerophylacea, or huge caverns, replete with air, disposed under ground; from whence, through numerous occult passages, that element is conveyed either to subterraneous receptacles of water, which, according to Kircher, are hereby raised into springs or rivers, or into the funds of subterraneous fire, which are hereby fed and kept alive for the preparation of metals, minerals, and the like.
AEROSTATION

Is a science newly introduced into the Encyclopædia. The word, in its primitive sense, denotes the science of insinuating weights in the air; but in its modern acceptance, it signifies aerial navigation, or the art of navigating through the atmosphere. Hence also the machines which are employed for this purpose are called aerostats, or aerostatic machines; and from their globular shape, air-ballons.

The romances of almost every nation have recorded instances of persons being carried through the air, both by the agency of spirits and by mechanical inventions; but till the time of the celebrated Lord Bacon, no rational principle appears to have been thought of by which this might be accomplished. Before that time, indeed, Friar Bacon had written upon the subject; and many had been of opinion, that, by means of artificial wings, fixed to the arms or legs, a man might fly as well as a bird; but these opinions were thoroughly refuted by Borelli in his treatise De Motu Animalium, where, from a comparison between the power of the nkeles which move the wings of a bird, and those which move the arms of a man, he demonstrates that the latter are utterly insufficient to strike the air with such force as to raise him from the ground. It cannot be denied, however, that wings of this kind, if properly constructed, and dexterously managed, might be sufficient to break the fall of a human body from an high place, so that some adventurers in this way might possibly come off with safety; though by far the greatest number of those who have rashly adopted such schemes, have either lost their lives or limbs in the attempt.

In the year 1672, Bishop Wilkins published a treatise, intitled, the Discovery of the New World; in which he mentions, though in a very indistinct and confused manner, the true principle on which the air is navigable; quoting, from Albertus de Saxonia and Francis Mendoca, *that the air is in some part of it navigable: and upon this static principle, any brass or iron vessel (suppose a kettle), whose sub stance is much lighter than that of water, yet being filled with the common air, it will swim upon it and not sink. So suppose a cup or wooden vessel upon the outward borders of this elementary air, the capacity of it being filled with fire, or rather ethereal air, it must necessarily, upon the same ground, remain swimming there, and of itself can no more fall than an empty ship can sink.* This idea, however, he did not by any means pursue, but relit his hopes entirely upon mechanical motions, to be accomplished by the mere strength of a man, or by springs, &c. and which have been demonstrated incapable of answering any useful purpose.

The only person who brought his scheme of flying to any kind of rational principle was the Jesuit Francis Lana, contemporary with Bishop Wilkins. He, being acquainted with the real weight of the atmosphere, justly concluded, that if a globular vessel were exhausted of air, it would weigh less than before; and con sidering that the solid contents of vessels increase in much greater proportion than their surfaces; he supposed that a metallic vessel might be made so large, that, when emptied of its air, it would be able not only to raise itself in the atmosphere, but to carry up passengers along with it; and he made a number of calculations necessary for putting the project in execution. But though the theory was here unexceptionable, the means proposed were certainly insufficient to accomplish the end: for a vessel of copper, made so thin as was necessary to make it float in the atmosphere, would be utterly unable to resist the external pressure; which being demonstrated by those skilled in mechanics, no attempt was made on that principle.

In the year 1709, however, as we were informed by Strange, a letter published in France in 1708, a Portuguese projector, Friar Guzman, applied to the king for encouragement to his invention of a flying machine. The principle on which this was constructed, if indeed it had any principle, seems to have been that of the paper kite. The machine was constructed in form of a bird, and contained several tubes through which the wind was to pass, in order to fill a kind of sails, which were to elevate it; and when the wind was deficient, the same effect was to be performed by means of bellows concealed within the body of the machine. The ascent was also to be promoted by the electric attraction of pieces of amber placed in the top, and by two spheres inclining magnets in the same situation.

These childish inventions show the low state of science at that time in Portugal, especially as the king, in order to encourage him to farther exertions in such an useful invention, granted him the first vacant place in his college of Barcelos or Santarem, with the first professorship in the University of Coimbra, and an annual pension of 600,000 reis during his life. Of this De Guzman, it is also related, that in the year 1736, he made a贝壳 basket of about seven or eight feet diameter, and covered with paper, which raised itself about 200 feet in the air, and the effect was generally attributed to witchcraft.

In the year 1766, Mr Henry Cavendish ascertained the weight and other properties of inflammable air, determining it to be at least seven times lighter than common air. Soon after which, it occurred to Dr Black, that perhaps a thin bag filled with inflammable air might be buoyed up by the common atmosphere: and he thought of having the allantois of a calf prepared for this purpose; but his other avocations prevented him from prosecuting the experiment. The same thought occurred some years afterwards to Mr Cavalllo; and he has the honour of being the first who made experiments on the subject. He first tried bladders; but the thinnest of these, however well scaped and prepared, were found too heavy. He then tried Chinese paper; but that proved so permeable, that the vapour passed through it like water through a sieve. His experiments, therefore, made in the year 1782, proceeded...
Aerostation discovered by Montgolfier.

But while the discovery of the art of aerostation seemed thus on the point of being made in Britain, it was all at once announced in France, and that from a quarter whence nothing of the kind was to have been expected. Two brothers, Stephen and John Montgolfier, natives of Annonay, and masters of a considerable paper manufactorythere, had turned their thoughts towards this project as early as the middle of the year 1782. The idea was first suggested by the natural ascent of the smoke and clouds in the atmosphere; and their design was to form an artificial cloud, by inclosing the smoke in a bag, and making it carry up the covering along with it. Towards the middle of November that year, the experiment was made at Avignon with a fine silk bag of a parallelopiped shape. In applying burning paper to the lower aperture, the air was rarefied, and the bag ascended in the atmosphere, and struck rapidly against the ceiling. On repeating the experiment in the open air, it rose to the height of about 70 feet.

An experiment on a more enlarged scale was now projected; and a new machine, containing about 650 cubic feet, was made, which broke the cords that confined it, and rose to the height of about 600 feet. Another of 35 feet in diameter rose about 1000 feet high, and fell to the ground three quarters of a mile from the place where it ascended. A public exhibition was next made on the fifth of June 1783, at Annonay, where a vast number of spectators assembled. An immense bag of linen, lined with paper, and containing upwards of 23,000 cubic feet, was found to have a power of lifting about 500 pounds, including its own weight. The operation was begun by burning chopped straw and wood under the aperture of the machine, which immediately began to swell; and after being set at liberty, ascended into the atmosphere. In ten minutes it had ascended 6000 feet; and when its force was exhausted, it fell to the ground at the distance of 7600 feet from the place whence it set out.

Soon after this, one of the brothers arrived at Paris, where he was invited by the Academy of Sciences to repeat his experiments at their expense. In consequence of this invitation, he constructed, in a garden in the Faubourg of St Germain, a large balloon of an elliptical form. In a preliminary experiment, this machine lifted up from the ground eight persons who held it, and would have carried them all off if more had not quickly come to their assistance. Next day the experiment was repeated in presence of the members of the academy; the machine was filled by the combustion of 50 pounds of straw made up in small bundles, upon which about 12 pounds of chopped wool were thrown at intervals. The usual success attended this exhibition: the machine soon swelled; endeavoured to ascend; and immediately after suf­fused itself in the air, together with the charge of between 4 and 500 pounds weight. It was evident that it would have ascended to a greater height; but as it was designed to all at once announce before the king and royal family at Versailles, the cords by which it was tied down was not cut. But in consequence of a violent rain and wind which happened at this time, the machine was

Some animals such as a cock, a duck, a sheep, a duck, were the first animals ever sent through the air.

In a preliminary experiment, this number of letters was thrown up; and immediately after this, one of the brothers arrived at Paris, where a great number of persons who held it, ascended about 500 pounds weight. It was next made on the fifth of June, at Annonay, where a vast number of spectators assembled. An immense bag of linen, lined with paper, and containing upwards of 23,000 cubic feet, was found to have a power of lifting about 500 pounds, including its own weight. The operation was begun by burning chopped straw and wood under the aperture of the machine, which immediately began to swell; and after being set at liberty, ascended into the atmosphere. In ten minutes it had ascended 6000 feet; and when its force was exhausted, it fell to the ground at the distance of 7600 feet from the place whence it set out.

account of his expériments.

The height of the whole apparatus was upwards of 1600 pounds. The experiment was performed on the 15th of October 1783. Mr Pilatre de Rozier offered himself to be the first aerial adventurer.

This new machine was constructed in a garden in the Faubourg of St Antoine. It was of an oval shape, about 48 feet in diameter and 74 in height; elegantly painted on the outside with the insign of the zodiac, circles of the king's name, and other ornaments. A proper gallery, stage, &c., were appended in the manner afterwards described; so that it was easy for the person who ascended to supply the fire with fuel, and thus keep up the machine as long as he pleased. The weight of the whole apparatus was upwards of 1600 pounds. The experiment was performed on the 15th of October 1783. Mr Pilatre having placed himself in the gallery, the machine was inflated, and permit­ted to ascend to the height of 84 feet, where he kept it aloft about for four minutes and a half; after which it descended very gently; and the wind had a tendency to ascend, that it rebounded to a considerable height after touching the ground. Two days after, he repeated the experiment with the same success as before; but the wind being strong, the machine did not sustain itself so well as formerly. On repeating the experiment in calmer weather, he ascended to the height of 210 feet. His next ascent was 262 feet; and in the descent, a gust of wind having blown the machine over some large trees of an adjoining garden, Mr Pilatre suddenly extricated himself from dangerous a situation, by throwing some straw and chopped wool on the fire, which raised him at once to a sufficient height. On descending again, he once more raised himself to a proper height by throwing straw on the fire. Some time after, he ascended in company with Mr Girond de Villette to the height of 330 feet; hovering over Paris at least nine minutes in sight of all the inhabitants, and the machine keeping all the while perfectly steady.

Thee experiments had shown, that the aerostatic machines might be raised or lowered at the pleasure of the
the persons who ascended: they had likewise discovered, that the keeping them fast with ropes was no advantage; but, on the contrary, that this was attended with inconvenience and hazard. On the 21st of November 1783, therefore, M. Pilâtre determined to undertake an aerial voyage in which the machine should be fully set at liberty. Every thing being got in readiness, the balloon was filled in a few minutes: and M. Pilâtre placed himself in the gallery, counterpoised by the Marquis d’Arlanc, who occupied the other side. It was intended to make some preliminary experiments on the ascending power of the machine: but the violence of the wind prevented this from being done, and even damaged the balloon essentially: so that it would have been entirely destroyed had not timely assistance been given. The extraordinary exertions of the workmen, however, repaired it again in two hours, and the adventurers set out. They met with no inconvenience during their voyage, which lasted about 2½ hours; during which time they had passed over a space of above five miles. — From the account given by the Marquis d’Arlanc, it appears that they met with several different currents of air; the effect of which was, to give a very sensible shock to the machine, and the direction of the motion seemed to be from the upper part downwards. It appears also that they were in some danger of having the balloon burst altogether; as the Marquis observed several round holes made by the fire in the lower part of it, which alarmed him considerably, and indeed not without reason. However the progress of the fire was easily stopped by the application of a wet sponge, and all appearance of danger ceased in a very short time.

This voyage of M. Pilâtre and the Marquis d’Arlanc may be said to conclude the history of those aerostatic machines which are elevated by means of fire; for though many other attempts have been made upon the same principle, most of them have either proved unsuccessful or were of little consequence. They have therefore given place to the other kind, filled with inflammable air; which, by reason of its smaller specific gravity, is both more manageable, and capable of performing voyages of greater length, as it does not require to be supplied with fuel like the others. This was invented a very short time after the discovery had been made by M. Montgolfier. This great man indeed designed to keep his method in some degree a secret from the world; but as it could not be concealed, that a bag filled with any kind of fluid lighter than the common atmosphere would raise itself, inflammable air was naturally thought of as a proper succedanum for the rarefied air of M. Montgolfier. The first experiment was made by two brothers Meûrs Robert and Charles, with the idea of undertaking something of the same kind with a balloon filled with inflammable air. The machine used on this occasion was formed of gores of silk, covered over with a varnish made of cossethuce, of a spherical figure, and measuring 271 feet in diameter. A net was spread over the upper hemisphere, and was fastened to an hoop which passed round the middle of the balloon. To this a sort of car, or rather boat, was suspended by ropes, in such a manner as to hang a few feet below the lower part of the balloon; and, in order to prevent the bursting of the machine, a valve was placed in it; by opening of which some of the inflammable air might be occasionally let out. A long silken pipe communicated with the balloon, by means of which it was filled. The boat was made of basketh work, covered with painted linen, and beautifully ornamented; being 8 feet long, broad, and 35 deep; its weight 130 pounds. At this time, however, as at the former, they met with great difficulties in filling the machine with inflammable air, owing to their ignorance of the most proper apparatus. But at last, all obstacles being removed, the two adventurers took their seats at three quarters after one in the afternoon of the first of December 1783. Persons skilled in mathematics were conveniently stationed with proper instruments to calculate the height, velocity, &c. of the balloon. — The weight of the whole apparatus, including that of the two adventurers, was found to be 6042 pounds, and the power of ascent when they set out was 20 pounds; so that the whole difference between the weight of this balloon and an equal bulk of common air was 6244 pounds. But the weight of the common atmosphere displaced by the inflammable gas was calculated to be 771 pounds, so that there remains 147 for the weight of the latter; and this calculation makes it only 5½ times lighter than common air.

At the time the balloon left the ground, the thermometer stood at 90° of Fahrenheit’s scale, and the quicksilver, in the barometer, at 30.18 inches; and, by means

AEROSTATION. History.

First aerial voyage made by Meûrs Rozier and Arlandes, naturally Angola by M. Charles and Roberts.
means of the power of ascent with which they left the
ground, the balloon rose till the mercury fell to 27 in-
ches, from whence they calculated their height to be
about 600 yards. By throwing out ballast occasion-
ally as they found the machine descending by the ex-
te of some of the inflammable air, they found it
practicable to keep at pretty near the same distance
from the earth during the rest of their voyage; the
quicksilver fluctuating between 27 and 27.65 inches,
and the thermometer between 53° and 57°, the whole
time. They continued in the air for the space of an
hour and three quarters, when they alighted at the
distance of 27 miles from Paris; having suffered no
inconvenience during their voyage, nor experienced
any contrary currents of air, as had been felt by
Messrs Piature and Arlandes. As the balloon still
reained a great quantity of inflammable gas, Mr Charles
determined to take another voyage by himself. Mr
Robert accordingly got out of the boat, which was
thus lightened by the removal of the inflammable air,
and this remaining in the boat, which was
understood to be blown up to a height of 4000 feet;
and having a velocity of 200 feet in a minute, he
was carried up with such velocity, that in twenty minutes
he was almost 9000 feet high, and entirely out of sight of terrestrial objects. At the
moment of his parting with the ground, the globe had
been rather flaccid; but it soon began to swell, and
the inflammable air escaped from it in great quantity
through the silken tube. He also frequently drew
the valve that it might be the more freely emitted,
and the balloon effectually prevented from bursting.
The inflammable gas being considerably warmer than
the external air, diffused itself all round, and was
diffused as warm atmosphere; but in ten minutes the
thermometer indicated a variation of temperature as
great as that between the warmth of summer and the
ordinary cold of winter. His fingers were benumbed
by the cold, and he felt a violent pain in his right
ear and jaw, which he ascribed to the dilatation of
the air in these organs as well as to the external cold.
The beauty of the prospect which he now enjoyed,
however, made amends for these inconveniences.
At his departure the sun was set on the valleys; but
the height to which Mr Charles was got in the atmo-
sphere, rendered him again visible, though only for
a short time. He saw, for a few seconds vapours
rising from the valleys and rivers. The clouds
seemed to ascend from the earth, and collect one upon
the other, still preserving their usual form; only their
colour was grey and monotonous for want of sufficient
light in the atmosphere. By the light of the moon,
he perceived that the machine was turning round with
him in the air; and he observed that there were con-
tary currents which brought him back again. He ob-
erved also, with surprize, the effects of the wind, and
that the streamers of his banners pointed upwards;
which, he says, could not be the effect either of his
descend or ascent; for he was moving horizontally at the
time. He, therefore, recollecting his promise of returning
to his friends in half an hour, he pulled the valve, and
accelerated his descent. When within 200 feet of the
earth, he threw out two or three pounds of ballast,
which rendered the balloon again stationary; but, in a
little time afterwards, he gently alighted in a field a
about three miles distant from the place whence he set
out; though, by making allowance for all the turn-
ings and windings of the voyage, he supposes that he
had gone through nine miles in all. By the calcula-
tions of M. de Manlier, he rose at this time not less
than 10,500 feet high; a height somewhat greater
than that of Mount Ararat. A small balloon, which
had been sent off before the two brothers set out on
their voyage, took a direction opposite to that of the
large one, having met with an opposite current of air,
probably at a much greater height.
The subsequent aerial voyages differ so little from
that just now related, that any particular description
of them seems to be superfluous. It had occurred to Mr
Charles, however, in his last flight, that there might be
a possibility of directing the machine in the atmosphere,
and this was soon attempted by Mr Jean-Pierre Blan-
chard, a gentleman who had, for several years before,
amused himself with endeavours to fly by mechanical
means, though he had never succeeded in the under-
taking. As soon as the discovery of the aeroftatic ma-
cines was announced, however, he resolved to add the
wings of his former machine to a balloon, and made no
doubt that it would then be in his power to direct him-
sely through the air at pleasure. In his first flight
he was disappointed at the impetuosity of a young gentle-
man, who insinuated, right or wrong, on ascending along
with him. In the feuffle which ensued on this occa-
sion, the wings and other apparatus were entirely de-
stroyed; so that Mr Blanchard was obliged to commit
himself to the direction of the wind; and in another
attempt it was found, that all the strength he could ap-
cly to the wings was scarce sufficient to counteract the
impression of the wind in any degree. In his voyage,
he found his balloon, at a certain period, acted upon
by two contrary winds; but, on throwing out four
pounds of ballast, he ascended to a place where he met
with the same current he had at leaving out from the
earth. His account of the sensations he felt during
this voyage, was somewhat different from that of Mr
Charles; having, in one part of it, found the atmos-
phere very warm, in another cold; and having once
found himself very hungry, and at another time almost
overcome by a propensity to sleep. The height
to which he rose, as measured by several observations with
mathematical instruments, was thought to be very little
less than 20,000 feet; and he remained in the atmo-
sphere an hour and a quarter.
The attempts of Mr Blanchard to direct his machine
Voyage of through the atmosphere, were repeated in the month
of April 1784, by Meffrs Morveau and Bertrand, at
Dijon, who raised themselves with an inflammable air
balloon to the height, as it was thought, of 13,000 feet;
passing through a space of 18 miles in an hour and 25
minutes. Mr Morveau had prepared a kind of oars
for directing the machine through the air; but they
were damaged by a gust of wind, so that only two of
them remained serviceable; by working these, how-
ever, they were able to produce a sensible effect on the
motion of the machine. In a third aerial voyage per-
fomed by Mr Blanchard, he seemed to produce some
effects by the agitation of his wings, both in ascending,
descending, moving forward, and even in some mea-
sure against the wind; however, this is vaspoled, with
some probability, to have been a mistake, as, in all his
succeeding voyages, the effects of his machinery could
not be perceived.
The experiment of Melleurs Charles and Robert in their former experiments, encouraged them to repeat them, with the addition of some machinery to direct their course. Having enlarged their former balloon to the size of an oblong spheroid 464 feet long and 27 feet in diameter, they made it to float with its longest part parallel to the horizon. The wings were made in the shape of an umbrella without the handle, to the top of which a stick was fastened parallel to the aperture of the umbrella. Five of these were disposed round the boat, which was near 17 feet in length. The balloon was filled in 2 hours, and, with the addition of 450 pounds of ballast, remained in equilibrium with the atmosphere. About noon, on the 19th of September, they began to ascend very gently in consequence of throwing out 24 pounds of ballast, but were soon obliged to throw out eight pounds more in order to avoid running against some trees. Thus they rose to the height of 1400 feet, when they perceived some thunder-clouds near the horizon. On this they ascended and descended, to avoid the danger, as the wind blew directly towards the threatening clouds; but, from the height of 600 feet to that of 4200 above the surface of the earth, the current was quite uniform and in one direction. During their voyage they lost one of their oars; but, found, that by means of those which remained, they considerably accelerated their course. From the account of their voyage, it would seem that they had passed safely through the thunder-clouds; as we are informed, that, about 40 minutes after three, they heard a loud clap of thunder; and, three minutes after, another much louder; at which time the thermometer sunk from 77 to 59 degrees. This sudden cold, occasioned by the approach of the clouds, condensed the inflammable air so that the balloon descended very low, and they were obliged to throw out 40 pounds of ballast; yet on examining the heat of the air within the balloon, they found it to be 104°, when that of the external atmosphere was only 63. When they had got so high that the mercury in the barometer stood only at 23 inches, they found themselves becalmed; so that the machine did not go even at the rate of two miles an hour; and, for an hour and a quarter, it seemed to be at rest. At length the wind was strong enough to make them advance, and they continued moving in a straight line at the rate of 24 miles an hour. They had then ascended 6000 feet. After having travelled about 150 miles, they descended, only on account of the approach of night, having still 200 pounds of ballast left.

Their conclusion, with regard to the effect of their wings, is as follows: "Those experiments show that far from going against the wind, as is said by some persons to be possible in a certain manner, and some aeronauts pretend to have actually done, we only obtained, by means of two oars, a deviation of 22 degrees: it is certain, however, that if we could have used our four oars, we might have deviated about 40 degrees from the direction of the wind, and as our machine would have been capable of carrying seven persons, it would have been easy for five persons to have gone, and to have put in action eight oars, by means of which a deviation of about 80 degrees would have been obtained.

"We had already observed (say they), that if we did not deviate more than 22 degrees, it was because the wind carried us at the rate of 24 miles an hour; and it is natural to judge, that, if the wind had been twice as strong as it was, we should not have deviated more than one-half of what we actually did; and, on the contrary, if the wind had been only half as strong, our deviation would have been proportionally greater."

Having thus related all that has been done with regard to the conducting of aerostatic machines through the atmosphere, we shall now relate the attempts that have been made to lessen their expense, by falling upon some contrivance to ascend without throwing out ballast, and to descend without losing any of the inflammable air. The first attempt of this kind was made by the Duke de Chartres; who, on the 15th of July, ascended with the two brothers, Charles and Robert, from the Park of St Cloud. The balloon was of an oblong form, made to ascend with its longest diameter horizontally, and measured 53 feet in length and 24 in breadth. It contained within it a smaller balloon filled with common air; by blowing into which with a pair of bellows, and thus throwing in a considerable quantity of common air, it was supposed that the machine would become sufficiently heavy to descend, especially as, by the inflation of the internal bag, the inflammable air in the external one would be condensed into a smaller space, and thus become specifically heavier. The power of ascent with which they fell out, seems to have been very great; as, in three minutes after parting with the ground, they were lost in the clouds, and involved in such a dense vapour that they could see neither the sky nor the earth. In this situation they seemed to be attacked by a whirlwind, which, besides turning the balloon three times round from right to left, shook, and beat it so about, that they were rendered incapable of using any of the means proposed for directing their course, and the thick stuff of which the helm had been compos'd was even torn away. No scene can be conceived more terrible than that in which they were now involved. An immense ocean of shapeless clouds rolled one upon another below them, and seemed to prevent any return to the earth, which still continued invisible, while the agitation of the balloon became greater every moment. In this extremity they cut the cords which held the interior balloon, and of consequence it fell down upon the aperture of the tube that came from the large balloon into the boat, and stopped it up. They were then driven upwards by a gust of wind from below, which carried them to the top of the stormy vapour in which they had been involved. They now saw the fun without a cloud; but the heat of his rays, with the diminished density of the atmosphere, had such an effect on the inflammable air, that the balloon became every moment ready to burst. To prevent this they introduced a stick through the tube, in order to push away the inner balloon from its aperture; but the expansion of the inflammable air pushed it so close, that
AEROSTATION.

History.

All attempts of this kind proved ineffectual. It was now, however, become absolutely necessary to give vent to a very considerable quantity of the inflammable air; for which purpose the Duke de Chartres himself bored two holes in the balloon, which tore open for the length of seven or eight feet. On this they descended with great rapidity; and would have fallen into a lake, had they not hastily thrown out 60 pounds of ballast, which enabled them just to reach the water's edge.

The success of the scheme for raising or lowering aerostatic machines by means of bags filled with common air being thus rendered dubious, another method was thought of. This was to put a small aerostatic machine with rarefied air under an inflammable air-balloon, but at such a distance that the inflammable air of the latter might be perfectly out of the reach of the fire used for inflating the former; and thus, by increasing or diminishing the fire in the small machine, the absolute weight of the whole would be considered as diminished or augmented. This scheme was unhappily put in execution by the celebrated Mr Pilatre de Rozier, and another gentleman named Mr Romaine. Their inflammable-air balloon was about 37 feet in diameter, and the power of the rarefied-air one was equivalent to about 60 pounds. They ascended without any appearance of danger or finer accident, but had not been long in the atmosphere when the inflammable-air balloon was seen to swell very considerably, at the same time that the aeronauts were seen to be confined in the balloon, very anxious to get down, and with great rapidity. There seemed to have been dead before he came to the ground; but Mr Romaine was alive when some persons coming up to the place were he lay, though he expired immediately after.

There are the most remarkable attempts that have been made to improve the science of aërostation; tho' a great number of other expeditions through the atmosphere have taken place. But of all the voyages which had been hitherto projected or put in execution, the most daring was that of Mr Blanchard and Dr Jeffries across the Straits of Dover which separate Britain from France. This took place on the 7th of January 1785, being a clear frothy morning, with a wind, barely perceptible, at N. W. The operation of filling the balloon began at 10 o'clock, and, at three quarters after twelve, every thing was ready for their departure. At one o'clock Mr Blanchard defied the boat to be pulled off, which now stood only two feet distant from that precipice finely described by Shakespeare in his tragedy of King Lear. As the balloon was scarcely sufficient to carry two, they were obliged to throw out all their ballast except three bags of ten pounds each; when they at last rose gently, though making very little way on account of there being so little wind. At a quarter after one o'clock, the barometer, which on the cliff stood at 29.7 inches, was now fallen to 27.3, and the weather proved fine and warm. They had now a most beautiful prospect of the south coast of England, and were able to count 37 villages upon it. After passing over several vessels, they found that the balloon, at 30 minutes after one, was descending, on which they threw out a flock and half of ballast; but as they saw that it still descended, and that with much greater velocity than before, they now threw out all the ballast. This still proving ineffectual, they next threw out a parcel of books they carried along with them, which made the balloon ascend, when they were about midway between France and England. At a quarter past two, finding themselves again descending, they threw away the remainder of their books, and, ten minutes after, they had a most enchanting prospect of the French coast.

Still, however, the machine descended; and as they had now no more ballast, they were fain to throw away their provisions for eating, the wings of their boat, and every other moveable they could easily spare. "We threw away, says Dr Jeffries, our only bottle, which, in its descent, cast out a jet like smoke, with a rushing noise; and when it struck the water, we heard and felt the shock very perceptibly on our car and balloon." All this proving insufficient to stop the descent of the balloon, they next threw out their anchors and cords, and at last stripped off their clothes,fastening themselves to certain firings, and intending to cut away the boat as their last resource. They had now the satisfaction, however, to find that they were rising; and as they passed over the high lands between Cape Blanc and Calais, the machine rose very fast, and carried them to a greater height than they had been at any former part of their voyage. They descended safely among some trees in the forest of Guiness, where there was just opening enough to admit them.

It would be tedious as well as unnecessary to recount all the other aerial voyages that have been performed in different parts of Europe: It appeared sufficient for the purpose of this article to notice those which were most remarkable and interesting; and therefore an account of the ingenious Mr Baldwin's excursion from Chester, alluded to above, shall now close our enumeration.

On the 8th of September 1783, at forty minutes past one P. M. Mr Baldwin ascended from Chester in Mr Lunardi's (a) balloon. After traversing in a variety of different directions, he first alighted, at 28 minutes after three, about 12 miles from Chester, in the neighborhood of Frodham; then reascending and pursuing his excursion, he finally landed at Rixton moss, five miles N. N. E. of Wavington, and 25 miles from Chester. Mr Baldwin has published his Observations and Remarks made during his voyage, and taken from minutes. Our limits will not admit of relating many accounts of this gentleman's adventurous excursions have been published in all the Newspapers, and therefore it appeared unnecessary to take up room with an account of them in this article.

(a)
many of his observations; but the few following are some of the most important and curious. "The sensation of ascending is compared to that of a strong pressure from the bottom of the car upwards against the soles of his feet. At the distance of what appeared to him seven miles from the earth, though by the barometer scarcely a mile and a half, he had a grand and most enchanting view of the city of Chester and its adjacent places below. The river Dee appeared of a red colour; the city very diminutive; and the town entirely blue. The whole appeared a perfect plain, the highest building having no apparent height, but reduced all to the same level, and the whole terrestrial prospect appeared like a coloured map. Just after his first ascent, being in a well-watered and maritime part of the country, he observed a remarkable and regular tendency of the balloon towards the sea; but shortly after rising into another current of air, he escaped the danger: this upper current, he says, was visible to him at the time of his descent, by a lofty found stratum of clouds flying in a safe direction. The perspective appearance of things to him was very remarkable. The lowest bed of vapour that first appeared as cloud was pure white, in detached fleeces, increasing as they rose: they presently coalesced, and formed, as he expresses it, a sea of cotton, tufting here and there by the action of the air in the undisturbed part of the cloud. The whole became an extended white floor of cloud, the upper surface being smooth and even. Above this white floor he observed, at great and unequal distances, a vast assemblage of thunder-clouds, each parcel consisting of whole acres in the densest form: he compares their form and appearance to the froth of pieces of ordnance, which had conflagrated as it were into mists of snow, and penetrated thro' the upper surface or white floor of common clouds, there remaining visible and at rest. Some clouds had motions in fluid and various directions, forming an appearance truly stupendous and majestic. He endeavours to convey some idea of the effects by a figure (and from which Fig. 10 of Plate III. is copied). A circular view he had from the car of the balloon, himself being over the centre of the view, looking down on the white floor of clouds and seeing the city of Chester through an opening, which discovered the landscape below, limited by surrounding vapour, to less than two miles in diameter. The breadth of the outer margin defines his apparent height in the balloon (viz. 4 miles) above the white floor of clouds. Mr Baldwin also gives a curious description of his tracing the shadow of the balloon over tops of volumes of clouds. At first it was small, in size and shape like an egg; but soon increased to the magnitude of the fun's disc, still growing larger, and attended with a most captivating appearance of an iris encircling the whole shadow at some distance round it, the colours of which were remarkably brilliant. The regions did not feel colder, but rather warmer, than below. The fan was hottest to him when the balloon was stationary. The discharge of a cannon when the balloon was at a considerable height, was distinctly heard by the aeronaut; and a discharge from the same piece, when at the height of 50 yards, so disturbed him as to oblige him for safety to lay hold firmly of the cords of the balloon. At a considerable height he poured down a pint bottle full of water; and as the air did not oppose a resistance sufficient to break the streams into small drops, it mostly fell down in large drops. In the course of the balloon's track it was found much affected by the water (a circumstance observed in former aerial voyages). At one time the direction of the balloon kept continually over the water, going directly towards the sea, so much as to endanger the aeronaut; the mouth of the balloon was opened, and he in two minutes descended into an under current blowing from the sea: he kept descending, and landed at Pollard farm in Rimley, 12 miles from Chester. Here he lightened his car by 31 pounds, and instantly reascending was carried into the interior part of the country, performing a number of different manoeuvres. At his greatest altitude he found his respiration free and easy. Several bladders which he had along with him crackled and expanded very considerably. Clouds and land, as before, appeared on the same level. By way of experiment, he tried the upper valve two or three times, the neck of the balloon being closed; and remarked, that the escape of the gas was attended with a growing noise like tumults, but not near so loud. Again, round the shadow of the balloon, on the clouds, he observed the iris. A variety of other circumstances and appearances he met with, is fancifully described; and at 53 minutes past three he finally landed.

The frequency of aerial voyages, accompanied with particular details of trilling and uninteresting circumstances, and apparently made with a view to promote the interest of particular persons, regardless of any advancement in knowledge, have now sunk the science of aëration so low in the opinion of most people, that that before giving any account of the most proper method of constructing these machines, it may seem necessary to premise something concerning the uses to which they may possibly be applied. These according to Mr Cavallo are the following.

1. The small balloons, especially those made of paper, served to precipitate the condensation of clouds, by means of smoke. (the paper, when wet, expanded very considerably.) A review of their appearance in various circumstances, in which they did not mean can be used; and letters or other small things may be easily sent by them, as for instance from ships on the sea, to places in the interior, from islands, or the like. The larger aerostatic machines may answer all the above-mentioned purpooses in a better manner; and they may, besides, be used as a help to a person who wants to ascend a mountain, a precipice, or to cross a river; and perhaps one of these machines tied to a boat by a long rope, may be in some cases, a better boat of safety than any that is used at present. The largest fort of machines, which can take up one or more men, may evidently be subservient to various economical and philosophical purpooses. Their conveying people from one place to place with great swiftness, and without trouble, may be of essential use, even if the art of guiding them in a different direction from that of the wind should never be discovered. By means of those machines the shape of certain seas and lands may be better ascertained: men may ascend to the tops of mountains they never visited before; they may be carried over marshes, and
Principles.

A E R O S T A T I O N.

...and dangerous grounds; they may by that means come out of a betted place, or an island; and they may, in hot climates, ascend to a cold region of the atmosphere, either to refresh themselves, or to observe the ice which is never seen below; and, in short, they may be thus taken to several places, to which human art hitherto knew of no conveyance.

"The philosophical uses, to which these machines may be subordinated, are numerous indeed; and it may be sufficient to say, that hardly any thing which passes in the atmosphere is known with precision, and that principally for want of a method of ascending into it. The formation of rain, of thunder-forms, of vapours, hail, snow, and meteors in general, require to be attentively examined and ascertained. The action of the barometer, the rarefaction and temperature of the air in various regions, the descent of bodies, the propagation both will ascend, and for the same reason. A have they any of the sicknesses which are prevalent in the atmosphere, cannot be exceeded. No one has felt the least of that giddiness consequent upon looking from, the top of a very high building or of a precipice, nor have they any of the sicknesses arising from the motion of a vessel at sea. Many have been carried by balloons at the rate of 30, 40, or even 50 miles an hour, without feeling the least inconvenience, or even agitation of the wind; the reason of which is, that as the machine moves with the nearly the velocity of the wind itself, they are always in a calm, and without uneasiness. Some have apprehended danger from the electricity of the atmosphere; and have thought that a stroke of lightning, or the smallest electric spark, happening near a balloon, might set fire to the inflammable air, and destroy both the machine and the adventurers. Mr. Cavallo has suggested several considerations for diminishing apprehensions of this kind. Balloons have been already raised in every season of the year, and even when thunder has been heard, without injury. In case of danger, the aeronauts may either baffle to the earth, or ascend above the region of the clouds and thunder-forms. Besides, as balloons are formed of materials that are not conductors of electricity, they are not likely to receive strokes, especially as being encompassed with air they fland insulated. Moreover, inflammable air by itself, or unmixed with a certain quantity of common air, will not burn; so that if an electric spark should happen to pass through the balloon, it would not set fire to the inflammable air, unless a hole was made in the covering.

The general principles of aerostation are so little different from those of hydrostatics, that it may seem superfluous to insist much upon them. It is a fact universally known, That when a body is immersed in any fluid, if its weight be less than an equal bulk of that fluid, it will rise to the surface; but if heavier, it will sink; and if equal, it will remain in the place where it is left. For this reason smoke ascends into the atmosphere, and heated air in that which is colder. The ascent of the latter is shown in a very easy and satisfactory manner by bringing a red-hot iron under one of the scales of a balance, by which the latter is instantly made to ascend; for, as soon as the red-hot iron is brought under the scale, the hot air being lighter than that which is colder, ascends, and strikes the bottom, which is thus impelled upwards, and the opposite scale descends, as if a weight had been put into it.

Upon this simple principle depends the whole theory of aerostation; for it is the same thing whether we render the air lighter by introducing a quantity of heat into it, or by causing a quantity of gas specifically lighter than the common atmosphere in a certain space; both will ascend, and for the same reason. A cubic foot of air, by the most accurate experiments, has been found to weigh about 554 grains, and to be expanded by every degree of heat, marked on Fahrenheit's thermometer, about 1/4th part of the whole. By heating a quantity of air, therefore, to 500 degrees of Fahrenheit, we will double its bulk when the thermometer stands at 54 in the open air, and in the same proportion we will diminish its weight; and if such a quantity of this hot air be inclosed in a bag, that the excess of the weight of an equal bulk of common air weighs more than the bag with the air contained in it, both the bag and air will rise into the atmosphere, and continue to do so until they arrive at a place where the external air is naturally so much rarified that the weight becomes equal; and here the whole will float.

The power of hot air in raising weights, or rather that by which it is itself impelled upwards, may be shewn in the following manner: Roll up a sheet of paper into a conical form, and, by thrusting a pin into it near the apex, prevent it from unrolling. Fasten it then, by its apex, under one of the scales of a balance by means of a thread, and, having properly counterpoised it by weights, put it into the opposite scale; apply the flame of a candle underneath, you will instantly perceive the cone to rise, and it will not be brought into equilibrium with the other but by a much greater weight than those who have never seen the experiment would believe. If we try this experiment with more accuracy, by getting proper receptacles made which contain determinate quantities of air, we will find that the power of the heat depends much more on the capacity of the bag which contains it than could be well supposed. Thus, let a cubical receptacle be made of a small wooden frame covered with paper capable of containing one foot of air, and let the power of a candle be tried with this as above directed for the paper cone. It will then be found that a certain weight may be raised; but a much greater one will be raised by having a receptacle of the same kind which contains two cubic feet; a still greater ought to be made by one of three feet, a yet greater by one of four feet, &c. and this even though the very same candle be made use of; nor is it known to what extent even the power of this small flame might be carried.

From these experiments it appears, that in the aerostatic machines constructed on Montgolfier's plan, it must be an advantage to have them as large as possible; because..."
AEROSTATION.

Principles.

How balloons might rise by the common heat of the atmosphere.

Because a smaller quantity of fire will then have a greater effect in raising them, and the danger from that element, which in this kind of machines is chiefly to be dreaded, will be in a great measure avoided. On this subject it may be remarked, that as the cubical contents of a globe, or any other figure of which balloons are made, increase much more rapidly than their surfaces, there must ultimately be a degree of magnitude at which the smallest imaginable heat would raise any weight whatever. Thus, supposing any aërostatic machine capable of containing 500 cubic feet, and the air within it to be only one degree hotter than the external atmosphere; the tendency of this machine to rise, even without the application of artificial heat, would be near an ounce. Let its capacity be increased 16 times; and the tendency to rise will be equivalent to a pound, though this may be done without making the machine 16 times heavier than before. It is certain, however, that all aërostatic machines have a tendency to produce or preserve heat within them, which would by no means be imagined by those who have not made the experiment. When Mefirs Charles and Robert made their longest aërial voyage of 500 miles, they had the curiosity to try the temperature of the air within their balloon, in comparison with that of the external atmosphere; and at this time they found, that when the external atmosphere was 65°, the thermometer, within the balloon, stood at 104°. Such a difference of temperature must have given a machine of the magnitude which carried them a considerable ascending power independent of any other cause, as it amounted to 41 grains on every cubic foot; and therefore in a machine containing 50,000 cubic feet would have been about 200 pounds. Hence we may easily account for what happened at Dijon, and is recorded by Mr Morveau. "A balloon, intended to be filled with inflammable air, being completed, was, by way of trial, filled with the common air, and in that state exposed to the atmosphere. Now it was observed, and indeed a similar observation had been made before, that the air within the balloon was much hotter than the external air: the thermometer in the former stood at 120°; whereas in the latter, even when the sun shone upon it, the thermometer stood at 84°. This showed a considerable degree of rarefaction within the balloon; and consequently it was suspected, that by means of this rarefaction alone, especially if it were to increase a little, the balloon might ascend. On the 30th of May, about noon, the wind being rather strong, agitated the balloon so that two men were employed to take care of it; but notwithstanding all their endeavours, it escaped from its confinement, and, lifting up about 65 pounds weight of cords, equal to a circle of many feet high, and, passing over some houses, went to the distance of 250 yards, where at length it was properly secured."

This difference between the external and internal heat being so very considerable, must have a great influence upon aërostatic machines, and will undoubtedly influence those filled with inflammable air as well as the other kind. Nor is it unlikely, that the short time which many aërial voyagers have been able to continue in the atmosphere, may have been owing to the want of a method of preventing this internal heat. It may naturally be supposed, and indeed it has always been found, that balloons, in passing through the higher regions of the atmosphere, acquire a very considerable quantity of moisture, not only from the rain or snow they sometimes meet with, but even from the dew and vapour which condenses upon them. On this an evaporation will instantly take place; and as it is the property of this operation to produce a very violent cold, the internal heat of the balloon must be soon exhausted in such a manner as to make it become specifically heavier than the common atmosphere, and consequently descend in a much shorter time than it would have done by the mere loss of air. To this, in all probability, we are to ascribe the descent of the balloon which carried Mefirs Blanchard and Jeffries; and which appeared extraordinary to many people, that they were obliged to have recourse to an imaginary attraction in the waters of the ocean in order to solve the phenomenon. This supposition is rejected by Mr Cavalcado, who explains the matter, by remarking, that in two former voyages made with the same machine, it could not long support two men in the atmosphere; so that we had no occasion to wonder at its weakness on this occasion. "As for its rising higher (says he) just when it got over the land, that may be easily accounted for. In the first place, the two travellers threw out their clothes just about that time; secondly, in consequence of the wind's then increasing, the balloon travelled at a much greater rate than it had done whilst over the sea; which increase of velocity lessened its tendency to descend: besides which, the vicissitudes of heat and cold may produce a very considerable effect; for if we suppose, that the air over the land was colder than that over the sea, the balloon coming into the latter from the former, continued to be hotter than the circumambient air for some time after; and consequently, it was comparatively much lighter when in the cold air over the land, than when in the hotter air over the sea; hence it floated easier in the former than in the latter case.""
of their shape.

For experimental purposes, both the inflammable and rarefied air-balloons may be made of paper; the former being made of that kind called thin-paper, varnished over with linseed-oil; the latter either of that or any other kind, without varnish. In order to avoid the danger of burning, however, it has been proposed to impregnate the paper of which these small rarefied air-balloons are made with solution of fulminate of potassa, alum, or some other salt; but this does not seem to be necessary. Those filled with inflammable air have been made of gold-beater skin or peeled bladders; but the cheaper material of paper is undoubtedly preferable.

For aerostatic machines of a larger size, the material universally employed is varnished silk, and for those of the rarefied-air kind, linen painted over with fine-size colour, or lined with paper. The best varnish for an inflammable air-balloon is that made with bird-lime, and recommended by Mr Faujas de Saint-Fond, in a treatise published on the subject. The following is his method of preparing it: “Take one pound of bird-lime, put it into a new proper earthen pot that can resist the fire, and let it boil gently for about one hour, viz. till it ceases to crackle; or, which is the same thing, till it is so far boiled, as that a drop of it being let fall upon the fire will burn: then pour upon it a pound of spirits of turpentine, stirring it at the same time with a wooden spatula, and keeping the pot at a good distance from the flames; at least the vapour of this essential oil should take fire. After this, let it boil for about six minutes longer; then pour upon the three pounds of boiling oil of nitrates, linseed, or poppy rendered drying by means of litharge; stir it well, let it boil for a quarter of an hour longer, and the varnish is made. After it has rested for 24 hours, and the sediment has gone to the bottom, decant it into another pot; and when you want to use it, warm, and apply it with a flat brush upon the silk stuff, whilst that is kept well stretched. One coat of it may be sufficient; but if two are necessary, it will be proper to give one each side, and to let them dry in the open air while the silk remains extended.”

Mr Cavallo gives the following method of preparing this varnish, which he prefers to that of M. d Sr St Fond.—“In order to render linseed-oil drying, boil it with two ounces of succarum faturna and three ounces of litharge, for every pint of oil, till the oil has dissolved them, which will be accomplished in half an hour; then put a pound of bird-lime and half a pint of the drying oil into a pot (iron or copper pots are the safest for this purpose), the capacity of which may be equal to about one gallon, and let it boil very gently over a slow charcoal fire till the birdlime ceases to crackle, which will be in about half or three quarters of an hour; then pour upon it two pints and a half more of drying oil, and let it boil for one hour longer, stirring it very frequently with an iron or wooden spatula. As the varnish, whilst boiling, and especially when it is nearly done, swells very much, care should be had to remove, in those cafes, the pot from the fire, and to replace it when the varnish fiddles, otherwise it will boil over. Whilst the fluid is boiling, the operator should, from time to time, examine whether the varnish has boiled enough; which is thus known:—Take some of it upon the blade of a knife, and then, after rubbing the blade of another knife upon it, separate the knives; and when on this separation, the varnish begins to form threads between the two, you may conclude that it is done; and, without losing time, it must be removed from the fire. When it is almost, though not quite, cold, add about an equal quantity of spirit of turpentine: mix it well together, and let it rest till the next day; when, having warmed it a little, strain and bottle it. It is too thick, add some more spirit of turpentine. When this varnish is laid upon the silk, the stuff should be made perfectly dry, and stretched; if the varnish, which ought to be used lukewarm, may fill up the pores of the fluid. The varnish should be laid once very thin upon one side of the stuff; and about 12 hours after, two other coats of it should be laid on, one on each side; and, 24 hours after, the silk may be used, though in cold weather, it may be left to dry some time longer.”

Much has been said in France of their elastic gum-
varnish, and its composition kept a secret; but Mr Baldwin, after many expensive trials, declares to the world what he considers as the secret; and it is merely this: "Take any quantity of caoutchouc, as two ounces averdupois; cut it into small bits with a pair of scissors; put a strong iron ladle (like that used by plumbers) over a common pilot or other fire. The fire must be gentle, glowing, and without smoke. When the ladle is hot, much below a red heat, put in a bit of iron or brass spoon. Two pounds or three times its weight of smoking oil, has stood a month, or not so long, on a lump of quicklime, to make it more or less drying), is to be put into the melted caoutchouc, and stirred till hot, and the whole poured into a glazed vessel, through a coarse gauze or fine sieve. When iced and clear, which will be in a few minutes, it will be fit for use either hot or cold." Mr Baldwin is not at liberty, he observes, to publish the art of laying on the varnish: but says, that it consists in making nointine motion in the varnish, which would create minute bubbles; that therefore brushes are improper. Mr Blanchard's method of making galum varnish for the silk of a balloon, is the following: "Divide elastic gum (caoutchouc) cut small in five times its weight of spirit of turpentine, by keeping them some days together; then boil one ounce of this solution in eight ounces of drying linseed-oil for a few minutes; lastly, strain it. It must be used warm." The pieces of silk for the balloon must be cut out of a proper size, according to the dimensions, after the varnish is sufficiently dry. They may be joined by laying about half an inch of the edge of one piece over the edge of the other, and sewing them by a double stitching. Mr Blanchard uses expeditiously the following method. He lays about half an inch of the edging of one piece flat over the edge of the other, and passes a hot iron over it; in doing which a piece of paper ought to be laid both under and over the silk. The joining may be rendered more secure by running it with a silk thread, and stitching a ribbon over it. The ribbons laid over seams may be stuck with common glue, provided the varnish of the silk is properly dried. When the glue is quite dry, the ribbons should be varnished over, to prevent their being unglued by the rain.

49

Of cutting the gores for a globe.

AEROSTATION.

Practice.

The best method of cutting the pieces of silk that are to form a balloon, is to describe a pattern of wood or stiff card-paper, and then to cut the silk upon it. As the edges of such a pattern are not perfect circles, they cannot be described by a pair of compasses; but the best method of drawing them is as follows. First, draw, on a flat surface two right lines AE and BC, perpendicular to each other. Secondly, find the circumference answering to the given diameter of the balloon in feet and decimals of a foot; and make AD and DE each equal to a quarter of the circumference, so that the whole length AE of the pattern may be equal to half the circumference. Thirdly, divided AD into 18 equal parts; and to the points of division apply the lines fg, hi, kl, &c. parallel to each other, and perpendicular to AD. Fourthly, divide the whole circumference in twice the given number of pieces, and make DC and BB each equal to the quotient of this division; so that the whole, BC, is equal to the greatest breadth of one of these pieces. Fifthly, multiply the abovementioned quotient by the decimals annexed to fg, viz. 0.99619, and then the product expresses the length of fg; again multiply the same length of DE by the decimals annexed to hi, and the product expresses the length of hi; and, in short, the product arising from the multiplication of the length of DC by the decimals annexed to each of the parallel lines, gives the length of that line. Lastly, having found the lengths of all these lines, draw by hand a curve-line passing through all the extremities of the said lines, and that is the edge of one quarter of the pattern. The other quarters may be easily described, by applying to them a piece of paper cut according to that already found.—Suppose, for example, that the diameter of the balloon to be constructed is 20 feet, and that it is required to make it of 12 pieces: then, in order to draw the pattern for those pieces, find the circumference of the balloon, which is 62.83 feet, and dividing it by four, the quotient is 15.7 feet; make therefore AD equal to 15.7 feet, and DE likewise of the same length. Divide the circumference 62.83 by 24, which is double the number of pieces that are to form the balloon, and the quotient, 2.618 feet, is the length of DC and likewise of BD; so that BC is equal to 5.236 feet. Then, having divided the line AD into 18 equal parts, and having drawn the parallel lines from those points of division, find the length of each of those lines by multiplying 2.618 by the decimals annexed to that line. Thus, 2.618 multiplied by 0.99619, gives 2.608 feet for the length of fg; and again, multiplying 2.618 by 0.98481, gives 2.578 feet for the length of hi; and so of the rest.—In cutting the pieces after such a pattern, care should be taken to leave them about three quarters of an inch all round larger than the pattern, which will be taken up by the seams.

To the upper part of the balloon there should be adapted, and well fitted in, a valve opening inward; to which should be fastened a string passing through a hole made in a small piece of round wood fixed in the lower part of the balloon opposite to the valve, the end of this string fastened to the car below, so that the aeronaut may open the valve when occasion requires. The action of this valve may be understood from fig. 6. A round brass plate AB has a round hole CD, about two or three inches diameter, covered on both sides with strong smooth leather. On the inside there is a shutter E, which is covered with leather, which is to close the hole CD; being about two inches larger in diameter than the hole. It is fastened to the leather of the plate AB; and by a spring, which need not be very strong, it is kept against the hole. The elasticity of the gas itself will help to keep it shut. This shutter the string is fastened, by which it is occasionally opened for the escape of gas. A small string
Practice. AEROSTATION.

Filling or other security should be fixed to the fuller and the plate, as not to admit a flutter to be observed beyond a certain line distance. To the lower part of the balloon two pipes should be fixed, made of the same stuff as the envelope; 8 inches diameter for a balloon of 30 feet, and proportionally larger for balloons of a greater capacity. They must be long enough for the car. For balloons of 18 feet and less diameter, one neck or pipe will be sufficient. These pipes are the apertures through which the inflammable gas is introduced into the balloon.

The car or boat is best made of wicker-work, covered with leather, and well painted or varnished over; and the proper method of suspending it, is by ropes proceeding from the net which goes over the balloon. This net should be formed to the shape of the balloon, and fall down to the middle of it, with various cords proceeding from it to the circumference of a circle about two feet below the balloon; and from that circle other ropes should go to the edge of the boat. This circle may be made of wood, or of several pieces of slender cane bound together. The meshes of the net may be small at top, against which part of the balloon the inflammable air exerts the greatest force; and increase in size as they recede from the top. A hoop has sometimes been applied round the middle of the balloon to fasten the net. This, though not absolutely necessary, is built made of pieces of cane bound together, and covered with leather.

With regard to the rarefied-air machines, Mr Cavallo recommends first to soak the cloth in a solution of turpentine and common fize, using one pound of each to every gallon of water; and when the cloth is quite dry, to paint it over in the inside with some earthy colour, and strong size or glue. When this paint has dried perfectly, it will then be proper to varnish it with oil varnish, which might dry before it could penetrate quite through the cloth. Simple drying linseed oil will answer the purpose as well as any, provided it be not very fluid.

It now only remains to give some account of the method by which aerostatic machines may be filled with their proper gas, in order to give them their power of ascendency into the atmosphere; and here we are enabled to determine with much greater precision concerning the inflammable-air balloons than the others. With regard to them, a primary consideration is, that the proper method of procuring the inflammable air. It may be obtained in various ways, as has been shown under the article AEROSCOPY. But the most advantageous methods are, by applying acids to certain metals; by exposing animal, vegetable, and some mineral substances, in a close vessel to a strong fire; or by transmitting the vapour of certain fluids through red-hot tubes.

1. In the first of these methods, iron, zinc, and vitriolic acid, are the materials most generally used. The vitriolic acid must be diluted by five or six parts of water. Iron may be expected to yield in the common way 1,700 times its own bulk of gas; or one cubic foot of inflammable air to be produced by 42 ounces of iron, the like weight of oil of vitriol, and 212 ounces of water. Six ounces of zinc, an equal weight of oil of vitriol, and 50 ounces of water, are necessary for producing the same quantity of gas. It is more proper to use the turnings or shavings of great pieces of iron, as of cannons, &c. than the filings of that metal, because the heat attending the vitriolic acid will be more readily through the interiors of the turnings when they are heated together, than through the filings, which stick closer to one another. The weight of the inflammable air thus obtained by means of acid of vitriol, is, in the common way of procuring it, generally one seventh part of the weight of common air; but with the necessary precautions for philosophical experiments, less than one-tenth of the weight of common air. Two other sorts of elastic fluids are sometimes generated with the inflammable air. These may be separated from it by passing the inflammable air through water in which quicklime has been dissolved. The water will absorb these fluids, cool the inflammable air, and prevent its overheating the balloon when introduced into it.

Fig. 7. of Plate III. represents an apparatus described by Mr Cavallo as proper for filling balloons of the size of two or three feet in diameter with inflammable air, after passing it through water.—A is the bottle with the ingredients; BCD a tube fastened in the neck of B, and passing through C, the cork of the other bottle, in which there is another hole made to receive the tube on which the balloon is tied. Thus it is plain, that the inflammable air coming out of the tube D will pass first through the water of the bottle E and then into the balloon. Two small casks may be used instead of the bottles A and E.

2. Inflammable air may be obtained at a much cheaper rate by the action of fire on various substances, but the gas which these yield is not so light as that produced by the evaporation of acids and metals. The substances proper to be used in this way are, pit-coal, asphaltum, amber, rock-oil, and other minerals; wood and especially oak, camphor-oil, spirits of wine, ether, and animal substances, which yield air in different degrees, and of various specific gravities; but pit-coal is the preferable substance. A pound of this exposed to a red heat, yields about three cubic feet of inflammable air, which, whether it be passed through water or not, weighs about one-fourth of the weight of common air. Dr Priestley found, as we have elsewhere noticed, that animal or vegetable substances will yield six or seven times more inflammable air when the fire is suddenly increased than when it is gently raised, though it be afterwards made very strong. Mr Cavallo observes, that the various substances above enumerated generally yield all their inflammable air in about one hour's time. The general method is, to incline the substances in iron or earthen vessels, and thus expose them to a strong fire sufficient to make the vessels red-hot: the inflammable air proceeding from the aperture of the vessel is received into a tube or receiver, and passing through the tube or worm, is at last collected in a balloon or other vessel. A gun barrel has often been used for effects of this kind. The substance is put into it to the fill full or eight inches of its lowest part; the remainder filled with dry sand: a tube, adapted to the mouth of the barrel, is brought into a balloon under an inverted receiver; and the part of the barrel containing the substance being put into the fire and made red-hot, the inflammable air is collected.
AEROSTATION. Practice.

It has indeed been recommended to use zinc instead of iron fillings, because white vitriol, the salt produced by the union of the vitriolic acid and zinc, is much more volatile than the green iron produced by the union of the same acid with iron. But though this is undoubtedly the case, it will as certainly be found, upon trial, that the superior price of the zinc will be more than an equivalent for all the advantage that can be derived from the additional price of the white vitriol.

For a balloon of 30 feet diameter, Mr Cavallo recommends 3900 pounds of iron fillings, as much oil of vitriol, and 19,500 pounds of water. These proportions, however, appear too great with respect to the acid and metal, and too little with respect to the water. Oil of vitriol will not exert its power upon iron unless it be diluted with five or six times its quantity of water; in which case, a much smaller quantity of both acid and metal will serve. Mr Lunardi, who from the number of his voyages had certainly much practical knowledge in aerostation, filled his balloon at Edinburgh and Glasgow with about 2000 pounds of iron (the borings of cannon procured from Carron), as much vitriolic acid, and 12,000 pounds of water. The iron was placed in his vessels in layers, with straw between them, in order to increase the surface. His apparatus was not materially different from that of Mr Cavallo, represented bottom of Plate I. fig. 2. where AA are two tins, about three feet in diameter and nearly two feet deep, inverted in large tins BB filled with water. In the bottom of each of the inverted tubes a hole is made, and a tube E of tin adapted, which is about seven inches in diameter, and seven or eight long. To these tubes the silken ones of the balloon are to be tied. Round each of the tubes B, five, six, or more strong casks are placed; in the top of each two holes are made, and to one of these holes a tin tube is adapted, and the flap shaped, that, passing over the edge of the tube B, and through the water, it may terminate with its aperture under the inverted tube A. The other hole of these casks serves for the introduction of materials, and is filled with a wooden plug. When the balloon is to be filled, put the net over it, and let it be suspended as shown by CDF; and having expelled all the common air from it, let the silken tubes be fastened round the tin ones EE; and the materials being put into the casks, the inflammable air, passing into the balloon, will soon distend, and render it capable of supporting itself; after which the rope GH may be slipped off. As the balloon continues to be filled, the net is adjusted properly round it; the cords that surmount it are fastened to the hoop MN; then the boat IK being placed between the two sets of casks, it is fastened to the hoop MN, and every thing that is required to be sent up, as ballots, instruments, &c. is placed in it. At last, when the balloon is little more than three quarters full, the silken tubes are separated from the tin ones of the inverted tubes, and their extremities being tied up, are placed in the boat. Lastly, the aeronauts being seated in the boat, the lateral ropes are slipped off, and the machine is aban doned to the air. (See Blanchard's balloon, Plate II.)

This apparatus was at last reduced by Mr Lunardi to its utmost simplicity, by using only two large casks, and suffering the vapour to go into the balloon without passing through water. Thus his balloon was filled.
in less than half an hour, when, before, it had required two hours at least. The dissipation of heat calls in the ground was also an additional convenience, as it created no confusion, and rendered the materials much more easily conveyed into them.

With regard to the rarefied-air balloons, the method of filling them is as follows. A scaffold ABCD, the breadth of which is at least two-thirds of the diameter of the machine, is elevated about six or eight feet above the ground. From the middle of it descends a well E, riling about two or three feet above it, and reaching to the ground, furnished with a door or two, through which the fire in the well is supplied with fuel. The well should be constructed of brick or of plastered wood, and its diameter should be somewhat less than that of the machine. On each side of the scaffold are erected two masts HI, KL, each of which has a pulley at the top, and rendered firm by means of ropes KG, KP, HJ, HG. The machine to be filled is to be placed on the scaffold, with the neck round the aperture of the well. The rope pailling over the pullies of the two masts, serves, by pulling its two ends, to lift the balloon about 15 feet or more above the scaffold; and the rest of the machine is represented by the dotted lines in the figure MNO. The machine is kept steady, and held down, whilst filling, by ropes passing through loops or holes about its equator; and these ropes may easily be disengaged from the machine, by filling them through the loops when it is able to sustain itself. The proper combustibles to be lighted in the scaffold are those which burn quick, and increase the smoke; because it is hot air, and not smoke, that is required to be introduced into the machine. Small wood and straw have been found to be very fit for this purpose. Mr Cavallo observes, as the result of many experiments with small machines, that spirits of wine are upon the whole the best combustible; but its price may prevent its being used for large machines. As the current of hot air ascends, the machine will soon dilate, and lift itself above the scaffold and gallery which was covered by it. The scullers, or sails, are then placed in the gallery. When the machine makes efforts to ascend, its aperture must be brought, by means of the ropes annexed to it, towards the side of the well a little above the scaffold; the fire-place is then suspended in it, the firelighted in the grate, and the lateral ropes being slipped off the scaffold, the machine is abandoned to the air. (See Mongolfier's balloon, Plate II.) It has been determined by accurate experiments, that only one-third of the common air can be expelled from these large machines; and therefore the ascending power of the rarefied air in them can be esteemed as only equal to half an ounce averduпоise for every cubic foot.

The conduct of balloons, when constructed, filled, and actually ascending in the atmosphere, is an object of great importance in the practice of aeronautics. The method generally used for elevating or lowering the balloons with rarefied air, has been the increase or diminution of the fire; and this is entirely at the command of the aeronaut, as long as he has any fuel in the gallery. The inflammable-air balloons have been generally raised or lowered by diminishing the fire in the boat, or by letting out some of the gas through the valve: but the alternate escape of the air in descending, and discharge of the ballast for ascending, will by degrees render the machine incapable of floating; for in the air it is impossible to supply the lobs of ballast, and very difficult to supply that of inflammable air. These balloons will also rise or fall by means of the rarefaction or condensation of the inclosed air, occasioned by heat and cold. It has been proposed to aid a balloon in its alternate motion of ascent and descent, by annexing to it a vessel of common air, which might be condensed for lowering the machine, and rarefied again, by expelling part of it, for raising the machine. But a vessel adapted to this purpose must be very strong; and, after all, the assistance afforded by it would not be very considerable. M. Meunier, in order to attain this end, proposes to inclose one balloon filled with common air in another filled with inflammable air: as the balloon ascends, the inflammable air is diluted, and of course compresses the internal balloon containing the common air; and by diminishing its quantity, lessens its weight. If it should be necessary to supply this lobs, he says it may be easily done by a pair of bellows fixed in the gallery. Others have proposed to annex a small machine with rarefied air to an inflammable-air balloon by ropes, at such a distance that the fire of the former might not affect the inflammable air of the latter, the whole apparatus, thus combined, of balloons formed on the two principles of heated and inflammable air, might be raised or lowered by merely increasing or diminishing the fire in the lower balloon.

Wings or oars are the only means of this sort that have been used with some success; and as Mr Cavallo observes, they seem to be capable of considerable improvement. Although great effects are not to be expected from them when the machine goes at a great rate, the best methods of moving those wings are by the human strength applied similarly to the oars of a waterman. They may be made in general of silk and wood, or of pitch and wood; and when used must be turned edgewise when they are moved in the direction in which the machine is intended to be impelled, but flat in the opposite direction. Fig. 9. Plate III. is the representation of one of Mr Blanchard's wings. Fig. 10. is one of those used by Mr Lunardi, which consists of many silk flutters or valves, ABCD, DEF, &c. every one of which opens on one side only, viz. ADBC opens upon the line AB, DECF opens upon the line DC, &c. In consequence of this construction, this sort of oars do not need being turned edgewise. Fig. 11. represents one of the wings constructed by Count Zambecari, which consists of a piece of silk stretched between two tin tubes set at an angle; but these wings are so contrived as to turn edgewise by themselves when they go on one direction. Other contrivances have been made to direct aerostatic machines, but they have mostly been invented to effect a power upon them as upon a flag. It appears, however, that they can have no effect when a machine is only moved by the wind alone, because the circumambient air is at rest in respect to the machine. The case is quite different with a vessel at sea, because the water on which it floats tends whilst the vessel goes on; but it must be time and experience that can realize the expectations suggested by these contrivances.
AESCHYLS, a town in the Netherlands, in the dukedom of Brabant, and capital of the dukedom of Aershot. It is on the river Demer, ten miles east of Malines or Mechlin, and eight north of Louvain. L. Long. 5. 4. N. Lat. 51. 15.

AERGUSINUS, an epithet given to such things as resemble or partake of the nature of the rust of copper.

AERGO, in natural history, properly signifies the rust of copper, whether natural or artificial. The former is found about copper mines, and the latter, called verderges, made by corroding copper-plates with acids. See verdigris.

AERUSCATORES, in antiquity, a kind of flogging beggars, not unlike gypsies, who drew money from the credulous by fortune-telling. It was also a denomination given to gripping exaudors, or collectors of the revenue. The Gallic, or priests of Cybele, were called Aerucker magus undris, and aeruscatens, on account of their begging or collecting alms in the streets; to which end they had little bellies whereby to draw people's attention to them, much like some orders of mendicants in some parts of Europe.

AER, or Aery, among sportmen. See Aery.

Æs exorium, in antiquity, a sum paid by baccalors, as a penalty for living single to old age. This tax for not marrying seems to have been first imposed in the year of Rome 350, under the censorship of M. Parius Camillus and M. Polthamus. At the census, or review of the people, each person was asked, Erus ex ore gentium? æs exorium posset, or fashion it? He who had no wife was hereupon fined after a certain rate, called æs exorium.

Æs per et librum was a formula in the Roman law, whereby purchases and sales are ratified. Originally the phrase seems to have been only used in speaking of things sold by weight, or by the feet; but it afterwards was used on other occasions. Hence even in adoptions, as there was a kind of imaginary purchase; the formula whereof expressed, that the person adopted was bought per et librum.

Æs Flamum, yellow copper, among the Romans, an appellation given to the crimson kind of brass.

Æs Callirhoe, a term used by the German miners, for a substance which sometimes occurs to those who work upon cobalt, and is used for the making the fine blue colour called finalis.

Æs Ulteria, a chemical preparation, made of thin leaves of copper, sulphur, and nitre, placed flatum super flamum in a crucible, and set in a charcoal fire till all the sulphur is consumed; after which, the copper is taken out of the crucible, and reduced to powder. Some quench the leaves of copper in vinegar, and repeat the calcination. Its principal use is in colouring glass, to which it gives a beautiful tincture. The forgers use it as a detergent, and some have given it internally; but it is certainly a very dangerous medicine, and should be avoided.

ÆSCHINES, a Socratic philosopher, the son of Charinus a funnager-maker. He was continually with Socrates; which occasioned this philosopher to say, that the funnager-maker's son was the only person who knew how to pay a due regard to him. It is said that poverty obliged him to go to Sicily to Dionysius the Tyrant; and that he met with great contempt from Plato, but was extremely well received by Aristotle, whom he showed some of his dialogues, and received from him a handsome reward. He would not venture to press his philosophy and Art in Athens, in the company of the high officers; but he set up a school to maintain himself. He afterwards wrote orations for the Roman, Phrynichus, in Phrygia, ranks him among the best orators, and mentions his orations as the standard of the pure Atticism style. Hermodor had spoken very highly of him. He also wrote several dialogues; of which there are only two extant, 1. concerning Virtue, whether it can be taught. 2. Eryxius, or Cretaceous; concerning riches, whether they are good. 3. Achelous, concerning death, whether it is to be feared. Sir le Clerc has given a Latin translation of them, with notes, and several dissertations prefixed by three oratoroi.

ÆSCHYLUS, the tragic poet, was born at Athens. Authors differ in regard to the time of his birth, some placing it in the 6th, others in the 7th Olympiad; but according to Stanley, who relies on the Athenian铭s, he was born in the 6th Olympiad. He was the son of Euphorion, and brother to Cynegius and Aminias, who distinguished themselves in the battle of Marathon, and the sea-fight of Salamis, at which engagements Æschylus was likewise present. In this last action, according to Liodoros Siculus, Aminias, the younger of the three brothers, commanded a squadron of ships, and behaved with so much conduct and bravery, that he sunk the admiral of the Persian fleet, and glorified himself above all the Athenians. To this brother his poet was under a particular obligation, for saving his life: Ælian relates, that Æschylus being charged by the Athenians with certain blasphemous expressions in some of his pieces, was accused of impiety, and condemned to be floned to death: they were just going to put the sentence in execution, when Aminias, with a happy prescience of mind, throwing aside his cloak, showed his arm without a band, which he had lost at the battle of Salamis in defence of his country. This sight made such an impression on the judges, that, touched with the remembrance of his valor, and with the friendship he showed for his brother, they pardoned Æschylus. Our poet, however, related the indignity of this persecution, and resolved to leave a place where his life had been in danger. He became more determined in his resolution when he found his pieces less pleasing to the Athenians than those of Sophocles, tho' a much younger writer. Some affirm, that Æschylus never sat down to compose but when he had drunk liberally. He wrote a great number of tragedies, of which there are but seven remaining; and notwithstanding the sharp censures of some critics, he must be allowed to have been the father of the tragic art. In the time of the Histiae, there was no public theatre to act upon; the theatres driving about from place to place in a cart. Æschylus furnished his actors with masks, and dressed them suitably to their characters. Hellicris is said to have introduced the basin, to make them appear more like heroes. The ancients gave Æschylus also the praise of having been the first who removed murders and shocking sights from the eyes of the spectators. He is said likewise to have defined the number of the choruses. M. Le Fevre has observed, that Æschylus never represented women in love in his tragedies; which, he says, was not suited to his genius; but, in representing a woman transported with fury, he was incomparable. Longinus says, that Æschylus...
Æsculapius has a noble boldness of expression; and that
his imagination is lofty and heroic. It must be owned,
however, that he affected pompous words, and that his
feuds too often obscured by figures: this gave Sal-
mus occasion to say, that he was more difficult to
be understood than the scripture itel. But notwithstanding
their imperfections, the character of his works was
highly honored by the Athenians, who made a public de-
cree that his tragedies should be played after his death.
He was killed in the 69th year of his age, by an eagle
letting full a tortoise upon his head as he was walking in
the fields. He had the honor of a pompous funeral from
the Sicilians, who buried him near the river Gel-
a; and the tragedians of the country performed plays
and theatrical exercises at his tomb.—The best edition
of his plays is that of London, 1663, fol. with a Lu-
tin translation, and a learned commentary by Thomas
Stanley.

Æschynomene, bastard sensitive-plant:
A genus of the decandria order, belonging to the dia-
delphia class of plants, and is characterized by these:
The calyx has one leaf; campion-like petal-like
flats; the lips equal, but the inferior one two-
cleft, the inferior tridentate. The corolla is pilo-
aceous; the banner curved and subfusiform; the alae
ovate, obtuse, and shorter than the banner; and the
carpus united, pointed, and the length of the ala.
The stamina consists of 10 simple g-lipped filaments;
the anthers small. The pistil is an ovoid pellucid
vulgaris; the style is styliform and ascending,
the stigma simple and somewhat obvolute. The pericar-
plus is a long comma-like, unilocular jointed pod.
The seeds are kidney-shaped, and solitary within each
joint. Of this genus there are reckoned six.

Species. 1. The alpina (as well as the rest of this gen-
us) is native of warm countries. It rises to the height
of four or five feet, having a single herbaceous flake,
which is rough in some parts. The leaves come out on
every side towards the top, forming a sort of head;
the flowers come out between the leaves, two or three
above, one after the other; after the flower is past,
the calyx becomes a flat jointed pod, which, when ripe,
parts at the joints, and in such division is lodged a single
kidney-shaped seed. 2. The American, feldam: more
than two feet in height. The flowers come out from
the leaves on branching footstalks, five or six to
gether; there are much less than the former, and of
a paler yellow color. The seed is lodged in pods like the
other. 3. The arborv. grows to the height of six or
seven feet, with a single stem; the flowers come out two
or three together, of a copper color, and as large as
those of the alpina. 4. The Sicilian hath woody stems, and
branches garnished with smooth leaves. The flowers
are small, of a deep yellow color, and consist of six
sepals hanging downward. The seed is contained in
a smooth pod not jointed. 5. The pinnata, rises to
the height of about three feet, has flowers of a pale
yellow color, which comes out sometimes single, at
other times two or three upon each footstalk. The seeds
are contained in a long-calcated pod having 13 or 14
divisions, each of which lodges a single seed. 6. The
grandiflora, rises six or eight feet high, with a woody
stem, sending out branches towards the top, garnished
with obtuse leaves. The flowers are large, yellow, and
succeeded by large pods containing kidney-shaped
seeds.

Cult. These plants are propagated by seeds,
which should be sown early in the spring, on a bed;
and when the pods have grown enough to be
removed, they should be placed in a sepulchral box
filled with light earth, and plunged into a hot-bed.
As they increase in size, they must be removed into
large pots; but if these are too large, the plants
will not thrive. They must be brought forward early in
the year, otherwise the second kind will not perfect its feed.

Æsculapius, in the Heathen mythology, the
god of physic, was the son of Apollo and the nymph
Cleonis. He was educated by the Centaur Chiron,
who taught him physic; by which means. Æsculapius
secured the most delicate diseases. But Jupiter, enraged
at his refraining to the Hippocrites, who had been torn
in pieces by his own horses, killed him with a thunder
bolt. According to Celsus, there were three deities
of this name: the first, the son of Apollo, worshipped
in Arcadia, who invented the probe, and landscapes for
wounds; the second, the brother of Mercury, killed
by lightning; and the third, the son of Ares and
Arotius, who first taught the art of tooth-drawing
and setting. At Epidaurus, Æsculapius's statue was
made of gold and ivory, with a long beard, his head
wound with rays, holding in one hand a knotty stick,
and the other entwined with a serpent; he was seated
on a throne of the same materials as his statue, and
had a dog lying at his feet. The Romans crowned him
with laurel, to represent his descent from Apollo, and
the Phyllistans represented him as bearded. The cock,
the raven, and the goat, were sacred to this deity. His
chief temples were at Pergamus, Smyrna, Tris, a city
in Ionia, and the isle of Cos; in all which, votive
tables were hung up, showing the diseases cured
by his assistance. But his most famous shrine was at Epidau-
rus; where, every five years, games were instituted to
him, nine days after the Ethiopian games at Corinth.

Æsculus, the Horse-chestnut:
A genus of the monogynia order, belonging to the heptandria
class of plants; and ranking, in the natural method,
under the 30th order, Tribulata. —The characters are:
The caulis is a small single-leaved, bellied perianthium,
divided into five segments. The corolla (except in the
bearded, where it is four-petaled and close) consists of
five roundish, flat expanding petals, unequal-colored,
and with narrow claws inserted into the calyx.
The stamina have seven filiform declinate filaments,
the length of the corolla; the anthers ascending. The
pistillum is a roundish germen, ending in a subulate
filum; the stigma pointed. The pericarpium is a
leathery, roundish, tribacular, three-valved capsule.
The seeds are two, sublobular. In this genus Van Rozen and Miller observe both male and herma-
phrodite flowers. There are two

Species. 1. The hippocampum, or common horse-
chestnut. It was brought from the northern parts of
Asia about the year 1570, and from Vienna about
1592. This tree makes a noble appearance all the
month of May, the exuberances of the branches being
terminated by fine spikes of flowers spotted with rose
colours, so that the whole tree becomes covered with them.
It is quick in its growth; so that in a few years it ar-
ives at a size large enough to afford a good shade in
summer,
summer, as also to produce plenty of flowers. They have, however, this great inconvenience, that their wood is of no use, being unfit even for burning; and their leaves beginning to fall in July, soon deprive the trees of their beauty. There is something very singular in the growth of these trees; which is, that the whole shoot is performed in less than three weeks after the buds are opened. — The nuts are reckoned good food for hares. In Turkey, they are ground, and mixed with the provender for these animals, especially those which are troubled with coughs, and broken winded. Deer are also very fond of the fruit; and at the time of their ripening keep much about the trees, but especially in strong winds, when the nuts are blown down, which they carefully watch, and greedily devour as they fall.

2. The pavia, or scarlet-flowering horse-chestnut, a native of Carolina, the Brazil, and the East. It grows to about fifteen or sixteen feet high; and there is a delicacy in this tree that makes it desirable. The bark of the young shoots is quite smooth, and the growing shoots in summer are of a redish hue. The leaves are palmated, being pretty much like those of the horse-chestnut, only much smaller, and the indentures at the edges are deeper and much more acute. The lobes of which they are composed are spear-shaped; they are five in number, are united at their base, and stand on a long red footstalk. The leaves grow opposite by pairs on the branches, which are spread abroad on every side. The flowers come out from the ends of the branches. The first appearance of the buds is in May; though they will not be in full bloom till the middle of June. They are of a bright red color, and consequently have a pleasing effect among the vast tribe of yellow-flowering forts which show themselves in bloom at that season. They continue in succession for upwards of six weeks, and sometimes succeeded by ripe seeds in our gardens.

Propagation and culture. The first species is propagated from the nuts. In autumn, therefore, when they fall, a sufficient quantity should be gathered. These should be sown soon afterwards in drills, about two inches in depth. If the nuts are kept till spring, many of them will be faulty; but where the eminence cannot be got ready before, and they are kept too long, it may be proper to put them in water, to try their goodness. The good nuts will sink, whilst those which are faulty will swim; so that by proving them this way you may be sure of good nuts, and have more promising hopes of a crop. In the spring the plants will come up; and when they have been one year, they may be taken up, their top-roots shortened, and afterwards planted in the nursery. When they are of sufficient size to be planted out finally, they must be taken out of the nursery with care, the great side-shoots and the bruised parts of the roots should be taken off, and then planted in large holes level with the surface of the ground, at the top of their roots; the fibres being laid spread and lapped in the fine mold, and the turf also worked to the bottom. A stake should be placed to keep them safe from the winds; and they must be fenced from the cattle till they are of a sufficient size to defend themselves. The best season for all this work is October. After the trees are planted, neither knife nor hatchet should come near them; but they should be left to Nature to form their beautiful parabolic heads, and assume their utmost beauty. — The horse-chestnut, like most other trees, delights most in good fat land; but it will grow exceedingly well on clayey and marley grounds.

Miller says, “When these trees are transplanted, their roots should be preferred as entire as possible, for they do not succeed well when torn or cut: nor should any of the branches be shortened, for there is scarce any tree that will not bear amputation better than this; so that when any branches are by accident broken, they should be cut off close by the stem, that the wound may heal over.”

The second species is propagated, 1. By budding it upon the young plants of the horse-chestnut. These stocks should be raised as was directed in that article. They should be planted in the nursery way, one foot asunder, and two feet distant in the rows, which should be kept clean of weeds, and must be dug between every winter till the operation is to be performed. After they have stood in the nursery-ground about two years, and have made at least one good summer’s floor, the summer following is the time for the operation. Then, having your cuttings ready soon after midsummer, the evenings and cloudy weather should be made choice of for the work. Whoever has a great number of trees to inoculate, must regard no weather, but keep working, to get his business over before the season ends; and, indeed, a good hand will be always pretty sure of success be the weather what it will. If the stocks were healthy, the summer following they will make pretty good shoots; and in a year or two after that will flower. This is one method of propagating this tree; and those plants that are propagated this way will grow to a larger size than those raised immediately from seeds. — 2. This tree also may be propagated by seeds; which will sometimes ripen with us, and may be obtained out of our gardens. The manner of raising them this way is as follows: Let a warm border be prepared; and if it is not naturally sandy, left drift-sand be mixed with the soil; and in this border let the seeds be sown in the month of March, about half an inch deep. After this, constant weeding must be observed; and when the plants are come up, if they could be shaded in the heat of the day, it would be much better. These, with now and then a gentle watering in a dry season, will be all the precautions they will require the first summer. The winter following, if the situation is not extremely well sheltered, protection must be given them from the hard black frosts, which will otherwise often destroy them; so that it will be the safest way to have the bed hooped, to cover them with mats in such weather, if the situation is not well defended: if it is, this trouble may be saved; for, even when young, they are tolerably hardy. In about two or three years they may be removed into the nursery, or planted where they are to remain, and they will flower in three or four years after. The usual nursery-care must be taken of them when planted in that way; and the best time for planting them there, or where they are to remain, is October; though they will grow exceeding well if removed in any of the winter months; but if planted late in the spring, they will require more watering, as the ground will not be so regularly settled.
ÆSOP, the Phrygian, lived in the time of Solon, about the 50th Olympiad, under the reign of Croesus the last king of Lydia. As to genius and abilities, he was greatly indebted to nature; but in other respects not to fortune, being born a slave and extremely deformed. St. Jerome, speaking of him, says he was fortunate in his birth, condition in life, and death; shining thereby at his deformity, servile state, and tragical end. His great genius, however, enabled him to support his misfortunes; and in order to alleviate the hardships of servitude, he composed those entertaining and instructive fables which have acquired him so much reputation. He is generally supposed to have been the inventor of that kind of writing; but this is contested by several, particularly Quintilian, who seems to think that Hesiod was the first author of fables. Æop, however, certainly improved this art to a very great degree; and hence it is that he has been accounted the author of this sort of productions:

Nunc ego possui veribus facinus.

If any thoughts in these iambics shine,

The invention’s Æop’s, and the veris is mine.

The first master whom Æop served, was one Carausus Demarchus, an inhabitant of Athens; and there in all probability he acquired his purity in the Greek tongue. After him he had several masters; and at length came under a philosopher named Idmon or Iadmon who enfranchised him. After he had recovered his liberty, he soon acquired a great reputation amongst the Greeks; so that, according to Meziriac, the report of his wisdom having reached Croesus, he sent to inquire after him, and engaged him in his service. He travelled through Greece, according to the same author: whether for his own pleasure, or upon the affairs of Croesus, is uncertain; and passing by Athens soon after Phalaris had usurped the sovereign power, and finding that the Athenians bore the yoke very impatiently, he told them the fable of the frogs who petitioned Jupiter for a king. The images made use of by Æop are certainly very happy inventions to instruct mankind; they polish all that is necessary to perfect a precept, having a mixture of the useful with the agreeable. Æop the fabulist (Aesius Gallus) was deservedly esteemed, since he did not, after the manner of the philosophers, rigidly and imperiously delineate such things as were proper to be advised and persuaded; but, framing entertaining and agreeable apologies, he thereby charms and captivates the human mind.

Æop was put to death at Delphi. Plutarch tells us that he came there with a great quantity of gold and silver, being ordered by Croesus to offer a sacrifice to Apollo, and to give a considerable sum to each inhabitant: but a quarrel arising between him and the Delphians, he sent back the money to Croesus; for he thought those to whom the prince designed it, had rendered themselves unworthy of it. The inhabitants of Delphi contrived an accusation of sacrilege against him; and pretending they had convicted him, threw him headlong from a rock. For this cruelty and injustice, we are told they were visited with famine and pestilence; and consulting the oracle, they received for answer, that the god designed this as a punishment for their treatment of Æop: they endeavoured to make an atonement, by raising a pyramid to his honour.

Æop (Clodiaus), a celebrated actor, who flourished about the 670th year of Rome. He and Roscius were contemporaries, and the best performers who ever appeared upon the Roman stage, the former excelling in tragedy, the latter in comedy. Cicero put himself under their direction to perfect his action. Æop lived in a most expensive manner, and at one entertainment is said to have had a dish which cost above eight hundred pounds; this dish, we are told, was filled with singing and speaking birds, some of which cost near 500. The delight which Æop took in these sorts of birds proceeded, as Mr. Bayle observes, from the expense. He did not make a dish of them because they could speak, according to the refinement of Pliny upon this circumstance, this motive being only by accident; but because of their extraordinary price. If they had been any birds that could not speak, and yet more scarce and dear than these, he would have procured such for his table. Æop's son was no less luxurious than the father, for he dissolved pearls for his guests to swallow. Some speak of this as a common practice of his; but others mention his falling into this excess only on a particular day, when he was treating his friends. Horace speaks only of one pearl of great value, which he dissolved in vinegar, and drank. Æop, notwithstanding his expenses, is said to have died worth above 160,000. When he was upon the stage, he entered into his part to such a degree, as sometimes to be feized with a perfect ecstacy: Plutarch mentions it as reported of him, that whilst he was representing Aneas deliberating how he should revenge himself on Thetis, he was so transported beyond himself in the heat of action, that with his truncheon he smote one of the servant crossing the stage, and laid him dead on the spot.

