ENCYCLOPÆDIA;
OR, A
DICTIONARY
OF
ARTS, SCIENCES,
AND
MISCELLANEOUS LITERATURE;
Constructed on a Plan,
by which
the different sciences and arts
are digested into the form of distinct
treatises or systems,
comprehending
the history, theory, and practice, of each,
according to the latest discoveries and improvements;
and full explanations given of the
various detached parts of knowledge,
whether relating to
natural and artificial objects, or to matters ecclesiastical,
civil, military, commercial, &c.
Including elucidations of the most important topics relative to religion, morals, manners,
and the economy of life;
together with
a description of all the countries, cities, principal mountains, seas, rivers, &c.
throughout the world;
a general history, ancient and modern, of the different empires, kingdoms, and states;
and
an account of the lives of the most eminent persons in every nation,
from the earliest ages down to the present times.

Compiled from the writings of the best authors, in several languages; the most approved dictionaries, as well of general science as of its
particular branches; the transactions, journals, and memoirs, of various learned societies, the ms. lectures of eminent
professors on different sciences; and a variety of original materials, furnished by an extensive correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.
ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.
VOL. X.
LES—MEC

INDOEI DISCANT, ET AMEN ME MINER PERITI.

PHILADELPHIA:
PRINTED BY THOMAS DOBSON, AT THE STONE HOUSE, NO 41, SOUTH SECOND STREET.
M.DCC.XCVIII.
[Copy-right secured according to law.]
LESTOFF, or LESTOFF, a town of Suffolk in England, situated on the sea shore, 117 miles north-west of London. It is concerned in the fisheries of the North-sea, cod, herrings, mackerels, and sprats; has a church, and a dissenting meeting house; and for its security, six eighteen-pounders, which they can move as occasion requires; but it has no battery. The town consists of 500 houses; but the streets, though tolerably paved, are narrow. It has a market on Wednesdays, and two fairs in the year for petty chapmen. The coast is there very dangerous for strangers.

LESTRANGE (Sir Roger), a noted writer in the 17th century, was descended from an ancient family, seated at Hunstanton-hall in the county of Norfolk, where he was born in 1616, being the youngest son of Sir Edmund L'Estrange baronet, a zealous royalist. Having in 1644 obtained a commission from King Charles I. for reducing Lynn in Norfolk, then in possession of the parliament, his design was discovered, and his person seized. He was tried by a court martial at Guildhall in London, and condemned to die as a traitor; but was reprieved, and continued in Newgate for some time. He afterwards went beyond sea; and in August 1653 returned to England, where he applied himself to the protection Oliver Cromwell, and having once played before him on the bass-viol, he was by some nicknamed Oliver's Fiddler. Being a man of parts, master of an easy humorous style, but withal in narrow circumstances, he set up a newspaper, under the title of The Public Intelligence, in 1653; but which he laid down upon the publication of the first London gazette in 1665, having been allowed, however, a consideration by government. Some time after the Popish plot, when the Tories began to gain the ascendency over the Whigs, he, in a paper called the Observer, became a zealous champion for the former. He was afterwards knighted, and served in the parliament called by King James II. in 1685. But things taking a different turn in that prince's reign, in point of liberty of conscience, from what most people expected, our author's Observer were diluted as not at all suitting the times. However, he continued licensor of the press till King William's accession, in whose reign he met with some trouble as a disaffected person. However, he went to his grave in peace, after he had in a manner survived his intellectual powers. He published a great many political tracts, and translated several works from the Greek, Latin, and Spanish, viz. Josephus's works, Cicero's Offices, Seneca's Morals, Erasmus's Colloquies, Eras's Fables, and Bonas's Guide to Eternity. The character of his style has been variously represented; his language being observed by some to be easy and humorous, while Mr Gordon says, "that his productions are not fit to be read by any who have taste or good-breeding. They are full of phrases picked up in the streets, and nothing can be more low or wanton."

LESTWETHIEL, a town of Cornwall in England, about 229 miles distant from London. It is a well-built town, where are kept the common gaol, the weights and measures for the whole county, and the county courts. It stands on the river Fowey, which brought up vessels from Fowey, before it was choked up with land coming from tin-mines, and therefore once flourishing trade is decayed; but it holds the bulvelage of coals, salt, malt, and corn, in the town of Fowey, as it does the anchorage in its harbour. It was made a corporation by Richard earl of Cornwall when he was king of the Romans, and has had other charters since. It contains of seven capital burgesses (whereof one is a mayor), and 17 assistants or common council. It is part of the duchy of Cornwall, to which it pays L. 111. 10. 10 a year for its liberties. Its chief trade is the woollen manufacture. Its church has a spire, the only one except that of Helston in the county. Its market is Friday, and its fairs are three. It first returned members to parliament in the 33rd of Edward I. They are chosen by their burgesses and assistants. It was anciently the fish-town, and the knights of the shire are still chosen here.

LETCLADE, a town of Gloucestershire, 90 miles from London, on the borders of Oxfordshire and Berks, and the great road to Gloucester; had anciently a monestary, and a priory of black canons. In this parish is Clay-hill. The market is on Tuesday; and it has two fairs. It is supposed to have been a Roman town: for a plain Roman road runs from hence to Cirencester; and by digging in a meadow near it some years ago, an old building was discovered, supposed to be a Roman bath, which was 30 feet long, 40 broad, and 4 high, suppotred with 100 brick pillars, curiously inlaid with stones of divers colours of clofiferick work. The Leech, the Coln, the Churn, and Isis, which all rise in the Cotswold-hill, join here in one full stream, and become one river, called the Thames, which begins here to be navigable, and barges take in butter, cheese, and other goods, at its quay for London.

LETHARGY, in medicine (from \textit{les} oblivia, and \textit{numbrest}, \textit{lazieust}), a disease consisting of profound dreams or sleepings, from which the patient cannot be awakened; or, if awakened, he remains stupid, without sense or memory, and presently falls again into his former sleep. See \textit{Medicine-Index}.

LETHARGY, in farriery. See there, § 9.
LET

[2]

LETHE, in the ancient mythology, one of the rivers of hell, signifying oblivion or forgetfulness, its waters having, according to poetic fiction, the peculiar quality of making those who drank them forget every thing that was past.

LETI (Gregorio), an eminent Italian writer, was defended of a family which once made a considerable figure at Bologna: Jeron, his father, was page to prince Charles de Medicis; served some time in the troops of the grand duke as captain of foot; and settling at Milan, married there in 1628. He was afterward governor of Almantea in Calabria, and died at Salerno in 1639. Our author was born at Milan in 1630, studied under the Jesuits at Cofenza, and was afterwards sent by an uncle to Rome, who would have him enter into the church; but he being averse to it, went into Geneva, where he studied the government and the religion there. Thence he went to Lausanne; and contrasting an acquaintance with John Anthony Coerlin, an eminent physician, lodged at his house, made profession of the Calvinist religion, and married his daughter. He settled at Geneva; where he spent almost twenty years, carrying on a correspondence with learned men, especially those of Italy. Some contéts obliged him to leave that city in 1679; upon which he went to France, and then into England, where he was received with great civility by Charles II., who, after his first audience, made him a present of a thousand crowns, with a promise of the place of historiographer. He wrote there the History of England; but that work not pleasing the court on account of his too great liberty in writing, he was ordered to leave the kingdom. He went to Amsterdam in 1682, and was honoured with the place of historiographer to that city. He died suddenly in 1701. He was a man of indefatigable application, as the multiplicity of his works show. The principal of these are, 1. The universal monarchy of Louis XIV. 2. The life of Pope Sixtus V. 3. The life of Philip II. King of Spain. 4. The life of the emperor Charles V. 5. The life of Elizabeth, queen of England. 6. The history of Oliver Cromwell. 7. The history of Great Britain, 5 vols 12mo. 8. The history of Geneva, &c.

LETTRUM, a county of Ireland, in the province of Connaught, 44 miles in length and 17 in breadth; bounded on the east and north-east by Cavan and Fermangh, by Sligo and Roscommon on the west and south-west, and by Longford on the east and south-east. It is a hilly country, with rank grass, which feeds a great number of cattle. The chief town is Letterm, seated not far from the river Shannon. It contains 4000 houses, 21 parishes, 5 baronies, 2 boroughs, and sends 6 members to parliament.