ÆSTIMATIO CAPITIS, a term met with in old law-books for a fine anciently ordained to be paid for offences committed against persons of quality, according to their several degrees.

ÆSTIVAL, in a general sense, denotes something connected with, or belonging to, summer. Hence æstival sign, æstival solstice, &c.

ÆSTUARIA, in geography, denotes an arm of the sea, which runs a good way within land. Such is the Chesapeake-bay, &c. ÆSTUARIES, in ancient baths, were secret passages from the hypocaust into the chambers.

ÆSTUARY, among physicians, a vapour-bath, or any other instrument for conveying heat to the body.

ÆSYMNIIUM, in antiquity, a monument erected to the memory of the heroes, by Æsumus the Megarean. He consulting the oracle in what manner the Megarians might be most happily governed, was answered, If they hold communion with the more numerous: whom he taking for the dead, built the said monument, and a sepulchre that took within its compass the monument; imagining, that thus the dead would afflict their confulsions. (Pausanias.)

ÆTH, or ÆTH, a strong little town in the Austrian Netherlands and province of Hainaut, situated on the river Dender, about twenty miles S. W. of Brussels.

ÆTHALIA, a lat. (anc. geog.) now Elba; an island.

AETh, island on the coast of Ethiopia, in compass an hundred miles, abounding in iron, as the still does. Stephanus calls it Aethale. The port of Aethalia was called Argus. (Diod. Sicul.)

AETHESAN, See AETHESAN.

Aether, is usually understood of a thin, subsible matter, or medium, much finer and rarer than air; which commencing from the limits of our atmosphere, pervades the whole heavenly space. - The word is Greek, ἀήθερος, supposed to be formed from the verb ἀφέω, "to burn, to flame." Some of the ancients, particularly Anaxagoras, supposing it of the nature of fire. See Fire.

The philosophers cannot conceive that the largest part of the creation should be perfectly void; and therefore they fill it with a species of matter under the denomination of aether. But they vary extremely as to the nature and character of this aether. Some conceive it as a body of a generis, appointed only to fill up the vacancies between the heavenly bodies; and therefore confined to the regions above our atmosphere. Others suppose it of so subsible and penetrating a nature, as to pervade the air, and other bodies, and polishes the pores and intervals thereof. Others deny the existence of any such specific matter; and think the air itself, by that immense tenuity and expansion it is found capable of, may diffuse itself through the interstellar spaces, and be the only matter found therein.

In effect, aether, being no object of our sense, but the mere work of imagination, brought only upon the stage for the sake of hypothesis, or to solve some phenomenon, real or imaginary; authors take the liberty to modify it as they please. Some suppose it of an elementary nature, like other bodies; and only distinguished by its tenuity, and the other affections consequent thereon: which is the philosophical aether. Others will have it of another species, and not elementary; but rather a sort of fifth element, of a purer, more refined, and spiritual nature, than the substances about our earth: and void of the common affections thereof, as gravity, &c. The heavenly species being the supposed region or residence of a more exalted class of beings, the medium must be more exalted in proportion. Such is the ancient and popular idea of aether, or aetherial matter.

The term aether being thus embarrased with a variety of ideas and arbitrarily applied to so many different things, the later and fewer philosophers choose to set it aside, and in lieu thereof substitute other more determinate ones. Thus, the Cartesians use the term materia fictilib; which is their aether: and Sir Isaac Newton, sometimes a fictile spirit, as in the close of his Principia; and sometimes a fictile or aetherial medium, as in his Optics.

The truth is, there are abundance of confederations, which seem to evince the existence of some matter in the air, much finer than the air itself. There is an unknown something, which remains behind when the air is taken away; as appears from certain effects which we see produced in vacuo. Heat, Sir Isaac Newton observes, communicated through a vacuum almost as readily as through air: but such communication cannot be without some interjacent body, to act as a medium. And such body may be fictible enough to penetrate the pores of glass; and may be very well con-

cluded to penetrate those of all other bodies, and consequently be diffused through all the parts of space which answers to the full character of an aether. See Heat.

The existence of such an aetherial medium being settled, that author proceeds to its properties; inferring it to be not only rarer and more fluid than air, but exceedingly more elastic and active: in virtue of which properties, he shows, that a great part of the phenomena of nature may be produced by it. To the weight, e. g. of this medium, it attributes gravitation, or the weight of all other bodies; and to its elaticity, the elastic force of the air and of nervous fibres, and the emission, reflection, refraction, and other phenomena of light; as also, sensation, muscular motion, &c. In fine, this same matter forms the primum mobile, the first source or spring of physical action in the modern system.

The Cartesians aether is supposed not only to pervade, but adequately to fill, all the vacancies of bodies; and thus to make an abdication in the universe.

But Sir Isaac Newton overturns this opinion from divers considerations; by showing, that the celestial spaces are void of all sensible resistance: for, hence it follows, that the matter contained therein must be immensely rare, in regard the resistance of bodies is chiefly as their densitity; so that if the heavens were thus adequately filled with a medium or matter, how fictible soever, they would resist the motion of the planets and comets much more than quicksilver or gold.

The late discoveries in electricity have thrown great light upon this subject, and rendered it extremely probable that the aether so often talked of is no other than the electric fluid, or solar light, which diffuses itself throughout the whole system of nature. See Electricity, Fire, Heat, Light, &c.

Aether, in chemistry, the lightest, most volatile, and most inflammable of all liquids, is produced by distillation of acids with redined spirit of wine. See Chemistry and Pharmacy (Indexes).

Aetherial Etymus, something that belongs to, or partakes of, the nature of Aether. Thus we say, the aetherial space, aetherial regions, &c.

Some of the ancients divided the universe, with respect to the matter contained therein, into elementary and aetherial.

Under the aetherial world was included all that space above the uppermost element, viz. fire. This they supposed to be perfectly homogeneous, incorruptible, unchangeable, &c. See Corruption. The Chaldees placed an aetherial world between the empyreum and the region of the fixed stars. Before which, they sometimes also speak of a second aetherial world, meaning by it the fiery orb; and a third aetherial world, by which is meant the planetary region.

Æthiopia. See ETHIOPIA.

Æthiops, Mineral, Natural, and Antimonial. See Pharmacy (Indexes).

Æthusa, in botany, a genus of the pentandria digyna class; and, in the natural method, ranking under the 45th order, Umbellate. The characters are: The calyx is an universal umbel expanding, the interior rays shorter by degrees; with a partial umbel, small, and expanding. There is no universal involucrum; the partial one is dissimilated, with three or five leaflets,
Aetian, born in Syria, was a grammarian, theologian, and physician. His followers were called Aetians.

Aetius, a famous physician, born at Amida in Mesopotamia, and the author of a work entitled Terrae Nativae, which is a collection from the writings of those physicians who went before him. He lived, according to Dr Friend, at the end of the 5th or the beginning of the 6th century.

Aetius, governor of Gallia Narbonensis in the reign of Valentinian III, forced the Franks who were passing into Gaul to repulse the Rhine. He defeated the Goths; and routed Attila king of the Huns, who invaded Gaul with an army of 700,000 men. But the emperor, jealous of the merit of this great man, killed him in 454 with his own hand, under the pretense that he had permitted the invasion of the Huns, after Attila's defeat.

Aetna, in the Itineraries Ethuna, supposed from δ
to burn; according to Bochart, from Athina, a furnace, or Ethuna, darknits, now Monte Cibele: a volcano or burning mountain of Sicily, situated in lat. 38° N. long. 15° E.

This mountain, famous from the remotest antiquity, both for its bulk and terrible eruptions, stands in the eastern part of the island, in a very extensive plain, called Val Demoni, from the notion of its being inhabited by devils, who torment the spirits of the damned in the bowels of this volcano.

Concerning the dimensions of mount Ætna, we can inconceivably extract any thing confident, even from the accounts of the latest and most ingenious travellers. Pindar, who lived about 435 years before Christ, calls it the Piller of heaven, on account of its great height. All modern writers likewise agree, that this mountain is very high, and very large; but differ excessively both as to its height and magnitude: some making it no less than twelve miles high, others eight, others fix, some four, while Mr Brydone, and Sir William Hamilton, who lately ascended to its highest summit, reduce its height to little more than two miles; nay, by some it is reduced to 10,036 feet, somewhat less than two miles. No less remarkable are the differences concerning its circumference: some making it only 60 miles round, others 100; and Signior Recupero, from whom Mr Brydone had his information in this respect, affirms it to be no less than 183 miles in circuit.

We are forry to detract from the merit of Mr Brydone, or to involve in obscurity what he hath been so much pains to elucidate; but every person who compares the account of mount Ætna's circumference, given by Signior Recupero, and to which Mr Brydone seems to have attented, with its apparent circumference on the map prefixed to that gentleman's tour through Sicily and Malta, must at once be struck with the prodigious disparity. Indeed, it is plain, that, in the map, the geographer hath not left room for any such mountain; nor can we help thinking, that, by comparing the distances of some of the Sicilian towns from one another, Signior Recupero's dimensions will be found excessively exaggerated. Certain it is, that there the geographer hath placed Catania, which stands at the foot of mount Ætna, on one side, no more than 38 miles from the most distant point of the river Alcanara.
is probably very uncertain.

If we are embarrassed with the circumference of Mount Etna, we are much more so with the accounts relating to its height; and one circumstance, particularly, creates almost insurmountable difficulties. It is agreed upon by all travellers, and among the rest by Sir William Hamilton, that from Catania, where the ascent first begins, to the summit, is no less than 50 miles. The descent on the other side we have no account of; but whatever supposition we make, the height of the mountain must be prodigious. If we suppose it likewise to be 30 miles, and that Mount Etna can be represented by an equilateral triangle, each of whose sides is 30 miles, we will have an amazing elevation indeed, no less than 26 miles perpendicular. Such a height being beyond all credibility, we must contradict the sides of our triangle, in proportion to its basis. We shall begin with allowing 10 miles for the difference between a straight line from Catania to the summit, and the length of the road, occasioned by the inequalities of the mountain; and supposing the descent on the other side to be somewhat shorter, we may call it 15 miles. Mount Etna will now be represented by a scalene triangle, whose base is 30 miles, its longest side 20, and its shortest 15; from which proportions we will still find its height to be but what height, and when all the various relations concerning the height of Etna are compared, we hope it will not be thought presumptuous in us to give it as our opinion, that the true dimensions of this mountain are yet unknown. The following measures are given by different authors:

- Height above the surface of the sea, 10,036 feet. Faujas de S. Fon in his Volcani of the Vivarais.
- Height 12,000 feet. Brydone. Tour to Sicily.
- Height 2500 toises. La Platriere, said as from Recupero.

Diameter 1500 toises — Diameter 30 miles. — Gentille Geogr, comp.

Others make its height only 2000 toises, and its superficies 300 square miles.

Concerning the products and general appearance of this volcano, authors are much better agreed. The journey from Catania to its summit has been lately described by three travellers, M. O'Orville, Mr Brydone, and Sir William Hamilton. All these agree, that this single mountain affords an epitome of the different climates throughout the whole world: towards the foot, it is very hot; farther up, more temperate; and grows gradually more and more colder the higher we ascend. At the very top, it is perpetually covered with snow: from thence the whole island is supplied with that article, so necessary in a hot climate, and without which the natives say Sicily could not be inhabited. So great is the demand for this commodity, that the bishop's revenues, which are considerable, arise from the sale of mount Etna's snow; and he is said to draw 1000l. a year from one small portion lying on the north side of the mountain.

Great quantities of snow and ice are like-wise exported to Malta and Italy, making a considerable branch of commerce. On the north side of this snowy region, Mr Brydone was assured, that there are several small lakes which never thaw; and that the snow mixed with the ashes and salt of the mountain are accumulated to a vast depth. The quantity of salts contained in this mountain, he, with great probability, conjectures to be one reason of the preservation of its snows; for salt creates the coldness of snow to a surprising degree.

In the middle of the snowy regions stands the great crater, or mouth of Etna; from which, though contrary to the usual method of travellers, we shall begin our particular account of this mountain. Sir William Hamilton describes the crater as a little mountain about a quarter of a mile perpendicular, and very steep, situated in the middle of a gently inclining plain, of about nine miles in circumference. Its entirely formed of ashes and stones; and, as Mr Hamilton was informed by several people of Catania, had been thrown up about 25 or 30 years before the time (1769) he visited Mount Etna. Before this mountain was thrown up, there was only a prodigious large chasm, or gulf, in the middle of the abovementioned plain; and it has been remarked, that about once in 100 years the top of Etna falls in; which undoubtedly must be the cafe at certain periods, or the mountain behaved continually to increase in height. As this little mountain, though emitting smoke from every pore, appeared solid and firm, Mr Hamilton and his companions went up to the very top. In the middle is a hollow, about two miles and a half in circumference, according to Mr Hamilton; three miles and a half, according to Mr Brydone; and three or four, according to Mr O'Orville. The inside is eroded with voids with falt and sulphur of different colours. It goes shelving down, from the top, like an inverted cone: the depth, in Mr Hamilton's opinion, nearly corresponding to the height of the little mountain. From many places of this space issue volumes of sulphurous smoke, which being much heavier than the circumambient air, instead of ascending in it, roll down the side of the mountain, till, coming to a more dense atmosphere, it floats off horizontally, and forms a large tract in the air, according to the direction of the wind; which, happily for our travellers, carried it exactly to the side opposite to which they were placed. In the middle of this funnel is the tremendous and unfathomable gulph, so much celebrated in all ages, both as the terror of this life, and the place of punishment in the next. From this gulph continually issue terrible and confused noises, which in eruptions are increased to such a degree as to be heard at a prodigious distance. Its diameter is probably very different at different times: for Mr Hamilton observed, by the wind clearing away the smoke from time to time, that the inverted hollow cone was contracted almost to a point; while Mr O'Orville and Mr Brydone found the opening very large. Both Mr Brydone and Mr Hamilton found the crater too hot to descend into it; but Mr O'Orville was bolder: and accordingly he and his fellow-traveller, fastened to ropes which two or three men held at a distance for fear of accidents, descended as near as possible to the brink of the gulph; but the small flames and smoke which issued from it on every side, and a greenish sulphur, and pumice-flakes, quite black, which covered the margin, would not permit them to come so near
as to have a full view. They only saw difficulty in the middle, a mass of matter which rose, in the shape of a cone, to the height of about 60 feet, and which towards the base, as far as their sight could reach, might be seen for 6 or 8 miles. While they were observing this substance, some motion was perceived on the north side, opposite to that whereon they stood: and immediately the mountain began to send forth smoke and ashes. This eruption was preceded by a fearful increase of its internal roarings; which, however, did not continue; but after a moment's dilatation, as if to give it vent, the volcano resumed its former tranquillity; but as it was by no means proper to make a longer stay in such a place, our travellers immediately returned to their attendants.

On the summit of mount Étna, Mr Hamilton observes, that he was sensible of a difficulty in respiration from the too great suffocation of the air, independent of what arose from the sulphurous smoke of the mountain. Mr Brydooe takes no notice of this, which probably arose from the air being in a more rarefied state at the time of Mr Hamilton's observations than of Mr Brydone's; the barometer, as observed by the former, standing at 18 inches and 10 lines, by the latter at 19 inches 6 lines.

In these high regions there is generally a very violent wind, which, as all our travellers found it constantly blowing from the south, may possibly be commonly directed from that point. Here Mr Brydone's thermometer fell to 27°.

The top of Étna being above the common region of vapours, the heavens appear with exceeeing great splendor.—Mr Brydone and his company observed, as they ascended in the night, that the number of stars seemed to be infinitely increased, and the light of each of them appeared brighter than usual: the whiteness of the milky-way was like a pure flame which shot across the heavens; and, with the naked eye, they could observe clusters of stars that were invisible from below. Had Jupiter been visible, he is of opinion that none of his satellitcs might have been discovered with the naked eye, or at least with a very small pocket-glass.

He likewise took notice of several of those meteors called falling stars; which appeared as much elevated as when viewed from the plain: a proof, according to Mr Blydone, that the celestial bodies move in regions “much beyond the bounds of some philosophers who have alligned to our atmosphere.”

To have a full and clear prospect from the summit of mount Étna, it is necessary to be there before sunrise; as the vapours rising by the sun, the day-time, will obscure every object: accordingly, our travellers took care to arrive there early enough; and all agree, that the beauty of the prospect from thence cannot be expressed.—Here Mr Brydone and Mr Hamilton had a view of Calabria in Italy, with the sea beyond it: the Lipari islands; and Stromboli a volcano at about 70 miles distance, appeared just under their feet; the whole island of Sicily, with its rivers, towns, harbours, &c. appeared distinct, as if seen on a map. Naples, a Sicilian author, affirms, that the African coast, as well as that of Naples, with many of its islands, have been discovered from the top of Étna. The visible horizon here is not less than 8 or 900 miles in diameter. The pyramidal shadow of the mountain reaches across the whole island, and far into the sea on the other side, forming a visible tract in the air, which, as the sun rises above the horizon, is shortened, and at last confined to the neighbourhood of Étna. The most beautiful part of the scene, however, in Mr Brydone's opinion, is the mountain itself, the island of Sicily, and the numerous islands lying round it. These last seem to be close to the skirts of Étna; the distances appearing reduced to nothing.

This mountain is divided into three zones, which division might properly enough be distinguished by the names of torrid, temperate, and frigid: they are, however, known by the names of the Fuedes; or Regions cultura, the cultivated or fertile region; the Sylviea, woody, osiperme region; and the Region deserta, the frigid, or desert zone, or region. These are plainly distinguished from the summit. The Region deserta is marked round by a circle of snow and ice, which extends on all sides to the distance of about eight miles, beginning at the foot of the crater. Greatest part of this region is smooth and even. This is immediately succeeded by the Sylviea, or woody region; which forms a circle of the most beautiful green, surrounding the mountain on all sides. This region is variegated with a vast number of mountains of a conical form, thrown up by Étna in those eruptions which burst out from its sides. Mr Hamilton counted 34 on the Carania side, each having its crater, many with large trees flourishing both within and without the craters. All these except a few of late date, have acquired a wonderful degree of fertility. The circumference of this zone, or great circle, according to Reeperbo, is not less than 700 or 80 miles. It is everywhere succeeded by the Regions cultura: which is much broader than the rest, and extends on all sides to the foot of the mountain. Here terrible devastations are sometimes committed by the eruptions; and the whole region is likewise full of conical mountains thrown up by them. The circumference of this region, is, by Reeperbo, reckoned 182 miles; but we have already given our reasons for rejecting these dimensions. This region is bounded by the sea to the south and south-east; and on all other sides, by the river Semetus and Alcantara, which form the boundaries of mount Étna.

About a mile below the foot of the great crater, are il Torre dal Foso, by some supposed to have been built by the philosopher Empedocles, who took up his habitation here, the better to study the nature of mount Étna. By others they are supposed to be ruins of a temple of Vulcan. They are of brick, and seem to have been ornamented with marble. Some where in this region also, Mr D'Orville found a great oblong block of polished marble, eight or ten feet high, and three or four thick; though how it came there was quite unaccountable to him. From Mr D'Orville's and Mr Brydone's accounts we must reckon this part of the mountain pretty steep; but Mr Hamilton says, that the ascent was so gradual, as not to be in the least fatiguing; and had it not been for the snows, they might have rode on their mules to the very foot of the crater.

The woody region extends eight or nine miles beyond the Region deserta, but differs greatly in the temperature of the climate. Mr Hamilton observed a gradual decrease of the vegetation as he advanced; the underparts being covered with large timber trees, which grew...
The woody region, especially the Culta, grew gradually less as he approached the third region, at last they degenerated into the small plants of the northern climates. He also observed quantities of juniper and tansey; and was informed by his guide, that later in the season (he visited Ætna in June 1769) there are a great many curious plants, and in some places rhubarb and saffron in great plenty. In Carrera’s history of Catania, there is a list of all the plants and herbs of Ætna, in alphabetical order.

This region is extolled by Mr. Brydone as one of the most delightful spots on earth. He lodged for a night in a large cave near the middle, formed by one of the most ancient lavas. It is called La Spelonca del Capi­ole, or the goat’s cavern, because it is frequented by those animals, which take refuge there in bad weather. Here his rest was disturbed by a mountain thrown up in the eruption 1766. It discharged great quantities of smoke, and made several explosions like heavy cannon fired at a distance; but they could observe no appearance of fire.

This gentleman likewise visited the eastern side of the Regione Culta, intending to have ascended that way to the summit, and defended again on the south side to Catania; but found it impracticable; though what the uninmountable difficulties were, he does not mention. On this side, part of the woody region was destroyed, in 1755, by an immense torrent of boiling water which issued from the great crater. Its traces were still very visible, about a mile and a half broad, and in some places more. The foil was then only beginning to recover its vegetative power, which it seems this torrent had destroyed for 4 years. Near this place are some beautiful woods of cork, and evergreen oak, growing absolutely out of the lava, the soil having hardly filled the crevices, and not far off our traveller observed 7 little mountains that seemed to have been formed by a late eruption. Each of these had a regular cop, or crater, on the top; and, in some, the middle gulph, or Vesorina, as the Sicilians call it, was still open. Into these gulphs Mr. Brydone tumbled down stones, and heard the noise for a long time after. All the fields round, to a considerable distance, were covered with large burnt stones discharged from these little volcanoes.

The woody region, especially the east side, called Carpineto, abounds with very large chestnut-trees; the most remarkable of which has been called, from its size, Castagno de Gueto Cavallari, or chestnut-tree of an hundred horse. M. Brydone was greatly disappointed at the sight of this tree, as it is only a bush of five large ones growing together; but his guides assured him, that all these five were once united into one stem; and Signor Recupero told him, that he himself had been at the expense of carrying up peatants with tools to dig round this bush of trees, and found all the stems united below ground in one root. The circumference, as measured by Mefirs Brydone and Glover, who accompanied him, amounted to 204 feet. Another of these, about a mile and a half higher on the mountain, is called Castagna del Cala: it rises from one odd stem to a considerable height; after which it branches out, and is a much finer object than the other: this was measured two feet above the ground, and found to be 76 feet in circumference. A third, called Castagna del Naro, is pretty nearly of the same size; and Maffi, one of the most esteemed Sicilian authors, affirms that he has seen solid oaks there upwards of 40 feet round. All these, growing on a thick rich soil, which seems originally to have been formed of ashes thrown out by the mountain.

Here the barometer stood at 26 inches 5 lines and an half, indicating an elevation of near 4000 feet. The Piedmontese district is covered with towns, villages, monasteries, &c., and is well peopled, notwithstanding the danger of such a situation: but the fertility of the soil tempts people to inhabit that country; and their superfluous confidence in their saints, with the propensity mankind have to despise danger which they do not see, render them as secure there as in any other place. Here, Sir William Hamilton observes, they keep their vines low, contrary to the custom of those who inhabit mount Vefuvius; and they produce stronger wines, but not in such abundance: here also many terrible eruptions have burst forth; particularly one in 1669. At the foot of the mountain raised by that eruption, is a hole, through which Sir William neuse ca­ Hamilton descended, by means of a rope, into several subterraneous caverns, branching out and extending much farther than he chose to venture, the cold there being excessive, and a violent wind extinguishing some of the torches. Many other caverns are known in this and the other regions of Ætna; particularly one near this place called La Spelonca della Palomba, (from the wild pidgeons building their nests there.) Here Mr. Brydone was told that some people had lost their fowls, from having advanced too far, imagining they saw devils and damned spirits. Some of these caverns are made use of as magazines for snow; which they are well adapted for, on account of their extreme cold. These are with great probability supposed by Sir William Hamilton to be the hollows made by the inflowing of the lava in eruptions.

In this region the river Aetis, so much celebrated by the poets, in the fable of Acis and Galatea, takes its rise. It bursts out of the earth at once in a large stream, runs with great rapidity, and about a mile from its source throws itself into the sea. Its water is remarkably cold; and so extremely cold, that it is reckoned dangerous to drink it: it is said, however to have a pithomous quality, from being impregnated with vitriol; in consequence of which cattle have been killed by it. It never freezes, but is said often to contract a greater degree of cold than ice.

Having thus given an account of this mountain in appearance, its quiet and peaceable state, we must now describe its several eruptions during the time of our journey, when it spreads destruction for many miles round, and is capable of striking the boldest with terror.

Sir William Hamilton, who has examined both Vefuvius and Ætna in a very accurate manner, never had an opportunity of seeing an eruption of the latter; but as he is of opinion that the two volcanoes agree perfectly in all respects, only that the latter is on a much larger scale than the former, we hope it will not be unacceptable to our readers to give an account of some of the general appearances of Vefuvius when in a state of eruption, the better to help their ideas concerning Ætna.

It has been already observed, that a smoke constantly issues from the top of Ætna, and that its internal noises never cease. The cave is the same with Vefu­
The first symptom of an approaching eruption is an increase of the smoke in fair weather: after some time, a puff of black smoke is frequently seen to shoot up in the midst of the white to a considerable height. These puffs are attended with considerable explosions: for if this burning matter gets not sufficient vent, the conmotions increase to a prodigious degree. In the night-time the lava appears like a stream of fire, accompanied with flame; but in the day time it has no such appearance; its progress is marked by a white smoke, which by the reflection of the red-hot matter in the night affumes the appearance of flame.

All the abovementioned symptoms preceded the great Eruption in eruption of Ætna in 1669. For several months before 1669, the lava broke forth, the old month, or great crater on the summit, was observed to send forth great quantities of smoke and flame; the top had fallen in, so that the mountain was much lowered; the islands also of Vulcan and Strombolli, two volcanoes to the westward of Sicily, were observed to rage more than usual. Eighteen days before the eruption, the sky was very thick and dark, with thunder, lightning, frequent concussions of the earth, and dreadful subterraneous bellows. On the 11th of March, some time before the lava got vent, a rent was opened in the mountain twelve miles in length, into which, when stones were thrown down, they could not be heard to strike the bottom. Burning rocks, 60 palms (15 of our feet) in length, were thrown up with violence, to the distance of a mile; others of a lesser size were carried three miles off; the internal noises of the mountain were exceedingly dreadful, and the thunder and lightning from the smoke scarce less terrible than they. When the lava at last got vent, it burst out of a vineyard, 20 miles below the great crater, and sprung up into the air to a considerable height. Here it formed a column of flames and ashes, not less, as Sir W. Hamilton conjectures, than half a mile perpendicular in height, and three miles in circumference. For 34 days neither fire nor flames had appeared: but soon after the lava got vent, the mountain became very quiet. The terrible effects of this fiery stream may be imagined from its amazing extent; being, as Sir W. Hamilton observes, no less than 14 miles long, and in many places six in breadth. In its course, it destroyed the habitations of near 30,000 persons; and meeting with a lake four miles in compass, it not only filled it up, though several fathoms deep, but made a mountain in the place of it. Having reached Catania, it destroyed part of its walls, and ran for a considerable length into the sea, forming a safe and beautiful harbour; which, however, was soon filled up by a fresh torrent of the same inflamed matter.

It is not easy for those who have never been present at those terrible operations of nature, to represent to their minds the horrors which must attend the breaking forth of the lava; for though the giving vent to this burning matter generally produces a celloation of the violent efforts of the internal fire, yet at the very instant of its explosion scarce anything can be conceived so dreadful. See VESUVIUS.

When the lava first issues, it appears very fluid, and Hamilton's runs with the rapidity of a swift river; but even then it obtrudes surprizingly the impression of solid bodies: for Sir W. Hamilton could not pierce that of Vesuvius with a stick driven against it with all his force; nor did the largest stone he was able to throw upon it sink, but made a slight impression, and then floated along. This happened almost at the very mouth, when the lava appeared

Thunders &forked or zig-zag lightning, sometimes attended with thunder, and sometimes not, but equally powerful with ordinary lightning. This phenomenon was observed by Sir William Hamilton in the smoke of Vesuvius, and has also been taken notice of in that of Ætna; and where this electrified smoke hath spread over a tract of land, much mischief hath been done by the lightning proceeding from it.

After these dreadfil appearances have continued sometimes four or five months, the lava begins to make its appearance. This is a stream of melted mineral matters, which in Vesuvius commonly boils over the top, but very seldom does so in Ætna; owing to the great weight of the lava, which long before it can be raised to the vast height of mount Ætna, bursts out through some weak place in its side. Upon the appearance of the lava, the violent eruptions of the mountain generally, though not always, cease; for if this burning matter gets not sufficient vent, the conmotions increase to a prodigious degree. In the night-time the lava appears like a stream of fire, accompanied with flame; but in the day-time it has no such appearance; its progress is marked by a white smoke, which by the reflection of the red-hot matter in the night affumes the appearance of flame.
Lava of 1669 described.

Mount Etna, as we have already remarked, has been a celebrated volcano from the remotest antiquity. Diodorus Siculus mentions eruptions of it as happening 500 years before the Trojan war, or 1693 years before the Christian era. From Homer's silence with regard to the phenomenon of Etna, it is to be presumed that the volcano had been many ages in a state of inactivity, and that no tradition of its burning remained among the inhabitants at the time he composed his Odyssey; perhaps it never had emitted flames since the country was peopled. The first eruption taken notice of by ancient, but no means contemporary authors, happened before the Greeks landed on the island, and is supposed to have scared the Sicani from the east part of Sicily.

Pindar, quoted above, is the oldest writer extant who speaks of Etna as a volcano. The first recorded eruption was in the time of Pythagoras. Plato was invited by the younger Dionysius to examine the flame of the mountain after the sixth. It threw up flames and lava near an hundred times between that period and the battle of Pharaldia; it was particularly furious while Sextus Pompeius was adding the horrors of war to its devastations. Charlemagne happened to be at Catania during one of the eruptions; and from his reign the chronicles mention fifteen down to that of the year 1669, the most terrible of them all. Since 1669 there have been several eruptions, but none of them comparable to it. In that which happened in 1706, the lava sprang up into the air to a considerable height, twelve miles below the summit; but formed a stream only six miles in length and one mile in breadth.

The last eruption happened in 1727. From the 10th to the 10th of July, there were signs of its approach. On the 11th, after a little calm, there was a subterraneous noise, like the sound of a drum in a clofe place, and it was followed by a copious burst of black smoke. It was then calm till the 15th, when the same prognostics recurred. On the 17th, the subterraneous noise was heard again; the smoke was more abundant, flight clouds of an earthquake followed, and the lava flowed from behind one of the two little mountains which form the double head of Etna. On the 18th, while the spectators were in anxious expectation of a more severe eruption, all was quiet, and continued so more than 12 hours: soon after they perceived some new shocks, accompanied with much noise; and the mountain threw out a thick fmoak, which, as the wind was westerly, soon darkened the eastern horizon: two hours afterwards a shower of fine black brilliant sand descended; on the east side it was a storm of fomes; and, at the foot of the mountain, a deluge of flashes of fire, of coria, and lava.

These appearances continued the whole day; at the setting of the sun the scene changed. A number of conical flames rose from the volcano; one on the north, another on the south, were very conspicuous, and rose and fell alternately. At three in the morning, the mountain appeared cleft, and the summit formed a burning mafs. The cones of light which arose from the crater were of an immense extent, particularly the two just
just mentioned. The two heads seemed to be cut away; and at their separation was a cone of flame, seemingly composed of many lesser cones. The flame seemed of the height of the mountain placed on the mountain; so that it was probably two miles high, on a base of a mile and a half in diameter. This cone was full covered with a very thick smoke, in which there appeared very brilliant flashes of lightning, a phenomenon which Ætna had not before afforded. At times, sounds like those from the explosion of a large cannon were heard seemingly at a less distance than the mountain. From the cone, as from a fountain, a jet of many flaming volcanic matters were thrown, which were carried to the distance of six or seven miles: from the base of the cone a thick smoke arose, which, for a moment, obscured some parts of the flame, at the time when the rivers of lava broke out. This beautiful appearance continued three quarters of an hour. It began the next night with more force; but continued only half an hour. In the intervals, however, Ætna continued to throw out flames, smoke, fumes ignited, and showers of sand. From the 20th to the 22d, the appearances gradually ceased. The stream of lava was carried towards Bronte and the plain of Lago.

After the eruption, the top of the mountain on the western side was found covered with hardened lava, scoria, and stones. The travellers were annoyed by smoke, by flowers of sand, mephitic vapours, and excessive heat. They saw that the lava which came from the western point divided into two branches, one of which was directed towards Lipecchio; the other, as we have already said, towards the plain of Lago. The lava on the western head of the mountain, had from its various shapes been evidently in a state of fusion: from one of the fissures, the odour was strongly that of sulphur. The thermometer, in descending, was at 40 degrees of Fahrenheit's scale; while near the lava, in the plain of Lago, it was 140 degrees. The lava extended two miles; its width was from 133 to 21 feet, and its depth 3 feet 2 inches. These are the most remarkable circumstances we have been able to collect; that might serve to give an adequate idea of this famous mountain. — Many things, however, concerning the extent, antiquity, &c. of the lavas, remain to be discussed, as well as the opinions of philosophers concerning the origin of the internal fire which produces so much mischief; but the consideration of these belongs to the general article Volcanó, to which the reader is referred. — The fate of Catania and Hybla, which have often been destroyed by eruptions, will be mentioned under their two words. Ætna, Ætna hail, Sol Ætnae, a name given by some authors to the salt ammoniac, which is found on the surface and sides of the openings of Ætna, and other burning mountains after their eruptions; and sometimes on the surface of the ferruginous matter which they throw out. This salt makes a very various appearance in many cases; it is sometimes found in large and thick cakes, sometimes only in form of a thick powder, scattered over the surface of the earth and stones. Some of this salt is yellow, some white, and some greenish. This salt is a concretion of nitre, sulphur, and vitriol, burnt and sublimed together; Borelli found once a vast quantity of this salt on mount Ætna, and tried many experiments on it: from whence he concluded, that this salt is so far from occasioning the explosions of that mountain, as some have supposed, that it does not exist in it, but is formed during the burning.

Phila. Trans. N° 100.

Ætolarcha, in Grecian antiquity, the principal magistrate or governor of the Ætolians.

APOLLO (Domitian), a famous orator, born at Nîmes, nourished under Tiberius and the three succeeding emperors. Quintilian makes frequent mention of him, and commends his pleadings. But he disgraced his talents, by turning informer against some of the most distinguished personages in Rome. Quintilian, in his youth, cultivated the friendship of Domitian very applaudingly. He tells us that his pleadings abounded with pious sayings, and that there were public collections of his witty sayings, some of which he quotes. He also mentions two books of his "On Wittefes." Domitian was once in great danger from an inscription he put upon a statue erected by him in honour of Caligula, where he declared that this prince was a second time consul at the age of 27. This he intended as an encomium, but Caligula taking it as a farce upon his youth, and his infringements of the laws, raised a process against him, and pleaded himself in person. Domitian instead of making a defence, repeated part of the emperor's speech with the highest marks of admiration; after which he fell upon his knees, and, begging pardon, declared, that he dreaded more the eloquence of Caligula than his imperial power. This piece of flattery succeeded so well, that the emperor not only pardoned, but also raised him to the consulship. After died in the reign of Nero, A. D. 59.

AFFA, a weight used on the Gold Coast of Guinea. It is equal to an ounce, and the half of it is called eggebe. Most of the blacks on the Gold Coast give these names to those weights.

AFFECTION, in a general sense, implies an attribute inseparable from its subject. Thus magnitude, figure, weight, &c. are affections of all bodies; and love, fear, hatred, &c. are affections of the mind. — Affection, signifying a settled bent of mind toward a particular being or thing, occupies a middle space between disposition on the one hand, and passion on the other. It is distinguishable from disposition, which being a branch of one's nature, originally, must exist before there can be an opportunity to exert it upon any particular object; whereas Affection can never be original, because, having a special relation to a particular object, it cannot exist till the object has once at least been presented. It is also distinguishable from Passion, which, depending on the real or ideal presence of its object, vanishes with its object: whereas Affection is a lasting connection; and, like other connections, subsists even when we do not think of the person. A familiar example will illustrate this. There may be in one person's mind a disposition to gratitude, which, through want of an object, happens never to be exercised; and which therefore is never discovered even by the person himself. Another, who has the same disposition, meets with a kindly office that makes him grateful to his benefactor: An intimate connection is formed between them, termed affection: which, like other connections, has a permanent existence, though not always in view.

See Moral Philosophy, on disposition.
Affection, for the most part, lies dormant, till an opportunity offer for exerting it; in that circumstance, it is converted into the passion of gratitude; and the opportunity is eagerly seized on to testify gratitude in the warmest manner.

Affection, among physicians, signifies the same as desire. Thus the hysteric affection is the same with the hysteric disease.

Affluers, or Affilers, in law, persons appointed in courts-leets, courts baron, &c. to settle, upon oath, the fines to be imposed upon those who have been guilty of faults arbitrarily punishable.

Affetuoso, or Con Affetto, in the Italian music, intimates that the part to which it is added ought not to be played in a tender moving way, and consequently rather slow than fast.

Affiance, in law, denotes the mutual plighting of troth between a man and woman to marry each other.

Affidavit, signifies an oath in writing, sworn to a false affirmation that what they say is true; and if they make a false affirmation, they are subject to the penalties of perjury.

Affirmation, in logic, the affecting the truth of any proposition.

Affirmation, in law, denotes an indulgence allowed to the people called Quakers; who, in cases where an oath is required from others, may make a solemn affirmation that what they say is true; and if they make a false affirmation, they are subject to the penalties of perjury.

Affirmative, in grammar. Authors distinguish affirmative particles; such is, yes. - The term affirmative is sometimes used substantively. Thus we say, the affirmative is the more probable side of the question: there were so many votes, or voices, for the affirmative.

Affix, in grammar, a particle added at the close of a word, either to diversify its form or alter its signification. We meet with affixes in the Saxon, the German, and other northern languages; but more especially in the Hebrew, and other oriental tongues. The Hebrew affixes are single syllables, frequently single letters, subjoined to nouns and verbs; and contribute not a little to the brevity of that language. The oriental languages are much the same as to the radicals, and differ chiefly from each other as to affixes and prefixes.

Affluat, literally denotes a blast of wind, breath, or vapour, striking with force against another body. The word is Latin, formed from ad "to," and flare "to blow." Naturalists sometimes speak of the affluats of serpents. Tully uses the word figuratively, for a divine inspiration; in which sense, he ascribes all great and eminent accomplishments to a divine affluat. The Pythagorean priests being placed on a tripod or perforated stool, over a holy cave, received the divine affluat, as a late author expresses it, in her belly; and being thus inspired, fell into agitations, like a phrenetic; during which the pronouned, in hollow groans and broken sentences, the will of the deity. This affluat is supposed, by some, to have been a subterraneous flame, or exhalation, wherewith the priests were literally inspired. Accordingly, it had the effects of a real physical disease; the paroxysm of which was so vehement, that Plutarch observes it sometimes proved mortal. Van Dale supposes the pretended inspiration of the Pythia to have arisen from the fumes of aromatics.

Affliction, is not itself, in propriety of medical
Africa lies south of Europe, and west of Asia. It is bounded on the north by the Mediterranean, which separates it from the former; on the north-east, by the Red Sea, which divides it from Asia, and to which it is attached by a neck of land called the Isthmus of Suez, about 60 miles over, separating the Mediterranean from the Red Sea. On the west, south, and east, it is bounded by the main ocean so that it is properly a vast peninsula, bearing some faint resemblance of a pyramid, the base of which is the northern part, running along the shores of the Mediterranean; and the top of the pyramid is the most southerly point, called the Cape of Good Hope. Its greatest length from north to south is 12,000 miles; its greatest breadth from east to west is 3,000 miles; reaching from Lat. 32° N. to 35° S. and from Long. 17° W. to 51° E.

Though the greatest part of this continent hath been in all ages unknown both to the Europeans and Africans, its situation is more favourable than either Europe or Asia for maintaining an intercourse with other nations. It flanks, as it were, in the centre of the three other quarters of the globe; and has thereby a much nearer communication with Europe, Asia, and America, than any one of these has with another. For, (1) it is opposite to Europe in the Mediterranean, for almost 1,000 miles in a line from east to west; the distance feldom 100 miles, never 100 leagues; and sometimes not above 20 leagues. (2) It is opposite to Asia for all the length of the Red Sea, the distance sometimes not exceeding five leagues, seldom fifty. (3) Its coast for the length of about 2,000 miles lies opposite to America at the distance of from 100 to 200 leagues, including the islands; whereas America, unless where it may be a terra incognita, is no where nearer Europe than 1,000 leagues; and Asia, than 2,500.

As the equator divides this continent almost in the middle, the far greatest part of it is within the tropics; and of consequence the heat in some places is almost insupportable by Europeans, being there greatly increased by vast deserts of burning sand. It cannot be doubted, however, that, were the country well cultivated, it would be extremely fertile; and would produce in great abundance not only the necessaries, but also the luxuries, of life. It has been affirmed, that the fuggars of Barbadoes and Jamaica, as also the ginger, cotton, rice, pepper, pimento, cocoa, indigo, &c. of these islands, would thrive in Africa to as much perfection as where they are now produced. Nor can it be doubted, that the East Indian spices, the tea of China and Japan, the coffee of Mocho, &c. would all thrive in some parts of the African coast; as this continent has the advantage of feeling no cold, the climate being either very warm or very temperate.

Whatever may be the case with the internal parts of Africa, it is certain that its coasts are well watered with many very considerable rivers. The Nile and the Niger may be reckoned among the largest in any part of the world, America excepted. The first discharges itself into the Mediterranean, after a prodigious course from its source in Abyssinia. The origin neither of the Nile, nor of the Niger, is certainly known; but that of the latter is supposed to run through a act of land little les than 3,000 miles. Both these rivers annually overflow their banks, fertilizing by that means the countries through which they pass. The Gambia and Senegal rivers are only branches of the Niger. Many vast ridges of mountains also run through different parts of this continent; but their extent is very little known. Some of the most remarkable are, (1.) Those called Atlas, lying between the 20th and 25th degree of north latitude, and supposed almost to divide the continent from east to west. (2.) The mountains of the moon, so called on account of their great height; supposed to be the boundaries between Abyssinia and some of the interior kingdoms. (3.) The mountains of Sierra Leone, so called on account of their abounding with lions, and likewise supposed to be the boundaries of some of the nations. (4.) Those called by the ancients the mountains of God, on account of their being subject to perpetual thunder and lightning. Of all these, however, little more is known than their names.

To what we have already said concerning the produce of Africa, we may add, that no part of the world abounds with gold and silver in a greater degree. Here also ar a prodigious number of elephants; and it is surprising, that neither the ancient nor modern Europe...
peans, notwithstanding their extravagant and insati-
able thirst after gold and silver, should have endea-
voured to establish themselves effectually in a country
much nearer to them than either America or the East
Indies; and where the objects of their desire are found
in equal, if not greater, plenty.

Next to gold and silver, copper is the most valuable
metal; and on this continent is found in great plenty,
imfuch that the mountains of Atlas above
the ancients,

"Only a small part of this continent was known to
the ancients, viz. the kingdom of Egypt, and the nor-
tner coast, comprehending little more than what is
now known by the name of Barbary. It was divided
into Africa Propria, and Africa Interior. Africa Pro-
pria comprehended only the Carthaginian territories.
Africa Interior comprehended all other nations to the
southward of these territories, or those at a greater di-
stance from Rome. The only kingdoms, however,
with which the Romans had any connection, were the
Numidians, the Mauritanians, and the Gætuli. All
these, as well as Egypt, were swallowed up by that
e着重 enormous power, and reduced to the condition of
Roman provinces. But the Romans never seem to have
penetrated beyond the tropic of cancer. There appears,
indeed, to have been some intercourse between them
and the Ethiopians: but the latter always preserved
their liberty; and we find their queen Candace men-
tioned in the times of the apostles, when the Roman
country power was at its highest pitch.

Between the tropic of cancer and the equinocial
line, a multitude of savage nations were supposed to
have their residence, known by the names of Melano-
gætuli, Nigritæ, Blemmyæs, Dolopes, Aïlaceri, Lo-
tophagi, Ichthyophagi, Elephantophagi, &c. (which
are taken notice of, as well as the others already men-
tioned, under their proper names); but that Africa
was a peninsula, seems to have been totally unknown
both to the Europeans and Aïlaticas for many ages.—
It is probable indeed, that some of the Phenicians, and
their offspring the Carthaginians, were not ignorant;
as they carried navigation to a much greater height
than either the Greeks or Romans: but their discove-
ries were all concealed with the greatest care, lest other
nations should reap the benefit of them; and accord-
ingly we can now find no authentic accounts concern-
ing them. The navigation round Africa, in particular,
is recorded by the Greek and Roman writers rather as
a strange amusing tale than as a real transaction; and
as neither the progres of the Phenician and Carthagin-
ián discoveries, nor the extent of their navigation,
were communicated to the rest of mankind, all memo-
rials of their extraordinary skill in naval affairs seem
in a great measure to have perished, when the mari-
time power of the former was annihilated by Alexan-
der's conquest of Tyre, and the empire of the latter
was overthrown by the Romans.

That the peninsula of Africa, however, was in re-
ality failed round by the Phenicians, we have an in-
dible authority; for some of that nation under-
took the voyage, at the command of Necho king of E-
gypt, about 604 years before the Christian era. They
failed from a port in the Red Sea, and after three
years returned by the Mediterranean; and the very
objections that were made to the veracity of their
accounts at that time, are unfavourable proofs to us
that this voyage was really accomplished. They pre-
tended, that, having failed for some time, the sun
became more and more vertical, after which he appeared
in the north, and seemed to recede from them: that
as they returned, the sun gradually seemed to move
southwards; and, after becoming vertical once more,
appeared then in the south side of them as before they
set out. This, which we know must certainly have been
the case, was deemed incredible at that time, and uni-
versal ignorance concerning the extent of this conti-
nent prevailed till the 15th century. The first attempts
towards attaining a knowledge of Africa was made by
the Portuguese in 1412. Notwithstanding their vic-
nity, they had never ventured beyond Cape Non, situ-
ated in about N. lat. 27°: it had received its name
from a supposed impossibility of passing it. This year
they proceeded 160 miles farther, to Cape Bojador;
which stretching a considerable way into the Atlantic
ocean, with rocky cliffs, appeared too dreadful to the
navigators, that they returned without any attempt to
pass it. In an attempt to double this formidable cape,
they discovered the Madera islands in 1419: but Cape
Bojador continued to be the boundary of their conti-
nental discoveries till 1453; when they penetrated
within the tropics, and in a few years discovered the
river Senegal, Cape de Verd, and the islands which lie
off that promontory. In 1449, the western islands,
called the Azores, were discovered; and in 1471, they
first penetrated beyond the line; and were surprized to
find, that the torrid zone, contrary to the opinion of
the ancients, who imagined it to be burnt up
heat, was not only habitable, but fertile and
populous. In 1484, they proceeded 1500 miles beyond the line;
so that they began to entertain hopes of finding that
way a passage to the East Indies; and two years after-
wards, the Cape of Good Hope was discovered by Bar-
tholomew de Diaz; but it was not till the year 1497,
that the Portuguese, under Vasquez de Gama, actu-
ally doubled this cape, and discovered the true shape of the
continent. Thus the coasts of Africa were made per-
fectedly known; and probably the knowledge concerning
its interior parts would have been much greater than
it is, had not the general attention been called off from
this continent by the discovery of America in 1492.

The Romans for a long time maintained their power
in Africa: but in the year 426, Bonifacius, supreme
governor of all the Roman dominions in this quarter,
being compelled to revolt by the treachery of another
general called Actus, and finding himself unable to
contend with the whole force of the Roman em-
pire, called in Geneferic king of the Vandals to his aid;
who thereupon abandoned the provinces he had seized
in Europe, and paffed over into Africa. Bonifacius,
however,
AFRICA [ 227 ]

Africa. however, being soon after reconciled to his empress Placida, endeavoured in vain to persuade the Vandals to retire. Hereupon a war ensued, in which the barbarians proved victorious, and quickly over-ran all the Roman provinces in Africa. In the year 439, a peace was concluded; so that Numauid and some other countries were ceded to the Vandals, who soon after seized all the rest. These barbarians did not long enjoy this ill-gained possession: for, about the year 552, Belisarius drove them out, annexing the provinces to the eastern empire; and in 647, the Saracens, having conquered Musopotamia, Egypt (which is not included in the meaning of the word Africa), Punicia, Arabia, and Palæstine, broke like a torrent into Africa, which they quickly subdued. Their vast empire being in 96 divided into seven kingdoms, the African states retained their independence long after the others were subdued by the Turks; but in the beginning of the 16th century, being afraid of falling under the yoke of Spain, they invited the Turks to their assistance; who first protected, and then enslaved, them. They still continue in a kind of dependence on the Ottoman empire. They are not, however, properly speaking, the subjects of the grand Signior, but call him their protector, paying him an annual tribute. On the coasts, the natives are almost all addicted to piracy; and with such success have they carried on their employment, that the greatest powers in Europe become their tributaries, in order to procure liberty to trade on the Mediterranean.

Concerning even those states which are nearest to Europe, very little is known: but the interior nations are scarce known by name; nor do almost any two of the most learned moderns agree in their division of Africa into kingdoms; and the reason is, that fearfully any traveller hath ever penetrated into these inhospitable regions. According to the best accounts, concerning those regions of Africa lying between Egypt and Barbary, they are divided in the following manner. On the western coast, to the south of Barbary, lie the kingdoms of Biddulgerid, Zaara, Negroland, Loango, Congo, Anga, Benguela, and Terra de Natal. On the eastern coast beyond Egypt, are those of Nubia, Adal, Ajan, Zanguebar (between these two a large desert is interposed), Monomatapa, and Sofola. In the interior parts, the kingdoms of Lower Ethiopia, Abax, Menemuge, and Matanan, are made mention of. The most northerly part, called Caffaria, is well known for the habitation of the Hottentots. In many material circumstances, the inhabitants of this extensive continent agree with each other. If we except the people of Abyssinia, who are tawny, and profess a mixture of Christianity, Judaism, and Paganism, they are all of a black complexion. In their religion, except on the sea-coasts, which have been visited and settled by strangers, they are pagans; and the form of government is everywhere monarchical. Few princes, however, profess a very extensive jurisdiction: for as the natives of this part of Africa are greatly ignorant in all the arts of utility or refinement, they are little acquainted with one another; and generally united in small societies, each governed by its own prince. In Abyssinia, indeed, as well as in Congo, Loango, and Angolo, we are told of powerful monarchs; but on examination, it is found that the authority of these princes stands on a precarious footing, each tribe or separate body of their subjects being under the influence of a petty chief or of their own chiefs, styled Negusi, to whose commands, however contrary to those of the Negus Negash, or king of kings, they are always ready to submit.

The fertility of a country so prodigiously extensive, might be suppos'd more various than we find it to be; yet, there is no medium found in this part of Africa, with regard to the advantages of soil; it is either perfectly barren or extremely fertile. This arises from the intense heat of the sun; which, where it meets with sufficient moisture, produces the utmost luxuriance; and in those countries were there are few rivers, reduces the surface of the earth to a barren land. Of this sort are the countries of Anian and Zaara; which, for want of water, and consequently of all other necessaries, are reduced to perfect deserts, as the name of the latter denotes. In those countries, on the other hand, where there is plenty of water and particularly where the rivers overflow the land part of the year as in Abyssinia, the productions of nature, both of the animal and vegetable kinds, are found in the highest perfection and greatest abundance. The countries of Mandingo, Ethiopia, Congo, Angola, Batua, Tractus, Monomatapa, Cafati, and Mchemenugu, are extremely rich in gold and silver. The bafir metals, likewise, are found in these and many other parts of Africa. But the persons of the natives make the most considerable article in the produce and traffic of this miserable quarter of the globe.

On the Guinea or western coast, the English trade to James Fort, and other settlements near and up the river Gambia; where they exchange their woolen and linen manufactures, their hardware, and spirituous liquors, for the persons of the natives. By the treaty of peace in 1784, the river of Senegal, with its dependencies, were given up to France. Gold and ivory, next to the slave trade, form the principal branches of African commerce. These are carried on from the same coast, where the Dutch and French, as well as English have their settlements for this purpose.

The Portuguese are in possession of the east and west coast of Africa, from the Tropic of Capricorn to the Equator; which immense tract they became masters of by their succcssive attempts and happy discovery and navigation of the Cape of Good Hope. From the coast of Zanguebar, on the eastern side they trade not only for the articles abovementioned, but likewise for several others; as sea, aloes, cineraria, ambergris, and frankincense. The Dutch have settlements towards the southern part of the continent, in the country called Caffaria, or the land of the Hottentots, particularly Cape Town, which is well settled and fortified; where their ships bound to India usually put in, and trade with the natives for their cattle, in exchange for which they give them spirituous liquors. The Portuguese being sovereigns of the greatest part of the coast, have a number of black princes their tributaries. There are some independent princes who have extensive dominions; particularly the kings of Dahome and Welo, the most noted of any for the infamous slave trade. Upwards of 200 European nations traded with Africa in human flesh; and encouraged in the Negro countries, wars, rapine, defolation,
defolation, and murder, that the West India islands might be supplied with that commodity. The annual exportation of poor creatures from Africa for slaves hath exceeded 100,000; numbers of whom are driven down like prey, perhaps 1,000 miles from the coast, who are generally inhabitants of villages that have been surrounded in the night by armed force, and carried off to be sold to traders. Nor do the planters, who purchase them, use any pains to instruct them in religion, to make them amends for the oppression thus exercised upon them. It is said they are unnaturally averse to everything that tends to it; yet the Portuguese, French, and Spaniards, in their settlements, succeed in their attempts to instruct them, as much to the advantage of the commerce as of religion. It is for the fake of Christianity, and the advantages accompanying it, that English slaves embrace every occasion of deferting to the settlements of these nations. But upon this subject the feelings and reflection of that nation have of late been abundantly roused, and in the investigation of it the wisdom of the legislator is soon to be employed.

AFRICAN COMPANY, a society of merchants, established by King Charles the II. for trading to Africa, which trade is now laid open to all the subjects, paying 10 per cent. for maintaining the forts.

AFRICANUS (Julius), an excellent historian of the third century, the author of a chronicle which was greatly esteemed, and in which he reckons 5,000 years from the creation of the world to Julius Caesar. This work, of which we have now only a fragment, was finished the 22nd year of the vulgar era. Africanus also wrote a letter to Origens on the history of Susanna, which he reckoned supposititious; and we have still a letter of his to Ari- fides, in which he reconciles the seeming contradictions in the two genealogies of Christ recorded by St. Matthew and St. Luke.

AFSLAGERS, persons appointed by the burgomasters of Amsterdam to preside over the public sales made in that city. They must always have a clerk of the secretary's office with them, to take an account of the sale. They correspond to our brokers, or auctioneers.

AFT, in the sea language, the same with ABOBT.

AFTBRIRTH, in midwifery, signifies the membranes which surrounded the infant in the womb, generally called the secundines. See MIDWIFERY.

AFTERMATH, in husbandry, signifies the grasr which springs or grows up after mowing.

AFTERNOON, the latter half of the artificial day, or that space between noon and night.

AFTER-PAINS, in midwifery, excessive pains felt in the groin, loins, &c. after the woman is delivered.

AFTER-SWARMs, in the management of bees, are those which leave the hive some time after the first has swarmed. See Bee.

AFWESTAD, a large copper-work belonging to the crown of Sweden, which lies on the Dala, in the province of Dalecarlia, in Sweden. It looks like a town, and has its own church. Here they make copper-plates; and have a mint for small silver coin, as well as a royal post-office. W. Long. 14. 10. N. Lat. 58. 10.

AGA, in the Turkish language, signifies a great lord or commander. Hence the age of the Janizaries is the commander in chief of that corps; as the general of horse is denominated Huseinage. The age of the Janizaries is an officer of great importance. He is the only person who is allowed to appear before the grand signor without his arms across his breast in the posture of a slave. Emanss at Constantinople are in possession of most of the principal posts of the seraglio: The title age is given to them all, whether in employment or not. This title is also given to all such men without employ, and especially to wealthy landholders.

We find also ages in other countries. The chief officers under the Khan of Tartary are called by this name. And among the Algerines, we read of ages chosen from among the blackest of the Barbary pirates, and sent to govern the cities and garrisons of that state. The age of Algiers is the president of the divan, or Senate. For some years, the age was the supreme officer; and governed the state in the absence of the caliph. But the sultan rising against the boluk bahris, or ages, massacred most of them, and transferred the sovereign power to the caliph, with the title of Toy or King.

AGADES, a kingdom and city of Negroland in Africa. It lies nearly under the tropic of Cancer, between Gubur and Cano. The town stands on a river that falls into the Niger; it is walled, and the king's palace is in the midst of it. The king has a retinue, who serve as a guard. The inhabitants are not so black as other negroes, and consist of merchants and artificers. Those that inhabit the fields are shepherds or herdsmen, whose cottages are made of boughs, and are carried about from place to place on the back of oxen. They are fixed on the spot of ground where they intend to feed their cattle. The houses in the city are flatly, and built after the Barbary fashion. This kingdom was, and may be still, tributary to the king of Tombut. It is well watered; and there is great plenty of grass, cattle, fenna, and manna. The prevailing religion is the Mahometan, but very loosely professed. N. Lat. 26. 10. E. Long. 9. 10.

AGALLOCHUM. See XYLO ALOES.

AGALMATA, in antiquity, a term originally used to signify any kind of ornaments in a temple; but afterwards for the statues only, as being most conspicuous.

AGAMEMNON, the son of Atreus by Erope, was captain-general of the Trojan expedition. It was foretold to him by Cpaidra, that his wife Clytemnestra would be his death: yet he returned to her; and accordingly he was slain by Agamemnon, who had gained up on his wife in his absence, and by her means got the government into his own hands.

AGANIPPIDES, in ancient poetry, a designation given to the muses, from a fountain of mount Helicon, called Aganippos.

AGANIPPE, in antiquity, a fountain of Boeotia at mount Helion, on the borders between Phocis and Boeotia, sacred to the muses, and running into the river Perimessaus. (Pliny, Paul. 8.) Ovid seems to make Aganippe and Hippocrene the same. Solinus more truly distinguishes them, and attributes the blending them to poetical licence.

AGAPE, in ecclesiastical history, the love-feast, or feast of charity, in use among the primitive Christians; when
AGA [229] AGA

AGARIC. See Agaricus.

Female Agaric. See Boletus.

Mineral Agaric, a marly earth resembling the vegetable of that name in colour and texture. It is found in the fissures of rocks, and on the roofs of caverns; and is sometimes used as an astringent in fluxes, hemorrhages, &c.

AGARICUS, or Mushroom, a genus of the order of fungi, belonging to the cryptogamia class of plants. Species and uses. Botanical writers enumerate 35 species belonging to this genus; of which the most remarkable are the following.

1. The campœstris, or common mushroom, has the top or cap first of a dirty cream colour, convex, and, if but just expanding, the under part, or what is called the gills, is of a bright flesh red: this colour lasts but a little time before it turns darker; and when the plant is old, or has been some time expanded, the gills become of a dark brown, the cap almost flat, of a dirty colour, and often a little scaly. It differs much in size in different plants, being from an inch to seven inches broad. The general use of it is well known. It is found in woods, old pastures, and by road-sides, and is in the greatest perfection in September. There is a variety of this with a yellowish white cap and white gills: this is very firm, but seldom expands so freely as the true sort, and when broiled will exude a yellowish juice. It is probable this sort is not pernicious, though it is always rejected by such as can distinguish it.

2. The pratenis, or champignon, is very common upon heaths and dry pastures. A number of them generally come up in a place, ranged in curved lines or circles. The cap is small, almost flat, from one to two or three inches diameter, of a pale buff colour, often crimped at the edges, and, when dry, tough like leather or a thin piece of fine cork. The gills are of the colour of the cap; are thinly placed; with a short one, and sometimes two, coming from the edge of the cap between each. The stalk or pillar is also of the colour of the cap; it is long, flender, and at the way of a thickness. This plant has but little smell; is rather dry; and yet, when broiled or fried, it communicates a good flavour. In perfection at the same time with the former.

3. The chantarellus, or chantarelle agaric, is rather a smaller fungus than the former. The cap is yellow, of different hues in different plants, some being of a pale yellow, and others of an orange colour. It is generally sunk in the middle, somewhat resembling a tunnel, and its edges are often twisted and contorted so as to form flounces or angles. The gills are of a deeper colour than the outside, are very fine, even, numerous, and beautifully branched. The ramifications begin at the stalk, and are variously extended towards the edge of the cap. The pillar is of the same colour as the cap, is seldom inflected in the centre, but rather sideways; it is flint, thickish at the root, and the gills mostly run down the top, which make it appear small in the middle. This plant broiled with salt and pepper has much the flavour of a roasted cockle; and is esteemed a delicacy by the French, as is the former. It is found in woods and high pastures, and is in perfection about the end of September.

4. The delicatiss, or orange agaric. The general size-
size of the cap of this species is from two to four inches broad. Its form is circular, with the edges bent inwards; convex on the upper surface, except in the centre, where it is a little depressed, so as nearly to resemble the apex of a smooth apple. The colour is a burnt yellow, streaked with ash and yellowish brown, from the centre to the edge, and when it is broken it emits a gold colour juice. The gills are of a deep yellow, and a few of them come out by pairs at the stalk, but divide immediately, and run straight to the edge of the cap. The stalk or pillar is thinnest near the middle, thickest at the root, and when cut transversely, it is quite white in the centre, with a fine yellow ring that goes to the edge. The fungus, well seasoned and then broiled, has the exact flavour of a roasted muscle. Its prime time is September, and it is to be found in high dry woods.

5. The cinnamomeus, or brown mushroom, has a cap the colour of fresh-tanned hides. At first it is hemispherical, firm, even, and fleshy, with motley a small Rising in the centre; but when old it is quite flat. The gills are of a yellowish brown, not very distant from each other, bent like a knee at the pillar, and have a short one or two runs from the edge of the cap between each. The pillar is near the length of a finger, firm, rather thick, brown at the base, of a forked yellow upward, and, when cut transversely, of a fine white grain. The cap in different plants is from two to five inches broad. The whole plant has a pleasant smell, and when broiled gives a good flavour. It is found in woods in September and October.

6. The violaceus, or violet mushroom. Its cap, when first expanded, is smooth, hemispherical, the main surface of a livid colour, but towards the margin it is of a better blue. When full grown or old, it becomes corrugated, and of a ruffly brown. The gills of a young plant are of a beautiful violet colour, and regularly placed. The pillar is of the colour of the gills, short, of a conical form, but swelled at the base into a sort of bulb. Its upper part is surmounted with an iron-coloured wool, which, in a plant just expanding, stretches across to the edge of the cap like a web. This species requires much broiling; but when sufficiently done and seasoned, it is as delicious as an oyster. It is found in woods in October. Hudson's bulbous is only a variety of this plant.

The above are the only species that can be safely recommended as edible: though there are some other sorts which are frequently eaten by the country people; and it is probable the greatest part of those with firm fleshy caps might be eaten with safety, provided they were chosen from dry grounds. It is well known that soil and situation have a great influence upon the properties of plants; and these being of a singular nature, and absolutely between that of an animal and vegetable, may be more powerfully affected than a complete species of either, by reason they have neither leaves nor branches to carry off the noxious damps and vapours of a stagnant soil, as a perfect vegetable has; nor have they any gros excremental discharges, like those of living animal. The gills must doubtly exude from their supravital moisture; but their situation is such, that any thick piece from the earth may lodge in them, and by clogging their excretory ducts, render the plants morbid. Thus they soon run into a state of putrefaction, and become a prey to worms, flies, and other insects. The common mushroom, which is in general clean (though we have several others better) is not safely eaten when produced upon a moist soil. Those who gather mushrooms for sale should therefore have particular regard to the lands they collect them from, especially if they know they are to be broiled; but if they are intended for catchup, perhaps they may be less cautious, as the salt and spices with which the juice is boiled may correct any evil disposition in the plants. But, even in this case, catchup made of mushrooms taken from a dry soil has a more aromatic and pleasant flavour than that which is made of those taken from a moist one, and it will always keep a great deal better.

Of the poisonous sorts, the two following are the most singular:

7. The mufcarius, or reddish mushroom, has a large hat, almost flat, either white, red, or crimson, sometimes better with angular red warts; the gills are white, flat, and inflexibly spear-shaped; the pillar is hollow, the cap fixed to the middle of the pillar, limber, and hanging down. This species grows in pastures, and is said to destroy bugs effectually if the juice is rubbed upon the walls and bed-posts. The inhabitants of the north of Europe, whose houses are greatly inhabited by bugs, eat this mushroom, and the flies upon tasting the leaf drop are instantly poisoned. An infusion of common peppermint in milk answers the same purpose; but the flies through time become wise enough not to taste it; and though vast numbers are at first destroyed, it is impossible to clear a house of these insects by this means. This is the moucho-more of the Russians, Kamtschadales, and Koraics, who use it as an instrument of intoxication. They sometimes eat it dry, sometimes immersed in a fermented liquor made with the epilobium, which they drink notwithstanding the dreadful effects. They are first feized with convulsions in all their limbs, then with a raging such as attends a burning fever. A few phantoms, gay or gloomy (according to their constitution), present themselves to their imaginations: some dance, others are seized with unspeakable pangs and phantoms, gay or gloomy (according to their constitution), present themselves to their imaginations: some dance, others are seized with unspeakable horrors. They perfonify this mushroom; and, if its effects urge them to suicide, or any dreadful crime, they say they obey its commands. To fit themselves for premeditated affinations, they take the moucho-more. Such is the fascination of drunkenness, among these people, that nothing can induce them to forbear this dreadful potion!

8. The glyceatos, or long-stalked mushroom, has an hemispherical hat tapering to a point, and clammy; the pillar is long, cylindrical, and white; the gills are white, and not concave, duffled with a fine powdery substance on each side; the root is bulbous, long, and hooked at the end. It is found in September, in woodlands and pastures. This species is thought to be poisonous; and we have the following account of the symptoms produced by eating it, in Dr Percival's Essays. "Robert Usherwood, of Middletown, near Manchester, a strong healthy man, aged 50 years, early in the morning gathered and eat what he fancied to be a mushroom. He felt no symptoms of indisposition, till five o'clock in the evening; when, being very thirsty, he drank near a quart of table-beer. Soon afterwards he became universally swollen, weak, and in great agonies. A severe vomiting and purging succeeded,
succeeded, with violent cramps in his legs and thighs, and discharged several pieces of the fungus, but with little or no violent pain or nausea. His pains and evacuations continued, almost without intermission, till the next night; when he fell into a found, and awoke in the morning perfectly easy, and free from complaint."

Many of the different species of this genus grow on cows or horses dung, on dunghills, on rotten wood, in cellars, or on the trunks of trees; of which the most remarkable is,

9. The quercinus, or agaric of the oak. This is of various sizes, sometimes not exceeding the bigness of the fist, sometimes as large as a man's head. It takes at least a year or two to grow to its full size. It is dark coloured, hard, heavy, and woody; it is sometimes used by the dyers, as an ingredient in the black dye. It is sometimes used as a food. It is remarkable is,

Cultures. Only the efulent kinds of mushrooms are cultivated; and the following method is used by the gardeners who raise them for sale.---If the young mushrooms cannot be procured from gardens, they must be looked for in rich pastures during the months of August and September: the ground must be opened about a foot thick, and put under cover to prevent wet getting to it. The spawn commonly appears in about two months after the mixture is made: but proportionally sooner the more effectually the air is excluded, provided the mixture is not kept so close as to heat. Old thatch, or litter which has lain long abroad so as not to ferment, is the best covering. The spawn has the appearance of white mould shooting out into long strings, by which it may be easily known wherever it is met with. The spawn is the best time to gather it, as some will appear, perhaps in a month after making; and when the beds are made in summer or winter, they are much longer before they produce. In any season, however, they ought not to be hastily destroyed; since mushroom-beds have been known to produce very plentifully, even after the spawn has lain in them five or six months. When the beds are destroyed, the spawn should be carefully preserved, and laid up in a dry place, at least five or six weeks before it is again planted.---The difficulty of managing mushroom-beds is, to keep them always in a proper degree of moisture. In the summer season they may be uncovered to receive gentle showers of rain at proper times; and in long dry seasons the beds should now and then be watered, but much wet ought by no means to be suffered to come to them. During the winter season they must be kept as dry as possible, and so closely covered as to keep out cold. In frosty, or very cold weather, if some warm litter, shaken out of a dung-heap, is laid on, the growth of the mushrooms will be promoted: but wetness in the bed, a covering of dry litter must be interposed; which should be renewed as it decays; and, as the cold increases, the covering must be thickened. By attending to these directions, plenty of mushrooms may be produced all the year round. For a peculiar, perhaps fabulous, method of producing mushrooms, see the article Lycurus.

Physicians have disputed much about the qualities of mushrooms; some considering them as a rich nourishment, and perfectly innocent, when properly chosen; and others affearing them to be extremely deleterious. Most of the fungi are indeed of a hurtful quality; and, with respect to the whole tribe, the efulent are very few. Efulent mushrooms are very nutritive; they are therefore a rich nourishment, and much akin to animal food; on which account they may be indulged in considerable quantity to strong persons. It requires, however, skill to distinguih this efulent kind; and very few, especially of those who are commonly employed to gather them, viz. the servants, have succeeded Culusius, or other authors who have been at the pains to distinguih them. Perhaps efulent mushrooms, if old, acquire a dangerous acrimony; and for these reasons Dr Cullen is of opinion that it is for the most part prudent to avoid them. In the warm climates they may be used as light food; but here it is preposterous to use them along with animal food, as they do not correct its alkaline tendency.
Agate.

AGATE or ACHAT, (among the Greeks and Latins, 

Agatés, and Achatés, from a river in Sicily, on the banks of which it was first found), a very extensive genus of the fienitic-gemmed gems.

These stones are variegated with veins and clouds, but have no zones like those of the onyx. They are composed of chrysolite debased by a large quantity of earth, and not formed, either by repeated injections round a central nucleus, or made up of plates laid evenly on one another; but are merely the effect of one simple concretion, and variegated only by the disposition given, by the fluid they were formed in, to their differently coloured veins or matters.

Agates are arranged according to the different colours of their ground. Of those with a white ground there are three species. (1.) The deudrachates, noosa 

fione, or aborescent agate. This seems to be the same with what some authors call the achates with rosemary in the middle, and others achates with little branches of black leaves. (2.) The dull, milky-looking agate. This, though greatly inferior to the former, is yet a very beautiful stone. It is common on the shores of rivers in the East Indies, and also in Germany and some other parts of Europe. Our lapidaries cut it into counters for card-playing, and other toys of small value. (3.) The lead-coloured agate, called the pho­

sniates by the ancients.

Of the agates with a reddish ground there are four species. (1.) An impure one of a flesh-coloured white, which is but of little beauty in comparison with other agates. The admixture of flesh-colour is but very slight; and it is often found without any clouds, veins, or other variegations; but sometimes it is prettily veined or variegated with spots of irregular figures, having limbed or ridged edges. It is found in Germany, Italy, and some other parts of Europe; and is wrought into toys of small value, and often into the German gun­

flints. It has been sometimes found with evident specimens of the perfect molles bedded deep in it. (2.) That of a pure blood colour, called hamschates, or the blood agate, by the ancients. (3.) The clouded and spotted agate, of a pale flesh colour, called by the ancients the carnelion agate, or sardachates. 4. The red-lead coloured one, variegated with yellow, called by the ancients the corall agate, or corala-achates, by the ancients.

Of the agates with a yellowish ground there are only two known species; the one of the colour of yellow wax, called cerachates by the ancients; the other a very elegant stone, of a yellow ground, variegated with white, black, and green, called the lemnos, and leontes for the ancients.

Lastly, Of the agates with a greenish ground, there is only one known species, called by the ancients juf­

baches.

Of all these species there are a great many varieties; some of them having upon them natural representations of men and different kinds of animals, &c. These representations are not confined to the agates whose ground is of any particular colour, but are occasionally found on all the different species. Velusius had in his custody a flesh-coloured agate on one side of which appeared a half-moon in great perfection, represented by a milky semicircle; on the other side, the phases of 

sopher, or the evening-star, whence he denominated it 
a phonolitan agate. An agate is mentioned by Kir­

cher *, on which was the representation of a heroine armed; and one in the church of St Mark in Venice has the representation of a king's head adorned with a diadem. On another, in the museum of the prince of Gonzaga, was represented the body of a man with the cloths in a running posture. A still more curi­

ous one is mentioned by de Boot †, wherein appears a De Gem. 

circle struck in brown, as exactly as if done with a pair of compasses, and in the middle of the circle the exact figure of a bishop with a mitre on: but inverting the stone a little, another figure appears; and if it is turned yet further, two others appear, the one of a man, and the other of a woman. But the most celebrated agate of this kind is that of Pyrrhus, wherein were represented the nine muses, each with their proper attributes, and Apollo in the middle playing on the harp ‡. In the emperor's cabinet is an oriental agate of a fur. It is very large, brilliantly formed, being fashioned into a cup, whose diameter is an ell, abating two inches. In the cavity is found delineated in black specks, B. XRISTIS. S. XXX. prizing bigness, being found in Egypt, whose dia­

meter is an ell, abating two inches. In the cavity is found delineated in black specks, B. XRISTOS. S. XXX. prizing bigness, being fashioned into a cup, whose dia­

meter is an ell, abating two inches. In the cavity is found delineated in black specks, B. XRISTOS. S. XXX. prizing bigness.

Great medicinal virtues were formerly attributed to the agate, such as resisting poisons, especially those of the viper, scorpion, and spider; but they are now very justly rejected from medicinal practice. The oriental ones are all said to be brought from the river Cambay. A mine of agates was some time ago discovered in Transylvania, of divers colours; and some of a large size, weighing several pounds.

Agates may be stained artificially with solution of silver in spirit of nitre, and afterwards exposing the part to the sun; and though these artificial colours disappear on laying the stone for a night in aquafortis, yet a knowledge of the practicability of thus staining agates, must render these curious figures abovementioned strongly suspected of being the work not of nature, but of art. Some account for these phenomena from natural causes. Thus, Kircher, who had seen a stone of this kind in which were depicted the four letters usually inscribed on crucifixes, I. N. R. I. apprehends that some real crucifix had been buried under-ground, among stones and other rubbish, where the inscription happening to be parted from the cross, and to be received among a soft mould or clay susceptible of the impression of the letters, came afterwards to be petrified. In the same manner he supposes the agate of Pyrrhus to have been formed. Others resolve much of the wonder into fancy, and suppose those stones formed in the same manner with the Cambiuneus or Flo­

rence stones.

The agate is used for making cups, rings, seals, handles for knives and forks, hilts for swords and hangers, beads to pray with, snuff-boxes, patch-boxes, &c. being cut or fawed with no great difficulty. At Paris, none have a right to deal in this commodity except the wholesale mercers and goldsmiths. The sword-cutters are allowed to sell it, but only when made into handles for courtse de châtel, and ready to set in. The cutters have the same privilege for their knives and forks.

Considerable quantities of these stones are still found near the river Achates in Sicily. There are found in some of these the surprising representations above-

men-
AGA [233] AGA

Leyden, 1594, in 4to; and in Paris at the king's printing-house, 1660, in folio.

AGATHO, a tragic and comic poet, disciple to Prodicas and Socrates, applauded in Plato's Dialogues for his virtue and beauty. His first tragedy obtained the prize; and he was crowned in the presence of upwards of 23,000 men, the 48th year of the Olympiad. There is nothing now extant of his, except a few quotations in Aristotle, Athenaeus, and others.

AGATHOCLES, the famous tyrant of Sicily, was son of a potter at Reggio. He was a thief, a common soldier, a centurion, a general, and a pirate, all in a regular succession. He defeated the Carthaginians several times in Sicily, and was once defeated himself. He first made himself tyrant of Syracuse, and then of all Sicily; after which, he vanquished the Carthaginians again both in Sicily and Africa. But at length having ill success, and being in arrears with his soldiers, they matrified, forced him to fly his camp, and cut off the throats of his children, whom he left behind. Recovering himself again, he relieved Corfou, besieged by Callander; burnt the Macedonian fleet; returned to Sicily; murdered the wives and children of those who had murdered his; afterwards meeting with the soldiers themselves, he put them all to the sword; and ravaging the sea-coast of Italy, took the city of Lipponium. He was at length poisoned by his grandson Arthagathas, in the 72d year of his age, 390 years before Christ, having reigned 28 years.

AGATHYRNA, or AGATHYRNUS, AGATHYRSA, or AGATHYRIS, (anc. geog.), a town of Sicily; now S. Marco; as old as the war of Troy, being built by Agathyrinus, son of Eolus, on an eminence. The gentilitious name is AGATHYRNEUS; or, according to the Roman idiom, AGATHYRNENS.

AGAVE, the common American aloe: A genus of the monogynia order, belonging to the hexandria clafs of plants; and in the natural method ranking under the toth order, Coronaria. The characters are: There is no calyx: The corolla is monopetalons and funnelf-shaped; the border six-parted, with lanced erect divisions: The flamia conflit of six erect filaments, longer than the corolla; the anthera are linear, shorter than the filaments, and ventrally: The pellitum is an oblong germen: The stylus is filiform, the length of the flamia, and triangular: the stigma headed and triangular: The pericarpium is an oblong triangular capsule, trilocular and three-valved: The seeds are numerous. Of this genus, botanical writers enumerate eight species.

Of the American, or great American aloe, the items generally rise upwards of 20 feet high, and branch out on every side towards the top, so as to form a kind of pyramid: the fider floors being garnished with greenish yellow flowers, which stand erect, and come out in thick clusters at every joint: these make a fine appearance, and continue long in beauty: a succession of new flowers being produced for near three months in favourable seasons, if the plant is protected from the autumnal colds. The seeds do not ripen in England. It has been generally thought, that these plants do not flower till they are 100 years old: but this is a mistake; for the time of their flowering depends on their growth: so that in hot countries, where they grow...
... yield her productions without culture; men held all things in common, and lived in perfect friendship. This period is supposed to have lasted till the expulsion of Saturn from his kingdom. The **flour age** commenced when men began to deviate from the paths of virtue; and in consequence of this deviation, their lives became less happy. The **brass age** commenced on a further deviation, and the **iron age** took place in consequence of one still greater. A late author, however, reflecting on the barbarism of the first ages, will have the order which the poets allign to the four ages inverted; the first being a time of rudeness and ignorance, more properly denominated an **iron age**. When cities and states were founded, the **flour age** commenced; and since arts and sciences, navigation and commerce, have been cultivated, the **golden age** has taken place.

In some ancient northern monuments, the **rocks** or **flying age** corresponds to the **brass age** of the Greeks. It is called **rocks** or the rock age, on account of Mount Ararat, which reeled on Mount Ararat; whereas men were said to be defended or sprung from mountains; or from Sceva, and Pyyhia restoring the race of mankind, by throwing stones over their heads. The northern poets also style the fourth age of the world the **after age**, from a Greek king Madesis, or Mannas, who on account of his great strength was said to be made ifi, or because in his time people began to make use of weapons made of that wood.

Among the Jews, the duration of the world is also divided into three ages. 1. The **first age**, or the **first** age, was the space of time from the creation to Moses. 2. The **present age**, denotes the whole space of time from Moses to the coming of the Messiah; and 3. The **age to come**, denotes the time from the coming of the Messiah to the end of the world.

Various other divisions of the duration of the world into ages have been made by historians—the Sibylline oracles, wrote, according to some, by the Jews acquainted with the prophecies of the Old Testament, divide the duration of the world into ten ages; and according to Josephus, each age contained 870 years. It appears, by Virgil's fourth eclogue, and other testamities, that the age of Augustus was repited the end of those ten ages, consequently as the period of the world's duration.

By some, the space of time commencing from Constantinople, and ending with the taking of Constantinople by the Turks in the 15th century, is called the **middle age**; but others choose rather to date the middle age from the division of the empire made by Theodosius at the close of the 4th century, and extend it to the time of the emperor Maximilian I. in the beginning of the 16th century, when the empire was first divided into circle. —The **middle** is by some denoted the **barbarous age**, and the latter part of it the **lame** age. Some divide it into the **non-academic** and **academic** ages. The first includes the space of time from the 6th to the 9th centuries, during which schools or academies were lost in Europe. The second from the 9th century, when schools were restored, and universities established, chiefly by the care of Charlemagne.

The several ages of the world may be reduced to three grand epochs, viz. the **age** of the law of nature, called by...
AGÉ

by the Jews the "age" of from Adam to Moses; the
age of the Jews, from Moses to Christ; and
the age of grace, from Christ to the present year.

Age is also frequently used in the same sense with
century, to denominate a duration of 100 years.

Age likewise signifies a certain period of the
duration of human life, by some divided into four stages,
namely, infancy, youth, manhood, and old age; the
first extending to the 14th year, the second to the 25th,
the third to the 56th, and the fourth to the end of life;
by others divided into infancy, childhood, youth,
manhood, and old age.

Age, in law, signifies a certain period of life, when
persons of both sexes are enabled to do certain acts.
Thus, one at twelve years of age ought to take the
oath of allegiance to the king in a lease; at fourteen
he may marry, choose his guardian, and claim his lands
held in socage. Twenty-one is called full age, a man
or woman being then capable of acting for themselves,
of managing their affairs, making contracts, disposing
of their estates, and the like.

Age of Trees. Thence after a certain age wagers.
An oak at a hundred years old ceases to grow. The
usual rule for judging of the age of wood, is by the
number of circles which appear in the
trunk or
arm, which was kept
about
three
years,
and one of gold,
and the
enlargement of a year: though some
suppose the growth of a year: though it is supposed the growth of a year: though some reject
this method as precarious, alleging that a simple cir-
cle is sometimes the produce of several years: besides,
that, after a certain age, no new circles are formed.

Age-prior, in law, is when an action being brought
against a person under age, for lands defended to him,
he, by motion or petition, shows the matter to the
court, praying the action may be set aside till his full age,
which the court generally agrees to.

AGELNOTH, Egelnoth, or Ethelnoth, in
Latin Adelnothus, archbishop of Canterbury,
in the
reign of Canute the Great, succeeded Livinging in
that year 1020. This prelate famed the Good,
was the son of Agilmer, and, at the time of his election,
dean of Canterbury. After his promotion he
went to Rome, and received his pall from Pope Bene-
dict VIII. In his way thither, as he passed through
Pavia, he purchased for an hundred talents of silver
and one of gold, St Augulfin's arm, which was kept
there as a reliquary; and sent it over to England as a pre-
fetant to Leofric earl of Coventry. Upon his return, he
is said to have raised the fee of Canterbury to its for-
mer lustre. He was much in favour with King Can-
ute, and employed his interest with that monarch to
good purposes. It was by his advice the king lent
over large sums of money for the support of the foreign
churches; and Malmesbury observes, that this prince
was prompted to acts of piety, and restrained from ex-
cesses, by the regard he had for the archbishop. Agel-
noth, after he had had 17 years in the fee of Can-
terbury, departed this life the 29th of October, 1038,
and was succeeded by Eadulf, king Harold's chap-
lain.—This archbishop was an author, having written,
1. A Panegyric on the blessed Virgin Mary. 2. A
Letter to Earl Leofric concerning St Augulfin. 3.
Letters to several persons.

AGEMA, in Macedonian antiquity, was a body of
soldiery, not unlike the Roman legion.