LETTER a character used to express one of the simple sounds of the voice; and as the different simple sounds are expressed by different letters, the, by being differently compounded, become the visible signs or characters of all the modulations and mixtures of sounds used to express our ideas in a regular language; (See Language.) Thus, is by the help of speech we render our ideas audible; by the assistance of letters we render them visible, and by their help we can wrap up our thoughts, and send them to the most distant parts of the earth, and read the transactions of different ages. As to the first letters, what they were, who first invented them, and among what people they were first in use, there is still room to doubt: Philo attributes this great and noble invention to Abraham; Jofephus, St Ireneus, and others, to Enoch; Biliander, to Adam; Eusebius, Cicero, Alexander, Cornelius Agrippa, and others, to Moses; Pomponius Mela, Herodian, Rufus Pictus, Pliny, Lucan, &c. to the Phcenicians; St Cyprin, to Satora; Tacitus, to the Egyptians; some, to the Ethiopians; and others, to the Chinese: but, with respect to these last, they can never be intitled to this honour, since all their characters are the signs of words, formed without the use of letters; which renders it impossible to read and write their language without a vast expence of time and trouble; and absolutely impossible to print it by the help of types, or any other manner but by engraving or cutting in wood. See Printing.

There have been also various conjectures about the different kinds of letters used in different languages; thus, according to Crito, Moses invented the Hebrew letters; Abraham, the Syrac and Chaldean; the Phcenicians, those of Attica, brought into Greece by Cadmus, and from thence into Italy by the Pelagians; Nicostrata, the Roman; Isis, the Egyptian; and Vulfilas, those of the Goths.

It is probable, that the Egyptian hieroglyphics were the first manner of writing; but whether Cadmus and the Phcenicians learned the use of letters from the Egyptians, or from their neighbours of Judea or Samaria, is a question; for since some of the books of the Old Testament were then written, they are more likely to have given them the hint, than the hieroglyphics of Egypt. But whereforever the Phcenicians learned this art, it is generally agreed, that Cadmus the son of Agenor first brought letters into Greece; whence, in following ages, they spread over the rest of Europe. See alphabet and Writing.

Letters make the first part or elements of grammar; an assemblage of these compose syllables and words, and these compose sentences. The alphabet of every language consists of a number of letters, which ought each to have a different sound, figure, and use. As the difference of articulate sounds was intended to express the different ideas of the mind, so one letter was originally intended to signify only one sound, and not, as at present, to express sometimes one sound and sometimes another; which practice has brought a great deal of confusion into the languages, and rendered the learning of the modern tongues much more difficult than it would otherwise have been. This consideration, together with the deficiency of all the known alphabets, from their wanting some letters to express certain sounds, has occasioned several attempts towards an universal alphabet, to contain an enumeration of all such single sounds or letters as are used in any language. See Alphabet.

Grammarians distinguish letters into vowels, consonants, mutes, liquids, diphthongs, and characters. They are likewise divided into capital and small letters. They are also denominated from the shape and turn of the letters; and in writing are distinguished into different hands, as round-text, German-text, round hand, Italian, &c. and in printing, into Roman, Italic, and black letter.

The term Letter, or Type, among printers, noto-

.
Accordingly Cicero says; "In writing letters, we use make of common words and expressions." And
Seneca more fully, "I would have my letters to be like my discourses, when we either sit or walk togeth
er, unquoted and easy." And what prudent man, in his common discourse, aims at bright and
strong figures, beautiful turns of language, or lab
oured periods? Nor is it always requisite to attend
to exact order and method. He that is master of
what he writes, will naturally enough express his
thought without perplexity and confusion; and more
than this is seldom necessary, especially in familar
letters.

Indeed, as the subjects of epistles are exceedingly
various, they will necessarily require some variety in
the manner of expression. If the subject be something
weighty and momentous, the language should be
strong and solemn: in things of a lower nature, more
free and easy; and upon lighter matters, jocose and
pleasent. In exhorations, it ought to be lively and
vigorous: in congratulations, kind and compassionate;
and in advising, grave and serious. Its style should be
clear and distinct: in requests, modest: in commendations, friendly; in prosperity cheerful, and
mournful in adversity. In a word, the style ought to
be accommodated to the particular nature of the thing
about which it is conversant.

Besides, the different character of the person, to
whom the letter is written, requires a like difference
in the modes of expression. We do not use the fame
language to private persons, and those in a public sta
tion; to superiors, inferiors, and equals. Nor do we
express ourselves alike to old men and young, to the
great and illustrious, to courtiers and philosophers,
to our friends and strangers. Superiors are to be ad
ressed with respect, inferiors with courtesy, and
equals with civility; and every one's character, sta
tion, and circumstances of life, with the relation we
stand to him, occasions some variety in this respect.

But when friends and acquaintances correspond by
letters, it carries them into all the freedom and good
humour of conversation; and the nearer it resembles
that, the better, since it is designed to supply the room
of it. For when friends cannot enjoy each others
company, the next satisfaction is to converse with
each other by letters. Indeed, sometimes greater
freedom is used in epistles, than the same persons
would have taken in discourse together; because,
as Cicero says, "A letter does not blush." But still
nothing ought to be said in a letter, which, considered
in itself, would not have been fit to say in discourse;
though modesty perhaps, or some other particular
reason, might have prevented it. And thus it fre
quently happens in requests, reproofs, and other cir
cumstances of life. A man can ask that by writing,
which he could not do by words, if present; or blame
what he thinks amiss in his friend with greater liberty
when absent, than if they were together. From hence
it is easy to judge of the fineness of any expression to
stand in an epistle, only by considering, whether the
same way of speaking would be proper in talking with
the same person. Indeed, this difference may be al
lowed, that as persons have more time to think, when
they write, than when they speak; a greater accura
cy of language may sometimes be expected in one,

A 2 than
than the other. However, this makes no odds as to the kind of style; for every one would choose to speak as correctly as he writes, if he could. And therefore all such words and expressions, as are unbecoming in conversation, should be avoided in letters; and a many simplicity free of all affectation, plain, but decent and agreeable, should run through the whole. This is the usual style of Cicero’s epistles, in which the plainness and simplicity of his dictation is accompanied with something so pleasant and engaging, that he keeps up the attention of his reader, without frustrating him to tire. On the other hand, Pliny’s style is frequently witty; but generally so full of turns and quibbles upon the sound of words, as apparently to render it more flift and affected than agrees with conversation, or than a man of sense would choose to diflince, were it in his power. You may in some measure judge of Pliny’s manner, by one short letter to his friend, which runs thus: "How fare you? As I do in the country? pleasantly? that is, at leisure? For which reason I do not care to write long letters but to read them; the one as the effect of niceness, and the other of idleness. For nothing is more idle than your nice folks, or curious than your idle ones. Farewell." Every sentence here consists of an antithesis, and a jingle of words, very different from the style of conversation, and plainly the effect of study. But this was owing to the age in which he lived, at which time the Roman eloquence was sunk into puns and an affectation of wit; for he was otherwise a man of fine sense and great learning.

**Letter of Attorney**, in law, is a writing by which one person authorizes another to do some lawful act in his stead; as to give seisin of lands, to receive debts, bail a third person, &c.

The nature of this instrument is to transfer to the person to whom it is given, the whole power of the maker, to enable him to accomplish the act intended to be performed. It is either general or special: and sometimes it is made revocable, which is when a bare authority is only given; and sometimes it is irrevocable, as where debts, &c. are assigned from one person to another. It is generally held, that the power granted to the attorney must be strictly pursued; and that where it is made to three persons, two cannot execute it. In most cases, the power given by a letter of attorney determines upon the death of the person who gave it. No letter of attorney made by any feamen, &c. in any ship of war, or having letters of marque, or by their executors, &c. in order to empower any person to receive any share of prizes or bounty-money, shall be valid, unless the same be made revocable, and for the use of such seamen, and be signed and executed before, and attested by, the captain and one other of the signing officers of the ship, or the mayor or chief magistrate of some corporation.

**Letter of Free or Over**, are writings sealed with the great seal of England, whereby a man is authorized to do, or enjoy any thing, which, of himself, he could not do. See Patent. They are so called by reason of their form; as being open, with the seal affixed, ready to be flown for the confirmation of the authority given by them.

**Lettuce**, in botany. See Lactuca.
LEUCOMA, in surgery, a disorder of the eye, otherwise called **albug**, See **Albug**, and **Surgery**.

**LEUCOPETRA**, (anc. geog.) so called from its white colour (Strabo); a promontory of the Bruttii, in the territory of Rhegium: the termination of the Apennine. The outmost extremity of the Bruttii, or the modern **Calabria Ultra**; as the Japygium is of the ancient Calabria, or the modern **Calabria Cura**.