AGENOGLANS, Acanoglans, or Azo-
oglans, in the Turkish policy, are children purchased
from the Tartars, or raised every third
year, by way of
tribute, from the Christians tolerated in the Turkish
empire. Thence, after being circumcised and instructed
in the religion and language of the tyrannical masters,
are learnt the exercises of war, till they are of a pro-
er age for carrying arms, and from this corps the Ja-
inillaries are recruited. With regard to those who are
thought unfit for the army, they are employed in the
lowest offices of the seraglio. Their appointments are
very small, not exceeding seven or eight and a half
per day, which amount to about threepence-halfpenny
Sterling.

AGEN, a city of France, on the river Garonne,
the capital of Agenois in Guienne, and the see of a bishop.
The gates and old walls, which are yet remaining, show
that this city is very ancient, and that its former cir-
cuit was not so great as the present. The palace,
wherin the prebendal holds his fequisitions at this day, was
here before called the castle of Montravel, and is seated
without the walls of the old city, on the side of the
fole. There are likewise the ruins of another castle called La Sague, which was without the walls close
by a brook. Though the situation of Agen is very
convenient for trade and commerce, the inhabitants
are so very indolent that there is very little;
of which the neighbouring cities take the advantage. It is fea-
ed on the bank of the river Garonne, in a pleasant
country: but itself is a very mean and disagreeable place,
the houses being ill built, and the streets narrow, crook-
ed, and dirty. E. Long. o. 39. N. Lat. 44. 12.

AGENDA, among philosophers and divines, signi
fies the duties which a man lies under an obligation to
perform: thus, we meet with the agenda of a Chri
tian, or the duties he ought to perform, in opposition
to the eredenda, or things he is to believe.

AGENDA, among merchants, a term sometimes used
for a memorandum-book, in which is set down all the
busineses to be transacted during the day, either at
home or abroad.

AGENDA, among ecclesiastical writers denote the
service or office of the church. We meet with agenda
maturina & vesperiuna, morning and evening pray-
ers; agenda diei, "the office of the day;" whether
fast or fast day; agenda mortuorum, called also simply
agenda, "the service of the dead."

AGENDA is also applied to certain church-books,
compiled by public authority, prescribing the order
and manner to be observed by the ministers and peo-
ple in the principal ceremonies and devotions of the
church. In which sense, agenda amounts to the fame
with what is otherwise called ritual, liturgy, aca
lithia, missal, formular, directory, &c.

AGENHINE, in old writers, signifies a guest
that has lodged at an inn for three nights, after
which time he was accounted one of the family; and if
he offended the king's peace, his host was answer-
able for him. It is also written Hogenhine and
Hogenhynse.

AGENORIA, in mythology, the goddess of con-
rage and industry, as Venera was of indolence.

AGENT, in a general sense, denotes any active
power or cause. Agents are either natural or moral.
Natural agents are such inanimate bodies as have a
power
power to act upon other bodies in a certain and determinate manner; as, gravity, fire, &c. Moral agents, on the contrary, are rational creatures, capable of regulating their actions by a certain rule.

Agent, is also used to denote a person intrusted with the management of an affair, whether belonging to a society, company, or private person.

Agents in rebus, one of the ranks of officers in the court of the Constantinopolitan emperors, whose business was to collect and convey the corn both for the army and household; to carry letters and messages from court to all parts of the empire; to regulate courts, and their vehicles; to make frequent journeys and expeditions through the provinces, in order to inspect any motions, disturbances, or machinations tending that way, and to give early notice thereof to the emperor.

The agents in rebus, are by some made synonymous with our post-masters, but their functions were of great extent. They correspond to what the Greeks called ἀρχηγοί, and the Latins perpenduli. There were various orders or degrees of agents in rebus; as, tribuni, primicerii, senatoris, duumviri, biarchi, circitores, equites, tyranni, &c. through all which they rose gradatim. Their chief, who resided at Constantinople, was denominated princeps; which was a poilt of great dignity, being reckoned on a level with that of proconsul. They were settled in every part of the empire; and are also said to have served as interpreters.

Agent, in Roman antiquity, a certain portion of land allowed to each citizen. See Agrarian Law.

Ager Picinus, or Picenum, (anc. geog.) a territory of Italy to the south-east of Umbria, reaching from the Apennine to the Adriatic. The people are called Picentes (Cicero, Livy), distinited from the Picenians on the Tuscan seas, though called by Greek writers Πικενοι. This name is said to be from the bird Picus, under whose conduct they removed from the Sabines, of whom they were a colony.

Ageratium, bastard hemp, agrimony; a genus of the polygama equalis order, belonging to the fynegena class of plants; and in the natural method ranking under the 49th order, Compositae diffidi. The characters are: The common calyx is oblong, with many scales. The compound corolla is uniform; the corollas hermaphroditic, tubular and numerous; the proper corolla is funnel-shaped; the border 4-cleft, and expanded. The fruticos conflit of 5 capillary very short filaments; the anthera is cylindric and tubular. The pistillum is an oblong germin, with a filiform stylus, and two slender erect ilacmata. There is no pericarpium; the calyx unchanged. The seeds are solitary, oblong, and angular. The receptaculum is naked, convex, and very small. Of this genus there are three species; the conyzaoides, the hounionanum, and the altissimum. All these are natives of warm climates. The two first are annual plants, and consequently can be propagated only by seeds; which, however, come to perfection in England. The third species will bear the feverest cold of Britain, but its seeds do not ripen in it.

Ageratum, of Maudlin. See Achillea.

Agesilaus, king of the Lacedaemonians, the son of Archidamus, was raised to the throne notwithstanding the superior claim of Leotychides. As soon as he came to the throne, he advised the Lacedaemonians to be beforehand with the king of Persia, who was making great preparations for war, and to attack him in his own dominions. He was himself chosen for this expedition; and gained so many advantages over the enemy, that if the league which the Athenians and the Thesbians formed against the Lacedaemonians had not obliged him to return home, he would have carried his victorious arms into the very heart of the Persian empire. He gave up, however, all these triumphs readily, to come to the face of his country, which he happily relieved by his victory over the allies in Boeotia. He obtained another near Corinth; but to his great mortification, the Thesbians afterwards gained several over the Lacedaemonians. These misfortunes at first raised somewhat of a clamour against him. He had been tick during the first advantages which the enemy gained; but as soon as he was able to act in person, by his valour and prudence he prevented the Thesbians from reaping the advantages of their victories; insomuch that it was generally believed, had he been in health at the beginning, the Lacedaemonians would have sustained no losses, and that all would have been lost had it not been for his assistance. It cannot be denied but he loved war more than the interest of his country required; for if he could have lived in peace, he had saved the Lacedaemonians several losses, and they would not have been engaged in many enterprises which in the end contributed much to weaken their power. He died in the third year of the 104th Olympiad, being in the 83rd year of his age, and 41st year of his reign. Agesilaus would never suffer any picture or sculpture to be made of him, and prohibited it also by his will: this is supposable to have been a consequence of his own deformity; for he was of a short stature, and lame of one foot, so that strangers used to despise him at first sight. His fame went before him into Egypt, and there they had formed the highest idea of Agesilaus. When he landed in that country, the people ran in crowds to see him; but great was their surprise when they saw an ill-dressed, shaven, mean-looking little fellow lying upon the graft; they could not forbear laughing, and applied to him the fable of the mountain in labour. He was, however, the first to jest upon his own person; and such was the gaiety of his temper, and the strength with which he bore the roughness of exercise, that these qualities made amends for his corporal defects. He was extremely remarkable for plainness and frugality of his dress and way of living. "This (says Cornelius Nepos) is especially to be admired in Agesilaus; when very great pretences were sent him by kings, governors, and states, he never brought any of them to his own house; he changed nothing of the diet, nothing of the apparel of the Lacedaemonians. He was contented with the same house in which Euriphienes the founder of his family had lived; and whoever entered there, could see no sign of debauchery, none of luxury, but on the contrary, many of moderation and abstinence; for it was furnished in such a manner, that it differed in nothing from that of any poor or private person." Upon his arrival in Egypt, all kind of provisions were sent to him; but he chose only the most common, leaving the perfumes, the confections, and all that was esteemed most delicious, to his servants. Agesilaus was extremely fond of his children, and would often amuse himself by joining
joining in their diversions: one day when he was surprised riding upon a dapple with them, he said to the person who had seen him in this posture, "Forbear talking of it till you are a father."

**AGG** or **AGGONNA**, a British settlement on the gold-coast of Guinea. It is situated under the meridian of London, in 6 degrees of N. Lat.

**AGGER**, in the ancient military art, a work of fortification used for the defence of towns, camps, &c. In which fence it is the same with what was otherwise called *collum*, and in interstices *aggerum*; and among the moderns *limes*, sometimes *caulicary*, *turræ* &c. The agger was usually a bank, or elevation of earth or other matter, bound and supported by timber; having sometimes turrets on the top, wherein the workmen, engineers, and soldiers were placed. It was also accompanied with a ditch, which served as its chief defence. The usual materials of which it was made were earth, earthworks, flacks, &c. and even trunks of trees, roped, &c. variously erected, and interwoven some in the figure of ovals; whence they were called *scellati axem*. Where these were wanting, stones, bricks, tiles, supplied the office: on some occasions, arms, utensils, pack-faddles, were thrown in to fill it up. We even read of aggers formed of the carcasses of the slain; sometimes of dead bones mixed with lime; and even with the heads of slaughtered citizens. For want of dead binding, or fold materials, aggers have sometimes tumbled down, with infinite mischief to the men. The barbarians used to carry on a work of this kind nearer and nearer towards the place, till at length they reached the very wall. The methods taken, on the other side, to defeat them, were by fire, especially if the agger were of wood; by sapping and undermining, it of earth; and, in some cases, by erecting a counter agger.

The height of the agger frequently equal to that of the wall of the place. Caesar tells us of one he made, that was 30 feet high and 330 feet broad. Besides the use of aggers before towns, the generals used to carry on a work of this kind nearer and nearer towards the place, till at length they reached the very wall. The methods taken, on the other side, to defeat them, were by fire, especially if the agger were of wood; by sapping and undermining, it of earth; and, in some cases, by erecting a counter agger.

There were vast aggers made in towns and places on the sea-side, fortified with towers, castles, &c. Those made by Caesar and Pompey at Brundium, are famous. Sometimes aggers were even built across arms of the sea, lakes, or morasses; as was done by Alexander before Tyre, and by M. Anthony and Cassius. The wall of Severn, in the north of England, may be considered as a grand agger, to which belong several lesser ones. See **SERVVS**, *Wall.*

**AGGER**, in ancient writers, likewise denotes the middle part of a military road, raised in a ridge, with a gentle slope on either side, to make a drain for the water, and keep the way dry.

The term is also used for the whole road, or military way. Where highways were to be made in low grounds, as between two hills, the Romans used to raise them above the adjacent land, so as to make them on a level with the hills. These banks they called *aggeres*. Berger mentions several in Gallia Belgica, which were thus raised ten, fifteen, or twenty feet above ground.

—They are sometimes also called *aggeres calcvati*; and now generally known by the name *causeway*.

**AGGERHUSYS**, a city of Norway, capital of the province of the same name. It is subject to Denmark, and situated in E. Long. 28° 37′ and N. Lat. 59° 30′.

**AGGERS-HERRED**, a district of Christland, and a disocese of Norway. It consists of three parochial places; namely, Agger, Lejre Barum, and Ager.

**AGGLUTINANTS**, in pharmacy, a general name for all medicines of a glutinous or viscid nature; which, by adhering to the solids, contribute greatly to repair their loss.

**AGGLUTINATION**, in a general sense, denotes the joining two or more things together, by means of a proper glue or cement.

**Agglutination**, among physicians, implies the action of uniting the parts of a body, separated by a wound, cut, &c. It is also applied to the action of such internal medicines as are of an agglutinating quality, and which, by giving a glutinous consistence to the animal-fluids, render them more proper for nourishing the body.

**AGGREGATE**, in a general sense, denotes the union of several things added together, or the collection of them into one whole. Thus, a house is an aggregate of stones, wood, mortar, &c. It differs from a mixed or compound, inasmuch as the union of these last is more intimate than between the parts of an aggregate.

**Aggregates**, in botany, is a term used to express those flowers, which are composed of parts or florets, so united by means either of the receptacle or calyx, that no one of them can be taken away without destroying the form of the whole. They are opposed to simple flowers, which have no such common part, and are usually divided into seven kinds, viz. the aggregate, properly so called, whose receptacle is dilated, and whose florets are supported by foot-flats; such as the blue daily, thrift, or sea-plants, &c.; the compound; the *umbellifer*; the *cymo*; the *amethyst*; the *glauca*; and the *bisculosa*.

**Aggregation**, in physics, a species of union whereby several things which have no natural dependence or connection with one another are collected together, so as in some sense to constitute one. Thus, a heap of sand, or a mass of ruins, are bodies by aggregation.

**AGHER,** a town of Ireland, which sends two members to parliament. It is situated in the southern part of Ulster, not far from Clogher.

**AGHRIM,** a town of Ireland, in the county of Wicklow, and province of Leinster, situated about 13 miles south west of Wicklow.

**Aghrim,** in Galway: a small village, distant about 21 miles from Dublin, and rendered memorable by a decisive battle fought there, and at Kilcombonon-hill, the 12th of July 1691, between general Ginkel and Monxfuir St Ruth, the commanders under king William III. and James II., when St Ruth, the general of the Irish army, with 7000 of his men, were slain; but of the English only 600. The victory was the more considerable, as the English army consisted of no more than 18,000 men; whereas the Irish were computed at 20,000 foot and 1000 horse and dragoons. They lost likewise nine pieces of brass cannon, all their ammunition,
AGI

AGI

AGIDES, in the Turkish armies, a kind of pioneers employed in fortifying camps, smoothing roads, and the like offices.

AGILIT\Y, an aptitude of the several parts of the body to motion. — The improving of agility was one of the chief objects of the institution of games and exercises. The athletes made particular profession of the science of cultivating and improving agility. Agility of body is often fupposed peculiar to some people; yet it seems left owing to anything peculiar in their frame and structure, than to practice.

AGINCOURT, a village of the French Netherlands, situated in East Long. 2° 10' N. Lat. 50° 35'; famous on account of the victory obtained by Henry V. of England over the French, in 1415.

The army of Henry, after landing in France, was by various accidents reduced to 10,000 men, of whom not a few were sick, or slowly recovering from sickness; — they had to traverse a long tract of country, infested by exasperated enemies, from whom they were to procure provisions, lodgings, guides, intelligence, and every thing they wanted; — that country was defended by many strong towns, intersected by deep rivers, and guarded by an army of 100,000, or (according to some contemporary writers) 140,000 men.

Henry, undaunted by all these dangers and difficulties, departed from Harfleur, marching his army in three lines, with bodies of cavalry on the wings. He proceeded by very easy journeys, that he might not fatigue his troops, or discourage them by the appearance of a flight; observing the strictest discipline, and paying generously for every thing he received; which induced the country people to bring provisions to his camp, in spite of all the commands they had received to the contrary. To keep his men in spirits, and from repining, the king fared as ill as the meanest soldier, always appearing with a cheerful countenance, and addressing them in the most friendly and encouraging language. They arrived at the village of Agincourt, in the county of St. Pol, on the evening of October 24th; and there beheld the whole French army, at a small distance, directly in their route. The king took an attentive view of it from an eminence; and being fully convinced that it was impossible to proceed any further on his way to Calais without a battle, and equally impossible to return to Harfleur with so great an army in his rear, he resolved to hazard an action next morning, as the only means of preserving himself and his little army from destruction.

The English army lodged that night in the villages of Agincourt, Maisonneville, and some others; where they met with better accommodation than they had been accustomed to for some time past, and spent part of their time in mutual exhortations to fight bravely in the approaching battle. The king, overhearing some of his nobles expressing a wish that the many brave men who were idle in England were present to assist them, is said to have cried out—“No! I would not have one man more:—if we are defeated, we are too many— if it shall please God to give us the victory, as I trust he will, the smaller our number the greater our glory.” The moon happening to shint very bright,

Henry, with some of his best officers, carefully examined the ground, and pitched upon a field of battle, admirably calculated to preserve a small army from being surrounded by a great one. It was a gentle declivity from the village of Agincourt, of sufficient extent for his small army, defended on each side by hedges, trees, and brush-wood. Having placed guards and kindled fires on all sides, the king and his army betook themselves to rest; except such as were of a more ferocious turn of mind, and, considering that as the last night of their lives, spent it devotion.

The French, exulting in their numbers, confident of victory, and abounding in provisions, spent the night in noisy festivity, and in forming fanciful schemes about the disposal of their prisoners and their booty. It was in general resolved to put all the English to the sword, except the king and the chief nobility, who were to be taken prisoners for the sake of their ransom.

On the morning of Friday, the memorable 25th of October, A. D. 1415, the day of Crispin and Crispianus, the English and French armies were ranged in order of battle, each in three lines, with bodies of cavalry on each wing. The Constable D'Albert, who commanded the French army, fell into the snare that was laid for him, by drawing up his army in the narrow plain between the two woods. This deprived him, in a great measure, of the advantage he should have derived from the prodigious superiority of his numbers; obliged him to make his lines unnecessarily deep, about 30 men in file; to crowd his troops, particularly his cavalry, so close together, that they could hardly move or use their arms; and, in a word, was the chief cause of all the disasters that followed. The French, it is said, had a considerable number of cannon of different sizes in the field; but we do not hear that they did any execution, probably for want of room. The first line of the French army, which consisted of 8000 men-at-arms on foot mixed with 4000 archers, with 500 men-at-arms mounted on each wing, was commanded by the Constable D'Albert, the dukes of Orleans and Bourbon, and many other nobles; the dukes of Alençon, Brabant, and Bar, &c. conducted the second line; and the earls of Marle, Damartine, Fauconberg, &c. were at the head of the third line. The King of England employed various arts to supply his defect of numbers. He placed 200 of his best archers in ambush, in a low meadow, on the flank of the first line of the French. His own first line consisted wholly of archers, four in file; each of whom, besides his bow and arrows, had a battle-axe, a sword, and a stake pointed with iron at both ends, which he fixed before him in the ground, the point inclining outwards, to protect him from cavalry; which was a new invention, and had a happy effect. That he might not be incumbered, he dismissed all his prisoners, on their word of honour to surrender themselves at Calais, if he obtained the victory; and lodged all his baggage in the village of Agincourt, in his rear, under a slender guard. The command of the first line was, at his earnest request, committed to Edward duke of York, assisted by the lords Beaumont, Willoughby, and Fanhope; the second was conducted by the king, with his youngest brother Humphrey duke of Gloucester, the earls of Oxford, Marshal, and Suffolk; and the third was led by the duke
formed. the king, in shining armour, with a crown of gold and jewels on his helmet, mounted on a fine white horse, rode along them, and addressed each corps with a cheerful countenance and animating speeches. To inflame their resentment against their enemies, he told them, that the French had determined to cut off three fingers of the right hand of every prisoner; and to rout their love of honour, he declared, that every soldier in that army who behaved well, should from henceforth be deemed a gentleman, and be entitled to bear coat-armour.

When the two armies were drawn up in this manner, they stood a considerable time gazing at one another in solemn silence. But the king, dreading that the French would discover the danger of their situation and decline a battle, commanded the charge to be found, about ten o'clock in the forenoon. At that instant, the first line of the English kneeled down, and killed the ground; and then starting up, discharged a flight of arrows, which did great execution among the crowded ranks of the French. Immediately after, upon a signal being given, the archers in ambush arose, and discharged their arrows on the flank of the French line, and threw it into some disorder. The battle now became general, and raged with uncommon fury. The English archers, having expended all their arrows, threw away their bows, rushing forward, made dreadful havoc with their swords and battle-axes. The first line of the enemy was, by these means, defeated; its leaders being either killed or taken prisoners. The second line, commanded by the duke of Alençon, (who had made a vow either to kill or take the king of England, or to perish in the attempt), now advanced to the charge, and was encountered by the second line of the English, conducted by the king. This conflict was more close and furious than the former. The duke of Gloucester, wounded and unhorsed, was protected by his royal brother till he was carried off the field. The duke of Alençon forced his way to the king, and assailed him with great fury; but that prince brought him to the ground, where he was instantly dispatched. Discriminated by this disaster, the second line made no more resistance; and the third fled without striking a blow; yielding a complete and glorious victory to the English, after a violent struggle of three hours duration.

The king did not permit his men to pursue the fugitives to a great distance, but encouraged them to take as many prisoners as they could on or near the field; in which they were so successful, that, in a little time, their captives were more numerous than his soldiers. A great proportion of these prisoners were men of rank and fortune; for many of the French nobility being on foot, and loaded with their heavy armour, could not make their escape. Among these were the dukes of Orleans and Bourbon, the marshal Boucicaut, the counts D'Eu, Vendome, Richemont, and Harcourt, and 7000 barons, knights, and gentlemen. The French left dead on the field of battle, the countable D'Alberit, the three dukes of Alençon, Brabant, and Bar, the archbishop of Sens, one marshal, 13 earls, 92 barons, 1500 knights, and a far greater number of gentlemen, besides several thousands of common soldiers. Even the French historians acknowledge, that the loss of the English was inconsiderable: those of English contemporary writers who make it the greatest, affirm, that it did not exceed 100, and that the duke of York and the earl of Suffolk were the only great men who fell on that side in this memorable action.

AGIO, in commerce, is a term chiefly used in Holland, and at Venice, to signify the difference between the value of bulk-frock and the current coin. The agio in Holland is generally three or four per cent, and at Rome it is from 15 to 25 per cent, but at Venice the agio is fixed at 20 per cent.

AGIOSYMANDRUM, a wooden instrument used by the Greek and other churches, under the dominion of the Turks, to call together assemblies of the people. The agiosymandrum was introduced in the place of bells, which the Turks prohibited their Christian subjects the use of, lest they should make them subversive to feditious.

AGIS, king of Lacedaemon, was descended from Ageiolus II. in a right line. He projected the reformation of his kingdom, by the restoring of the laws of Lycurgus; but he fell under the weight of an enterprise that could not but be disagreeable to all those who had great possessions, and had been long accustomed to the tweets of a voluptuous life. Agis being in the flower of his age, and having a very refined sense of glory, practised the ancient discipline first in his own person; his clothes and his table were according to the manners of former times; which is so much the more to be admired, because Ageiiratra his mother and Archidama his grandmother had brought him up voluptuously. When he found his people's minds, he found the younger fort opposed his project less than those who had enjoyed a relaxation of discipline several years. The greatest difficulty was expected to arise from the women. They had at that time more credit than ever; for their power is never greater than when luxury is in fashion. Ageiolus's mother did not at all relish the proposed reformation. She must have lost her riches, which gave her a share in a thousand forts of intrigues; for she opposed the design at once, and treated it as a chimera. But her brother Ageiilus, whom Agis had engaged in his interests, knew how to manage her in such a manner that she promised to second the enterprise. She endeavoured to gain the women: but instead of suffering themselves to be persuaded, they applied to Leonidas the other king of Lacedaemon, and humbly besought him to frustrate the designs of his colleague. Leonidas durst not oppose it openly, for fear of irritating the people; to whom the reformation was agreeable, because they found their account in it. He contented himself with counterminating it by intrigues, and fowing suspicions as if Agis had aspired to tyranny, by pulling down the rich and raising the poor. Agis did not fail to propose his new laws to the senate, relating to the discharge of debts, and a new division of the lands. Leonidas, being supported by the rich, opposed this project so strongly, that there was one voice more against it than for it. He paid dear for his success in this affair. Lyfander, one of the Ephors, who had been the grand promoter of the reformation, called him to account; alleged the ecclesiastical signs; and put to death Cleombros, a prince of the royal blood and son-in-law to Leonidas, to make sure of the kingdom.
Agis. [240] Agis,

Kingdom. Leonidas being frightened at this took refuge in a temple, where his daughter, the wife of Cleombrotus, followed him. He was summoned: and because he did not appear, he was degraded of his dignity, which was conferred on Cleombrotus. He obtained leave to retire to Tegæa. The New Ephor had Lyfander and Mandroclidas tried for innovation; these persuaded the two kings to unite and turn out these Ephors. The thing was brought about; but not without a great uproar in the city. Ageislaus, one of the Ephors that succeeded those who were just turned out would have caused Leonidas to be killed on the way to Tegæa, if Agis had not sent him a strong guard. The reformation might then have been established, if Ageislaus had not found means to elude the good intentions of the two kings. Whist this was transacting, the Achalans asked alms; which was given them, and Agis had the command of the troops. It acquired a good deal of reputation in this campaign. At his return, he found his affairs so embroiled by the ill conduct of Ageislaus, that it was impossible for him to maintain himself. Leonidas was recalled to Lacedæmon; Agis retired into the city and Cleomenes into another. The wife of the latter beheld herself in such a manner that she became the admiration of every body. Leonidas was content with banishing his son-in-law; after which he applied himself entirely to the ruin of Agis. One of the Ephors, who had no mind to return what Agestratas had lent him, was the principal instrument of the misfortune of this family. Agis never went out of his sanctuary but to battle. One day, as he was returning from thence to the temple, he was seized by that Ephorus and carried to prison. Then he was brought to his trial and condemned to death, and delivered to the executioner. His mother and grandmother used all the intreaty and importunity imaginable, that, as he was king of Lacedæmon, he might at least be permitted to plead his cause before the people. But they were apprehensive his words would make too great an impression, and therefore they ordered him to be strangled that very hour. The Ephorus who was in debt to Agestratas permitted that princes to go into the prison; which he granted likewise to Agis’s grandmother; but he gave orders to strangle them one after another. Agestratas died in a manner that was extremely to her honour. The wife of Agis, who was a princess of great fortune and prudence, and one of the finest ladies in Greece, was forced away from her apartment by king Leonidas, and obliged to marry his son, who was then very young, and hardly fit for marriage.

Agistment, Agitage, or Agitation, in law, the taking in other people’s cattle to graze at so much per week. The term is peculiarly used for the taking cattle to feed in the king’s forests, as well as for the profits arising from that practice. It is also used, in a metaphorical sense, for any tax, burden, or change; thus, the tax levied for repairing the banks of Romney-marsh was called agistment.

Agistor, or Agistator, an officer belonging to forests, who has the care of cattle taken in to be grazed, and levies the moneys due on that account. They are generally called queft-takers or gift-takers, and are created by letters-patent. Each royal forest Agisthor has four agitators.

Agisymba (anc. geog.), a district of Libya Interior, according to Agathemus, situated to the south-west of the Ethiopæs Anthropophagi; the parallel passing through which, at 16° to the south of the equator, was the utmost extent of the knowledge of the ancients to the fourth (Ptolemy).

Agitation, the act of shaking a body, or toiling it backwards and forwards. Agitation, in physics, is often used for an interline commotion of the parts of a natural body. Fermentation and effervescence are attended with a brisk agitation of the particles.

Agitation is one of the chief causes or instruments of mixture: by the agitation of the parts of the blood and chyle, in their continual circulation, purification is in a good measure effected. Butter is made out of milk by the same means: in which operation, a separation is made of the oleous parts from the serum, and a conjunction of the pleas together. Digestion itself is only supposed to be an insensible kind of agitation.

Agitation is reputed one of the symptoms of inspiration. Petit informs us, that, in the last century, Pépin de there are in a church in Italy, for the space of a year, Sybilla, Li. a vapour of an extraordinary kind, which put all the people into trembling and agitations, and unless they got away betimes, set them a dancing, with strange contrejorions and gesticulations. This seems to verify what has been related of the temple of Delphi.

Agitation is also used in medicine for a species of exercice popularly called faining. Maurice prince of Orange found this method a relief against the severe pains of the gout and stone. Bartholine mentions fits of the toothach, deafness, &c. removed by vehement agitations of the body.

Agitator, in antiquity, a term sometimes used for a charioteer, especially those who drove in the circus at the curule games.

Agitators, in the English history, certain officers set up by the army in 1647, to take care of its interests. — Cromwell joined the agitators, only with a view to serve his own ends; which being once accomplished, he found means to get them abolished.

Aglaia, the name of the youngest of the three Graces, espoused to Vulcan.

Aglionby (John), an English divine, chaplain in ordinary to king James I. a man of universal learning, who had a very considerable hand in the translation of the New Testament appointed by king James I. in 1604.

Agmen, in antiquity, properly denotes a Roman army in march: in which sense, it stands contrastingly from aces, which denoted the army in battle array; though, on some occasions, we find the two words used indifferently for each other. The Roman armies, in their marches, were divided into primus agmen, answering to our vanguard; medium agmen, our main-battle; and posterior agmen, the rear-guard.

The order of their march was thus: After the first signal with the trumpets, &c. the tents were taken down, and the baggage packed up; at the second signal, the baggage was to be loaded on the horses and carriages; and at the third signal, they were to begin their march. First
AGNATE, in law, any male relation by the father's side.

AGNELE, an ancient French gold coin, first struck under the reign of St Louis, worth about twelve sous six deniers. The agnel is also called sometimes mouton d'or, and agnel d'or. The denomination is supposed to have arisen from the figure of a lamb, agnus, or sheep, struck on one side.

AGNO, a river of Naples, which, taking its rise in the mountainous parts of Terra di Lavoro, washes the town of Accra; and, falling between Capua and Averla, falls into the Mediterranean, about seven miles north of Pazzollu.

AGNOETIC (from αγνοετι, to be ignorant of,) in church-history, a sect of ancient heretics, who maintained that Christ, considered as to his human nature, was ignorant of certain things, and particularly of the time of the day of judgment. Eulogius, patriarch of Alexandria, ascribes this hereby to certain solitaries in the neighbourhood of Jerusalem, who built their opinion upon the text Mark xiii. 32. "Of that day and hour knoweth no man, no not the angels who are in heaven, neither the Son, but the Father only."—The fame pas sage was made use of by the Arians; and hence the orthodox divines of those days were induced to give various explanations thereof. Some allege, that our Saviour here had no regard to his divine nature, but only spoke of his human. Others understand it thus, That the knowledge of the day of judgment does not concern our Saviour considered in his quality of Messiah, but God only: which is the most natural solution.

AGNOMEN, in Roman antiquity, a kind of fourth or honorary name, given to a person on account of some extraordinary action, virtue, or other accomplishment. Thus the agnomen AFRICANUS was bestowed upon Publius Cornelius Scipio, on account of his great achievements in Africa.—The agnomen was the third or honorary name, given to a person on account of his achievements. Thus the agnomen CECROPE was the third name of the king of Macedon, Cecrops, who was supposed to have distributed the regular supply, by Colles and religious deriving considerable pecuniary advantage from selling these AGNUSES DEI to tame, and presenting them to others. The pope provides a regular supply, by consecrating once in seven years; they are distributed by the master of the wardrobe, and received by the cardinals and other prelates, with great reverence, in their caps and mitres.—The ceremony they pretend to derive from an ancient custom of the church, wherein part of the paschal taper consecrated on Holy Thursday was distributed among the people, to perfume their houses, fields, &c. in order to drive away evils, and to preserve them from forms and temptations. The AGNUSES DEI is forbidden to be brought into England under pain of incurring a premonition, 13 Eliz. cap. 2.

AGNUS DEI is also a popular name for that part of the mass wherein the priest, striking his breast three times, rehearse, with a loud voice, a prayer beginning with the words AGNUSES DEI.—The AGNUSES DEI is said to have been first brought into the ritual by pope Sergius.

AGNUS SYPHICUS. See SYPHIAN LAMB.

AGOGE, among ancient musicians, a species of modulation, where in the notes proceed by contiguous degrees.

AGON, among the ancients, implied any dispute or content, whether it had regard to bodily exercises or the accomplishments of the mind; and therefore poets, musicians, painters, &c. had their agonies, as well as the athletes. Games of this kind were celebrated at most of the heathen festivals; with great solemnity, either annually, or at certain periods of years. Among the latter were celebrated at Athens, the agon gymnicus, the agon nemeus instituted by the Argives in the 53d Olympiad, and the agon olympius instituted by Heracles 430 years before the first Olympiad.—The Romans also, in imitation of the Greeks, instituted contests of this kind. The emperor Diocletian, after the death of one under the name of agon solus the contest of the fun; Diocletian another, which he called agon capitolinus, which was celebrated every fourth year, after the manner of the Olympic games. Hence the years, instead of juftra, are sometimes numbered by agonies.

AGON also signified one of the ministers employed in the Heathen sacrifices, and whose business it was to strike the victim. The name is supposed to have been derived from hence, that flapping ready to give the stroke he asked, Agon? or Agone? Shall I strike?

AGONALES, an epithet given to the salii.

AGONALIA, in Roman antiquity, festivals celebrated in honour of Janus, or the god Agonian, whom the Romans invoked before undertaking any affair of importance.

AGONALIS CIRCUS, now La Piazza Navona, a long, large, beautiful street in the heart of Rome, adorned with fountains, and the obelisk of Caracalla, still retaining the form of that circus. The reason of the name Agonalis is either unknown or doubtful. Ovid seems to derive it from the agones, or solemn games,
AGONIUM, in Roman antiquity, was used for the day on which the red facrorum sacrificed a victim, as well as for the place where the games were celebrated, otherwise called agon.

AGONOTHETAE, or AGONOTHESES, in Grecian antiquity, was the president or superintendent of the sacred games; who not only defrayed the expense attending them, but inspected the manners and discipline of the athletes, and adjudged the prizes to the victors.

AGONY, any extreme pain. It is also used for the pangs of death. Much of the terror of death consists in the pangs and convulsions wherewith the agony is attended; though we have reason to believe that the pain in such cases is ordinarily not extremely acute; a course of pain and sickness having usually stupified and indispersed the nerves for any quick sensations.

However, various means have been thought of for mitigating the agony of death. Lord Bacon considers this as part of the province of a physician; and that not only when such a mitigation may tend to a recovery, but also when, there being no further hopes of a recovery, it can only tend to make the passage out of life more calm and easy. Complacency in death, which Augustus so much desired, is certainly no small part of happiness. Accordingly the author last cited ranks eubenasia, or the art of dying easily, among the disdainers of science; and does not even seem to disapprove of the course Epicurus took for that end.

---Hinc fxyias ebrios hast aquas.

Opium has been applied for this purpose, with the applause of some, but the condemnation of more.

AGONYCLITAE, or AGONYCLITAE, in church-history, a sect of Christians, in the 7th century, who professed always standing, as thinking it unlawful to kneel.

AGORÆUS, in heathen antiquity, an appellation given to such deities as had statues in the market-place; particularly Mercury, whose statue was to be seen in almost every public place.

AGORANOMUS, in Grecian antiquity, a magistrate of Athens, who had the regulation of weights and measures, the prices of provisions, &c.—The agora, at Athens, were ten in number; five belonging to the city, and as many to the pirates; though others make them fifteen in all, of whom they allotted ten to the city. To these a certain toll or tribute was paid, by all who brought anything to sell in the market.

AGOUTI, or AGOUT. See Mus.

AGRA, the capital town of a province of the same name, in Indostan, and in the dominions of the Great Mogul. It is looked upon as the largest city in these parts, and is in the form of a half-moon. A man on horseback can hardly ride round it in a day. It is surrounded with a wall of red stone, and with a ditch 100 feet wide. The palace is prodigiously large, and the seraglio commonly contains above 1000 women. There are upwards of 800 baths in this town; but that which travellers most admire, is the mausoleum of one of the Mogul's wives, which was 20 years in building. The indigo of Agra is the most valuable of all that comes from the East Indies. This town is seated on the river Jumna, about 50 miles above its confluence with the Teshum, and is 300 miles N. E. of Surat. E. Long. 79. 12. N. Lat. 26. 29.

AGRARIAN LAWS, among the Romans, those relating to the division and cistiruption of lands, of which there were a great number; but that called the Agrarian Law, by way of eminence, was published by Spurrus Calvis, about the year of Rome 268, for dividing the conquered lands equally among all the citizens, and limiting the number of acres which each citizen might enjoy. The Roman lands were of several kinds; some conquered from the enemies, and not yet brought to the public account; others brought indeed to the public, but clandestinely usurped by private great men; lastly, others purchased with the public money, in order to be divided. Agrarian laws, either for dividing lands taken from the enemy, or the public lands, or those purchased with the public money, were easily padded with disturbance; but those whereby private rich men were to be deprived of their lands, and the common people put in possession of what had been held by the nobility, were never attempted without great discontents.

Several laws were for the necessity of agrarian laws in England: but an act has entered to deeply into the subject as Mr. Harrington in his Oceana, which the reader who chooses may consult.

AGREDÀ, a town of Spain, in Old Castile, near the frontiers of Aragon, and about three leagues south-west of Taragon.

AGRIA, called by the Germans Egria, is a small but strong town in Upper Hungary, and is a bishop's see. It is situated on a river of the same name, and has a castle called Erav. It was besieged by the Turks in 1552, with 70,000 men; but they left 8000 in one day; and were obliged to raise the siege, though their garrison consisted only of 2000 Hungarians, affiduated by the women, who performed wonders on this occasion. However, it was afterwards taken by Mats'omet III. in 1566; but was taken by the emperor in 1587; since which time it has continued under the dominion of the house of Austria. It is 47 miles north-east of Buda, and 55 south-west of Caslovia. E. Long. 20. 10. N. Lat. 48. 10.

AGRICOLA, (Cnemus Junius), born at Frejus in Pro-
Agricola. Provence, was, in Vespasian's time, made lieutenant to Vettius Bolanus in Britain; and, upon his return, was ranked by that emperor among the patricians, and made governor of Aquitania. This post he held three years; and upon his return he was chosen consul, and afterwards appointed governor of Britain, where he greatly distinguished himself. He reformed many abuses occasioned by the avarice or negligence of former governors, put a stop to extortion, and caused justice to be impartially administered. Vespasian dying about this time, his son Titus, knowing the great merit of Agricola, continued him in the government. In the spring, he marched towards the north, where he made some new conquests, and ordered forts to be built for the Romans to winter in. He spent the following winter in concerting schemes to bring the Britons to conform to the Roman customs. He thought the best way of diverting them from rising and taking arms, was to soften their rough manners, by proposing to them new kinds of pleasure, and insipring them with a desire of imitating the Roman manners. Soon after this, the country was adorned with magnificent temples, porticos, baths, and many other fine buildings. The British nobles had at length their sons educated in learning; and they who before had the utmost aversion to the Roman language, now began to study it with great avidity; they wore likewise the Roman habit; and, as Tacitus observes, they were brought to consider those things as marks of politeness, which were only so many badges of slavery. Agricola, in his third campaign, advanced as far as the Tweed; and in his fourth, he subdued the nations betwixt the Tweed and the friths of Edinburgh and Dumbarton, into which the rivers Glotta and Bodotria discharge themselves; and here he built fortresses to shut up the nations yet unconquered. In his fifth, he marched beyond the friths; where he made some new acquisitions, and fixed garrisons along the western coasts, over against Ireland. In his sixth campaign he passed the river Bodotria, ordering his fleet, the first which the Romans ever had in those parts, to row along the coasts, and take a view of the northern parts. In the following spring, the Britains raised an army of 30,000 men; and the command was given to Galgacus, who, according to Tacitus, made an excellent speech to his countrymen on this occasion. Agricola likewise addressed his men in very strong and eloquent terms. The Romans gained the victory, and 10,000 of the Britains are said to have been killed. This happened in the reign of the emperor Domitian; who, growing jealous of the glory of Agricola, recalled him, under pretence of making him governor of Syria. Agricola died soon after; and his death is suspected to have been occasioned by poison given him by that emperor. Tacitus the historian married his daughter, wrote his life, and laments his death in the most pathetic manner.

Agriculture

Definition. May be defined, The art of disposing the earth in such a manner as to produce whatever vegetables we desire, in large quantity, and in the greatest perfection of which their natures are capable. — But though by this definition, agriculture, strictly speaking, includes in it the cultivation of every species of vegetable whatever, and consequently comprehends all that is understood gardening and planting, we mean here to con-
agriculture.

History. The antiquity of this art is undoubtedly beyond that of all others; for we are informed by Scripture, that Adam was sent from the garden of Eden to till the ground; and, this being the case, he certainly must have known how to do so.—It would be ridiculous, however, to imagine that he was acquainted with all the methods of ploughing, harrowing, sowing, &c. which are now made use of; and it would be equally so to suppose, that he used such clumsy and unartful instruments as wooden hooks, horns of oxen, &c. to dig the ground, which were afterwards employed for this purpose by certain savages: but as we know nothing of the particular circumstances in which he was situated, we can know as little concerning his method of agriculture.

The prodigious length of life which the antediluvians enjoyed, must have been very favourable to the advancement of arts and sciences, especially agriculture, to which it behoved them to apply themselves in a particular manner, in order to procure their subsistence. It is probable, therefore, that even in the antediluvian world, arts and sciences had made great progress, nay, might be farther advanced in some respects than they are at present. Of this, however, we can form no judgment, as there are no histories of those times, and the scripture gives us but very slight hints concerning these matters.

No doubt, by the terrible catastrophe of the flood, which overwhelmed the whole world, many sciences would be entirely lost, and agriculture would suffer; as it was impossible that Noah or his children could put in practice, or perhaps know, all the different methods of cultivating the ground that were formerly used. The common methods, however, we cannot but suppose to have been known to him and his children, and by them transmitted to their posterity: so that as long as mankind continued in one body, agriculture, when it was carried so far, as to be the amusement of different nations, the arts, agriculture especially, would necessarily advance; and that they did so, is evident from the undertaking of the tower of Babel. It is from the dispersion of mankind consequent upon the confusion of tongues, that we must date the origin of savage nations. In all societies where different arts are cultivated, there are some persons who have a kind of general knowledge of most of those practised through the whole society, while others are in a manner ignorant of every one of them. If we suppose a few people of understanding to separate from the rest, and become the founders of a nation, it will probably be a civilized one, and the arts will begin to flourish from this origin; but, if a nation is founded by others whose intellects are in a manner callous to every human science (and of this kind there are many in the most learned countries), the little knowledge or memory of arts that were among the original founders will be lost, and such a people will continue in a state of barbarism for many ages, unless the arts be brought to them from other nations.

From this, or similar causes, all nations of equal antiquity have not been equally savage, nor is there any solid reason for concluding that all nations were originally unskilled in agriculture; though as we know not the original instruments of husbandry used by mankind when living in one society, we cannot fix the date of the improvements in this art. Different nations have always been in a different state of civilization; and agriculture, as well as other arts, has always been in different degrees of improvement among different nations at the same time.

From the earliest accounts of the eastern nations, we have reason to think, that agriculture has at all times been underfoot by them in considerable perfection; seeing they were always supplied not only with the necessaries, but the greatest luxuries of life.

As soon as the descendants of Abraham were settled in Palestine, they generally became husbandmen, from the chiefs of the tribe of Judah to the lowest branch of the family of Benjamin. High birth or rank did not at that time make any distinction, for agriculture was considered as the most honourable of all employments; witness the illustrious examples of Gideon, Saul, and David.

The Chaldeans, who inhabited the country where agriculture had its birth, carried that valuable art to a degree of excellence unknown in former times. They cultivated their lands with great affiduity, and seem to have found out some means of restoring fertility to an exhausted soil, by having plentiful harvests in succession; on which account they were not obliged, as their predecessors had been, to change their situations, in order to obtain a sufficiency for themselves and their numerous flocks and herds.

The Egyptians, who, from the natural fertility of their country by the overflowing of the Nile, raised every year vast quantities of corn, were so familiar of the blessings resulting from agriculture, that they ascribed the invention of that art to Osiris. They also regarded Isis, their second deity, as the discoverer of the use of wheat and barley, which before grew wild in the fields, and were not applied by that people to the purposes of food. Their superstitious gratitude was shown so far as to worship those animals which were employed in tillage; and even to the produce of their lands, as leeks, onions, &c.

The divine honours paid to Bacchus in India were derived from the same source, he being considered in that country as the inventor of planting vineyards, and the other arts attendant upon agriculture.

It is also related of the ancient Persians, on the most respectable authority, that their kings laid aside their grandeur once every month to eat with husbandmen. This is a striking instance of the high estimation in which they held agriculture; for at that time arts were practised among that people in great perfection, particularly those of weaving, and embroidery. The precepts of the religion taught by their ancient magi, or prêcis, included the practice of agriculture.

The Jews, among them was obliged to work out his salvation by pursuing all the labours of agriculture: And it was a maxim of the Zendavesta, that he who sows the ground with care and diligence, acquires a greater degree of religious merit, than he could have gained by the repetition of ten thousand prayers.

The Phoenicians, so well known in scripture by the name of Philistines, were also remarkable for the attention to, and skill in agriculture. But finding themselves
Agriculture.

History.

Itself too much disturbed and confined by the incursions and conquests of the Israelites, they spread themselves throughout the greatest part of the Mediterranean islands, and carried with them their knowledge in the arts of cultivation.

Mago, a famous general of the Carthaginians, is said to have written no less than 28 books on the subject; which Columella tells us were translated into Latin by the express order of the Roman Senate. We are informed by the ancient writers, that Ceres was born in Sicily, where she first invented the arts of tillage and of sowing corn. For the essential service, she was, agreeably to the superstition of those ages, deified, and worshipped as the goddess of plenty. The truth of this is, that in the time of Ceres, the island, through her endeavours and the industry of the people, became very fruitful in corn; and agriculture was there esteemed a honourable employment, that even their kings did not disdain to practise it with their own hands.

But time, which at first gave birth to arts, often caused them to be forgotten when they were removed from the place of their origin. The descendants of Noah, who settled in Europe, doubled carried their knowledge of agriculture with them into the regions which they successively occupied. But those who took possession of Greece were such an uncivilized race, that they fed on roots, herbs, and acorns, after the manner of beasts. Pelagus had taught them the culture of the oak, and the use of acorns as food; for which service, we are told, divine honours were paid him by the people.

The Athenians, who were the first people that acquired any tincture of polite arts, taught the use of corn to the rest of the Greeks. They also instructed them how to cultivate the ground, and to prepare it for the reception of the seed. This art we are told, was taught them by Trippolemus. The Greeks soon perceived that bread was more wholesome, and its taste more delicate than that of acorns and the wild roots of the fields; accordingly they thanked the gods for such an unexpected and beneficial present, and honoured the benefactor.

As the arts of cultivation increased, and the blessings they afforded became generally experienced, the people soon preferred them to whatever the ravages of conquest, and the cruel depredations of savage life, could procure. And accordingly we find, that the Athenian kings, thinking it more glorious to govern a small state fitly, than to aggrandize themselves, and enlarge the extent of their dominions by foreign conquests, withdrew their subjects from war, and mostly employed them in cultivating the earth. Thus, by continued application, they brought agriculture to a considerable degree of perfection, and soon reduced it to an art.

Hefiod was the first we know of among the Greeks who wrote on this interesting subject. According to the custom of the Oriental authors, he wrote in poetry, and embellished his poem with luxuriant descriptions and sublime imagery. He calls his poem Weeks and Days, because agriculture requires exact observations on times and seasons. Xenophon has also, in his Oeconomics, remarked, that agriculture is the nursing mother of the arts. For, says he, "where agriculture succeeds prosperously, there the arts thrive; but where the earth uselessly lies uncultivated, there the other arts are destroyed."

Other eminent Greek writers upon agriculture were, Democritus of Abdera, Socrates, Archytas, Tarentinus, Arisotle, and Theophrastus, from whom the art received considerable improvements.

The ancient Romans esteemed agriculture so honourable an employment, that the most illustrious senators of the empire, in the intervals of public concerns, applied themselves to this profession; and such was the simplicity of those ages, that they assumed no appearance of magnificence and splendor, or of majesty, but when they appeared in public. At their return from the toils of war, the taking of cities, and the subduing of hostile nations, their greatest generals were impatient till they were again employed in the arts of cultivation.

Regulus, when in Africa, requested of the Senate to be recalled, left his farm might suffer, for want of proper cultivation, in his absence; and the Senate wrote him for answer, that it should be taken care of at the public expense, while he continued to lead their armies.

Cato the censor, after having governed extensive provinces, and subduing many warlike nations, did not think it below his dignity to write a Treatise on Agriculture. This work (as we are told by Servius) he dedicated to his own son, it being the first Latin treatise written on this important subject; and it has been handed down to us in all its purity, in the manner that Cato wrote it.

Varro composed a treatise on the same subject, and on a more regular plan. This work is embellished with all the Greek and Latin erudition of that learned author, who died 28 years before the commencement of the Christian era. Virgil, who lived about the same time, has, in his Georgics, adorned this subject with the language of the Muses, and finely illustrated the precepts and rules of husbandry left by Hesiod, Mago, and Varro.

Columella, who flourished in the reign of the emperor Claudius, wrote 12 books on husbandry, replete with important instruction.

From this period to that of the reign of Constantine Paganus, husbandry continued in a declining state; but that wise emperor caused a large collection of the most useful precepts relating to agriculture to be extracted from the best writers, and published them under the title of Georgics. It has been ascertained, that he made this collection with his own hand; and the truth of the assertion is not improbable, as it is well known, that after he had conquered the Saracens and the Arabians, he not only practised and encouraged, but studied the arts of peace, fixing his principal attention on agriculture, as their best foundation.

After the death of Constantine, however, the increasing attention of the people to commerce, and the ignorance and gross superstition of the ages which succeeded, seems to have rendered agriculture an almost neglected science. The irruptions of the northern nations soon abolished any improved system. These innumerable and enterprising barbarians, who over-ran all Europe, were originally shepherds or hunters, like the present Tartars and the savages of America. They esteemed themselves with possessing those vast deserts made by
by their own ravages, without labour or trouble, cultivating only a very small spot near their habitations; and in this trifling husbandry only the meaelst flaves were employed; so that the art itself, which formerly was thought worthy of the study of kings, was now looked upon as mean and ignoble; a prejudice which is scarcely effaced at present, or at least but very lately. — During this period, therefore, we find no vestiges of any thing tolerably written on the subject. None attempts were made to revive it, or to improve it, till the year 1478, when Cretienzone published an excellent performance on the subject at Florence. This roused the lumbering attention of his countrymen, several of whom soon followed his example. Among these, Tartti, Steffano Augustino Gallo, Sanovino, Lauro, and Tarello, deserve particular notice.

At what time agriculture was introduced into Britain, is uncertain. When Julius Caesar first invaded that island, it was not wholly unknown. That conqueror was of opinion, that agriculture was first introduced by some of those colonies from Gaul which had settled in the southern parts of Britain, about 100 years before the Roman invasion.

It is not to be expected that we can now be acquainted with many of the practices of these ancient husbandmen. It appears, however, that they were not unacquainted with the use of manures, particularly marle. This we have on the authority of Pliny, who tells us, that it was peculiar to the people of Gaul and of Britain; that its effects continued 80 years; and that no man was ever known to marle his field twice, &c. — It is highly probable, too, that time was at this time also used as a manure in Britain, it being certainly made use of in Gaul for this purpose at the time of Julius Caesar's invasion.

The establishment of the Romans in Britain produced great improvements in agriculture, inasmuch that prodigious quantities of corn were annually exported from the island; but when the Roman power began to decline, this, like all the other arts, declined also, and was totally destroyed by the depredations of the invader. The unhappy Britons were now exposed to frequent incursions of the Scots and Picts, who destroyed the fruits of their labours, and interrupted them in the exercise of their art. After the arrival of the Saxons in the year 449, they were involved in such long wars, and underwent so many calamities, that the husbandmen gradually lost much of their skill, and were at last driven from those parts of the country which were most proper for cultivation.

After the Britons retired into Wales, though it appears from the laws made relative to this art, that agriculture was thought worthy of the attention of the legislature, yet the instruments employed in the management thereof were unfruitful. It was enacted that no man should undertake to guide a plough who could not make one; and that the driver should make the ropes of twisted willows, with which it was drawn. It was usual for six or eight persons to form themselves into a society for fitting out one of these ploughs, providing it with oxen and every thing necessary for ploughing; and many minute and curious laws were made for the regulation of such societies. If any person laid dung on a field with the consent of the proprietor, he was by law allowed the use of that field for one year. If the dung was carried out in a cart, in great abundance, he was to have the use of the land for three years. Whoever cut down a wood, and converted the ground into arable, with the consent of the owner, was to have the use of it for five years. If any one folded his cattle, for one year, upon a piece of ground belonging to another, with the owner's consent, he was allowed the use of that field for four years.

Thus, though the Britons had in a great measure lost the knowledge of agriculture, they appear to have been very affiduous in giving encouragement to such as would attempt a revival of it; but, among the Anglo-Saxons, things were not at present in so good a state. These refractory and haughty warriors, having contracted a distant and contempt for agriculture, were at pains to enact laws to prevent its being followed by any other than women and slaves. When they first arrived in Britain, they had no occasion for this art, being supplied by the natives with all the necessaries of life. After the commencement of hostilities, the Saxons subsisted chiefly by plunder; but having driven out or exterminated most of the ancient Britons, and divided their lands among themselves, they found themselves in danger of starving, there being now no enemy to plunder; and therefore they were obliged to apply to agriculture.

The Saxon princes and great men, who, in the division of the lands, had received the greatest shares, are said to have subdivided their estates into two parts, which were called the in-lands and the out-lands. The in-lands were those which lay most contiguous to the manor-house of their owner, which he kept in his own possession, and cultivated by his slaves, under the direction of a bailiff, for the purpose of raising provisions for the family. The out-lands were those at a greater distance from the house, and were let to the cottars, or farmers of those times, at very moderate rents. By the laws of Ina king of the West Saxons, who reigned in the end of the seventh and beginning of the eighth century, a farm consisting of ten hides, or eight-ploughlands, was to pay the following rent: "Ten casks of honey; three hundred loaves of bread; twelve cauls of strong ale; thirty cauls of small ale; two oxen; ten wethers; ten geese; twenty hens; ten cheefes; one caulk of better; five salmon; twenty pounds of forage; and one hundred eels." From this low rent, the imperfection of agriculture at that time is easily discoverable: but it is still more so from the low prices at which land was then sold. In the ancient history of the church of Ely, published by Dr Gale, there are accounts of many purchases of lands by Adelin, the founder of that church, and by other benefactors, in the reign of Edgar the Peaceable, in the seventh century. By comparing these accounts, it appears, that the ordinary price of an acre of the best land in that part of England, in those times was no more than 16 Saxon pennies, or about four shillings sterling; a very trifling price, even in comparison with that of other commodities at the same time. For, by comparing other accounts, it appears, that four sheep were then equal in value to an acre of the best land, and one horse of the same value with three acres. The frequent and deplorable famines which afflicted England about this time, are further instances of the wretched state of agriculture. In 1043, a quarter of wheat sold for
from 60 Saxon pence (15 shillings sterling), and at that time equal in value to seven or eight pounds sterling at present.

The invasion of the Normans, in 1066, contributed very much to the improvement of agriculture; for, by that event, many thousands of husbandmen from Flanders, France, and Normandy, settled in Britain, obtained estates or farms, and cultivated them after the manner of their country. The implements of husbandry, used at this time, were of the same kind with those employed at present; but some of them were less perfect in their construction. The plough, for example, had but one flint or handle, which the ploughman guided with one hand, having in his other hand an instrument which served both for cleaning and mending the plough, as well as for breaking the clods. The Norman plough had two wheels; and in the light soil of Normandy was commonly drawn by one or two oxen; but, in England, a greater number was often required; their carts, harrows, scythes, sickles, and hoes, from the figures of them still remaining, appear to have been nearly of the same construction with those that are now used. In Wales, they did not use a flint for reaping their corn, but an instrument like the blade of a knife, with a wooden handle at each end.—Their chief manure, next to dung, seems still to have been marl. Summer following of lands designed for wheat, and ploughing them several times, appear to have been frequent practices of the English farmers in this period.

We are, after all, very much in the dark as to the state and progress of agriculture in Great Britain previous to the fourteenth century. That it was very generally practised, especially in the eastern, southern, and midland parts of England, is certain; but of the mode, and the success, we are left almost totally ignorant. In the latter end of the fifteenth century, however, it seems to have been cultivated as a science, and received very great improvement.

A. At this time in England Fitzherbert, Judge of the Common-Places, flourished with distinguished eminence in the practical parts of husbandry. He appears to have been the first Englishman who studied the nature of soils, and the laws of vegetation, with philosophical attention. On these he formed a theory confirmed by experiments, and rendered the study pleasing as well as profitable, by realizing the principles of the ancients, to the honour and advantage of his country. Accordingly, he published two treatises on this subject: the first, intitled The Book of Husbandry, appeared 1524; and the second, called The Book of Surveying and Improvements, in 1529. These books, being written at a time when philosophy and science were but just emerging from that gloom in which they had long been buried, were doubtless replete with many errors; but they contained the rudiments of true knowledge, and revived the study and love of art, the advantages of which were obvious to men of the least reflection. We therefore find that Fitzherbert's books on Agriculture soon raised a spirit of emulation in his countrymen, and many treatises of the same kind successively appeared, which time has however deprived us of, or at least have become so very scarce as to be found in the libraries of the curious.

About the year 1660, France made some considerable efforts to revive the arts of husbandry, as appears from several large works, particularly Les Jeux de l'Agriculture; and the Gomme des Foiurs, by Bernard de Pailly, a poor porter, who seems to have been placed by fortune in a station for which nature never intended him; Le Théâtre d'Agriculture, by Deféure; and L' Agriculture et genre Rustique, by Meiffers Etienne, Liebault, &c.

Nearly in the same period, the practice of husbandry became more prevalent among this people and the French, than the publishing of books on the subject. Their intention seemed to be that of carrying on a private lucrative employment, without instructing their neighbors. Whoever therefore became detestful of copying their method of agriculture, was oblig'd to visit that country, and make his own remarks on their practice.

The principal idea they had of husbandry was, by keeping the lands clean and in fine tilth, to make a farm resemble a garden as nearly as possible.

Such an excellent principle, at first setting out, led them of course to undertake the culture of small farms only, which they kept free from weeds, continually turning the ground, and manuring it plentifully and judiciously. When they had by this method brought the soil to a proper degree of cleanliness, health, and sweetness, they chiefly cultivated the more delicate grases, as the safest means of obtaining a certain profit upon a small estate, without the expense of keeping many draught horses and servants. A few years experience was sufficient to convince them, that ten acres of the best vegetables for feeding cattle, properly cultivated would maintain a larger flock of grazing animals than forty acres of common farm grass on land badly cultivated. They also found, the best vegetables for this purpose were lucerne, flaxman, trefoil of all kinds, fiddle turnips, &c.

The grand political secret of their husbandry, therefore, consisted in letting farms on improvement. They were also to have discovered nine forts of manure; but what they all were we are not particularly informed. We find, however, that marl was one of them; the use and virtues of which appear also to have been well known in England two hundred years ago, although it was afterwards much neglected. They were the first people among the moderns who ploughed in green crops for the sake of fertilizing the soil; and who confined their sheep at night in large sheds built on purpose, the floors of which were covered with sand or virgin earth, &c. which the shepherd carried away each morning to the compost dunghill.

In England, during the civil wars, though the operations and improvements in husbandry suffered some temporary checks, there flourished several excellent writers on the subject, and the art itself received considerable encouragement. Sir Hugh Platt was one of the most ingenious husbandmen of the age in which he lived; yet so great was his modesty, that all his works, except his Paradise of Flora, seem to be posthumous. He held a correspondence with most of the lovers and patrons of agriculture and gardening in England; and such was the justice and modesty of his temper, that he always named the author of every discovery communicated to him. Perhaps no man in any age discovered, or at least
AGRICULTURE.

leat brought into use, so many new kinds of manure. This will be evident to those who read his account of the compost and covered dung-hills, and his judicious observations on the fertilizing qualities lodged in salt, street-dirt, and the fulriage of streets in great cities, clay, fuller’s earth, moorish earths, dung-hills made in layers, fern, hair, calcination of all vegetables, malt-dirt, willow-tree earth, foaper’s ashes, urine, marle, and broken pitchparks.

Gabriel Plattes may be said to have been an original genius in husbandry. He began his observations at an earlier period, in the reign of Queen Elizabeth; and continued them down to the Commonwealth. But notwithstanding the great merit of this writer, and the essential service he had rendered his country by his writings, the public ungratefully suffered him to starve and perish in the streets of London; nor had he a shirt on his back when he died.

Samuel Hartlib, a celebrated writer on agriculture in the last century, was highly esteemed and beloved by Milton, and other great men of his time. In the preface to his work intitled His Legacy, he laments that no public director of Husbandry was established in England by authority; and that they had not adopted the Flemish method of letting farms upon improvement. This remark of Hartlib’s procured him a pension of L. 100 a-year from Cromwell; and the writer afterwards, the better to fulfill the intention of his benefactor, procured Dr. Beatt’s excellent annotation on the Legacy, with other valuable papers from his numerous correspondents.

The time in which Hartlib flourished seems to have been an era when the English husbandry rofe to great perfection, compared with that of former ages; for the preceding wars had impoverished the country gentlemen, and of course made them industrious. They found the cultivation of their own lands to be the most profitable station they could fill. But this wise turn was not of long continuance. At the restoration, they generally became infected with that intoxication and love of pleasure which succeeded. All their industry, and knowledge were exchanged for neglect and dissipation; and husbandry deserted almost entirely into the hands of common farmers.

Evelyn was the first writer who inspired his countrymen with a desire of reviving the study of agriculture; and he was followed by the famous Jethro Tull. The former, by his admirable treatises on earth and on planting, and the latter, by showing the superior advantages of the drill-husbandry, excited numbers to bring their theory to the test of fair experiment.

Many valuable and capital improvements have, since that period, been made in English husbandry; and these great men have been succeeded by a variety of writers, many of whom have done essential service, by enlightening the minds of their countrymen, and exciting them to emulation.

About the middle of the last century, Ireland began to make a considerable figure in the art of husbandry. It must indeed be confessed, that the Irish had very strong prejudices in favour of a wretched method of agriculture, till Blyth opened their eyes by his excellent writings. Since that time, a spirit of improvement has more or less been promoted, and in many instances carried on with great zeal, by the

nobility, clergy, and gentry of that kingdom. In proof of this, it will be sufficient to observe, that the Transations of the Dublin Society for encouraging Husbandry are now cited by all foreigners in their memoirs relating to that subject. And the observations of that discerning and judicious writer, Arthur Young, Esq; in his late Tour through that kingdom, show, that in many respects improvements there have of late years made a progress nearly as rapid as in England.

After the peace of Aix-la-Chapelle, most of the nations of Europe, by a sort of tacit consent, applied themselves to the study of agriculture, and continued to do so, more or less, amidst the universal confusion that succeeded.

The French found, by repeated experience, that they could never maintain a long war, or procure a tolerable peace, unless they could raise corn enough to support themselves in such a manner as not to be obliged to harass terms on the one hand, or to perish by famine on the other. This occasioned the king to give public encouragement to agriculture, and even to be present at the making of several experiments. The great, and the rich of various ranks and stations, followed his example; and even the ladies were candidates for a share of fame in this public-spirited and commendable undertaking.

During the hurry and distresses of France in the war of 1756, considerable attention was paid to agriculture. Prize-questions were annually proposed in their rural academies, particularly those of Lyons and Bourdeaux; and many judicious observations were made by the Society for improving agriculture in Brittany.

Since the conclusion of that war in 1763, matters have been carried on there with great vigour. The university of Amiens made various proposals for the advancement of husbandry; and the Marquis de Tourbilly (a writer who proceeded chiefly on experience) had the principal direction of a Georgical society established at Tours.

The society at Rouen also deserves notice; nor have the king and his ministers thought it unworthy their attention. There are at present about fifteen societies existing in France, established by royal approbation, for the promoting of agriculture; and these have twenty co-operating societies belonging to them.

About this time vigorous exertions began to be made in Russia to introduce the most approved system of husbandry which had taken place in other parts of Europe. The present Empress has sent several gentlemen into Britain and other countries to study agriculture, and is giving it all possible encouragement in her own dominions.

The art of agriculture has also been for near 50 years publicly taught in the Swedish, Danish, and German universities, where the professors may render efficient service to their respective countries, if they understand the practical as well as the speculative part, and can converse with as much advantage with the farmer as with Virgil and Columella.

Even Italy has not been totally inactive. The Neapolitans of this age have condescended to recur to the first rudiments of revived husbandry, and began to study anew the Agricultural System of Crecenzio, first published in 1478. The people of Bergamo have pur-
A G R I C U L T U R E.

In an art so extensively useful to mankind, and which has been so universally practised since the creation of the world, it is natural to expect the most exact and perfect theory. But in this we are totally disappointed.

One reason of this want of a distinct theory of agriculture is, the ignorance of what is properly the food of vegetables; for as the art of agriculture consists principally in feeding them with a proper quantity of food, in the most favourable circumstances, it is evident, we might proceed upon a much surer foundation if we could ascertain what their proper nourishment is, than we can do without this knowledge.

The reason of the great differences regarding the practice, probably, is the difficulty of making experiments in agriculture. It is not in this art as in Mechanics, Chemistry, &c. where an experiment can be made in hour, or a day or two at farthest: an experiment in agriculture cannot be properly made in less than several years. Some favourable circumstances, quite foreign to the experiment itself, may concur to produce plentiful crops for a year or two; and
and thus the farmer may be induced to publish his fancied improvements; which falling in the hands of others, or perhaps even in his own on a repetition of the experiment, the new improvements are totally neglected, and things continue in their old way. Were he, however, capable of seeing and handling the food of vegetables, as well as he can do that of a horse or an ox, and procuring it in any imaginable quantity, it is plain, that he would be able to cause vegetables grow in their utmost luxuriance, or, if we may be allowed the expression, _fatten_ them, with as great certainty as he can fatten a horse or an ox, when he hath plenty of proper food to give them.—To ascertain what this food is, therefore, must be a step towards the perfection of agriculture; and to this we shall contribute our endeavour.

**Sect. I. Of the proper Food of Plants.**

We shall not here spend time in refuting the theories of those who imagined the vegetable food to consist of oily and fatuous substances. A more probable supposition has been, That Water and Air are the proper vegetable food, to which alone they owe their increase in bulk and weight.—That plants cannot be supported _ex cepta se_; plants._—That plants cannot be supported from whatever substance, conftitute at least one species of vegetable food; and when vegetables are put into such circumfances that the stems of purifying bodies can have access to them, we are sure they will thrive the better.

The Doctor also found, that by agitating putrid air in water, part of which was exposed to the atmosphere, the water acquired a very putrid noxious smell; which shows, that water, as well as air, is capable of absorbing those effluvia which are found proper food for vegetables.

We cannot help concluding, therefore, that in the continual ascent of water in vapour, and its descent again in rain, which is a much more effectual _agitation_ than could be made by Dr Priestley, the water must be very intimately combined with the phlogistic or putrid effluvia which are contained in the air. To this union we are led strongly to suppose that rain-water owes its fertilizing qualities; for the purest spring waters, though most wholesome for animals, are not found to be fit for promoting the growth of vegetables.—As, therefore, vegetables evidently receive nourishment both by their leaves and roots, and incerase remarkably in bulk by absorbing the putrid effluvia from the air; and as

they likewise increase in bulk by admitting water to their roots, and more so when the water contains much of that kind of effluvia than when it contains less: so we would conclude, that the nourishment received by the roots of plants is of the same kind with that received by their leaves; and that this food may be given them in greater plenty than they naturally receive it, by impregnating the air which surrounds them, or the water which moistens them, with a greater quantity of putrid matter than what they contain in a natural state.

**Sect. II. The foregoing Theory confirmed from considerations on the nature of vegetable _nourishment_, and the different kinds of Manures found proper for fertilizing the Soil.**

Though plants will grow on any kind of earth, All kinds of and food vigorously, if plentifully supplied with earth nourished; yet some kinds of soils are found to be more proper for supplying them with nourishment than others.—We cannot, indeed, allow the inferences to be quite fair, which some would draw from experiments on plants set in mere sand, &c.; viz. that the earth is of no other use to vegetation than to afford a proper support to the plant, that it be not easily moved out of its place; because the experiments made on single vegetables are always performed in or very near houses, where the air is by no means so pure as in the open fields, and consequently where they have an opportunity of receiving as much nourishment from the air as may compensate the want of what they would have derived from the earth if planted in a rich soil. Lord Kames, in the Gentleman Farmer, mentions an experiment wherein a pea was planted on some cotton spread on water, in a phial. It sprang, and pulsed roots through the cotton into the water. The plant grew vigorously, and, at the time of his writing the experiment, carried large pods full of ripe food.—From this experiment, or others of a similar kind, however, a farmer would not be thought to act very judiciously, who should conclude that nothing more was requisite to produce a plentiful crop, than to keep his fields contantly soaking with water, and apply his labour only for that purpose, without regarding either tillage, manure, or the difference of soils. Experience has abundantly shown, that by certain operations performed on the earth itself, it is rendered much more capable of supplying vegetables with plenty of nourishment than if such operations were omitted; and that some kinds of soils cannot without certain additions be rendered fit for this purpose as others; and this is what constitutes the difference between a rich and a poor soil.

That species of earth which is capable of supply- ing the vegetable kingdom with nourishment in the greatest plenty, is found best in well cultivated gardens. It is not, however, even in these, found in perfect purity; being constantly mixed with greater or less proportions of sand, small stones, &c. It can be had by itself, and entirely separated from all other substances, only by suffering vegetable or animal bodies to putrefy. By undergoing this operation, they are at last reduced into a kind of earth, which appears perfectly the same, from whatever substance it is produced. Of this earth Dr Lewis gives us the following characters. It is in- diffoluble.
AGRICULTURE.

There may perhaps be another cause why putrefaction will be of benefit to consumptions. It is well known, that, after some days of drought, on the falling of rain that moistens the earth, there arises a grateful smell, which we are all sensible of; and this is commonly attributable to the vegetables, which before flipples, but now refreshed by rain, perspire more copiously. But Reaumur observed, that a like fragrancy is also perceptible after rain when the corn has been cut down in the fields, where there only remains dry stubble; and examining the matter more particularly, he found that dry earth is without smell, but as soon as it is moistened to the degree of having the confidence of letting play, it then diffuses a strong smell; but if more water is added, the smell is diminished, may even quite disappear. Neither does it seem an easy matter to exhaust that power of producing smells which the earth is possessed of. Every day, during a fortnight, he made cakes of moistened earth; and having dried and wetted them over again, he could not perceive that the earth was less fragrant after all these repeated experiments, if it was again wetted. He further observed, that this fragrancy does not diffuse itself to anything at a great distance, without being much diminished, and soon entirely gone.—It has been observed, that this expiration of the earth ceases if thunder and storms soon follow: while they continue, it begins to return; and when over, the same fragrancy of the earth for some hours affects the smell of a man as he walks along over a considerable tract of ground. There is one, I believe, but has sometimes made this observation; and hence the earth, when moistened to a certain degree, seems to exhale fragrant odours, and indeed varies in various places, as we are sensible of from their diversity. They are for the most part of a fabulous quality; as some perfumes quite faint and languid in the summer-heats perceive themselves wonderfully refreshed, whilst, after rain, they snuff up the fragrant odor. In some places those effluvia are perhaps bad, and may be the causes of diseases.

This property of emitting a fragrant smell is likewise taken notice of by Dr Home in his Principles of Agriculture and Vegetation. Some physicians have preferred a bath of earth for the cure of consumptive patients; and Dr Solano de Luque was of opinion, that the earth had the property of absorbing contagious misfortunes into it; but whether it can absorb these misfortunes from living bodies or not, it certainly can absorb them from dead ones; for a piece of putrid meat will be much sweetened by lying for a short time in the ground.

From all this we cannot indeed infer, that putrid air is sweetened by mere earth; but we discover what transmutations are perhaps more important, namely, that though earth is the common receptacle of all putrid matters both animal and vegetable, there is a change made on them when in it, which cannot be made either by air or water. Thus, if the carcase of a small animal is left to putrefy in the air, it becomes exceedingly offensive, and continues so from first to last. The same thing happens if it is left to putrefy in water. But, in earth, the carcase is quite different. After the carcase is consumed, the earth which has absorbed all the putrid effluvia, instead of exhaling an offensive odour, diffuses an agreeable one; and thus we may see that it is endowed with a power no less remarkable than that of at

The existence of such a power as that of transmutation we will be obliged to own, whatever we imagine the vegetable food to consist of; for it is impossible to solve the phenomena of vegetation by attractions and repulsions. If we suppose the vegetable food to be felt, let us attack and repel it as we will, it remains felt from first to last. Let us suppose it water, the cafe is the fame; and, by mere attraction, nothing but mafies of salt, or pools of water, could be produced. The cafe is the fame on our hypothesis; for, supposing plants compos'd of the patriarch effulsion of others, and of dead animals, if nature was ended with no other power than attraction or repulsion, the vegetable would necessarily be a corrupted mafs like that of which it was compos'd.—This power, as we have already seen, resides only in the earth, and in the vegetables themselves; air and water can indeed act as powerful agents, but cannot transform or compound. We must next consider the nature of those different operations, which, from time immemorial, have been performed on the earth, in order to cause it produce the greatest crops of vegetables. If all of these shall be found conspiring to one general purpose, then the shortest and most easy method of attaining that purpose is undoubtedly the most proper to be practised in agriculture, whether it hath been as yet put in execution or not. There are,

1. Frequent ploughing, or following. The immediate consequences of this is to expel different quantities of the soil to the action of the air and sun, which will not fail to exert their solvent powers upon it. In consequence of this action, the earth is partly reduced to powder; many of the roots of vegetables, with which it always abounds, are dissolved and putrefied; and the earth produced from them mixes with the reft, as well as the effuvia they emit during their dilution. The earth soon begins again to exert its prolific powers, and a crop of vegetables is produced. By a repetition of the ploughing, there are turned with their roots upwards, are exposed to the solvent powers of the air and light; in consequence of which they die, are purrefed, and more of the native foil is reduced to powder, and mixed with them. By a frequent repetition of this process, the foil becomes vastly more tender, and approaches to the nature of garden mould, and its fertility is considerably increased.

Lord Kames is of opinion, that the reafon of the fertility of any foil being increafed by following, is, that its capacity of retaining water is increafed. But this cannot be admitted; for so far from being more difpofed to retain water by its pulverification, the foil is evidently more difpofed to part with it, either by evaporation, or by effufling the moisture to percolate thro' it. In this refpect it is far inferior to clay; for though dry garden-mould absorbs water much more quickly than clay, it also dries much sooner, and thus all the advantage is lost.

The fertilizing quality of water will easily be accounted for on the fame principles. When grown vegetables are covered with water, their growth, however vigorous before, is immediately flop'd, unless they be of the aquatic kind: they die, are difolved, and putrefied, in which cafe, their finer parts are undoubtedlv aborbed by the earth: and thus the floating, as it is called, of fields with water, anfwers the purpofe of following, with very little trouble. This is not all; forflaguating water always depofites a feditlent, which mixing with the difpofed parts of the vegetables all over the field, forms an excellent manure; and when the water is allowed to run off, the heat of the fab fon brings the highest degree of putrefaction on the dead vegetables; the effuvia of which, mixing with the mud depofited from the water, makes it exceedingly rich.

Upon the fuppofition of oily and faltine food for vegetables, this operation must certainly be prejudicial; for nothing can so effectually deprive any fubftance of falt as fleping it in water. Neither will water either deposit oil from itself, or fuffer it to mix with the ground if accidentially brought to it; nay, though a field were previously impregnated with oil, upon percolating it with water great part of the oil would be feparated, and rise to the top: so that, in either cafe, this operation could not fail to impoverifh land rather than enrich it; and as vegetables are found to be supplied with food in plenty by an operation which muft undoubtedly tend to take away both oils and faltines from them, we cannot help thinking this a demonstration, that their food is composed neither of oil nor falt.

3. Manuring, or mixing the foil with different fubftances.—We shall here confine ourselves to thofe which are of undoubted efficacy, and have their eredit etabli{hed by long experience. These are, 1. lime, chalk, marle, thells, or other earths, called by the chemifs calcareous earths; 2. foat; 3. ashes; 4. dung of different kinds.—(1) The lime, chalk, marle, and thells, are all found to be of the fame nature. The marle differs from the reft, only in having a mixture of clay along

---

To those who reckon the food of vegetables to con-"
Part I. AGRICULTURE.

Theory. along with its calcareous part. These contain neither fall nor oil of any kind; they readily imbibe water, and as readily part with it. Quicklime, indeed, retains water very obnubilatingly; but such lime as is laid upon the ground soon returns to the same state in which it originally was; and powdered limetone is found to answer as well for the purposes of manure as that which has been burnt; so that here we may consider them all as substances of the same class. If any of these substances are mixed with dead animal or vegetable bodies, they remarkably quicken their dissolution and corruption, as appears from Sir John Pringle's experiments. When mixed with the soil, therefore, they most undoubtedly exert their powers on living substances as they find there, in the same manner as they do on others; that is, they must hasten their dissolution and putrefaction, and give the pure vegetable mould an opportunity of absorbing their purrid streams, and consequently of being fertilized by it in the same manner as by purrid substances of any kind.

(2.) Those who contend for oily and fatty principles in the vegetable food, avail themselves of the usefulness of foot as a manure; which is not only oily of itself, but affords a great quantity of volatile salt, along with some neutral sal-ammoniac. It must be remembered, however, that not an atom either of volatile salt or sal-ammoniac can be extracted from foot without a considerable heat, which no soil can give, nor could any vegetable bear. Neither doth its oil appear without a great degree of heat: and though it feels somewhat unctuous to the touch, this is but a mere deception; for no true oil, capable of floating on water, can be obtained from foot without distillation. It is impossible, therefore, that foot can act upon the soil either as an oily or a saline substance; how far it is capable of dissolution by putrefaction, or being otherwise converted into an earth, hath not yet been determined by experiments; but as it yields, on distillation, the same principles which are obtained from animal or putrid vegetable substances, it is probable that foot enriches the ground in the same manner that they do. (3.) The use of ashes in manure is likewise urged as an argument for the food of vegetables being of a saline nature; as it is known, that the common alkaline salts are procured by lixiviating the ashes of wood and other vegetables. Experience, however, shows us, that ashes are of no less a nature after the salts are extracted from them than before. Indeed, if there be any difference, it is in favour of the washed ashes. The alkali itself, though in Sir John Pringle's experiments it was found to be antiseptic, or a refiter of putrefaction, is nevertheless a powerful disinfectant; and as it must soon lose its alkaline properties when mixed with the earth, in consequence of the universal existence of the vitriolic acid, those substances which it has dissolved will be more disposed to putrefaction than before, and consequently tend to fertilize the ground in the manner we have already described. The washed ashes are fibres, or promotors of putrefaction, and consequently act in the same manner as chalk or limetone. (4.) All kinds of dung are so much disposed to putrefaction, that it is difficult to imagine any other way in which they can be serviceable to vegetation than by their purrid effluvia. People indeed may dream of imaginary salts in dung; but if they knew or considered the difficulty of procuring fall of any kind from dung, they would probably alter their sentiments. The volatile salts procured from this as well as other animal matters, are mere creatures of the fire; putrid urine produces them indeed without heat, but several other animal substances. Nevertheless, other purrid substances will fertilize the ground as well as urine, and therefore must act in some other way than by their salts. Though Dr Priestley's experiments had never been made, we could have formed no other rational supposition concerning the manner in which purrid substances fertilize the earth, than what we have already done; but as he has shown that vegetables are prodigiously increased in bulk by the mere contact of these purrid streams, where no saline substances that could have access to them, we cannot help thinking this a decisive experiment concerning the manner in which the ground is fertilized by manuring with dung or other purrid substances.

We shall conclude this part of the subject with an account of some experiments concerning the effects of saline substances on the growth of vegetables. The following are related by Lord Kames, in his Gentleman Farmer. A number of Jerusalem artichokes were set in pots filled with pure sand. One plant was kept as a standard, being nourished with water only. Other plants of the same kind were nourished with water in which salt of tartar, a fixed alkali, was dissolved. These grew more vigorously than the standard plant; but, by reiterated waterings, there came to be such an accumulation of the fixed alkali among the sand, as to make the plants decay, and at last to die. Some plants were nourished with water in which sal-ammoniac, a volatile alkali, was dissolved. These grew also well for some time; but, like the former, were destroyed by frequent waterings of it. Weak lime-water promoted the growth of its plants more than common water. But water completely saturated with quicklime, produced more noxious than that which contained a fixed alkali, though less than that which contained a solution of volatile alkali. Urine promoted, for a long time, the growth of its plants; and the most purrid appeared to have the strongest effect; but at last it totally destroyed them. Water impregnated with purrid animal and vegetable substances, did more efficiently promote the growth of its plants than any other solution; and in every stage of the proofs appeared to be Salutary. With regard to other saline substances, there are not many experiments which can be depended upon concerning their qualities as manure. Mr Anderson relates an experiment made with common salt; the success of which, we apprehend, may justly enough be taken as a specimen of what is to be expected from manures of a similar kind. He marked out a circle of six feet diameter in the middle of a grass-field, which he disfigurised by driving a stake in its centre. All over this circle he sowed common salt, which, about the stake, lay near an inch thick on the ground. In this stake he left it to the operation of nature. The grass sprang up as usual, neither better nor worse about the stake than in the rest of the field, and the place where the circle was could be distinguished only by the stake, which was left there for some years.

Upon these experiments we need make very few observations. They are so much in favour of our theory, that they seem made on purpose to confirm it. The fixed
Agriculture.

Part I.

Theory.

fixed alkali employed in Lord Kames's experiments would first exert its solvent powers on such heterogeneous substances as it met with among the sand: for no sand can be supposed to be perfectly free of these. As long as it exerted its strength on these only, the plant would thrive, for the reasons we have already mentioned; but having exhausted the small quantity of substances contained in the sand, it would next attack the plant itself, which consequently would decay and die. The same effects would necessarily follow in a greater degree from strong lime-water which contains lime in its caustic state; for this is a more powerful solvent than fixed alkali itself, and would not fail to destroy everything it touched; nor is it at all improbable that the plant would seem to grow vigorously by the dissolution of part of its own roots, more nourishment being by this means given to those which remained found.

Volatile alkali is likewise a powerful solvent: but, by reason of its volatility would exert its caustic power on the plant sooner than either lime or fixed-alkali; and accordingly it seems to have been the most destructive of any thing that was tried. It seems owing to this, that muriatic urine at last destroyed the plants whose growth it so long promoted; while water impregnated with other purrid matters, which yield no volatile alkali without heat, proved always salutary.

From all this, we may draw the following general conclusion, viz. That the principal end which a farmer ought to keep in view, is to impregnate his ground as much as possible, with substances which either actually contain purrid matter, or which are in their own nature feptic, or promoters of putrefaction. To impregnate the air with purrid effluvia is impolitic: and though it could be done, would be highly dangerous; for however salutary such effluvia may be to vegetables, nothing can be more fatal to mankind. The purrid substances, therefore, can only be used by mixing them with the earth; and in whatever manner they can be most perfectly, and in the greatest quantity, mixed with the soil, there the best crops may be expected.

Sect. III. Of the different Soils, and the Manures most proper for each.

According to the theory we have just now laid down, the richest soil must be that which contains the greatest quantity of purrid matter, either animal or vegetable; and such is the earth into which animal and vegetable substances dissolve themselves. Was this earth to be had in perfection, it is evident it could not stand in need of manure of any kind, or be the least enriched by it; for containing an immense quantity of purrid matter, it would freely communicate it to the vegetables planted in it, which would grow in the most luxuriant manner, without requiring any other care than that of keeping them constantly supplied with water. If we suppute the crop left upon the ground to putrefy and mix with the earth as before, the soil will contain the same quantity of purrid matter the second year that it did the first, and be equally prolific: but if the crop is removed to another place, and nothing is brought back to enrich the ground in its stead, it is evident, that it will contain less of the true vegetable food the second year than it did the first, and consequently be less prolific. For some time, however, the difference will not be perceptible; and people who are in possession of such ground may imagine that they enjoy a soil which will be perpetually fertile; but long experience has taught us, that the richest soils will at last be exhausted by repeated cropping without manure, as according to our theory they ought to be.

Where the ground has been suffered to remain uncultivated for many ages, producing all that time succulent plants which are easily putrefied, and trees, the leaves of which likewise contribute to enrich the ground by their falling off and mixing with it, the soil will in a manner be totally made up of pure vegetable earth, and be the richest, when cultivated, that can be imagined. This was the case with the lands of America. They had remained uncultivated perhaps since the creation, and were endowed with an extraordinary degree of fertility; it is nevertheless certain that such grounds as have been long cultivated, were so much exhausted, as to be not much better than the generality of cultivated grounds in France or England. Here, then, we have an example of one species of poor soil; namely, of poor soil one that has been formerly very rich, but has been so much deprived, by repeated cropping, of great parts of the vegetable food it contained. The farmer, who in possession of such ground, would no doubt willingly restore it to its former state; the present question is, What must be done in order to obtain this end? We have mentioned several kinds of manures which long practice has recommended as serviceable for improving ground: we shall suppose the farmer tries lime, or chalk; for, as we have already seen, their operations upon the soil must be precisely the same. This substance, being of a septic nature, will act upon such parts of the soil as are not putrefied, or but imperfectly so; in consequence of which, the farmer will reap a better crop than formerly. The septic nature of the lime is not altered by any length of time. In ploughing the ground, the lime is more and more perfectly mixed with the earth, and gradually exerts its power on every putrefiable matter it touches. As long as any matter of this kind remains, the farmer will reap good crops: but when the putrefiable matter is all exhausted, the ground then becomes perfectly barren; and the caustic qualities of the lime are more unjuftly blamed for burning the ground, and reducing it to a caput mortuum; while it is plain, the lime has only done its office, and made the soil yield all that it was capable of yielding.

When the ground has been long uncultivated, producing all the time plants, not succulent, but such as are very difficultly disolved, and in a manner incapable of putrefaction; there the soil will be excessively barren, and yield very scanty crops, tho' cultivated with the greatest care. Of this kind are those lands covered with heath, which are found to be the most barren of any, and the most difficulty brought to yield good crops. In this case lime will be as serviceable, as it was detrimental in the other: for by its septic qualities, it will continually reduce more and more of the soil to a purrid state; and thus there will be a constant succession of better and better crops, by the continued use of lime when the quantity first laid on has exerted all its force. By a continued use of this manure the ground will be gradually brought nearer and nearer to the nature of garden-mould; and, no doubt, by proper care, might be made

End to be kept in view by a farmer.

Richest soils must at last be impoverished.

One species of poor soil meliorated by lime.
made as good as any; but it will be as great a mistake to imagine, that, by the use of lime, this kind of soil may be rendered perpetually fertile, as to think that the other was naturally so; for though lime enriches this soil, it does so, not by adding vegetable food to it, but by preparing what it already contains; and when all is properly prepared, it must as certainly be exhausted as in the other case.

Poor soils, how restored.

Here, then, we have examples of two kinds of poor soils; one of which is totally destroyed, the other greatly improved, by lime, and which therefore requires very different manures; lime being more proper for the latter than dung; while dung, being more proper to restore an exhausted soil than lime, ought only to be used for the first. Besides dunging land which has been exhausted by long cropping, it is of great service to let it lie fallow for some time: for to this it owed its original fertility; and what gave the fertility originally cannot fail to restore it in some degree.

By attending to the diffusion between the reasons for the poverty of the two kinds in the part above mentioned, we will always be able to judge with certainty in what cases lime is to be used, and when dung is proper. The mere poverty of the soil is not a criterion whereby we can judge; we must consider what hath made it poor. If it is naturally so, we may almost infallibly conclude, that it will become better by being manured with lime. If it is artificially poor, or exhausted by continual cropping, we may conclude that lime will entirely destroy it. We apprehend, that this is natural kind of poverty only which Mr. Anderson says in his Essays on Agriculture, may be remedied by lime; for we can scarce think that experience would direct any person to put lime upon land already exhausted. His words are,

"Calcaneous matters act as powerfully upon land that is naturally poor, as upon land that is more richly impregnated with those substances that tend to produce a luxuriant vegetation."

"Writers on agriculture have long been in the custom of dividing manures into two classes; viz. Exciting manures, or those that tended directly to render the soil more prolific, however fertile it may be; among the foremost of which was dung: Exciting manures, or those that were supposed to have a tendency to render the soil more prolific, merely by acting upon those enriching manures that had been formerly in the soil, and giving them a new stimulus, so as to enable them to operate anew upon that soil on which they had formerly fertilized. In which clays of stimulating manures, lime was always allowed to hold the foremost place."

"In consequence of this theory, it would follow, that lime could only be of use as a manure when applied to rich soils—and when applied to poor soils, would produce hardly any, or even perhaps hurtful, effects."

"I will frankly acknowledge, that I myself was so far imposed upon by the beauty of this theory, as to be hurried along with the general current of mankind, in the firm persuasion of the truth of this observation, and for many years did not sufficiently advert to those facts that were daily occurring to contradict this theory. I am now, however, firmly convinced, from repeated observations, that lime, and other calcaneous manures, produce a much greater proportional improvement upon poor soils than such as are richer."

That lime alone, upon a poor soil, will, in many cases, produce a much greater and more lasting degree of fertility than dung alone.

Thus far Mr. Anderson's experience is exactly conformable to the theory we have laid down, and what ought to happen according to our principles. He mentions, however, some facts which seem very strongly to militate against it; and indeed he himself seems to proceed upon a theory altogether different.

"Calcaneous matter alone (says he) is not capable of raising plants to perfection—it would be necessary to be mixed with it in certain proportions, before it can form a proper foil. It remains, however, to be determined, what is the due proportion of these ingredients for forming a proper foil.

"We know that neither chalk, nor marl, nor lime, can be made to nourish plants alone; and soils are sometimes found that abound with the two first of these to a faulty degree. But the proportion of calcaneous matter in the first is so much larger than could ever be produced by art, where the soil was naturally deficate of these substances, that there seems to be no danger of erring on that side. Probably it would be much safer to correct the defects of these soils in which calcaneous matters superabound, by driving earth upon them as a manure, than is generally imagined; as a very small proportion of it sometimes affords a very perfect foil."

I shall illustrate my meaning by a few examples.

"Near Sandifer, in the county of Cashel, there is a very extensive plain on the sea-coast, endowed with a very soil, with a most singular degree of fertility. In all seasons perpetually it produces a motl luxuriant herbage, although it never suffered any manure since the creation; and has been for time immemorial subject to the following course of crops.

"1. Bear, after once ploughing from grass, usually a good crop.

"2. Bear, after once ploughing, a better crop than the first.

"3. Bear, after once ploughing, a crop equal to the first.

"4. 5. and 6. Natural grass, as clofe and rich as could be imagined, might be cut, if the possession so inclined, and would yield an extraordinary crop of hay each year."

"After this the fame course of cropping is renewed. The foil that admits of this singular mode of farming, appears to be a pure incoherent sand, deficate of the finest particle of vegetable mould; but, upon examination, it is found to consist almost entirely of broken shells: the fine mould here bears such a small proportion to the calcaneous matter, as to be scarce perceptible, and yet it forms the most fertile soil that ever I yet met with.

"I have seen many other links (downs) upon the sea-shore, which produced the most luxuriant herbage, and the clofeft and sweetest pile of grass, where they confined of holly (sand) which, without doubt, derive their extraordinary fertility from that cause."

"A very remarkable plain is found in the island of Jir-eve, one of the Hebrides. It has been long employed as a common; so that it has never been disturbed by the plough, and affords annually the most luxuriant crop of herbage, consisting of white clover, and
other valuable pasture-grasses, that can be met with anywhere. The soil consists of a very pure shelly sand.

From these examples, I think it is evident, that a very small proportion of vegetable mould is sufficient to render calcareous matter a very rich soil. Perhaps, however, a larger proportion may be necessary when it is mixed with clay than with sand; as poor chalky soils seem to be of the nature of that composition.

To these examples brought by Mr Anderson, we may add some of the same kind mentioned by Lord Kames. His lordship having endeavoured to establish the theory of water being the only food of plants, tho' he himself frequently deviates from that theory, yet thinks it possible, upon such a principle, to make a soil perpetually fertile.

"To recruit (says he) with vegetable food, a soil impoverished by cropping, has hitherto been held the only object of agriculture. But here opens a grander object, worthy to employ our keenest industry, that of making a soil perpetually fertile. Such soils actually exist; and why should it be thought, that imitation here is above the reach of art? Many are the instances of nature being imitated with success. Let us not despair, while any hope remains; for invention never thinks it impossible, UpOn such a principle, to make a soil perpetually fertile.

A field perpetually solid on careons earth promises of a success; but it must be remembered, that imitation is not a power to retain moisture sufficient for its plants; and at the same time must be of a nature that does not harden by moisture. Calcareous earth promises to answer both ends: it prevents a soil from being hardened by water; and it may probably also invigorate its retentive quality. A field that got a sufficient dose of clay-marle, carried above 50 succceive rich corps, without either dung or fallow. Doh not a soil so meliorated draw near to one perpetually fertile! Near the east side of Fife, the coast for a mile inward is covered with fen-fand, a foot deep or so; which is extremely fertile, by a mixture of fea-shells reduced to powder by attrition. The powdered shells, being the fame with shell-marle, make the sand retentive of moisture; and yet no quantity of moisture will unite the sand into a solid body. A soil so mixed, seems to be not far distant from one, perpetually fertile. Thence, it is true, are but faint eflays; but what will not perseverance accomplish in a good cause!"

Having thus, in a manner, positively determined with Mr Anderson, that no dose of calcareous matter can possibly be too great, we cannot help owning ourselves surprised on finding his Lordship expressing himself as follows: "An over-dose of shell-marle, laid perhaps an inch, and an inch and a half, or two inches thick, produces, for a time, large crops; but at last it renders the field a caput mortuum, capable of neither corn nor grass; of which there are too many instances in Scotland; the same probably would follow from an over-dose of clay-marle, stone-marle, or pounded lime-flour."—To account for this, he is obliged to make a supposition directly contrary to his former one; namely, that calcareous matter renders the soil incapable of retaining water. This phenomenon, however, we think is solved upon the principles first laid down, in a satisfactory manner, and without the least inconsistency. As to rendering soils perpetually fertile, we cannot help thinking the attempt altogether chimerical and vain. There is not one example in nature of a soil perpetually fertile, where it has no supply but from the air, and the rain which falls upon it. The above recorded examples can by no means, be admitted as proofs falls chimerical of perpetual fertility. We know, that the grass on the banks of a river is much more luxuriant than what grows at a distance; the reason is, that the water is attracted by the earth, and communicates its fertilizing qualities to it; but was the river to be dried up the grass would soon become like the rest. Why should not the ocean have the fame power of fertilizing plains near its shores, that rivers have of fertilizing small spots near their banks? We see, however, that it hath not; for the sea-shores are generally sandy and barren. The reason of this is, that the waters of the ocean contain a quantity of loose acid*; and this acid is poisonous to plants; but abstracting this acid part, we hesitate not to affirm, that sea-water is more fertilizing than river-water. It is impossible to know how far the waters of the ocean penetrate under ground through a sandy soil. Where they meet with nothing to absorb their acid, there the ground is quite barren; but in passing through an immense quantity of broken shells, the calcareous matter we are very certain, will absorb all the acid; and thus the soil will be continually benefited by its vicinity to the ocean. All the above fields, therefore, are evidently supplied with nourishment from the ocean: for if the salt-water has sufficient efficacy to render fields which are in its neighbourhood barren, why should it not render them fertile when the cause of barrenness is removed from its waters?

After all, the field in Caithness, mentioned by Mr Anderson, seems to have been perpetually fertile only in grass; for though the second year it carried a better crop of bear than it did the first, yet the third year the crop was worse than the second, and only equal to the first. Had it been ploughed a fourth time, the crop would probably have been worse than the first. Ground is not near so much exhausted by grass as corn, even though the crop be cut, and carried off; and still left, if it only feeds cattle, and is manured by their dung; which appears to have been the case with this field. Lord Kames, indeed, mentions fields in Scotland, that, past memory, have carried succeseive crops of wheat, pea, barley, oats, without a fallow, and without a manure; and particulars one on the river Carron, of nine or ten acres, which had carried 409 corps of oats without intermission, and without manure; but as we are not acquainted with any such fields, nor know any thing about their particular situation, we can form no judgement concerning them.

Before the two kinds of soils above mentioned, there are others, the principal ingredient of which is clay or sand. The first of these is apt to be hardened by the heat of the sun, so that the vegetables can scarce penetrate it in such a manner as to receive proper nourishment. The second, if it is not fattened to as to receive a great deal of moisture, is very apt to be parched up in summer, and the crop destroyed; nor has it sufficient adhesion to support plants that have few roots and grow high. From these opposite qualities, it is evident, that these two forms are not for one another: the clay would give a sufficient degree of firmness to the sand, and the sand would break the
Part I. AGRICULTURE.

Theory.—According to Dr. Home's experiments, however, land is the most manure for clay that can be added. He recommends marl or moss. To reduce clay-ground as near as possible to the form of pure vegetable mould, it must first be pulverized. This is most effectually performed by ploughing and harrowing; but care must be taken not to plough it while too wet, otherwise it will concret into hard clods which can scarcely be broken. After it is pulverized, however, some means must be taken to prevent it from concretting again into the same hard masses as before. According to Lord Kames, though clay, after pulverization, will concret into as hard a mass as before, if mixed with water; yet if mixed with dunhill juice, it will not concret any more. Lime also breaks its tenacity, and is very useful as a manure for this kind of soil.

The conclusion we with the practical farmer to draw from our theory is, that there is a certain limit to the fertility of the earth, both as to duration and degree, at any particular time; that the nearer any soil approaches to the nature of pure gaden-mould, the nearer it is to the most perfect degree of fertility; but that there are no hopes of keeping it perpetually in such a state, or in any degree of approximation to it, but by constant and regular manuring with dung. Lime, chalk, marl, &c. may be proper to bring it near to this state, but are absolutely unfit to keep it continually so. They may indeed for several years produce large crops; but the more they increase the fertility for some years, the sooner will they bring on an absolute barrenness; while regular manuring with plenty of dung will always ensure the keeping up the soil in good condition, without any occasion for fallow. What we have said concerning the use of lime, &c. applies likewise to the practice of frequent ploughing, though in a less degree. This tends to meliorate ground that is naturally poor, by giving an opportunity to the vegetable parts to putrefy; but when that is done, it tends to exhaust though not so much as lime. A judicious farmer will constantly strive to keep his lands always in good condition, rather than to make them suddenly much better; lest a few years should convince him that he was in reality doing almost irreparable mischief, while he fancied himself making improvements. As for the ridiculous notions of stimulating the ground by saline manures, we hope they will never enter the brain of any rational practitioner of agriculture.

Sect. IV. Of the different kinds of Vegetables proper to be raised with a view to the Melioration of Soil.

The methods of meliorating soils, which we have mentioned above, consisting of tedious and laborious operations that yield no return at first, it is natural for a farmer to wish for some method of meliorating his ground, and reaping crops at the same time. One very considerable step towards the melioration of ground is, its pulverization. This is accomplished by repeated ploughings (a), as already mentioned; especially if performed in autumn, that the ground may be exposed to the winter's frost; but these ploughings yield no crop as long as the field is not tilled. By planting in the field, however, those vegetables whose roots swell to a considerable bulk, the ground must be constantly acted upon by the swelling of their roots in all directions; and thus the growing of the crop itself may be equal, or superior, in efficacy to several ploughings, at the same time that the farmer enjoys the benefit of it. The plant most remarkable for the swelling of its roots is the potato; and by none is the ground meliorated more, or even so much. They are not, however, equally proper for all soils. In clay they do not thrive, nor are pulvurate; but in hard gravelly or sandy soils, they grow to a large size, and are of an excellent quality. Turnips likewise contribute to meliorate the ground, by the swelling of their roots, though not so much as potatoes. They have this advantage, however, that they thrive in almost any soil. In clay ground, peas and beans thrive exceedingly well, and therefore are proper in this kind of soil as a preparatory for other kinds of grain. These push their roots deep into the ground, and cover it with their leaves more than other crops; so that the fun has not so much access as when it is covered with other kinds of grain. Wherever any of these kinds of vegetables are raised, it is observable, that more or less blackness is communicated to the soil: an evident sign of its melioration; this being the colour of the true vegetable mould, or 'soil foil,' as it is called.

Besides the abovementioned plants, carrots, parsnips, cabbages, and all those vegetables which sink their roots deep in the ground, answer the same purpose of loosening and pulverizing the earth: but as they will not thrive but on ground already well cultivated, they cannot be raised to any advantage for the purpose of meliorating a poor soil.

It hath been customary in many places, particularly in England, to sow turnips, pea, buck-wheat, &c. and then to plough them down for manuring the land. This being similar to that operation of nature by which the renders the uncultivated soils so exceedingly fertile, cannot fail of being attended with singular advantages; and might be looked upon as preferable even to driving dung on the land to fatten it, was it not attended with the entire loss of a crop for that year.

Sect. V. Of destroying Weeds.

What we have already said regarding the cultivation of the soil, respects only the fitting of it for producing all kinds of vegetables indiscriminately. Experience, however, shows, that the ground is naturally much more disposed to produce and nourish some kinds of vegetables than others; and those which the earth seems most to delight in, are commonly such as are of very little use to man; but if neglected, will increase to such a degree, as entirely to destroy the plants intended to be raised, or at least hinder them from coming to perfection, by depriving them of nourishment. The clearing the ground of weeds, therefore, is an article of great importance in agriculture, than the disposing it to produce vegetables of any kind in plenty.

(a) This, however, must be understood with some limitation: for it appears from experience, that many light and thin soils receive detriment rather than advantage from frequent ploughings; particularly in summer, when the sun exhalas the nutritive particles in great abundance.
The weeds may be divided, according to the time of their duration, into annual, or such as spring from a seed, and die the same year; and perennial, that is, such as are propagated by the roots, and last for a number of years. The first kind are the least noxious, and most easily destroyed. For this purpose it will be sufficient to let them spring up till near the time of ripening their seed, and then plough them down before it comes to maturity. It is also of service to destroy such weeds as grow in borders, or neglected corners, and frequently scatter their seeds to a great distance; such as the thistle, dandelion, rag-weed, &c. these are sufficient to propagate their species through a considerable distance, as their seeds are carried with the wind to very considerable distances. A farmer ought also to take care, that the small seeds of weeds, separated from corn in winnowing, be not fown again upon the ground; for this certainly happens when they are thrown upon a dunghill; because, being the natural offspring of the earth, they are not easily destroyed. The best method of preventing any mischief from this cause, would be to burn them.

Perennial weeds cannot be effectually destroyed, but by removing the roots from the ground, which is often a matter of some difficulty. Many of these roots strike so deep in the ground, that they can scarcely be got out. The only method that can be depended upon in this case, is frequent ploughing, to render the ground as tender as possible; and harrowing with a particular kind of harrow, which shall hereafter be described, in order to collect these perilous roots. When collected, they ought to be dried and burnt, as the only effectual method of infuring their doing no further mischief.

There is a particular species of weed, peculiar only to grafs-lands, of a soft spongy nature, called fog, which it is found very difficult to exterminate. Where the land can be conveniently tilled, this weed may be destroyed by covering it with a crop of peas, potatoes, &c. or, passing a heavy roller over the ground will be of great service; for fog owes its origin to too great a laxity of the soil, and will not grow upon firm ground.

Besides these kinds of weeds which are of an herbaceous nature, there are others which are woody, and grow to a very considerable size; such as broom, furze, or whins, and thorns. Broom is an evergreen shrub, that thrives best in sandy soil; and there it grows so vigorously, as scarce to admit any gras under it. It propagates by seed which grows in pods; and these, when fully ripe, break with violence, scattering the seeds all around. Thus, a field which is overgrown with broom, besides the old plants, always contains an infinite number of young ones; so that though the old plants die when cut over, a fresh crop constantly springs up. It may, however, be destroyed by frequent ploughing and harrowing, in the same manner as other perennial weeds are; for it does not for some time carry any seed, and the frequent ploughing encourages the vegetation of all those that are already in the ground, which cannot fail of being destroyed by frequent repetitions of the operation. Another method of destroying broom, is by pasturing the field where it grows with sheep. A few of the old bushes may be left as a shelter, and the rest will be in a good measure prevented from spreading by the cropping of the sheep. These animals are very fond of broom, and greedily devour every young shoot; so that if any remain after the first year, there will not be a vestige the second. If this method of extirpating broom is equally effectual with that of frequent ploughing, it is certainly much more profitable, as there is no food more nourishing to sheep than young broom. Brooms, however, is said to have a singular effect upon sheep; it makes them drink so effectually, that when heated with a little driving, they rumble over, and lie without motion.

The whin is a fine evergreen shrub, carrying a sweet-smelling flower all the year round. It propagates both by seed and by its roots, which spread sometimes to the distance of ten or twelve feet; and hence, when once established, it is with difficulty extirpated. The best method is to set fire to the whins in frosty weather; for trolf has the effect to wither whins, and make them burn readily. The stumps must then be cut over with a hatchet; and when the ground is well softened by rain, it may be ploughed up, and the roots taken out by a harrow adapted to that purpose. If the field is soon laid down to grass, the whins will again spring up in great abundance, from the seeds, and small parts of the roots left in the ground. In this cafe, pasturing with sheep is an effectual remedy; as they are no less fond of young whins than of young broom; and if there are a sufficient number, they will not leave a single plant above ground. But if grass is not immediately wanted, the most effectual method of clearing a field of whins, is by reiterated ploughings.

The thorn, or bramble, spreads its roots very wide, and at the same time sinks them deep in the earth. Though cut in the winter, it rifies, and comes to such perfection as to carry fruit in summer. It can only be extirpated by ploughing up the ground, and collecting the roots.

**Sect. VI. Of the most proper kinds of Vegetables to be raised for the purposes of feeding Cattle.**

**Though this must be an article of the utmost consequence to every farmer, we do not find that it has been much considered. Mr. Anderson seems to have been the first writer on agriculture who hath properly attended to this subject; and what he hath wrote upon it, is rather a catalogue of desiderata, than anything else: and indeed the desiderata on this subject are so many and so great, that we must acknowledge ourselves very unable to fill them up.—To attain to a competent knowledge in this respect, the following things must be taken into consideration.**

1. The wholefomeness of the food for cattle, with regard to health and strength, or frame.
2. The quantity that any extent of ground is capable of yielding.
3. The quantity necessary to feed the different kinds of cattle.
4. The labour of cultivation; and, (5) The soil they require to bring them to perfection, and the effect they have upon it.

With regard to the wholefomeness, it is plain, that as the natural food of wild cattle is the green succulent plants they meet with all the year round, food of this kind, could it be had, must be preferable to hay; and accordingly we find that cattle will always prefer succulent vegetables where they can get them. To find plants
plants of this kind, and having proper qualities in other respects, you must search among those which continue all the year round, or come to their greatest perfection in the winter time. Of these, cabbages bid fair for holding the first place; both as being very succulent, and a very large quantity of them growing upon a small space of ground. In Mr Young's Six Months Tour, we have an account of the produce of cabbages in many different places, and on a variety of soils. The produce by Mr Crow at Keplin, on a clay soil, was, on an average of six years, 33 tons per acre; by Mr Smelt at the Leaues, on a sandy gravel, 38 tons per acre; by Mr Scroop at Danby, on an average of six years, 37 tons per acre; and the general average of all the accounts given by Mr Young, is 36 tons per acre.

Cabbages, however, have the great inconvenience of sometimes imparting a disagreeable flavour to the milk of cows fed with them, and even to the flesh of other cattle. This, it is said, may be prevented by carefully picking off the decayed and withered leaves; and very probably this is the case; for no vegetable inclines more to putrefaction than this; and therefore particular care ought to be taken to pull off all the leaves that have any symptoms of decay. Dr Priestley found that air was rendered noxious by a cabbage-leaf remaining in it for one night, though the leaf did not show any symptom of putrefaction. For milk-cows, probably the cabbages might be rendered more proper food by boiling them.

The culture of the turnip-rooted cabbages has lately been much practiced, and greatly recommended, particularly for the purpose of a late spring feed; and seems indeed to be a most important article in the farming economy, as will be shown in its proper place.

Turnips likewise produce very bulky crops, though far inferior to those of cabbages. According to Mr Young's calculation, the finest soil does not produce above five tons of turnips per acre; which is indeed a very great disproportion; but possibly such a quantity of turnips may not be confumed by cattle as of cabbages; an ox, of 80 stone weight, cat 210 lbs. of cabbages in 24 hours, besides seven pound of hay.

Carrots are found to be an excellent food for cattle of all kinds, and are greatly relished by them. In a rich sand, according to Mr Young's account, the produce of this root was 200 bushels per acre. In a finer soil, it was 640 bushels per acre. A lean hog was fatt ed by carrots in ten days time; he eat 156 lbs; and his fat was very fine, white, firm, and did not boil away in the drolling. They were preferred to turnips by the cattle; which having tasted the carrots, soon became fond of them, as difficulty to be made to eat the turnips at all. It is probable, indeed, that carrots will make a more wholesome food for cattle than either cabbages or turnips, as they are strongly antiseptic; inasmuch as to be used in poultices for correcting the fancies of cancers. It is probably owing to this, that the milk of cows fed on carrots is never found to have any bad taint. Six hores kept on them through the winter without oats, performed their work as usual, and looked equally well. This may be looked upon as the last of their falsity as a food; and it certainly can be no detriment to a farmer to be so much verifiable in medical matters, as to know the impropriety of giving putrefactive food to his cattle. It is well known, that a prodigious difference there is in the health of the cattle fed on peas when fed on potatoes, in comparison of what they enjoy when supplied with food of a contrary nature; and why may there not be a difference in the health of beasts, as well as of men, when in similar circumstances?—It is also very probable, that as carrots are more solid than cabbages or turnips, they will go much farther in feeding cattle than either of them. The above mentioned example of the hog seems some kind of confirmation of this; he being fed, for ten days together, with 21 lbs. least weight of carrots than an ox devoured of cabbages and hay in one day. There is a great disproportion, it must be owned, between the bulk of an ox and that of a hog; but we can scarce think that an ox will eat as much at a time as ten hogs. At Parlington in Yorkshire, 20 work horses, four bullocks, and six milk-cows, were fed on the carrots that grew on three acres, from the end of September till the beginning of May; and the animals never tasted any other food but a little hay. The milk was excellent, and 30 hogs were fattened upon what was left by the other cattle.

Potatoes likewise appear to be a very palatable food for all kinds of cattle; and not only oxen, hogs, &c. are easily fed by them, but even poultry. The cheapness of potatoes compared with other kinds of food for cattle, cannot well be known, as, besides the advantage of the crop, they improve the ground more than any other known vegetable. According to a correspondent of the Bath Society*, of roasting pork is never so moil and delicate as when fed with potatoes, and killed from the barn-door without any confinement. For bacon and hams, two bushels of pea-meal should be well incorporated with four bushels of boiled potatoes, which quantity will fat a hog of twelve stone (fourteen pounds to the stone). Cows are particularly fond of them: half a bushel at night, and the same proportion in the morning, with a small quantity of hay, is sufficient to keep three cows in full milk; they will yield as much, and as sweet butter as the best grafts. In fattening cattle, I allow them all they will eat: a beast of about 35 stone will require a bushel per day, but will fatten one-third sooner than on turnips. The potatoes should be clean washed, and not given until they are dry. They do not require boiling for any purpose but fattening hogs for bacon, or poultry; the latter eat them greedily. I prefer the champion potato to any sort I ever cultivated. They do not answer so well for horses and colts as I expected (at least they have not with me), though some other gentlemen have approved of them as substitutes for oats.

* Letters and Papers agricUll're, &c. vol. iii. art. 16.
largely fed hogs, and esteemed equal in value to barley; it is much more easily grown than barley, as a malt-will grind it completely. Whins are very food of the grain; poultry of all sorts are speedily fattened by it; and the bottom of the plant affords food for bees at a very opportune season of the year, when the meadows and trees are mostly stripped of their flowers. Probably the grain may hereafter be even found a material article in distillation, should a sufficient quantity be raised with that view. From the success of some experiments detailed in the Bath Society-papers, and for which a premium was bestowed, it has been inferred, that this article ought in numerous cafes to supercede the practice of summer-fallowing.

Whins have lately been recommended as a very proper food for cattle, especially horses; and are recommended by Mr Anderson in a particular manner. They have this advantage, that they require no culture, and grow on the very worst soil; but they are troublesome to cut, and require to be bruised in a mill constructed for this purpose; neither is the ground at all mollicated by letting whins grow upon it for any length of time. Notwithstanding these disadvantages, however, as whins continue green all the year round, and when bruised will afford an excellent succulent food, which seems possessed of strongly invigorating qualities, they may be looked upon as the cheapest winter-food that can possibly be given to cattle. According to the calculations of Mr Edelin of Gareford, a single acre, well cropped with whins, will winter six horses: at three or four years growth, the whole crop should be taken, cut close to the ground, and carried to the mill; in which the whins are to be bruised, and then given to the horses. Four acres ought to be planted, that one may be cut each year, at the proper age to be cut; and he reckons the labour of one man sufficient for providing food to this number of horses. He says they all prefer the whins to hay or even to corn.

The herb called burnet hath likewise been recommended as proper food for cattle, on account of its being all eye-keeper; and further recommended, by growing almost as fast in winter as in summer. Of this herb, however, we have very various accounts. In a letter addressed by Sir James Caldwell, F. R. S. to the Dublin Society, the culture of this plant is strongly recommended on the authority of one Bartholomew Rocque, farmer at Wallam-Green, a village about three miles south-west of London.

What gave occasion to the recommendation of this plant, was, that about the year 1760, Mr Wych, chairman of the committee of Agriculture of the London Society for the encouragement of arts, manufactures, and commerce, came to Rocque (who was become very eminent by the premiums he had received from the society), and told him, he had been thinking, that as there are many animals which subsist wholly upon the fruits of the earth, there must certainly be some plant or herb fit for them that naturally vegetate in winter; otherwise we must believe the Creator, infinitely wise and good, to have made creatures without providing for their subsistence; and that if there had been no such plants or herbs, many species of animals would have perished before we took them out of the hands of nature, and provided for them dry meat at a season, when, indigenous plants having been indiscriminately excluded, under the name of weeds, from cultivated fields and places set apart for natural grass, green or rough meat was no longer to be found. Rocque allowed the force of this reasoning; but, and the knowledge of a grass, or artificial pasture, that would vegetate in winter, and produce green fodder for cattle, was lost; at least, that he knew of no such plant. Mr Wych, however, knowing how very great the advantage would be of discovering a green fodder for winter and early in the spring, wrote to Berne, and also to some considerable places in Sweden, stating the same argument, and asking the same question. His answers to these letters were the same that had been given by Rocque. They owned there must be such a plant, but declared they did not know it.

Mr Wych then applied again to Rocque; and desired him to search for the plant to much desired, and to certainly existing. Rocque set about this search with great alacrity; and finding that a plant, called burnet, was of very speedy growth, and grew near as fast in winter as in summer, he took a handful of it and carried it into his stable, where there were five horses; every one of which he fed it with the greatest eagerness, snatching it even without first smelling it. Upon the success of this experiment he went to London, and bought all the burnet-feed he could get, amounting to no more than eight pounds, it having been only used in fields; and he paid for it at the rate of 45s. a pound. Six of the eight pounds of feed he sowed upon half an acre of ground, in March, in the year 1761, with a quarter of a peck of spring-wheat, both by hand. The seed being very bad, it came up but thin. However, he sowed the other two pounds in the beginning of June, upon six rood of ground: this he mowed in the beginning of August; and at Michaelmas he planted the plants on about 20 rood of ground, giving each plant a foot every way, and taking care not to bury the heart. The plants bore two crops of seed the year following; the first about the middle of June, the second about the middle of September; but the June crop was the best. The year after, it grew much taller, and produced two crops of seed, both very good. As it ought not to be cut after September, he let it stand till the next year; when it sheltered itself, and grew very well during all the winter, except when there was a hard frost; and even during the frost it continued green, though it was not perceived to grow. In the March following it covered the ground very well, and was fit to receive cattle.

If the winter is not remarkably severe, the burnet, though cut in September, will be 18 inches long in March; and it may be fed from the beginning of February till May: if the cattle are taken off in May, there will be a good crop of feed in the beginning of July. Five weeks after the cattle are taken off, it may be removed, if that is preferred to its lasting for feed; it grows at the rate of an inch a-day, and is made into hay like other grasses. It may be mown three times in one summer, and should be cut just before it begins to flower. Six rood of ground has produced 1150 pounds at the first cutting of the third year after it was sowed; and, in autumn 1763, Rocque found no less than 300 bushels of the feed.

According to Rocque, the soil in which burnet flourishes best, is a dry gravel; the longest drought never burs
Part I.  

AGRICULTURE.

Theory.

hurts it: and Sir James Caldwell affirms, that he saw a very vigorous and exuberant plant of this kind, growing from between two bricks in a wall in Rocque's ground, without any communication with the soil; for he had cut away all the fibres of the root that had frstched downward, and penetrated the earth, long before the

Bursett was found equally fit for feeding cows, sheep, and horses; but the sheep must not be suffered to crop it too close. Though no feed was left among the hay, yet it proved nourishing food: and Roquette kept a horse upon nothing else, who, at the time of writing the account, was in good heart, and looked well. He affirmed also, that it cured horses of the distemper called the gravis, and that by its means he cured one which was thought incurable; but lays, it is only the first crop which has this effect.

This is the substance of Sir James Caldwell's letter to the Dublin Society, at least as to what regards the culture of Bursett; and it might reasonably be expected, that a plant, whose use was recommended to the public with so much parade, would soon have come into universal use. We are surprised, therefore, on looking into Mr. Miller's Dictionary, to find the following words, under the article Poterium:—"This plant has of late been recommended by persons of little skill, to be sown as a winter pulslum for cattle: but whoever will give themselves the trouble to examine the grounds where it naturally grows, will find the plants left uncut by the cattle, when the grass is not cropped; besides, in wet winters, and in strong land, the plants arc of short duration, and therefore very unfit for that purpose: nor is the produce sufficient to tempt any person of skill to engage in its culture; therefore I wish those perfons to make trial of it in small quantities, before they embark largely in these new schemes."—Mr. Anderfon, too, in his Essays on Agriculture, mentions the produce of bursett being so small, as not to be worth cultivating.

Upon the authority of Mr. Rocque, likewise, the white beet is recommended as a most excellent food for cows; that it vegetates during the whole winter, consecutively is very forward in the spring: and that the most profitable way of feeding cows is, to mow this herb, and give it to them green all the summer. It grew in Roquette's garden, during a very great drought, no less than four feet high, from the 30th of May to the 3d of July, which is more than one month and four days. In summer it grows more than an inch a day; and is best sown in March; a bushel is enough for an acre, and will not cost more than ten shillings. It thrives best in a rich, deep, light soil; it is a great fodder for cattle, and does not communicate any taint to the milk. It produces great abundance of leaves in summer, which may be cut three or four times without injuring the plant. The leaves are more palatable to cattle than most other garden plants, and are found to be very wholesome. The farmers in those parts of Germany where it is chiefly cultivated, and subterranean, it is sold, prefer this species of beet, for feeding cattle, to cabbages, principally because they are not liable to be hurt by worms or insects; but they think they are not so nourishing as turnips, potatoes, or carrots, and that cattle are not nearly so soon fattened by this root as by carrots, parnips, or cabbages. It has even been asserted, that this root affords less nourishment than any of those that have been commonly employed for feeding cattle. This does not correspond with the pompous accounts with which the public have been entertained. Upon the whole, however, it is a plant which seems to deprive the attention of farmers; as on some soils, and in particular circumstances, it may prove a very useful article for the above purposes.

In Mr. Anderson's essays, we find it recommended to make trial of some kinds of grasses, which probably would not only answer for fresh fodder during the winter, but might also be cut for hay in summer. This is particularly the case with that species called fseep's purple sieve and fseep's fseew-gras. We have seen a small patch of this grass in winter 1773; which, having been cut in the month of August or September preceding, was favored from that period, and had advanced before winter to the length of five or six inches; forming the clover pile that could be imagined. And although we had about six weeks of very intense frost, with snow; and about other six weeks, immediately succeeding that, of exceeding keen frost every night, with frequent thaws in the day-time, without any snow, during which time almost every green thing was destroyed; yet this little patch continued all along to retain as fine a verdure as any meadow in the month of May; hardly a point of a leaf having been withered by the uncommon severity of the weather. And as this grass begins to vegetate very early in the spring, I leave the reader to judge what might be the value of a field of grass of this kind in these circumstances.

Of another kind of grass, called purple sieve, Mr. Anderson gives the following character. "It retains its verdure much better than rye-grasses during the winter. But it had more of its points killed by the weather than the former. It likewise rifes in the spring, at least as early as rye-grasses."

This ingenious farmer has also made experiments on the culture of these and several other kinds of grasses; which being very well worthy of attention, we shall here insert. 1. Purple sieve-grasses. "Although this grass is very often found in old pastures, yet it has but a few flower-stalks; and as it is greedily eaten by all domestic animals, these are seldom suffered to appear; so that it usually remains there unperturbed. But it seems to be better able to endure the peculiar ceremony of the dung of dogs than almost any other plant; and is therefore often to be met with in dog-hills, as I call the little hills by road-sides where dogs usually pis and dung: and as it is allowed to grow there undisturbed, the farmer may have an opportunity of examining the plant, and becoming acquainted with its appearance."

"The leaves are long and small, and appear to be roundish,
PLANT is the same family with the former, and agrees with it in several respects; although they may be easily distinguished from one another. Its leaves, like the former, in its natural state, are always rounded, but much smaller; being little bigger than large horse-hairs, or twines-bristles, and seldom exceed six or seven inches in length. But these springing out of the root in tufts, so close upon one another, that they resemble, in this respect, a close hair-brush more than any thing else I know; so that it would seem naturally adapted to form that thick short pile of grass in which sheep are known chiefly to delight. Its flower-stalks are numerous, and sometimes attain the height of two feet; but are more usually about 12 or 15 inches high.

Upon gathering the seeds of this plant, and sowing them as the former, it was found that they sprang up as quickly as any other kind of grass; but the leaves are at first no bigger than a human hair. From each side spring up one or two of these hair-like filaments, that in a short time send out new off-sents, so as quickly to form a sort of tuft, which grows larger and larger, till it at length attains a very large size, or till all the intervals are closed up, and then it forms the closest pile of grass that it is possible to imagine. In April and May it put forth an innumerable quantity of flower-stalks, that afforded an immense quantity of hay; it being so close throughout, that the fythe could scarcely penetrate it. This was allowed for, and till the seed was ripened; but the bottom of these stalks were quite blanched, and almost rotten for want of air before that time.

This

Part I. Theory.

This was the appearance that it made the first year after it was sowed; but I have reason to think, that, after a few years, it Likewise produces fewer seed-flats, and a greater quantity of leaves than at first. But however that may be, it is certain, that if those are cut down in the spring, it does not, like rye-grass, have a continual tendency to run to seed; but is at once determined to push forth a quantity of leaves without almost any flatts at all: and as all domestic animals, but more especially sheep, are extremely fond of this grass, if they have liberty to pasture where it grows, they bite it so close as never to search in vain for it, when he is treading upon it with his feet. The best way to discover it in any pasture, is to search for it in winter, when the tusks of it may be easily distinguished from every other kind of grass, by their extraordinary elongates, and the deep green colour of the leaves.

It is thus to grow in almost any soil: although it is imagined that it would flourish best in a light sandy soil, as it can evidently live with less moisture than almost any other kind of grass; being often seen to remain in the fods that have been employed in coping for stone-dykes, after all the other grasses that grew in them have disappeared. It is likewise found in poor barren foids, where hardly any other plant can be made to grow at all; and on the surface of dry worn-out peat-mots, where no moisture remains sufficient to support any other plant whatever; but in neither of those situations does it thrive: as it is there only a weak and unwholesome plant, very unlike what it is when it has the good fortune to be established upon a good soil; although it is seldom met with in this last state than in the former.

I will not here repeat what has been already said about the particular property that this plant possesses of continuing all winter; nor point out the benefits that the farmer may reap from this valuable quality. He need not, however, expect to find any verdure in winter on such plants as grow upon the looses moity soil above mentioned; nor, as the frosts in winter always have a power of freezing this soil, the roots of the plants are so lacerated thereby, as to make it, for some time in the spring, to appear dead. Nor will he often perceive much verdure in winter upon those plants that grow upon poor hungry foids, which cannot afford abundant nourishment to keep them in a proper state of vegetation at all times: but such plants as grow on earthen dykes, which usually begin to vegetate with vigour when the annual rains come on, for the most part retain their verdure at that season almost as well as if they were in good garden-ground.

I have been very particular in regard to this plant; because, in as far as my observations have ye gone, it promises on many accounts to make a most valuable acquisition to the farmer, and therefore justly demands a very particular share of his attention.

3. The *bokus lanatus*, or creeping foft-grasses of Hudson. This is considered by our author as one of the most valuable kinds of meadow-grasses; its pile being exceedingly close, soft, and succulent. It delights much in moisture, and is seldom found on dry ground, unless the soil is exceedingly rich. It is often found on those patches near springs, over which the water frequently flows; and may be known by the uncommon formness and succulence of the blade, the lively light green colour of the leaves, and the matted intertexture of its roots. But, notwithstanding the formness of its first leaves, when the seed-flats advance, they are rough to the touch, so that the plant then affumes a very different appearance from what we were led to expect.

The car is branched out into a great number of segments. This modification somewhat like the oat, but much smaller. This kind of grasses, however, would not be easily cultivated, on account of a kind of soft membrane that makes the seeds adhere to the stalk, and to one another, after they are separated from it, as if they were intermixed with cobweb, so that it is difficult to get them separated from the stalk, or to spread readily in sowing. It spreads, however, so fast by its running roots, that a small quantity sowed very thinly, would be sufficient to flock a large field in a short time.

There are the kinds of *grasses*, properly so called, which have not as yet been cultivated, that Mr Anderson thinks the most likely to be of value; but besides these he recommends the following, of the pastures.

1. Milk-vetch, *lignoreous-vetch*, or milk-wort. This plant, in some respects, very much resembles the common white clover; from the top of the root a great number of shoots come out in the spring, spreading along the surface of the ground every way round it; from which arise a great many clusters of bright yellow flowers, exactly resembling those of the common brome. These are succeeded by hard round pods, filled with small kidney-shaped seeds. From a supposed resemblance of a cluster of these pods to the fingers of an open hand, the plant has been sometimes called *ladies fingers*. By others it is called *crow-toes*, from a fancied resemblance of the pods to the toes of a bird. Others, from the appearance of the blossom, and the part where the plant is found, have called it *feaf*, improperly *fell-broom*. It is found plentifully almost everywhere in old grass-lands; but as every species of domestic animals eat it, almost in preference to any other plant, it is seldom allowed to come to the flower in pasture grounds, unless where they have been accidentally saved from the cattle for some time; so that it is only about the borders of corn-fields, or the sides of inclosures to which cattle have not access, that we have an opportunity of observing it. As it has been imagined that the cows which feed on these pastures, where this plant abounds, yield a quantity of rich milk, the plant has from that circumstance, obtained its most proper English name of *milk-vetch*.

One of the greatest recommendations of this plant is its good quality, that it grows in poor barren ground, where almost no other plant can live. It has been observed in ground too poor, that even heath, or ling (*eica comunes*), would fearfully grow; and upon bare obdurate clays, where no other plant could be made to vegetate; in which the surface remained entirely uncovered, unless where a plant of this kind chance to be established; yet even in these unfavourable circumstances, it flourished with an uncommon degree of luxuriance, and yielded as tender and succulent, though not such abundant floots, as if reared in the richest manured fields. In dry barren lands, also, where almost no other plant could be made to live, it has been found to send out such a number of healthy floots all around as.
The flanks of the milk-vetch are weak and slender, so they spread upon the surface of the ground, unless they are supported by some other vegetable. In ordinary soils they do not grow to a great length, nor produce many flowers; but in richer fields the flanks grow to a much greater length, branch out a good deal, carry few or no flowers or seeds. From these qualities our author did not attempt at first to cultivate it with any other view than that of pasture; and with this intention, sowed it expecting to derive no material benefit from it till he deftined from cutting his field. In this, however, he was agreeably disappointed; the milk-vetch growing, the first season, as tall as his great clover, and forming exceeding fine hay; being scarce distinguishable from lucerne, but by the slenderness of the flanks, and proportional smallness of the leaf.

Another recommendation to this plant is, that it is perennial. It is several years after it is sowed before it attains to its full perfection; but, when once established, it probably remains for a great number of years in full vigour, and produces annually a great quantity of fodder. In autumn 1775, Mr. Anderson cut the flanks from an old plant that grew on a very indifferent soil; and after having thoroughly dried it, he found that it weighed 14 ounces and a half.

The flanks of this plant do not come up in the spring, till the middle, or even the end of May, without endangering the loss of the pasture. This is owing to the height of ten or twelve feet, having very strong stems and roots, which no other vegetable could support themselves without rotting till they attained a great height.

Some other plants, hitherto unnoticed, is recommend ed by our author to the attention of the farmer; viz., the common yarrow, (Achillea millefolium), or hundred-leaved grass. Concerning this plant, he remarks, that, in almost every fine old pasture, a great proportion of the growing vegetables with which the field is covered, consists of it; but the animals which feed there are so fond of the yarrow, as never to allow one field-flank of it to come to perfection. Hence these feed-flanks are never found but in neglected corners, by the fides of roads; and are so disagreeable to cattle, that they are never tasted; and thus it has been erroneously thought that the whole plant was refused by them. The leaves of this plant have a great tendency to grow very thick upon one another, and are therefore peculiarly adapted for pasture. It arrives at its greatest perfection in rich fields that are naturally fit for producing a large and succulent crop of grass. It grows also upon clays, and is among the first plants that strike root in any barren clay that has been lately dug from any considerable depth; so that this plant, and thistles, are usually the first that appear on the banks of deep ditches formed in a clayey soil. All animals delight to eat it; but, from the dry aromatic taste it possesses, it would seem peculiarly favourable to the constitution of sheep. It seems altogether unfit for hay.

Besides these plants, which are natives of Great Britain there are others, which, though natives of other countries, are found to thrive very well in Britain; and have been raised with such success by individuals,
Part I.

AGRICULTURE.

Theory.

...videails, as highly to merit the attention of every farmer. Among these the first place is claimed by lucerne.

This is the plant called medica by the ancients, because it came originally from Media, and on the culture of which they bestowed such great care and pains. It hath a perennial root, and annual stalks, which, in good foil, rise to three feet, or sometimes more in height; its leaves grow at a joint like those of clover; the flowers which appear in June, are purple, and its pods of a screw-like shape, containing seeds which ripen in September. All sorts of domestic cattle are fond of the plant, especially when allowed to eat it green, and black cattle may be fed very well with the hay made from it; but an excess of this food is said to be very dangerous.

Lucerne has the property of growing very quickly after it is cut down, inasmuch that Mr Rocque has mowed it five times in a season, and Mr Anderson affirms he has cut it no less than six times. It is, however, not very easily cultivated; in consequence of which it sometimes does not succeed; and as it dies entirely in the winter, it is perhaps inferior to the fescue grasses already mentioned, which, tho' defiled and neglected, might probably yield as rich a crop as lucerne, without any danger of a miscarriage.

Another grass was brought from Virginia, where it is a native, and fown by Rocque in 1763. This grass is called Timothy, from its being brought from New-York to Carolina by one Timothy Hanlon. It grows best in a wet soil; but will thrive in almost any. If it is fown in August, it will be fit for cutting in the latter end of May or beginning of June. Horfes are very fond of it, and will leave lucerne to eat it. It is also preferred by black cattle and sheep; for a square piece of land having been divided into four equal parts, and one part sowed with lucerne, another with fan-foil, a third with clover, and the fourth with timothy, some horfes, black cattle, and sheep, were turned into it, when the plants were all in a condition for pasturage; and the timothy was eaten quite bare, before the clover, lucerne, or fan-foil, was touched.

One valuable property of this grass is, that its roots are strong and interwoven with one another, so that they render the wettest and softest land, on which a horse could not find footing, firm enough to bear the heaviest cart. With the view of improving boggy lands, therefore, so as to prevent their being poisoned with the feet of cattle, Mr Anderson recommends the cultivation of this kind of grass, from which he has little expectation in other respects.

Sect. VII. Of the Diseases of Plants.

These are divided by Tournefort into the following classes. 1. Those which arise from too great an abundance of juice. 2. From having too little. 3. From its bad qualities. 4. From its unequal distribution; and 5. From external accidents.

Too great an abundance of juices causes at first a prodigious luxuriant growth of the vegetable; so that it does not come to the requisite perfection in a due time. Wheat is subject, in some climates, to a disease of this kind; it vegetates excessively, without ever carrying ripe grain; and the same disease may be artificially produced in any grain, by planting it in too rich a soil. Too much rain is apt likewise to do the same. When a vegetable is supplied too abundantly with juices, it is very apt to rot; one part of it overflows another in such a manner as to prevent the access of fresh air; upon which putrefaction soon ensues, as has been already observed with regard to the fescue grasses.

In grass, or any herbaceous plants, where the leaves are only wanted, this over luxuriance cannot be called a disease, but is a very desirable property; but in any kind of grain, it is quite otherwise. Dr Home, in his Principles of Agriculture and Vegetation, calls the luxuriance in grain among the diseases arising from this cause. He is of opinion, that too great an abundance of juices in a vegetable will produce diseases similar to those occasioned by depletion in animal bodies; viz. flagellations, corruptions, varices, carotises, &c. along with the too great luxuriance we have just now mentioned, which he expresses by "too great an abundance of water-hoofs." Hence he is induced to clas the smut among diseases arising from this cause; it being a corruption happening molt in rainy feasons, and to weak grain. Like other contagious diseases, he tells us, the smut may be communicated from the infected to healthy grain. As a preventative, he recommends steeping the grain in a strong pickle of sea-folk. Besides the effect vented, which this has upon the grain itself, it is useful for separating the good from the bad; the best seed falling to the bottom, and the faulty swimming on the top of the liquor. For the same purpose, a ley of wood-ashes and quicklime is recommended by some; and, by others, a solution of saltpetre or copperas; after which the grain is to be dried with flacked lime, or dry turfs. This solution, however, we can by no means recommend, as it seems most likely to kill the grain entirely.

According to Dr Home, dung is a preventative of Diseases from too great moisture; in confirmation of which, he relates the following experiment. "Two acres of poor ground, which had never got any manure, were follow'd with a design to be fown with wheat; but the scheme being altered, some dung was laid on a small part of it, and the whole fowed, after it had got five furrows, with barley. A great quantity of rain fell. The barley on that part which was dunged was very good; but what was on the rest of the field turned yellow after the rains, and when ripe was not worth the reaping." 74

The want of nourishment in plants may be easily known by their decay; in which case, the only remedy is, to supply them with food, according to the methods we have already directed; or to remove from their neighbourhood such other plants as may draw off the nourishment from those we wish to cultivate.—In the Memoirs of the Academy of Sciences for 1728, Mr Du Hamel mentions a disease, which he calls mortis, that attacks saffron in the spring. It is owing to another plant, a species of trefoil, fixing some violet-coloured threads, which are its roots, to the roots of the saffron, and flocking out its juice. This disease is prevented by digging a trench, which saves all the unaffected plants. The bad qualities, or unequal distributions, of the juices of plants, are the occasion of so few of the diseases to which vegetables in every country are subject, that we forbear to mention them at present. Most of the diseases of plants are owing to external accidents, particularly to the depredations of insects.—The insects by which the greatest devastations are committed in Great Britain are, flies, caterpillars, grubs, and flies. The flies and caterpillars feed on the leaves and young shoots;

76. Grubs.

77. Turnip fly.

Prevented by fumiga-

tion, &c.

78. Theory.

80. Turnips, when young, are apt to be totally destroyed by a multitude of black flies, from whence called the turnip fly. As a preventative of the same, some advise to mix with brown surf, but this is improper, as brimstone is found to be poisonous to vegetables. The best method seems to be the fumigation of the fields with smoke of half-dried vegetables. For this purpose weeds will answer as well as any. This fumigation must no doubt be often repeated, in order to drive away the innumerable multitudes of these insects which are capable of destroying a large field of turnip. Some have supposed that the fly is either engendered in new dung, or enticed by it; and have therefore advised the manure to be laid on in the autumn preceding, by which it loses all its nutritious qualities, while its nutritive ones are retained, notwithstanding these might be supposed liable to some degree to be exhausted by the sun. This method is said to have been averted by experiments; and it is added, that another material advantage accruing from autumn manuring for turnips is, that all the seeds contained in the dung, and which of course are carried on the land with it, vegetate almost immediately, are mostly killed by the severity of the winter, and the few that remain seldom avoid destruction from the plough-share. The following method has also been recommended as a preventative of the fly:—About Midsummer, take the first opportunity when it rains, or there is an apparent certainty of rain approaching, to sow your turnip seed; if about the full moon, the better. In this case, neither harrow, brush, nor roll, after sowing. The natural heat of the ground at that season, and the consequent fermentation occasioned by copious rain, will give an astonishingly quick vegetation to the seed, which in a few days will be up and out of all danger from the fly. At all events, low not till it rains; it is better to wait a month, or even longer, for rain, than to low (merely for the sake of fowing about the usual time) when the ground is parched with heat. By the scorching of the sun, the oil and vegetable quality of the seed are exhausted; and the few weak plants that come up will be destroyed by the fly before they attain strength to put forth their rough leaves. The fly infests the ground abundantly in dry hot weather, but does no injury in rain. The falling rain will sufficiently wash the turnip-feed into the ground without harrowing it in; which, instead of merely covering, too often buries this small seed so great a depth, as never afterwards to get above ground.

The following remedies are also recommended as having often proved successful:—A small quantity of foot sown over the land at their first appearance. Branches of elder with the leaves bruised, drawn in a grate over them. Musk mixed with the feed before it is sown. And sulphur burnt under it, after moistening it with water in which tobacco has been steeped.

But flowerers on the plants as soon as they appear above ground, are esteemed the best preservatives. They enfeeble and kill the fly, and hasten the plants into the rough leaf, in which state they are out of danger. The sweet smell of the turnip has been thought to attract the fly; upon which supposition, the remedy appeared to consist in overpowering that smell by one which is strong, fetid, and disagreeable. Hence it has been recommended, that upon an acre of turnips sown in the usual way, a peck or more of dry foot be thrown after the ground is finished, and in as regular a way as he sows the feed.

Some time ago an infest, called the corn-butterfly, committed such ravages while in its verminous state, terrify in France, that upwards of 200 parishes were ruined by it; and the ministry offered a reward to the discoverer of an effectual remedy against this destroying worm. The cure which was at last discovered, was to heat the corn, in an oven, so much as not to destroy its vegetative power, but sufficiently to destroy the small worms which made their nest in the substance of the grain, and at last eat out the substance so completely that nothing could be got from the husk, even by boiling it in water. It is certain, that though insects can bear a great deal of cold, they are easily destroyed by a slight degree of heat; nor is the vegetative power of corn easily destroyed, even when kept for a long time in a pretty strong heat. This method must therefore be very effectual for destroying all kinds of insects.
Part I. AGRICULTURE.

The curled disease in potatoes has long been a subject of investigation and experiment among farmers; and the knowledge of its cause and cure forms yet to remain a desideratum. The Agricultural Society at Manchester, a few years ago, offered a premium for discovering by actual experiment the cause of the disease in question; and a great variety of letters were, in consequence, addressed to them upon the subject. As these contain many interesting observations both on the disease itself and the best methods hitherto adopted for preventing it, the following abstracts of them may not improperly be introduced in this place.

I. According to the writer of the first letter, the disease is caused by an insect produced by frosts or bad keeping before setting; and the newest kinds, such as have been raised within these nine or ten years, are most apt to curl, because they will not stand to be kept in winter and spring before setting, as the old kinds will. In autumn 1776, he got up a bed of potatoes to lay by in winter, leaving plenty in the ground as regular as possible; and, before the severity of winter came on, covered part of the bed with straw and peat-haulm, and left the other part of the bed uncovered. That part of the bed which was covered was quite free from curled ones; but the uncovered part produced a great many curled, owing, as the writer says, to frosts and severity of the weather.

II. This writer had about a quarter of an acre of potatoes, well manured with cow and horse dung, and took the greatest care in picking the fine smooth-skinned potatoes for sets; yet nine out of ten parts were curled. He attributes the cause of this disease to a white grub or insect, which he found near the root, about half an inch long, with eight or ten legs, its head brown and hard; as upon examining a number of the curled roots, he found them all bitten, chiefly from the surface to the root, which of course stopped the progress of the sap, and threw them into a curl. The uncurled roots were not bitten. He tried a few experiments as follow:—First, he put foot to the insects in the rows for two days; and after that, he put lime to them for the same time, but they still kept lively; next he put a little salt, which destroyed them in a few hours. From which he infers, that if coarse salt were put into the ground at the time the land is preparing for potatoes, it would effectually cure this disemmerer.

III. In this letter, the cause of the disease is attributed to the method of earthing the stems while in cultivation; and the branches, striking root into the new earthed-up soil, it is said, produces potatoes of such a nature as the year following to cause the disease complained of.

To prevent the disease, it is recommended to take the sets from those potatoes that have not bred any from the branch covered; or otherwise, to dig the part the sets are to be raised from.

IV. According to this writer, the disorder proceeds from potatoes being set in old-tilled or worn-out ground; for though those potatoes may look tolerably well, yet their sets will molt, if not, produce curled potatoes. Hence he is convinced, that no sets ought to be used from old-tilled or couch-grass land; and that, in order to have good sets, they should be procured from land that was purposely followed for them; from fresh ley land where they are not curled; or from ley land that was burnt last spring. He directs to plant them on virgin mould, and the potatoes will have no curled ones among them; and to keep them for winter, from any other kind.

To avoid the uncertainty of getting good sets, he recommends crabs to be gathered from potatoes growing this year on fresh land free from curl, and the next spring to sow them on fresh ley land; and continue to plant their sets on fresh ley land yearly, which he is convinced will prevent the curl.

All the good potatoes he saw this year, either on fresh ley land or on old-tilled land, were raised from sets that grew upon fresh ley land last year; and where he has seen curled potatoes, he found, upon inquiry, the potato-sets grew upon old-tilled and worn-out land last year. He gives as a general reason for the disorder, that the land is oftener curbed than it had used to be, much more corn being now raised than formerly.

V. In 1772, this writer planted some potatoes by accident full nine inches deep; when taken up, many of the plants were rotted, and a few curled. He kept the whole produce for feed, and planted two acres with it in 1773, not quite six inches deep. The crop was amazingly great; and he did not observe any curled plants among them. In 1774, many of these were planted in different soils; yet they were not infected with the curled disease, that not one in twenty escaped. In 1775, the complaint of this disease became general. In 1776, it occurred to him that the good crop of 1773 was owing to the accidental deep setting of 1772; and that the reason why the same seed became curbed in 1774, was their being set so near the surface in 1773; and attributes the disease to the practice of ebb-setting. In 1777, he took some potatoes from a crop that was curled the year before, and after cutting the sets, left them in a dry room for a month. Half were planted in ground dug fourteen days before; the other half, having been steeped in a brine made of whitters ashes for two hours, were also planted in the same land at the same time. The steeped ones came up ten days before the others, and hardly any misseed were curled. The unsteeped ones generally failed, and those few that came up were mottly curled.

He therefore advised as a remedy, 1. That the potatoes intended for next year's sets be planted nine inches deep. 2. That they remain in the ground as long as the season will permit. 3. That these sets be well defended from frosts till the beginning of March. 4. That the sets be cut a fortnight before planting. 5. That they be steeped, as above, two hours in brine or ley. 6. That the dung be put over the sets. And 7. That fresh sets be got every year from sandy soils near the coast, or on the shore.

P.S. At planting, the hard dry sets should be cast aside, for they will probably be curbed. Curled potatoes always proceed from sets which do not rot or putrefy in the ground.

VI. This writer had five drills of the old red potatoes, and four of the winter whites, growing at the same time in the same field. The drills were prepared exactly
He allows, that the curl has frequently happened to persons who have used large potatoes for sets; for, as all roots are not equally affected, some curled ones may be mixed with the rest.

To prevent the evil, cut your sets from clean and middle-sized potatoes, gathered from places as clear of the curl as possible; preferve them as usual till spring.

If any are harder or grafter in cutting than usual, caft them aside. He would also recommend the raising a fresh fort from the crap produced on the forts least affected, which in Lancashire are the long-duns.

X. Set potatoes with the sprits broke off, and they will (says the writer of this letter) be curled ones; if set with the sprits on, they will not be curled. Again, take a potato which is sprit, and cut a set off with two lights: break one sprit off, and let the other stay on, and set it; the former will be curled, and the latter will not.

When you have holed your potatoes, take them out, before they are sprit, and lay them dry until you have set or sown them, and you will have no curled potatoes.

XI. This writer was at the expense of procuring sets at fifty miles distance, and where this disease was not known. The first year’s trial was successful; the year following he procured sets from the same place, but one-fifth of his crop was infected. By way of experiment, he planted sets from roots which had been infected the year before, and some of these produced, healthy plants, free from all infection. As every effect must have a cause, he supposed it might be some infect, which, living on the leaves, gave them a curled and sickly appearance, as is the case in the leaves of many shrubs and trees. But whether the infect is lodged in the old sets, and to be destroyed at the time of planting, or, proceeding from some external cause, can only be destroyed afterwards, he is not yet certain, although he has made the following experiments.

On a piece of ground that had not been dug for 20 years, he planted four rows of sets, which he knew to be perfectly clear; the drills were two feet distant, the sets one foot distant in each drill. He then planted on the same ground four rows with sets from curled potatoes at equal distances; in each row were about 20 sets.

Lot 1st, the curled flare.

No. 1. Without manure, | No. 3. In foot.

2. In salt. | 4. In quicklime.

Lot 2d, the clear sets.

No. 1. Without manure. | No. 3. In foot.

2. In salt. | 4. In quicklime.

These planted in salt and foot in both lots were destroyed. In lot 1, 2d, and 3d, all curled. Lot 2, 1d, and 4d, which is clear.

This experiment was made on a supposition that the infect lodged in the set, and must be destroyed by planting. But of that he is not fully satisfied. He repeated salt, foot, and quicklime, on the branches of several curled potatoes. Salt destroyed all he touched with it. Lime and foot had, he thought, a partial effect on the plants. After some time, they appeared almost as healthy as the rest. Thus, although he had done little towards the cure, he flatters himself he has pointed
Part I.

AGRICULTURE.

Theory.

pointed out the cause, the infects on the curled plants being not only very numerous, but visible to the naked eye.

XII. This writer ascribes the cause of the disease to the fruit, and keeps in winter and spring before setting. They are liable to be damaged by frost after they are set, but may be prevented by covering. If it be asked, why frost did not injure them formerly? he answers, it is only the new kinds which are apt to curl. To this may be added, that leaf care is now taken of the feed than formerly. To prevent the latter, let them remain in the ground covered with haulm or litter, till the time they are wanted for setting; and, in case no haulm touches them afterwards, they will be free from the disease.

XIII. This writer says, the red potato was as generally planted as the winter-white and the Lincolnshire kidney are now. The first, being a later potato, did not sprout so early as the others. The white sprouts very early, and therefore should first be moved out of the place where they have been preserved in the winter. Instead of that, they are often let remain till their roots and sprouts are matted together. On separating them, these sprouts are generally rubbed off, and they are laid by till the ground is ready; during which interval they sprout a second time: but these second sprouts, being weak and languid, will shrivel, ficken, and die; and the fruit at the roots will be small, hard, ill-shaped, and of an brown colour.

Now, if putting off the sprouts once or more, before the sets are put in the ground, be the cause (as he verily believes it is) of the curled disease, an easy remedy is at hand. When the potatoes intended for sets are dug up, lay them in a well aspeck as dry as possible: in such a situation they will not sprout so soon. The best time for removing most forts, is the first fine day after the 24th of February. Cut them into sets as soon as possible, and let them remain covered with dry fand till the ground is prepared, which should be a winter fallow. Lay the sets in without breaking off any of the sprouts, for the second will not be so vigorous. This accounts for one sprout out of three from the same set being curled. The two items not curled arose from two later eyes, and were first sprouts. The sprout curled was a second, the first having been rubbed off.

XIV. This writer says, that last spring one of his neighbours cut and set, in the usual way of drilling, some loads of the largest potatoes he could procure; and more than half of them proved curled. Being a few sets short of the quantity wanted, he planted some small potatoes which he had laid by for the pigs. These being fully ripe and solid, there was not a curled plant among them. He apprehends, the others being curled was owing to their not being fully ripe. A crop of potatoes, set this year in rows on ground that bore a crop of them last year, were mostly curled; but many plants came up from seed left in the ground last season, and there was not a curled one among them.

XV. Of late years, this writer says, great improvements have been made in setting potatoes and cutting the sets. The ground is dried cleaner and dunged stronger. Many people, in drilling, wrap up the sets entirely in the dung; by which means, though their potatoes are larger, the disease seems to be increased. They also cut their sets out of the richest and largest potatoes, which is perhaps another cause of this evil. In cold countries, where they set their own feed, which has grown on poor land, with least dung, they have no curled plants. On the contrary, when they bought rich and large potatoes for feed, they have been curled in great quantities. He believes, the richness and largeness of the feed is the cause of the evil; for he does not remember to have seen a curled plant which did not spring from a set of a large potato.

XVI. This writer apprehends the curled disease in potatoes to proceed from a defect in the planta feminalis, or feed-plant; and from comparing curled ones with others, there appeared to be a want of, or inability in, the powers of expanding or unfolding the parts of the former; which, from this defect, forms thrivelled, flared, curled fnts. On examining some of the sets at the time of getting the crop, he found them hard and undecayed; so hard, indeed, that some of them would not be soft with long boiling. This led him to think, that some manures might have the same effect on them as tanners oose has on leather, and so harden them. The embargo plant could not come forth with ease; but a closer examination taught him otherwise, and that they grow equally in all manures.

Some have thought that the fermentation is occasioned by too great quantities being heaped together; but the writer has seen an instance, wherein a single potato, preferred by itself, when set, produced fnts of the curled kind. He thinks the most consistent and rational opinion is, that the disease is occasioned by the potatoes being taken from the ground before the faments, or miniature-plant, is properly matured and ripened.

For let it be observed, that the potato, being a native of a warmer climate, has there more fun, and a longer continuance in the ground, consequently, it has not the same natural causes in a cold climate to mature the feed-plant as in its native state. All the opportunities, therefore, ought to be given in which the climate will admit for nature to complete her work, and fit the faments for the next state of vegetation, especially in those intended for feed. But if the potato be taken up before the feed-plant is fully matured, or the air and sap-veffels have acquired a proper degree of firmness or hardness, it must, when thus robbed of further nutrition, shrivel up; and when the vellels, in this immature state, come to act again in the next state of vegetation, they may produce plants which are curled.

If it be asked, why are they more common now than formerly? he answers, that before the present mode of setting them took place, people covered them, while in the ground, with straw, to protect them from frost.

If it be asked, why one set produces both curled and smooth sets? he answers, we suppose every eye to contain a planta feminalis; that all the embryos, or feed-plants, contained in one potato, are nourished by one root; that, as in ears of corn, some of these feed-plants may be nourished before others.

One of his neighbours, last year, set two rows of potatoes.
AGRICULTURE.

The head is that part of the plough which goes in the ground; therefore the fleshy and narrow over it is, the friction will be the less, and the plough more easily drawn; but the longer the head is, the plough goes more readily, and is not so easily put out of its direction by any obstructions that occur. Twenty inches is considered as a mean length; and five inches is the most convenient breadth.

The sheath, E, is driven into the mortoise, and thus fixed to the head A B. It is not perpendicular to the head, but placed obliquely, so as to make the angle formed by the lines A B and E B about 60 degrees. The sheath is about 3 inches long, besides what is driven into the mortoise (fig. 1); about three inches broad, and one inch thick. The sheath is fixed to the mould-board, as in fig. 11. E, in the same manner as the wreft is fixed to the head in fig. 7.

The mould-board, is designed to turn over the earth of the furrow made by the plough; and it is obvious, that, according to the position of the sheath, the mould-board will turn over the earth of the furrow more or less suddenly. Besides, when it forms a less angle with the head than 60 degrees, the plough is in great danger of being checked, as the farmers term it.
Part II. AGRICULTURE.

The Larger Handle, F A, is fixed to the head, by driving it into the mortise of (fig. 1.). It is placed in the same plane with the head; and its length from A F is about five feet four inches, and its diameter at the place where it is fixed to the beam is about two inches and a half, and tapers a little to the top F. About ten inches from A, there is a curve in the handle, which, when F is raised to its proper height, makes the lower part of it nearly parallel to the sheath E B. This curve is designed to strengthen the handle. The proper position of the handle is, when the top F is about three feet two inches higher than the bottom of the head A B.

The longer the handles, the plough is the more easily managed, because the levers are more distant from the centre of motion. The higher the top of the handles, the plough is more easily raised out of the ground, provided they be no higher than the lower part of a man's breast.

The Beam, is fixed to the larger handle and the sheath, all of which are placed in the same plane with the head. The length of it, from H to I, is about six feet; its diameter is about four inches. When the plough is in the ground, the beam should be just high enough not to be accompanied by any thing on the surface.

The position of the beam depends on the number of cattle in the plough. When two horses are yoked, the beam should be placed in such a manner as to make the perpendicular distance between the bolt-hole of the beam and the plane of the head about 21 inches; when four horses are yoked, two a-broad, this distance should only be about 18 inches.

The Sock, B P, is fixed to the end of the beam, and is about two feet long. In fitting the Sock to the head, the point ought to be turned a little to the land or left side; because otherwise it is apt to come out of the beam altogether. When turned to the left, it likewise takes off more land; when turned upwards, the plough goes shallow; and when downwards, it goes deeper.

The Coultre, is fixed to the beam, and is about two feet ten inches long, two inches and a half broad, sharp at the point and before, and thick on the back, like a knife. It is fixed and directed by wedges, so as to make the point of it equal to, or rather a little below the handle, and is fixed and directed to the beam by two bolts, and has notches by which the coultre may be fixed either above or below the beam. A D is the fore-bolt upon which the coultre turns; and B C are four notches, between which the coultre is turned to the right or left of the beam.

The Wreft, B D, is fixed to the head, and is about 26 inches long, two broad, and one thick. It is fixed to the head at B, in such a manner as to make the angle contained between the lines A B and B D about 25 degrees. Two hands are seldom or never placed in the same plane with the head, but gradually raised from the place where it is fixed to it, that is, from B to K, as in fig. 8. The position of the wret determines the nature of the furrow. When the wret is wide and low the furrow is wide; and when it is narrow and high the furrow is narrow.

Fig. 9. represents the two Handles, fixed together by the two rungs. The larger handle has already been described: the lesser one is a few inches shorter, and does not require to be quite so strong. The distance of the handles at the little rung depends on the position of the wret. Their distance at M and P is about two feet six inches. The lesser handle is fixed to the mould board at M, fig. 10, and to the wret K B, at L.

The Bridle, or Muzzle, is another article belonging to the plough. It is fixed to the end of the beam, and the cattle are yoked by it. The muzzle commonly used is a curved piece of iron, fixed to the beam by a bolt through it. A B C is the muzzle, A C the bolt by which it is fixed to the beam; D is the swingle-tree or croft-tree, to which the traces are fixed; and B is a hook, or cleat, as it is commonly called, which joins the muzzle and swingle-tree.

Some use another kind of muzzle, A B C D. It is fixed to the beam by two bolts, and has notches by which the cleek of the swingle-tree may be fixed either to the right or the left of the beam. There are also different holes for the hind-bolt to pass thro', by which the draught may be fixed either above or below the beam. A D is the fore-bolt upon which the muzzle turns; and B C are four notches, between which any two of which the cleek of the swingle-tree may be fixed. When the cleek is fixed at B, the plough is turned towards the farm land, and takes off a broader furrow; and when fixed at C, it is turned towards the ploughed land, and takes off a narrower furrow. E and F are the holes on each side thro' which the hind-bolt passes. When the ball is put thro' the highest two, the holes being thereby brought to the middle of the beam, the fore-part of the muzzle is raised above the beam, and the plough is made to go deeper; and when put through the lowest two, the fore-part of the muzzle is sunk below the beam, and the plough is made to go shallower. This muzzle may be so constructed as to have the same play with the common one. A is the end of the beam; B a plate of iron fixed into it, and with a similar one in the other side, is riveted into it by bolts; C is the muzzle fixed to these plates of iron by the bolt D, which bolt may be put through any of the holes E E. From the contruction of this muzzle it is plain, that it has the same play with the common one, and that by it the land of the plough may be altered at pleasure.

Of all forms, that of the Scotch plough is the best. Properties of the Scotch plough, especially where stones abound; and no less fit for strong clays than ploughs hardened by drought. The length of its head gives it a firm hold of the ground; its weight prevents it from being thrown out by stones; the length of the handles gives the ploughman great command to direct its motion.
AGRICULTURE.

Part I.

Practice; and by the length of its head, and of its mould-board, it lays the furrow-line cleverly over. This plough was contrived during the infancy of agriculture, and was well contrived: in the soils above described, it has not an equal.

In what soil improper.

But a tender foil, it is improper, because it adds greatly to the expense of ploughing, without any counterbalancing benefit. The length of the head and mould-board increases the friction, and consequently it requires a greater number or oxen or horses than are necessary in a shorter plough. There is another particular in its form, that resists the draught: the mould-board makes an angle with the stock, instead of making a line with it gently curved backward. There is an objection against it no less solid, that it does not stir the ground perfectly: the hinder part of the wret rifes a foot above the sole of the head; and the earth that lies immediately below that hinder part, is left unfurried. This is ribbing land below the surface, similar to what is done by ignorant farmers on the surface.

These defects must be submitted to in a foil that requires a strong heavy plough; but may be avoided in a cultivated foil by a plough differantly constructed. Of all the ploughs fitted for a cultivated foil free of stones, that introduced into Scotland about 20 years ago, by James Small in Blackadder Mountain, Berwickshire, is the best. It is now in great request; and with reason, as it avoids all the defects of the Scots plough. The shortness of its head and of its mould-board lessen the friction greatly; from the point of the stock to the back part of the head it is only 30 inches: and the whole length, from the point of the beam to the end of the handles, between eight and nine feet. The stock and mould-board make one line gently curving; and consequently gather no earth. Instead of a wret, the under edge of the mould-board is in one plain with the sole of the head; which makes a wide furrow, without leaving any part unfurried. It is termed the chain-plough, because it is drawn by an iron chain fixed to the back part of the beam immediately before the coulter. This has two advantages: first, by means of a mizzle, it makes the plough go deep, or shallow; and second, it stiffens the beam less than if fixed to the point, and therefore a flenderer beam is sufficient.

This plough may be well considered as a capital improvement; not only by saving expence, but by making better work. It is proper for loams; for coarse-clays; and, in general, for every sort of tender foil free of stones. It is even proper for opening up pasture-ground, where the soil has been formerly well cultivated.

A feathered stock is used in the Scotch plough. The difference between it and the feathered stock will be best understood by comparing their figures. Fig. 14, is the common stock, and fig. 15, the feathered one.

From the construction of the feathered stock, it is obvious, that it must meet with greater resistance than the common fock. However, when the plough takes off the earth of the furrow broader than that part of the fock which goes upon the head, it is more easily drawn than the plough with the common fock; for the earth which the common fock leaves to be opened by the wret, is more easily opened by the feather of the other fock. In ley, the feathered fock makes the plough go more easily, because the roots of the grass, which go beyond the reach of the plough, are more easily cut by the feather, than they can be torn afunder by the common fock. The feathered fock is also of great use in cutting and destroying root-weeds. The common fock, however, answers much better in strong land.

It is proper here to add, that in fitting the feathered fock to the head, the point of it should be turned a little from the land, or a little to the right hand.

If we look back 30 years, ploughs of different constructions did not enter even into a dream. The Scotch plough was universally used, and no other was known. There was no less ignorance as to the number of cattle necessary for this plough. In the south of Scotland, six oxen and two horses were universal; and in the north, ten oxen, sometimes 12. The first attempt to lessen the number of oxen was in Berwickshire. The low part of that county abounds with stone, clay, and marl, the most substantial of all manures, which had been long used by one or two gentlemen. About 25 years ago it acquired reputation, and spread rapidly.

As two horses and two oxen were employed in every marl-cart; the farmer, in summer-fallowing, and in preparing land for marl, was confined to four oxen and two horses. And as that manure afforded plenty of succulent straw for oxen, the farmer was surprized to find that four oxen did better now than six formerly. Marling, however, a laborious work, proceeded slowly, till people were taught by a noted farmer in that county, what industry can perform by means of power properly applied. It was reckoned a mighty talk to marl five or six acres in a year. That gentleman, by plenty of red clover for his working-cattle, accomplished the marling 50 acres in a summer. That gentleman, by plenty of red clover for his working-cattle, accomplished the marling 50 acres in a summer. That gentleman, by plenty of red clover for his working-cattle, accomplished the marling 50 acres in a summer. That gentleman, by plenty of red clover for his working-cattle, accomplished the marling 50 acres in a summer.

Having so much occasion for oxen, he tried with success, two oxen and two horses in a plough; and that practice became general in Berwickshire.

Advantages of the chain-plough. The great friction occasioned in the Scotch plough by a long head, and by the angle it makes with the mould-board, necessarily requires two oxen and two horses, whatever the soil be. The friction is so much less in the chain-plough, that two good horses are found sufficient in every soil that is proper for it. Besides, the reducing the draught to a couple of horses has another advantage, that of rendering a driver unnecessary. This saving on every plough, where two horses and two oxen were formerly used, will, by the strictest computation, be L. 15 Sterling yearly; and where four horses were used, no less than L. 20 Sterling.

There is now scarce to be seen in the low country of Berwickshire a plough with more than two horses, which undoubtedly in time will become general. We know not of one further improvement, that of using two oxen instead of two horses. That draught has been employed with success in several places; and the saving is so great, that it must force its way everywhere. It may be confidently affirmed, no soil firred in a proper season, can ever require more than two horses and two oxen in a plough, even supposing it the stiffest clay. In all other soils, two good horses, or two good oxen abreast, may be relied on for every operation of the chain-plough.

A chain-plough of a smaller size than ordinary, drawn
Part II. AGRICULTURE.

Practice.

A small single-horse plough, drawn by a single horse, is of all the most proper for horse-hoeing, supposing the land to be mellow, which it ought to be for that operation. It is sufficient for making harrows to receive the dung, for ploughing the drills after dunging, and for hoeing the crop.

A still smaller plough of the same kind may be recommended for a kitchen-garden. It can be reduced to the smallest size, by being made of iron; and where the land is properly dressed for a kitchen-garden, an iron plough of the smallest size drawn by a horse will save much fpade-work. In Scotland, thirty years ago, a kitchen-garden was an article of luxury merely, because at that time there could be no cheaper food than oatmeal. At present, the farmer maintains his servants at double expense, as the price of oat-meal is doubled; and yet he has no notion of a kitchen-garden more than he had thirty years ago. He never thinks, that living partly on cabbage, kail, turnip, carrot, would save much oat-meal: nor does he ever think, that change of food is more wholesome, than vegetables alone, or oat-meal alone. We need not recommend potatoes, which in feanty crops of barley, where the land is light and drained, have proved a great blessing: without them, the labouring poor would frequently have been reduced to a starving condition. Would the farmer but cultivate his kitchen-garden with as much industry as he bestowed on his potato crop, he need never fear want; and he can improve. A very small expense would inclose an acre for a kitchen-garden to each of his tenants; and it is the landlord who ought to give a beginning to the potatoe crop, he need never fear want; and he can make his potatoe crop, he need never fear want; and he can

Nor is this the only case where a single-horse plough may be profitably employed. It is sufficient for feeding barley, where the land is light and well-dressed. It may be used in the second or third ploughing of fallow, to encourage annual weeds, which are destroyed in subsequent ploughings.

The Rotheram Plough, Plate VII, Fig. 3.

The Rotheram plough is a machine of very simple construction, and easily worked. AB is the beam, CD the shaft, EBD the main handle, FR the smaller handle, GH the coulter, KI the fork or share, NP the bridle, S the fly-band, and ML a piece of wood in place of a head. The whole of this plough should be made of ash or elm; the irons should be fleeced and well-tempered; and that part of the plough which is under ground in tilling should be covered with plates of iron. The difference between this and the common plough seems to confit in the bridle at the end of the beam, by which the ploughman can give the plough more or less land by notches at N, or make it cut deeper or shallower by the holes at P; in the coulter or share, which are fo made and set as to cut off the new furrow without tearing; and in the mould-board, which is fo shaped at first to raise a little, and then gradually turn over the new cut furrow with very little refiistance. But the greatest advantage attending it, is its being fo easy of draught, that it will do double the work of any common plough.

The Paring plough is an instrument used in several parts of England for paring off the surface of the ground, in order to its being burnt. Mr Bradley has given the following description of a very simple instrument of this kind: From A to A (fig. 15) is the plough-beam, and a paring about seven feet long, made out of the block B, which is of clean timber. FK, CC are the sheaths or standards, made out of the ins. GID is the paring plate, and fastened to it with a bolt and key on each side, as at D. E is the paring plate of iron laid with steel, about four inches wide, and from 12 to 18 inches long. This plate must be made to cut on the sides, which are bolted to the standards as well as at the bottom part. FF are two iron braces to keep the standards from giving way: these standards must be mortised near the outsides and through the block. GG are the plough handles, which must be fixed slope-ways between the beam and the standards. The pin-holes in the beam, the use of which is to make the plough cut more or less deep, by fixing the wheels nearer to or farther from the paring plate, should not be above two inches

Fig. 1 represents the four-coultled plough of Mr Tull. Its beam is ten feet four inches long, whereas that of the common plough is but eight. The beam is straight in the common plough, but in this it is straight only from a to b, and thence arched: so that the line let down perpendicularly from the corner at a, to the even surface on which the plough stands, would be 11 inches; and if another line were let down from the turning of the beam at b to the same surface, it would be one foot eight inches and a half; and the third line let down to the surface from the bottom of the beam at that part which bears upon the pillow, will show the beam to be two feet ten inches high in that part. At the distance of three feet two inches from the end of the beam a, at the plough-tail, the first coulter, or that next the share, is let through; and at 13 inches from this, a second coulter is let through: a third at the same distance from that; and, finally, the fourth at the same distance from the third, that is, 13 inches: and from a to b is seven feet.

The crookedness of the upper part of the beam of this plough is contrived to avoid the too great length of the three foremost coulters, which would be too much if the beam was straight all the way; and they would be apt to bend and be displaced, unless they were very heavy and clumsy. Ash is the best wood to make the beam of, it being sufficiently strong, and yet light. The beam in this plough is to be seven inches broad. The fixing of the share in this, as well as in the common plough, is the nicest part, and requires the utmost art of the maker; for the well-going of the plough wholly depends upon the placing this. Supposing the axis of the beam, and the left side of the share, to be both horizontal, they must never be set parallel to each other: for if they are, the tail of the share bearing against the trench as much as the point, would cause the point to incline to the right hand, and it would be carried out of the ground into the furrow. If the point of the share should be set fo, that its side should make an angle on the right side of the axis of the beam, this inconvenience would be much greater; and if its point should incline much to the left, and make too large an angle on that side with the axis of the beam, the plough would run quite to the left hand;
AGRICULTURE.