**LEUCOPETRIANS**, in ecclesiastical history, the name of a fanatical sect which sprang up in the Greek and Eastern churches towards the close of the 12th century; the fanatics of this denomination professed to believe in a double trinity, rejected wedlock, abstained from fleshly indulgences, considered the sacraments of Baptism and the Lord's Supper, and all the various branches of external worship; placed the essence of religion in internal prayer alone, and maintained, as it is said, that an evil being, or genius, dwelt in the breast of every mortal, and could be expelled thence by no other method than by perpetual supplication to the Supreme Being. The founder of this enthusiastic sect is said to have been a person called **Leucopetra**, and his chief disciple Typhon, who corrupted by fanatical interpretations, several books of Scripture, and particularly St. Matthew's Gospel.

**LEUCOPHELMATIA**, in medicine, a kind of dropsy, otherwise called **anaforcaea**, See **Jades subjoined to** **Medicine**.

**LEUCOTHOE** or **LEUCO THEA** (fáb. hist.), the wife of Athamas, changed into a sea deity; see **io**. She was called **Mataia** by the Roman. She had a temple at Rome, where all the people, particularly women, offered vows for their brother's children. They did not in treat the deity to protect their own children, because Io had been unfortunate in hers.

No female slaves were permitted to enter the temple; or if their curiosity tempted them to transgress this rule, they were beaten with the greatest severity. To this supplicating for other people's children, Ovid adds in these lines:

*Quam non tanum lancea pro filio sua pia mater adduxit, / Ipse parum fuisse parum paren.***

**LEUCTRA** (anc. geog.), a town of Boeotia, to the west of Thebes, or between Platea and Iphigia, where the Lacedemonians had a great defeat given them by Epaminondas and Pelopidas the Thewan generals. The Theban army consisted of 6000 men, where as that of the enemy was at least thrice that number; but Epaminondas trusted most in his horse, wherein he had much the advantage, both in their quality and good management; the rest he endeavoured to supply by the disposition of his men, and the vigour of the attack. He even refused to suffer any to serve under him in the engagement, but such as he knew to be fully resolved to conquer or die. He put himself at the head of the left wing, opposite to Cleombrotus king of Sparta, and placed the main forces of the battle there; rightly concluding, that if he could break the body of the Spartans, which was but 12 men deep, whereas his own was so, the rest would be soon put to flight. He closed his own with the fiercest band, which was commanded by Pelopidas; and placed his horse in front. His right, from which he had drawn so many men, he ordered to fall back,
LEV [6] LEV

Lev, in a flating line, as if they declined to fight, that they might not be too much exposed to the enemy, and might serve him for a corps of reserve in case of need. This was the wise disposition which the two Theban generals made of their few but resolute forces; and which succeeded in every part, according to their will. Epaminondas advanced with his left wing, extending it obliquely, in order to draw the enemy's right from the main body; and Pelopidas charged them with such desperate force and fury, at the head of his battalion, before they could reunite, that their horse, not being able to stand the shock, were forced back upon their infantry, which threw the whole into the greatest confusion: so that though the Spartans were of all the Greeks the most expert in recovering from any surprise, yet their skill on this occasion either failed them or proved of no effect; for the Thebans, observing the dreadful impression they had made on them with their horse, pulled furiously upon the Spartan king, and opened their way to him with a great slaughter.

Upon the death of Cleombrotus, and several officers of note, the Spartans, according to custom, renewed the fight with double vigour and fury, not so much to revenge his death as to recover his body, which was such a established point of honour as they could not give up without the greatest disgrace. But here the Theban general wisely chose rather to gratify them in that point, than to hazard the success of a second onset; and left them in possession of their king, whilst he marched straight against their other wing, commanded by Archidamus, and consisted chiefly of such auxiliaries and allies as had not heartily engaged in the Spartan interest: these were so discouraged by the death of the king and the defeat of that wing, that they betook themselves to flight, and were presently after followed by the rest of the army. The Thebans, however, pursued them so closely, that they made a second dreadful slaughter among them; which completed Epaminondas's victory, whereupon master of the field, and erected a trophy in memory of it. This was the conclusion of the famed battle of Leuctra, in which the Lacedemonians lost 4000 men, and the Thebans but 300.

LEV. An instrument wherewith to draw a line parallel to the horizon, by means of which the true level, or the difference of ascent or descent between several places, may be found, for conveying water, draining fields, &c.

There are several instruments of different contrivance and matter, invented for the perfection of levelling; all of which, for the practice, may be reduced to the following.

Air-Level, that which shows the line of level by means of a bubble of air inclosed with some liquor in a glass-tube of an indeterminate length and thickness, whose two ends are hermetically sealed. When the bubble fixes itself at a certain mark, made exactly in the middle of the tube, the plane or ruler wherein it is fixed is level. When it is not level, the bubble will rise to one end. This glass-tube may be set in another of brasses, having an aperture in the middle, whence the bubble of air may be observed. The liquor wherewith the tube is filled is oil of tartr, or aqua seconda; these not being liable to freeze as common water, nor to rarefaction and condenation, as spirit of wine is. This application of a bubble of air was the invention of Dr Hooke.

There is one of these instruments made with sights, being an improvement upon that last described, which, by the addition of more apparatus, becomes more commodious and exact. It consists of an air-level, fig. 1. about eight inches long, and seven or eight lines in diameter, set in a brass-tube, 2, with an aperture in the middle, C. The tubes are carried in a strong brass-tuber, a foot long; at whose ends are fixed two sights, 3, 3, exactly perpendicular to the tube, and of an equal height, having a square hole formed by two fillets of brass crossing each other at right angles, in the middle whereof is drilled a very little hole, through which a point on a level with the instrument is depressed. The brass tube is fastened on the ruler by means of two screws; one whereof, marked 4, serves to raise or depress the tube at pleasure, for bringing it towards a level. The top of the ball and socket is riveted to a little ruler that springs one end whereof is fastened with a fret to the great ruler, and at the other end has a screw, 5, serving to raise and depress the instrument when nearly level.

The instrument just described however, is yet less commodious than the following one; because though the holes be ever so small, yet they will still take in too great a space to determine the point of level precisely.

The instrument alluded to consists of an air-level, with telescope sights. This level (fig. 2.) is like the last; with this difference, that instead of plain sights, it carries a telescope to determine exactly a point of level at a good distance. The telescope is a little brass-tube about 15 inches long, fastened on the same ruler as the level. At the end of the tube of the telescope, marked 1, enters the little tube 1, carrying the eye-glas and an hair horizontally placed in the focus of the object-glas, 2; which little tube may be drawn out, or pulled into the great one, for adjusting the telescope to different sights; at the other end of the telescope is placed the object-glas. The screw 3, is for raising or lowering the little fork, for carrying the hair, and making it agree with the bubble of air when the instrument is level; and the screw 4, is for making the bubble of air; D or E, agree with the telescope: the whole is fitted to a ball and socket. M. Hayagens is said to be the first inventor of this level which has this advantage, that it may be inverted by turning the ruler and telescope half round; and if then the hair cut the same point that it did before, the operation is just.

It may be observed, that one may add a telescope to any kind of level, by applying it upon, or parallel to, the base or ruler, when there is occasion to take the level of remote objects.

Dr Delaguiers contrived an instrument by which the difference of level of two places, which could not be taken in less than four or five days with the best telescope-levels, may be taken in a few hours. The instrument is as follows. To the ball C (fig. 3.) is joined a recurve tube BA, with a very fine bore, and a small bubble at top A, whose upper part is open. It is evident from the make of this instrument, that if it be inclined in carrying, no prejudice will be done to the liquor, which will always be right both in the ball and tube when the instrument is set upright. If the air at C be so expanded with heat, as to drive the liquor
liquor to the top of the tube, the cavity A will receive the liquor, which will come down again and settle at D, or near it, according to the level of the place where the instrument is, as soon as the air at C returns to the same temper as to heat and cold.

To prove the same degree of heat, when the different observations are made, the machine is fixed in a tin vessel, EF, filled with water up to g h, above the ball, and a very sensitive thermometer has also its ball under water, that one may observe the liquor at D, in each experiment, when the thermometer stands at the same height as before. The water is poured out when the instrument is carried; which one may do conveniently by means of the wooden frame, which is set upright by the three screws S, S, S, fig. 4. and a line and plummet P P, fig. 5. At the back part of the wooden frame, from the piece at top K, hangs the plummet P, over a brass point at N; M m are brackets to make the upright board K N continue at right angles with the horizontal one at N. Fig. 6. represents a front view of the machine, supposing the fore part of the tin vessel transparent; and here the brass socket of the recurve-tube, into which the ball is ferewed, has two wings at 11, fixed to the bottom, that the ball may not break the tube by its endeavour to emerge when the water is poured in, as high as g h.