Plate VI.

The different parts of this instrument are represented by No 1, 2, 3 of fig. 6. A A &c. a square frame 3 feet 4 inches from the fore to the hind part, by 4 feet 3 inches, the breadth of the machine within side; the timber (when of fir) 4 inches square, placed on two wheels B B. 3 feet diameter, a little more or less (the old fore-wheels of a chaise may answer the purpose), to support the hind part of the machine.

C C &c. are fixed strong pieces of wood, called bulls, 3 feet long, 5 inches and a half broad, the thickness 6 inches at E. and tapering to 3 inches at F. Into these bulls are fixed the cutting wheels, which are iron, 13 inches diameter, 3 lbs. of an inch thick at the centre, about an inch diameter for piercing holes to fix the iron axles in; from that they are to be of such thickness, as allow the edges to be well steel'd. The wheels are fixed by two bolts going through the bulls, with eyes on one end for the axles of the wheels to run in, and nuts and ferrules on the other to make them very firm and fast in the bulls, to prevent their interfering with the weights L L &c. resting on them.

G G. &c. are hollow pieces of wood, called thistles, each 3 inches long, which include the bolts M M. and keep the bolts C C &c. at their proper distances, but may be made longer or shorter at pleasure, according as the sward requires to be cut in larger or smaller pieces. They are in two pieces bound together, and joined by a strap of leather or cord, which allows them to be readily changed when the cutting wheels require to be kept at more or less distance.

The iron bolt M M. goes through two pieces of wood or iron P. P. 7 inches long, clear of the wood, supported by iron stays fixed to the frame, and through all the bulls. It requires to be strong, as the draught of the horses terminate there.

H H. No 2. and 3. a cylinder or segment of wood, 7 inches diameter, called a rocking tree, which goes across the frame, and moves on the pivots fixed into it, one at each end, supported by an iron bolt or piece of wood mortised into the frame, 8 inches high, as appears in No 2. and 3. to which 6 chains or ropes are fixed by hooks, at different distances, as you want your cuts, 9, 8, 7, or 6 inches from one another, and are joined to the end of each bull in which the cutting wheels run; so that when the rocking tree is turned about by the lever I. fixed in the middle of it, all the bulls, with their cutting wheels, are raised out of the ground at once, as in No 3. by which means the machine may be turned, or moved from place to place with great ease, without any danger of straining the wheels.

L L L. &c. No 1. 2. 3. are weights of treefunito, 26 inches long and 6 inches broad; the under one 4 inches thick, the upper one 3 inches thick; weighing about 64 lb. the under, and 48 the upper; each of them having two holes, through which iron spikes, firmly fixed in the bulls, pass, in order to keep them steady.

When the ground is easily cut, the under stone may answer; when more difficult, the other stone may be added; so that every wheel may have 7 stone-weight upon it, which has been found sufficient for the stiffest land and toughest sward the machine has ever been tried on. Cast iron weights will answer fully better, but are more expensive.

The lever I. No 2, 3. which ought to be 5 feet long, must have a sliding rope on it; fixed to the back part of the frame; so that when the cutting wheels are all taken out of the ground three or four inches, by the rocking tree's being turned partly round by the lever, the rope may be fixed to it by a loop over the pin R. No 3. (it ought to be placed 3 feet 4 inches from the extremity of the lever I.) Thus all the cutting wheels are kept out of the ground till the machine is turned; and then by moving the loop off the pin, it flips back towards the frame, and the lever is gently let back to its place, as in No 2. by which the cutting wheels are put into their former posture, by the weights fixed on the bulls in which they run. The levers may be made of good tough ash.

P. P. No 1.
to which the sward-cutter, consisting of four, six, or more cutting wheels, is never liable, from these being entirely independent of one another, cutting the ground across the ridges before ploughing, and rendering that operation easier to two horses than it would be to three without its being cut. The furrow being cut across, falls finely from the plough in squares of any size required not under six inches, in place of long fiss of tough sward feld and imperfectly broke by the four-coulered plough.

This instrument is very fit for preparing ground for burn-bating, as it will save much hand-labour.

It may be properly used in crofs-cutting clover of one or two years standing, to prepare the ground for wheat, if the land is stiff and moist enough.

It may be applied to cutting and crofs-cutting pasture-ground, intended to have manure of any kind put upon it to meliorate the grafs. In this it will far exceed the scarificator mentioned in one of Mr Young's tours; as that instrument is liable, as well as the four-coulered plough, to be thrown out of its work when meeting with a stone or other interruption. This the sward-cutter is proof against, which is looked on as its greatest excellence.

In preparing for barley, the sward-cutter excels a roller of any kind in reducing the large hard clods in clay land, occasioned by a sudden drought, after its being ploughed too wet; and it is likewise very proper for reducing such clay land when under a summer-fallow. In this operation, the sward-cutter is greatly to be preferred to the cutting-roller, likewise mentioned by Mr Young in one of his tours; for, the wheels of the latter being all dependent on another, when one is thrown out by a stone, three or four must share the same fate. Besides, the cutting-roller has but few wheels in fix feet; whereas the sward-cutter has fix in four feet three inches, at nine inches distance; and, if necessary, may have them so near as fix inches.

After old grafs-ground is cut across with the sward-cutter and ploughed, it has a very uncommon and worklike appearance, from each square turned over by the plough being raised up an inch or two at the side left moved by the earth-board; so that the field, when finished, is all prettily waved, and resembles a piece of water when blown on by a gentle breeze. By this means a very great deal of the land's surface is exposed to the frost and other influences of the air, which cannot fail to have a good effect on it.

Two horses are sufficient for the draught of a double-horse sward-cutter, and one horse for a single-horse one. One man manages the machine and drives the horses. He begins his operation by first measuring off 20 or 30 paces from the machine, less or more as he inclines, and there fixes a pole. He then cuts the field crofs, as near at right angles with the ridges as he can. When the cutting wheels are past the last furrow about a yard or so, and the machine is upon the outmost ridge of the field on which it must turn, he must stop the horses; then take hold of the lever 1. No. 2. and by pulling it to him he raises the cutting wheels out of the ground, which are kept to by the loop of the rope being put over the pin R. in the lever 1. No.3. till the machine is turned and brought to its proper place, which is done by measuring off the same distance for-
The cutting wheels are exactly over the outmost furrow, then, on the horces being stopped, the rope is flit off the pin \( R \), and the lever returned to its former place, as represented \( N \), which holds the weights L. L. &c. to force the cutting wheels into the ground again. He then goes on till the interval between the first and second stroke of the machine is all cut. In this manner the field is to be finished, after which you may begin to plough when you please. (N. B. There must be a pole at each side of the field.

It is of no consequence whether the land to be fward-cut is in crooked ridges or straight, in flat ridges or in very high raised ones. Be the surface ever so uneven, the cutting wheels, being all independent of one another, are forced by their weights into every furrow or hollow.

One fward-cutter will cut as much in one day as six ploughs will plough.

The land may lie several months in winter after being fward-cut, when there is no vegetation to make the cuts grow together again, but the sooner it is ploughed after cutting the better, that it may have the benefit of all the winter's frost, which makes it harrow better in feed-time.

When the ground is harrowed, the harrows ought to go with the waves which appear after ploughing, not against them, as by that means they are less apt to tear up the furrows all into squares. This, however, need only be attended to the two first times of harrowing, as they are called.

Any common wright and smith may make the instrument. It is very strong, very simple, and easily managed and moved from place to place; and, if put under cover, will last many years.

It was invented some time ago by the honourable Robert Sandilands; and is represented in the Plate as it has been lately improved by him, the price being at the same time reduced from L. 15 or L. 16 to L. 5 or L. 6.

3. The Brake.

The brake is a large and weighty harrow, the purpose of which is to reduce a stubborn soil, where an ordinary harrow makes little impression. It consists of four square bulls, each side five inches, and six feet and a half in length. The teeth are 17 inches long, bending forward like a coulter. Four of them are inserted into each bull, fixed above with a screw-nut, having 12 inches free below, with a heel close to the under part of the bull, to prevent it from being pulled back by flanes. The nut above makes it easy to be taken out for sharpening. This brake requires four horses or four oxen. One of a different size will not answer the purpose; one of a larger size will require six oxen: in which case the work may be performed at less expense with the plough.

This instrument may be applied to great advantage in the following circumstances. In the following strong clay that requires frequent ploughings, a breaking between every ploughing will pulverize the soil, and render the subsequent ploughings more easy. In the month or March or April, when strong ground is ploughed for barley, especially if bound with couch-grafs, a cross-breaking is preferable to a cross-ploughing, and is done at half the expense. When ground is ploughed from the state of nature, and after a competent time is cross-ploughed, the brake is applied with great success, immediately after the cross-ploughing, to reduce the whole to proper tith.

Let it be observed, that a brake with a greater number of teeth than abovementioned, is improper for ground that is bound together by the roots of plants, which is always the case of ground new broken up from its natural state. The brake is soon choked, and can do no execution till freed from the earth it holds. A less number of teeth would be deficient in pulverizing the soil.

4. The Harrow.

HARROWS are commonly considered as of no use but to cover the seed; but they have another use scarce less essential, which is to prepare land for the seed. This is an article of importance for producing a good crop. But how imperfectly either of these purposes is performed by the common harrow, will appear from the following account of it.

The harrow commonly used is of different forms. Imperfections of the common harrow.

The first we will mention has two bulls, four feet long and 18 inches square, with four wooden teeth in each. A second has three bulls and 12 wooded teeth. A third has four bulls, and 20 teeth of wood or iron, 10, 11, or 12 inches square. Now, in fine mould, the last may be sufficient for covering the seed; but none of them are sufficient to prepare for the seed any ground that requires subduing. The only tolerable form is that with iron teeth; and the bare description of its imperfections will show the necessity of a more perfect form. In the first place, this harrow is by far too light for ground new taken up from the state of nature, for clays hardened with spring-drought, or for other stubborn soils: it floats on the surface; and after frequent returns in the same furrow, nothing is done effectually. In the next place, the teeth are too thick set, by which the harrow is apt to be choked, especially where the earth is bound with roots, which is commonly the case. At the same time, the lightness and number of teeth keep the harrow upon the surface, and prevent one of its capital purposes, that of dividing the soil. Nor will fewer teeth answer for covering the seed properly. In the third place, the teeth are too thin for reducing a coarse soil to proper tith; and yet it would be in vain to make them longer, because the harrow is too light for going deep into the ground. Further, the common harrows are ill contrived, as to ride at every turn one upon another. Much time is lost in disengaging them. Lastly, it is equally unfit for extirpating weeds. The ground is frequently left bound with couch-grafs, as to make the furrow-side stand upright, as when old lea is ploughed: notwithstanding much labour, the grafs-roots keep the field, and gain the victory.

A little reflection, even without experience, will make it evident, that the same harrows, whatever be

different forms, adapted for different purposes. They are all of the same weight, drawn each by two horses. Birch is the best wood for them, because it is cheap, and not apt to split. The first is composed of four bulls, each four feet ten inches long, three and a quarter inches broad, and three and a half deep; the interval between the bulls is one inch and three-fourths inches; so that the breadth of the whole harrow is four feet. The bulls are connected by four heaths which go through each bull, and are fixed by timber-nails driven through both. In each bull five teeth are inserted, ten inches free under the bull, and ten inches afunder. They are of the same form with those of the brake, and inserted into the wood in the same manner. Each of these teeth is three pounds weight; and where the harrow is made of birch, the weight of the whole is six stone 14 pounds. Dutch. An erect bridle is fixed at a corner of the harrow, three inches high, with four notches for drawing higher or lower. To this bridle a double tree is fixed for two horses drawing abreast, as in a plough. And to strengthen the harrow, a flat rod of iron is nailed upon the harrow from corner to corner in the line of the draught.

Fig. 4.

The second harrow consists of two parts, connected together by a crank or hinge in the middle, and two chains of equal length, one at each end, which keep the two parts always parallel, and at the same distance from each other. The crank is so contrived, as to allow the two parts to ply to the ground like two unconnected harrows; but neither of them to rise above the other, more than if they were a single harrow without a joint. In a word, they may form an angle downward, but not upward. Thus they have the effect of two harrows in curved ground, and of one weighty harrow in a plain. This harrow is composed of six bulls, each four feet long, three inches broad, and three and a half deep. The interval between the bulls is nine and a half inches; which makes the breadth of the whole harrow, including the length of the crank, to be five feet five inches. Each bull has five teeth, nine inches free under the wood, and ten inches afunder. The weight of each tooth is two pounds; the refit as in the former.

Fig. 5.

The third consists also of two parts, connected together like that last mentioned. It has eight bulls, each four feet long, two and a half inches broad, and three deep. The interval between the bulls is eight inches, and the breadth of the whole harrow including the length of the crank, is five feet four inches. In each bull are inserted five teeth, seven inches free under the wood, and ten and a half inches afunder, each tooth weighing one pound. The refit as in the two former harrows.

These harrows are a considerable improvement. They ply to curved ground like two unconnected harrows; and when drawn in one plain, they are in effect one harrow of double weight, which makes the teeth pierce deep into the ground. The imperfection of common harrows, mentioned above, will suggest the advantages of the set of harrows here recommended. The first is proper for harrowing land that has long lain after ploughing, as where oats are sown on a winter-furrow, and in general for harrowing stiff land: it pierces deep into the soil by its long teeth, and divides it minutely. The second is intended for covering the seed: its long teeth lay the seed deeper than the common harrow can do, which is no slight advantage. By placing the seed considerably under the surface, the young plants are, on the one hand, protected from too much heat, and, on the other, have sufficiency of moisture. At the same time, the seed is so well covered that none of it is lost. Seed slightly covered by the common harrows wants moisture, and is burnt up by the sun; besides, that a proportion of it is left upon the surface uncovered. The third harrow supplies what may be deficient in the second, by smoothing the surface, and covering the seed more accurately. The three harrows make the ground finer and finer, as hecules do liat; or, to use a different comparison, the first harrow makes the bed, the second lays the seed in it, the third, smooths the cloths. They have another advantage not inferior to any mentioned: they mix manure with the soil more intimately than can be done by common harrows; and upon such intimate mixture depends greatly the effect of manure as has already been explained. To conclude, these harrows are contrived to answer an established principle in agriculture. That fertility depends greatly on pulverizing the soil, and on an intimate mixture of manure with it, whether dung, lime, marl, or any other.

The Chain and Screw Harrow. Fig. 8. is the plan of a harrow also invented by Mr Sandilands, and to which he has given the name of the chain and screw harrow. Its properties are, that if your ridges be high, and you wish to harrow them from one end to the other, by lengthening the chain (which the screw commands), the harrow, when drawn along, forms an angle downwards, and mills none of the curve of the ridge, so far as it extends (which may be nine feet, the distance from A to B. The extent, in the contrary direction is five feet six inches). When the crowns of the ridges have got what is thought sufficient harrowing lengthwise, you shorten the chain by the screw, which forms an angle upwards: the harrow is then drawn by the horses, one on each side of the furrow; which completely harrows it, and the sides of the ridge, if 18 feet broad.

When you want to harrow even ground or high ridges across with the screw, you can bring the harrow to be horizontal, so as to work as a solid harrow without a joint.

The teeth are formed and fixed in the common manner, square, not in the fashion of coalters; and are nine or ten inches below the wood, and of such strength as it is thought the land requires. The teeth cut, or rather tear, the ground at every four inches without variation, though seemingly placed irregularly; and this without any risk of choking, except sometimes at the extreme angles, where the teeth are necessarily near each other; but which may be cleaned with the greatest ease, by raising them a little out of the ground. The figures 1, 2, &c. point out where the 12 teeth on each side of the harrow are placed.

Where a strong brake-harrow is not necessary, by making the teeth shorter and lighter, you may have 48 teeth, which will tear the ground at every two inches, cover the seed well, and make a fine mould.

It is recommended, that harrows for every purpose, and
The roller is an instrument of capital use in husbandry, though scarcely known in ordinary practice; and, where introduced, it is commonly fo flignt to as to have very little effect.

Rollers are of different kinds; stone, cast-iron, wood. Each of these has its advantages. We would recommend the last, constructed in the following manner. Take the body of a tree, six feet ten inches long, the larger the better, made as near a perfect cylinder as possible. Surround this cylinder with three rows of fillies, one row in the middle, and one at each end. Line these fillies with planks of wood equally long with the roller, and so narrow as to ply into a circle. Bind them fast together with iron-rings. Beech-wood is the belt, being hard and tough. The roller thus mounted, ought to have a diameter of three feet ten inches. It has a double pair of shafts for two horses at each end. These are sufficient in level ground; in ground not level, four horses may be necessary. The roller without the shafts ought to weigh 200 stone Dutch; and the larger diameter makes this great weight easy to be drawn.

Rolling wheat in the month of April is an important article in loofe foil; as the winter-rains preffing down the foil leave many roots in the air. Barley ought to be rolled immediately after the feed is fown, especially where grain-feeding is fown with it. The belt time for rolling a gravelly foil, is as soon as the mould is fof dry as to bear the roller without clinging to it. A clay foil ought neither to be tilted, harrowed, nor rolled, till the field be perfectly dry. And as rolling a clay foil is chiefly intended for smoothing the surface, a dry feafon may be patienfly waited for, even till the crop be three inches high. There is the greater reason for this precaution, because much rain immediately after rolling is apt to cake the surface when drought follows. Oats in a light foil may be rolled immediately after the feed is fown, unlefs the ground be fo wet as to cling to the roller. In a clay foil, delay rolling till the grain be above ground. The proper time for fowing grain-feeding in an oat-field, is when the grain is three inches high; and rolling should immediately succeed, whatever the foil be. Flax ought to be rolled immediately after fowing. This should never be neglected; for it makes the feed pull equally, and prevents after growth; the bad effect of which is visible in every step of the process for fowing flax. The first year’s crop of fown graffes ought to be rolled as early the next iping as the ground will bear the horses. It fixes all the roots precisely as in the case of wheat. Rolling the second and third crops in loofe foil is an useful work; though not fo essential as rolling the firft crop.

In the firft place, rolling renders a loofe foil more compact and folid; which encourages the growth of plants, by making the earth clap close to every part of every root. Nor need we be afraid of rendering the foil too compact; for no roller that can be drawn by two or four horses will have that effect. In the next place, rolling keeps in the moifure, andbinds drought to penetrate. This effect is of great moment. In a dry feafon, it may make the difference of a good crop, or no crop, especially where the foil is light. In the third place, the rolling grain-feeding, besides the foregoing advantages, facilitates the moving for hay; and it is to be hoped, that the advantage of this practice will lead farmers to mow their corn alfó, which will increase the quantity of straw both for food and for the dunghill.

There is a small roller for breaking clods in land intended for barley. The common way is, to break clods with a mall, which requires many hands, and is a laborious work. This roller performs the work more effectually, and at much lefs expense; let a harrowing precede, which will break the clods a little; and after lying a day, or a day and a half, to dry, this roller will dissolve them into powder. This however does not preclude the use of the great roller after all the other articles are finifhed, in order to make the foil compact, and to keep out the summer-drought. A stone roller four feet long, and fifteen inches diameter, drawn by one horfe, is sufficient to break clods that are easily difolved by preflure. The use of this roller in preparing land for barley is gaining ground daily, even among ordinary tenants, who have become fenfible both of the expence and toil of using wooden malls. But in a clay foil, the clods are fometimes too firm, or too tough, to be fubdued by fo light a machine. In that cafe, a roller of the fame size, but of a different conftuction, is necefly. It ought to be furred round with circles of iron, fix inches alunder, and seven inches deep; which will cut even the moft hard born clods, and reduce them to powder. Let not this instrument be considered as a finical refinement. In a fiff clay, it may make the difference of a plentiful or fcarcy crop.

6. The FALLOW-CLEANING MACHINE.

This was invented by Mr Aaron Ogden, a fmith at Alton-under-Lyne, near Manchester in Lancashire. It is intended for cleaning fallows from weeds, &c. by the machine which exhaust the riches of the foil. A, A, is the frame; B, the firft roller; C, the second ditto; in which laft are two cranks to move the arms D, D, which work the rake up the directors fixed on the plank E. The underfide of the lower ends of these directors are harrow to cut the clods and let them come on the upper side. Each alternate heel of the share is longer than the intermediate one, that they may not have more than one-half to cut at once. At the back of the plank E are two fcrews to let it loofe, that the directors may be let higher or lower. The shares are to penetrate the ground two or three inches, to raife the quicks till the rake I, I, raifes them into the cart H, where a man must be ready with a muck-hook to clear them backward when gathered. In the rake I are two teeth for every space of the directors, that foanes, &c. may be gathered without damage. K, K, are two fnapes, by which the machine is drawn: under them are two hooks placed low to raife the machine in turning, by the help of the shares; and the axle-tree of the cart should be fixed upon a pin, that it may turn like a waggion. F, F, are the triggers to throw the rake behind the roots. The long teeth at G, G, are to clean the roller C, I, I, is the rake which gathers up the weeds into
Part II. AGRICULTURE.

Practice.

into the cart H, and is drawn above the trigger F by the working of the arms D, D, expressed by the dotted lines at d d. The triggers e, of which there is one on each side, move on the pivots a, so that when the points b of the rake, have been drawn up by the directors E to the part marked c, the trigger, giving way p, permits the rake to pass; but immediately falling, the rake returns along the upper surface of the trigger marked e, e, and of course falls on the weeds when it comes to the end, a little beyond the pivot a. The reader will observe, that the boarding is taken away on one side, in the Plate, in order to give a more perfect view of the inner part of the machine; and in fact it would perhaps be better if all the boarding, marked L, L, was taken away, and frame-work put in its stead. The cart H might undoubtedly also be made lighter. The wheels M, M, appear described by the end of the roller N, to be divided by four fruit lines into eight equal segments, as represented at P. Let the fame be done at the other end of the roller, and parallel lines be drawn from one corresponding point to the other the length of the roller; mark the points with figures 1, 2, 3, 4, 5, 6, 7, 8; afterwards draw oblique lines, as from 1, at the end of O to 2, at the other end, and from 2 to 3, &c. on these oblique lines the spikes are to be fixed at equal distance in eight circles, described on the circumference of the roller. The spikes of the small roller B are fixed in the same manner, except that the diameter being smaller, there are only six instead of eight rows. R is another view of the directors, with the plank E on which they are fixed; and S is a section of a part of the plank, with one of the directors as fixed, in which may be seen the heel m, from whence to the point of the share n is a sharp cutting edge. See the same letters in figure R. T is one of the long teeth to be seen at G; it is bent towards the roller C, which it serves to cleanse. When the end of the rake b, after riling above c, is pulled, by the motion of the arms D, D, along the upper part e, of the trigger F, and comes to the end beyond a; as it falls, the part of the arm marked e reffs in the notch p, till it is again raised by the motion of the roller C with the rake. The roller C is to be one foot diameter, the spikes nine inches long, that they may go through the furrow (if the soil should be loose) into the hard earth, the more effectually to work the rake, which otherwise might be so overcharged as to caufe the roller to drag without turning. In the rake-ends b their should be pivots, with rollers or pullers on, to go in the groove, to take off the friction; and they would likewise take the triggers more fully as the rake comes back. The rake should also be hung so far backward, that when it is fallen the arms of it may lie in the same plane or parallel with the directors, on which it comes up (which will require the frame to be two inches longer in the model). This will cause the rake to fall heavier, and drive the teeth into the roots, and bring them up without flattering. These teeth must be made of steel, very fine, and so long as to reach down to the plank on which the directions are fixed, that is to say, six inches long (the directors are also to be made six inches broad above the plank). The rake-head should also fall a little before the crank is at its extremity, which will cause the rake to push forward to let the teeth come into the roots. The rake-teeth must drop in the same plane with the roller and wheels, or on the surface of the earth. No more space should be given from the roller C to the long teeth at G G than that the rake may just miss the spikes of the roller C and fall on the places before mentioned. As the first roller B was intended to cleanse the second C more than for any other use, it may be omitted when the machine is made in large, as Mr. Ogden has lately found that the long teeth at G G answer the end alone, and this renders the machine about a sixth part shorter. Now, to fit any fort of earth, there should be to each machine three planks, with directors at different spaces, to act occasionally; in the first, the spaces between the directors should be eight inches wide, in the second six, and the third four. This will answer the same end as having to many machines.

As there may be some objections to the rake not leaving the roots when it has brought them up, Mr. Ogden has several methods of cleansing it; but as he would make it as simple as possible, he chooses to let it be without them at present; but suppose it should bring some roots back again with it, it will probably lose them before it gets back to the extremity; whence they will lie light, and be of but little detriment to the others coming up. Mr. Ogden would have the first machine made four feet six inches wide, the teeth divided into equal spaces the outsides into half spaces.

This machine, whether made to be worked by hand, drawn by a horse, or fixed to a plough, and used with it, is extremely simple in the construction, and not machine, liable to be put out of order; as there is but one movement to direct the whole, nor does it require any skill in working. It will sow wheat, barley, oats, rye, clover, cole-seed, hemp, flax, Canary, rape, turnip, besides a great variety of other kinds of grain and seeds broad cast, with an accuracy hitherto unknown. It is equally useful in the new husbandry, particularly when fixed to a plough; it will then drill a more extensive variety of grain, pulse, and seed (through every gradation, with regard to quantity), and deliver each kind with greater regularity than any drill-plough whatever. When used in this manner, it will likewise be found of the utmost service to farmers who are partial to the old husbandry, as, among many other very valuable and peculiar properties, it will not only sow in the broad-cast way with a most singular exactness, but save the expense of a seedman; the seed being sown (either over or under furrow at pleasure), and the land ploughed, at the same operation.

Perhaps a fair and decisive experiment for ascertaining the superior advantages of broad-casting or drilling any particular crop was never before practicable; as the seed may now be put in with the utmost degree of regularity, in both methods of culture, by the same machine;
Agriculture

Practice.

Machine; consequently, the feed will be fown in both
cases with equal accuracy, without which it is impos-
tible to make a just decision.

The excellence of this machine consists in spreading
any given quantity of feed over any given number of
acres, with a mathematical exactness, which cannot be
done by hand; by which a great saving may be made
in feeding the ground, as well as benefiting the ex-
cyeted crop.

There has always been a difficulty in sowing turnip
seed with any degree of exactness, both from the mi-
nuteneat of the feed, and the smallness of the quantity
required to be fown on an acre. Here the machine
has a manifest advantage, as it may be set to fow the
least quantity ever required on an acre; and with an
accuracy the best feedman can never attain to.

It will also fow clover, cole, flax, and every other
kind of small feed, with the utmost degree of regularity.

It will likewise broad-cast beans, peas, and tares, or
drill them with the greatest exactness, particularly
when constructed to be used with a plough.

Another advantage attending the use of this ma-
chine, is that the wind can have no effect on the fall-
ing of the feed.

Of the Machine when made to be used without a
Plough, and to be drawn by a Horse.—It may in
this cafe be made of different lengths at the desire of
the purchaser. The upper part AAAAA, contains
the hoppers from which the grain or feed descends into
the spouts. The several spouts all rest upon a bar,
which hangs and plays freely by two diagonal
supporters BB; a trigger fixed to this bar bears a catch wheel; this being fixed on the axle, occasions a regular and
continual motion, or jogging of the spouts, quicker or
slower in proportion to the pace the person fowing
with it drives; and of course, if he quickens his pace,
the bar will receive a greater number of strokes from
the catch wheel, and the grain or feed will feed the
faster. If he drives slower, by receiving fewer strokes,
the contrary must take place. In going along the
side of a hill, the strength of the stroke is corrected by
a spring which acts with more or less power, in pro-
portion as the machine is more or less from a hori-
zontal position, and counteracts the difference of gravity in
the bar, so that it presses, in all situations, with a pro-
per force against the catch wheel. This spring is un-
necessary if the land be pretty level. At the bottom
of the machine is placed an apron or shelf in a sloping
position, and the corn or feed, by falling thereon from
the spouts above, is scattered about in every direction
under the machine, and covers the ground in a most
regular and uniform manner.

To fow the corn or bean drills, there are moveable
spouts (see fig. 10.) which are fixed on, or taken off
at pleasure, to direct the feed from the upper spout to
the bottom of the furrow.

The machine is regulated for fowing any particular
quantity of feed on an acre by a brass slider, A, fig. 7,
fixed by screws against a brass bridge on each of the
spouts. The machine is prevented from feeding while
turning at the ends, by only removing the lever, E,
fig. 2, out of the channel G, to another at H, on the
right hand of it, which carries back the bar from the
catch-wheel, and occasions the motion of the spouts to
cease, and at the same time brings them upon a level
by the action of the diagonal supports; so that no
corn or feed can fall from them.

The machine in this form is particularly useful for
broads-casting clover upon barley or wheat; or for fow-
ing any other kind of feed, where it is necessary that
the land should first be harrowed exceedingly fine and
even.

Manner of using the Machine when drawn by a
Horse.—Place the machine about two feet from the
ends of the furrows where you intend it shall begin to
fow. Fill the hoppers with feed, and drive it forward
with the outside wheel in the first furrow. When you
are at the end of the length, at the opposite side of the
field, lift the lever E, fig. 2, into the channel H, and
the machine will instantly stop fowing. Drive it on
about two feet and then turn. Fill the hoppers again
if necessary; then remove the lever back again into the
channel G, and in returning, let the outside wheel of
the machine go one furrow within the track which
was made by it, in falling from the opposite end: as
for example, if the wheel passed down the eighth fur-
row from the outside of the field, let it return in the
seventh; and in every following length let the outside
wheel always run one furrow within the track made
by the same wheel: because the breadth sown is about
nine inches less than the distance between the wheels.

Let the machine be kept in a perpendicular situa-
tion. If the farmer wishes to sow more or less feed
on any one part of the field than the other, it is only
raising the handles a little higher, or finking them a
litle lower than usual, and it will occasion a sufficient
alteration; and should the land turn be left in breadth
than the machine, those spouts which are not wanted
may be taken up from the bar, and prevented from
feeding, by turning the knob above them.

Also when the land required to be fown has what is
called a vent, that is, when the sides of the field run in
an oblique line to the furrows, which by this means
are unequal in length: the spouts must be taken up or
let down in succession by turning the knobs; as that
part of the machine, where they are placed, arrives at
the ends of the furrows. This is done while the ma-
chine is going forwards.

If the land be tolerably level, the machine may be
fixed by the screw in the front, and the machine may
then be used by any common harrow boy.

Method of regulating the Machine.—In each spout
is fixed a bridge, (see fig. 7.) with an aperture in it, B,
for the grain or feed to pass through. This aperture
is enlarged or contracted by a slider, A, which passes
over it; and when properly fixed for the quantity of feed
designed to be sown on an acre, is fastened by means
of two strong screws firmly against the bridge. This
is made use of in fowing all kinds of feed, where it is
required to fow from one belt upwards on an acre.

To fow one, two, three gallons, or any of the inter-
mediate quantities, as of clover, cole-feed, &c. the
brass plate, fig. 6. is placed between the bridge and the
slider, with the largest aperture B downwards, which
aperture is enlarged or contracted by the slider as be-
fore. To fow turnips, the same plate is placed be-
tween the bridge and the slider, with its smallest ap-
erture A downwards, and the hollow part about the same
aperture inwards.

Fig. 1. is a view of the regulator, by which the
aperture
Part II. AGRICULTURE.

The apertures in the several spouts are all set exactly alike, with the utmost care, to make them feed equally. The extreme height of the largest aperture is equal to the breadth A B, and the breadth at C is equal to the height of the smallest aperture used, viz. that for turnips. The side AC, is divided into 60 equal parts, and on it move the slider or horse D; which being placed at any particular degree, according to the quantity of feed required to be sown on an acre, is fixed upon it, by a screw on the side of the slider or horse.

When this is done, the end of the regulator is put through the aperture in the bridge or plate (whichever is intended to be used), and the slider against the bridge in the spout, raised by it, till it stops against the horse on the regulator; then the slider is fastened against the bridge firmly by the two screws; care being taken at the same time that it stands nearly square.

By this means the spouts (being all fixed in the same manner) will feed equally. It is easy to conceive that the size of the apertures, and consequently the quantity of feed to be sown on an acre, may be regulated with a far greater accuracy than is required in common practice.

The spouts may be regulated with the utmost nicety, in five minutes, to sow each particular feed, for the whole season. But a little practice will enable any person, who possesses but a very moderate capacity, to make the spouts feed equally, even without using the regulator (A).

Of the Machine when made to be used by Hand.—The difference of the machine in this case, is that it is made lighter, with but three spouts, without shafts, and is driven forward by the handles. It hath also a bolt in front, which being pushed in by the thumb, releases the machine; so that it can then easily be placed in a perpendicular position. This alteration is necessary to keep the handles of a convenient height, in sowing up and down a hill, where the slope is considerable; and is done while the machine is turning at the end of the length. The method of regulating and using it is the same as when made to be drawn by a horse.

Of the Machine, when constructed to be used with a Plough.—This is, without doubt the most useful application of the machine, and it can be fixed without difficulty to any kind of plough, in the same manner as to that represented fig. 7.

The advantages arising from the use of it are great and numerous; for, besides the increase in the crop, which will be injured by the seeds being broad-cast with a mathematical nicety, a large proportion of feed (the value of which alone, in a few months, will amount to more than the price of the machine) and the feedman’s labour will be saved. The feed may likewise be sown either under or over furrow; or one cast each way, as practised by some farmers. The feed also, being cast by the machine upon the fresh ploughed land, may be immediately harrowed in, before the mould has loft any part of its moisture; which in a dry season will greatly promote the crop. In drilling any kind of grain, pulse, or feed, it polishes every property that can be wished for in the belt drill-plough, nor will it (as most of them do) bruise the feed, or feed irregularly. The contrivance of the machine is the same as the large ones, except being made with one hopper and spout instead of several, and the apron moveable instead of being fixed, as may be seen by inspecting fig. 4. The only alteration necessary to make the machine broad-cast or drill is, in the former case to place the apron B, fig. 1. at the bottom of the machine, upon the hooks FP, hoping either towards the furrows or the imploughed land, according as it is intended to sow the feed, either under or over furrow. Whenever the apron is required to be shifted, it is done in less than a second of time; as it only requires to be moved up or down with the hand, when a catch fixes it.

To prepare it for drilling, instead of the apron, place the long spout, fig. 10, upon the brackets, on the front of the machine, by the ears AA, to receive the feed from the upper spout, and to the lower end of it, by a small cord, to that hook upon which the apron is hung for broad-casting, which is next the plough (see fig. 3.) the feed will then be directed by the long spout, to the centre of the furrow, near the heel of the plough. The spring for correcting the strength of the broke, is necessary only when they are required to go along the side of a considerable declivity. The machine, when fixed to a plough, does not require the smallest degree of skill in using, as nothing is necessary but to keep the hopper filled, which will contain a sufficient quantity of feed to go upwards of 140 rods, before it will want re-filling, when three bushels and a half are sown on an acre. The accuracy with which it will broad-cast, may in some measure be conceived, by considering that the feed regularly descends upon the apron or shelf, and is from thence scattered upon the ground, in quantity exactly proportioned to the speed of the plough; also that each cast spreads to the third furrow; and by this means flushes upon the last. In this manner it is continually filling up till the whole field is completely covered; so that it is impossible to leave the smallest space without its proper quantity of feed.

When the plough is wanted for any other purpose.

(a) Proper directions are given with each machine for using it, as also for fixing the sliders to sow any particular quantity of corn or feed on an acre, so as to enable any person to set the spouts.

The prices of the machine (exclusive of the packing cases) are as follow. If constructed to be used with a single furrow plough; the wheel, with the axle and checks included, $8.00, regulator, brass-plates for broad-casting or drilling turnips, lucerne, tares, wheat, barley, &c. &c. &c. and every article necessary for fixing it included, three guineas and a half. If made with a spring (for sowing on the side of a hill, where the slope is considerable), but which is very rarely necessary, five shillings more. If made to be fixed to any double-furrow plough, four guineas and a half.

The large machine, fig. 2, when made to broad-cast seven furrows at a time, and to be drawn by a horse, eight guineas and a half. If constructed to sow five furrows at a time, and to be used by hand, six guineas. These are also five shillings more if made with a spring.
the machine, with the wheel at the heel of the plough for giving it motion, can be removed or replaced at any time in five minutes.

Fig. 11 represents the machine fixed to a double furrow cresting plough, and prepared for drilling. As this plough may not be generally known, it will not be improper to observe, that it is chiefly used for creating the land with furrows (after it has been once ploughed and harrowed); which method is necessary when the feed is to be sown broad-cast upon land that has been a clover- lay, &c., because, if the feed be thrown upon the rough furrows, a considerable part of it will fall between them, and be unavoidably lost, by laying to deep buried in the earth. This mode answers extremely well, and partakes of both methods of culture; the double-furrow plough, is made with two upper aprons for broad-casting, two aprons for double-furrow ploughing, two long spouts for drilling, two aprons for broad-casting, and with a double hopper; but in other respects the same as when intended for a single furrow plough: it is used in all cases with the greatest ease imaginable.

The interval between the points of the two shares of a creasing plough is usually ten inches; the beam about nine feet long; and the whole made of a light construction.

An more particular explanation of the figures.—Fig. 1. The machine fixed to a Kentish turn-wrest plough. A, The machine. B, the apron upon which the feed falls and rebounds upon the land, in broad-casting. C, Lid to cover the hopper. D, Wheel at the heel of the plough. E, Strap. FF, Hooks upon which the apron turns by a pivot on each side. G, Stays, to keep the machine steady. H, Lever to prevent it from sowing.

Fig. 2. The machine constricted to be drawn by a horse. AAA, The hoppers. BB, The diagonal supports. CCC, The upper spouts. D, The apron or shelf upon which the feed falls from the upper spouts. E, The lever, which carries back the bar, and prevents the machine from sowing. FF, Staples upon the handles, through which the reins pass, for the man who conducts the machine, to direct the horse by. I, Screw to fix the machine occasionally. N, B. The knobs (by turning which each particular spout may be taken from off the bar, and thereby prevented from feeding) are over each upper spout; but, to prevent confusion, are not lettered in the Plate.

Fig. 3. Is the same machine with that in fig. 1. The dotted lines, expressing the situation of the long spout, when the apron is removed, and the machine adapted for drilling.

Fig. 4. Also the same machine, with the front laid open to show the inside. A, The catch-wheel fixed upon the axle. BB, The axle upon which the machine hangs between the handles of the plough. C, The pulley, by which the strap from the wheel at the heel of the plough turns the catch-wheel. D, The bar, upon which the upper spout rests, suspended by the diagonal supporters EE, bearing against the catch-wheel by the trigger F, and thereby kept in motion while the plough is going. G, the apron in a flopping position, upon which the corn or feed falls from the upper spout, and is scattered by rebounding upon the land. It turns upon pivots, and by this means throws the feed either towards the right hand or left at pleasure.

Fig. 5. The upper spout.

SECT. II. Preparing Land for Cropping.

I. OBSTRUCTIONS TO CROPPING.

In preparing land for cropping, the first thing that obstructs occurs, is to consider the obstructions to regular ploughing. The most formidable of these,are stones lying above or below the surface, which are an impediment to a plough, as rocks are to a ship. Stones above the surface may be avoided by the ploughman, though not without loss of ground; but stones below the surface are commonly not discovered till the plough be hattered to pieces, and perhaps a day’s work lost. The clearing land of stones is therefore necessary to prevent mischief. And to encourage the operation, it is attended with much actual profit. In the first place, the stones are useful for fences; when large they must be blown, and commonly fall into parts proper for building. And as the blowing, when gunpowder is furnished, does not exceed a halfpenny for each inch that is bored, these stones come generally cheaper than to dig as many out of the quarry. In the next place, as the soil round a large stone is commonly the best in the field, it is purchased at a low rate by taking out the stone. Nor is this a trifle; for not only is the ground loft that is occupied by a large stone, but also a considerable space round it, to which the plough has not access without danger. A third advantage is greater than all the rest; which is, that the ploughing can be carried on with much expedition, when there is no apprehension of stones: in stony land, the plough must proceed so slow as not to perform half of its work.

To clear land of stones, is in many instances an undertaking
Part II.

AGRICULTURE.

A clay soil of any thickness is never peopled with springs; but it is peopled with water, which settles on the surface as in a cup. The only remedy is high narrow ridges, well rounded. And to clear the furrows, the furrow of the foot-ridge ought to be considerably lower, in order to carry off the water cleverly. It cannot be made too low, as nothing hurts clay soil more than the stagnation of water on it; witness the hollows at the end of crooked ridges, which are absolutely barren. Some gravelly soils have a clay bottom, which is a substantial benefit to a field when in grays, as it retains moisture. But when in tillage, ridges are necessary to prevent rain from settling at the bottom; and this is the only case where a gravelly soil ought to beridged.

Clay soils that have little or no level, have sometimes a gravelly bottom. For discharging the water, the best method is, at the end of every ridge to pierce down to the gravel, which will absorb the water. But if the furrow of the foot-ridge be low enough to receive all the water, it will be more expedient to make a few holes in that furrow. In some cases, a field may be drained, by filling up the hollows with earth taken from higher ground. But as this method is expensive, it will only be taken where no other method answers. Where a field happens to be partly wet, partly dry, there ought to be a separation by a middle ridge, if it can be done conveniently; and the dry part may be ploughed while the other is drying.

The low part of Berwickshire is generally a brick clay, extremely wet and poachy during winter. This in a good measure may be prevented by proper inclosing, as there is not a field but can be drained into lower ground all the way down to the river Tweed. But as this would lessen the quantity of rain in a dry climate, such as is all the east side of Britain, it may admit of some doubt whether the remedy would not be as bad as the disease. (See the article Draining.)

2. Bringing into culture, land from the state of nature.

To improve a moor, let it be opened in winter when it is wet, which has one convenience, that the plough cannot be employed at any other work. In spring, after frost is over, a light harrowing will fill up the teams with mould, to keep out the air, and rot the sod. In that state let it lie the following summer and winter, which will rot the sod more than if laid open to the air by ploughing. Next April, let it be cross-ploughed, braked, and harrowed, till it be sufficiently pulverised. Let the manure laid upon it, whether lime or dung, be intimately mixed with the soil by repeated harrowings. This will make a fine bed for turnip-feed if town bread-cast. But if drills be intended, the method must be

(a) By this expression it is not meant that the ground really becomes acid, but only that it becomes unfit for the purposes of vegetation. The natural products of such a soil are rushes and four grasses which last appears in the furrows, but seldom in the crown of the ridge; is dry and insubstantial like a chip of wood; and feels rough when trod backwards.
be followed that is directed afterward in treating more directly the culture of turnip.

A successful turnip-crop, sown on the ground with fleece, is a fine preparation for laying down a field with grass-seeds. It is an improvement upon this method, to take one or two successive crops of turnip, which will require to be followed by the second and following crops. This will thin the soil, and enrich it greatly.

The best way of improving swampy ground after draining, is paring and burning. But where the ground is dry, and the soil so thin that the surface cannot be pared, the best way of bringing it into tillth from the state of nature, as mentioned above, is to plough it with a feathered foot, laying the grassy surface under. After the new surface is mellowed with frost, fill up all the seams by harrowing crofs the field, which by excluding the air will effectually rot the sod. In this state let it lie frosty and winter. In the beginning of May after, a cross ploughing will reduce all to small fragments, which must be nearly crooked with the brake, and make it ready for a May or June crop. If these square pieces be allowed to lie long in the sap without breaking, they will become tough and not be easily reduced.

3. Forming RIDGES.

The first thing that occurs on this head, is to consider what grounds ought to be formed into ridges, and what ought to be tilled with a flat surface. Dry soils, which suffer by a lack of moisture, ought to be tilled flat, which tends to retain moisture. And the method for such tilling, is to go round and round from the circumference to the centre, or from the centre to the circumference. This method is advantageous in point of expedition, as the whole is finished without once turning the plough. At the same time, every inch of the soil is moved, instead of leaving either the crown or the furrow unmoved, as is commonly done in tilling ridges. Clay soil, which suffers by water standing on it, ought to be laid as dry as possible by proper ridges. A loamy soil is the middle between the two mentioned. It ought to be tilled flat in a dry country, especially if it inclines the soil first mentioned. In a moist country, it ought to be formed into ridges, high or low according to the degree of moisture and tendency to clay.

In grounds that require ridging, an error prevails, that ridges cannot be raised too high. High ridges labour under several disadvantages. The soil is heaped upon the crown, leaving the furrows bare: the crown is too dry, and the furrows too wet: the crop, which is always best on the crown, is more readily shaken with the wind, than where the whole crop is of an equal height: the half of the ridge is always covered from the sun, a disadvantage which is far from being sight in a cold climate. High ridges labour under another disadvantage in ground that has no more level than barely sufficient to carry off water: they sink the furrows below the level of the ground; and consequently retain water at the end of every ridge. The furrows ought never to be sunk below the level of the ground. Water will more effectually be carried off by leveling the ridges both in height and breadth; a narrow ridge, the crown of which is but 18 inches higher than the furrow, has a greater slope than a very broad ridge where the difference is three or four feet.

Next, of forming ridges where the ground hangs considerably. Ridges may be too steep as well as too horizontal; and if to the ridges be given all the steepness of a field, a heavy shower may do irreparable mischief. To prevent such mischief, the ridges ought to be fo directed crofs the field, as to have a gentle slope for carrying off water slowly, and no more. In that respect, a hanging field has greatly the advantage of one that is nearly horizontal; because in the latter, there is no opportunity of a choice in forming the ridges. A hill is of all the best adapted for directing the ridges properly. If the soil be gravelly, it may be ploughed round and round, beginning at the bottom and ascending gradually to the top in a spiral line. This method of ploughing a hill, requires no more force than ploughing on a level; and at the same time it overcomes the great inconvenience of a gravelly hill, that rains go off too quickly; for the rain is retained in every furrow. If the soil be such as to require ridges, they may be directed to any slope that is proper.

In order to form a field into ridges, that has not been formerly cultivated, the rules mentioned are easily put in execution. But what if ridges be already formed, that are either crooked or too high? After seeing the advantage of forming a field into ridges, people were naturally led into an error, that the higher the better. But what could tempt them to make their ridges crooked? Certainly this method did not originate from design: but from the laziness of the driver suffering the cattle to turn too hastily, instead of making them finish the ridge without turning. There is more than one disadvantage in this slovenly practice. First, the water is kept in by the curve at the end of every ridge, and flows the ground. Next, as a plough has the least friction possible in a straight line, the friction must be increased in a curve, the back part of the mouldboard pressing hard on the one hand, and the coulter pressing hard on the other. In the third place, the plough moving in a straight line, has the greatest command in laying the earth over. But when the straight line of the plough is applied to the curve of a ridge in order to heighten it by gathering, the earth moved by the plough is continually falling back, in spite of the most skilful ploughman.

The inconveniences of ridges high and crooked are so many, that one would be tempted to apply a remedy at any risk. And yet, if the soil be clay, it would not be advisable for a tenant to apply the remedy upon a lease shorter than two nineteen years. In a dry gravelly soil, the work is not difficult nor hazardous. When the ridges are cleared two or three years successively in the course of cropping, the operation ought to be concluded in one summer. The earth, by reiterated ploughings, should be accumulated upon the furrows, so as to raise them higher than the crowns: they cannot be raised too high, for the accumulated earth will subside by its own weight. Crofs-ploughing once or twice, will reduce the ground to a flat surface, and give opportunity to form ridges at will. The same method brings down ridges in clay soil; only let care be taken to carry on the work with expedition; be-
Part II.

AGRICULTURE.

cause a hearty shower, before the new ridges are formed, would soak the ground in water, and make the farmer suspend his work for the remainder of that year at least. In a strong clay, we would not venture to alter the ridges, unless it can be done to perfection in one season. On this subject Mr. Anderson has the following observations.

"The difficulty of performing this operation properly with the common implements of husbandry, and the obvious benefit that accrues to the farmer from having his fields level, has produced many new inventions of ploughs, harrows, drags, &c. calculated for speedily reducing the fields to that state; none of which have as yet been found fully to answer the purpose for which they were intended, as they all indiscriminately carry the earth that was on the high places into those that were lower; which although it may, in some cases render the surface of the ground tolerably smooth and level, is usually attended with inconveniences far greater, for a considerable length of time, than that which it was intended to remove.

"For experience sufficiently shows, that even the best vegetable mould, if buried for any length of time far beneath the surface as to be deprived of the beneficial influences of the atmosphere, loses its virtue, if I may be allowed to express it; becomes an inert, lifeless mass, little fitted for nourishing vegetables, and constitutes a foil very improper for the purposes of the farmer. It therefore behoves him, as much as in him lies, to preserve, on every part of his field, an equal covering of that vegetable mould that has long been uppermost, and rendered fertile by the modifying influence of the atmosphere. But, if he suddenly levels his high ridges by any of these mechanical contrivances, he of necessity buries all the good mould that was on the top of the ridges in the old furrows; by which he greatly impoverished one part of his field, while he too much enriched another; insomuch that it is a matter of great difficulty, for many years thereafter, to get the field brought to an equal degree of fertility in different places; which makes it impossible for the farmer to get an equal crop over the whole of his field by any management whatever; and he has the mortification frequently, by this means, to see the one half of his crop rotted by an over-luxuriance, while other parts of it are weak and sickly, or one part ripe and ready for reaping, while the other is not properly filled; so that it were, on many occasions, better for him to have his whole field reduced at once to the same degree of poorness as the poorest of it, than have it in this state. An almost impracticable degree of attention in spreading the manures may indeed in some measure get the better of this; but it is so difficult to perform this properly, that I have frequently seen fields that had been thus levelled, in which, after thirty years of continued culture and repeated dressings, the marks of the old ridges could be distinctly traced when the corn was growing, although the surface was so level that no traces of them could be perceived when the corn was off the ground.

"But this is a degree of perfection in levelling that cannot be usually attained by following this mode of practice; and, therefore, is but seldom seen. For all that can be expected to be done by any levelling man-

chine, is to render the surface perfectly smooth and even in every part, at the time that the operation is performed; but, as in this case, the old hollows are suddenly filled up with loose mould to a great depth, while the earth below the surface upon the heights of the old ridges remains firm and compact, the new-raised earth after a short time subsides very much, while the other parts of the field do not sink at all; so that in a short time the old furrows come to be again below the level of the other parts of the field, and the water of course is suffered in some degree to stagnate upon them; so much that, in a few years, it becomes necessary once more to repeat the same levelling process, and thus renew the damage that the farmer sustains by this pernicious operation.

"On these accounts, if the farmer has not a long leaf, it will be found in general to be much his interest sometimes not to leave the ridges as he found them, rather than to attempt to alter their direction; and, if he attends with due caution to moderate the height of these old ridges, he may reap very good crops, although perhaps at a somewhat greater expense of labour than he would have been put to upon the same field, if it had been reduced to a proper level surface, and divided into straight and parallel ridges.

"But, whereas a man is secure of possessing his ground for any considerable length of time, the advantages that he will reap from having level and well-laid-out fields, are so considerable as to be worth purchasing, if it should even be at a considerable expense. But the lofs that is sustained at the beginning, by this mechanical mode of levelling ridges, if they are of considerable height, is so very great, that it is perhaps doubtful if any future advantages can ever fully compensate it. I would therefore advise, that all this levelling apparatus should be laid aside; and the following more efficacious practice be substituted in its stead: A practice that I have long followed with success, and can safely recommend as the very best that has yet come to my knowledge.

"If the ridges have been raised to a very great height, as a preparation for the ensuing operations, thou of them may be first eleven, or failed out, as it is called in levelling, different places; that is, ploughed so as to lay the earth on each ridge from the middle towards the furrows. But, if they are only of a moderate degree of height, this operation may be omitted. When you mean to proceed to level the ground, let a number of men be collected, with spades, more or fewer as the nature of the ground requires, and then let a plough to draw a furrow directly across the ridges of the whole field intended to be levelled. Divide this line into as many parts as you have labourers, allotting to each one ridge or two, or more or less, according to their number, height, and other circumstances. Let each of the labourers have orders, as soon as the plough has passed that part assigned him, to begin to dig in the bottom of the furrow that the plough has just made, about the middle of the side of the old ridge, keeping his face towards the old furrow, working backwards till he comes to the height of the ridge, and then turn towards the other furrow, and repeat the same on the other side of the ridge, always throwing the earth that he digs up into the deep old furrow between the ridges,
A C R I C U L T U R E.

Practice.

Let it be a rule, to direct the ridges north and south, if the ground will permit. In this direction the east and west sides of the ridges, dividing the furrows equally between them, will ripen at the same time.

It is a great advantage in agriculture, to form ridges as narrow as possible, so narrow, and so low, as to admit the crowns and furrows to be changed alternately every crop. The soil near each surface of the ridges, is the best; and by such ploughing, it is always kept near the surface, and never buried. In high ridges, the soil is accumulated at the crowns and furrows left bare. Such alterations of crown and furrow, is easy where the ridges are no more but seven or eight feet broad. This mode of ploughing answers perfectly well in sandy and gravelly soils, and even in loam; but it is not safe in clay soil. In that soil, the ridges ought to be 12 feet wide, and 20 inches high; to be preferred always in the same form by casting, that is, by ploughing two ridges together, beginning at the furrow that separates them, and ploughing round and round till the two ridges be finished. By this method, the separating furrow is raised a little higher than the furrows that bound the two ridges. But at the next ploughing, that inequality is corrected, by beginning at the bounding furrows, and going round and round till the ploughing of the two ridges be completed at the separating furrow.

For this purpose a new instrument, termed a cleaning harrow, has been introduced by Lord Kames, and is strongly recommended (1). It is one entire piece, like the first of those mentioned above, consisting of seven bulls, four feet long each, two and one-fourth inches broad, and three-fourths deep. The bulls are united together by thongs, similar to what are mentioned above. The intervals between the bulls being three and three-fourths inches, the breadth of the whole harrow is three feet five inches. In each bull are inserted eight teeth, each nine inches free below the wood, and distant from each other six inches. The weight of each tooth is a pound, or near it. The whole is firmly bound by an iron plate from corner to corner in the line of the draught. The reef as in the harrows mentioned above. The size, however, is not invariable. The cleaning harrow ought to be larger or less according as the soil is stiff or free.

To give this instrument its full effect, stones of such a size as not to pass freely between the teeth ought to be carried off, and clods of that size ought to be broken. The ground ought to be dry, which it commonly is in the month of May.

In preparing for barley, turnip, or other summer-crop, begin with ploughing and cross-ploughing. If the ground be not sufficiently pulverized, let the great brake be applied, to be followed successively with the 1st and 2d harrows. In stiff soil, rolling may be proper. Plate VI. or twice between the acts. These operations will loosen every root, and bring some of them to the surface.

(1) In his Gentleman Farmer, to which performance the practical part of this article is materially indebted.
Part II.

AGRICULTURE.

Practice.

This is the time for the 3d harrow, conducted by a boy mounted on one of the horses, who trots smartly along the field, and brings all the roots to the surface: there they are to lie for a day or two, till perfectly dry. If any stones or clods remain, they must be carried off in carts. And now succeeds the operation of the cleaning harrow. It is drawn by a single horse, directed by reins, which the man at the opposite corner puts over his head, in order to have both hands free. In this corner is fixed a rope, with which the man from time to time raises the harrow from the ground, to let the weeds drop. For the sake of expedition, the weeds ought to be dropped in a straight line across the field, whether the harrow be full or not; and seldom is a field so dirty but that the harrow may go 30 yards before the teeth are filled. The weeds will be thus laid in parallel rows, like those of hay raked together in rows. The weeds will be thus laid in parallel rows, like those of hay raked together in rows. The weeds will be thus laid in parallel rows, like those of hay raked together in rows. The weeds will be thus laid in parallel rows, like those of hay raked together in rows. The weeds will be thus laid in parallel rows, like those of hay raked together in parallel rows, like those of hay raked together in parallel rows, like those of hay raked together in parallel rows, and then the weeds may be carried clean off, as to admit the view, this way of cleaning land will appear operose; but upon trial, neither the labour nor expense will be found immediate. At any rate, the labour and expense ought not to be grudged; for if a field be once thoroughly cleaned, the weeds must be very few, or the farmer very indolent, to make it necessary to renew the operation in less than 20 years. In the worst feasons, a few years pasture is always under command; which effectually destroys triennial plants, such as thistles and couch-grasses. The horse-hoeing will clean and prepare the surface for the 3d harrow, ploughed up the land, and in the beginning of September sow three bushels of rye per acre, either to feed off the sheep in the spring or to stand for harvest. If you feed it off, sow winter vetches in August or September, and make them into hay the following summer. Then get the land into fine tillage as possible, and sow it with fain-foin, which, with a little manure once in two or three years, will remain and produce good crops for 20 years together. Light poor land, which seldom produces good crops of anything till well manured. After it is well ploughed, sow three bushels of buck-wheat per acre, in April or May: When in bloom, let your cattle lie in a few days to eat off the beet, and tread the other down; this done, plough in what remains immediately. This will soon ferment and rot in the ground; then lay it fine, and sow three bushels of rye per acre. If this can be got off early enough, sow turnips; if not, winter vetches to cut for hay. Then get in it good tillage and sow turnip-rooted cabbages, in rows three feet apart. This plant seldom fails, if it has sufficient room, and the intervals be well horeshoe'd; and you will find it the beet spring-feed for sheep when turnips are over. The horse-hoeing will clean and prepare the land for fain-foin; for the sowing of which April is reckoned the best season. The usual way is to sow it broad-cast, four bushels to an acre; but the writer prefers sowing it in drills two feet asunder, for then it may be horse-hoed, and half the seed will be sufficient.

5. On the Nature of Different Kinds of Soils, and the Plants proper to each.

1. Clay, which is in general the stiffest of all soils, and contains an unctuous quality. But under the term clays, earths of different sorts and colours are included. One kind is so offensive, that scarcely any thing will subdue it; another is so hungry and poor, that it absorbs whatever is applied, and turns it into its own quality. Some clays are thinner than others, and the fatte is the best; some are more soft and slippery. But all of them retain water poured on their surfaces, where it flags, and chills the plants, without sinking into the soil. The Kloven of clay prevents the roots and fibres of plants from spreading in search of nourishment. The blue, the red, and the white clay, if strong, are unfavourable to vegetation. The flavy and looser clays are less so; but none of them are worth any thing till their texture is so loosened by a mixture of other substances, and opened, as to admit the influence of the sun, the air, and frosts. Among the manures recommended for clay, sand is of all others to be preferred; and fia-sand the best of all where it can be obtained: This most effectually breaks the cohesion.

The reason for preferring sea-sand is, that it is not formed wholly (as most other sands are) of small stones; but contains a great deal of calcareous matter in it, such as, shells grated and broken to pieces by the tide; and also of salts. The smaller the sand is the more easily it penetrates the clay; but it abides less time in it than the larger.

The next best land is that washed down by rains on gravelly soils. Those which are dry and light are the worst. Small gritty gravel has also been recommended by the best writers on agriculture for these soils; and in many instances we have found them to answer the purpose.

Shell-marle, ashes, and all animal and vegetable substances, are good manures for clay; but they have been found most beneficial when sand is mixed with them. Lime has been often used, but the writer of this section would not recommend it, for he never found any advantage from it, when applied to clays.

The crops most suitable for such lands are, wheat, beans, cabbages, and rye-grass. Clover seldom succeeds, nor indeed any plants whose roots require depth, and a wide spread in the earth.

2. Chalk. Chalky soils are generally dry and warm, and if there be a tolerable depth of mould, fruitful; producing great crops of barley, rye, peas, vetches, clover, trefoil, burnet, and particularly fain-foil. The latter plant flourishes in a chalky soil better than any other. But if the surface of mould be very thin, this soil requires good manuring with clay, marle, loam, or dung. As these lands are dry, they may be sown earlier than others.

When your barley is three inches high, throw in 10 lb. of clover, or 15 lb. of trefoil, and roll it well. The next summer mow the crop for hay; feed off the aftermath with sheep; and in winter give it a top-drying of dung. This will produce a crop the second spring, which should be cut for hay. As soon as this crop is carried off, plough up the land, and, in the beginning of September, sow three bushels of rye per acre, either to feed off the sheep in the spring or to stand for harvest. If you feed it off, sow winter vetches in August or September, and make them into hay the following summer. Then get the land into fine tillage as possible, and sow it with fain-foil, which, with a little manure once in two or three years, will remain and produce good crops for 20 years together.

3. Light poor land, which seldom produces good crops of anything till well manured. After it is well ploughed, sow three bushels of buckwheat per acre, in April or May: When in bloom, let your cattle lie in a few days to eat off the beet, and tread the other down; this done, plough in what remains immediately. This will soon ferment and rot in the ground; then lay it fine, and sow three bushels of rye per acre. If this can be got off early enough, sow turnips; if not, winter vetches to cut for hay. Then get in it good tillage and sow turnip-rooted cabbages, in rows three feet apart. This plant seldom fails, if it has sufficient room, and the intervals be well horseshoe'd; and you will find it the beet spring-feed for sheep when turnips are over.
The horse-hoeing will not only clean the crop, but
earth up the plants, and render them more luxuriant
and lasting.

If you sow it broad-cast, give it a top-dressing in
December or January, of roten dung, or ashes, or
which is still better, of both mixed up in compost.

From various trials, it is found that taking only one
crop in a year, and feeding the after-growth, is better
than to mow it twice. Cut it as soon as it is in full
bloom, if the weather will permit. The hay will be
the sweeter, and the strength of the plants less im-
paired, than if it flanks till the feed is formed.

4. Light rich land, being the most easy to cultivate
to advantage, and capable of bearing most kinds of
grain, pulse, and herbage, little need be said upon it.

One thing however is very proper to be observed, that
such lands are best adapted to the drill husbandry,
especially where machines are used, which require shal-
low furrows to be made for the reception of the feed.

This, if not prone to coach-grafts, is the best of all
soils for lucerne; which, if sown in two feet drills, and
kept clean, will yield an astonishing quantity of the
most excellent herbage. But lucerne will never be cul-
tivated to advantage where coach-grafts and weeds
are very plentiful; especially where machilles are used, which
be cultivated to advantage where couch-grafs and weeds
are very plentiful; and to mend it, that it

Part II. AGRICULTURE.

Practice. — that have sprung from the last stirring. The destruction of weeds is a capital article in fallowing; yet to blind are people to their interest, that nothing is more common than a fallow field covered with charlock and wild mustard, all in flower, and 10 or 12 inches high. The field having now received two harrowings and two breakings, is prepared for manure, whether lime or dung, which without delay ought to be incorporated with the soil by a repeated harrowing and a gathering furrow. This ought to be about the beginning of September, and as soon after as you please the seed may be sown.

As in ploughing a clay soil it is of importance to prevent poutching, the hinting furrows ought to be done with two hoofs in a line. If four ploughs be employed in the same field, to one of them may be allotted the care of finishing the hinting furrows.

Loam, being a medium between sand and clay, is of all soils the fittest for culprits, and the least subject to changes. It does not hold water like clay; and when wet, it dries sooner. At the same time, it is more retentive than sand of that degree of moisture which promotes vegetation. On the other hand, it is more subject to couch-grasses than clay, and to other weeds; to destroy which, fallowing is still more necessary than in clay.

Beginning the fallow about the first of May, or as soon as barley-feed is over, take as deep a furrow as the soil will admit. Where the ridges are low and narrow as that the crown and furrow can be changed alternately, there is little or no occasion for water furrowing. Where the ridges are so high as to make it proper to cleave them, water-furrowing is proper. The second ploughing may be at the distance of five weeks. Two crops of annuals may be got in the interim, the first by the brake and the next by the harrow; and by the same means eight crops may be got in the season.

The ground must be cleared of couch-grasses and knot-grass roots, by the cleaning harrow described above. The time for this operation is immediately before the manure is laid on. The ground at that time being in its loofest state, parts with its grass roots more freely than at any other time. After the manure is spread, and incorporated with the soil by breaking or harrowing, the seed may be sown. If the ground is strongly harrowed, it is drawn so easily to carry off the moisture. To leave it rough without harrowing has two advantages: it is not apt to cake with moisure, and the inequalities make a sort of shelter to the young plants against frost. But if it lie flat, it ought to be smoothed with a light harrow after the seed is sown, which will facilitate the course of the rain from the crown to the furrow.

A sandy soil is too loose for wheat. The only chance for a crop is after red clover, the roots of which bind the soil; and the instructions above given for loam are applicable here. Rye is a crop much fitter for sandy soil than wheat; and, like wheat, is generally sown after a summer-fallow.

Lastly, sow wheat as soon in the month of October as the ground is ready. When sown a month more early, it is too farward in the spring, and apt to be hurt by frost; when sown a month later, it has not time to root before frost comes on, and frost spoils it out of the ground.

Setting of wheat, a method which is reckoned one of the greatest improvement in husbandry that has taken place this century. It seems to have been first suggested by planting grains in a garden from mere curiosity, by persons who had no thought or opportunity of extending it to a lucrative purpose. Nor was it attempted on a larger scale, till a little farmer near Norwich began it about 17 years since, upon less than an acre of land. For two or three years only a few followed his example; and those were generally the butt of their neighbours meritment for adopting so singular a practice. They had, however, considerably better corn and larger crops than their neighbours: this, together with the saving in feed, engaged more to follow them: while some ingenious persons, observing its great advantage, recommended and published its utility in the Norwich papers. These recommendations had their effect. The curiosity and inquiry of the Norfolk farmers (particularly round Norwich) were excited, and they found sufficient reason to make general experiments. Among the rest was one of the largest occupiers of lands in this county, who set 57 acres in one year. His successes, from the visible superiority of his crop, both in quantity and quality, was so great, that the following autumn he set 300 acres, and has continued the practice ever since. This noble experiment established the practice, a capital and was the means of introducing it generally among improve the intelligent farmers in a very large district of land; men in a there being few who now sow any wheat, if they can agriculture, procure hands to set it. It has been generally observed, that although the set crops appear very thin during the autumn and winter, the plants thicker and spread prodigiously in the spring. The ears are indisputably larger, without any dwarfish or small corn; the grain is of a larger bulk, and specifically heavier per bushel than when sown.

The land on which this method is particularly pro Method, is either after clover, flable, or on which trefoil and grafs-feed were sown the spring before the land. These grounds, after the usual manuring, are once turned over by the plough in an extended flag or turf, at ten inches wide; along which a man, who is called a dibber, with two setting-irons, somewhat bigger than ram-roads, but considerably bigger at the extremity, steps backwards along the turf and makes the holes about four inches asunder every way, and an inch deep. Into these holes the droppers (women, boys, and girls) drop two grains, which is quite sufficient. After this, a gate buffalo with thorns is drawn by one horse over the land, and closes up the holes. By this mode, three pecks of grain is sufficient for an acre; and being immediately buried, it is equally removed from vermin or the power of frost. The regularity of its raising gives the best opportunity of keeping it clear from weeds, by weeding or hand-hoeing.

Wheat-setting is a method peculiarly beneficial when peculiar corn is dear; and, if the season be favourable, may be advantage of extended with great benefit to the farmer. Sir Thomas Beever of Hatchel-Hall in Norfolk, found the produce to be two bushels per acre more than from the wheat which is sown; but having much less small corn intermixed with it, the sample is better, and always fetches a higher price, to the amount generally of two shillings per quarter.
This method, too, favors to the farmer and to the public six pecks of feed-wheat in every acre; which, if nationally adopted, would do itself afford bread for more than half a million of people.

Add to these considerations, the great support given to the poor by this second harvest, as it may be called, which enables them to diminish their rents and maintain their families without having recourse to the parish. The expense of fattening by hand is now reduced to about ten shillings per acre; which, in good weather, may be done by one dibbler, attended by three droppers, in two days. This is five shillings per day; of which, if the dibbler gives to the children sixpence each, he will have himself three shillings and sixpence for his day's work, which is much more than he can possibly earn by any other labour so easy to himself. But put the case, that the man has a wife who dabbles with him, and two or three of his own children to drop to him, you see his gains will then be prodigious, and enough to ensure a plenty of candidates for that work, even in the least populous parts of the country.

It is, however, to be observed with regard to this method, that in seasons when feed-corn is very cheap, or the autumn particularly unfavourable to the practice, it must certainly be baffled. In light lands, for instance, a very dry time prevents dibbling; as the holes made with the instruments will be filled up again by the mould as fast as the instrument is withdrawn. So, again, in a very wet season, on strong and stiff clays, the feet in the dibblers cannot be made to penetrate the earth thus drawn over them. But these extremes of dry and wet do not often happen, nor do they affect lands of a moderately confined texture, or both light and heavy soils at the same time, so that the general practice is in fact never greatly impeded by them.

**Propagating of wheat by dividing and transplanting its roots.** In the Philosophical Transactions for 1768, we have a very extraordinary experiment, of which the following is an abstract. On the 2d of June 1766, Mr C. Miller sowed some grains of the common red wheat; and on the 8th of August a single plant was taken up and separated into 18 parts, and each part was then observed to tiller. These plants having been divided into several side-shoots, by about the middle of September some of them were then taken up and divided, and the rest of them between that time and the middle of October. This second division produced 67 plants. These plants remained through the winter, and another division of them, made between the middle of March and the 10th of April, produced 500 plants. These were then divided no further, but permitted to remain. The plants were in general stronger than any of the wheat in the fields. Some of them produced upwards of 180 ears from a single root. Many of the ears measured ten inches in length, and contained between 60 and 70 grains.

The whole number of ears which, by the process above mentioned, were produced from one grain of wheat, was 21,109, which yielded three pecks and three quarters of clear corn, the weight of which was 27 lb. 7 ounces; and from a calculation made by counting the number of grains in an ounce, the whole number of grains was about 570,820.

By this account we find, that there was only one general division of the plants made in the spring. Had a second been made, Mr Miller thinks the number of plants would have amounted to 2,000 instead of 500, and the produce thereby much enlarged.

The ground was a light black earth, upon a gravelly bottom; and consequently, a bad foil for wheat. One half of the ground was well dunged, the other half had no manure. There was, however, not any difference discoverable in the vigour, or growth, or produce, of the plants.

It must be evident, that the expense and labour of setting in the above manner by the hand, will render it impracticable upon a large scale so as to be productive of any utility. A correspondent of the Bath Society, therefore (Robert Bogle, Esq. of Baldowin, near Glasgow), with a view to extend the practice, has proposed the use of the harrow and roller until some better implements be invented. This method occurred to him from attending to the practice usual with farmers on certain occasions, of harrowing their fields after the grain is sprung up. Upon investigating the principles upon which these practices are founded, he found them confined merely to that of pulverizing the earth, without any attention to Mr Miller's doctrine. They said, "that after very heavy rains, and then exceltive dry weather, the surface of their lands were apt to be caked, the tender fibres of the young roots were thereby prevented from pushing; and of course the vegetation was greatly obstructed; in such infatuates, they found very great benefit from harrowing and rolling."

These principles he acknowledges to be well founded, so far as relates to pulverizing; but contends, that the benefit arising from harrowing and rolling is not derived from pulverizing entirely, but also from subdividing and enabling the plants to tiller (as it is termed). "The harrow (he observes) certainly breaks the incrustation on the surface, and the roller crumbles the clods; but it is also obvious, that the harrow removes a great many of the plants from their original situations; and that if the corn has begun to tiller at the time it is used, the roots will be, in many instances, subdivided, and then the application of my system of subdivision comes into play. The roller then serves to plant the roots which have been torn up by the harrow."

But on this the Society observe, that the teeth of a objections.

harrow are too large to divide roots so small and numerous as are those of grain; and whenever such roots (however tillered) stand in the line any tooth makes, they will, if small, be only turned on one side by the earth yielding to their lateral pressure, or, if large, the whole root will probably be drawn out of the ground. The principal offices, therefore, derived from harrowing and rolling these crops are, opening the soil between the plants, earthing them up, breaking the clods, and closing the earth about their roots.

In a subsequent letter, Mr Bogle, without contesting these points, further urges the scheme of propagating wheat by dividing and transplanting its roots. "I have conversed (says he) much with many practical farmers, who all admit that my plan has the appearance not only of being practical, but advantageous. I have also seen in the ninth number of Mr Young's Annual of Agriculture, the account of an experiment which strongly corroborates my theory. It was made by the Rev. Mr Pike of Edmonton. From this, and other experiments
experiments which have been made under my own eye, I foresee clearly, that the system is practicable, and will certainly be productive of great benefit, should it become general. Besides the saving of nine-tenths of feed in the land sown broad-cast, other very important advantages will attend the setting out of wheat from a feed-bed, such as an early crop; the certainty of good crops; rendering a thinner fallow unnecessary; saving dung; and having your wheat perfectly free from weeds without either hand or horse-hoeing. Five hundred plants in April produced almost a builch of grain. My gardener says, he can set one thousand plants in a day, which is confirmed by the opinion of two other gardeners. Mr Miller found no difference in the produce of what was planted on lands that had dung, and on what had none, except where the land was improper for wheat at all."

Upon the same subject, and that of harrowing all kinds of corn, we are informed, Mr Bogle, afterwards communicated to the Society his thoughts more at large, together with authentic accounts which were made at his instance, and which were attended with very great success. These, however, were received too late for publication in the last (3d) volume of their papers. But the Society, conceiving his system may be attended with considerable advantages if brought into general practice, have given, at the end of the volume, a few of his leading principles. Mr Bogle states.

1. That he has known many instances of very great crops having been obtained by harrowing fields of corn after they were sown; and therefore recommends the practice very warmly.

2. That he has also received an authentic account of one instance where the same good effects were produced by ploughing the field.

3. On the system of transplanting, he states, that a very great proportion of the feed will be saved, as a farmer may have a nursey, or small patch of plants, from which his fields may be supplied; he calculates that one acre will yield plants sufficient for 100 acres.

4. That a very great increase of crops may be obtained by this method, probably a double crop, may perhaps a triple quantity of what is reaped either by drilling, or by the broad-cast husbandry.

5. That a great part of the labour may be performed by infants, men and women, and also by children, who are at present supported by the parish charity; and that of course the poor's rates may be considerably reduced.

6. That the expense will not exceed from 20s. to 30s. per acre, if the work be performed by able-bodied men and women; but that it will be much lower, if that proportion of the work which may be done by employing young boys and girls should be allotted to them.

7. That in general he has found the distance of nine inches every way a very proper distance for setting out the plants at; but recommends them to be tried at other spaces, such as six, eight, or even 12 inches.

8. That he conceives an earlier crop may be obtained in this manner than can be obtained by any other mode of cultivation.

9. That a clean crop may also be procured in this way, because if the land be ploughed immediately before the plants are set out, the corn will spring much quicker from the plants than the weeds will do from their seeds, and the corn will thereby bear down the growth of the weeds.

10. That such lands as are overflowed in the winter and spring, and are of course unfit for sowing with wheat in the autumn, may be rendered fit for crops of wheat by planting them in the spring, or even in the summer.

11. That he has known instances of wheat being transplanted in September, October, November, February, March, April, and even as late as the middle of May, which have all answered very well.

12. That he has known an early kind of wheat, known as late as the middle of May, which has ripened in very good time; and from that circumstance he conceives, if the plants should be taken from that early kind, the feafon of transplanting might be prolonged at least till the first of July, perhaps even later.

13. That he has reason to think wheat, oats, and barley, are not annuals, but are perennials, provided they are eaten down by cattle and sheep, or are kept low by the fycythe or sickle; and are prevented from sprouting or coming to the ear.

14. That one very prevalent motive with him in prosecuting this plan, is, that he is of opinion it may enable government to devise means of supporting the vagrant poor, both old and young, who are now to meet with everywhere, both in towns and in the country, and who are at present a burden on the community; but if such employment could be struck out for them, a comfortable subsistence might be provided for them by means of their own labour and industry; and not only save the public and private charitable contributions, but may also render that class of people useful and profitable subjects; instead of their remaining in a state of beggary, distress, and perhaps a prodigal and vicious course of life.

Lately, Mr Bogle had hinted at a secondary object, which
which he has in view, from this mode of cultivation, which he apprehends may in time, with a small degree of attention, prove extremely advantageous to agriculture.—It is, that in the first place, the real and intrinsic value of different kinds of grain may be more accurately ascertained by making a comparison of it with a few plants of each kind set out at the same time, than can be done when grown in drills or broad-cast; and when the most valuable kinds of wheat, oats, or barley, are discovered, he states, that in a very short time (not exceeding four or five years) a sufficient quantity of that valuable kind may be procured to supply the kingdom with feed from a single grain of each kind; for he calculates, that 47,000 grains of wheat may be produced by divisibility in two years and three months.

Upon these propositions the Society observes, "That although Mr Bogle appears to be too sanguine in his expectations of seeing his plan realized in general practice, it certainly merits the attention of Gentlemen Farmers. We with them to make fair experiments, and report their successes. Every grand improvement has fairly originated with gentlemen; and thence the circle spreads, and separates them from each other. In the view, from which we may be induced to build upon the crown of the earth, it is, that of its place, and separates them from each other. In this form to clay-foil in particular, there is no rule in nature. It is probably a native of Britain: it will grow on the worst soil with very little preparation. For that reason, before turnip was introduced, it was always the first crop upon land broken up from the state of nature. Upon such land, may it not be a good method, to build upon the crown of every ridge, in the form of a wall, all the surface-earth, one sod above another, as in a fold for sheep? After standing in this form all the summer and winter, let the walls be thrown down, and the ground prepared for oats. This will secure better to summer-fallow and to low, when in the autumn. But the preferable method, especially in clay-foil, is to turn over the field after harvest, and to lay it open to the influences of frost and air, which lessens the tenacity of clay, and reduce it to a free mould. The surface-foil by this means is finely mellowed for reception of the seed; and it would be a pity to bury it by a second ploughing before sowing. In general, the bulk of clay-foils are rich; and skillful ploughing without dung, will probably give a better crop, than unskillful ploughing with dung.

Effect of frosts upon tilled land.

As winter-ploughing enters into the culture of oats, we must remind the reader of the effect of frost upon tilled land. Providence has neglected no region intended for the habitation of man. If in warm climates the soil be mellowed by the sun, it is no less mellowed by frost in cold climates. Frost acts upon water, by expanding it into a larger space. Frost has no effect upon dry earth; witness sand, upon which it makes no impression. But upon wet earth it acts most vigorously: it expands the moisture, which requiring more space puts every particle of the earth out of its place, and separates them from each other. In that view, frost may be considered as a plough superior to any that is made, or can be made, by the hand of man: its action reaches the minutest particles; and, by dividing and separating them, it renders the soil loose and friable. This operation is the most remarkable in tilled land, which gives free access to frost. With respect to clay-foil in particular, there is no rule in husbandry more essential than to open it before winter in hopes of frost. It is even advisable in a clay-foil to leave the stubble rank; which, when ploughed in before winter, keeps the clay loose, and admits the frost into every cranny.

To apply this doctrine, it is dangerous to plough clay-foil when wet: because water is a cement for clay, and binds it so as to render it unfit for vegetation. It is, however, less dangerous to plough wet clay before winter than after. A succeeding frost corrects the bad effects of such ploughing; a succeeding drought increases them.

The common method, is to sow oats on new-ploughed land in the month of March, as soon as the ground is tolerably dry. If it continues wet all the month of March, it is too late to venture them after. It is much preferable method of in the early spring, which seldom happens before the first of March, and the seed is sown as soon as the ground is sufficiently dry for its reception. Frost has a stronger effect on such clays than on natural clay. And if the field be laid open before winter, it is rendered so loose by frost as to be soon drenched in water. The particles at the same time are so small as that the first drought in spring makes the surface clay or crust. The difficulty of reducing this crust into mould for covering the oat-seed, has led farmers to delay ploughing till the month of March. But we are taught by experience, that this soil ploughed before winter, is sooner dry than when the ploughing is delayed till spring; and as early sowing is a great advantage, the objection of the superficial crustling is easily removed by the firr harrow above described, which will produce abundance of mould for covering the seed. The ploughing before winter not only produces early sowing, but has another advantage: the surface-foil that had been mellowed during winter by the sun, frost, and wind, is kept above.

The drelling a loamy soil for oats differs little from drelling a clay-foil, except in the following particular, that being less hurt by rain, it requires not high ridges, and therefore ought to be ploughed crown and furrow alternately.

Where there is both clay and loam in a farm, it is obvious from what is said above, that the ploughing of the clay after harvest ought first to be dispatched. If both cannot be overaken that reason, the loam may be delayed till the spring with less hurt.

Next of a gravelly soil; which is the reverse of clay, as it never suffers but from want of moisture. Such a soil ought to have no ridges; but be ploughed circularly from the centre to the circumference, or from the circumference to the centre. It ought to be tilled after harvest: and the first dry weather in spring ought to be laid hold of to sow, harrow, and roll; which will preserve it in sap.

The culture of oats is the simplest of all. That grain is probably a native of Britain: it will grow on the worst soil with very little preparation. For that reason, before turnip was introduced, it was always the first crop upon land broken up from the state of nature. Upon such land, may it not be a good method, to build upon the crown of every ridge, in the form of a wall, all the surface-earth, one sod above another, as in a fold for sheep? After standing in this form all the summer and winter, let the walls be thrown down, and the ground prepared for oats. This will secure...
Agriculture

Practice.

secure one or two good crops; after which the land may be dished for a crop of barley and grass-seeds. This method may answer in a farm where manure is scanty.

Culture of barley.

This is a culmiferous plant that requires a mellow soil. Upon that account, extraordinary care is requisite, where it is to be sown in clay. The land ought to be stirred immediately after the foregoing crop is removed, which lays it open to be mellowed with the froth and air. In that view, a peculiar sort of ploughing has been introduced, termed ribbing; by which the greatest quantity of surface possible is exposed to the air and froth. The obvious objection to this method is, that half of the ridge is left unmoved. And to obviate that objection, the following method is offered, which moves the whole soil, and at the same time exposes the same quantity of surface to the froth and air.

Ribbing.

As soon as the former crop is off the field, let the ridges be gathered with as deep a furrow as the soil will admit, beginning at the crown and ending at the furrow. This ploughing loosens the whole soil, giving free access to the air and froth. Soon after begin a second ploughing in the following manner. Let the field be divided by parallel lines across the ridges, with intervals of 30 feet or so. Plough once round an interval, beginning at the edges, and turning the earth toward the middle of the interval; which covers a foot or so of the ground formerly ploughed. Within that foot plough another round similar to the former; and after that, other rounds, till the whole interval be finished, ending at the middle. Instead of beginning at the edges, and ploughing toward the middle, it will have the same effect to begin at the middle and to plough toward the edges. Plough the other intervals in the same manner. As by this operation the furrows of the ridges will be pretty much filled up, let them be cleared and water-furrowed without delay. By this method, the field will be left waving like a plot in a kitchen-garden, ridged up for winter. In this form, the field is kept perfectly dry; for beside the capital furrows that separate the ridges, every ridge has a number of crofs furrows that carry the rain instantly to the capital furrows. In hanging grounds retentive of moisture, the parallel lines abovementioned ought not to be perpendicular to the furrows of the ridges, but to be directed a little downward, in order to carry rain-water the more hastily to these furrows. If the ground be clean, it may lie in that state winter and spring, till the time of feed-furrowing. If weeds happen to rise, they must be destroyed by ploughing, or breaking, or both; for there cannot be wore husbandry, than to put feed into dirty ground.

This method resembes common ribbing in appearance, but is very different in reality. As the common ribbing is not preceded by a gathering furrow, the half of the field is left tilltild, compact as when the former crop is removed, impervious in a great measure to air or froth. The common ribbing at the same time removes the rain-water on every ridge, preventing it from descending to the furrows; which is hurtful in all soils, and poisonous in clay soil. The flitching here described, or ribbing, if you please to call it so, prevents these noxious effects. By the two ploughings the whole field is opened, admitting freely air and froth; and the multitude of furrows lays the surface perfectly dry, giving an early opportunity for the barley seed.

But further, as to the advantage of this method: When it is proper to sow the feed, all is laid flat with the brake, which is in easy operation upon the soil that is dry and pulverized; and the feed-furrow which succeeds, is so shallow as to bury little or none of the surface earth; whereas the flitching for barley is commonly done with the deepest furrow; and consequently buries all the surface-soil that was mellowed by the froth and air. Nor is this method more expensive; because the common ribbing must always be followed with a feed furrow in a flitching furrow, which is favored in the method recommended. Nay, its less expensive; for after common ribbing, which keeps in the rain water, the ground is commonly sowed, as to make the flitching a laborious work.

It is well known that barley is less valuable when it does not ripen equally; and that barley which comes up speedily in a dusty soil, most gains a great advantage over feed-weeds. Therefore, first take out about one-third of the contents of the socks of feed barley or bear, to allow for the swelling of the grain. Lay the socks with the grain to steep in clean water; let it lie covered with it for at least 24 hours. When the ground is so dry as at present, and no likelihood of rain for 10 days, it is better to lie 36 hours. Sow the grain wet from steeping, without any addition of powdered quick-lime, which, though often recommended in print, can only poison the feed, suck up part of its useful moisture, and burn the hands of the lower. The feed will flavor better, as clean water has no tenacity; only the lower must put in a fourth or a third more feed in bulk than usual of dry grain, as the grain is swelled in that proportion: narrow it in as quickly as possible after it is sown; and though not necessary, give it the benefit of fresh furrow, if convenient. You may expect it up in a fortnight; at farthest.

The following experiment by a correspondent of the Bath society being considered as a very interesting one, is here subjoined.

"The last spring (1782) being remarkably dry, I foaked my feed-barley in the black water taken from a experimenter which constantly receives the drainage of my meadows on dung-heap and stables. As the light corn floated on the top, I skimmed it off, and let the rest stand 24 hours. On taking in the water, I mixed the feed grain with a sufficient quantity of filled wood-ashes, to make it sper regularly, and sowd three fields with it. I began sowing the 16th, and finished the 23rd of April. The produce was 60 bushels per acre, of good clean barley, without any small or green corn, or weeds at harvest. No person in this country had better grain. I sowed also several other fields with the same feed dry, and without any preparation; but the crop, like those of my neighbors, was very poor; not more than twenty bushels per acre, and much mixed with good corn and weeds when harvested. I followed one of the feed dry on one ridge in each of my former fields, but the produce was very poor in comparison of the other parts of the field."

Where the land is in good order, and free of weeds, April
April is the month for fowing barley. Every day is proper, from the first to the last.

The dressing of loamy soil and light soil for barley, is the same with that described; only that to plough dry soil is not altogether so essential as in dressing clay-soil. Loamy soil or clay may be firmer a little moister; better, however, delay a week or two, than to plough when moist. Clay must never be ploughed moist, even though the season should escape altogether. But this will seldom be necessary; for not in one year out of 20 will it happen, but that clay is dry enough for ploughing some time in May. Frost may correct clay ploughed wet after harvest; but ploughed wet in the spring, it unites into a hard mass, not to be broken by hard labour.

On the cultivation of this grain we have the following observations by a Norfolk farmer.

The best soil, he observes, is that which is dry and healthy, rather light than stiff, but yet of sufficient tenacity to retain the moisture. On this kind of land the grain is always the best bodied and coloured, the nimbler in the land, and has the thinnest rind. Those are qualities which recommend it most to the maltster. If the land is poor, it should be dry and warm; and when so, it will often bear better corn than richer land in a cold and wet situation.

In the choice of your seed, it is needful to observe, that the best is of a pale lively colour, and brightness, without any deep redness, or black tinge at the tail. If the rind be a little firrved, it is the better; for that slight firrving proves it to have a thin skin, and to have sweated in the mow. The necessity of a change of feed by not sowing two years together what grew on the same soil, is not in any part of husbandry more evident than in the culture of this grain, which, if not frequently changed, will grow coarser and less capable of resisting the force of winds, or supporting themselves under heavy rains.

From our great successes in setting and drilling clover, some of our farmers tried these methods with barley; but did not find it answer their expectations, except on very rich land.

I have myself had 80 flalks on one root of barley, which all produced good and long ears, and the grain was better than any other, but the method is too expensive for general practice. In poor land, low thin, or your crop will be worth little. Farmers who do not reason on the matter, will be of a different opinion; but the fact is indisputable.

When the barley is sowed and harrowed in, he advises that the land be rolled after the first shower of rain to break the clods. This will close the earth about the roots, which will be a great advantage to it in dry weather.

When the barley has been up three weeks or a month, it is a very good way to roll it again with a heavy roller, which will prevent the sun and air from penetrating the ground to the injury of the roots. This rolling, before it branches out, will also cause it to tiller into a great number of flalks; so that if the plants be thin, the ground will be thereby filled, and the flalks strengthened.

If the blade grows too rank, as it sometimes will in a warm wet spring, mowing is a much better method than feeding it down with sheep; because the slythe takes off only the rank tops, but the sheep being fond of the sweet end of the flalk next the root, will often bite it close as to injure the future growth.

4. BUCK-WHEAT.

The uses of this plant have been mentioned in the cultivation of preceding part, no. 46. It delights in a mellow sandy soil; but succeeds well in any dry loose healthy and moderately so in a free loamy stone braith. A stiff clay is its aversion, and it is entirely labour lost to sow it in a wet poachy ground. The proper season for sowing is from the last week of May or the beginning of June. It has been found, however, so early as the beginning of April, and so late as the 22d of July, by way of experiment; but the latter was rather extreme to be chosen, and the former was in danger from frost. In an experiment upon a small piece of ground, the grain of two different crops was brought to maturity in the summer 1787. After spring feedings, a crop of turnip-rooted cabbage, or vetches, there will be sufficient time to sow the land with buck-wheat. Probably, in dry summers, a crop of vetches might even be mown for hay early enough to introduce a crop of this grain after it.
Part II. AGRICULTURE.

Practice. on Brillington Common (a), having been first tolerably well cleansed from bramble, furze, &c. received one ploughing. To reduce the irregularities of the surface, it was rolled; and on the 9th of June in that year, two bullocks and a half of buck-wheat per acre were ploughed in the ground rolled again without harrowing.

The vegetation appeared in five or six days, as is constantly the case be the weather wet or dry. The growth was so rapid, that the form, with which this land greatly abounded, was completely kept under.

About the middle of September the crop was mown, but by reason of a great deal of rain that time, it was not secured until the beginning of October; hence a great deal of the grain by shedding, as well as some eaten by birds. However, there were saved about 24 Winchester bushels per acre; and, notwithstanding its long exposure to the weather, received no sort of damage, only perhaps that the fuel and molt perfect grain was the first to fall from the plant. The ground after this had almost the appearance of a fallow, and was immediately ploughed.

When it had lain a moderate time to mellowate, and to receive the influences of the atmosphere, it was harrowed, sown with Lammas wheat, and ploughed in under furrow, in a contrary direction to the first ploughing. Thus a piece of land, which in the month of April was altogether in a state of nature, in the following November was seen under a promising crop of what is well styled the king of grain, and this without the aid of manure, or of any very great degree of tillage. Nor was the harvest by any means deficient; for several persons concurring in such things estimated the produce from 26 to 30 bushels per acre. As soon as the wheat crop was taken off, the ground had one ploughing, and on the first of September following was sown with turnip-feed. The turnips were not large, but of an herbage so abundant as in the following spring to support 120 ewes with their lambs, which were fed on it by folding four weeks. After this it was manured with a composition of rotten dung and natural earth, about 20 peat loads per acre, and planted with potatoes. The crop failed for L.13.0, besides a considerable number used in the family; and a quantity referred with which ten acres were planted the following season. The ensuing autumn it was again sown both with wheat, and produced an excellent crop. In the spring of 1784, it was manured and planted with potatoes, as in the preceding instance; the crop (the tolerably good) by no means equal to the former, producing about 100 sacks per acre only. In spring 1785, the land was now for a third time under a crop of wheat; it being intended to try how far this mode of alternate cropping, one year with potatoes and another with wheat, might be carried.

From the result of the preceding and other experiments, by Nehemiah Bartley Esq. of Bridg, as detailed in the Bath Society Papers, it would seem, that the culture of this plant ought in many cases to be adopted instead of a summer-following: for the crop produced appears not only to be so much clear gain in respect to such practice, but also affords a considerable quantity of straw for fodder and manure; besides that a summer following is far from being so advantageous a preparation for a succeeding crop.

S. BEANS.

The proper fallow for beans is a deep and moift clay. There was lately introduced into Scotland a method of sowing beans with a drill-plough, and horse-hoeing the intervals; which, besides affording a good crop, is a dressing to the ground. But as that method is far from being general, we keep in the common track.

As this grain is early sown, the ground intended for it should be ploughed before winter, to give access to the root and air; beneficial in all soils, and necessary in a clay soil. Take the first opportunity after January when the ground is dry, to loosen the soil with the harrow first described, till a mould be brought up on it. Sow the feed, and cover it with the second harrow. The third will smooth the surface, and cover the feed equally. These harrows make the very best figure in sowing beans; which ought to be laid deep in the ground, not less than six inches. In clay soil, the common harrows are altogether insufficient. The mould, which has rested long after ploughing, is rendered compact and solid: the common harrows knit the surface: the feed is not covered: and the first hearty shower of rain lays it above ground. Where the farmer overtakes not the ploughing after harvest, and is reduced to plough immediately before sowing, the plough answers the purpose of the first harrow; and the other two will complete the work.

But the labour of the first harrow is ill faved; as the ploughing before winter is a fine preparation, not only for beans, but for grain of every kind. If the ground ploughed before winter happen to be of moisture to cake, the first harrow going along the ridges, and crossing them, will loosen the surface, and give access to the air for drying. As soon as the ground is dry, sow without delaying a moment. If rain happen in the interim, there is no remedy but patience till a dry day or two come.

Clay-clay, ploughed before winter, seldom fails to cake. Upon that account, a second ploughing is necessary before sowing: which ought to be performed with an ebb furrow, in order to keep the frood-mould as near the surface as possible. To cover the seed with the plough is expressed by the phrase to sow under furrow. The clods raised in this ploughing are a fort of shelter to the young plants in the chilly spring-months.

The foregoing method will answer for loam. And as for a sandy or gravelly foil, it is altogether improper for beans.

Though we cannot approve the horse-hoeing of beans, with the intervals that are commonly allotted for turnips, yet we would strongly recommend the drilling them at the distance of ten or 12 inches, and keeping the intervals clean of weeds. This may be done by hand-hoeing, taking opportunity at the same time to lay fresh foil to the roots of the plants. But as this is an expensive operation, and hands are not always to be got, a narrow plough, drawn by a single horse, might be used, with a mould-board on each side to scatter the earth

(a) A very rough piece of land, at that time just inclosed.
earth upon the roots of the plants. This is a cheap and expeditious method; it keeps the ground clean; and nourishes the plants with fresh foil.

As beans delight in a moist soil, and have no end of growing in a moist season, they cover the ground totally when sown broad cast, keep in the dew, and exclude the sun and air: the plants grow to a great height; but carry little feed, and that little not well ripened. This displays the advantage of drilling; which gives free access to the sun and air, dries the ground, and affords plenty of ripe feed.

6. Pease.

Pease are of two kinds; the white and the gray. The cultivation of the latter only belongs to this place. There are two species of the gray kind, distinguished by their time of ripening. One ripens soon, and for that reason is termed *hastfed*; the other, which is flower in ripening, is termed *cold feed*.

Pease, a leguminous crop, is proper to intervene between two culmiferous crops; i.e., for the profit of a peaef-crop, than for meliorating the ground. Pease, however, in a dry season, will produce fix or seven bolls each acre; but, in an ordinary season, they seldom reach above two, or two and a half. Hence, in a moist season, red clover feems a more beneficil crop than pease; as it makes as good winter food as pease, and can be cut green thrice during summer.

A field intended for cold feed ought to be ploughed in October or November; and in February, as soon as the ground is dry, the feed ought to be sown on the winter-furrow. A field intended for hot feed ought to be ploughed in March or April, immediately before sowing. But if infected with weeds, it ought to be also ploughed in October or November.

Pease laid a foot below the surface will vegetate; but the most approved depth is six inches in light soil, and four inches in clay soil; for which reason, they ought to be sown under furrow when ploughing is delayed till spring. Of all grain, beans excepted, they are the least in danger of being buried. Pease are sown from beans, loosing a dry soil and a dry feed. Horse-hoeing would be a great benefit, could it be performed to any advantage; but peas grow expeditiously, and soon fall over and cover the ground, which bars ploughing. Horse-hoeing has little effect when the plants are new sprung; and when they are advanced to be benefitted by that culture, their length prevents it. Fast growing at the same time is the case of their carrying too little feed; the feed is buried among the leaves; and the sun cannot penetrate to make it grow and ripen. The only practicable remedy to obtain grain, is thin sowing; but thick sowing produces more straw, and mellow the ground more. Half a ball for an English acre may be reckoned thin sowing; three fifths, thick sowing.

Notwithstanding what is said above, Mr Hunter, a noted farmer in Berwickshire, began some time ago to sow all his peas in drills; and never failed to have great crops of corn as well as straw. He sowed double rows at a foot interval, and two feet and an half between the double rows, which admit horse-hoeing. By that method, he had also good crops of beans on light land.

**Part II.**

Pease and beans mixed are often sown together, in order to catch different seasons. In a moist season, the beans make a good crop; in a dry season, the peas.

The growth of peas is commonly checked by drought in the month of July; but promoted by rain in August. In July, peas is parched; in August, it recovers verdure. Where peas are so far advanced in the dry season as that the feed begins to form, their growth is indeed checked, but the feed continues till sown. If only in the blossom at that season, their growth is checked a little; but they become vigorous again in August, and continue growing without filling till stoped by frost. Hence it is, that cold feed, which is early sown, has the best chance to produce corn; nor feed, which is late sown, has the best chance to produce straw.

The following method is practised in Norfolk, for sowing peas upon a dry light soil, immediately opened from furrow. The ground is pared with a plough extremely thin, and every furrow is laid exactly on its back. In every furrow a double row of holes is made. A pea dropt in every hole lodges in the slaty ground immediately below the seed, thrusts its roots horizontally, and has sufficient moisture. This method enabled Norfolk farmers, in the barren year 1740, to furnish white peas at 12s. per bushel.

II. Plants cultivated for Roots. [See also Art. III.]

1. Turnip.

**Turnip delights in a gravelly soil;** and there it can Culture of be raised to the greatest perfection, and with the least turnips, hazard of miscarrying. At the same time, there is no soil but will bear turnip when well prepared.

No peron ever deferred better of a country, than he who first cultivated turnips in the field. No plant is better fitted for the climate of Britain, no plant prospers better in the coldest part of it, and no plant contributes more to fertility. In a word, there has not for two centuries been introduced into Britain a more valuable improvement.

Of all roots, turnip requires the finest mould; and to that end, all harrows' bolls is the best. In order to give access to frost, the land ought to be prepared by ribbing after harvest, as above directed in preparing land for barley. If the field be not subject to annuals, it may lie in that state till the end of May; otherwise the weeds must be destroyed by a breaking about the middle of April; and again in May, if weeds rise. The first week of June, plough the field with a shallow furrow. Lime it if requisite, and harrow the lime into the soil. Draw single furrows with intervals of three feet, and lay dung in the furrows. Cover the dung sufficiently, by going round it with the plough, and forming the three-feet spaces into ridges. The dung comes thus to lie below the crown of every ridge.

The season of sowing must be regulated by the time of the season and intended for feeding. Where intended for feeding in method of November, December, January, and February, the sowing feed ought to be sown from the 1st to the 20th of June. Where the feeding is intended to be carried on to March, April, and May, the feed must not be sown till the end of July. Turnip sown earlier than above directed, flowers that very summer, and runs fast to seed; which renders it in a good measure unfit for food.
Part II.

AGRICULTURE.

Practice. Food. If sown much later, it does not apple, and there is no food but from the leaves.

Thy by a drill-plough the seed may be sown of any thickness, the safest way is to low thick. Thin sowing is liable to many accidents, which are far from being counter-balanced by the expense that is saved in thinning. Thick-sowing can bear the ravage of the black fly, and leave a sufficient crop behind. It is a protection against drought, gives the plants a rapid progress, and establishes them in the ground before it is necessary to thin them.

The sowing turnip broadcast is universal in England, and common in Scotland, though a barbarous practice. The eminent advantage of turnip is, that beside a profitable crop, it makes a most complete fallow; and the latter cannot be obtained but by horse-hoeing. Upon that account, the sowing turnip in rows at three feet distance is recommended. Wider rows answer no profitable end, straight rows afford not room for a horse to walk in. When the turnip is about four inches high, annual weeds will appear. Go round every interval with the slightest furrow possible, at the distance of two inches from each row, moving the earth from the rows toward the middle of the interval. A thin plate of iron must be fixed on the left side of the plough, to prevent the earth from falling back and burying the turnip. Next, let women be employed to weed the rows with their fingers; which is better, and cheaper done, than with the hand-hoe. The hand-hoe, besides, is apt to disturb the roots of the turnip that are to stand, and to leave them open to drought by removing the earth from them. The standing turnip are to be at the distance of twelve inches from each other; a greater distance makes them swell too much; a less distance affords them not sufficient room. A woman soon comes to be expert in finger-weeding. The following hint may be necessary to a learner. To secure the turnip that is to stand, let her cover it with the left hand; and with the right pull up the turnip on both sides. After thus freeing the standing turnip, the may safely use both hands. Let the field remain in this state until the appearance of new annuals make a second ploughing necessary; which must be in the same furrow with the former, but a little deeper. As in this ploughing the iron plate is to be removed, part of the looser earth will fall back on the roots of the plants: the rest will fill the middle of the interval, and bury every weed. When weeds begin again to appear, then is the time for a third ploughing in an opposite direction, which lays the earth to the roots of the plants. This ploughing may be about the middle of August; after which, weeds rise very faintly. If they do rise, another ploughing will clear the ground of them. Weeds that at this time rise in the row, may be cleared with a hand-hoe, which can do little mischief among plants distant twelve inches from each other. It is certain, however, that it may be done cheaper with the hand. (A) And after the leaves of turnips in a row meet together, the hand is the only instrument that can be applied for weeding.

In swampy ground, the surface of which is best reduced by paring and burning, the feed may be sown in rows with intervals of a foot. To save time, a drill-plough may be used that moves three or four rows at once. Hand-hoeing is proper for such ground; because the soil under the burnt \textit{firatum} is commonly full of roots, which digest and rot better under ground than when brought to the surface by the plough. In the mean time, while these are digesting, the alleys will secure a good crop.

In cultivating turnips to advantage, great care should be taken to procure good, bright, nimble, and well-dried feed, and of the best kinds.

The Norfolk farmers generally raise the oval white, the large green-topped, and the red or purple-topped kinds, which from long experience they have found to be the most profitable.

The roots of the green-topped will grow to a large size, and continue good much longer than others. The red or purple-topped will also grow large, and continue good to the beginning of February; but the roots become hard and stringy sooner than the former.

The green-topped growing more above ground, is of more danger of fulfilling injury from feverer frosts than the red or purple, which are more than half covered by the soil; but it is the ffootest and sweetest, when grown large, of any kind. We have seen them brought tolerable a foot in diameter, and equally good as garden turnips.

Turnips delight in a light soil, consisting of sand and loam mixed; for when the soil is rich and heavy, although the crop may be as great in weight, they will be rank, and run to flower earlier in spring. Turnip-feed, like that of grain, will not do well without frequent changing. The Norfolk feed is sent to most parts of the kingdom, and even to Ireland, but after two years it degenerates; so that those who wish to have turnips in perfection should procure it fresh every year from Norwich, and they will find their account in so doing. For from its known reputation, many of the London feedmen fell, under that character, feed raised in the vicinity of the metropolis, which is much inferior in quality.

When the plants have got five leaves, they should be hoed, and set out at least six inches apart. A month afterward, or earlier if it be a wet season, a second hoeing should take place, and the plants be left at least 14 inches distant from each other, especially if intended for feeding cattle; for where the plants are left thicker, they will be proportionably smaller, unless the land is very rich indeed.

Some of the best Norfolk farmers sow turnips in drills three feet asunder, and at a second hoeing leave them a foot apart in the rows. By this means the trouble and expense of hoeing is much lessened, and the crop of equal weight as when sown in the common method of sowing.
AGRICULTURE.

Part II.

first prejudiced against the practice) are now come into it, and find their account in so doing.

2. POTATOES.

The choice of soil is not of greater importance in any other plant than in a potato. This plant in clay soil, or in rank black loam lying low without ventilation, never makes palatable food. In a gravelly or sandy soil, exposed to the sun and to free air, it thrives to perfection, and has a good relish. But a rank black loam, though improper to raise potatoes for the table, produces them in great plenty; and the product is, as already observed, a palatable food for horned cattle, hogs, and poultry.

The spade is a proper instrument for raising a small quantity, or for preparing corners or other places inaccessible to the plough; but for raising potatoes in quantities, the plough is the only instrument.

As two great advantages of a drilled crop are, to destroy weeds, and to have a fallow at the same time with the crop, no judicious farmer will think of raising potatoes in any other way. In September or October, as soon as that year's crop is removed, let the field have a rolling furrow, a cross-breaking next, and then be cleared of weeds by the cleaning harrow. Form it into three-foot ridges, in that state to lie till April, which is the proper time for planting potatoes. Cross-brake it, to raise the furrows a little. Then the well-digested horse-dung along the furrows, upon which lay the roots at eight inches distance. Cover up the roots with the plough, going once round every row. This makes a warm bed for the potatoes; has dung below, and a loose covering above, that admits every ray of the sun. As soon as the plants appear above ground, go round every row a second time with the plough, which will lay upon the plants an additional inch or two of mould, and at the same time bury all the tops. This will complete the ploughing of the ridges. When the potatoes are six inches high, the plough, with the deepest furrow must go twice along the middle of each interval in opposite directions, laying earth first to one row, and next to the other. And to perform this work, a plough with a double mould-board will be more expeditious. But as the earth cannot be laid close to the roots by the plough, the spade must succeed, with which four inches of the plants must be covered, leaving little more but the tops above ground; and this operation will at the same time bury all the weeds that have sprung since the former ploughing. What weeds arise after must be pulled up with the hand. A hoe is never to be used here: it cannot go so deep as to destroy the weeds without cutting the fibres of the plants; and if it skim the surface, it only cuts off the heads of the weeds, and does not prevent their pushing again.

In the Bath Society Papers, we have the following particular practical observations on the culture and use of potatoes, given as the result of various experiments made for five years successively on that valuable root, the growth of which cannot be too much encouraged.

When the potatoe crop has been the only object in view, the following method is the most eligible.

The land being well pulverized by two or three good harrowings and ploughings, is then manured with 15 or 20 cart-loads of dung per acre, before it receives its
Part II.

Agriculture.

Practice. Left earth. Then it is thrown on to what the Suffolk farmers call the Trench-back, which is narrow and deep ridge-work, about 15 inches from the centre of one ridge to the centre of the other. Women and children drop the sets in the bottom of every furrow 15 inches apart; men follow, and cover them with large holes, a foot in width, pulling the mould down so as to bury the sets five inches deep; they must receive two or three hand-hoeings, and be kept free from weeds; always observing to draw the earth as much as possible to the stems of the young plants. By repeated trials, the first or second week in April is found the most advantageous time for planting.

In the end of September or the beginning of October, when the haulm becomes withered, they should be ploughed up with a strong double breasted-plough. The workman must be cautious to set his plough very deep, that he may strike below all the potatoes, to avoid damaging the crop. The women who pick them up, if not carefully attended to, will leave many in the ground, which will prove detrimental to any succeeding corn, whether wheat or barley. To avoid which inconvenience, let the land be harrowed, and turn the swine in to glean the few that may be left by their negligence.

By this method, the sets will be 15 square inches from each other; it will take 19 bushels to plant an acre; and the produce, if on a good mixed loamy soil, will amount to 300 bushels.

If the potatoes are grown as a preparation for wheat, it is preferable to have the rows two feet two inches from each other; hand-hoeing only the space from plant to plant in each row; then turning a small furrow from the inside of each row by a common light plough, and afterwards with a double-breasted plough with one horse, split the ridge formed by the first ploughing thoroughly to clean the intervals. This work should not be done too deep the first time, to avoid burying the tender plants; but the land should be ploughed as deep as possible; and the closer the mould is thrown to the stems of the plants, the more advantageous it will prove. Thus 15 bushels will plant an acre, and the produce will be about 300 bushels; but the land, by the summer ploughings, will be prepared to receive feed-wheat immediately, and almost ensure a plentiful crop.

The potato-sets should be cut a week before planting, with one or two eyes each, and the pieces not very small; two bushels of fresh soaked lime should be spread over the surface of the land as soon as planted, which will effectually prevent the attacks of the grub.

The expense attending an acre of potatoes well cultivated in the first method, supposing the rent 20 shillings, tithe and town charges rather high (as in Suffolk), taking up, and every thing included, will be about six pounds. In the last method, it would be somewhat reduced.

"When predilections for old customs are fostered (adds the author), I hope to see the potato admitted in the confiant course of crops by every spirited husbandman. The most beneficial effects will, I am certain, accrue from such a system. The advantages in my neighbourhood are apparent: I cultivated and fed my own children upon them, and my poorer neighbours feebly followed the example. A great proportion of every cottage's garden is now occupied by this root, and it forms a principal part of their diet. Potatoes are cheap and excellent substitutes for peas in soups and broths, allowing double the quantity.

"Although it is nearly a transcript of the directions given by a very ingenious author, yet shall take the liberty of inserting a receipt for making a potato-soup, which I have weekly distributed amongst the poor to their great relief.

A cheap preparation for the poor.

Ninety pints of water to be boiled with the above ingredients on a flow fire until reduced to 60, which require one peck of coals, value threepence. I have added the expense of every article according to their prices with me, that gentlemen may nearly perceive how cheap a rate they can feed 60 of their poor neighbours. I find from experience, a pint of this soup, with a small piece of the meat, is sufficient to satisfy a hearty working man with a good meal. If vegetables are plentiful, some of every sort may be added, with a few sweet herbs.

"I hope my inferring the above, will not be esteem'd improper, though somewhat deviating from the culture of potatoes, it may possibly be a means of rendering them more extensively useful."

A premium having been offered by the abovementioned Society for the cultivation of potatoes by farmers, &c. whose rent does not exceed 40l. per annum, the following methods were communicated, by which those who have only a small spot of ground may obtain a plentiful crop.

First, then, the earth should be dug 12 inches deep, if the soil will allow of it; after this, a hole should be cultivated open about six inches deep, horse-dung, or long litter should be put therein about three inches thick; this hole should not be more than 12 inches in diameter; upon this dung or litter, a potato should be planted whole, upon which a little more dung should be heaped, and then earth must be put thereon. In like manner the whole plot of ground must be planted, taking care that each potato be at least 16 inches apart; and when the young shoots make their appearance, they should have fresh mould drawn round them with a hoe; and if the tender shoots are covered, it will prevent the frost from injuring them; they should again be earthed when the shoots make a second appearance, but not be covered, as in all probability the season will then be less severe. A plentiful supply of mould should be given them, and the person who performs this business should never tread upon the plant, or the hillock that is raised round it; as the lighter the earth is, the more room the potato will have to expand. From a single root thus planted, very near 40 pounds weight of large potatoes were obtained, and from almost every other root upon the same plot of ground from 15 to 20 pounds weight; and except the soil be stony or gravelly, 10 pounds or half a peck of potatoes may almost always be obtained from each root, by pursuing
the foregoing method. But note, cuttings or small sets will not do for this purpose.

The second method will suit the indolent, or those who have not time to dig their ground, and that is, where weeds much abound and have not been cleared in the winter, a trench may be opened in a straight line the whole length of the ground, and about six inches deep; in this trench the potatoes should be planted about ten inches apart; cuttings or small potatoes will do for this method. When they are laid in the trench, the weeds that are on the surface may be pared off on each side about 10 inches from it, and be turned upon the plants; another trench should then be dug, and the mould that comes out of it turned carefully on the weeds. It must not be forgot, that each trench should be regularly dug, that the potatoes may be throughout the plot 10 or 12 inches from each other. This loveny method will in general raise more potatoes than can be produced by digging the ground twice, and dibbling in the plants; and the reason is, that the weeds light the foil, and give the roots room to expand. They should be twice hoed, and earthed up in rows. And here note, that if cut potatoes are to be planted, every cutting should have two eyes, for though fewer sets will be obtained, there will be a greater certainty of a crop, as one eye often fails or is destroyed by grubs in the earth.

Where a crop of potatoes fail in part (as will sometimes be the case in a dry season), a method may still be made by laying a little dung upon the knots of the straw or haulm of those potatoes that do appear, and covering them with mould; each knot or joint thus ordered will, if the weather prove wet afterwards, produce more potatoes than the original roots.

From the smallest potatoes planted whole, from four to six pounds at a root were obtained, and some of the single potatoes weighed near two pounds. These were dug in as before-mentioned, in trenches where the ground was covered with weeds, and the foil was a stiff loamy clay.

A good crop may be obtained by laying potatoes upon turf at about 12 or 14 inches apart, and upon beds of about six feet wide; on each side of which a trench should be opened about three feet, and the turf that comes from thence should be laid with the grassy side downward upon the potatoes; a spit of mould should next be taken from the trenches, and be spread over the turf; and in like manner the whole plot of ground that is designed to be planted must be treated. And remark, that when the young shoots appear, another spit of mould from the trenches should be fired over the beds so as to cover the shoots; this will prevent the frost from injuring them, encourage them to expand, and totally destroy the young weeds; and when the potatoes are taken up in the autumn, a careful person may turn the earth again into the trenches, so as to make the surface level; and it will be right to remark, that from the same ground a much better crop of potatoes may be obtained the following year.

For field planting, a good (if not the best) method is to dig the land, which should be once ploughed previous thereto; and when it is ploughed a second time, a careful person should drop the potato plants before the plough in every third furrow at about eight or ten inches apart. Plants that are cut with two eyes are best for this purpose. The reason for planting them at such a distance as every third furrow, is, that when the shoots appear, ahorse-hoe may go upon the two vacant furrows to keep them clean; and after they are thus hoed, they should be moulded up in ridges; and if this crop be taken up about October or November, the land will be in excellent condition to receive a crop of wheat. Lands that are full of twitch or couch-grass may be made clean by this method, as the horse-hoeing is as good as a summer-fallow: and if, when the potatoes are taken up, women and children were to pick out fitches, not any traces of it would remain; and by laying it on heaps and burning it, a quantity of ashes would be produced for manure.

After ploughing, none should ever dibble in potatoes, as the persons who dibble, plant, or hoe them, will all tread the ground; by which means it will become so bound, that the young fibres cannot expand, as has already been observed. Good crops have indeed been obtained by ploughing the land twice, and dropping the plants in every other furrow, and by hand-hoeing and earthing them up afterwards as the gardeners do peas; but this method is not equal to the other.

Vacant places in hedge-rows might be grubbed and planted with potatoes, and a good crop might be expected, as the leaves of trees, thorns, &c. are a good manure, and will most advantageously encourage their growth, and gratify the wishes of the planter; who by cultivating such places, will then make the most of his ground, and it will be in fine order to receive a crop of corn the following year.

**Account of the culture, expenses, and produce of six acres of potatoes, being a fair part of near 70 acres, raised by John Billing, Esq., and for which the premium was granted him in the year 1784.**

P 0
As potatoes are a comfortable food for the poor people, the field on which the above experiment was made, was an oat-bubble in the autumn of 1785. In October it was ploughed, and left in a rough state during the winter. In April it was cross-ploughed and harrowed. On the 8th of May the field was marked out into beds or ridges eight feet wide, leaving a space of two feet wide for an alley between every two ridges. The manure (a compost of stable dung, virgin earth, and scrapings of a turnpike road) was then brought on the land, and deposited in small heaps on the centre of each ridge, in the proportion of about 30 cart-loads to each acre. A trench was then opened with a spade breadth-way of the ridge; about four inches deep; in this trench the potato-sets were placed, at the distance of four inches from each other. The dung was then spread in a trench on the sets, and a space or slit of 14 inches in breadth, dug in upon them. When the plants were about six inches high, they were carefully hoed, and soon after the two feet intervals between the ridges were dug, and the contents thrown around the young plants. This refreshment, added to the ample manuring previously bestowed, produced such a luxuriance and rapidity of growth, that no weed could show its head.

The shortest and most certain method of taking up potatoes, is to plough once round every row at the distance of four inches, removing the earth from the plants, and gathering up with the hand all the potatoes that appear. The distance is made four inches, to prevent cutting the roots, which are seldom found above that distance from the row on each side. When the ground is thus cleared by the plough, raise the potatoes with a fork having three broad toes or claws; which is better than a spade, as it does not cut the potatoes. The potatoes thus laid above ground must be gathered with the hand. By this method scarce a potato will be left.

Bett method of taking them up.

Of preferring them.

Potatoes are a comfortable food for the poor people, it is of importance to have them all the year round. For a long time, potatoes in Scotland were confined to the kitchen-garden; and after they were planted in the field, it was not imagined at first that they could be used after the month of December. In late years they have been found to answer even till April, which has proved a great support to many a poor family, as they are easily cooked, and require neither kiln nor mill. But there is no cause for stopping there. It is easy to preserve them till the next crop: When taken out of the ground, lay in the corner of a barn a quantity that may serve till April, covered from frost with dry straw presed down: bury the remainder in a hole dug in dry ground, mixed with the husks of dried oats, rye, or the dry leaves of trees, over which build a stack of hay or corn. When the pit is opened for taking out the potatoes, the eyes of what have a tendency to push must be cut out; and this cargo will serve all the month of June. To be fill more certain of making the old crop meet the new, the setting of a small quantity may be delayed till June, to be taken up at the ordinary time before frost. This cargo, having not arrived to full growth, will not be so ready to push as what are set in April.

If the old crop happen before the new crop is ready, the interval may be supplied by the potatoes of the new crop that lie next the surface, to be picked up with the hand; which, far from hurting the crop, will rather improve it.

3. Carrot and Parsnip.

Of all roots, a carrot requires the deepest soil. It Culture of carrot.

The ground must be prepared by the deepest furrow that can be taken, the sooner after harvest the better; immediately upon the back of which, a ribbing ought to succeed, as directed for barley. At the end of March, or beginning of April, which is the time for fowing the seed, the ground must be smoothed with a rake. sow the seed in drills, with intervals of a foot for hand-hoeing; which is an expensive operation where the crop is confined to an acre or two; but if the quantity of ground be greater, the intervals ought to be three feet, in order for horse-hoeing.

In flat ground without ridges, it may be proper to make parallel furrows with the plough; ten feet from each other, in order to carry off any redundant moisture.

At Parlington in Yorkshire, from the end of September to the first of May, 23 work-horses, four bullocks, and six milk-cows, were fed on the carrots that grew on three acres; and these animals never tasted any other food but a little hay. The milk was excellent; and, over and above, 50 hogs were fattened upon what was left by the other beasts. We have this fact from unoubted authority.

The culture of parsnips is the same with that of parsnips.

III. Plants cultivated for Leaves, or for both Leaves and Root.

There are many garden-plants of these kinds. The plants proper for the field are cabbage, red and white colewort plain and curled, turnip-rooted cabbage, and the root of scurd, or red cabbage.

Cabbage is an interesting article of husbandry. It is easily raised, is subject to few diseases, refits frost more than turnip, is palatable to cattle, and sooner fills them than turnip, carrot, or potatoes.

The season for setting cabbage depends on the use Culture of it is intended for. If intended for feeding in November, December, and January, plants procured from feed down the end of July the preceding year must be set in March or April. If intended for feeding in March, April, and May, the plants must be set the first week.
Agriculture.

Practice.

Part II.

Week of the preceding July, from seed sown in the end of February or beginning of March the same year. The late setting of the plants retards their growth; by which means they have a vigorous growth the following spring. And this crop makes an important link in the chain that connects winter and summer green food. Where cabbage for spring-food happens to be supplied the want. After the rye is consumed, there is time sufficient to prepare the ground for turnips.

And now to prepare a field for cabbage. Where the plants are to be set in March, the field must be made up after harvest, in ridges three feet wide. In that form let it lie all winter, to be mellowed with air and frost. In March, take the first opportunity, between wet and dry, to lay dung in the furrows. Cover the dung with a plough, which will convert the furrow into a crown, and consequently the crown into a furrow.

Set the plants upon the dung, distant from each other three feet. Plant them so as to make a straight line across the ridges, as well as along the furrows, to which a gardener's line (stretched perpendicularly across the furrows will be requisite. This will set each plant at the distance precisely of three feet from the plants that surround it. The purpose of this accuracy is to give opportunity for ploughing, not only along the ridges, but across them. This mode is attended with three signal advantages: it saves hand-hoeing, it is a more complete dressing to the soil, and it lays earth nearly round every plant.

If the soil be deep and composed of good earth, a trench ploughing after the preceding crop will not be amiss; in which case, the time for dividing the field into three-feet ridges, as above, ought to be immediately before the dunging for the plants.

If weeds happen to rise so close to the plants as not to be reached by the plough, it will require very little labour to destroy them with a hand-hoe.

Unless the soil be much infested with annuals, twice ploughing after the plants are set will be a sufficient dressing. The first removes the earth from the plants; the next, at the distance of a month or so, lays it back. Where the plants are to be set in July, the field must be ribbed as directed for barley. It ought to have a flight ploughing in June before the planting, in order to loosen the soil, but not so as to bury the surface-earth; after which the three-feet ridges must be formed, and the other particulars carried all as above with this soil. Which a gardener's line must be ribbed as to make a straight line, and three feet as well as along the furrows, to which a gardener's line (stretched perpendicularly across the furrows must be requisite. This will set each plant at the distance precisely of three feet from the plants that surround it. The purpose of this accuracy is to give opportunity for ploughing, not only along the ridges, but across them. This mode is attended with three signal advantages: it saves hand-hoeing, it is a more complete dressing to the soil, and it lays earth nearly round every plant.

2. As to the turnip-rooted cabbages, their importance and value seem only to have been lately ascertained. In the Bath Society Papers we have the following account of Sir Thomas Beevor's method of cultivating them; which from experience he found to be cheaper and better than any other.

"In the first or second week of June, I sow the same quantity of seed, hoe the plants at the same size, leave them at the same distance from each other, and treat them in all respects like the common turnip. In this method I have always obtained a plentiful crop of them; to ascertain the value of which I need only inform you, that on the 23rd day of April last, having two acres left of my crop, found, and in great perfection, I divided them by fold hurdles into three parts of nearly equal dimensions. Into the first part I put 24 small bullocks of about 30 stone weight each (140 to the stone), and 30 middle-sized fat wethers, which, at the end of the fifth week, after they had ty and va­

eaten down the greater part of the leaves, and some part of the roots, I shifted into the second division, and then put 70 lean sheep into what was left of the first; these fed off the remainder of the turnips left by the fat stock, and so they were shifted through the three divisions, the lean flock following the fat as they wanted food, until the whole was consumed.

"The 24 bullocks and 30 fat wethers continued in the turnips until the 21st of May, being exactly four weeks; and the 70 lean sheep until the 29th, which is one day over four weeks; so that the two acres kept my 24 small bullocks and 110 sheep four weeks (not reckoning the overplus day of keeping the lean sheep); the value, at the rate of keeping at that feast, cannot be ascertained in any common year at left that 44. a week for each sheep, and 15. 6d. per week for each bullock, which would amount together to the sum of £ 14: 10: 8: for the two acres.

"You will hardly, I conceive, think I have set the price of keeping the stock at two high a rate; it is beneath the price here in almost every spring, and in this lat it would have cost double, could it have been procured; which was so far from being the case, that hundreds of sheep and lambs were sent, and the rest greatly pinch'd for want of food.

"You will observe, gentlemen, that in the valuation of the crop abovementioned I have claimed no allowance for the great benefit the farmer receives by being enabled to suffer his grass to get into a forward growth, nor for the superior quality of these turnips in fattening his stock; both which circumstances must stamp new and a great additional value upon them. But as their continuance on the land may seem to be injurious to the succeeding crop, and indeed will deprive the farmer totally of either oats or barley; so to supply that loss I have always sown buck-wheat on the land from which the turnips were left by the fat stock; and so I shifted, I sowed my clover or other grass seeds with the buck-wheat, in the same manner as with the oat or barley crops.

"Thus you see, that in providing a most incomparable vegetable food for cattle, in that season of the year in which the farmer is generally most in diftress, and his cattle almost starved, a considerable profit may be obtained, much beyond what is usually derived from his former practice, by the great produce and price of a crop raised at so easy an expense as that of buckwheat, which, with us, sells commonly at the same price as barley, and on times more, and but very rarely for less.

"The land on which I have usually sown turnip-rooted cabbages is a dry mixed soil, worth 15s. per acre.

To the preceding account the Society have subjoined the following note: "Whether we regard the importance
Agriculture.

Practise.

Recommendation by the Bath Agricultural Society. To raise the land intended for the plantation of the root of turnip, it may be necessary to judge as much old manure as may be necessary for the feed-bed, as the roots are thick with plants which are sufficient to plant an acre. The land should be dug as shallow as possible, turning the ashes in, and the seed should be sown in the beginning of April.

The land intended for the plantation to be cultivated and dugged as for the common turnip. About Midsummer (or sooner if the weather will permit) will be a proper time for planting, which is best done in the following manner: the land to be broken into one boat ridges, upon the tops of which the seed are to be set, at about 18 inches distance from each other. As soon as the weeds rise, give a hand-hoeing, afterwards run the ploughs in the intervals, and fetch a furrow from each ridge, which, after laying a fortnight or three weeks, is again thrown back to the ridges; if the weeds rise again, it is necessary to give them another hand-hoeing. If the young plants in the seed-bed should be attacked by the fly, few wood ashes over them when the dew is on, which will effectually prevent the ravages they would otherwise make.

To raise the turnip-rooted cabbage for transplanting, the best method yet discovered is, to breast-plough and burn as much old manure as may be judged necessary for the feed-bed, two perches well finkèd with plants which are sufficient to plant an acre. The land should be dug as shallow as possible, turning the ashes in, and the seed should be sown in the beginning of April.

The land intended for the plantation to be cultivated and dugged as for the common turnip. About Midsummer (or sooner if the weather will permit) will be a proper time for planting, which is best done in the following manner: the land to be broken into one boat ridges, upon the tops of which the plants are to be set, at about 18 inches distance from each other. As soon as the weeds rise, give a hand-hoeing, afterwards run the ploughs in the intervals, and fetch a furrow from each ridge, which, after laying a fortnight or three weeks, is again thrown back to the ridges; if the weeds rise again, it is necessary to give them another hand-hoeing. If the young plants in the seed-bed should be attacked by the fly, few wood ashes over them when the dew is on, which will effectually prevent the ravages they would otherwise make.

The culture of the root of scarcity. The racion de deficit, or root of scarcity, (Beta cicla) delights in a rich loamy land well dugged. It is directed to be sown in rows, or broad-cast, and as soon as the plants are of the size of a goose-quill, to be transplanted in rows of 18 inches distance, and 18 inches a part, one plant from the other: care must be taken in the sowing, to sow very thin, and to cover the seed, which lays in the ground about a month, an inch only. In transplanting, the root is not to be shortened, but the leaves cut at the top; the plant is then to be planted with a setting tick, so that the upper part of the root shall appear about half an inch out of the ground; this last precaution is very necessary to be attended to. These plants will strike root in twenty-four hours, and a man a little accustomed to planting, will plant with ease 1800 or 2000 a-day. In the feed-bed, the plants, like all others must be kept clear of weeds: when they are planted out, after once hoeing, they will take care of themselves, and succour every kind of weed near them.

The best time to sow the feed is from the beginning of March to the middle of April: it is, however, advised to continue sowing every month until the beginning of July, in order to have a succession of plants. Both leaves and roots have been extolled as excellent both for man and beast. This plant is said not to be liable, like the turnip, to be destroyed by insects, for no insect touches it, nor is it affected by excessive drought, or the changes of seasons. Horned cattle, horses, pigs, and poultry, are exceedingly fond of it when cut small. The leaves may be gathered every 12 or 15 days; they are from 20 to 40 inches long, by 22 to 25 inches broad. This plant is excellent for milch cows, when given to them in proper proportions, as it adds much to the quality as well as quantity of their milk; but care must be taken to proportion the leaves with other green food, as otherwise it would adore the milk, and fatten them too much, it being of so exceeding fattening a quality. To put all these properties beyond doubt, however, further experiments are wanting.

 Sect. IV. Culture of Grasses. The latter end of August, or the beginning of September, is the best season for sowing grass-feeds, as down fields are cleared away on the roots of the young grass to fix them. If you would have fine pasture, never sow on foul ground. On the contrary, plough it well, and clear it from the roots of couch-grass, reed-harrow, fern, broom, and all other noxious weeds. If you are suffered to remain, you will soon get above, and destroy your young grass. Rake thech us in heaps, and burn them on the land, and spread the ashes as a manure. These ploughings and harrowings should be repeated in dry weather. And if the soil be clayey and wet, make some under-drains to carry off the water, which, if suffered to remain, will not only chill the grass, but make it four. Before sowing, lay the land as level and fine as possible. If your grass-feeds are clean, (which should always be the case) three bushels will be sufficient per acre. When sown, harrow it in gently, and roll it in with a wooden roller. When it comes up, fill up all the bare spots by fresh feed, which, if rolled to fix it, will soon come up, and overtake the rest.

In Norfolk they sow clover with their grasses, particularly with rye grass; but this should not be done except when the land is designed for grass only three or four years, because neither of these kinds will last long in the land. Where you intend it for a continuance, it is better to mix only small white Dutch clover, or marle grass, with your other grass feed, and not more than eight pounds to an acre. These are abiding plants, spread clofe on the surface, and make the sweetest feed of any for cattle. In the following spring, root up thistles, hemlock, or any large plants that appear. This is the best and easiest method of proceeding in laying down fields to grass is extremely injudicious. Some few barley with their grasses, which they suppose to be useful in finding them, without considering how much the corn draws away the nourishment from the land.

Others take their feeds from a four hay-ridge; by different kinds of which means, besides filling the land with rubbish and weeds, what they intend for dry foils may have come grasses from moif, where it grew naturally, and vice versa. The conclusion is, that the ground, instead of being covered with a thick sward, is filled with plants unnatural to it. The kinds of grass most eligible for pasture lands are, the annual-meadow, creeping, and fine bent, the fox-tails, and cobby dog's-tail, the poa, the fescues, the vernal, orch-grasses.
AGRICULTURE.

Part II.

The proper season for fowing red clover, is from the middle of April to the middle of May. It will spring from the first of March to the end of August; but such liberty ought not to be taken except from necessity.

There cannot be a greater blunder in husbandry, than to be sparing of feed. Ideal writers talk of fowing an acre with four pounds. That quantity of feed, say they, will fill an acre with plants as thick as they ought to stand. This rule may be admitted where grain is the object; but it will not answer with respect to grass. Grass-feed cannot be fown too thick: the plants shelter one another; they retain all the dew; and they must push upwards, having no room laterally. Observe the place where a check of pease, or of other grain, has been set down for fowing: the seed drop there accidentally grows more quickly than in the rest of the field fown thin out of hand. A young plant of clover, or of fain-foin, according to Tull, may be raised to a great size where it has room; but the field will not produce half the quantity. When red clover is fown for cutting green, there ought not to be less than 24 pounds to an acre. A field of clover is seldom too thick; the smaller a stem be, the more acceptable it is to cattle. It is often too thin; and when fo, the stems tend to wood.

Red clover is commonly sown with grain; and the most proper grain has been found by experience to be clover with flax. The foil must be highly cultivated for flax as well as for red clover. The proper season for fowing is the same for both; the leaves of flax being very small, admit of free circulation of air; and flax being an early crop, is removed so early as to give the clover time for growing. In a rich soil it has grown to fall, as to afford a good cutting that very year. Next to flax, barley is the best companion to clover. The foil must be loose and free for barley; and so it ought to be for clover: the season of fowing is the same; and the clover is well established in the ground, before it is overtopped by the barley. At the same time, barley commonly is sooner cut than either oats or wheat. In a word, barley is rather a nurse than a stepmother to clover during its infancy. When clover is fown in spring upon wheat, the foil, which has lain five or six months without being stirred, is an improper bed for it; and the wheat, being in the vigour of growth, overtops it from the beginning. It cannot be fown along with oats, because of the hazard of frost; and when fown as usual among the oats three inches high, it is over-topped, and never enjoys free air till the oats be cut. Add, that where oats are sown upon the winter furrow, the foil is rendered as hard as when under wheat.—Red clover is sometimes sown by itself without other grain: but this method, beside losing a crop, is not salutary; because clover in its infant state requires shelter.

As to the quantity of grain proper to be sown with clover: In a rich foil well pulverized, a peck of barley on an English acre is all that ought to be ventured. Two Linlithgow firlets make the proper quantity for an acre that produces commonly 30 bushels of barley, half a firlet for what produces nine bolls. To those who are governed by custom, so small a quantity will be thought ridiculous. Let them only consider, that a rich ffoil in perfect good order, will with a single feed of

grafs, and the ray, or rye-grafs. We do not, however, approve of fowing all these kinds together; for not to mention their ripening at different times, by which means you can never cut them all in perfection and full vigour, no kind of cattle are fond of all a-like.

Horses will scarcely eat hay which oxen and cows will thrive upon; sheep are particularly fond of some kinds, and refuse others. The Darnel-grafs, if not cut before several of the other kinds are ripe, becomes so hard and wiry in the flanks, that few cattle care to eat it.

Such gentlemen as with a particular account of the abovementioned grasses, will be amply gratified in consulting Mr. Stillingsfeet on this subject. He has treated it with great judgment and accuracy, and those who follow his directions in the choice of their grasses will be under no small obligation to him for the valuable information he has given them. The substance of his observations are given in the article Grasses in this Dictionary.

The grasses commonly fown for pasture, for hay, or to cut green for cattle, are red clover, white clover, yellow clover, rye-grafs, narrow-leaved plantain commonly called ribwort, fain foin, and lucerne.

Red clover is of all the most proper to be cut green for summer-food. It is a biennial plant when fuffered to perfect its seed; but when cut green, it will last three years, and in a dry foil longer. At the same time the safest course is to let it stand but a single year: if the second year's crop happen to be scanty, it proves, like a bad crop of pease, a great encourager of weeds by the shelter it affords them.

Here, as in all other crops, the goodness of feed is of importance. Choose plump feed of a purple colour, because it takes on that colour when ripe. It is red when hurt in the drying, and of a faint colour when ripe.

Red clover is luxuriant upon a rich foil, whether clay, loam, or gravel; it will grow even upon a moor, when properly cultivated. A wet foil is its only bane; for there it does not thrive.

To have red clover in perfection, weeds must be extirpated, and stones taken off. The mould ought to be made as fine as harrowing can make it; and the surface be smoothed with a light roller, if not sufficiently smooth without it. This gives opportunity for distributing the feed evenly, which must be covered by a small harrow with teeth no larger than that of a garden rake, three inches long, and six inches asunder. In harrowing, the man should walk behind with a rope in his hand fixed to the back part of the harrow, ready to difentangle it from stones, clods, turnip or cabbagereeds, which would trail the feed, and displace it.

Nature has not determined any precise depth for the feed of red clover more than for other feed. It will grow vigorously from two inches deep, and it will grow when barely covered. Half an inch may be reckoned the most advantageous position in clay soil, a whole inch in what is light or loofe. It is a vulgar error, that small feed ought to be sparingly covered. Milled by the error, farmers commonly cover their clover-fed with a bulky branch of thorn; which not only covers it unequally, but leaves part on the surface to wither in the air.

Plate V. fig. 7.

Of red clover.
Part II. AGRICULTURE.

White and yellow clover, ribwort, rye-grass, of barley produce 20 or 30 vigorous stems. People may litter themselves with the remedy of cutting barley green for feed, if it happens to oppress the clover. This is an excellent remedy in a field of an acre or two; but the cutting an extensive field for food must be slow; and while one part is cutting, the clover is smothered in other parts.

The culture of white clover, of yellow clover, of ribwort, of rye-grass, is the fame in general with that of red clover. We proceed to their peculiarities. Yellow clover, ribwort, rye-grass, are all of them early plants, blooming in the end of April or beginning of May. The two latter are evergreens, and therefore excellent for winter pasture. Rye-grass is left by frost than any of the clovers, and will thrive in a moist soil: nor in that soil is it much affected by drought. In a rich soil, it grows four feet high; even in the dry summer 1775; it rose to three feet eight inches; but it had gained that height before the drought came on. These grasses are generally fown with red clover for producing a plentiful crop. The proportion of feed is arbitrary; and there is little danger of too much. When rye-grass is fown for procuring feed, five firlots wheat-measure may be fown on an acre; and for procuring feed of ribwort, 40 pounds may be fown.

The roots of rye-grass spread horizontally: they bind the foil by their number; and the small, are yet vigorous as to thrive in hard soil. Red clover has a large tap-root, which cannot penetrate any foil but what is open and free; and the largeness of the root makes the foil fill more open and free. Rye-grass, once a great favourite, appears to be discarded in most parts of Britain. The common practice has been, to sow it with red clover, and to cut them promiscuously the beginning of June for green feed, and a little later for hay. This indeed is the proper season for cutting red clover, because at that time it begins to flower; but as at that time the feed of the rye-grass is approaching to maturity, its growth is stopped for that year, as much as of oats or barley cut after the feed is ripe. Oats or barley cut green before the feed forms, will afford two other feedings, as to thrive in hard soil. Red clover has a large tap-root, which cannot penetrate any soil but what is open and free; and the largeness of the root makes the soil fill more open and free. Rye-grass, once a great favourite, appears to be discarded in most parts of Britain. The common practice has been, to sow it with red clover, and to cut them promiscuously the beginning of June for green feed, and a little later for hay. This indeed is the proper season for cutting red clover, because at that time it begins to flower; but as at that time the feed of the rye-grass is approaching to maturity, its growth is stopped for that year, as much as of oats or barley cut after the feed is ripe. Oats or barley cut green before the feed forms, will afford two other cuttings; which is the cafe of rye-grass, of yellow clover and of ribwort. By such management, all the profit will be drawn that these plants can afford.

When red clover is intended for feed, the ground ought to be cleared of weeds, were it for no other purpose than that the feed cannot other wise be preferred pure: what feeds escape the plough ought to be taken out by the hand. In England, when a crop of feed is intended, the clover is always first cut for hay. This appears to be done, as in fruit-trees, to check the growth of the wood, in order to encourage the fruit. This practice will not answer in Scotland, as the feed would often be too late for ripening. It would do better to eat the clover with sheep till the middle of May, which would allow the feed to ripen. The feed is ripe when, upon rubbing it between the hands, it parts readily from the husk. Then apply the feth, spread the crop thin, and turn it carefully. When perfectly dry, take the first opportunity of a hot day for threshing it on boards covered with a coarse sheet. Another way is subject to risk, is to stack the dry hay, and to thresh it in the end of April. After the first threshing, expose the husks to the sun, and thresh them over and over till no feed remain. Nothing is more efficacious than a hot sun to make the hulks part with its feed; in which view it may be expected to the feed by parcels, an hour or two before the stack is applied.

White clover intended for feed, is managed in the same manner. No plant ought to be mixed with rye-grass that is intended for feed. In Scotland, much rye-grass feed is hurt by transplanting that rule. The feed is ripe when parts easily with the husks. The yellow roots of the stem is an her indication of its ripeness; in which particular it resembles oats, barley, and other culmiferous plants. The best manner to manage a crop of rye-grass for feed, is to bind it loosely in small sheaves, widening them at the bottom to make them stand erect; as is done with oats in moist weather. In that state they may stand till sufficiently dry for threshing. By this method they dry more quickly, and are less hurt by rain, than by close binding and putting the sheaves in chocks like corn. The worst way of all is to spread the rye-grass on the moist ground, for it makes the feed malten. The sheaves, when sufficiently dry, are carried in close carts to where they are to be threshed on a board, as mentioned above for clover. Put the straw into a rick when a hundred stone or more are threshed. Carry the threshing-board to the place where another rick is intended; and let on till the whole feed be threshed, and the straw ricked. There is necessity for close carts to save the feed, which is apt to drop out in a hot sun; and, as observed above a hot sun ought always to be chosen for threshing. Carry the feed in sacks to the granary or barn, there to be separated from the husks by a fanner. Spread the feed thin upon a timber-floor, and turn it once or twice a day till perfectly dry. If suffered to take a heat, it is useless for feed.

The writers on agriculture reckon fainfoin preferable to clover in many respects: They say, that it produces a larger crop; that it does not hurt cattle when eaten green; that it makes better hay; that it continues four times longer in the ground; and that it will grow on land that will bear no other crop. Sainfoin has a very long tap-root, which is able to pierce very hard earth. The roots grow very large; and the larger they are, they penetrate to the greater depth; and hence it may be concluded, that this grass, when it grows well, receives a great part of its nourishment from below the scape of the foil: of course, a deep dry soil is best for the culture of fainfoin. When plants draw their nourishment from that part of the soil that is near the surface, it is not of much consequence whether their number be great or small. But the case is very different when the plants receive their food not only near, but also deep below, the surface. Besides, plants that shoot their roots deep are often supplied with moisture, when those near the surface are parched with drought.

To render the plants of fainfoin vigorous, it is necessary that they be sown thin. The best method of doing this is by a drill; because, when sown in this manner, not only the weeds, but also the supernumerary plants, can easily be removed. It is several years before fainfoin comes to its fullest strength; and the number of plants sufficient to flock a field, while in this imperfect rate, will make but a poor crop for the first year or two. It is therefore necessary that it be sown in such a manner as to make it easy to take up plants...
in such numbers, and in such order, as always to leave in the field the proper number in their proper places. This can only be done, with propriety, by fowing the plants in rows by a drill. Supposing a field to be drilled in rows at ten inches distance, the partitions may be hand-hoed, and the rows dressed in such a manner as to leave a proper number of plants. In this situation the field may remain two years; then one-fourth of the rows may be taken out in pairs, in such a manner as to make the beds of fifty inches, with six rows in each, and intervals of thirty inches, which may be ploughed. Next year, another fourth of the rows should be hand-hoed, and the rows drilled in such a manner as to make the beds of fifty inches, with six rows in each, and intervals of thirty inches. All of which may be hoed at once or alternately, as it may be found most convenient.

The great quantity of this grass which the writer on this subject assures us may be raised upon an acre, and the excellence and great value of the hay made of it, should induce farmers to make a complete trial of it, and even to use the spade in place of the hoe, or hoe-plough, if necessary.

The plants taken up from up a field of sainfoin may be set in another field; and if the transplanting of this grass succeeds as well as the transplanting of lucerne has done with Mr. Lunin de Chateauvieux, the trouble and expense will be sufficiently recompensed by the largeness of the crops. In transplanting, it is necessary to cut off great part of the long tap-root; this will prevent it from striking very deep into the soil, and make it pull out large roots in a sloping direction from the cut end of the tap-root. Sainfoin managed in this manner, will thrive even on shallow land that has a wet bottom, provided it be not overstocked with plants.

Whoever inclines to try the culture of this grass should take great pains in preparing the land, and making it as free from weeds as possible.

In England, as the roots strike deep in that chalky soil, this plant is not liable to be so much injured by drought as other grasses are, whose fibres lie horizontally, and lie near the surface. The quantity of hay produced is greater and better in quality than any other. But there is one advantage attending this grass, which renders it superior to any other; and that arises from feeding with it. The prodigious increase of milk which it makes is astonishing, being nearly double that produced by any other green food. The milk is also better, and yields more cream than any other; and the butter procured from it is better coloured and flavoured.

The following remarks by an English farmer are made from much experience and observation.

Sainfoin is much cultivated in those parts where the soil is of a chalky kind. It will always succeed well where the roots run deep; the white soil of all for it is where there is a bed of cold wet clay, which the render fibres cannot penetrate. This plant will make a greater increase of produce, by at least 50 times, than common grass or turf upon poor land. Where it meets with chalk or stone, it will extend its roots through the cracks and chinks to a very great depth in search of nourishment. The dryness of more consequence than the richness of land for sainfoin; although land that is both dry and rich will always produce the largest crops.

It is very commonly sowed broadcast; but it is found to answer best in drills, especially if the land be made fine by repeatedly ploughing, rolling, and harrowing. Much depends on the depth which this grass is sown. If it be sown more than an inch deep, it will fail to grow; and if it be sown shallow, it will pull out its roots above ground, and there will be killed by the air. March and the beginning of April are the best seasons for sowing it, as the severity of winter and the drought of summer are equally unfavourable to the young plants. A bushel of seed sown broadcast, or half that quantity in drills, if good, is sufficient for an acre. The drills should be 30 inches apart, to admit of horse-hoeing between them. Much, however, depends on the goodness of the seed, which may be best judged of by the following marks.

The hulk being of a bright colour, the kernel plump, of a grey or bluish colour without, and, if cut across, greenish and fresh within; if it be thin and floury, and of a yellowish cast, it will seldom grow. When the plants stand single, and have room to spread, they produce the greatest quantity of pasture, and the feed ripens best. But farmers in general, from a mistaken notion of all that appears to be waste ground being unprofitable, plant them close, that they choke and impoverish each other, and often die in a few years. Single plants will often produce half a pound of hay, when dry. On rich land this plant will yield two good crops in a year, with a moderate share of culture. A good crop must not be expected the first year; but, if the plants stand not too thick, they will increase in size the second year prodigiously.

No cattle should be turned on the field the first winter after the corn is off with which it is sown, as their feet would injure the young plants. Sheep should not come on the following summer, because they would bite off the crown of the plants, and prevent their blooming again. A small quantity of foapers sashes as a top-dressing will be of great service, if laid on the first winter.

If the sainfoin be cut just before it comes into bloom, it is admirable food for horned cattle; and if cut thus early, it will yield a second crop the same season. But if it proves a wet season, it is better to let it stand till its bloom be perfect; for great care must be taken, in making it into hay, that the flowers do not drop off, as cows are very fond of them; and it requires more time than other hay in drying. Sainfoin is so excellent a fodder for horses, that they require no oats while they eat it, although they be worked hard all the time. Sheep will also be fattened with it faster than with any other food.

If the whole season for cutting proves very rainy, it is better to let the crop stand for feed, as that will amply repay the loss of the hay; because it will not only fetch a good price, but a peck of it will go as far as a peck and a half of oats for horses.

The best time of cutting the seeded sainfoin is when the greatest part of the seed is well filled, the first
Part II.  

AGRICULTURE.  

Practice.  

blown ripe, and the last blown beginning to open. For want of this care some people have lost most of their feed by letting it stand too ripe. Seeded fainfoin should always be cut in a morning or evening, when the dew renders the stalks tender. If cut when the sun shines hot, much of the feed will fall out and be lost.

An acre of very ordinary land, when improved by this grass, will maintain four cows very well from the first of April to the end of November; and afford, besides, a sufficient store of hay to make the greater part of their feed the four months following.

If the soil be tolerably good, a field of fainfoin will last from 15 to 20 years in prime; but at the end of seven or eight years, it will be necessary to lay on a moderate coat of well-rotted dung; or, if the soil be very light and sandy, of marle. By this means the future crops, and the duration of the plants in health and vigour, will be greatly increased and prolonged. Hence it will appear, that for poor land there is nothing equal to this grass in point of advantage to the farmer.

Clover will last only two years in perfection; and often, if the soil be cold and moist, near half the plants will rot, and bald patches be found in every part of the field the second year. Besides, from our frequent rains during the month of September, many crops left for feeding are lost. But from the quantity and excellent quality of this grass (fainfoin), and its ripening earlier, and continuing in vigour so much longer, much rick and certain expense is avoided, and a large annual profit accrues to the farmer.

The writers on agriculture, ancient as well as modern, below the highest encomiums upon lucerne as affording excellent hay, and producing very large crops. Lucerne remains at least 10 or 12 years in the ground, and produces about eight tons of hay upon the Scots acre. There is but little of it cultivated in Scotland. However, it has been tried in several parts of that country; and it is found, that, when the feed is good, it comes up very well, and stands the winter frost. But the chief thing that prevents this grass from being more used in Scotland, is the difficulty of keeping the soil open and free from weeds. In a few years the surface becomes so hard, and the turf so strong, that it destroys the lucerne before the plants have arrived at their greatest perfection: so that lucerne can scarce be cultivated with success there, unless some method be fallen upon of destroying the natural grass, and prevent the surface from becoming hard and impenetrable. This cannot be done effectually by any other means than horse-hoeing. This method was first proposed by Mr. Tull, and afterwards practiced successfully by M. de Chateauneuf near Geneva. It may be of use therefore to give a view of that gentleman's method of cultivating lucerne.

He does not mention any thing particular as to the manner of preparing the land; but only observes in general, that no pains should be spared in preparing it. He tried the fowing of lucerne both in rows upon the beds where it was intended to stand, and likewise the fowing it in a nursery, and afterwards transplanting it into the beds prepared for it. He prefers transplanting; because, when transplanted, part of the tap-root is cut off, and the plant floors out a number of lateral branches from the cut part of the root, which makes it spread its roots nearer the surface, and consequently renders it more easily cultivated; besides this circumstance adapts it to a shallow soil, in which, if left in its natural state, it would not grow.

The transplanting of lucerne is attended with many advantages. The land may be prepared in the summer for receiving the plants from the nursery in autumn; by which means the field must be in a much better situation than if the feed had been fown upon it in the spring. By transplanting, the rows can be made more regular, and the intended distance more exactly observed; and consequently the hoeing can be performed more perfectly, and with less expense. Mr. Chateauneuf likewise tried the lucerne in single beds three feet wide, with single rows; in beds three feet nine inches wide, with double rows; and in beds four feet three inches wide, with triple rows. The plants in the single rows were four inches asunder, and those in the double and triple rows were about eight or nine inches. In a course of three years he found, that a single row produced more than a triple row of the same length. The plants of lucerne, when cultivated by transplanting, should be at least six inches asunder, to allow them room for extending their crowns.

He further observes, that the beds or ridges ought to be raised in the middle; that a small trench, two or three inches deep, should be drawn in the middle; and that the plants ought to be set in it in the spring, and in a warm soil, covered with earth up to the neck. He says, that if the lucerne be fown in the spring, and in a warm soil, it will be ready for transplanting in September; that, if the weather be too hot and dry, the transplanting should be delayed till October; and that, if the weather be unfavourable during both these months, this operation must be delayed till spring. He further directs, that the plants should be carefully taken out of the nursery, so as not to damage the roots; that the roots be left only about six or seven inches long: that the green crops be cut off within about two inches of the crown; that they be put into water at noon, or as soon as taken up, there to remain till they are planted, and that they should be planted with a planting-stick, in the same manner as cabbages.

He does not give particular directions as to the times of horse-hoeing; but only lays in general, that the intervals should be stirred once in the month during the whole time that the lucerne is in a growing state. He likewise observes, that great care ought to be taken not to suffer any weeds to grow among the plants, at least for the first two or three years; and for this purpose, that the rows, as well as the edges of the intervals where the plough cannot go, should be weeded by the hand.

Burnet is peculiarly adapted to poor land; besides, it proves an excellent winter-pasture, when hardly any thing else vegetates. Other advantages are, it makes good butter; it never blows or sweats cattle; it is fine pasture for sheep; and will flourish well on poor, light, sandy, or stony soils, or even on dry chalk hills.

The cultivation of it is neither hazardous nor expensive.
If the land is prepared as is generally done for turnips, there is no danger of its failing. After the first year, it will be attended with very little expense, as the flat circular spread of its leaves will keep down, or prevent the growth of weeds.

On the failure of turnips, either from the fly or the black worm, some of our farmers have sown the land with burnet, and in March following had a fine pasturage for their sheep and lambs. It will perfect its seed twice in a summer; and this seed is said to be as good as oats for horses; but it is too valuable to be applied to that use.

It is sometimes sown late in the spring with oats and barley, and succeeds very well; but it is best to sow it finely in the beginning of July, when there is a prospect of rain, on a small piece of land, and in October following, transplant it in rows two feet apart, and about a foot distant in the rows. This is a proper distance, and gives opportunity for hoeing the intervals in the succeeding spring and summer.

After it is fed down with cattle, it should be harrowed clean. Some horses will not eat it freely at first, but in two or three days they are generally very fond of it. It affords rich pleasant milk, and in great plenty.

A gentleman farmer near Maidstone some years since sowed four acres as soon as the crop of oats was got off, which was the latter end of August. He threw in 32 tons of seed per acre, broadcast; and no rain falling until the middle of September, the plants did not appear before the latter end of that month. There was however a good crop, and in the spring he let the plants out with a turnip-hoe, leaving them about a foot distant from each other. But the drill method is preferable, as it saves more than half the feed. The land was a poor dry gravel, not worth three shillings an acre for any thing else.

The severed root never injures this plant: and the oftener it is fed the thicker are its leaves, which spring constantly from its root.

No branch of husbandry requires more skill and sagacity than a proper rotation of crops, as to keep the ground always in heart, and yet to draw out of it the greatest profit possible. Some plants rob the soil, others are gentle to it: some bind, others loosen. The nice point is, to intermix crops, so as to make the greatest profit consistently with keeping the ground in trim. In that view, the nature of the plants employed in husbandry must be accurately examined.

The difference between culmiferous and leguminous plants, is occasionally mentioned above. With respect to the present subject, a closer inspection is necessary. Culmiferous plants, having small leaves and few in number, depend mostly on the soil for nourishment, and little on the air. During the ripening of the feed, they draw probably their whole nourishment from the soil; as the leaves by this time, being dry and withered, must have loft their power of drawing nourishment from the air. Now, as culmiferous plants are chiefly cultivated for their feed, and are not cut down till the seed be fully ripe, they may be pronounced all of them to be robbers, some more, some less. But such plants, while young, are all leaves; and in that state draw most of their nourishment from the air. Hence it is, where that green for food to cattle, a culmiferous crop is far from being a robber. A hay-crop accordingly, even where it confists mostly of rye-grass, is not a robber, provided it be cut before the feed is formed; which at any rate it ought to be, if one would have hay in perfection. And the foggage, excluding the frost by covering the ground, keeps the roots warm. A leguminous plant, by its broad leaves, draws much of its nourishment from the air. A cabbage, which has very broad leaves, and a multitude of them, owes its growth more to the air than to the soil. One fact is certain, that a cabbage cut and hung up in a damp place, prefers its verdure longer than other plants.

At the same time, a feed is that part of a plant which requires the most nourishment: and for that nourishment a culmiferous plant must be indebted entirely to the soil. A leguminous crop, on the contrary, when cut green for food, must be very gentle to the ground. Peas and beans are leguminous plants; but being cultivated for seed, they seem to occupy a middle station: their feed makes them more severe than other leguminous crops cut green; their leaves, which grow till reaping, make them less severe than a culmiferous plant left to ripen.

These plants are distinguished, remarkably by the following circumstance. All the seeds of a culmiferous plant ripen at the same time. As soon as they begin to form, the plant becomes stationary, the leaves wither, the roots cease to push, and the plant when cut down is blanched and sapless. The seeds of a leguminous plant are formed successively: flowers and fruit appear at the same time in different parts of the plant. This plant accordingly is continually growing, and pushing its roots. Hence the value of bean or pea straw above that of wheat or oats: the latter is withered and dry when the crop is cut; the former, green and succulent. The difference therefore, with respect to the soil, between a culmiferous and leguminous crop, is great. The latter, growing till cut down, keeps the ground in constant motion, and leaves it the plough loose and mellow. The former gives over growing long before reaping; and the ground, by want of motion, turns compact and hard. Nor is this all. Dew falling on a culmiferous crop after the ground begins to harden, rests on the surface, and is sucked up by the next sun. Dew that falls on a leguminous crop, is shaded from the sun by the broad leaves, and sinks at leisure into the ground. The ground accordingly, after a culmiferous crop, is not only hard, but dry; after a leguminous crop, it is not only loofe, but soft and unechoes.

Of all culmiferous plants, wheat is the most severe, by the long time it occupies the ground without admitting a plough. And as the grain is heavier than that of barley or oats, it probably requires more nourishment than either. It is observed above, that as peas and beans draw part of their nourishment from the air by their green leaves while allowed to stand, they draw the lefs from the ground; and by their constant growing they leave it in good condition for subsequent crops. In both respects they are preferable to any culmiferous crop.

Culmiferous crops, as observed above, are not robbers when cut green: the soil, far from hardening, is kept...
Part II. AGRICULTURE.

Practic. kept in constant motion by the pulling of the roots, and is left more tender than if it had been left at rest without any bearing crop.

Bulbous-rooted plants are above all successful in dividing and pulverizing the soil. Potato-roots grow six, eight, or ten inches under the surface; and, by their size and number, they divide and pulverize the soil better than can be done by the plough; consequently, whatever be the natural colour of the soil, it is black when a potato-crop is taken up. The potato, however, with respect to its quality of dividing the soil, must yield to a carrot or parsnip; which are large roots, and pierce often to the depth of 18 inches. The turnip, by its tap-root, divides the soil more than can be done by a fibrous-rooted plant; but as its bulbous root grows mostly above ground, it divides the soil less than the potato, the carrot, or the parsnip.

Red clover, in that respect, may be put in the same class with turnip.

Whether potatoes or turnip be the more gentle crop, appears a puzzling question. The farmer bears feed, and probably draws more nourishment from the soil than the latter, when cut green. On the other hand, potatoes divide the soil more than turnip, and leave it more loose and friable. It appears no less puzzling, to determine between cabbage and turnip: the former draws more of its nourishment from the air, the latter leaves the soil more free and open.

The reft of the whole is what follows: Culmiferous plants are robbers; some more, some less: they at the same time bind the soil; some more, some less. Leguminous plants in both respects are opposite; if any of them rob the soil, it is in a very slight degree; and all of them without exception loosen the soil. A culmiferous crop, however, is generally the more profitable: but few soils can long bear the burden of such crops, unless relieved by interjected leguminous crops.

Thee, on the other hand, without a mixture of culmiferous crops, would soon render the soil too loose.

These preliminaries will carry the farmer some length in directing a proper rotation of crops. Where dung, lime, or other manure, can be procured in plenty to recruit the soil after severe cropping, no rotation, whatever, is proper to profitable in a strong soil, than wheat, peas, or beans, barley, oats, fallow. The whole farm may be brought under this rotation, except so far as hay is wanted. But as such command of manure is rare, it is of more importance to determine what should be the rotation when no manure can be procured but the dung collected in the farm. Considering that culmiferous crops are the more profitable in rich land, it would be proper to make them more frequent than the other kind. But as there are few soils that will admit such frequent culmiferous crops without suffering, it may be laid down as a general rule, that alternate crops, culmiferous and leguminous, ought to form the rotation. Nor are there many soils that will stand good, even with this favourable rotation, unless relieved from time to time by fallowing a few years. If such extended rotation be artfully carried on, crops without end may be obtained in a tolerable good soil, without any manure but what is produced in the farm.

It is scarce necessary to be mentioned, being known to every farmer that clay answers best for wheat, moist clay for beans, loam for barley and peas, light soil for turnip, sandy soil for rye and buckwheat; and that oats thrive better in coarse soil than any other grain. Now, in directing a rotation, it is not sufficient that a culmiferous crop be always succeeded by a feredered, leguminous; attention must also be given to, that no crop be introduced that is unfit for the soil. Wheat, being a great binder, requires more than any other crop a leguminous crop to follow. But every field is not proper: potatoes are the greatest openers of soil; but they are improper in a wheat soil. Neither will turnip answer, because it requires a light soil. A very loose soil, after a crop of rye, requires rye-grass to bind it, or the treading of cattle in ploughing: but to bind the soil, wheat must not be ventured; for it succeeds ill in loose soil.

Another consideration of moment in directing the rotation, is to avoid crops that encourage weeds. Peas is the fittest of all crops for succeeding to wheat, because it renders the ground looser and mellow, and the same soil agrees with both. But beware of peas, unless the field be left by the wheat perfectly free of weeds, because peas, if not an extraordinary crop, suffer weeds. Barley may be ventured after wheat, if the farmer be unwilling to lose a crop. It is indeed a robber; better, however, any crop, than run the hazard of poisoning the soil with weeds. But to prevent the necessity of barley after wheat, the land ought to be fallowed before the wheat: it cleans the ground thoroughly, and makes peas a secure crop after wheat. And after a good crop of peas, barley never fails. A horse-hoed crop of turnip is equal to a fallow for rooting out weeds; but turnip does not suit land that is proper for wheat. Cabbage does well in wheat soil; and a horse-hoed crop of cabbage, which eradicates weeds, is a good preparation for wheat to be succeeded by peas; and a crop of beans diligently hand-hoed, is in that view little inferior. As red clover requires the ground to be perfectly clean, a good crop of it ensures wheat, and next peas. In loam, a drilled crop of turnip or potatoes prepares the ground, equal to a fallow, for the same succession.

Another rule is, to avoid a frequent repetition of the same species. For to produce good crops, change of species is no less necessary than change of feed. The same species returning every second or third year, will infallibly degenerate, and be a scanty crop. This is remarkably the case of red clover. Nor will our fields bear pleasantly perpetual crops of wheat after fallow, which is the practice of some English farmers.

Hitherto in the fame field. We add one rule concerning rotation in different fields; which is to avoid crowding crops one after another in point of time; but to choose such as admit intervals sufficient for leisurely dressing, which gives opportunity to manage all with the same bands, and with the same cattle; for example, beans in January or February, peas and oats in March, barley and potatoes in April, turnip in June or July, wheat and Rye in October.

For illustrating the foregoing rules, a few instances of exceptional rotations will not be thought amiss. Able rotations.

The following is an usual rotation in Norfolk. Firstly, wheat after red clover. Secondly, barley. Third, turnip. Fourth, barley with red clover. Fifth, clover cut for hay. Sixth, a second year's crop of clover commonly
Part II.

AGRICULTURE.

Practice.

Dung is given to the wheat and turnip; against this rotation several objections lie. Barley after wheat is improper. The two crops of barley are too near together. The second crop of clover must be very bad, if pasturing be the best way of consuming it; and if bad it is a great encourager of weeds. But the strongest objection is, that red clover repeated so frequently in the same field cannot fail to degenerate; and of this the Norfolk farmers begin to be sensible. Salton in East Lothian is a clay soil; and the rotation there is, Wheat after fallow and dung. Second, barley after two ploughings; the one before winter, the other immediately before the feed is fown. Third, oats. Fourth, peas. Fifth, barley. Sixth, oats; and then follow. This rotation consists chiefly of robbing crops. Peas are the only leguminous crop, which even with the fallow is not sufficient to loosen a stiff soil. But the soil is good, which in some measure hides the badness of the rotation. About Seaton, and all the way from Preston to Gosford, the ground is still more severely handled: wheat after fallow and dung, barley, oats, peas, wheat, barley, oats, and then another fallow. The soil is excellent; and it ought indeed to be so, to support many rounds of such cropping.

In the parishes of Tranent, Aberlady, Dirleton, North-Berwick, and Athelstanefoord, the following rotations were formerly universal, and to this day are much more frequent than any other mode.

1. After fallow with dung, wheat, barley, oats, peas and beans, barley, oats, wheat.
2. After fallow and dung, barley, oats, peas and beans, wheat, barley, oats, pea, wheat.
3. After fallow and dung, wheat, oats, pea, barley, oats, wheat.
4. After fallow and dung, barley, oats, beans, wheat, pea, barley, oats.

In the several Tours of Young, the itinerant farmer, are found, in the best counties of England, examples without end, of rotations no less exceptional than many of those mentioned.

7. Pasture, Pasture, Pasture, Pasture, Pasture.

Rotation in a clay soil.

When the rotation is completed, the seventh inclosure having been six years in pasture, is ready to be taken up for a rotation of crops which begins with oats in the year 1781, and proceeds as in the sixth inclosure. In the same year 1781, the fifth inclosure is made pasture, for which it is prepared by fowing pasture grasses seeds with the barley of the year 1780. And in this manner may the rotation be carried on without end. Here the labour is equally distributed; and there is no hurry nor confusion. But the chief property of this rotation is, that two culminating or white-corn crops are never found together: by a due mixture of crops, the soil is preserved in good heart without any adventitious manure. At the same time, the land is always producing plentiful crops: neither hay nor pasture get time to degenerate. The whole dung is laid upon the fallow.

Every farm that takes a grasses-crop into the rotation must be inclosed, which is peculiarly necessary in a clay soil, as nothing is more hurtful to clay than pasturing.

Rotation in a light soil.

1. 1775. 1776. 1777. 1778. 1779. 1780.
7. Pasture, Pasture, Pasture, Pasture, Pasture.

For the next rotation, the seventh inclosure is taken up for corn, beginning with an oat crop, and proceeding in the order of the fourth inclosure, in place of which, the third inclosure is laid down for pasture by sowing pasture-grasses with the last crop in that inclosure, being barley. This rotation has all the advantages.

Fields not to be kept too long in pasture.
This leads to the hands that are commonly engaged to cut down corn. In Scotland, the universal practice was, to provide a number of hands, in proportion to the extent of the crop, without regard to the time of ripening. By this method, the reapers were often idle for want of work; and what is much worse, they had often more work than they could undertake, and ripe fields were laid open to baking winds. The Lothians have long enjoyed weekly markers for reapers, where a farmer can provide himself with the number he wants; and this practice is creeping into neighbouring shires. Where there is no opportunity of such markets, neighbouring farmers ought to agree in borrowing and lending their reapers.

One should imagine, that a caution against cutting corn when wet is unnecessary; yet from the impatience of farmers to prevent shaking, no caveat is more fo. Why do they not consider that corn standing dry in half a day, when in a close field, the weather must be favourable if it dry in a month? In moist weather it will never dry.

With respect to the manner of cutting, we must pre. Manner of cutting: that barley is of all the most difficult grain to be dried for keeping. Having no huf, rain his easy access; and it has a tendency to malton when wet. Where the ground is properly smoothed by rolling, it seems best to cut it down with the flythe. This manner being more expeditious than the fliske, removes it sooner from danger of wind; and gives a third more straw, which is a capital article for dung, where a farm is at a distance from other nature. We except only corn that has lodged; for there the fliske is more convenient than the flythe. As it ought to be dry when cut, bind it up directly; if allowed to lie any time fit the swath, it is apt to be discoloured. Barley flown with grass-seeds, red clover especially, requires a different management. Where the grass is cut along with it, the difficulty is great of getting it for dry as to be ventured in a stack. The best way is, to cut the barley with a fliske above the clover, so that nothing but clean barley is bound up. Cut with a flythe the fliske and grasses: they make excellent winter food. The same method is applicable to oats; with this only difference, that when the field is exposed to the west wind, it is left necessary to bind immediately after mowing. As wheat commonly grows higher than any other grain, it is difficult to manage it with the flythe, for which reason the fliske is preferred in England. Peas and beans grow so irregularly, as to make the fliske necessary.

Sect. VI. Of Reaping Corn and Hay Crops, and Storing them up for use.

Culmiferous plants are ripe when the stem is totally white: they are not fully ripe if any green streaks remain. Some farmers are of opinion, that it would not be cut before it is fully ripe. Their reasons are, first, that ripe wheat is apt to shatter; and next, that the flour is not so good. With respect to the last, it is contrary to nature, that any seed can be better in an unripe state than when brought to perfection; nor will it be found so upon trial. With respect to the first, wheat, at the point of perfection, is not more apt to shatter than for some days before; the husks begin not to open till after the seed is fully ripe; and then suffering the crop to it is no more as ticklish: after the minute of ripening, it should be cut down in an instant, if possible.