After the Doctor had contrived this machine, he considered, that as the tube is of a very small bore, if the liquor should rise into the ball at A (fig. 5.) in carrying the instrument from one place to another, some of it would adhere to the sides or the ball A, and upon its descent in making the experiment, so much might be left behind, that the liquor would not be blank, screw, to shut up the hole at A, as soon as one experiment is made, that, in carrying the machine, the air in A may balance that in C, so that the liquor shall not run up and down the tube, whatever degree of heat and cold may act upon the instrument, in going from one place to another. Now, because one experiment may be made in the morning, the water may be so cold, that when a second experiment is made at noon the water cannot be brought to the same degree of cold it had in the morning; therefore, in making the first experiment, warm water must be mixed with the cold, and when the water has stood some time, before it comes to be as cold as it is likely to be at the warmest part of that day, observe and set down the degree of the thermometer at which the spirit stands, and likewise the degree of the water in the barometer at D; then ferew on the cape at A, pour out the water, and carry the instrument to the place whose level you would know; then pour in your water, and when the thermometer is come to the same degree as before, open the screw at v m, and observe the liquor in the barometer.

The Doctor's scale for the barometer is ten inches long, and divided into tenths; so that such an instrument will serve for any heights not exceeding ten feet, each tenth of an inch answering to a foot in height. The doctor made no allowance for the decrease of density in the air, because he did not propose this machine for measuring mountains (though, with a proper allowance for the decreasing density of the air, it will do very well), but for heights that want to be known in gardens, plantations, and the conveyance of water, where an experiment that answers two or three feet in the distance of 20 miles, will render this a very useful instrument.

Artillery Foot—Level, is in form of a square, having its two legs or branches of an equal length; at a junction whereof is a little hole, whence hangs a thread and plummet playing on a perpendicular line in the middle of a quadrant. It is divided into twice 45 degrees from the middle. Fig. 7.

This instrument may be used on other occasions, by placing the ends of its two branches on a plane, for when the thread plays perpendicularly over the middle division of the quadrant, that plane is assuredly level. To use it in gunnery, place the two ends on the piece of artillery, which you may raise to any proposed height, by means of the plummet, whose thread will give the degree above the level.

Carpenter's and Mason's LEVEL, consists of a long ruler, in the middle whereof is flattened, at right angles, another somewhat bigger, at the top of which is fastened a line, which, when it hangs over a fiducial line at right angles with the base, shows that the said base is horizontal. Sometimes this level is all of one board. Fig. 8.

Gunner's Level, for levelling cannons and mortars, consists of a triangular brass plate, about four inches high, fig. 9. at the bottom of which is a portion of a circle, divided into 45 degrees; which number is sufficient for the highest elevation of cannons and mortars, and for giving shot the greatest range: on the centre of this segment of a circle is ferewed a piece of brass, by means of which it may be fixed or ferewed at pleasure; the end of this piece of brass is made fo as to serve for a plummet and index, in order to show the different degrees of elevation of pieces of artillery. This instrument has also a brass foot, to set upon cannons or mortars, so as, when those pieces are horizontal, the instrument will be perpendicular. The foot of this instrument is to be placed on the piece to be elevated, in such a manner, as that the point of the plummet may fall on the proper degree: this is what they call levelling the piece.

Mason's Level, is composed of three rules, so joined as to form an oblong-rectangle, somewhat like a Roman A; at the vertex whereof is a levelled thread, from which hangs a plummet, that plusses over a fiducial line, marked in the middle of the base, when the thing to which the level is applied is horizontal; but declines from the mark, when the thing is lower on the one side than on the other.

Plumb or Pendulum Level, which shows the horizontal lines by means of another line perpendicular to that described by a plummet or pendulum. This instrument, fig. 10. consists of two legs or branches, joined together at right angles, whereof that which carries the thread and plummet is about a foot and a half long: the thread is hung towards the top of the branch, at the point 2. The middle of the branch where the thread plusses is hollow, so that it may hang free every where; but towards the bottom, where there is a little blade of silver, whereon is drawn a line perpendicular to the telescope, the said cavity is covered by two pieces of brass, making as it were a kind of cafe, left the wind should agitate the thread; for which reason the silver blade is covered with a glass G, to the
end that it may be seen when the thread and plummet play upon the perpendicular: the telescope is fastened to the other branch of the instrument, and is about two feet long; having an hair placed horizontally across the focus of the object-glass, which determines the point of the level. The telescope must be fitted at right angles to the perpendicular. It has a ball and socket, by which it is fastened to the foot, and was invented by M. Piccard.

Reflecting Level, that made by means of a pretty long surface of water representing the same object inverted which we see erected by the eye, so that the point where these two objects appear to meet is on a level with the place where the surface of the water is found. This is the invention of M. Mariotte.

There is another reflecting level consisting of a mirror of steel, or the like, well polished, and placed a little before the object-glass of a telescope, suspended perpendicularly. This mirror must make an angle of 45° with the telescope, in which case the perpendicular line of the said telescope is converted into a horizontal line, which is the same line of level. This is the invention of M. Caffini.

Water Level, that which shows the horizontal line by means of a surface of water or other liquor; founded on this principle, that water always places itself level.

The most simple is made of a long wooden trough or canal, whose sides are parallel to the base; so that being equally filled with water, its surface shows the line of level. This is the chorobates of the ancients.

Chorobata.-

See also made with two cups fitted to the two ends of a pipe, three or four feet long, about an inch in diameter, by means of which the water communicates from the one to the other cup; and this pipe being moveable on its stand by means of a ball and socket, when the two cups become equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glass three or four inches long, fastened to each extreme of the pipe with wax or mastic. Into the pipe is poured some common or coloured water which flows itself through the cylinders by means whereof the line of level is determined; the height of the water, with respect to the centre of the earth being always the same in both cylinders; this level, though very simple, is yet very commodious for levelling small distances.

Level of Mr. Huygens's invention, consists of a telescope a, fig. 11, in form of a cylinder, going through a ferrill, in which it is fastened by the middle. This ferrill has two flat branches b, one above, and the other below: at the ends whereof are fastened little moving pieces, which carry two rings, by one of which the telescope is suspended to an hook at the end of the screw 3, and by the other a pretty heavy weight is suspended, in order to keep the telescope in \textit{equilibrio}. This weight hangs in the box 5, which is almost filled with linseed oil, oil of walnuts, or other matter that will not easily coagulate, for more aptly settling the balance of the weight and telescope. The instrument caries two telescopes close and very parallel to each other, the eye-glasses of the one being against the object-glass of the other, that one may see each way without turning the level. In the focus of the object-glasses of each telescope must a little hair be strained horizontally, to be raised and lowered as occasion requires by a little screw. If the tube of the telescope be not found level when suspended, a ferrill or ring, \textit{f}, is put on it, and is to be slid along till it fixes to a level. The hook on which the instrument is hung is fixed to a flat wooden cross; at the ends of each arm whereof there is a hook serving to keep the telescope from too much agitation in using or carriage.

To the said flat cross is applied another hollow one, that serves as a case for the instrument; but the two ends are left open, that the telescope may be secured from the weather and in a condition always to be used. The foot of this instrument is a round brass plate, to which are fastened three brass ferrills, moveable by means of joints wherein are put staves, and on this foot is placed the box.

Fig. 12. marked \textit{I}, is a balance-level; which being suspended by the ring, the two sights, when in \textit{equilibrio}, will be horizontal, or in a level.

Spirit Level. The most accurate levelling instrument, and that possessed of the greatest essential advantages in use, is the spirit-level; which was at first contrived by the late Mr. Sifon, and to which the small additions and improvements have been since made. The following is a description of one of the best of these levels, as made by the principal mathematical instrument makers.