The best way for drying peas, is to keep separate of the handful that are cut; in this way they wet pre. Early, they dry as soon. In the common way of heap- ing peas together for compounding a sheaf, they wet as early, and dry not so soon. With reaper-shapes, the top of the handful left out, ought to be laid on the bottom of the turner, which gives ready access to the wind. By this method peas and beans are ready for the stack in half the ordinary time.

A sheaf commonly is made as large as can be contained in two lengths of the corn: these being laid up and tied, the binder pretends it down with his knee, and binds it hard as totally to exclude the air. If there be any moisture in the crop, which seldom fails, a process of fermentation and putrefaction commences;
Agriculture.

Part II.

Carrying off the sheaves.

Every article is of importance that hastens the operations in a country, subjected to unequal harvest weather; for which reason, the most expedient method should be chosen for carrying corn from the field to the stack-yard. Our carriages are generally too small or too large. A sled is a very awkward machine; many hands are required, and little progress is made. Wagons and large carts are littleleaf dilatory, as they must stand in the yard till unloaded sheaf by sheaf. The best way is, to use long carts moveable upon the axle, so as to throw the whole load on the ground, which is forked up to the stack by a hand appointed for that purpose. By this method, two carts will do the work of four or five.

Stacking.

Building round stacks in the yard is undoubtedly preferable to housing corn. There it is that up from the air, and it must be exceedingly dry; if it contract not a mutiline, which is the first step to putrefaction. Add to this, that in the yard, a stack is preferred from rats and mice, being fin on a pedestal; whereas no method has hitherto been invented for preferring corn in a house from such destructive vermin. The proper manner of building, is to make every sheaf incline downward from its top to its bottom. Where the sheaves are laid horizontally, the stack will take in rain both above and below. The best form of a stack is that of a cone placed on a cylinder; and the top of the cone should be formed with three sheaves drawn to a point. If the upper part of the cylinder be a little wider than the under, so much the better.

The delaying to cover a stack for two or three weeks, though common, is, however, exceedingly absurd; for if much rain fall in the interim, it is beyond the power of wind to dry the stack. Vegetation begins in the external parts, flush out the air from the internal; and to prevent a total putrefaction, the stack must be thrown down, and exposed to the air, every sheaf. In order to have a stack covered the moment it is finished, straw and ropes ought to be ready; and the covering ought to be so thick as to be proof against rain.

Scotland is subject not only to floods of rain, but to high winds. Good covering guards against the former, and ropes carefully applied guard against the latter. The following is a good mode. Take a hay-rope well twisted, and surround the stack with it, two feet or so below the top. Surround the stack with another such rope immediately below the casing. Connect these two with ropes in an up-and-down position, distant from each other at the casing about five or six feet. Then surround the stack with other circular ropes parallel to the two first mentioned, giving them a twist round every one of these that lie up and down by which the whole will be connected together in a sort of net-work. What remains is, to finish the two feet at the top of the stack. Let it be covered with bunches of straw laid regularly up and down; the under part to be put under the circular rope first mentioned, which will keep it fast, and the upper part be bound by a small rope artfully twisted, commonly called the crown of the stack. This method is preferable to the common way of laying long ropes over the top of the stack, and tying them to the belting-rope; which flattens the top, and makes it take in rain. A stack covered in the way here described, will stand two years secure both against wind and rain; an a notable advantage in a variable climate.

The great aim in making hay is, to preserve as much of the sap as possible. All agree in this; and yet it differs widely in the means of making that aim effectual. To describe all the different methods would be equally tedious and unprofitable. We shall confine ourselves to two, which appear preferable to all others. A crop of rye-grass and yellow clover ought to be spread as cut. A day or two after, when the dew is evaporated, rake it into a number of parallel rows along the field, termed wind-rows, for the convenience of putting it up into final cocks. After turning the rows once and again, make small cocks weighing a stone or two. At the distance of two days or so, put two cocks into one, observing always to mix the tops and bottoms together, and to take a new place for each cock, that the least damage possible may be done to the grass. Proceed in putting two cocks into one, till sufficiently dry for tramp-ricks of 100 stone each. The easiest way of erecting tramp-ricks, is to found a rick in the middle of the row of cocks that are to compose it. The cocks may be carried to the rick by two persons joining arms together. When all the cocks are thus carried to the rick within the distance of 40 yards or so, the rest of the cocks will be more expeditiously carried to the rick, by a rope wound about them and dragged by a horse. Two ropes are sufficient to secure the ricks from wind the short time they are to stand in the field. In the year 1775, 10,000 stone were put into tramp-ricks the fourth day after cutting. In a country far wet as many parts of Scotland are, expeditions of mighty consequence in the drying both of hay and corn. With respect to hay intended for horned cattle, it is by the generality held an improvement, that it be heated a little in the stack. But we violently suspect this doctrine to have been invented for exciting indolent management. An ox, it is true, will eat hay; but it will always be found that he prefers sweet hay; and
Part II.

AGRICUL TURE.

Practice.

Hay of red clover.

It cannot well be doubted, but that such hay is the most salutary and the most nourishing.

The making hay consisting chiefly of red-clover requires more care. The season of cutting is the last week of June, when it is in full bloom; earlier it may be cut, but never later. To cut it later would indeed produce a weightier crop; but a late first cutting makes the second also late, perhaps too late for drying. At the same time, the want of weight in an early first cutting, is amply compensated by the weight of the second.

When the season is too variable for making hay of the second growth, mix straw with that growth, which will be a substantial food for cattle during winter. This is commonly done by laying strata of the straw and clover alternately in the stack. But by this method, the strata of clover, if they do not heat, turn mouldy at least, and unpalatable. The better way is, to mix them carefully with the hand before they be put into the stack. The dry straw imbibles moisture from the clover and prevents heating.

But the best method of hay-making seems to be that recommended by Mr. Anderson. "Instead," says he, "of allowing the hay to lie, as usual in most places, for some days in the straw after it is cut, and afterwards alternately putting it up into cocks and spreading it out, and topdressing it in the sun, which tends greatly to bleach the hay, excites its natural juices, and subjects it very much to the danger of getting rain, and thus runs a great risk of being of good little, I make it a general rule, if possible, never to cut hay but when the grass is quite dry; and then make the gatherers follow close upon the cutters, putting it up immediately into small cocks about three feet high each when new put up, and of as small a diameter as they can be made to stand with; always giving each of them a kind of thrashing, by drawing a few handfuls of the hay from the bottom of the cock all around, and laying it lightly upon the top with one of the ends hanging downwards. This is done with the utmost care and expedition; and when it is once in that state, the hay is as dry as if a perfect and immediate drying had already been done. For this reason, if at any time during a course of good settled weather you should begin to cut in the morning before the dew is off the grass, keep back the gatherers till the dew is evaporated; allowing that which was first cut to lie till it is dry before it is cocked. In this case, you will almost always find that the uncut grass will dry sooner than that which has been cut when wet; and, therefore, the gatherers may always begin to put up that which is fresh cut before the other; which will usually require two or three hours to dry after the new-cut hay may be cocked. And if, at any time, in case of necessity, you should be obliged to cut your hay before it is dry, the same rule must be observed, always to allow it to remain in the straw till it is quite dry; but, as there is always a great risk of being long in getting it

(a) If the hay is to be carried to any considerable distance, this part of the labour may be greatly abridged, by causing the carriers to take two long ricks of a sufficient strength, and having laid them down by the small cocks, parallel to one another, at the distance of one and a half, or two feet asunder, let them lift three or four cocks, one after another, and place them carefully above the ricks, and then carry them altogether, as if upon a hand-barrow, to the place where the large rick is to be built.
A R G I C U L T U R E.

Part II.

A stack of clover-hay in the same circumstances weighs somewhat less.

Sect. VII. Manures.

The manures commonly used are dung, lime, shell-marl, clay-marl, and stone-marl. Many other substances are used; shavings of horn, for example, refuse of malt, and even old rags: but as the quantity that can be procured is inconsiderable, and as their application is simple, we shall confine us time upon them.

Dung is the chief of all manures; because a quantity of it may be collected in every farm, and because it makes the quickest return. A field sufficiently dunged will produce good crops four or five years.

Dung of animals that chew the cud, being more thoroughly purerfeed than that of others, is fit to be mixed with the foil without needing to be collected into a dunghill. A horse does not chew the cud; and in horfe-dung may be perceived straw or rye-grafs broken into small parts, but not dissolved: it is proper therefore that the putrefaction be completed in a dunghill. It ought to be mixed there with cool materials: for it is, that, in a dunghill by itself, it singses and burns instead of putrefying. The difference between the dung of a horse and of a horned animal, is visible in a pasture-field: the graps round the former is withered; round the latter, it is ranker and more verdant than in the rest of the field. A mixture of dry and moist stuff ought to be studied: the former attracting moisture from the latter, they become equally moist.

To prevent sap from running out of a dunghill, its surface should be a little below the surface; and to hinder prevent rain from running into it, it should be surrounded with a ring of foil. If the soil on which the dunghill stands be porous, let it be paved, to prevent the sap from sinking into the ground. If moisture happen to superabound, it may be led off by a small gutter to impregnate a quantity of rich mould laid down to receive it, which will make it equal to good dung.

Straw should be prepared for the dunghill, by being laid under cattle, and sufficiently moistened. When laid dry into a dunghill, it keeps it open, and admits too much air, and prevents putrefaction.

Dung from the stable ought to be carefully spread on the dunghill, and mixed with the former dung. When left in heaps upon the dunghill, fermentation and putrefaction go on unequally.

Complete putrefaction is of importance with regard to the seed of weeds that are in the dunghill: if they remain found, they are carried out with the dung, and infest the ground. Complete putrefaction is of still greater importance by pulverizing the dung; in which condition it mixes intimately with the foil, and operates the most powerfully. In land intended for barley, undigested dung has a very bad effect: it keeps the ground open, admits drought, and prevents the seed from sprouting. On the other hand, when thoroughly rotted, it mixes with the foil, and enables it to retain moisture. It follows, that the properest time for dunging a field,
Part II. **Agriculture.**

**Practice.**

315

207 **Time for dunging.**

Dung should be spread, and ploughed into the ground without delay. When a heap lies two or three weeks, some of the moisture is imbied into the ground, which will produce tufts of corn more vigorous than in the rest of the field. There cannot be a worse practice than to lead our dung before winter, leaving it exposed to frost and snow. The whole spirit of the dung is extracted by rain, and carried off with it. The dungdivvided of its sap becomes dry in spring, and incapable of being mixed with the mould. It is turned over whole by the plough, and buried in the furrow.

208 **Manner of dunging.**

As dung is an article of the utmost importance in husbandry, one should imagine, that the collecting it would be a capital article with an industrious farmer. Yet an ingenious writer, observing that the Jamaicans are in this particular much more industrious than the British, ascribes the difficulty of procuring dung in Jamaica. "In England, where the long winter enables a farmer to raise what quantity he pleases, it is not collected with any degree of industry. But in Jamaica, where there is no winter, and where the heat of the sun is a great obstruction, the farmer must be industrious, or he will never get any dung." Cool interest is not alone a sufficient motive with the indolent, to be active. As dung is of great importance in husbandry, a farmer cannot be too afidious in collecting animal and vegetable substances that will rot. One article of that kind there is, to collect which there is a double motive, and yet is neglected almost every where. A farm full of weeds is a nuisance to the neighbourhood: it poisons the fields around; and the pollestor ought to be disgraced as a pest to society. Now the cutting down every weed before the feed is formed, answers two excellent purposes. First, it encourages good crops, by keeping the ground clean. Next, these weeds mixed with other materials in a dunghill, may add considerably to the quantity of dung.

210 **Of lime.**

Next of lime, which is a profitable manure, and greatly so when it can be got in plenty within a moderate distance. The benefit of lime is so visible, that the use of it has become general, where the price and carriage are in any degree moderate.

However people may differ in other particulars, all agree, that the operation of lime depends on its intimate mixture with the soil; and therefore that the proper time of applying it, is when it is perfectly powdered and the soil at the same time in the highest degree of pulverization. Lime of itself is absolutely barren: and yet it enriches a barren soil. Neither of the two produces any good effect without the other: and consequently, the more intimately they are mixed, the effect must be the greater.

Hence it follows, that lime ought always to be flaked with a proper quantity of water, because by that means it is reduced the most effectually into powder. Lime left to be flaked by a moist air, or accidental rain, is seldom or never thoroughly reduced into powder; and therefore can never be intimately mixed with the soil. Sometimes an opportunity offers to bring home shell-lime before the ground is ready for it; and it is commonly thrown into a heap without cover, trudging to rain for flaking. The proper way is, to lay the shell-lime in different heaps on the ground where it is to be spread, to reduce these heaps into powder by flaking it with water, and to cover the flaked lime with sods as to defend it from rain. One however should avoid as much as possible the bringing home lime before the ground be ready for it. Where allowed to lie long in a heap, there are two bad consequences: first, lime attracts moisture, even though well covered, and runs into cloths, which prevents an intimate mixture; and, next, we know, that burnt limestone, whether in shells or in powder, returns gradually into its original state of limestone; and upon that account also, is less capable of being mixed with the soil. And this is verified by a fact, that, after lying long, it is so hard bound together as to require a pick to separate the parts.

For the same reason, it is a bad practice, though common, to let spread lime lie on the surface all winter. The bad effects above mentioned take place here in part: and there is another; that rain washes the lime down to the furrows, and in a hanging field carries the whole away.

As the particles of powdered lime are both small and heavy, they quickly sink to the bottom of the furrow, if they be not taken to prevent it. In that view, it is a rule, that lime be spread, and mixed with the soil, immediately before fowing, or along with the feed. In this manner of application, there being no occasion to move it till the ground be flirred for a new crop, it has time to incorporate with the soil, and does not readily separate from it. Thus, if turnip-feed is to be fown broadcast, the lime ought to be laid on immediately before fowing, and harrowed in with the feed. If a crop of drilled turnip or cabbages be intended, the lime ought to be spread immediately before forming in drills. With respect to wheat, the lime ought to be spread immediately before feed-furrowing. If spread much earlier, before the ground be sufficiently broken, it will sink to the bottom. If a lighter feed is taken, for barley, the lime ought to be spread after feed-furrowing, and harrowed in with the feed. In a strong soil, it sinks not so readily to the bottom; and therefore, before fowing the barley, the lime ought to be mixed with the soil by a brake. Where moor is furrowed for a crop of oats next year, the lime ought to be laid on immediately before the last ploughing, and braked in as before. It has sufficient time to incorporate with the soil before the land be flirred again.

The quantity to be laid on depends on the nature of the soil. Upon a strong soil, 70 or 80 bolls of shells are not more than sufficient, reckoning four small flirtos to the boll, termed wheat-measurens; nor will it be an oversode to lay on 100 bolls. Between 50 and 60 may suffice upon medium soils; and upon the thin or gravelly, between 30 and 40. It is not safe to lay a much greater quantity on such soils.

It is common to lime a pasture-field immediately before ploughing. This is an unsafe practice; it is thrown to the bottom of the furrow, from which it is never fully gathered up. The proper time for liming

R 2
Agriculture.

Part II.

Summer is the proper season for marling; because in that season the marl, being dry, is not only lighter, but is easily reduced to powder. Frost however is not improper for marling, especially as in frost there is little opportunity for any other work.

Marl is a heavy body, and sinks to the bottom of the furrow, if indirectly ploughed. Therefore the first crop should always have an ebb furrow. During the growing of that crop, the marl has time to incorporate with the soil, and to become a part of it; after which it does not readily separate.

Sect. VIII. Principles and Operations of the New or Horfhe-hoeing Husbandry.

The general properties attributed to the new husbandry may be reduced to two, viz. the promoting the growth of plants by hoeing, and the saving of seed; both of which are equally profitable to the farmer.

The advantages of tillage before sowing have already been pointed out. In this place we must confine ourselves to the utility of tillage after sowing. This kind of tillage is most generally known by the name of horfhe-hoeing.

Land fowed with wheat, however well it may be cultivated in autumn, sinks in the winter; the particles get nearer together, and the weeds rise; so that in spring, the land is nearly in the same situation as if it never had been ploughed. This, however, is the season when it should branch and grow with moft vigour; and consequently stands in need of ploughing or hoeing, to destroy the weeds, to supply the roots with fresh earth, and, by dividing anew the particles of the soil, to allow the roots to extend and collect nourishment.

It is well known, that, in gardens, plants grow with double vigour after being hoed or transplanted. If plants growing in arable land could be managed with care and safety in this manner, it is natural to expect, that their growth would be promoted accordingly. Experience shows, that this is not only practicable, but attended with many advantages.

The operation of hoeing in winter wheat, though some of the roots be moved or broken, the plants receive no injury, for this very circumstance makes them send forth a greater number of roots than formerly, which enlarge their pature, and consequently augment their growth.

Sickly wheat has often recovered its vigour after a good hoeing, especially when performed in weather not very hot or dry.

Wheat, and much grass as is sown before winter, requires hoeing more than oats, barley, or other grain sown in the spring; for, if the land has been well ploughed before the sowing of spring-corn, it neither has time to harden, nor to produce many weeds, not having been exposed to the winter’s snow and rain.

Of Sowing.

As, in the practice of the New Husbandry, plants grow with greater vigour than by the old method, the sowing in the New Husbandry land should be sowed thinner. It is this principle of the new husbandry that has been chiefly objected to; for, upon observing the land occupied by a small number of plants, people are apt to look upon all the vacant.

Practi.

Limestone beat small makes an excellent manure, and suppies the want of powdered lime where there is no fuel to burn the lime. Limestone beat small has not hitherto been much used as a manure; and the proportion between it and powdered lime has not been ascertained. What follows may give some light.

Three pounds of raw lime is by burning reduced to two pounds of shell-lime. Yet nothing is expelled by the fire but the air that was in the limestone; the calcareous earth remains entire. Erge, two pounds of shell-lime contain as much calcareous earth as three pounds of raw lime. Shell-lime of the best quality, when flaked with water, will measure out to thrice the quantity. But as limestone loses none of its bulk by being burnt into shell, it follows, that three bushels of raw lime contain as much calcareous earth as six bushels of powdered lime; and consequently, if powdered lime poftels not some virtue above raw lime, three bushels of the latter beat small should equal as a manure six bushels of the former.

Shell-marl, as a manure, is managed in every respect like powdered lime; with this only difference, that a fifth or a fourth part more in measure ought to be given. The reason is, that shell-marl is less weigh-ty than lime; and that a ball of it contains less calcareous earth, which is the frustrating part of both.

Clay and fine marls, with respect to husbandry, are the same, though in appearance different.

The goodness of marl depends on the quantity of calcareous earth in it: which has been known to amount to a half or more. It is too expensive if the quantity be less than a third or a fourth part. Good marl is the most substantial of all manures; because it improves the weakest ground to equal the best borough-acres. The low part of Berwickshire termed the Merse, abounds everywhere with this marl; and is the only county in Scotland where it is plenty.

Land ought to be cleared of weeds before marling; and marling is performed with the harrow and the brush, in order that the marl may be equally spread. Marl is a folil on which no vegetable will grow; its efficacy depends, like that of lime, on its pulverization, and intimate mixture with the soil. Toward the former, alternate drought and moisture contribute greatly, as also frost. Therefore, after being evenly spread, it ought to lie on the surface all winter. In the month of Octo-ber it may be roused with a brake; which will bring to the surface, and expel to the air and frost, all the hard parts, and mix with the soil all that is powdered. In that respect it differs widely from dung and lime, which ought to be ploughed into the ground without delay. Oats in the new marl, which will answer for being the first crop after marling better than any other; and it will succeed though the marl be not thoroughly mixed with the soil. In that cafe, the marl ought to be ploughed in with an ebb furrow immediately before sowing, and braked thoroughly. It is tickish to make wheat the first crop: if sown before winter, root swells the marl, and is apt to throw the seed out of the ground; if sown in spring, it will suffer more than oats by want of due mixture.
Part II. AGRICULTURE.

Prep. can't space as lost. But this prejudice will soon be removed when it is considered, that, in the best land cultivated in the common method, and sown very thick, each seed produced but one or two ears; that, in the same land, the thinner, every seed produces two or three ears; and that a single seed sometimes produces

In the common method, there are many more plants that can find sufficient nourishment, and as it is impossible to lift them by hoeing; numbers die before they attain maturity, the greatest part remain sickly and drooping; and thus part of the seed is lost. On the contrary, in the new method, all the plants have as much food as they require; and as they are, from time to time, alleviated by hoeing, they become more vigorous as to equal in their production the numerous but sickly plants cultivated in the common method.

Of Hoeing.

The new husbandry is absolutely impracticable in lands that are not easily ploughed. Attempting to cultivate land according to this husbandry, without attending to this circumstance, that it is practicable in no land except in such as have already been brought into good tillth by the old method, has gone far to make it contemptible in many places.

When a field is in good tillth, it should be sown so thin as to leave sufficient room for the plants to extend their roots. After being well ploughed and harrowed, it must be divided into rows, at the distance of thirty inches from one another. On the sides of each of these rows, two rows of wheat must be sown six inches distant from each other. By this means there will be an interval of two feet wide between the rows, and every plant will have room enough to extend its roots, and to supply it with food. The intervals will likewise be sufficient for allowing the earth to be hoed or tilled without injuring the plants in the rows.

The first hoeing, which should be given before the winter, is intended to drain away the wet, and to diffuse the earth to be mellowed by the frosts. These two ends will be answered by hoeing the rows to little distance from the rows, and throwing the earth taken from the furrows into the middle of the intervals. This first hoeing should be given when the wheat is in ear.

The second hoeing, which is intended to make the plants branch, should be given after the hard frosts are over. To do this with advantage, after stirring the earth about near the rows, the earth which was thrown in the middle of the intervals should be turned back into the furrows. This earth, having been mellowed by the winter, supplies the plants with excellent food, and makes the roots extend.

The third hoeing, which is intended to invigorate the stalk, should be given when the ears of the corn begin to show themselves. This hoeing may, however, be very light.

But the last hoeing is of the greatest importance, as it enlarges the grain, and makes the ears fill at their extremities. This hoeing should be given when the wheat is in bloom; a furrow must be drawn in the middle of the interval, and the earth thrown to the right and left on the root of the plants. This supports the plants, prevents them from being laid, and prepares the ground for the next sowing, as the soil is then to be put in the middle of the ground that formed the intervals.

The best season for hoeing is two or three days after rain, or soon after rain as the soil will quit the instrument in hoeing. Light dry soils may be hoed almost any time, but this is far from being the case with strong clay soils: the season for hoeing such is frequently short and precarious; every opportunity therefore should be carefully watched, and eagerly embraced. The two extremes of wet and dry, are great enemies to vegetation in strong clay soils. There is a period between the time of clay soils running together, as to puddle by superfluous wet, and the time of their baking by drought, that they are as tradable as need be. This is the juncture for hoeing; and so much land as shall be thus feasibly hoed, will not cake or crust upon the surface, as it otherwise would have done, till it has been soaked or drenched again with rain; in which case the hoeing is to be repeated as soon as the soil will quit the instrument, and as often as necessary; by which time the growing crop will begin to cover the ground, so as to act as a screen to the surface of the land against the intense heat of the sun, and thereby prevent, in great measure, the bad effects of the soil's baking in dry weather.

By this successive tillage, or hoeing, good crops will be obtained, provided the weather is not very favourable.

But as strong, vigorous plants are longer before they arrive at maturity, corn raised in the new way is later in ripening than any other, and must therefore be sown earlier.

In order to prepare the intervals for sowing again, some well-rotted dung may be laid in the deep furrows made in the middle of the intervals; and this dung must be covered with the earth that was before thrown towards the rows of wheat. But, if the land does not require mending, the deep furrow is filled without any dung. This operation should be performed immediately after the harvest, that there may be time to give the land a flight before the rows are sowed; which should occupy the middle of the space which formed the intervals during the last crop. The intervals of the second year take up the space occupied by the stubble of the first.

Supposing dung to be necessary, which is denied by many, a very small quantity is sufficient; a single layer, put in the bottom of each furrow, will be enough.

Description of the Instruments for only used in the New Husbandry.

Fig. 1. is a marking plough. The principal parts of Instrument this plough is to straight and regulate the ridges. The first line is traced by the eye, by means of three poles, placed in a straight line. The plough draws the first furrow in the direction of this line; and at the same time, with the tooth A, fixed in the block of wood near the end of the cross-pole or slider B, marks the breadth of the ridge at the distance intended. The ploughman next traces the second line or rut made by the tooth, and draws a small furrow along it; and continues in this manner till the whole field is laid out in straight and equidistant ridges.
Plate VIII.

Fig. 2. is a plough for breaking up lea, or turning up the bottom of the land when greatly exhausted. By its construction, the width and depth of the furrows can be regulated to a greater certainty than by any other hitherto known in this country. Its appearance is heavy, but two horses are sufficient to plough with it in ordinary free land; and only four are necessary in the stiffest clay-soils. This plough is likewise easily held and tempered. A, is the sword fixed in the hizors B, which runs through a mortise E, at the end of the beam C, and regulates the depth of the furrow by raising or depressing the beam; it is fixed by putting the pin D thro' the beam and sword, and is movable at E.

Fig. 3. is a jointed brake-harrow with 24 teeth, shaped like coulters, and standing at about an angle of 80 degrees. By this instrument the land is finely pulverized, and prepared for receiving the seed from the drill. It requires four horses in full and two in open land. This harrow is likewise used for levelling the ridges; which is done by pressing it down by the handles where the ridge is high, and raising it up when low.

Fig. 4. is an angular weeding harrow, which may follow the brake when necessary. The seven hindmost teeth should stand at a more acute angle than the rest, in order to collect the weeds, which the holder can draw at pleasure, by raising the hinder part, which is fixed to the body of the harrow by two joints.

Fig. 5. is a pair of harrows with shafts. This harrow is used for covering the seed in the drills, the horse going in the furrow.

Fig. 6. is a drill-plough, constructed in such a manner as to throw at once two rows of beans, peas, or wheat. This machine is easily wrought by two horses. A, is the hopper for containing the seed; B, circular boxes for receiving the seed from the hopper; CC, two square boxes which receive the seed from small holes in the circular boxes, as they turn round; and last of all, the seed is dropped into the drills through holes in the square boxes, behind the coulters D. The cylinder E follows, together with the wheel F, which regulates the depth of the coulters, and covers the seed; the harrow G comes behind all, and covers the seed more completely. H, H, two sliders, which, when drawn out, prevent the seed from falling into the boxes; and, I, is a catch which holds the rungs, and prevents the boxes from turning, and loosing feed at the ends of the ridges.

Fig. 7. is a single hoe-plough of a very simple construction, by which the earth in the intervals is stirred and laid up on both sides to the roots of the plants, and at the same time the weeds are destroyed. A A are the mould-boards, which may be raised or depressed as follows, according as the farmer wants to throw the earth higher or lower upon the roots.

Fig. 8. is a drill-rake for peas. This instrument, which is chiefly calculated for small inclosures of light grounds, is a sort of strong plough rake, with four large teeth at a, a, b, and c, a little incurved. The distance from a to a, and from b to b, is nine inches. The interval between the two inner teeth a and b, is three feet six inches, which allows sufficient room for the hole-plough to move in. To the piece of timber e, forming the head of the rake, are fixed the handles d, and the beam ε, to which the horse is fastened. When this instrument is drawn over a piece of land made thoroughly fine, and the man who holds it bears upon the handles, four furrows fi, gi, hi, will be formed, at the distance determined by the construction of the instrument. These furrows may be accurately preserved, provided that the teeth as return when the ploughman comes back, after having ploughed one turn, in two of the channels formed before, marked b, b, thus all the furrows in the field will be traced with the same regularity. When the ground is thus formed into drills, the pea may be scattered by a single motion of the hand at a certain distance from one another into the channels, and then covered with the flat part of a hand-rake, and pressed down gently. This instrument is so simple, that any workman may easily make or repair it.

On Plate IX. is delineated a patent drill machine, lately invented by the Reverend James Cooke of Heaton-Norris near Manchester. A, the upper part of the feed-box. B, the lower part of the same box. C, a movable partition, with a lever, by which the grain or feed is let fall at pleasure from the upper to the lower part of the feed-box, from whence it is taken up by cups or ladles applied to the cylinder D, and dropped into the funnel E, and conveyed thereby into the furrow or drill made in the land by the coulter F, and covered by the rake or harrow G. H, a lever, by which the wheel is lifted out of generation with the wheel K, to prevent the grain or feed being scattered upon the ground, while the machine is turning round at the end of the land, by which the harrow G is also lifted from the ground at the same time, and by the same motion, by means of the crank, and the horizontal lever h, h. I, a sliding lever, with a weight upon it, by means of which, the depth of the furrows or drills, and consequently the depth that the grain or feed will be deposited in the land, may be easily ascertained. M, a screw in the coulter beam, by turning of which, the feed-box B is elevated or depressed, in order to prevent the grain or feed being crushed or bruised by the revolution of the cups or ladles. Fig. 12. a rake with iron teeth, to be applied to the under side of the rails of the machine, with staples and screw nuts at a, by which many useful purposes are answered, viz. in accumulating caulk or hay into rows, and as a scutariator for young crops of wheat in the spring, or to be used upon a fallow; in which case, the feed-box, the ladle cylinder, the coulters, the funnels, and harrows, are all taken away.

This side view of the machine is represented, for the sake of perspicuity, with one feed-box only, one coulter, one funnel, one harrow, &c. whereas a complete machine is furnished with five coulters, five harrows, seven funnels, a feed-box in eight partitions, &c. with ladies of different sizes, for different sorts of grain and feeds.

These machines, (with five coulters sixteen guineas, with four coulters fifteen guineas) equally excel in letting or planting all sorts of grain and feeds, even carrot feed, to exactness, after the rate of from eight to ten chain acres per day, with one man, a boy, and two horses. They deposite the grain or feed in any given quantity from one peck to three bushels per acre, regularly and uniformly, and that without grinding or bruising the feed, and at any given depth, from half an inch to half a dozen inches, in rows at the distance of
The person who attends the machine should put down the lever H soon enough at the end of the land, that the cups or ladles may have time to fill, before he begins to sow; and at the end of the land, he must apply his right hand to the middle of the rail between the handles, by which he will keep the coulters in the ground, while he is lifting up the lever H with his left hand, to prevent the grain being scattered upon the headland, while the machine is turning round; this he will do with great ease, by continuing his right hand upon the rail between the handles, and applying his left arm to the left handle, in order to lift the coulters out of the ground while the machine is turning round.

If there be any difficulty in using the machine, it consists in driving it straight. As to the person who attends the machine, he cannot possibly commit any errors, except such as are wilful, particularly as he sees at one view the whole process of the business, viz. that the coulters make the drills of a proper depth; that the funnels continue open to convey the grain or feed into the drills; that the rakes or harrows cover the grain sufficiently; and when feed is wanting in the lower boxes B, which he cannot avoid seeing, he readily supplies them from the upper boxes A, by applying his hand, as the machine goes along, to the lever C. The lower boxes B should not be suffered to become empty before they are supplied with feed, but should be kept nearly full, or within an inch or so of the edge of the box.

If chalk lines are made across the backs of the coulters, at such a distance from the ends as the seed should be deposited in the ground (viz. about two inches for wheat, and from two to three for spring corn), the person that attends the machine will be better able to ascertain the depth the seed should be deposited in the drills, by observing, as the machine goes along, whether the chalk lines are above or below the surface of the land; if above a proper weight must be applied to the lever L, which will force the coulters into the ground; if below, the lever L and weight must be reversed, which will prevent their sinking too deep.

In different parts of the kingdom, lands or ridges are of different sizes: where the machine is too wide for the land, one or more funnels may occasionally be stopped with a little loose paper, and the feed received into such funnel returned at the end of the land, or sooner if required, into the upper feed-box. But for regularity and expedition, lands confining of so many feet wide from outside to outside, as the machine contains coulters, when fixed at twelve inches distance, or twice or three times the number, &c. are best calculated for the machine. In wet soils or strong clays, lands or ridges of the width of the machine, and in dry soils, twice the width, are recommended. For fowing of narrow high-ridged lands, the outside coulters should be let down, and the middle ones raised, so that the points of the coulters may form the same curve that the land or ridge forms. And the loose foil hallowed down into the furrows should be returned to the edges of the lands or ridges from whence it came, by a double mould-board or other plough, whether the land be wet or dry.

Clover or other hays, intended to be sown by the machine.
Agriculture.

Part II.

1. It is indispensably necessary that the farmer be furnished with a drill and hoe-plough.

2. The new husbandry may be begun either with the winter or spring corn.

3. The land must be prepared by four good ploughings, given at different times, from the beginning of April to the middle of September.

4. These ploughings must be done in dry weather, to prevent the earth from kneading.

5. The land must be harrowed in the same manner as it were sowed in the common way.

6. The rows of wheat should be sowed very straight.

7. When the field is not very large, a line must be straitened across it, by which a rill may be traced with a hoe for the horse that draws the drill to go in; and when the rows are sown, so inches must be left between each rill. But, when the field is large, stakes at five feet distance from each other must be placed at the two ends.

8. The fowing should be finished at the end of September, or the beginning of October.

9. The furrows must be traced the long way of the land, that as little ground as possible may be left in the head-lands.

10. The rows, if it can be done, should run down the slope of the land, that the water may get the easier off.

11. The feed-wheat must be plunged into a tub of lime-water, and stirred, that the light corn may come to the surface and be skimmed off.

12. The feed must be next spread on a floor, and frequently stirred, till it is dry enough to run through the valves of the hopper of the drill.

13. To prevent fruit, the feed may be put into a ley of allies and lime.

14. Good
Part II. AGRICULTURE.

14. Good old bread-wheat should be chosen in preference to new, as it is found by experience not to be so subject to fin.  
15. After the hoppers of the drill are filled, the horse must go slowly along the furrow that was traced. That a proper quantity of seed may be sown, the aperture of the hopper must be fitted to the size of the grain.  
16. As the drill is seldom well managed at first, the field should be examined after the corn has come up, and the deficiencies supplied.

17. Upon wet soils or strong clays, wheat should not be deposited more than two inches deep, on any account whatever; nor less than two inches deep, on dry soils. From two to three inches is a medium depth for all spring corn. But the exact depth at which grain should be deposited in different soils, from the lightest land to the strongest clay, is readily ascertained only by observing at what distance under the surface of the land, the secondary or coronal roots are formed in the springing.

18. Stiff lands, that retain the wet, must be stirred or hoed in October. This should be done by opening a furrow in the middle of the intervals, and afterward, filling it up by a furrow drawn on each side, which will raise the earth in the middle of the intervals, and leave two small furrows next the rows, for draining off the water, which is very hurtful to wheat in winter.

19. The next stirring must be given about the end of March, with a light plough. In this stirring the furrows made to drain the rows must be filled up by earth from the middle of the intervals.

20. Some time in May, the rows must be even; which, though troublesome at first, soon becomes easy, as the weeds are soon kept under by tillage.

21. In June, just before the wheat is in bloom, another stirring must be given with the plough. A deep furrow must be made in the middle of the intervals, and the earth thrown upon the sides of the rows.

22. When the wheat is ripe, particular care must be taken, in reaping it, to trample as little as possible on the ploughed land.

23. Soon after the wheat is carried off the field, the intervals must be turned up with the plough, to prepare them for the seed. The great furrow in the middle must not only be filled, but the earth raised as much as possible in the middle of the intervals.

24. In September, the land must be again sowed with a drill, as above directed.

25. In October, the stubble must be turned in for forming the new intervals; and the same management must be observed as directed in the first year.

We pretend not to determine whether the old or new husbandry be preferable in every country. With regard to this point, the climate, the situation of particular land, skill and dexterity in managing the machinery, the comparative expence in raising crops, and many other circumstances, must be accurately attended to before a determination can be given.

The following comparative view of the old and new methods of culture, was furnished for the editors of Mr Tull’s Horse-hoeing Husbandry, by a gentleman who for some years practised both in a country where the soil was light and chalky, like that from which he drew his observations. It is necessary to remark, that in the new husbandry each article is stated at its full value, and the crop of each year is four bushels short of the other; though, in several years experience, it has equalled and generally exceeded those of the neighbourhood in the old way.

"An estimate of the expence and profit of 10 acres of land in 20 years."

Third and fourth years, lying in grasses, cost nothing, so that the expence of ten acres in four years comes to 44L. 11s. 8d. and in twenty years to 222 18 4.

First years produce is half a load of wheat per acre, at 7l. 35 0 0
Second years produce is two quarters of barley per acre, at 1l. 20 0 0
Third and fourth years grasses is valued at 1l. 10s. per acre 15 0 0

So that the produce of ten acres in four years is 70 0 0
And in twenty years it will be 350 0 0
Deduct the expence, and there remains clear profit on ten acres in twenty years by the old way 127 18

II. In the new way.

First year's extraordinary expence is, for ploughing and manuring the land, the same as in the old way. L. 22 0 0

Ploughing
ARGUMENT.

Ploughing once more, at 4s.

Seed, nine gallons per acre, 2 0 0

Drilling, at 7d. per acre 0 5 0

Hand-hoeing and weeding, at 2s. 6d. per acre 1 5 0

Horse-hoeing six times, at 10s. per acre 5 0 0

Reaping, binding, and carrying, at 6s. per acre 3 0 0

The standing annual charge on ten acres 2 15 10

Therefore the expense on ten acres in twenty years is 275 16 8

Add the extraordinaries of the first year, and the sum is 297 16 8

The yearly produce is at least two quarters of wheat per acre, at 11. 8s. per quarter; which, on ten acres in twenty years amounts to 560 0 0

Therefore, all things paid, there remains clear profit on ten acres in 20 years by the new way 262 3 4

"So that the profit on ten acres of land in twenty years, in the new way, exceeds that in the old by L. 125 : 1 : 8, and consequently is considerably more than double thereof; an ample encouragement to practice a scheme, whereby so great advantage will arise from so small a quantity of land, in the compass of a twenty-one years lease; one year being allowed, both in the old and new way, for preparing the ground.

"It ought withal to be observed, that Mr Tull's husbandry requires no manure at all, though we have here, to prevent objections, allowed the charge thereof for the first year; and moreover, that though the crop of wheat from the drill-plough is here put only at two quarters on an acre, yet Mr Tull himself, by actual experiment and measure, found the produce of his drilled wheat-crop amounted to almost four quarters on an acre."

It appears also from a comparative calculation of expense and profit between the drill and common husbandry, taken from Mr Baker's report to the Dublin Society of his experiments in agriculture for the year 1765, that there is a clear profit arising upon an Irish acre of land in 15 years in the drill husbandry of L. 27 : 19 : 2; and in the common husbandry of L. 27 : 19 : 1: and therefore a greater profit in the drilled acre in this time of L. 24 : 4 : 9, which amounts to L. 1 : 12 : 34 per annum. From hence he infers, that in every 15 years the fee-simple of all the tillage-lands of the kingdom is lost to the community by the common course of tillage. In stating the accounts, from which their result is obtained, no notice is taken of fences, water-cutting the land, weeding and reap ing; because these articles depend on a variety of circumstances, and will, in general, exceed in the common husbandry those incurred by the other.

Besides, the certainty of a crop is greater in this new way than in the old way of sowing; for most of the accidents attending wheat crops, are owing to their being late sown, which is necessary to the farmer in the old way; but in the horse-hoeing method the farmer may plough two furrows whereon the next crop is to stand immediately after the first crop is. In this manner of husbandry, the land may be ploughed dry and drilled wet, without any inconvenience; and the seed is never planted under the furrow, but placed just at the depth which is most proper, that is, at about two inches; in which case it is easy to preserve it, and there is no danger of burying it. Thus the feed has all the advantage of early sowing, and none of the disadvantages that may attend it in the other way, and the crop is much more certain than by any other means that can be used.

The condition in which the land is left after the crop, is no less in favour of the horse-hoeing husbandry than all the other articles. The number of plants is the great principle of the exhausting of land. In the common husbandry, the number is vastly greater than in the drilling way, and three plants in four often come to nothing, after having exhausted the ground as much as profitable plants; and the weeds which live to the time of harvest in the common way, exhaust the land no less than so many plants of corn, often much more. The horse-hoeing method destroys all the weeds in the far greater part of the land, and leaves that part exhausted and perfectly fresh for another crop. The wheat plants being also a third part of the number at the utmost of those in the sowing way, the land is so much the less exhausted by them; and it is very evident from the whole, that it must be, as experience proves that it is, left in a much better condition after this than after the common husbandry.

The farmers who are against this method object, that it makes the plants too strong, and that they are more liable to the black or blights of insects for that reason; but as this allows that the hoeing can, without the use of dung, give too much nourishment, it is very plain that it can give enough; and it is the farmer's fault if he do not proportion his pains so as to have the advantage of the nourishment without the disadvantages. It is also objected, that as hoeing can make poor land rich enough to bear good crops of wheat, it may make good land too rich for it. But if thins should happen, the sowing of wheat on it may be let alone a while, and in the place of it the farmer may have a crop of turnips, carrots, cabbages, and the like, which are excellent food for cattle, and cannot be over-nourished: or, if this is not chosen, the land, when thus made too rich, may soon be sufficiently impoverished by sowing corn upon it in the common old way.

The method of horse-hoeing husbandry, so strongly recommended by Mr Tull, is objected to by many on account of the largeness of the intervals which are to be left behind the rows of corn. These are required to be about five feet wide; and it is thought that such wide spaces are so much lost earth, and that the crop is to be so much the less for it. But it is to be observed, that the rows of corn separated by these intervals need not be single: they may be double, triple, or quadruple, at the pleasure of the farmer; and four rows thus standing as one will have the five foot interval but one-fourth of its bigness as to the whole quantity, and it will be but as fifteen inch intervals to plants
in single rows. Corn that is sown irregularly in the common way, seems indeed to cover the ground better than that in rows; but this is a mere deception; for the stalks of corn are never so thick as when they come out of one plant, or as when they stand in a row; and a horse-hoed plant of corn will have 20 or 30 stalks in a piece of ground of the same quantity, where an unhoed plant will have only two or three stalks. If these stalks of the hoed plant were separated and planted over the intervals, the whole land would be better covered than it is in the common way; and the truth is, that though these hoed fields seem to contain a much less crop than the common fowen fields, yet they in reality do contain a much greater. It is only the different placing that makes the fown crop seem the larger, and even this is only while both crops are young.

The intervals are not lost ground, as is usually supposed, but when well horse-hoed they are all employed in the nourishment of the crop, the roots of the plants in the adjoining rows spreading themselves thro' the whole interval, and drawing such nourishment from it, that they increafe accordingly. When the plants stand in the scattered way, as in common fowing, they are too close to one another; each rob its neighbours of part of their nourishment, and consequently the earth is soon exhausted, and all the plants half starved. The close fanding of them also prevents the benefit of after­tilling, as the hoe cannot be brought in, nor the ground by any means stirred between them to give it a new breaking, and consequently afford them new food.

Experiments have abundantly proved, that in large grounds of wheat where the different methods have been tried, those parts where the intervals were large have produced the greatest crops, and those where hoeing was used without dung have been much richer. Than where dung was used without hoeing. If it were poffible that plants could fand as thick, and thrive as well over the whole surface of the ground, as they do in the rows separated by thefe large intervals, the crops of corn for produced would be vastly greater than any that have been heard of; but the truth is, that plants receive their growth not according to the ground they fand on, but to the ground they can extend their roots into; and therefore a single row may contain more plants than a large interval can nourifh, and therefore the fame number that fand in that row, and no more than thofe, could be nourifh'd, if fattered over the whole interval; and they would be much worfe nourifh'd in that way; because while the interval is void, the earth may be ftrirred about them, and new roots will be formed in great numbers from every one broken by the instruments and new nourifhment laid before these roots by the breaking the particles of earth, by which the plants will have supplies that they cannot have when fattered over the whole surface, because the ground is then all occupied, and cannot be moved between the plants.

All foils and all situations are not equally proper for this method of planting in rows with large intervals and hoeing between. The lightest foils ferve to be best for it, and the rough and wet clays the worft. Such grounds as lie on the sides of hills are also less proper than others for this work.

This method is not fo proper in common fields, but that not in respect of the foil, but of the husbandry of the owners, whofe usually in the old way, and change the species of corn, and make it necessary to fallow every second, third or fourth year. Nevertheless it has been founded by later experiments, that the intervals between the rows of plants, as recommended by Mr Tull, were too great, perhaps double of what they should be in the most profitable method of culture; by which means much less crops are obtained than might be produced at nearly the fame expense. This has rendered the profits of the drill method much less than they would have been in a more judicious practice, and, consequently, has proved a great disadvantage to it in comparison with the broad-caft. Mr Tull was led into this, partly from the want of more perfect instruments for hoeing, and of ploughs proper for drilling.

To the preceding statements, the following observations by Sir John Attifrucher, published among the Select Papers of the Bath Society, may not be improperly subjoined.

The fowen process which the drill-husbandry has Observ­made in many parts of Great Britain since Mr Tull's time, he observes, has been principally owing to the John A newwant of proper drill-ploughs. Before drilling can be­ come general, these ploughs muft be simple, fuch as a common ploughman accustomed to ufe frong instru­ments can ufe without breaking, and fuch also as com­mon workmen can easily make or repair. Mathematical accuracy he considers as not required for delivering the feed: for it matters very little whether there be a quarter of a peck more or fefs fown, if it be deli­vered with tolerable regularity. He therefore had a plough made, according to his own directions, by a common plough-wright, of fufficient strength for any land made fit for turnips or wheat. It was tried on very rough ground unfit for fowing, in order to acf­tain its strength; and it had been ufed for eighteen years without its needing any repair. It is a double drill­plough, which fows two ridges at a time, the horse going in the furrow between them, and of courfe does not tread upon the ground intended to be fawn; which with a fingle drill-mufi be the cafe, and does much harm by the horfes feet sinking and making holes in the fine ground, which retain the water, and hurt the wheat when young.

He proceeds to obferve, "That having read Mr Forbes upon the extensive practice of the new husbandry, and some other authors, who gave a more clear and definite account of the different operations in drill­ing than had herefore been given, I wished to try them, and to adapt my plough to fow the quantities therein directed. It was, however, adjusted to fow a smaller quantity, and the feed was not fpeeled.

"Not having ground fo proper as I wished, it was dril­led on the fide of a field, the foil of which was light and fandy, and in fuch bad order, that the preceding crop was a very indifferen't one. It was therefore man­ured with a compoft dung-hill.

"After cros-ploughing and manuring, it was laid into four and a half feet ridges, then harrowed and drilled with one peck and a half of wheat on an acre and a quarter, which is nearly one peck and a fifth per English acre. It was dril­led the 27th of October, and rolled after drilling. The crop was late in its appearance, and very backward in the spring."

A G R I C U L T U R E.

Part II.

March 31st, it was horse-hoed one furrow from the rows.

April 8th, it was hand-hoed and weeded in the rows.

25th, horse-hoed again, laying a furrow back to the rows.

May 15th, hand-hoed the second time.

June 1st, horse-hoed from the rows.

July 14th, horse-hoed to the rows.

At this last hoing, as many of the carts were beaten down into the intervals by wind and rain, a man went before the horse-hoe, and turned the ears back

bufhels and such dung.

found to be right. But

The land adjoining was sown with beans and peas, which were a good advantage without manure.

As the produce appeared so great, from land in such bad order, it was carefully measured again, and known to be right. But this increase, though great, was not so large as Mr. Crake of Glasgow had without dung.

Mr. Randal says, *It is an experimented fact, that on a fine loam excellently prepared, 144 bushels have been produced from one acre. And, I believe, it is not known what the increase may be brought to in rich land by high cultivation.*

Some years since, I had beans dropt alternately with potatoes, at two feet distance in the rows, which were three feet apart, and ploughed in the intervals. The land adjoining was sown with beans and peas, which were a good crop; but those towns among the potatoes a better one. I pulled one stem of the beans planted with the potatoes, which had three branches rising from the bottom, and it produced 225 beans. In all the trials of drilled beans, most of the stems had two branches, with many pods upon each. From these and other instances, I believe it is not yet known to what increase grain may be brought by drilling, good cultivation, and manure.

Horse-hoeing is certainly preferable to close drilling or hand-hoeing; but the latter is superior to broadcast.

Horse-hoeing the full depth increases the crop, by making it tiller or branch more than it otherwise would do; and the advantage is distinctly observable every hoeing, by the colour of the grain. It prepares the ground for the next crop, at the same time that it increases the crop growing, which hand-hoeing does not, although it may destroy the weeds. Thus drilled ground is kept in a loose open state, to receive the benefit of the influence of the air and weather, which broadcast has not; and it is evident, from certain experience, that crops may be drilled many years to good advantage without manure.

Suppose the crops only 20 bushels per acre, what course of broadcast crops will give 51. an acre for the course? But suppose they are dunged the same as any ground in the most approved course, there is the greatest reason to expect as much as in the above experiment, which is 28 and three-quarters, and at 5s. per bushel amounts to 71. 3s. 9d.

Calculations may be of service to those who wish to try drilling, and have few books to direct them.

*One acre is 10 chains long, of 660 feet, or 220 yards long, and one yard broad, containing 4840 square yards. Then if the ridge is four feet six inches, this makes 14 ridges, and three feet to spare. This length of 220 yards, multiplied by 14 (the number of ridges) gives a length of yards 3080, to which add 146 for the spare three feet, and it will be 3226 yards. And as two rows are drilled on a ridge, the number of rows will be in length 6452 yards; but as a deduction of 172 yards must be made for the head ridges, suppose three yards each, &c. The whole length to be sown will be 6280 yards clear. Now a gallon (Winchester) holds about 80,000 grains. The quantity recommended to be drilled by Mr. Forbes and others, being six gallons, or two-thirds of a bushel per acre, is nearly 78 grains to a yard, or 26 to a foot. But in my experiment, by this calculation, it was only about 11 grains to a foot; which is quite sufficient, if the feed be good, and it be not destroyed by vermin.*

Now with regard to the quantity of land this drill-plough may sow, if a horse walks at the rate of two miles per hour, he goes 16 miles in eight hours, or 28,460 yards. As he sows two ridges at once, this is seven lengths and two-thirds per acre, or 1686 yards to sow an acre, being nearly 17 acres in a day.

Four horse-hoeings are calculated equal to two ploughings. In plain ploughing they suppoze the ridge is ploughed with four furrows, or eight for twice ploughing. The four horse-hoeings are eight furrows, equal to two ploughings.

Mr. Tull directs four hoeings, and Mr. Forbesfive. First, in November, when the plant has four blades. 2dly, in March, deep, and nearer the rows than the former; both these hoeings should be from the rows. 3dly, Hand-hoed when it begins to spindel, if the earth be crumbly, to the rows. 4thly, When it begins to blossom, from the rows, but as near to them as in the second hoing. 5thly, When done blooming, to ripen and fill the grain, to the rows.

The night hoeing Mr. Tull does not direct, but Mr. Forbes advises it, as being of essential service in filling the grain, and saving trouble in making the next feed-furrows. They advise the patent or sowing-plough for horse-hoeing; and the expense is calculated by Mr. Crake at one guinea per acre, reaping included.

*But let us suppoze the following, which are the prices in the country I live in (Fife).*

Whole expense per acre, | - | 1 | 2 | 6 |

Drill husbandry is, as a good writer has justly defcrib'd, *the practice of a garden brought into the field.*

Every man of the least reflection must be sensible, that the practice of the garden is much better than that of the field, only a little more expensive; but if (as is the case in the most particular farms) this extra expense be generally much more than repaid by the superior goodness and value of drilled crops, it ought to have no weight in comparing the two modes of husbandry.
In the broadcast method the land is often sown in bad tilth, and always scattered at random, sometimes by very unskilful hands. In drilling, the land must be in fine order; the seed is set in trenches drawn regularly, all of nearly an equal depth, and that depth suited to the nature of each kind of seed. These seeds are also distributed at proper distances, and by being equally and speedily covered, are protected from vermin and other injuries; so that the practice of the garden is here exactly introduced into the field.

In the broadcast method the feed falls in some places too thick, in others too thin; and being imperfectly covered, a part of it is devoured by vermin which follow theower: another part is left exposed to rain or frost, or to heats, which greatly injure it. When harrowed, a great part of it (small seeds especially) is buried too deep, that if the soil be wet, it perishes before it can vegetate.

Again: When thus sown there is no meddling with the crop afterwards, because its growth is irregular. The soil cannot be broken to give it more nourishment, nor can even the weeds be destroyed without much inconvenience and injury.

But in the drill-husbandry the intervals between the rows, whether double or single, may be handled; and thereby nourishment may repeatedly be given to the plants, and the weeds almost totally destroyed.

The very same effects which digging has upon young flubs and trees in a garden, will result from horse-hoeing in a field, whether the crop be corn or pulse:

For the reason of the thing is the fame in both cafes, and being founded in nature and fact, cannot ever fail.

In drilling, no more plants are raised on the soil than it can well support; and by dividing and breaking the ground they have the full advantage of all its fertility.

The plough prepares the land for a crop, but goes no further; for in the broadcast husbandry it cannot be used: but the crop receives greater benefit from the tillage of the land by the horse-hoe, while it is growing, than it could in the preparation. No care in tilling the land previous to sowing can prevent weeds rising with the crop; and if these weeds be not destroyed while the crop is growing, they will greatly injure it. In the broadcast husbandry this cannot be done, but in drilling, the horse-hoe will effect it easily.

And what adds to the farmer’s misfortune is, that the most pernicious weeds have roots winged with down, which are carried by the wind to distant distances; such are thistles, sow-thistles, clover-foot, and some others.

If the expense of horse-hoeing be objected, there are two answers which may very properly be made: The first is, that this expense is much less than that of hand-hoeing were it practicable, or of hand-weeding. The second is, that it is more than repaid by the quantity of seed saved by drilling; to say nothing of the extra quantity and goodness of the crops, which are generally self-evident.

Upon the whole: If the particular modes of cultivating land by the new husbandry should, after all, be considered as perhaps too limited to be universally adopted; yet it has been of great use in raising sufficient concerning the old method, and in turning the views of philosophers and farmers towards improving in general. Many real improvements in agriculture have been the consequences of these sufficiencies; and as this spirit of inquiry remains in full vigour, a solid foundation is laid for expecting still further improvements in this useful art.
A GRIGENTI, speedily back to their old connections. But as if it had been decreed that all friendship should be fatal to their repute, the reconciliation and its effects drew up on the anger of the Carthaginians. By this enemy their cities were routed, their city taken, their race almost extirpated, and scarce a vestige of magnificence was left. Agrigentum lay 50 years buried under its own ruins; when Timoleon, after triumphing over the Carthaginians, and restoring liberty to Sicily, collected the descendants of the Agrigentines, and sent them to re-establish the dwellings of their forefathers. Their exertions were rewarded with astonishing success; for Agrigentum rose from its ashes with such a renewal of vigour, that in a very short time we find it engaged in the bold scheme of feizing a lucky moment, when Athagocles and Carthage had reduced Syracuse to the lowest ebb, and arrogating to itself supremacy over all the Sicilian republics. Xenodicus was appointed the leader of this arduous enterprise; and had his latter operations been as fortunate as his first campaign, Agrigentum would have acquired such a preponderance of reputation and power, that the rival states would not even have dared to attack it. But a few brilliant exploits were succeeded by a severe overthrow; the Agrigentines loft courage, disagreed in council, and humbly sued for peace when he left Sicily to the mercy of her enemies, a period very little mention of it occurs in the history, nor do we know the precise time of the Saracens. The principal part of the ancient city lay in the vale; the present town, called Girgenti, occupies the mountain on which the citadel of Coeclus stood. It was difficult to be more judicious and fortunate in the choice of situation for a large city. The inhabitants were here provided with every requisite for defence, pleasure, and comfort; a natural wall, formed by abrupt rocks, prevented a strong barrier against intruders; pleasant hills sheltered them on three sides without impeding the circulation of air; before them a broad plain watered by the Acragas, gave admissitance to the sea-breeze, and to a noble prospect of that awful element; the port or emporium lay in view at the mouth of the river, and probably the road across the flat was lined with gay and populous suburbs. The hospitality and parade for which the Agrigentines are celebrated in history were supported by an extensive commerce: by means of which, the commonwealth was able to reift many shocks of adversity, and always to rise again with fresh splendour. It was, however, crushed by the general fall of Grecian liberty; the feeble remnants of its population, which had survived so many calamities, were at length driven out of its walls by the Saracens, and obliged to lock themselves up for safety among the bleak and inaccessible rocks of the present city. At the north-east angle of the ancient city, upon some foundations of ancient regular stones, a church has been erected; a road appears hewn in the solid rock for the convenience of the votaries that visited this temple in ancient days. It was then dedicated to Cerers and her daughter Proserpine, the peculiar patronesses of Sicily. Bishop Blafse has succeeded to their honours. At the fifth-east corner, where the ground, rising gradually, ends in a bold eminence, which is crowned with majestic columns, are the ruins of a temple said to have been consecrated to Juno. To the west of this, stands the building commonly called the Temple of Concord; the stone of which, and the other buildings, is the fame as that of the neighbouring mountains and cliffs, a conglutination of sea-land and shells, full of perforations, of a hard and durable texture, and a deep reddish brown colour. This Doric temple has all its columns, entablature, pediments, and wall entire; only part of the roof is wanting. It owes its preservation to the piety of some Christians, who have covered half the nave, and converted it into a church consecrated under the invocation of St Gregory, bishop of Girgenti. Proceeding in the same direction, you walk between rows of sepulchres cut in the rock wherever it admitted of being excavated by the hand of man, or was so already by that of nature. Some mafles of it are hewn into the shape of coffins; others drilled full of small square holes employed in a different mode of interment, and serving as receptacles of urns. One ponderous piece of the rock lies in an extraordinary position; by the failure of its foundation, or the shock of an earthquake, it has been loosened from the general quarry, and rolled down the declivity, where it now remains upright with the cavities turned upwards. Only a single column marks the confufed heaps of mofs-grown ruins belonging to the temple of Hercules. It flows on a projecting rock above a chasm in the ridge, which was cut through for a passage to the emporium. In the same track, over some hills, is founded the building usually called the tomb of Thero. It is surrounded by aged olive-trees, which cast a wild irregular shade over the ruin. The edifice inclines to the pyramidal shape, and consists at present of a triple pilum and a base supporting a square pedestal: upon this plain solid foundation is reared a second order, having a window in each front, and at each angle two Ionic pilasters crowned with an entablature of the Doric order. Its inside is divided into a vault, a ground room, and one in the Ionic style, communicating with each other by means of a small internal staircase. In the plain are seen the fragments of the temple of Ecualius; part of two columns and two pilasters, with an intermediate wall, support the end of a farmhouse, and were probably the front of the cells. Pursuing the track of the walls towards the west, you arrive at a spot which is covered with the gigantic remains of the temple of Jupiter the Olympian, minutely described by Diodorus Siculus. It may literally be said that it has not one stone left upon another; and it is barely possible, with the help of much conjecture, to discover the traces of its plan and dimensions. Diodorus
AGRIMONY (Agrimonia) is a genus of the dicinga order, belonging to the dodecandra clafs of plants, and in the natural method ranking under the 35th order, Senticeae. The characters are thefe: The calyx is a monophyllous perianthium, divided into five acute fragments, perifcent, and fcccaded with another calyx: The corolla consists of five petals, flat, and cre­nated at the ends: The faminae have ten capillary tils­ments, shorter than the corolla, and inferted into the calyx; the anthers are small, didymous, and compre­fled; the stigminas have a germcn beneath; the flfli are two, fimple, and the length of the flamina: There is no pericarpium; the calyx is contracted in the neck, and indurated: The feeds are two, and roundish. Of this genus there are five fpecies enumerated by botani­
cal writers; but none of them have any remarkable Agrimony properties except the two following.

Species and properties. 1. The eupatoria, or com­mon agrimony, grows naturally in several parts of Brit­ain by the sides of hedges and of woods. It is much of a usual occafiion, but when fed with bread and wine. The Canadians are said to have known the inftation of the root in burning furners with great success. An infiuation of six ounces of the crown of the root in a quart of boiling water, sweetened with honey, and if a pint of it drank three times a-day, is an effectual cure for the jaundice, according to Dr Hill. He advifes to begin with a vomit, afterwards to keep the belly soluble, and to continue the medicine as long as any symptoms of the difeafe remain. It is said to be an aperient, detefier, and strengthener of the vifera.

Hence it is recommended in fcroburn disoders, in de­bility and laxity of the interines, &c. Digefed in whey, it affords an ufeful diet-drink for the spring­feafon, not ungrateful to the palate or stomac h. Doc­tor Allton fays, that the beft mode of adminiftering this herb is in powder, when the intention is to cor­rororate; and that if thus taken in a large quantity, we may expect many of the eftects of the bark from it in agues.

2. The odorata, or sweet-feented agrimony. This grows near four feet high; the leaves have more pinea than the former; the ferratures of the leaves are also sharper, and, when handled they emit an agreeable odour. The leaves of this fpecies make an agreeable cooling tea, which is fometimes preferred by phy­ficians as a drink for people in fevers.

Culture. Both offe fpecies may be propagated ei­ther by seed, or by parting the roots in autumn when the leaves begin to decay. The seeds ought alfo to be fown in this feafon; for if kept out of the ground till spring, they seldom come up that year.—Agrimony is a hardy perennial plant, and will thrive in almost any foil or fitation; but the plants should not be placed nearer one another than two feet, that the roots may have room to spread.

HEMP Agrimony. See Eupatorium.

WATER HEMP. Agrimonia. See Byrns.

AGRIONIA, in Grecian antiquity, feiftivals an­nually celebrated, by the Borotians, in honour of Bacchus. At thofe feiftivals, the women pretended to fearch after Bacchus as a fugitive; and, after some time, gave over their inquiry, faying, that he was fed to the Mufes, and was concealed among them.

AGRIOPHAGI, in antiquity, a name given to thofe who fed on wild beafis. The word is Greek, compounded of agrion "wild," "favage," and opho- "I eat." The name is given, by ancient writers, to certain people, real or fabulous, faid to have fed alo­gether on lions and panthers. Pliny and Solinus speak of Agriophagi in Ethiopia, and Pol每位 of others in India on this fide the Ganges.

AGRIPPA, in midwifery, a term applied to chil­dren, brought forth with their feet foremost.

AGrippa (Herod), the fon of Arifobulus and Mariamne, and grandson to Herod the Great, was born in the year of the world 3997, three years before the birth of our Saviour, and seven years before the vulgar era. After the death of Arifobu­
us his father, Josephus informs us, that Herod his
grandfather took care of his education, and sent him
to Rome to make his court to Tiberius. The
emperor conceived a great affection for Agrippa, and
placed him near his son Drusus. Agrippa very soon
won the graces of Tiberius, and of the emperor An-
tonia. But Drusus dying suddenly, all those who
had been much about him were commanded by Tibe-
rius to withdraw from Rome, lest the sight and pref-
ce of them should renew his affliction. Agrippa,
who had indulged his inclination to liberality, was ob-
liged to leave Rome overwhelmed with debts, and in
a very poor condition. He did not think it fit to go
to Jerusalem, because he was not able to make a figure
there suitable to his birth. He therefore went to
Rome to take his freedom, and presented himself
and grandson of Antonia, who had married Herodias
for some time with great generosity. He made him
of Agrippa; so that Herod
had accepted of the charge of historiographer to the empe-

rator.

A Gr [329]

AGRIPPINA, daughter of Germanicus, sister of Caligula, and mother of Nero, a woman of wit, but excessively lewd. She was twice married, the last time to Claudius her own uncle; whose the prompting to make way for Nero her son, Nero afterward caused her to be murdered in her chamber, when the bid the executioner flab her first in the belly that had brought forth such a monster.

AGrippina colonia urborum (anc. geog.), now Cologne: so called from Agrippina, the daughter of Germanicus, and mother of Nero, who had a colony set thither at her request by the emperor Claudius, to the place of her birth. See Cologne.

AGrippinians, in church-history, the followers of Agrippina bishop of Carthage, in the third century, who first introduced and defended the practice of re-baptism.

AGROM, a disease frequent in Bengal and other parts of the Indies, wherein the tongue chaps and cleaves in several places, being extremely rough, and sometimes covered with white spots. The Indians are very fearful of this disease, which they attribute to extreme heat of the stomach. Their remedy is, to drink the juice of mint.

AGrostema, Wild Lynchis, or Campion: A genus of the pentagynia order, belonging to the dendrania class of plants; and in the natural method ranking under the 22d order, Caryophyllis. The characters are: The calyx is a single-leaved perianthium, leathery, tubular, quinquedentated, and pellucid. The corolla consists of five ungulate petals: The flamina has ten filiform filaments; the anthers are simple: The pistillum has an egg-shaped germenis; the style are five, filiform, erect, and the length of the flamina. The filaments are simple: The pericarpium is an oblong covered capsule, having two cells and five valves: The seeds are numerous and kidney-shaped; the receptacula are as many as the seeds, the interior ones gradually longer.

Species. The most remarkable are, 1. The githago, hairy wild lychins, or common campion, which grows naturally in corn-fields in most parts of Britain. The flowers appear in June, are generally purple, sometimes white, and by cultivation yellow.

2. The coronaria, or single-robe campion. Of this species there are four varieties; one with deep red, another with white, another with purple, and a third with white flowers; and a fort with double flowers, which has turned most of the others out of the gardens.

3. The flos jovis, or umbelliferous mountain-campion, grows naturally upon the Helvetican mountains. It is a low plant with woolly leaves: the flower-flum rifes near a foot high; the flowers grow in umbels on the top of the stalk, and are of a bright red colour. They appear in July, and the seeds ripen in September.

Culture. The first and third species are annual plants, so must be propagated by seeds; but as the first is found naturally in corn-fields, it is very seldom cultivated in gardens; the third sort should have a shady situation, and thrives best in a strong soil. The second species is perennial, but only those varieties which have double flowers produce any seeds; the double kind, therefore, as it produces no seeds, must be propagated by parting the roots in autumn, after the flowers are past. In doing this, every head which can be clipped off with roots should be parted; these should be planted in a border of fresh, unturned earth, at the distance of six inches one from the other, observing to water them gently until they have taken root; after which they will require no more; for much wet is very injurious to them, as is also dung. In this border they may remain till spring, when they should be planted in the borders of the flower-garden, where they will be very ornamental during the time of their flowering, which is in July and August. This plant is cat by hores, goats, and sheep.

AGrostis, Bent-grass, in botany: A genus of the eriogonum order, belonging to the digynia class of plants; and, in the natural method, ranking under the 4th order, Gramina. The characters are: The calyx is a one-flowered, two-valved, pointed gluma, rather less than the corolla. The corolla is two-valved and pointed. The flaminae have three capillary filaments, which are larger than the corolla. The anthere are forked. The pistillum has a roundish germenis; the style are two, reflected, and villous: the stigma bifid longitudinally. The pericarpium is the corolla growing to the seed, not gaping. The seed is one, globular, and pointed at both ends. There are 15 species; eight of them natives of Britain.

AGrostographia, signifies the history or description of grasces. See Grass.

Agrround, the situation of a ship whose bottom, or any part of it, hangs, or rests upon the ground, so as to render her immovable, till a greater quantity of water floats her off, or till ice is drawn out into the stream by the application of mechanical powers.

AGryphia, among physicians, implies an inaptitude to sleep, a troublesome symptom of feverish and other disorders.

AGYPhia, in the Greek church, implies the vigil of any of the greater festivals.

Agu, a general name for all periodical fevers, which, according to the different times of the returns of the six cold paroxysms, are denominated tertian, quartan, and quinquat; See Medicine (Index).

Agu-Gate, the popular name for a hard tumour on the left side of the belly, lower than the falle ribs, said to be the effect of intermitting fevers.

Agu Tree, a name given to the fatasfars, on account of its febrifuge qualities.

Agüéprise, a town of France, situated on the Rhone, about 15 miles north of Clermont.

Aguillaneuf, or Aguillaneuf, a form of rejoicing used among the ancient Franks on the first day of the year. The word is compounded of the French A"cro" guu" millet," and I'an neuf "the new year." Its origin is traced from a druid-ceremony: the priests used to go yearly in December, which with them was reputed a sacred month, to gather millet of the oak, and throw it in great solemnity. The prophets marched in the front, singing hymns in honour of their deities.
A G U

AGURAH, in Jewish antiquity, the name of a Agurah, silver coin, otherwise called gorah and keseitha.

AGURIM, or AGERVUM (anc. geogr.), a town of Sicily in the Val di Demona, near the river Semtau. The people were called Populai Argeriam and Agurina by Pliny. It was the birth-place of Diodorus Siculus, as he himself testifies; but he calls Agryrum, as it is now called S. Filippo d'Agirone, which modern name seems to confirm that Agryrum is the true reading.

AGUSADURA, in ancient customs, a fee due from vassals to their lord for the harpooning their ploughing tackle. Anciently the tenants in some manors were not allowed to have their rural implements harpooned by any but whom the lord appointed; for which an acknowledgment was to be paid, called Agusadura, in some places Agysage: which some take to be the same with what was otherwise called Reillage, from the ancient French reille, a ploughshare.

AGUTT, in zoology, the trivial name of a species of the mole, belonging to the mammalia grises of Linnæus. See Mus.

AGYEI, in antiquity, a kind of obelisks, sacred to Apollo, erected in the vestibule of houses, by way of security.

AGYNIANI, in church-history, a sect who condemned all use of flesh, and marriage, as not instituted by God, but introduced at the instigation of the devil. The word is compounded of the privative ene and woman. They are sometimes also called Agynenfer, and Agynos, and are said to have appeared about the year 694. It was no wonder they were of no long continuance. Their tenets coincide in a great measure with those of the Abellians, Gnostics, Cerdonians, and other preachers of chaffity and abstinence.

AGYRTA, in antiquity, a kind of strolling impostors running about the country, to pick up money by telling fortunes at rich men's doors, pretending to cure diseases by charms, sacrifices, and other religious mysteries; also to expiate the crimes of their deceased ancestors, by virtue of certain oaths and fummonages; to torment their enemies, by the use of magical verbes and the like. The word is Greek a gynaie, formed of the verb a gynen, I congregate; alluding to the practice of Charletons, who gather a crowd about them.

AGYRTA, among the Greeks, amount to the same with Ersercatere among the Latins, and differ not much from Gypsies in Britain.

AHAB, son of Omri, king of Israel, succeeded his father A. M. 3086, and surfeited all his predecessors in iniquity and wickedness. He married Jezebeth the daughter of Ethbaal king of the Sidonians, who introduced the idols of Baal and Ashtore among the Israelites, and engaged Ahab; in the worship of these false deities. God, being provoked by the sins of Ahab, sent the prophet Elijah to him (1 Kings xvii. 1, seq.) who declared to him, that there would be a famine of three years continuance. The dearth having lasted three years, the prophet defied Ahab to gather all the people to mount Carmel, and with them the prophets of Baal: when they were thus assembled, Elijah cawed fire from heaven upon his sacrifice, while all which he offered of God that it should rain; and then the earth recovered its former fertility.

Six years after this, Ben-hadad king of Syria (chap. [XX. .

AGUILAR, a town of Spain, in the province of Navarre, about 24 miles west of Estella. Aguilarr Del Campo, a town of Old Castile, with the title of marquifate, about 15 leagues north of the city of Burgos.

AGUILONIUS (Francis), a Jesuit, born at Brussels; he was rector of the Jesuits college at Antwerp, and eminent for his skill in mathematics. He was the first who introduced that science among the Jesuits in the low countries: he wrote a book of Optics, and was employed in finishing his Optics and Dioptrics, when death prevented him in 1617.

AGUIRA (Joseph Senez de), a Benedictine, and one of the most learned men in the 17th century, was born March 24, 1630. He was censor and secretary of the supreme council of the inquisition in Spain, and interpreter of the scriptures in the university of Salamanca. He printed three volumes in folio upon Philology, a commentary upon Aristotle's ten books of Ethics, and other pieces. He died at Rome Augut 19, 1699.

AGUL, in botany, a synonyme of the hedyarum. See HEDYARUM.

AGUR. The xxxth chapter of the Proverbs begins with this title: "The words of Agur, the son of Jakeh," which, according to the signification of the original terms, may be translated, as the Vulgate has it, Verba congregantis, filii comomens; which translation Le Clerc condemns, supposing these to be proper names, which ought not to be translated. These words are rendered by Lewis de Dieu: "The words of him who has recollected himself, the son of obedience." The generality of the fathers and commentators will have it, that Solomon describes himself under the name of Agur the son of Jakeh; others conjecture that Agur, as well as Lemuel (in chap. xxxi. 1.) were wise men who lived in the time of Solomon, and were his interlocutors in the book of Proverbs; an opinion which F. Calmet thinks is without the least shew of probability, this book being nothing like a dialogue. This last expeditor thinks it probable, that Agur was an inspired author different from Solomon, whose sentences it was thought fit to join with those of this prince, because of the conformity of their matter.

AGULLAR, a town of Spain, in the province of Navarre, about 24 miles west of Estella. AGULLAR DEL CAMPO, a town of Old Castile, with the title of marquise, about 15 leagues north of the city of Burgos.

AGULLONIUS (Francis), a Jesuit, born at Brussels; he was rector of the Jesuits college at Antwerp, and eminent for his skill in mathematics. He was the first who introduced that science among the Jesuits in the low countries: he wrote a book of Optics, and was employed in finishing his Optics and Dioptrics, when death prevented him in 1617.

AGUILLA, in botany, a synonyme of the hedyarum. See HEDYARUM.

AGUR. The xxxth chapter of the Proverbs begins with this title: "The words of Agur, the son of Jakeh," which, according to the signification of the original terms, may be translated, as the Vulgate has it, Verba congregantis, filii comomens; which translation Le Clerc condemns, supposing these to be proper names, which ought not to be translated. These words are rendered by Lewis de Dieu: "The words of him who has recollected himself, the son of obedience." The generality of the fathers and commentators will have it, that Solomon describes himself under the name of Agur the son of Jakeh; others conjecture that Agur, as well as Lemuel (in chap. xxxi. 1.) were wise men who lived in the time of Solomon, and were his interlocutors in the book of Proverbs; an opinion which F. Calmet thinks is without the least shew of probability, this book being nothing like a dialogue. This last expeditor thinks it probable, that Agur was an inspired author different from Solomon, whose sentences it was thought fit to join with those of this prince, because of the conformity of their matter.
...xx.) laid siege to Jerusalem... But God, provoked at this proud Syrian, sent a prophet to Ahab, not only to assure him a victory, but to instruct him likewise in what manner he was to obtain it. Ahab was ordered to review the princes of the provinces, which he found to be a choice company consisting of 232 young men, who were to command the people in Samaria, amounting to about 7000 men: with this small army Ahab was directed to fall upon the great host of the Syrians, and that at noon-day, while Ben-hadad and the 32 kings that accompanied him were drinking and making merry. Ben-hadad having notice that they were marching out of the city, ordered them to be brought before him alive, whatever their designs were: but the young men, followed by this small army, advanced, and killed all that opposed them, such a panic seized the Syrian troops, that they began to fly; and even Ben-hadad himself mounted his horse and fled with his cavalry; which Ahab perceiving, pursued them, killed great numbers of them, and took a considerable booty. After this the prophet came to Ahab...
AHAZ, the son and successor of Ahab king of Israel, reigned two years, part alone and part with his father Ahab, who ordained him his associate in the government a year before his death. Ahaaz initiated his father's impieties (1 Kings xxii. 52, seq.), and paid his adoration to Baal and Ashtar, the worship of whom had been introduced in Israel by Jezebel his mother. The Moabites, who had been always obedient to the kings of the ten tribes ever since their separation from the kingdom of Judah, revolted after the death of Ahab, and refused to pay the ordinary tribute. Ahaaz had not leisure or power to reduce them (2 Kings i. 1, 2, &c.); for about the same time, the prophet Elijah went to Ahaaziah, and declared to him the evil that the Lord had declared he would bring upon his house for his impieties; but the prince, upon hearing the sound of her feet, said, "Come in, thou wife of Jeroboam, why feignest thou thyself to be another? for I am sent to thee with heavy tidings." Then he commanded her to go and tell Jeroboam all the evil that the Lord had declared he would bring upon his house for his impieties; that soon as she should enter into the city her son Ahaaziah should die, and should be the only one of Jeroboam's house that should come to the grave or receive the honours of a burial. Ahaaziah in all probability did not long survive the time of this last prophecy; but with the time and manner of his death we are not acquainted.

AHITOPHEL, a native of Gilo, was for some time the counsellor of king David, whom he at length deserted, by joining in the rebellion of Absalom. This prince, upon his being preferred to the crown by the greatest part of the Israelites, sent for Ahitophel from Gilo (2 Sam. xv. 12.), to assist him with his advice in the present state of his affairs: at that time Ahitophel's counsels were received as the oracles of God himself (chap. xvi. 4.). Nothing gave David more uneasiness than this event; and when Hushai his friend came to wait on him and attend him in his flight, he intreated him to return rather to Jerusalem, make a shew of offering his services to Absalom, and endeavour to frustrate the prudent measures which should be proffered by Ahitophel. When Absalom was come to Jerusalem, he desired Ahitophel to deliberate with his other counsellors upon the measures which were proper for him to take. Ahitophel advised him in the first place to abate his father's concubines; so that when his party should understand that he had dishonoured his father in this manner, they might conclude that there were no hopes of a reconciliation, and therefore eschew his interest more resolutely. A tent, therefore, being prepared for this purpose upon the terrace of the kings palace, Absalom, in the sight of all Israel, lay with his father's concubines. The next thing Ahitophel proposed was in the terms following: "Let me now choose out 12,000 men, and I will arise and pursue after David this night, and I will come upon him while he is weary and weak-handed, and I will make him..."
Ahu (chap. viii.) to march with the whole army of the Israelites against Ai, and treat this city and the kingdom thereof as he had treated Jericho, with this difference, that he gave the plunder of the town to the people. Joshua sent by night 30,000 men to lie in ambush behind Ai; having first well instructed those who had the command of them in what they were to do; and the next day, early in the morning, he marched against the city with the remainder of his army. The king of Ai perceiving them, fellied hastily out of the town with all his people, and fell upon the forces of the Israelites; who upon the first onset fled, as if they had been under some great terror.

As soon as Joshua saw the enemy all out of the gates, he raised his shield upon the top of a pike, which was the signal given to the ambush; whereupon they immediately entered the place, which they found without defence, and set fire to it. The people of Ai perceiving the smoke ascending, were willing to return, but discovered those who had set fire to the city before their rear, which had happened under the influence of Hushai's advice, and was determined to prevent the death which he had deserved, and which David would probably have inflicted on him, as soon as he should be reftitted on his throne.

Ahmella, in botany. See Bidens.

Aholibah and Aholah, are two feigned names made use of by Ezekiel (xxiii. 4.) to denote the two kingdoms of Judah and Samaria. Aholah and Aholibah are represented as two sisters of Egyptian extraction. Aholah flands for Samaria, and Aholibah for Jerusalem. The first signifies a tent; and the second, my tent is in her. They both prostituted themselves to the Egyptians and Assyrians, in imitating their abominations and idolatries: for which reason they were abandoned to those very people for whom they had shown so passionate and so impure an affection; they were carried into captivity, and reduced to the severest servitude.

Ahouai, in botany, a synonyme and also the trivial name of the species of Cerbera.

A-hull, in the sea-language, the situation of a skiff, for her fish are fished on account of the violence of the wind, and when having lathed her helm on the lee-tide, the lies nearly with her side to the wind and sea, her head being somewhat inclined to the direction of the wind.

Ahun, a town in France, in the Upper Marche and generality of Moulins, and is a royal jurisdiction. It is treated on the river Creufe, near a Benedictine abbey of the same name, eight miles south-east of Gueret, 50 north-east of Lomages, and 55 south-east of Moulins. E. Long. 2. 8. N. Lat. 49. 5.

Ahuy, a town of Sweden. It is small, but very strong by its situation, and has a good port. It is in the principality of Gotland, in the territory of Blekingy, near the Baltic sea, about 18 miles from Christianstad. E. Long. 14. 10. N. Lat. 56. 20.

Ai, (anc. geog.) a town in Judaea, to the north of Jericho, called Arz by Jophusas, and the inhabitants Anatar. Joshua having sent a detachment of 3000 men against Ai, God permitted them to be repulsed on account of Achan's sin, who had violated the anathema pronounced against the city of Jericho. But after the expiation of this offence, God commanded Joshua
AICUROU fed on several sorts of commodities, especially wine.

The governor's inner leg, inner rein, failed, wherein the Greeks had given the preference in his treatise of Dancing, and used to avoid the necessity of corrections. The inner heel, inner leg, outer rein, &c. are called inner aids; as the outer heel, outer leg, outer rein, &c. are called outer aids.

AIDS, in the French customs, certain duties paid on all goods exported or imported into that kingdom. Court of AIDS, in France, a sovereign court established in several cities, which has cognizance of all causes relating to the taxes, gabelles, and aids, imposed on several sorts of commodities, especially wine.

Ajans, in the manage are the same with what some writers call sheriffs, and used to avoid the necessity of corrections. The inner heel, inner leg, outer rein, &c. are called inner aids; as the outer heel, outer leg, outer rein, &c. are called outer aids.

AIDAN, a famous Scotch bishop of Lindisfarne, or Holy Island, in the 7th century, was employed by Oswald king of Northumberland in the conversion of the English, in which he was very successful. He died in 617.

AIGHENEDALE, the name of a liquid measure used in Lancashire, containing seven quarts.

AIGLE, a bailiwick in the territory of Romand, consists of mountains and valleys, the principal of which are the Aigle and Bex. Through these is the great road from Vaillais into Italy. When you pass by Villeneuve, which is at the head of the lake of Geneva, you enter into a deep valley three miles wide, bordered on one side by the Alps of Switzerland, and on the other with the shores of Savoy, and crossed by the river Rhone. Six miles from thence you meet with Aigle, a large town, seated on a wide part of the valley, where there are vineyards, fields, and meadows. The governor's castle is on an eminence that overlooks the town, and has a lofty marble tower. This government has nine large parishes; and is divided into four parts, Aigle, Bex, Olon, and Ormont. This last is among the mountains, and joins to Rougemont. It is a double valley, abounding in pasture-land. Iviron, in the diocese of Aigle, was in part buried by the fall of a mountain occasioned by an earthquake in 1584.

AIGLE, a small town, in France, in Upper Normandy, twenty-three miles from D'Evereux, and thirty-eight from Rouen. It is surrounded with walls and ditches, has six gates, three suburbs, and three parishes. It trades in corn, toys, and more particularly in needles and pins. E. Long. 1°. N. Lat. 49°. 45'.

AIGUILLON, a small town in France in the province of Guienne, situated at the confluence of the rivers Garonne and Lot.
AILUTSC, in heraldry, denotes a crofs with its four ends sharpened, but so as to terminate in obtuse angles.—It differs from the crofs fitchee, in as much as the latter tapers by degrees to a point, and the former only at the ends.

AILANA, AILATH, or AHELOTH, anciently a town of Arabia Petraea, situated near the Sinus Eilatites of the Red Sea. It was also called Elath, and Eloth, (Stephanus, Strabo, Moles.) The fame with Eilana.

AILE, in law, a writ which lies where a person's grandfather, or great-grandfather, being feized of lands, &c. in fee simple, the day that he died, and a stranger abates and enters the same day, and dispossesses the heir of his inheritance.