Fig. 13, is a representation of the instrument mounted on its complete staves, copied (except the letters) from Mr. Adams's Graphical Essays, Plate xviii. fig. 3. The telescope (ABC) is made from 15 inches to 2 feet in length, as may be required. It is achromatic, of the best kind, and shows the objects erect. In the focus of the eye-glases are exceedingly fine cross wires, the intersection of which is evidently shown to be perfectly in the axis of the tube; for by turning it round on its two supports DE, and looking through the telescope, the intersection of the wires will constantly cut the same part of the object viewed. By turning the screw \textit{a} at the side of the telescope, the object-glass at \textit{g} is moved; and thus the telescope is exactly adapted to the eye. If these cross wires are at any time out of their adjustment, which is discovered by their intersection not cutting the same part of the object during the revolution of the telescope on its axis, they are easily adjusted by means of the four screws bc, placed on the telescope about an inch from the end for the eye. These screws \textit{c}, in perpendicular directions to one another, by unfurring one and tightening the other opposite to the wire, so that if connected with it, it may be moved either way at pleasure; and in this manner the wire perpendicular to it may be moved, and thus the intersection of the wires brought exactly in the axis of the tube.

To the telescope is fixed, by two small screws ce, the level tube containing the spirits, with a small bubble of air: This bubble of air, when the instrument is well adjusted, will lie exactly in the same place, in or near the middle of its tube, whether the telescope be reversed or not on the supports, in which case it is kept unmoved.

It is evident that the axis of the telescope, or the intersection of the wires as before shown, must be in this case
Levels.

LEVELLING.

In this facile mode of adjustment consists the new improvement of the instrument; and it is hereby capable of being adjusted by only one station and one object, which will at the same time determine it to be in a true level. If by change of weather, accident, or otherwise, the instrument should have lost its level adjustment or face, it may thus be readily refixed and re-adjusted at the first station; which is an advantage none of the instruments formerly made have been capable of. The two supporters \( D, F \), on which the level rests and turns, are shaped like the letter \( V \). The telescope rests within the upper part of them; and the inner sides of each of these \( Y \) are tangents to the cylindrical tube of the telescope, which is turned to a true cylinder, and each touches it but at one place only.

The lower end of these supporters are inserted into a strong brass plate \( F, E, \) and fit as to stand perpendicularly on it. One is kept fast by a tightening screw \( G \), and to the other is applied a fine threaded screw \( H \), to adjust the tube when on its supporters to a true level. To the supporter \( D \) is sometimes applied a line of tangents as far as \( 12 \) degrees, in order to take an angle of depression or elevation to that extent. Between the supporters is also sometimes fixed a compass-box \( L \), divided into 360 degrees, and again into four \( 90^\circ \); having a centre pin and needle, and trigger, at \( d \), to throw off the needle from the centre when not used; so in this manner it constitutes a perfect circumferentor, connected with all the foregoing improvements. This plate is fixed on a conical brass ferrel \( K \), which is adapted to the bowl of the instrument of a cone at top of the brass head of the flaves, having a ball and socket, with three bowl-ball joints, two strong brass parallel plates \( L, L \), the four screws \( c, c \) for adjusting the horizontal motion, a regulating screw \( M \) to this motion, and a fastening screw \( N \) to tighten it on the cone when necessary. The fastening screw \( N \), and the regulating screw \( M \), by which the whole instrument is moved, with accuracy through a small space in an horizontal direction, was an addition of Mr. Ramsden's.

The manner of adjusting the spirit-level at the first station.

The whole being now placed steadily on its stand, it must be rendered parallel to the axis of the telescope before you adjust the horizontal motion. To this end the telescope must be placed in a line with two of the screws \( c, c \), and that levelled thereby till the bubble of air in the spirit-tube keeps its position in the middle, while turned about two or three points, making nearly right angles at the centre to one another.

If the horizontal motion being thus adjusted, the rims \( f, f \) of the \( Y \) is to be opened, the telescope taken off and laid the contrary way upon the supporters. If the bubble of air then rests exactly the same, the level and telescope are adjusted rightly to one another; but if the bubble does not remain the same, the end to which the air bubble goes must be noticed, and the distance of it from the telescope altered; correcting one half the error by the screws \( c, c \), and the other half by the screws \( e, e \).

Now the intersection of the wires being directed to any distant object, it may be one of the vales of the flaves hereafter described: if they continue to be against it precisely while the telescope is turned round on its \( Y \), it proves, as before mentioned, that the axis of the telescope coincides with the intersection of the wires, and that the instrument will give the true level direction.

The operation of levelling being of a very accurate and important nature, and the best instrument when out of its adjustment being of little use, it is quite necessary that every person using such an instrument should have it ready in his power to correct it; and the one above described appears to be the best adapted for that purpose of any hitherto contrived.

LEVELLING may be defined, the art which infurates us in finding how much higher or lower any given point on the surface of the earth is than another; or, in other words, the difference in their distance from the centre of the earth.

The practice of levelling therefore consists, 1. In finding one station only. or, in other words, the difference in their distance from the centre of the earth.

With regard to the theory of levelling, we must observe, that a plumb-line, hanging freely in the air, points directly towards the centre of the earth; and a line drawn at right angles, crossing the direction of the plumb-line, and touching the earth's surface, is a true level only in that particular spot; but if this line which crosses the plumb be continued for any considerable length, it will rise above the earth's surface, and the apparent level will be above the true one, because the earth is globular; and this rising will be as the square of the distance to which the said right line is produced; that is to say, however much it is raised above the earth's surface at one mile's distance, it will rise four times as much at the distance of two miles, nine times at the distance of three, &c. This is owing to the globular figure of the earth; and this rising is the difference between the true and apparent level, the real curve of the earth being the true level, and the tangent to it the apparent level. Hence it appears, that the less distance we take betwixt any two stations, the truer will be our operations in levelling; and so soon does the difference between the true and apparent levels become perceptible, that it is necessary to make an allowance for it, if the distance betwixt the two stations exceeds two chains in length. The following is an infallible rule for determining the allowance to be made:

"Multiply the number of Gunter's decimal lines that are contained in length between any two stations where the levels are to be taken by itself, and add the product arising therefrom by \( \frac{1}{100} \); which is a common multiplier for all manner of distances for this purpose on account of the earth's curvature: then divide the second product arising therefrom by \( 100,000 \); or, which is also the same, with the daff of the pen cut off five figures on the right hand side of the product, and what remains on the left side is inches, and the five figures cut off decimal parts of an inch."
Levelling. The following is A Table of the Curvature of the Earth, and shows the quantity below the apparent level at the end of every number of chains to 100.

</table>

Levelling is either simple or compound. The former is when the level points are determined from one station, whether the level be fixed at one of the points or between them. Compound levelling is nothing more than a repetition of many simple operations.

An example of simple levelling is given Plate CCLXXI. fig. 1, where A B are the station points of the level; C D the two points ascertaincd. Let the height CH, HN, from whence also the number of chains and inches below the apparent level at the end of every number of chains is to be determined. The figure 12. stations are marked. Stakes ought then to be driven in at the limits of each station, as A, B, C, D, &c. They ought to be about two or three inches above the ground, and driven 18 inches into it. Stakes should also be driven in at each station of the instrument, as 1, 2, 3, 4, &c.

From A to C be - 6 0 0
From B to D be - 9 0 0

The difference - 3 0 0

If the station points of the level are above the line of sight, as in fig. 2, and the distance from A to C be six feet, and from B to D nine feet, the difference will still be three feet which B is higher than A.

As an example of compound levelling, suppose it were required to know the difference of height between the point A on the river Zame, and N on the river Belams, fig. 3. (As our author could find no factitious examples in any English author, he copied this and the following ones from M. le Febure). In this operation stakes should be driven down at A and N, exactly level with the surface of the water; and these stakes should be so fixed, that they may not be changed until the whole operation be finished; a plan of the ground between the two rivers should then be made, by which it will be discovered, that the shortest way between the rivers is by the dotted line AC, CH, HN, from whence also the number of stations necessary to be taken will be determined. The operator will also be enabled to distribute them properly according to the nature and situation of the ground.

In the figure 12 stations are marked. Stakes ought then to be driven in at the limits of each station, as A, B, C, D, &c. They ought to be about two or three inches above the ground, and driven 18 inches into it. Stakes should also be driven in at each station of the instrument, as 1, 2, 3, 4, &c.

The operation may be begun in the following manner. Let the first station be at 1, equally distant from the two points A and B, which themselves are distant 166 yards. Write down on in one column the first limit A; in another, the number of feet, inches, and tenths; with the points of sight indicated on the station-staff at A, viz. 7. 6. 0. In the third column, the second limit B; in the fourth, the height indicated at the station-staff B, viz. 6. 0. 0. Lastly, in the fifth column, the distance from one station-staff to the other; which in this case is 166 yards. Remove now the level to the point marked 2, which is in the middle between B and C, the two places where the station-staves are to be held; observing that B, which was the second limit in the former operation, is the first in this. Then write down the observed heights as before: in the first column B; in the second 4. 6. 0; in the third C; in the fourth 5. 6. 2; in the fifth 560, the distance between B and C.

It being impossible, on account of the inequality of the ground at the third station, to place the instrument in the middle between the two station-staves, find the most convenient point as at 3; then measure exactly how far this is from each station-staff, and you will find that from 3 to C is 160 yards; from three to D, 80 yards: and the remainder of the operation will be as in the preceding station.

In the fourth operation, we must endeavour to compensate for any error which might have happened in the last. Mark out, therefore, 80 yards from the station-staff D to the point 4; and 160 yards from 4 to E; and this must be carefully attended to, as by such compensations the work may be much facilitated. Proceed in the same manner with the eight remaining stations, observing to enter every thing in its proper column; and when the whole is finished, add the sums of each column together, and then subtract the lesser from the greater: the difference, which in the present case is 5. 4. 8, shows the ground at N to be thus much lower than the ground at A.

To obtain a section of this level, draw the dotted line oo, fig. 4, either above or below the plane which may be taken for the level or horizontal line. Let fall then perpendiculac upon this line from all the station-points and places where the station-staves were fixed. Beginning now at A, set off 7 feet 6 inches upon the line from A to a for the height of the level-point determined on the staff at this place, draw a line through a parallel to the dotted line oo, which will cut the third perpendicular at b, the second station-staff. Set off from this point downwards six feet to B, which shows the second limit of the first operation; and that the ground at B is one foot six inches higher than at A: place your instrument between the two lines at the height of the level line, and trace the ground according to its different heights. Now set off on the second station-staff B, four feet six inches to C, the height determined by the level at the second station; and from C draw a line parallel to oo, which will cut the fifth perpendicular at d, the third station-staff. From this point set off 3 feet 6 inches, downwards to C, which will be our second limit with respect to the preceding one and the third with respect to the fifth. Then draw your instrument in the middle between B and C, and delineate the ground with its inequalities. Proceed.
Levelling. 

Levelling, indeed, in the same manner from station to station, till you arrive at the last \( N \), and you will have the profile of the ground over which the level was taken.

This method answers very well where only a general profile of the different stations is required; but where it is necessary to have an exact detail of the ground between the limits, we must then go to work more particularly. Suppose, therefore, the level to have been taken from \( A \) to \( N \) by another route, but on a more uniform ground, in order to form a canal marked \( O, P, Q, R, S, T, U, X, Y \). Draw at pleasure a line \( Z, Y \), fig. 5, to represent the level, and regulate the rest; then let fall on this line perpendiculars to represent the flaks at the limits of each station, taking care that they be fixed accurately at their respective distances from each other. The difference between the extreme limits, in this case, ought to be the same as in the former, viz., 5 feet 4 inches. Set off this measure upon the perpendicular at the first limit; and from prolonging the perpendicular, mark off at \( a \) the height determined at the first station; then do the same with the second and third, and so on with the following, till this part of the work is finished; there remains then only to delineate in detail the ground between the stations, the distances in this example being doubled larger on account of the detail.

To obtain the section of the ground between \( O \) and \( P \), place your instrument at one of the limits, as \( P \), fixing it so that the cross hairs may answer to the point \( C \); then look towards the first limit \( a \), raising or depressing the vane till it coincides with the intersection of the cross hairs; and the line of sight from one point to the other will mark the level or horizontal line.

To set off the height of the brink of the river above the first limit, drive a stake down close to the ground at \( a \); and place your station-staff upon it, observing where the hairs intersect the vane, which will be 5 feet 10 inches; then, laying off upon the line \( ax \) the distance from the first to the last stake, let fall from thence a perpendicular, and set off thereon 14 to \( a \), which gives the height at the last stake; or, which is the fact, the height from the edge of the river above the surface of the water, as is evident from the section. Drive a second stake at \( 6 \), in a line between the limits; place the station-staff upon this stake, and observe the height 4. 6. intersected by the cross hairs; the instrument will remaining in the same situation. Set off on the level-line the distance from the first stake \( a \) to the second \( b \); and then let fall a perpendicular, and mark upon it 4. 6 to \( b \), which gives the height of the ground at this place.

The small hollow \( c \) is marked out by driving down a third stake even with the ground, in the middle of it at \( c \); but the exact distance of the second stake \( b \) from the third \( c \), must be marked upon the instrument, as \( b \) will fall a perpendicular from \( c \), and set off upon it 6. 8. \( c \), pointed out by the cross hairs on the staff, which determines the depth of the hollow, as appears from the figure. As the distances between the stakes are now very short, they can easily be marked by the operator, who can settle any little inequalities by a comparison with those already ascertained. Proceed thus with the other stations till you arrive at the last, and you will always obtain an accurate section of your work; by which it is easy to form a just estimation of levelling, the land to be dug away, in order to form the canal, by adding the depth to be given to it.

In great heights such as this, it will be necessary to proceed by small descents, as from \( A \) to \( D \). The instrument must be adjusted with all possible care; and it will even be proper, in some part of the work, to use a smaller instrument. The following is a table of the different operations used in making this level, it having been taken from M. le Febure's practice.

In this case only two levellings are made between \( A \) and \( D \), though more would have been necessary; but they are omitted to avoid confusion. In the fourth station the height found was 16 feet 8 inches; but on account of the great length, it was requisite to reduce the apparent level to the true one, which is always necessary where the length is considerable. At the last limit we get the height from \( N \) to \( e \); then from \( e \) to \( l \); from \( f \) to \( K \), fig. 7 &c. all which added together, and the correction for the curvature, gives 47 feet 3 inches. Now, by adding each column together, and subtracting one from the other, we have 51 feet 9 inches for the height which the point \( A \) is above \( K \), the bottom of the basin, and which will cause the jet d'eau to rise about 45 feet. The general section of this operation is shown at fig. 7. 8, but an exact profile of the mountain is more difficult; as requiring many operations; though some of these might be obtained by measuring from the level line without moving the instrument.

The last example given by our author is likewise from M. le Febure, and includes a length of near five German miles (25 quarters) in a straight line, and 9 or 10 (45 or 50 English lines) including the turnings and windings. In this instance the river \( Raynor \) was measured from Lignebrook to Villebour. The first operation was to drive stakes at several parts of the river even with the water's edge; the first of which a little above the mills of Lignebrook showed the upper water-mark, and another showed the lower water-mark at the same mills. Two flaks above and below the mills of Mazurance, somewhat more than half way between Lignebrook and Villebour, pointed out...
out the difference between high and low water there, and formed likewise the third and fourth limit of the operation; while the stakes above and below the mills of Villebourg pointed out the difference between high and low water, and likewise formed the last limits of the operation.

These marks were all made at the edge of the water exactly even with its surface, and all made at the different parts of the river nearly at the same instant of time. The principal limits of the levelling (says Mr. Adams) being already fixed and determined, it remains to find the level between the limits, according to the methods already pointed out, using every advantage that may contribute to the success of the work, and in the same time avoiding all obstacles and difficulties that may retard or injure the operations. The first rule is always to take the shortest possible way from one limit to another, though this rule ought not to be followed if there are considerable obstacles in the way; as hills, woods, marshy ground, or if, by going aside, any advantage can be obtained. In the present case it was found necessary to deviate very considerably from the general rule, in order to take in several points, the surfaces of which might all be taken for a perfect level, and thus levels were frequently taken across the country for a considerable way. The difference of height between the mills of Lignebruk and Villebourg was at last found to be about 19 feet, indicating a deficient of not quite a foot in a mile.

LEVELLING-STATES, instruments used in levelling, serving to carry the marks to be observed, and at the same time to measure the heights of those marks from the ground. They usually consist of two mahogany flaves ten feet long, in two parts, that slide upon one another to about 5½ feet, for the more portable carriage. They are divided into 1000 equal parts, and numbered at every tenth division by 10, 20, 30, 40, &c. to 1000; and on one side the feet and inches are also sometimes marked.

A vane A slides up and down upon each side of these flaves, which by brafs springs will stand at any part. These vanes are about 10 inches long and 4 inches broad; the breadth is first divided into three equal parts, the two extremes painted white, the middle space divided again into three equal parts which are reds; the middle one of them is also painted white, and the two other parts black; and thus they are fitted to all the common distances. These vanes have each a brass wire across a small square hole in the centre, which serves to point out the height correctly, by coinciding with the horizontal wire of the telecope of the level.

LEVEN, a river of Lenox or Dunbartonshire in Scotland. See Lenox.