AILLESBURY, AYLESBURY, or ALESBURY, a borough town in Buckinghamshire, consisting of about 400 houses. It consists of several streets, though the houses are not very contiguous: the ftreel round about the market-place, in the middle of which is a convenl hall, where the fuch as are held, and form one of the ftreets for the county. It fends two members to Parliament: has a market on Saturdays: and three fairs for cattle, viz. on the Saturday before Palmfunday, June 14th, and September 25th. It is sixty miles south-east of Buckingham, and forty-four north-west of London. W. Long. 0.40. N. lat. 51.40.

AILMER, or ÆTHELMARE, Earl of Cornwall, and Devonshire, in the reign of king Edgar. It is not known of what family he was. His authority and wealth were great, and so also in appearance was his piety. He founded the abbey of Cerne, in Dorsetfure; and had so great a veneration for Edward, the brother of St Edmund the martyr, who had lived a hermit in that country, near the silver well, as they called it, that, with the affiilance of Archbishop Dunstan, he translated his relics to the old church of Cerne. In 1016, when Canute, the fon of Sweine, invaded England, and found himself foutly oppoled by that valiant Saxon prince Edmund Ironfide, the fon of Æthelred, the Earl Ailmer, with that arch traitor Eadric Streone, Earl of Mercia, and Earl Algar, joined the Dane againft their natural prince, which was one great caufe of the Saxons ruin. He did not long survive this: and we find mentioned in history only one fon of his, whose name was Æthelward, Earl of Cornwell, who followed his father's maxims, and was properly rewarded for it. For in 1018, Canute reaping the benefit of their treasons, and perceiving that the traitors were no longer ufeul, he caused the infamous Eadric Streone, and this Earl Æthelward, to be both put to death.

AILRED, or EALRED, abbot of Revelcy in Lincolnshire, in the reigns of Stephen and Henry II. He was born in 1169, of a noble family, and educated in Scotland with Henry the fon of king David. On his return to England, he became a monk of the Cifterian order, in the monastery of Revelcy, of which he afterwards was made Abbot. He died on the 12th of January 1166, aged 57, and was buried in his monaftery. “He was (fays Leland) in great esteem during his life; celebrated for the miracles wrought after his death; and admitted into the catalogue of saints.” He was author of several works; most of which were published by Gilbo the Jefuit at Douay, 1631; part of them may be also found in the Bibliotheca Cifterciensis and Bibliotheca Patrum. His principal work is the Speculum charitatis. Leland, Bale, and Pits, mention several manuscripts which were never published.

AILSA, an infufled rock on the western coast of Scotland, between the shores of Airthire and Cantyre. It is two miles in circumference at the base, is accessible only at one place, and rises to a great height in a pyramidal form. A few goats and rabbits pick up a subsistence among the short grasfs and furze; but the importance of the rock consists in the great variety and boundless numbers of birds, by which it is frequented, particularly the gannets and solan-geese, whose young are fed at the beft tables, and bring a good price. Other birds are caught for their feathers. The rock is rented from the Earl of Caflis at L. 33 per annum. The depth of the water around the base is from 7 to 48 fathoms. It is surrounded with excellent banks, well flocked with cod and other white fishes.

AIRNSWORTH (Th. A), a eminent nonconformist divine, who, about the year 1590, distinguished himself among the Browniffs; which drew upon him such troubles that he was obliged to retire to Holland, and became minister of a church at Amsterdam. His skill in the Hebrew language, and his exellent Annotations on the Holy Scriptures, which are still highly esteemed, gained him great reputation. He also wrote several pieces in defence of the Browniffs, and several other works.

AIRNSWORTH (Robert), born at Woodyale in Lancashire in 1660, was master of a boarding-school at Bithnal-green, from whence he removed to Hackney, and to other places in the neighbourhood of London. After acquiring a moderate fortune, he retired, and lived privately till the time of his death, which happened in 1743. We are indebted to him for the best Latin and English Dictionary extant, he published it in quarto 1736; and in 1752, the fourth edition, under the care of Doctor Ward of Grefham, College, and the Rev. William Younge, was enlarged to two vols folio.

AIR, in natural philosophy, a thin fluid, claflic, transparent, ponderous, comprefisible, and dilatable. It is such a fluid, that, when it is feparated from the earth, it may expand its bounds without any limits; and, being confined, do not abatement of any of its qualities. It is observable, that air thus qualified can affefl the vertigoes, and other nervous affections; and after taking cold, it is evident, the air can enter with all its powers into the colics, fluxes, coughs, and consumptions produced by damp, moth and nitrous air, it is evident it can corrupt and spoil the noble organs, &c.

Circulation of AIR in Rooms. To render the circulation of air fensible, let the air of a room be heated by a strong fire, whilst the air of a contiguous room is cold; then let the door between the two rooms be opened, in which cafe the hot air of one room being lighter, will pass through the upper part of the opening of the door into the cold room: and, on the contrary, the cold...
Air of the other room being heavier, will pass into the former room through the lower part of the opening; accordingly, it will be found, that applying a lighted candle at the top, in the middle, and at the lower part of the opening between the two rooms, a strong current of air will appear to pass from the hot into the cold room near the top; a contrary current of air will appear to pass from the latter into the former room near the lower part of the said opening; whilst in the middle there is little or no motion at all, as may be clearly perceived by the direction of the flame of the candle.

It is for the same reason that when the fire is lighted in a chimney, a strong current of air is occasioned to enter the room, which may be felt by applying the hand near the key-hole, or other such small openings, if the doors and windows are shut; for the air over the fire being heated, becomes lighter, and ascends into the chimney, consequently other colder air must supply its place, which forces its way through all the small openings it can find. Were a room with a fire in it to be perfectly closed, excepting the chimney, the air in it would soon become unwholesome for respiration, and the fire would be soon extinguished, besides other inconveniences. Hence it appears, that those persons mistake who expatiate to keep the air of a room sweet and wholesome, especially for convalescents, by accurately stopping all the smallest openings that admission of air. When the current of air that enters into a room is on some side of it where it falls immediately upon the persons who sit in the room, then it may be offensive, especially to delicate constitutions. In that case, such opening should be closed; but at the same time another opening should be made for admitting fresh air, in another more convenient part, for a circulation of air, especially in rooms where a fire is kept, is not only salutary and useful, but is absolutely necessary.

In an ingenious publication, intitled, A Practical Treatise on Chimneys, there are the following remarks relating to the proper method of admitting air into a room, and of expelling the contaminated air. The author, directing to make a vent-hole near the top of the room, in order to expel the heated and contaminated air, "this," says he "might be done by means of a small tube opening into the room, either in or near the ceiling; which might either be carried to the top of the building, or be made to communicate with the external air by a small perforation through the wall at the roof of the room; by means of either of which, a proper circulation would be established, and the foul air be carried off."

For the fire would no sooner have warmed any particles of air within the room, than these would be greatly expanded, and rise immediately upwards, so as to fill the higher parts of the room with rarefied air; and as other particles would be successively heated and rarefied in their turn, by their expansive force they would press upon the sides of the apartment in every place, so as to force the lightest particles through the opening left for that purpose in the top of the room; by which means the foulest air would be gradually drawn off, without deceasing again into the lower regions to the annoyance of the company. But in order to admit fresh air into the room, "Let," says he, "another opening be made in the ceiling of the room, having a communication with a small pipe that should lead from thence either to the outside of the wall, or to any other part of the building that might be judged more convenient, where it should be bent, and conducted downwards, till it reached the ground, where it should be left open, to communicate with the external air. In this situation the cool external air would be forced in at the lower opening of the tube, and made to ascend into the apartment in proportion to the quantity that escaped towards the higher regions by means of the ventilator. And as that weighty air would no sooner enter the room, that it would tend towards the floor by its own natural gravity; it would gradually mix with the heated air in its descent—become, in some measure, warmed by that means, and equally dispersed through the room, so as slowly and imperceptibly to reach the candles and the company in the room, and supply them with a sufficient quantity of fresh and wholesome air, without the inconveniences to which the company are subjected by the usual way of admitting fresh air (A). For if it enters near the floor of the apartment, it is hurried along in a rapid undivided stream towards the fire-place, and striking upon the legs and inferior parts of the body, afflicts them with a strong sensation of cold. To overcome the effects of this, large fires must be kept; by which other parts of the body are exposed to an extraordinary degree, which is productive of most of those disorders that are pernicious to the young, and often prove fatal to the old, during the winter season, in those cold regions.

Thus might our apartments be kept constantly, and moderately, and equally warm, at a moderate expense, without endangering our health on the one hand, by respiring a confined, stagnant, and purrid air, or, on the other hand, by subjecting ourselves to such danger of catching colds, consumptions, and rheumatic complaints, by being exposed to such exceedingly unequal

(A) Such readers as have been little acclimated to speculations of this sort, will be at a loss to comprehend in what manner two holes, both of them in the roof the room, and communicating with the air, without any valve, or other contrivance, for opening or closing of themselves, should yet answer the two very opposite purposes; one, of constantly bringing cool air into the room without emitting any warm air—and the other, of as constantly emitting warm and admitting no cool air. They will please to advert, that the one of these tubes communicates with the atmosphere at the bottom of the house, and the other towards the top; the opening of the one is beneath the level of the room, that of the other above it. Now, as the air is more dense at the surface of the ground than at any height above it, the warm rarefying air will naturally incline at that opening where it meets with least resistance, which must invariably be through that which opens to the external air at the greatest height; and as the cool air will naturally be pressed into the room by that opening where the air is most weighty, this must invariably be by that which is nearest the surface of the earth.
Air

The reader will easily perceive, that all that has been here said has a reference only to those apartments in cold climates, and rigorous weather, where fire to warm them becomes necessary. In warmer regions, or during the summer-seaon, there can be no objection to the wheel-ventilator in the window.—It is a simple contrivance, and a safe and effectual mean of preferring the air in our apartments sweet and wholesome at that season.

It is a vulgar error among many people, to believe that fire purifies the contaminated air, by destroying the noxious particles mixed with it; and for this reason they think, that the fire kept in a room where the air is tainted, purifies the room, by rendering the air in it again fit for respiration. Indeed, a fire kept in a room or apartment where the air is tainted, is as the cafe with hospitals, goals, and the like, does certainly purify the apartment, and the practice is very useful; but this effect is only because the fire promotes the circulation of the air, and dries the dampness of rooms, furniture, &c. so that it is not the infected air that is purified, but is new, fresh, and wholesome air, that by the action of the fire has taken the place of the infected air; which infected air, being rared by the heat, has been expelled from the apartment. Fire and combustion in general is so far from purifying contaminated air, that it actually contaminates a prodigious quantity of it in a short time; so that not only a common fire, but even a lighted candle, when kept in a well-clofed room, wherein the external air has not a free access, instead of purifying, renders the air of that room noxious.

Instrument for ascertaining the Purity or Wholesomeness of respirable air. See EUDIMETER.

Air Balloons, a general name given to bags of any light substance filled with inflammable air, or other permanently elastic fluid, whose specific gravity is considerably less than that of common atmospheric air. The consequence of their being filled in this manner, is, that if they are of any considerable magnitude, they ascend in the air; to an amazing height; and will not only ascend in this manner by themselves, but carry up along with them great weights, and continue to rise till they attain an height in which the circumambient air is of the same specific gravity with themselves. In this situation they will either float or be driven in the direction of the wind or current of air in which they are exposed, remaining in these elevated regions till the fluid escapes by the bursting of the bags from the superior elasticity of the fluid, or by its gradual evaporation through the pores of the envelope. The history, principles, &c. of these machines are detailed under the article Aerostation.

Air-Bladder, in siles. See Comparative Anatomy. chap. iii. and Ichthyology.

Air-Gun, a pneumatic machine for exploding bullets, &c. with great violence.

The common air-gun is made of brass, and has two barrels; the inside barrel A, fig. 8. which is of a small bore, from whence the bullets are exploded; and a large barrel E C L R on the outside of it. There is a sringe EMNP fixed in the block of the gun, by which the air is injected into the cavity between the two barrels through the valve E P. The ball K is put down into its place in the small barrel, with the hammer, as in any other air-gun. At S L is another valve; being opened by the trigger O, permits the air to come behind the bullet, so as to drive it out with great force. If this valve be opened and that suddenly, one charge of condensed air may be sufficient for several discharges of bullets; but if the whole air be discharged on one single bullet, it will drive it out with a great force. This discharge if effected by means of a lock, fig. 9, placed here as usual in other guns; for the trigger being pulled, the cock will go down and drive the lever O, fig. 8, which will open the valve, and let in the air upon the bullet K. Air-guns of late years have received very great improvements in their construction. Fig. 10, is a representation of one made by the late Mr. B. Martin of London, and now by several of the mathematical instrument and gun-makers of that metropolis. For simplicity and perfection it exceeds any other heretofore contrived. A is the gun-barrel, with the lock, floor, ram-rod, and of the size and weight of a common fowling-piece. Under the lock, at b, is a round feel tube, having a small moveable pin in the inside, which is pushed out when the trigger a is pulled, by the spring worked within the lock; to this tube, a hollow copper-ball e serves, perfectly air-tight. This copper-ball is fully charged with condensed air by the sringe B (fig. 7.) previous to its being applied to the tube b of fig. 10. It is then evident, that if a bullet be rammed down in the barrel, the copper ball, being fast at b, and the trigger a be pulled, that the pin in b will, by the action of the spring-work within the lock, forcibly strike out into the copper ball; and thereby pushing in suddenly a value within the copper ball, let out a portion of the condensed air; which air will rush up through the aperture of the lock, and forcibly act against the bullet, driving it to the distance of 60 or 70 yards or further. If the air is strongly condensed at every discharge, only a portion of the air escapes from the barrel; therefore, by decreasing the piece, another discharge may be made; and this is repeated to the amount of 15 or 16 times. An additional barrel is sometimes made, and applied for the discharge of shot, instead of the one above described.

The air in the copper ball is condensed by means of the sringe B (fig. 7.), in the following manner: The ball is ferewed quite close on the top of the sringe at b, at the end of the feel pointed rod a: is a stout ring through which passes the rod k: upon this rod the feet should be firmly set; then the hands are to be applied to the two handles i i, fixed on the side of the barrel of the sringe. Now, by moving the barrel B steadily up and down on the rod s the ball e will become charged with condensed air; and it may be easily known when the ball is as full as possible, by the irresistible action that the air makes against the pillow when you are working the sringe. At the end of the rod k is usually a four-square hole, which with the rod serves as a key to fasten the ball e fast on the screw b of the gun and sringe close to the orifice in the ball e. In the inside is fixed a valve and spring, which gives way for the admission of air; but upon its emission comes close up to the orifice, shutting up the internal air.
Air-guns. 

The piston-rod works air-tight, by a collar of leather on it, in the barrel B; it is therefore plain, when the barrel is drawn up, the air will rush in at the hole b. When the barrel is pushed down, the air therefrom will have no other way to pass from the preasure of the piston but into the balls at top. The barrel being drawn up, the operation is repeated, until the condensation is strong enough to resist the action of the piston.

Sometimes the syringe is applied to the end of the barrel C (see fig. 11), the lock and trigger shut up in a brass d; and the trigger pulled, or discharged made, by pulling the chain b. In this contrivance there is a round chamber for the condened air at the end of the syringe a, and it has a valve acting in a similar manner to that of the copper ball. When this instrument is not in use, the brass e is made to slide off, and the instrument then becomes a walking-flick; from which circumstance, and the barrel being made of cane, brass, &c. it has received the appellation of the Air-cane. The head of the cane unfastens and takes off at a, where the extremity of the piston rod in the barrel is shown: an iron rod is placed in a ring at the end of this, and the air condened in the barrel in a similar manner to that of the gun as above; but its force of action is not so strong as to resist the action of the piston.

The Magazine Air-gun was invented by that ingenious artist L. Colbe. By this contrivance ten bullets are lodged in a cavity, near the place of discharge, that they may be drawn into the shooting-barrel, and successively discharged as fast as to be nearly of the same use as so many different guns.

Fig. 12 represents the present form of this machine, where part of the stock is cut off, to the end of the injecting syringe. It has its valve opening into the cavity between the barrels, as before. K K is the small shooting-barrel, which receives the bullets from the magazine E D, which is of a serpentine form, and closed at the end D when the barrels are lodged in it. The circular part a b c, is the key of a cock, having a cylinde® hole through it, which is equal to the bore of the same barrel, and makes a part of it in the present situation. When the lock is taken off, the several parts Q, R, T, W, &c. come into view, by which means the discharge is made by pushing up the pin P, which raises and opens a valve V, to let the air against the bullet I, from the cavity F; which valve is immediately shut down again by means of a long spring of brass NN. This valve V being a conical piece of brass, ground very true in the part which receives it, will of itself be sufficient to confine the air.

To make a discharge, you will pull the trigger ZZ, which throws up the seer y a, and dingsages it from the stock a, upon which the strong spring WW moves the tumbler T, to which the cock is fixed. This, by its end v, bears down the end v of the tumbling lever R, which, by the other end m, raises at the same time the flat end of the horizontal lever Q; and by this means, of course, the pin P p, which stands upon it, is pushed up, and thus opens the valve V, and discharges the bullet. This is all evident from a bare view of the figure.

To bring another bullet to succeeed that marked I, instantaneously, turn the cylinde® cavity of the key of the cock, which before made part of the barrel K K, into the situation i, so that the part i may be at K; and hold the gun upon your shoulder, with the barrel downwards and the magazine upwards, by which means that bullet next the cock will fall into it out of the magazine, but go no farther into this cylinde® cavity than the two little sprigs s s, which detain it. The two circles represent the cock-barrel, where in the key abovementioned turns upon an axis not represented here, but visible in fig. 13. This axis is a square piece of steel, on which comes the square hole of the hammer H, fig. 14, by which the cylinde® cavity mentioned is opened to the magazine. Then opening the hammer, as in that figure, the bullet is brought into its proper place near the discharge-valve, and the cylinde® cavity of the key of the cock again makes part of the inward barrel K K.

It evidently appears how expedient a method this is of charging and discharging a gun; and were the force of condened air equal to that of gun-powder, such an air-gun would answer the end of several guns. In the air-gun, and all other cases where the air is required to be conden®ed to a very great degree, it will be requisite to have the syringe of a small bore, viz. not exceeding half an inch in diameter; because the pressure against every square inch is about 15 pounds; and therefore against every circular inch about 12 pounds. If therefore the syringe be one inch in diameter, when one atmosphere is injected, there will be a resistance of 12 pounds against the piston; and when 10 are injected, there will be a force of 120 pounds to overcome; whereas 10 atmospheres act against the circular half-inch piston (whose area is only one-fourth part so big) with only a force equal to 30 pounds; or 40 atmospheres may be injected with such a syringe, as well as 10 with the other. In short, the facility of working will be inversely as the squares of the diameter of the syringe.

Air-Jacket, a sort of jacket made of leather, in which are several bags, or bladders, composed of the same materials, communicating with each other. These are filled with air through a leather tube, having a brass stop-cock accurately ground at the extremity, by which means the air blown in through the tube is confined in the bladders. The jacket must be yet, before the air be blown into the bags, as otherwise it will immediately escape through the pores of the leather. By the help of these bladders, which are placed near the breast, the peron is supported in the water, without making the efforts used in swimming.

Air-Pipes, an invention for drawing foul air out of ships, or any other close places, by means of fire. These pipes were first found out by one Mr. Sutton, a brewer in London; and from him have got the name of Sutton's Air pipes. The principle on which their operation depends is known to every body, being indeed no other than that air is necessary for the support of fire; and, if it has not access from the places most adjacent, will not fail to come from those that are more remote. Thus, in a common furnace, the air enters through the air-hole; but if this is closed up, and a hole made in the side of the furnace, the air will rush in with great violence through that hole. If a tube of any length whatever is inserted in this hole, the air will rush through the tube into the fire, and of coil.
Air-pipes. consequence there will be a continual circulation of air in that place where the extremity of the tube is laid. Mr Sutton's contrivance then, as communicated to the Royal Society by Doctor Mead, amounts to no more than this. As, in every ship of any bulk, there is already provided a copper or boiling-place proportionable to the size of the vessel, it is proposed to clear the bad air, by means of the fire already used under the said coppers or boiling places for the necessary uses of the ship.

It is well known, that, under every such copper or boiler, there are placed two holes, separated by a grate, the first of which is for the fire, and the other for the ashes falling from the same; and that there is also a flue from the fire-place upward, by which the smoke of the fire is discharged at some convenient place of the ship.

It is also well known, that the fire once lighted in these fire-places, is only preferred by the constant draught of air through the forementioned two holes and flue; and that if the said two holes are closed up, the fire, though burning ever so briskly before, is immediately put out.

But if, after shutting the abovementioned holes, another hole be opened, communicating with any other room or airy place, and with the fire: its clear, the said fire must again be railed and burned as before, there being a like draught of air through the same as was before the flapping up of the first holes; this cafe differing only from the former in this, that the air feeding the fire will now be supplied from another place.

It is therefore proposed, that, in order to clear the holds of ships the bad air therein contained, the two holes abovementioned, the fire-place and flue-place, be both closed up with substantial and tight iron-doors; and that a copper or leaden pipe, of sufficient size, be laid from the hold into the flue-place, for the draught of air to come in that way to feed the fire. And thus it seems plain, from what has been already said, that there will be, from the hold, a constant discharge of the air therein contained; and consequently, that air, being discharged, must be constantly supplied by fresh air down the hatches or such other communications as are opened into the hold; whereby the fire must be continually freshened, and its air rendered more wholesome and fit for respiration.

And if into this principal pipe, so laid into the hold, other pipes are let in, communicating respectively either with the well or lower decks: it must follow, that part of the air, consumed in feeding the fire, must be respectively drawn out of all the places to which the communication shall be so made.

This account is so plain, that no doubt can remain concerning the efficacy of the contrivance; it is evident, that, by means of pipes of this kind, a continual circulation of fresh air would be occasioned thro' those places where it would otherwise be most apt to stagnate and putrefy. Several other contrivances have been used for the same purpose; and Doctor Hale's ventilators, by some unaccountable prejudice, have been reckoned superior in efficacy and even simplicity to Mr. Sutton's machine, which at its first invention met with great opposition*; and even when introduced by Dr Mead, who used all his interest for that purpose, was shamefuly neglected.

A machine capable of answering the same purpose was invented by Mr Defaguliers, which he called the ship's lungs. It consisted of a cylindrical box fixed up on one side, and fixed to a wooden pedestal. From the upper edge of the box issued a square trunk open at the end, and communicating with the cavity of the box. Within this box was placed a cylindrical wheel turning on an axis. It was divided into 12 parts, by means of partitions placed like the radii of a circle. These partitions did not extend quite to the centre, but left a space of about 18 inches diameter in the middle; towards the circumference, they extended as far as possible without interfering with the fire, so that the wheel might always be allowed to turn freely. Things being thus circumstanced, it is plain, that if the wheel was turned towards that side of the box on which the trunk was, every division would push the air before it, and drive it out through the trunk, at the same time that fresh air would come in through the open space at the centre, to supply that which was thrown out thro' the trunk. By turning the wheel swiftly, a strong blast of air would be continually forced out thro' the square trunk, on the fame principles on which a common fanner winnows corn. If the wheel is turned the opposite way, a draught of air may be produced from the trunk to the centre. If this machine, then, is placed in a room where a circulation of air is wanted, and the trunk made to pass through one of the walls; by turning the wheel swiftly round, the air will be forced with great velocity out of that room, at the same time that fresh air will enter through any chinks by which it can have access to supply that which has been forced out.

It is evident, that the circulation which is promoted by this machine, is entirely of the same kind with that produced by Mr Sutton's: the turning of the wheel in Mr Defaguliers's machine being equivalent to the rarefaction of the air by fire in Mr Sutton's: but that the latter is vastly superior, as acting of itself, and without intermission, requires no argument to prove. Mr Sutton's machine has yet another convenience, of which no other convenience for the same purpose can boast; namely, that it not only draws out putrid air, but destroys it by caufing it to pass through fire: and experience has abundantly shown, that though putrid air is thrown into a great quantity of fresh air, it is so far from losing its pernicious properties, that it often produces noxious diseases. We do not say, indeed, that putrid air becomes harmless by this means; but it is undoubtedly rendered less noxious than before; tho' whether it is equally innocent in the smoke of a fire fed in the common way, we cannot pretend to determine.

Besides this machine by Mr Defaguliers, the ventilators of Dr Hale, already mentioned, and those called wind-falls, are likewise used for the same purpose. The former of which is an improvement of the Helian-bellows*: the other is a contrivance for throwing fresh air into those places where putrid air is apt to lodge; but this has the last-mentioned inconvenience in a much greater degree than any of the others, as the blast of fresh air throws out that which was rendered putrid by stagnation, in such a manner as to contaminate all around it. See Wind-falls.
Air

Air-Thread, is also a contrivance by Doctor Hales to prevent the stagnation of putrid effluvia in jails, and other places where a great number of people are crowded together in a small space. It consists only of a long square trunk open at both ends; one of which is inserted into the ceiling of the room, the air of which is required to be kept pure; and the other extends a good way beyond the roof. Through this trunk a current of air is carried on, and the reason is, that the putrid effluvia which do so much mischief when collected, being much lighter than the pure atmosphere, arise to the top of the room; and, if there find a vent, will continually go out through it. These effluvia arise in very considerable quantity, being calculated by the late Dr Keill at no less than 39 ounces from one man in 24 hours.

These trunks were first made trial of by Mr Yeoman, over the House of Commons, where they were nine inches wide within, and over the Court of King's-bench in Westminster-hall, where they were six inches wide. They are sometimes made wider, and sometimes narrower; but the wider they are the longer they ought to be, more effectually to promote the ascent of the vapour. The reason why vapours of this kind ascend more swiftly through a long trunk than a short one, is, that the pressure of fluids is always according to their different depth, without regard to the diameter of their bases, or of the vessel which contains them; and, upon this principle, a gallon of water may be made to split a strong cork...PLANTS.

Air, in music, is taken in different senses. It is sometimes contradicted with harmony; and, in this sense it is synonymous with melody in general.—Its proper meaning is, a tune which is set to words, or to short pieces of poetry that are called songs.

In operas, we give the name of air to such pieces of music as are formed with measures and cadences, to distinguish it from the recitative; and, in general, every piece of music is called an air, which is formed for the voice, or even for instruments, and adapted to flanzas, whether it forms a whole in itself, or whether it can be detached from any whole of which it forms a part, and be executed alone.

If the subject admits of harmony, and is set in parts, the air is, according their number, denominated a duett, a trio, a quartette, &c. We need not follow Rouleau, and the other philologists, in their endeavours to investigate the etymology of the word air. Its derivation, though found and ascertained, would contribute little to illustrate its meaning in that remote sense, to which, through a long continuance of time, and the various vicissitudes of language, it has now palled. The curious may consult the same article in the Dictionnaire de Musique by M. Rouleau.

In modern music, there are several different kinds of air, each of which agrees to a certain kind of dancing, and from these dances the airs themselves take their specific names.

The air of our operas, are, if we may be permitted the
AIR [341]

the expression, the canvas or substratum upon which are painted all the pictures of imaginative music; melody is the design, and harmony the enchanting; every picturesque object selected from the most beautiful parts of nature, every reflected sentiment of the human heart, are the models which the artist imitates; whatever gains attention, whatever interests the soul, whatever charms the ear, or causes emotion in the heart, these are the objects of his imitation. See imitation.

An air which delights the ear, and discovers the learning of the composer; an air invented by genius, and composed with taste; is the noblest effort of music; it is this which explores the compass, and displays the delicacy, of a beautiful voice; it is in this where the charms of a well-conducted symphony shine; it is by this, that the passions, excited and inflamed by nice gradations, reach and agitate the soul through the avenues of external sense. After hearing a beautiful air, the mind is acquiescent and serene; the ear is satisfied, not disgusted: it remains impressed on the fancy, it becomes a part of our essence, we carry it with us, we are able to repeat it at pleasure: without the ability acquired by habit to breathe a single note of it, we execute it in our imagination in the same manner as we heard it upon the theatre: one sees the scene, the actor, the theatre; one hears the accompaniments and the applause. The real enthusiasm in music never forgets the beautiful airs which he has heard; when he chooses, he cautions the opera to recommence.

The words to which airs are adapted, are not always rearranged in regular succession, nor spoken in the same manner with those of the recitative; and, though, for ordinary, they are very short, yet they are interrupted, repeated, transposed, at the pleasure of the artist. They do not constitute a narrative, which once told is over: they either delineate a picture, which it is necessary to contemplate in different points of view; or inspire a sentiment in which the heart acquires with pleasure, and from which it is neither able nor willing to be disengaged; and the different phrases of the air, are nothing else but different manners of holding the same image. This is the reason why the subject of an air should be one. It is by these repetitions properly placed, it is by these redoubled efforts, that an impression, which at first was not able to move you, at length shakes your soul, agitates you, transports you out of yourself; and it is like upon the same principle, that the runnings, as they are called, or those long, mazy, and inarticulated inflections of the voice, which, in pathetic airs, frequently seem, though they are not always so, improperly placed; whilst the heart is affected with a sentiment exquisitely moving, it often expresses its emotions by inarticulate sounds, more strongly and feebly than it could by words themselves.

The form of airs is of two kinds. The small airs are often composed of two strains, which ought each of them to be sung twice; but the important airs in operas are frequently in the form of rondos.

AIR, or Ayr, in geography, a town of Scotland, capital of an extensive county of the same name. It stands on the river Air, and was formerly a place of good trade, and seat of fisheries; all of which have vanished, and the people now live by one another. Air appears from history and other documents, to have been a considerable place at the time of the Norman conquest. The vouchers of its antiquity are corroborated by an elegant building called the Greys, which has escaped the destructive rage of the last and preceding century. The date on this fragment of antiquity is 1055, consequently it hath stood in its place above 750 years; and it is to be wished, that the majority of the inhabitants may unite in preserving it from being destroyed by persons who have expressed a strong desire to that purpose. In 1557, the tax levied upon Air was £236 Scots; upon Glasgow only £202. In 1771, Air was attainted at 158 Stirl. and Glasgow at £18, £18. In 1771, the pickled herrings exported from Air were 6624 barrels; since the year 1777, none. These revolutions appear the more extraordinary, when we consider the very advantageous situation of Air both by land and by water; the fertility of the country; the riches of the sea; its contiguity to the western fisheries on one side, and to Glasgow on the other; the large returns for cattle, grain, and coal; the ample revenues of the town; and particularly the convenience of its harbour for fishing-vessels of every construction.—About a mile north from the town there is a lazaret-house, commonly called The King's Chapel, which King Robert de Bruce set apart for the maintenance of lepers.

AIRA, in botany: A genus of the triandria digyna class; and in the natural method ranking under the 4th order, Gramina. The characters are: The calyx is a two-flowered double-valved gume: The corolla is two-valved, and no rudiment of a flower between the florets: The stamina consist of three capillary filaments the length of the flower; the anthers are oblong, and forked at both ends: The pistillum is an egg-shaped germin: the styli are two, bluntly, and expanding; the stigmata are pubescent: There is no pericarpium; the including corolla grows to the seed: The seed is egg-shaped and covered. There are 14 species of the air, nine of which are natives of Britain. The English name is Hair-grass. See the general article Grass.

AIRANI, in church-history, an obscure sect of Arians, in the fourth century, who denied the consubstantiality of the Holy Ghost with the Father and the Son. They are otherwise called Arismani: some have said that they have taken their name from one Airas, who distinguished himself at the head of this party, in the reigns of Valentinian and Gratian.

AIRE, a town of France, in Proper Gascony, of which it is the capital, with a bishop's see. It is seated on the river Adour, on the declivity of a mountain. E. Long. o. 3. N. Lat. 43° 47'.

AIRE, a strong town in the Netherlands, in the county of Artois, with a castle. It was taken by the French in 1710, and was confirmed to them by the treaty of Utrecht. It is seated on the River Lis, 32 miles south of Dunkirk, and communicates with St. Omer's by a canal cut from the river Aa. E. Long. 2° 31'. N. Lat. 50° 38'.

AIRING, a term peculiarly used for the excising horsfes in the open air. It purifies the blood; purges the body from gross humours; and, as the jockies express it, teaches the horse how to make his wind take equally, and keep time with the other motions of his body. It also sharpens the stomack, and keeps the creature hungry; which is a thing of great consequence, as hunters and racers are very apt to have their stomack fall off, either from want of exercise, or from the too violent
exercise which they are often exposed to. If the horse be over fat, it is best to air him before fun-rise and after fun-setting; and in general, it is allowed by all, that nothing is more beneficial to those creatures than early and late airings. Some of our modern managers, however, dispute this: they say, that the cold of these times is too great for the creature; and that if, in particular, he is subject to catarrhs, rheums, or the like complaints, the dew and cold fogs, in these early and late airings, will be apt to increase all those disorders. Nature, we fee, also points out the fun-beams as of great use to these animals; those which are kept hardy and lie out all night, always running to those places where the sunshine comes, as soon as it appears in a morning. This should seem to recommend those airings that are to be made before fun-set, and a little time after fun-rise. As to the caution, so earnestly inculcated by Markham, of using these early and late airings for fat horses, it is found unnecessary by many: for they say, that the same effect may be produced by airings at warmer times, provided only that they are made longer; and that, in general, it is from long and found courage.

AIRS, in the manager, are the artificial motions of taming horses; as the demivolt, curvet, capriole, &c. AIRY, or AERY, among sportmen, a term expressing the neft of a hawk or eagle.

AJUGA, Bugle: A genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42d order, Afterfifiope. The characters are: The calyx is a short perianthium, monophyllous and persistent: The corolla is monopetalous and grinning: The flower consists of four erect filaments; the anthers are dimidiated: The pistillum has a four-cleft germin, a filiform style, and two slender stigmas. There is no perispermium; the calyx converging, and containing the seeds in its bome: The seeds are four, and oblong. The species enumerated by Linnaeus are, 1. The orientalis, with inverted flowers, which is a native of the east. 2. The generiftis, with woolly leaves and hairy cups, is a native of Swiftherland and of the southern parts of Europe. 3. The pyramidalis, or mountain-bugle, with a square pyramidal spike and blue flowers, is a native of Sweden, Germany, Switzerland, and the hilly parts of Britain. Sheep and goats eat it; cows are not fond of it; horses and fwine refuse it. 4. The reptans, common or pature bugle, with creeping suckers, and blue, red, or white blossoms, in long leafy spikes, is a native of the southern parts of Europe, and is met with in woods and moift places in many parts of Britain. The roots are a infringent, and firkle a black colour with vitriol of iron.

Culture. The first species is propagated by sowing the seeds soon after they are ripe, in a pot filled with loamy earth, and placed in a shady situation till autumn; when it muft be removed under a frame, and protected from the frosts. In the spring, after the plants are come up, let them be translated each into a separate pot, and in summer placed under a shady situation. The other sorts are easily propagated by their fide-floats, anducced bed in a moift shady situation.

AIUS LOCUTIUS, the name of a deity to whom the Romans erected an altar. The words are Latin, and signify a speaking voice. The following accident gave occasion to the Romans erecting an altar to the Aius Locutius. One M. Sedilius, a pheasant, acquainted the tribunes, that, in walking the streets by night, he had heard a voice over the temple of Vesta, giving the Romans notice that the Gauls were coming against them. This intimation was however neglected; but after the truth was confirmed by the event, Camillus acknowledged this voice to be a new deity, and erected an altar to it under the name of the Aius Locutius.

AJUTAGE, or ADJUTAGE, a kind of tube fitted to the mouth of the vessel through which the water of a fountain is to be played. To the different form and structure of ajutages, is owing to the great variety of fountains. See Fountain and Hydrostatics.

AIX, a small but ancient town in the duchy of Savoy, with the title of a marquifate. It is fét on the lake Bourget, at the foot of a mountain, between Chambrery, Annecy, and Rumilly. There is here a triumphal arch of the ancient Romans, but it is almost entirely ruined. The mineral waters bring a great number of strangers to this place. The place was originally called Aquae Gratianae, from the hot baths built there by the Emperor Gratian. L'Long. 7. 10. N. Lat. 45. 40.

AIX, an ancient city, the capital of Provence, in France. It is an archbishopric; and has a parliament, a court of aids, a chamber of accounts, a feneschal’s jurisdiction, a generality, and an university. It has that air of silence and gloom so common in character of places instituted of commerce or industry: It is, however, a well-built city; and most like Paris of any place in the kingdom, as well for the largeness of the buildings, as in respect of the politeness of the inhabitants. It is embellished with abundance of fine fountains, and several beautiful squares. The preachers square is on the side of a hill; it is about 160 yards in length, and is surrounded with trees, and houses built with stone three stories high. The town-hall is at one end of the city, and is distributed into several fine appartments: the two lowest are taken up by the board of accounts, and by the seneschal; that above is designed for the sittings of parliament. The hall of audience is adorned with the pictures of the kings of France on horseback. The hotel of the city is a handfome building, but laid by the houses of the narrow street in which it is placed. The cathedral church is a Gothic structure, with tombs of several earls of Provence, and some good pictures by French masters. The Corfe, or Orbi­telle, is a magnificent walk, above 300 yards long, formed by a triple avenue of elms, and two rows of regular and flatly houfe. The church of the fathers of the oratory is a handsome building; and not far from thence is the chapel of the blue pentents, which is full of paintings. The convent of preachers is very fine; in their church is a silver statue of the Virgin Mary almost as big as the life. There are other churches and buildings
buildings which contain a great number of rarities. The baths without the city, which were discovered not long since, have good buildings, raised at a vast expense, for the accommodation of those who drink the waters. Although Aix was the first Roman settlement in Gaul, it is not remarkable for ancient remains. The warm springs from which it is now known and frequented, induced Sextus Calvinus to found a colony here, to which he gave the name of Aqua Sextia. They were supposed to possess particular virtues in cases of debility; and several altars have been dug up sacred to Priapus, the inscriptions on which indicate their gratitude to that deity for his supposed skill and assistance. E. Long. 5. 32. N. Lat. 43. 32.

Aix, a small island on the coast of France, between the isle of Olceron and the continent. It is twelve miles north-west of Rochfort, and twelve south-west of Rochelle. W. Long 4. N. Lat. 46. 5.

Aix la Chapelle, a fine city of Germany, in the circle of Westphalia and duchy of Juliers. All authors are agreed about its antiquity, it being mentioned in Caesar's Commentaries and the Annals of Tacitus. The Romans had colonies and fortresses here, when they were at war with the Germans; but the mineral waters and the hot bath so increased its fame, that, in process of time, it was advanced to the privileges of a city, by the name of Aquae Graniæ, that is, the waters of Granius; that which it has now, of Aix la Chapelle, was given it by the French, to distinguish it from the other Aix. It is so called, on account of a chapel built in honour of the Holy Virgin by Charlemagne; who having repaired, beautified, and enlarged the city, which was destroyed by the Huns in the reign of Attila, in 451, made it the usual room of 162 feet in length and 60 in breadth. In this the new-elected emperor formerly entertained all the electors of the empire.

In regard to bathing, this also must be determined by the age, sex, strength, &c. of the patient, and by the season. The degree of heat of the bath should likewise be considered. The tepid ones are in general the best, though there are some cafes in which the hotter ones are most proper. But even in these, it is best to begin

Aix la chappelle is a free imperial city, and changes its magistracy every year on the eve of St John Baptist. The mayor is in the nomination of the elector palatine, in the quality of the duke of Juliers, as protector of the city. This place is famous for several councils and treaties of peace concluded here; particularly those between France and Spain in 1668, and between Great Britain and France in 1748.

The hot sulphureous waters for which this place has so long been celebrated, arise from several fountains, which supply eight baths constructed in different parts of the town. These waters near the sources are clear and pellucid; and have a strong sulphureous smell resembling the washings of a foul gun; but they lose this smell by exposure to air. Their taste is saline, bitter, and urinous. They do not contain iron. They are also neutral near the fountain, but afterwards are manifestly and pretty strongly alkaline, insomuch that clothes are washed with them without soap.—On the vaults above the springs and aqueducts of these waters is found, every year, when they are opened, a quantity of fine white-coloured flowers of sulphur, which has been sublimed from the waters.

The heat of the water of the hottest spring, by Dr Lucas's account, raises the quicksilver of Fahrenheit's thermometer to 136—by Montf. Monet's account, to 146—and the heat of the fountain, where they commonly drink, by Dr Lucas's account to 112.

Dr Simmons has given the following account of their several temperatures, as repeatedly observed by himself with a thermometer constructed by Nairne.

The spring which supplies the Emperor's bath (Bain de l'Empereur), the New Bath (Bain Neuf), and the Queen of Hungary's bath (Bain de la Reine de Hongrie), is heated to 127°.

St Quirin's bath (Bain de St Quirin), is heated to 112°.

The Rofe bath (Bain de la Rose), and the Poor's bath (Bain des pauvres), both which are supplied by the same spring, is heated to 112°.

Charles's bath (Bain de Charles), and St Cornelle's bath (Bain de St Cornelle), is heated to 112°.

The spring used for drinking is in the High street, opposite to Charles's bath; the heat of it at the pump is 106°.

Dr Lucas evaporated the water of the hottest spring (the Emperor's Bath), and obtained 268 grains of solid matter from a gallon, composed of 15 grains of calcareous earth, 10 grains of felenites, and 243 grains of a saline matter made up of sodium and sea salt. They are at first nauseous and harsh, but by habit become familiar and agreeable. At first drinking, also, they generally affect the head. Their general operation is by food and urine, without griping or diminution of strength; and they also promote perspiration. The quantity to be drank as an alternative is to be varied according to the constitution and other circumstances of the patient. In general, it is best to begin with a quarter or half a pint in the morning, and increase the dose afterwards to pints, as may be found convenient. The water is best drank at the fountain. When it is required to purge, it should be drank in large and often repeated draughts.
These waters are efficacious in diseases proceeding from indigestion and from weakness of the stomach and bowels. In rheumatisms; in the fever, seroplasma, and diseased states of the skin; in hysterical and hypochondriacal disorders; in nervous complaints and melancholy; in the stone and gravel; in paralytic complaints; in those evils which follow an injudicious use of mercury; and in many other caes. They ought not, however, to be given in hasty cafes where there is heat and fever, in putrid disorders, or where the blood is dissolued, or the constitution much broken down.

The time of drinking, in the first season, is from the beginning of May till the middle of June; and, in the latter season, from the middle of August to the latter end of September.

There are galleries or piazzas under which the company walk during the time of drinking, in order to promote the operation of the waters.—The poor's bath is free for every body, and is frequented by crowds of poor people.

It is scarcely necessary to add, that there are all kinds of amusements common to other places of public resort; but the harpers appear more splendid here than elsewhere, affuming titles, with an equipage suitable to them.—Aix la Chapelle is 21 miles from Spa, 36 from Liege, and 30 from Cologne. E. Long. 5. 48. N. Lat. 51. 55.

AIZOON, called by Mr. Miller's temperance; though the name Aizoon has been by some writers applied to opinion from, but not remarkable either for beauty or any other part of the college of Physicians, and one of the physicians at St. Thomas's Hospital; and, upon the establishment of the queen's household, appointed one of the physicians to her majesty.
and a fine poet. His conversation was of the most delightful kind; learned, instructive, and without any affection of wit, cheerful and entertaining.

Dr Akenfide died of a putrid fever, June 23, 1770; and is buried in the parish-church of St James's, Westminster.

His poems, published soon after his death in 1740 and 1750, consist of "The pleasures of imagination," two books of "Odes," a "Hymn to the Niads," and some "Inscriptions." The pleasures of imagination," his capital work, was first published in 1744; and a very extraordinary production it was from a man who had not reached his 22d year. He was afterwards sensible, however, that it wanted revision and correction; and he went on revising and correcting it for several years: but finding this unsatisfactory, he abandoned the purpose of correcting, and resolved to write the poem over anew upon a somewhat different and enlarged plan. He finished two books of his new poem, a few copies of which were printed for the use of the author and certain friends; of the first book in 1757, of the second in 1765. He finished also a good part of a third book, and an introduction to a fourth; but his most munificent and excellent friend, conceiving all that is executed of the new work, too inconsiderable to supple the place, and supersede the republication of the original poem, and yet too valuable to be withheld from the public, hath caufed them both to be inserted in the collection of his poems.

AKIBA, a famous rabbin, flourished a little after the destruction of Jerusalem by Titus. He kept the flocks of a rich citizen of Jerusalem till the age of his family, and then applied himself to study in the academies for 24 years; and was afterwards one of the greatest masters in Israel, he having 24,000 scholars. He declared for the impostor Barcochebas, whom he owned for the Messiah; and not only anointed him king, but took upon himself the office of his master of the horfe. The troops which the emperor Hadrian sent against the Jews, who under the conduct of this false Messiah had committed horrid massacres, exterminated this fanatic. Akiba was taken and put to death with great cruelty. He lived 120 years; and was buried with his wife in a cave upon a mountain not far from Tiberias, and his 24,000 scholars were buried round about him upon the same mountain. It is imagined he invented a fupposititious work under the name of the patriarch Abraham.

AKISSA T, the ancient Thyatira, a city in Natazia, in Asia, situated in a plain 18 miles broad, which produces plenty of cotton grain. The inhabitants, who are reckoned to be about 50,000, are said to be all Mahometans. The houses are built of nothing but earth or turf dried in the sun, and are very low and ill contrived: but there are six or seven mosques, which are all of marble. There are remarkable inscriptions on marble in several parts of the town, which are part of the ruins of ancient Thyatira. It is seated on the river Hermus, 50 miles from Pergamos. E. Long. 28° 30'. N. Lat. 38° 40'.

AKOND, an officer of justice in Persia, who takes cognizance of the causes of orphans and widows; of contracts, and other civil concerns. He is the head of the school of law, and gives lectures to all the subaltern officers; he has his deputies in all the courts of the kingdom, who, with the second judica, make all contracts.

Al, an Arabic particle prefixed to words, and signifying much the same with the English particle the: Thus they say, alkermes, alkoran, &c. i.e. the kermes, the koran, &c.

Al, or A L, a Saxon term, frequently prefixed to the names of places, denoting their antiquity; as Alborough, Alidgate, &c.

AL, a Latin term properly signifying a wing; from a resemblance to which several other things are called by the same name: Thus, Ala, is a term used by botanists for the hollow of a flalk, which either the leaf, or the pedicle of the leaf, makes with it, or it is that hollow turning, or sinus, placed between the stalk or branch of a plant and the leaf, whence a new offspring usually issues. Sometimes this is used for those parts or leaves otherwise called lobes or wings.

Ala (the plural number) is used to signify those petals or leaves of papilionaceous flowers, placed between those others which are called the vexillum and carina, and which make the top and bottom of the flowers. Instances of flowers of this structure are seen in those of pea and beans, in which the top leaf or petal is the vexillum, the bottom the carina, and the side ones the alae.

Ala is also used for those extremely slender and membranaceous parts of some seeds, which appear as wings placed on them; it likewise signifies those membranaceous expansions running along the stems of some plants, which are therefore called alated stalks.

A L, in anatomy, a term applied to the lobes of the liver, the cartilages of the nostril, &c.

A L, in the Roman art of war, were the two wings or extreme parts of the army drawn up in the order of battle.

ALABA, one of the three smallest districts of Biscay in Spain, but pretty fertile in rye, barley, and fruits. There are in it very good mines of iron, and it had formerly the title of a kingdom.

ALABANDA (anc. geog.), a town in Caria, near the Meander, situate beneath eminences resembling falks with pack-faddles, which gave rise to the jalak: and between Amyzo to the west and Stratonice to the east. Under the Romans they enjoyed ails, or a convention of jurisdiction, by Pliny reckoned the fourth in order: hence the proverb in Stephani, expressing their happiness. It was built by Alabandus, whom therefore they deemed a god. The people were called Alabaudi, Alabandus, &c; Cicero; and Alabandus, after the Greek manner, in coins of Augustus and Claudius; they were also called Alabendus (Livy).

ALABARCHA, in antiquity, a kind of magistrate among the Jews of Alexandria, whom the emperors allowed them to elect, for the superintendence of their policy, and to decide differences and disputes which arose among them.

ALABASTER (William) an English divine, was born at Hadley in the county of Suffolk. He was one of the doctors of Trinity college in Cambridge; and he attended the earl of Essex as his chaplain in the expedition to Cadiz in the reign of queen Elizabeth. It
and some considerable effect. However that matters, he joined himself to the Romish communion, but was disappointed in his expectations. He was soon displeased at this; he could not reconcile himself to the discipline of that church, which made no consideration of the degrees which he had taken before. It is probable too that he could not approve of the worship of creatures, which protestants are used to look upon with horror. Upon this move he turned immediately to the mystick, afforting, that Adam signified misery and misery, and of the rest. His verses were greatly esteemed. He wrote a Latin tragedy, intitled Roxana; which, when he was translated into a college at Cambridge, was attended with a very remarkable accident. There was a lady who was terrified at the last word of the tragedy, Seguar, Seguar, which was pronounced with a very shocking tone, that she left herfenes all her lifetime after. Alabaster was living in 1630. His Apparatus in Revolutionem Jesu Chrifti was printed at Antwerp, in 1607. Adamus, fugit Spiraculis Ubaram ex fuis Spiritualem Expeditionem ex auxiliis Pentagrammatum significationibus, and his Ecce Sponsus venit, fui tuba pulchritudinis, hoc est demonstratis quod non fit illicitum nec impossible computare durationem mundi & tempus secundum adventus Chrifti, they were printed at London. We may judge from these tittes what the taste and genius of the author was.

Alabaster, in natural history, a species of that genus of stones whose base is calcareous earth. It differs from the marble in being combined, not with the aerial, but with vitriolic acid; therefore, when mixed with any acid, no effequence appears. It is fusible in about 500 times its weight of water at the temperature of 60. It is fusible alone in a long-continued porcelain heat, or by the blow-pipe. Specific gravity 1.87. Texture granular, with thinning particles. In composition, and consequently in its chemical properties, it does not differ from gypsum, selinite, and plaster of Paris.

There are three species of alabaster. 1. The snowwhite thinning alabaster, or lydium of the ancients, is found in Taurus, in pieces large enough to make dikes, or the like. It cuts very freely, and is capable of a fine polish. 2. The yellowish alabaster, or phen-
ALABASTER MENDROIDE, a kind of laminated alabaster, beautifully variegated with the figures of shrubs, trees, &c. found in great abundance in the province of Hohenheim.

ALADINISTS, a sect among the Mahometans, answering to fire-chasers among us.

ALADILIA, a considerable province of Turkey, in Asia, in that part called Nacolia, between the mountains of Antitaurus, which separate it from Amasia, on the north, and from Carnimania on the west. It has the Mediterranean sea on the south; and the Euphrates, on the east, which divides it from Diarbeker. It comprehends the lesser Armenia of the ancients, and the east part of Cilicia.

ALAMA, it is now divided into two parts: the north, comprehended between Taurus, Antitaurus, and the Euphrates, is a beglerbeglic, which bears the name of Marash, the capital town; and the south, between mount Taurus and the Mediterranean, is united to the beglerbeglic of Aleppo. The country is rough, ragged, and mountainous; yet there are good pastures, and plenty of herbs and camels. The people are hardy and chieftain. The capital is Malatigah.

ALAIN (Chartier), secretary to Charles VII. king of France, born at Florence, of an ancient family, in the year 1386. He was the author of several works in prose and verse; but his most famous performance was his Chronicle of king Charles VII. Bernard de Girard, in his preface to the History of France, styles him "an excellent historian, who has given an account of all the affairs, particulars, ceremonies, speeches, answers, and circumstances, as he was present himself, or had information of." Giles Coroet tells us, that Margaret daughter to the king of Scotland, and wife to the dauphin, passing once through a hall where Alain lay asleep, the shop and killed him before all the company who attended some of them telling her, that it was strange the should kiss a man who had few charms in his person, she replied, "I did not kiss the man, but the mouth from whence proceed so many excellent sayings, so many wise discourses, and so many elegant expressions." Mr. Fontenelle, among his Dialogues of the Dead, has one upon this incident, between the princess Margaret and Plato. Mr. Patiquier compares Alain to Seneca, on account of the great number of beautiful sentences interpersed throughout his writings.

ALALIS, a considerable town of France, in the province of Languedoc, situated on the river Gardon, at the foot of the Cevennes. The Jesuits had a college in this place; and a fort was built here in 1689. It is 24 miles north of Montpellier, and 340 from Paris.

ALAMANNI (Lewis), in French Alamans, archbishop of Arles, and cardinal of St Cecilia, was one of the greatest men of the fifteenth century. The cardinal presided in the council of Basil, which deposed Eugenius IV. and elected the antipope Felix V. He was much contemned by Alain Sylvius, as a man extremely formed for presiding in such assemblies, firm and vigorous, illustrious by his virtue, learned, and of an admirable memory in recapitulating all that the orators and disputants had said. One day, when he had argued against the superiority of the pope over the council, he distinguished himself in such an eminent manner, that several persons went to kiss him, while others pressed even to kiss his robe. They extolled to the skies his abilities and genius, which had raised him, though a Frenchman, to a superiority over the Italians, notwithstanding all their natural facility and finesse. There is no need of asking, whether pope Eugenius thundered against the president of a council which deposed him. He deprived him of all his dignities, and treated him as a font of iniquity. However, notwithstanding this, Lewis Alamandus died in the odour of sanctity, and performed so many miracles after his death, that at the request of the canons and Celestine monks of Avignon, and the solicitation of the cardinal of Clermont, legate a latere of Clement VII. he was beatified by that pope in the year 1527.

ALAMANNI (Lewis) was born at Florence, of a noble family, on the 28th of October 1497. He was obliged to fly his country for a conspiracy against Julius de Mezié, who was soon after chosen pope under the name of Clement VII. During this voluntary banishment, he went into France; where Francis I. from a love to his genius and merit, became his patron. This prince employed him in several important affairs, and honoured him with the collar of the order of St. Michael. About the year 1549, he was admitted a member of the Inquisition, an academy newly erected at Padua, chiefly by Daniel Barbaro and Ugo Martelli. After the death of Francis, Henry duke of Orleans, who succeeded him in 1547, shewed no less favour to Alamann; and in the year 1551, sent him as his ambassador to Genoa: this was his last journey to Italy; and being returned to France, he died at Amboise on the 18th of April 1556, being in the 61st year of his age. He left many beautiful poems, and other valuable performances, in the Italian language. We have also some notes of his upon Homer's Iliad and Odyssey; those upon the Iliad were printed in the Cambridge edition of Homer in 1689; and Joshua Barnes has also infected them in his fine edition of Homer in 1711.

ALAMODALITY, in a general sense, is the accommodating a person's behaviour, dress, and actions, to the prevailing taste of the country or times in which he lives.

ALAMODALITY of writing, is defined the accommodation of mental productions, both as to the choice of subject and the manner of treating it, to the genius or taste of the times, in order to render them more acceptable to the readers.

ALAMODE, a phrase originally French, importing a thing to be in the fashion or mode. The phrase has been adopted not only into several of the living languages, as the English and High-Dutch, but some have even taken it into the Latin. Hence we meet with Alamodicus and Alamodatias.
ALAMO (Balshafar), a Spanish writer, born at Medina del Campo in Castile. After having studied the law at Salamanca, he entered into the service of Anthony Perez, secretary of state under Philip II. He was in high esteem and confidence with his master, upon which account he was imprisoned after the disgrace of this minister. He was kept in confinement 11 years when Philip III. coming to the throne, set him at liberty, according to the orders given by his father in his will. Alamos continued in a private capacity, till the duke of Olivarez, the favourite of Philip IV. called him to public employments. He was a man of wit as well as judgment, but his pen was superior to his tongue. He died in the 88th year of his age. His Spanish translation of Tacitus, and the aphorisms which he added in the margin, gained him great reputation. This work was published at Madrid in 1614; and was to have been followed, as mentioned in the king's privy council, He was kept in confinement 11 years yet appeared. The author composed the whole during his imprisonment.

ALAN (Cardinal William), was born at Roslil in Lancashire, in the year 1532. He went to Oxford at the age of 15, and in 1550 was elected fellow of Oriel college. In 1556, being then only 24 years old, he was chosen principal of St. Mary's hall, and one of the professors of the university. In 1558 he was made canon of York; but, upon queen Elizabeth's accession to the throne, he left England, and settled at Louvain in an English college, of which he became the chief support. In 1565 he visited his native country; but, on account of his extreme activity in the propagation of the Roman Catholic religion, he was obliged to fly the kingdom in 1568. He went first to Mechlin, and then to Doway, where he was made doctor of divinity. Soon after, he was appointed canon of Cambay, and then canon of Rheims. He was created cardinal on the 28th of July 1587, by the title of St. Martin in Montibus; and obtained from the king of Spain a rich abbey in the kingdom of Naples, and afterwards the bishopric of Mechlin. It is supposed to have been by the advice and instigation of this priest, that Philip II. attempted to invade England. He died on the 20th of October 1594, aged 63; and was buried in the English college at Rome. He was a man of considerable learning, and an elegant writer. He wrote many books in defence of the Roman religion. The most remarkable are: 1. A defence of the 12 martyrs in one year. Tho. Alfield was hanged for bringing, and publishing, this and other of Alan's works, into England, in the year 1584. 2. A declaration of the sentence of Sextus, &c. A work intended to explain the pope's bull for the excommunication of queen Elizabeth, and to exhort the people of England to take up arms in favour of the Spaniards. Many thousands of copies of this book, printed at Antwerp, were put on board the armada; but the enterprise failing, they were afterwards destroyed. 3. Of the worship due to saints and their relics, 1585. This treatise was answered by lord Burleigh, and is esteemed the most elegant of the cardinal's writings.

ALAND, an island of the Baltic seas, between Sweden and Finland, subjected to the former. It lies between 17 and 19 degrees of E. long. and between 59 and 61 degrees of Lat. at the entrance of the gulf of Bothnia.

ALARAF, in the Mahometan theology, the partition wall that separates heaven from hell. The word is plural, and properly written al araf; in the singular it is written al arf. It is derived from the Arabic verb arafa, to distinguish. Al araf gives the denomination to the seventh chapter of the alcoran, wherein mention is made of this wall. Mahomet seems to have copied his al araf, either from the great gulf of separation mentioned in the New Testament, or from the Jewish writers, who also speak of a thin wall dividing heaven from hell. Mahometan writers differ extremely as to the persons who are to be found on al araf. Some take it for a sort of limbo for the patriarchs, prophets, &c. others place here such whole good and evil works as exactly balance each other, that they deserve neither reward nor punishment. Others imagine this intermediate space to be possessed by those who, going to war without their parents leave, and suffering martyrdom there, are excluded for their disobedience, yet escape hell because they are martyrs.

ALARBES, a name given to those Arabians who live in tents, and distinguishes themselves by their drees from the others who live in towns.

ALARES, in Roman antiquity, an epithet given to the cavalry, on account of their being placed in the two wings of the army.

ALARIC, a famous general of the Goths. He entered Thrace at the head of 200,000 men, and laid waste all the country through which he passed. He marched next to Macedonia and Thessaly: the Thes- falians met him near the mouth of the river Peneas, and killed about 5000 of his army; nevertheless he advanced into Greece, and having ravaged the whole country, returned to Epirus, loaded with immense spoils: after having here five years, he resolved to turn his arms to the west. He marched through Panonia; and, finding little resistance, entered Italy, under the consulship of Silicho and Aurelianus, A.D. 400. After various battles and treaties, he at last took Rome by treachery, and permitted his soldiers to plunder it; this happened A.D. 409. Alaric, having laid waste a great part of Italy, intended to pass into Sicily; but a storm obliging him to land again, he besieged the city of Cosenza; and having taken it, he died there in 411, eleven years after he first entered Italy.

ALARM, in the military art, denotes either the apprehension of being suddenly attacked; or the notice thereof, signified by firing a cannon, firelock, or the like. False alarms are frequently made use of to harass the enemy, by keeping them constantly under arms. Sometimes also this method is taken to try the vigilance of the piquet-guard, and what might be expected from them in case of real danger.

ALARF, Bell, that rung upon any sudden emergency, as a fire, mutiny, or the like.

ALARF-PoF, or ALARF-place, the ground for drawing up each regiment in case of an alarm. This is otherwise called the rendezvous.

ALARF, wading, is the same with what is otherwise called an appeal, or challenge.
From his watch-tow'r in the skies,
Till the dappled dawn doth rise.

It continues its harmony several months, beginning early in the spring, on pairing. In the winter they assemble in vast flocks, grow very fat, and are taken in great numbers for the tables. They build their nest on the ground, beneath some clod, forming it of hay, dry fibres, &c. and lay four or five eggs. — These birds are taken in great quantities in the neighbourhood of Dunstable in England: the season begins about the 14th of September, and ends the 25th of February; and during that space, about 4000 dozen are caught, which supply the markets of the metropolis of that kingdom. See Bird-Catching. Vastly greater numbers than the above, however, are at times caught in different parts of Germany, where there is an excite upon them. Kekulé says, that the excite alone produces 6000 dollars every year to the city of Leipsic; whose larks are famous all over Germany as having the most delicate flavour. But it is not at Leipsic only that they are taken in such numbers, but also in the country about Naumburg, Merleburg, Halle, and other parts. — 2. The pretensis, or little-lark, has the two outward feathers of the wing edged with white, and frequents the meadows. It is found frequently in low marshy grounds: like other larks, it builds its nest among the graves, and lays five or six eggs. Like the wood-lark, it sits on trees; and has a most remarkable fine note, singing in all situations, on trees, on the ground, while it is perching in the air, and particularly in its deficient. This bird, with many others, such as the thrush, black-bird, willow-wren, &c. become silent about midsummer, and resume their notes in September: hence the interval is the most mute of the year's three vocal seasons, spring, summer, and autumn. Perhaps the birds are induced to sing again as the autumnal temperament resembles the vernal. — 3. The arborea, or wood-lark, is a native of Europe, and is distinguished by an annular white fillet about the head. It is inferior in size to the sky-lark, and is of a shorter thicker form; the colours are paler, and its note is less sonorous and less varied, though not less sweet. It perches on trees, and whistles like the black-bird. It will sing in the night; and, like the common lark, will sing as it flies. It builds on the ground, and makes its nest on the outside with moss, or within of dried grass, lined with a few hairs. It lays five eggs, dull, and blotched with deep brown marks, darkest at the thicker end. The males of this and the last are known from the females by their superior size. But this species is not near so numerous as that of the common kind. — 4. The campetris, has one half of its chief feathers of the wings brown, except two in the middle which are white, and the throat and breast are yellowish. — 5. The trivialis, whose chief feathers on the tail are brown, only half of the outermost is white, and the second is white at the end, in the shape of a wedge; there is likewise a double whitish line on the wings. It is a native of Sweden, and perches on the top of trees. — 6. The erithaca: the chief tail-feathers are black, but the two outermost are edged with white, and the head is crested. It is a native of Europe. It sings well, like the sky-lark; lays four or five eggs; and is said to hatch twice in a year. — 7. The mipsolleta: the chief tail-feathers are black, only
only the outermost two are obliquely half white. It is a native of Italy.—8. The alpestris: the chief wing-feathers are half white, the throat yellow, and it has a black streak under the eyes and on the breast. It inhabits North America, where it is migratory. It visits the neighbourhood of Albany the beginning of May, but goes farther north to breed. In winter it comes in flocks into Virginia and Carolina, returning North in spring. It feeds, during its stay in the more southern parts, on oats and other grain; and while at Albany, on the grass and the buds of Spurge-birch. It runs into holes; whence the natives of these last parts have given it the name of *chi-chop-pis-feto.* The English call it the ortolan, and reckon it delicious eating. By some it is called snow-bird, as being very plentiful in that season. It is frequently caught in great numbers by means of horse-hair springs placed in some bare place, the snow being scraped away, and a little chaff strewn about. It is always seen on the ground, and has little or no long. This bird is not peculiar to North America: we here of it in Germany also; and is in plenty throughout Russia and Siberia, going northward in spring. The magna, is yellow on the belly, with a crooked black streak on the breast, and the three side-feathers of the tail white. It is a native of Africa and America.—10. The New Zealand lark (Plate XVIII.) is seven and a half inches in length: the bill is half an inch, of a pale ash-colour, with the upper part black: the upper parts of the body are dusky, edged with pale ash-colour: the breast and belly are white: the legs reddish ash-colour, and the claws black. It inhabits Charlotte Sound, and is called *koko aruere.*

**ALAUTA** is a considerable river of Turkey in Europe, which, after watering the north-east part of Transylvania and part of Wallachia, falls into the Danube almost opposite to Nicopolis.

**ALAY,** signifying in the Turkish language "The Triumph," a ceremony which accompanies the assembling together the forces of that vast empire upon the breaking out of a war. It consists of the most invidious buffoonery, and is attended with acts of the most shocking barbarity. That which took place upon occasion of the late war between the Porte and Russia is described by Baron Tott in his Memoirs as follows.

"It consists in a kind of Masquerade, in which each trade successively presents to the spectators the mechanical exercizes of its respective art. The labourers draw his plough, the weaver handles his shuttle, the joiner his plain; and these different characters, seated in cars richly ornamented, commence the procession, and precede the standard of Mahomet, when it is brought out of the seraglio to be carried to the army, in order to inflame victory to the Ottoman troops.

"This banner of the Turks, which they name *Sundjat-Cherif,* or the Standard of the Prophet, is so revered among them, that, notwithstanding its reputation has been so often tarnished, it still retains their implicit confidence, and is the sacred signal unto which they rally. Every thing proclaims its sanctity. None but the emirs are allowed to touch it; they are its guards, and it is carried by their chief. The Muffulmen alone are permitted to look upon it. If touched by other hands, it would be defiled; if seen by other eyes, profaned. In short, it is encompassed by the most barbarous fanaticism.

"A long peace had unfortunately caused the ridiculous, and especially the danger of this ceremony to be forgotten. The Christians imprudently crowded to see it; and the Turks, who, by the situation of their houses, could make money of their windows, began to profit by the advantage; when an emir, who preceded the banner, proclaimed with a loud voice, 'Let no infidel dare to profane with his presence the holy standard of the prophet; and let every Mussulman who perceives an unbeliever make it known under pain of reprobation.'

"From that moment no asylum was to be found; even those became informers, who, by letting out their houses, had rendered themselves accomplices in the crime. A religious fury seized on every mind, and put arms in every hand; the more atrocious the cruelty, the more was it meritorious. No regard was paid to sex or age; pregnant women, dragged by the hair, and trodden under feet by the multitude, perished in the most deplorable manner. Nothing was respected by these monsters; and under such auspices the Turks commenced the war."

**ALB** or **ALBE,** in the Roman church, a vestment of white linen hanging down to the feet, and answering to the surplice of the English clergy. In the ancient church, it was usual, with those newly baptized, to wear an alb, or white vestment; and hence the *Sunday* after Easter was called *dominica in albis,* on account of the albs worn by those baptized on Easter-day.

**Ala** is also a name of a Turkish coin, otherwise called *Aser.*

**ALBA** (anc. geogr.), a town of the Marsi in Italy, situated on the north-side of the Lacus Fucinus, still retaining in its name. It stands upon an eminence, and is noted in Roman history for being the state prison where captive princes were shut up, after being barbarously dragged through the streets of Rome at the chariot wheels of a triumphant consul. Peres king of Macedon terminated his wretched career in this confinement, with his son, the last hope of an illustrious line of kings. Syphax the Numidian, and Biraunus king of the Averni, were also condemned to this gaol by the particular clemency of the senate, which sometimes indulged its savage disposition by putting its captives to death.

Alba being situated in the centre of Italy, amidst difficult mountainous passes, and far from all means of escape, was esteemed a most proper place for the purpose of guarding prisoners of importance. Artificial strength was added to its natural security by fortifications, which remain to this day in a state that proves their ancient solidity. For the entertainment of the garrison, which was required in a place of such consequence, an amphitheatre was erected, of which the ruins are still visible, as well as the foundations of a temple, and other buildings of Roman times.

Lucius Vitellius, brother to the emperor of that name, had a villa near this place, famous for the variety and excellence of its fruit-trees, which he had brought from Syria. His gardens were the nurseries where several of the most delicious stone-fruits, that are now so common in Europe, were first cultivated and multiplied. It
It must have been necessary at Alba to shelter trees transplanted from Alia, and to treat them with great tenderness and care, in order to rear them to perfection: for the climate of this high region is extremely rigorous in winter; the cold leaon falls long, and is accompanied with violent storms of wind and falls of snow. The lake has been often frozen entirely over.

Alba Firma, or Album, in old cufioms, denoted rent paid in silver, and not in corn, which was called black-mail.

Alba Terra, one of the numerous names for the philosopher's stone.

Alba Regalis. See STILL WEISSENBURGH.

Alba Helvetiorum, or Albavilus, (anc. geog.), afterwards called Vivarium, now Viviers, in the southeast of Languedoc, on the Rhone. In the lower age the inhabitants were called Albenes, and their city Civitas Albensium, in the Notitia Galliae. E. Long. 4° 45. Lat. 44° 50.

Alba Julia (anc. geog.) now Weissenburg, a town of Transylvania, on the river Marius, or Merich, to the west of Hermatrat, supposed to be called Alba Julia, after Julia Domna the mother of Caracalla. There are, however, several inscriptions found at or near Weissenburg, which bear Col. Apuln., without the least mention of Alba Julia, though inscribed after Caracalla's time. Add, that Ulpian, reciting the colonies of Dacia, calls this a river, over which was near Ulmaburg, a white town and living God, who created all things.

Alba Julia, there is a mention of the town and living God, who created all things.

Alba Longa (anc. geog.), a colony from Lavinium, in Latium, established by Acanthus the son of Anaes at the foot of the Mons Albanus, called Alba, from a white fow found by Anaes, which farrowed 30 white pigs at that spot; which circumstance was interpreted to portend the building of a city there in 30 years after (Proportius). The epithet Longa was added on account of its length. It was the royal residence till the building of Rome, as was foretold by Anchises (Virgil); it was destroyed by Tullius Hostilicus, all but the temple; and the inhabitants were transplanted to Rome (Strabo).

Alba Pompeia (anc. geog.), on the river Cela, now Ceno, in Liguria, the birth-place of the emperor Pertinax; a colony either established at first by Pompey, or re-established by him after having been before settled by Scipio. The inhabitants were called Alpenius Pompeiani. At this day the town is simply called Alba, without any epithet.

ALBAHURIM, figura septuagesima laterum, a figure of great importance according to astrological philosophers, who build their prognostics on it.

ALBAN (St) is said to have been the first person who suffered martyrdom for Christianity in Britain; he is therefore usually styled the protomartyr of that island. He was born at Verulam, and flourished towards the end of the third century. In his youth he took a journey to Rome, in company with Amphibalus a monk of Caereton, and served seven years as a soldier under the emperor Diocletian. At his return home, he settled in Verulam; and, through the example and instructions of Amphibalus, renounced the errors of paganisimus, in which he had been educated, and became convert to the Christian religion. It is generally agreed, that Alban suffered martyrdom during the great persecution under the reign of Diocletian; but authors differ as to the year when it happened; Bede and others fix it in 286; some refer it to the year 296; but Ulfius reckons it amongst the events of 323. The story and circumstances relating to his martyrdom, according to Bede, are as follows. Being yet a pagan (or at least it not being known that he was a Christian), he entertained Amphibalus in his house. The Roman governor being informed thereof, sent a party of soldiers to apprehend Amphibalus; but Alban, putting on the habit of his guest, presented himself in his stead, and was carried before that magistrate. The governor having asked him of what family he was, Alban replied, "To what purpose do you inquire of my family; if you would know my religion, I am a Christian." Then being asked his name, he answered, "My name is Alban; and I worship the only true and living God, who created all things." The magistrate replied, "If you would enjoy the happiness of eternal life, delay not to sacrifice to the great gods." Alban answered, "The sacrifices you offer are made to devils; neither can they help the needy, or grant the petitions of their votaries." His behaviour so enraged the governor, that he ordered him immediately to be beheaded. In his way to execution, he was stopped by a river, over which was a bridge so thronged with spectators that it was impossible to cross it; the faint, as we are told, lifted up his eyes to heaven, and the stream was miraculously divided, and afforded a passage for himself and a thousand more persons. Bede does not indeed give us the name of this river; but, notwithstanding this omission, the miracle, we suppose, will not be the less believed. This wonderful event converted the executioner upon the spot, who threw away his drawn sword, and, falling at St Alban's feet, defined he might have the honour to die with him. This sudden conversion of the headman occasioning a delay in the execution till another person could be got to perform the office, St Alban walked up to a neighbouring hill, where he prayed for water to quench his thirst, and a fountain of water sprang up under his feet; here he was beheaded, on the 23d of June. The executioner is said to have been a signal example of divine vengeance; for as soon as he gave the fatal stroke, his eyes dropped out of his head. We may see the opinion of Mr Milton in regard to this narrative, in his History of England. His words are these, speaking of St Alban, "The story of whose martyrdom, foiled and worse martyred with the faling zeal of some idle fancies, more fond of miracles than apprehensive of the truth, deserves no longer digression." Between 400 and 500 years after St Alban's death, Offa, king of the Mercians, built a very large and stately monastery in his memory, and the town of St Albans in Hertfordshire takes its name from that monastery.

ALBANA (anc. geog.), a sea-port town of Albia, on the Calpine sea, between the rivers Carius and Albanus; now called Bachi or Bachy, giving name to the Calpine sea, viz. Mare de Bachi. E. Long. 49°. Lat. 49°.

ALBANENSES, in church-history, the fame with Albigenenses, according to some: according to others, different. These, however, who are for distinguishing them.
Albani, a province of Turkey in Europe, on the Gulph of Venice, bounded by Livadia on the south, by Thessaly and Macedonia on the east, and on the north by Bofnia and Dalmatia. The people are strong, large, courageous, and good soldiers; but are said to be of a thievish disposition: the grand seigniors procure excellent soldiers from hence, particularly cavalry, known by the name of Armaus. There are several large towns in this province; and the inhabitants are almost all Christians of the Greek church, and descended from the ancient Scythians. Formerly it was part of the kingdom of Macedonia. Their chief manufactures are carpets. The principal places are Durazzo, Velona, Antivari, Scutari, Croya, Aleifo, Dibra, Doligno, and Albanopolis. Long. from 28° to 32° E. Lat. from 39° to 43° N.

Albania, a country of Asia, bounded on the west by Iberia; on the east by the Caspian Sea; on the north by Mount Caucasus; on the south by Armenia, and the river Cyrus, now Kura; which, springing from the Mochian mountains that separate Colchis from Armenia, and watering the country of Mogen, receives the Araxes and Araxes, and falls into the Caspian Sea within a small distance from the southern borders of this country. — The whole country formerly called Albania, now goes under the names of Shirwan and Elg-Georgi, and is extremely fruitful and pleasant. The ancient historians take notice of the Albanian men being tall, strong-bodied, and, generally speaking, of a very graceful appearance; far excelling all other nations in comeliness as well as stature. Modern travelers take no notice of the appearance of the men, but extol the beauty of the women, which seems to be unnoticed by the ancients. The Albanians were anciently an independent and powerful people; but we find no mention made of their kings till the reign of Alexander the Great, to whom the king of Albania is said to have presented a dove of an extraordinary size. — It does not appear that the Alba-
ALBANO, a town of Italy, on a lake of the same name, in the Campagnia of Rome. It was called by the ancients Albam Lompanis, and built out of the ruins of the ancient Alba Longa, which was destroyed by Tullus Hostilius. It stands within twelve miles south-east of Rome, and for the pleasantries of its situation is the summer retirement of a great many Roman princes. It is likewise the see of a bishop, who is one of the six senatorial cardinals. The town is famous for its excellent wine, and the ruins of a mausoleum, which, according to the tradition of the inhabitants, was made for Aesculapius. The prospect from the garden of the Capuchins is extremely pleasant, taking in the Campagna of Rome, and terminating in a full view of the Tufcan sea. Close by the town lies the Alban lake, an oval figure, and about seven miles in circumference, which, by reason of the high mountains round it, looks like the area of a great amphitheatre. It abounds with excellent fish, and over against the hermitage it is said to be unfishable. The mountain of Albano is called Montea Cavos, on the top of which was a celebrated temple dedicated to Jupiter and Juno. Near the Capuchins there is another convent of Franciscans; and not far from thence the palace of Cardinal Barberini, remarkable for very pleasant gardens, with the ruins of ancient baths, and several old fragments of Mosaic work. E. Long. 13° 10'. N. Lat. 41° 43'.

There is likewise another town of the same name in the Basilicate of the kingdom of Naples, remarkable for the fertility of the surrounding territory, and for the nobility of the inhabitants.

ALBANS (St.), a market town of Hertfordshire, is a very great thoroughfare, accommodated with good inns, on the north-west road from London, at the distance of 21 miles. This town sends two members to parliament, gives the title of duke to the noble family of Beauclerke, and has one of the best markets for wheat in England. St. Albans is seated near the ruins of an ancient Roman city, by Tacitus called Verolam; and by the Saxons Watlingestefter, because it is seated on the road called Watling's street. Nothing now remains of Verolam but the ruins of old walls; in the fields adjacent to which they continue to find Roman coins, as they formerly found tessellated pavements. In memory of St. Alban, Offa, king of the Mercians, anno 795, erected an abbey, calling it St. Albans; and near it the town of the same name was afterwards built. The church of the abbey is remaining to this day: time and the weather have made it look like stone on the out side; but if you break a bit off, the redness of the brick immediately appears. When the monasteries were dissolved, the townsmen paid L. 400 to prevent its being levelled with the ground, and have since converted it into a parish church, which, for its largeness, beauty, and antiquity, claims a particular regard. It had a very noble font of solid brass, in which the children of the kings of Scotland were used to be baptized; and was brought from Edinburgh, by Sir Philip Lee, when that city was in flames: but in the times of the late civil wars, it was taken away. Not many years since, a tomb was discovered in this church, said to be that of Humphrey Duke of Gloucester: when the leaden coffin was opened, the body was pretty entire, being preserved in a sort of pickle. There was a flatey cross in the middle of the town, as there were in many other places where queen Eleanor's body rested when it was brought out of the north for interment at Westminster; but it has been demolished, as some say, by the inhabitants. The market-days are Wednesdays and Saturdays. W. L. o. 12. N. L. 51. 44.

ALBANUS MONS (anc. geog.), now called Mount Alban, 16 miles from Rome, near where Alba Longa stood.

ALBANUS MONS (anc. geog.), to the north of Hatria, called Alba by Strabo; the extremity of the Alps, which, together with the mountains to the east, joining it, called Mons Belis, separates the farther Liburnia and Dalmatia from Pannonia.

ALBANY, a city of North America, in the state of New-York, situated upon the west side of Hudson's river, 160 miles north of the city of New-York. It contains about 4000 inhabitants, collected from almost all parts of the northern world. The houses are built in the old Dutch Gothic style, with the gable end to the street, and are seldom more than one story and a half high; they are by no means elegant, but are kept very clean. Albany, from its being seated on a fine river, at the head of flool navigation, surrounded with a rich and extensive back country, and the store-house of the trade to and from Canada, is in a flourishing condition. It has of late, however, had a formidable rival in the new city of Hudson. W. Long. 44° 29'. N. Lat. 42° 36'.

ALBARAZIN, a strong town, and one of the most ancient of the kingdom of Arragon in Spain. It is seated upon an eminence, near the river Guadalquivir, a little below its source, and on the frontiers of Valencia and New Castile. It is the seat of a bishop; and produces the best wool in all Arragon. It is about 100 miles east of Madrid. E. Long. 2° 10'. N. Lat. 40° 22'.

ALBARI, in antiquity, properly denoted those who gave the whitening to earthen vessels, &c. in which sense they flood contradistinguished from Dealbatori, who whitened walls.

ALBARIUM OPUS, in the ancient building, the incrustation or covering of the roofs of houses with white plaster, made of mere lime. This is otherwise called opus album. It differs from Tectarium, which is a common name given to all roofing or ceiling, including even that formed of lime and sand, or lime and marble; whereas Albarium was restrained to that made of lime alone.

ALBATROSS, in ornithology, a species of the diomedes. See Dromedia.

ALBAZIN, a town of Greater Tartary, with a strong castle. It is situated upon the river Amur, or Yamour, and belongs to the Musscovites. E. Long. 103° 30'. N. Lat. 54° 0'.

ALBE, a small piece of money, current in Germany, worth only a French sol and seven deniers.

ALBEMARLE, or AUMARLE, a town of France, in Upper Normandy, and in the territory of Caux, from whence the noble family of Keppel takes the title of Earl. The ferges of this town are in high esteem.

Albertus Magnus, a Dominican friar, and afterwards bishop of Ratibon, was one of the most
learned men and most famous doctors of the 13th century. He is said to have acted as a man-midwife; and some have been highly offended that one of his pro-
fession should follow such an employment. A book intitled De Natura Rerum, of which he was reputed
the author, gave rise to this report. In this treatise there are several infractions for midwives, and so much skill shown in their art, that one would think the author
could not have arrived at it without having himself practiced; but the advocates for Albert say he was not the writer thereof, nor of that other piece De
Secretis Mutilorum; in which there are many phrases and expressions unavoidable on such a subject, which
gave great offence, and raised a clamour against the supposed author. It must be acknowledged, however, that there are, in his Comment upon the Master of Sentences, some questions concerning the practice of con-
jugal duty, in which he has used some words rather too gross for chaste and delicate ears: but they allege what he himself used to say in his own vindication, that he came to the knowledge of so many monstrous things at confession, that it was impossible to avoid touching upon such questions. Albert was certainly a man of a most curious and inquisitive turn of mind, which gave rise to other accusations brought against him. They say, that he laboured to find out the philosopher's stone, that he was a magician; and that he made a machine in the shape of a man, which was an oracle to him, and explained all the difficulties he
proposed. He had great knowledge in the mathematics, and by his skill in that science might probably have formed a head with springs capable of articulating sounds; like to the machines of Boetius, of which Caiusdiros has said, "Metals lowe; the birds of Diomedes trumpet in brays; the brazen serpent hisses; counterfeited swallows chatter, and such have no proper note, from brays send forth harmonious music." John Matthaeus de Luna, in his treatise De Rerum Historiis, has attributed the invention of fire-arms to
Albert; but in this he is confused by Naude, in his Apologie des Grandis Hommes. We are told, that Albert was naturally very dull, and so incapable of instruction as to be upon the point of quitting the cloister, from despair of learning what his habit required: but that the Holy Virgin appeared to him, and asked him in which he chose to excel, philosophy or divinity? that having chosen the former, she assured him he would become incomparable therein; but that, as a punish-
ment for not preferring divinity, he should think, before he died, into his former stupidity. It is added, that after this apparition he had an infinite deal of wit; and that he advanced in all the sciences with so quick a progress, as utterly astonished his masters; but that three years before his death, he flopped short when reading a divinity-lecture at Colign; and having in vain endeavoured to recall his ideas, he found that the Virgin's prediction was accomplished. "It would be very unnecessary (says Sully, after relating these particulars) to observe that they are fables. Those who would believe me need not be told this, since they would judge in the same manner of their own accord; and as for such as think otherwise, they would not alter their opinion by reading here, that I am of a dif-
f erent way of thinking." Albert died at Colign, November 15, 1280. His works were printed at Lyons, in 1651, in 21 volumes in folio.

Albertus, a gold coin, worth about 14 French livres: it was coined during the administration of Albertus archduke of Austria.

Albesia, in antiquity, a kind of shields otherwise called Decumena. See Decumana.

Albi, a city of France, the capital of the Albigeois, in Languedoc, and the see of an archbishop. The cathedral is dedicated to St. Clelia, and has one of the finest choirs in the kingdom. Here is a very valuable silver shrine, of exquiste workmanship, of the Mosaic kind: it contains the relics of St. Clair, the first bishop of this city. The chapel of this pretended saint