LEVER, in mechanics, is a bar of iron or wood, one part of which being supported by a prop, all other parts turn upon that prop as their centre of motion. This instrument is of two kinds. First, the common form, where the weight we desire to raise rests at one end of it, our strength is applied at the other end, and the prop is between both. When we fill up the fire with a poker, we make use of this lever; the poker is the lever, it rests upon one of the bars of the grate as a prop, the incumbent fire is the weight to be overcome, and the other end held in the hands the strength or power. In this as in all the rest, we have only to increase the distance between the strength and prop to give the man that works the instrument greater power.

The lever of the second kind, has the prop at one end, the strength is applied to the other, and the weight to be raised rests upon them. Thus in raising the water-plug in the streets, the workman puts his iron lever through the hole of the plug, till he reaches the ground, and then raising his prop, lifts the plug with his strength at the other end of the lever. In this lever also, the farther the distance of the prop from the strength, the greater is the workman's power.

These instruments, as we see, assist the strength, but sometimes a workman is obliged to act at a disadvantage, in raising either a piece of timber or a ladder upon one end. We cannot without grammatical propriety, call this a lever, since such a piece of timber in fact in no way contributes to raise the weight. In this case, the man, who is the strength or power, is in the middle, the part of the beam already raised is the weight, the part yet at the ground is the prop on which the beam turns or rests. Here the man's strength will be diminished, in proportion to the weight it supports. The weight will be greater the farther it is from the prop, therefore the man will bear the greater weight the nearer he is to the prop. See Mechanics.

LEVERET, among sportsmen, denotes a hare in the first year of its age.

LEVIGATION, in pharmacy and chemistry, the reducing hard and ponderous bodies, to an impalpable powder, by grinding them on a porphyry, or in a mill. See Chemistry, n. 399.

A new method of reducing powders to a great degree of finenesses has lately been invented by means of a fanner. This has the advantage over the other methods, in being much more expeditious, and attended with less trouble and expense; the degree of fineness to which they are reducible being thus also in a manner unlimited. The construction of the fanner employed for this purpose is different from that employed for winnowing corn; the blast not being collected into a small compass as in the latter, but diffused over a considerable space, left a violent blast should hurry off both coarse and fine together. For this purpose, the leaves of the fanner are made as long in the direction parallel to the axis as can be done conveniently. In the other direction projecting from it, they differ not from the ordinary length, nor do they in the general situation with respect to each other. Before the leaves is a wooden partition reaching half way up, to prevent the gross powder from falling in among the leaves, which reaches about half way from bottom to top; and about two feet or less from this, according to the size of the fanner, is another partition in a sloping direction, reaching from the bottom of the box to near the top. The whole is enclosed in a large box fix or seven feet long, having in the end farther off from the leaves a slit equal to the space left between the top of the box and the sloping partition already mentioned. On the top of this is another box, extending from the farthermost end of the former to the hopper which holds the coarse powder, with a hole in the end nearest to the fanner; and upon this another box,
LEV (13)

LEWDNESS. See Fornication. Lewdness is punishable by the English law by fine, imprisonment, &c. And Mich. 15 Car. II. a person was indicted for open lewdness, in throwing his naked body in a balcony, and other misdemeanors; and was fined 2000 marks, imprisoned for a week, and bound to his good behaviour for three years. 1 Sid. 168. In times past, when any man granted a lease of his house, it was usual to insert an express covenant, that the tenant should not entertain any lewd women, &c.

LEVITE, in a general sense, means all the descendants of Levi, among whom were the Jewish priests themselves, who, being descended from Aaron, were likewise of the race of Levi. In a more particular sense, Levite is used for an order of officers in that church, who were employed in performing the manual service of the temple. They were obedient to the priests in their ministration, and brought them wood, water, and other necessaries for the sacrifice. They sang and played upon instruments in the temple and in other places. They applied themselves to the study of the law, and were the ordinary judges of the country, but always subordinate to the priests. Their functions were the tythes of corn, fruit, and cattle, throughout Israel: but the priests were intitled to a tenth of the city tythes, by way of first-fruits to the Lord.

Eight and forty cities were assigned for the residence of the Levites, of which the priests claimed thirteen, six whereof were chosen for cities of refuge. They were consecrated, before they entered upon their ministry, by having their flesh washed, their clothes sprinkled with water of expiation. Imposition of hands was used in consecration, and two bullocks were offered at the door of the tabernacle. They waited weekly, and by turns, in the temple, beginning their attendance on one sabbath and ending the next. During this time they were maintained out of the offerings, &c. In the time of Solomon, the number of Levites, from the age of 20 and capable of serving, was 38,000.

LEVITICUS, a canonical book of the Old Testament, so called from its containing the laws and regulations relating to the priests, Levites, and sacrifices.

LEVITY, in physiology, the privation or want of weight in any body when compared with another that is heavier than it; in which sense it stands opposed to gravity.

LEUK, a town of Switzerland, almost in the middle of the Valais, remarkable for its natural strength, for the assembly of the flocks that often meet there, and for its baths, whose water is so hot that they will boil eggs.

LEUNCLAUVIUS (Joannes), a learned German, was descended from a noble family, and born at Amelbrun in Westphalia, 1533. He travelled through almost all the countries in Europe. While he was in Turkey, he collected very good materials for an "History of the Ottoman Empire," which he published, and also several other pieces concerning it, in Latin. He gave Latin translations also of Xenophon, Zophimus, &c. To a knowledge of the learned languages he added that of the civil law. He died at Vienna in 1593, aged 60.

LEUSDEN (John), a celebrated philologer, born in
LEWES, a large well-built town of Sussex in England, seated on an eminence on the banks of the river Ouse, 50 miles from London. It is famous for a bloody battle near it, wherein King Henry III. was defeated and taken prisoner by the barons: and is so ancient, that we read the Saxon king Athelstan appointed two mint-houses here, and that in the reign of Edward the Confessor it had 127 burgesses. It is a borough by prescription, by the style of contables and inhabitants. The contables are chosen yearly. It has handsome streets and two suburbs, with six parish churches. It carries on a good trade; and the river Ouse runs through it, which brings goods in boats and barges from a great distance. On this river are several iron-works, where cannon are cast for merchant-ships, besides other useful works. A charity-school was opened here in 1711, where 20 boys are taught, clothed, and maintained, at the expense of a private gentleman, by whom they were also furnished with books; and 8 boys more are taught here at the expense of other gentlemen. Here are horse-races almost every summer for the king’s plate of L. 100. The roads here are deep and dirty; but then it is the richest soil in this part of England. The market here runs through it, which is not more than a year, and sometimes a whole summer is not dry enough to make the roads passable. It is cheap living here; and the town not being under the direction of a corporation, but governed by gentlemen, it is reckoned an excellent retreat for half-pay officers, who cannot so well confine themselves to the rules of a corporation. It sends two members to parliament.

LEWIS, one of the largest of the Hebrides or western islands of Scotland, extending about 60 miles in length from north to south, and from 13 to 14 in breadth, consisting of a great number of isles and rocks, and parted by the sea into two divisions, called Lewis and Harris, the former lying to the westward of the other. Lewis belongs to the shire of Ross; is divided by several channels, distinguished by several names, and portioned out among different proprietors; but the Lewis, strictly so called, stretches about 36 miles in length, from the north point of Bowling-head to the southern extremity of Harris. The air is temperately cold, moist, and healthy: great part of the low ground is flooded with lakes; the soil is arable in many places, and has been counted fruitful in oats, barley, rye, flax, and hemp. The soil in these parts is a light sand, which the inhabitants manure with foot and sea-ware: but great part of the island is covered with heath. The labouring people dig the land with spades, and break the clods with small harrows, the foremost teeth of which are made of wood, and the remainder of rough heath, which smooths what the others have broken; and this harrow is drawn by one man, having a strong trace of horse-hair across his breast. Of their corn they not only make malt for ale, but likewise a strong spirit called trellareg, which is the whisky, or ukebeanagh, three times distilled. Lewis abounds with convenient bays and harbours, in which are caught, in great plenty, cod, ling, and herring: here are likewise whales of different sizes, which the natives drive into the bays, and kill with harpoons. These bays afford great plenty of shell-fish, such as clams, oysters, cockles, mussels, limpets, weals, and such a prodigious quantity of spout-fish is sometimes cast up from the sand off Loch-tua, that they infect the air, and render it unhealthy to the neighbouring inhabitants, who are not able to confume them, either by eating, or using them as manure for the fields. Some of these islands yield like wise produce small coral and coralline. The fresh water lakes are well stored with trout and eels, and the rivers yield...
The land-animals reared in this island, are cows, horses, sheep, goats, hogs, and deer; all these are of a diminutive size. The beef, mutton, and pork, are juicy and delicious; the horses are active and hardy: the deer, which are of the red kind, confine themselves to the chace of Geveraul, about 15 miles in compass, which affords tolerable pasturage; but in the winter, when the ground is covered with frost and snow, these animals are forced to feed on sea-ware, and endure all the rigour of the sea, without any shelter from wood or cope, for there is not a tree to be seen; nevertheless, the roots of very large trees, which have been cut by the axe, are found in different places. There is likewise a small grove of birch and hazel on the south-west side of Loch-Stornaway.

The inhabitants of Lewis are well-proportioned, tall, fair, sanguine, strong, and healthy. They are in general sober, circumplexed, and hospitable; dexterous in shooting, swimming, and leaping; bold and skilful mariners; and so temperate, that they will tug at the oar all day, without any other provifion than bread and water, with a fuiff of tobacco.

Along this coast we fee several natural remains or forts, called Duin; fuch as Duin royly, Dan-coradel, and Dan-eifer. There are also the remains of some old cairns, and other monuments of antiquity. At Stornaway village we fee the ruins of a fort destroyed by the English garrison sent thither by Oliver Cromwell. To the northward of Brago there is a round tower built of large stones, three stories high, tapering towards the top, with a double wall, and a circular staircase between, by which one may go quite round the building. On the heaths and summits of hills there are feveral cairns or heaps of stones, which served either for graves or beacons. In the parish of Barvas we fee a fingle stone called the thrashey, standing upright, above 20 feet high, and almost as much in breadth. Three stones, about 12 feet high each, are feen standing on the north side of antiquity; and another others standing fingle at great distances, and in remote parts of the island. But the moft remarkable monument of this kind appears by the village of Clafernife. Here we fee 39 pyramidal fones standing upright, about six or seven feet high from the furface, each about two feet in breadth. They are placed in form of an avenue, eight feet wide; the distance between every fone amounting to fix feet, and a fingle piece fands at the entrance. This avenue leads to a circle of 12 fones of the fame dimensions, with one in the centre 15 feet in length, and shaped like a rudder: on the eafh, south, and west fides of this circle, are four fones, fuch as thofe that compofe this round and avenue, forming three lines, or as it were, the body of the circle. This is fuppofed to have been a Druid temple; and tradition reports, that the chief Druid ftood by the large fone in the centre, and harangued the audience. At the distance of a quarter of a mile there is another circle of the fame nature; but without the range and avenue.

In all probability, thefe, as well as the monuments we have defcribed in our account of the Orkneys, and Stone-henge on Salisbury-plain, were places of worship erected by the Druids in the time of Pagan fuperfition. The chief town in Lewis is called Stornaway.

There is a considerable number of inferior adjacent isles and rocks, fome of which hardly deferve to be mentioned; fuch as the small islet Garve at the mouth of Lock_carly, Berniay, Padda, Bernera Minor, and Bernera Major, Kailify, Cavay, Carvay, Gremin, Pabay, Shirein, Vexay, Wuya the Larger and Lesser, and the Flannan islands, which the fearmen denominate the northerm hunters. These are visited every summer by the inhabitants of the Lewis, who go thither in quest of fowls, egges, down, quilis, and feathers, as well as to fear or kill the fheep that are kept here for fulture. As these islands are very steep and rocky, the visitors, after having landed and climbed up the rock by a ladder, uncover their heads, and, making a turn fun-ways, thank God for having escaped the danger they have undergone. In the largest islet are the ruins of a chapel dedicated to St Flannan, from whom the isles derive their name. Thither the fowlers repairing, strip themselves of their upper garments, which being laid upon a flone, they advance towards the altar, and repeat three prayers; an exercife which is performed every morning and evening. They obferve many other fuperflitious customs during their residence on these rocks; and when they have loaded their boat with their purchafe, return to the larger islands. Among the islands belonging to the Lewis, we may likewise take notice of the fmall isle of Pignies, fo called, because bones refeembling thofe of human creatures, but of very fmall dimensions, have been dug out of the ground.

The isle of Lewis is divided into the two parifhes of Barvas and Eye; and in each of these one minifter is fettled; but there is a great number of churches and chapels dedicated to different faints, in the different ifles which compofe this cloffer. All these were fancuaryes before the reformation, but now they are divifed of that privilege. The people of these ifles are Prefsbyterians, with a few Protestants of the English communion, and a fmall number of Roman Catholics. The Protestants obferve the festivals of Chriftmas, Good Friday, Easter, and Michaelmas; on the laft of which the individuals of both fexes perform an anniversary cavelcade.

LEWIS, or LOUTIS, the name of feveral kings of France. See FRANCE.

LEWIS VII. anno 1137, was the firft who had the courage to oppose the encroachments of the popes on the regal authority: Pope Innocent II. excommunicated him for appointing an archbishop of Bourges; but Lewis defended his prerogatives, and put the priests to death who had been the authors of the quarrel. In 1147, he put himself at the head of an army of 90,000 men, and marched against the Saracens, in the second crusade, but was defeated; and returning into France by sea, was taken by the Greeks, but rescued by Roger king of Sicily. His queen Eleonora accompanied him in this expedition; and being suspected of infidelity, with Saladin, a young Turk,
Lewis divorced her, and she was married six weeks after to Henry duke of Normandy, (Henry II. king of England). Lewis died in 1180, aged 60.

Lewis IX. anno 1226 (cannulized), was one of the greatest monarchs of France; equally memorable for his valour and his virtues, but unfortunately milled by the superlition of the times: he sacrificed his own repose, and the welfare of his kingdom, to the folly of crusading.

1248, leaving France to the care of his minister, he embarked for Egypt; attended by his queen, his three brothers, and the flower of the French nobility. At first his victories were rapid: he took Damietta in 1249; but the following year he was defeated and taken prisoner by the Turks, with all the nobility in his train, and the greatest part of his army. The sultan sent to him in prison, to demand an exorbitant sum for his ransom; and his answer being truly noble, deserves to be recorded: "Tell the sultan, that a king of France is not to be ransomed with money; I will give the sum required for my people, and Damietta for my self." These terms were accepted; and a peace was concluded with the sultan, on condition: 1st. that ten years elapsed before the sultan returned to France, he diminished the taxes, revoked those which the cupidity of the financiers had introduced; 2nd. fifteen million ducats; 3rd. several furlaughs estates; 4th. several churches and hospitals; and effectually overturned the ecclesiastical jurisdiction of the court of Rome, by his pragmatic sanction in 1269, which established the independency of the Gallican church. Thirteen years residence in his capital indemnified his subjects for his absence; but his pious zeal prevented the enjoyment of this happiness: he embarked for the sixth crusade in 1270; and died the same year, at the siege of Tunis, aged 55.

Lewis XI. anno 1461. His oppressions obliged his subjects to enter into a league against him, styled "Ligue de bien publique," in which his brother the duke of Berry and some of the principal nobility were concerned: they solicited succours from John duke of Calabria, who joined them with 5000 Swiss (the first introduction of Swiss soldiers into the French armies.) His reign was almost one continued scene of civil war: and it is computed that 4000 of his subjects were executed in public and privately, either for being in arms against him, or suspected by him. In his last illness, he drank the warm blood of children, in the vain hope of restoring his decayed strength. He died in 1483, aged 66. The polls for letters were established in his reign, owing to his eagerness for news; the first introduction of this nature in Europe.

Lewis XII. anno 1492, styled the Just, and the Father of his people; memorable for his valour in the field, and his wisdom in the cabinet. A great general; but unfortunate towards the end of his reign, when he did not command his troops in person: his orders transmitted from home were misunderstood, or wilfully disobeyed; and he had the mortification, before he died to see the total expulsion of the French from the possessions he had acquired for them by his personal bravery. At 53 years of age, he married the princess Mary of England, sister of Henry VIII. and being of a delicate constitution, fell a victim (according to the French historians) to an excess of abstinence; for he died in about two months after his nuptials, in 1515.

Lewis XIII. anno 1610, increased the military reputation of his country, and made considerable additions to its domains. The beginning of his reign was occupied in civil wars with his mother and his Protestant subjects; in which he was excited to continue by his famous minister cardinal Richelieu, who attended him to the siege of Rochelle, the last of the Huguenot party. This place was reduced by famine to further, in 1628, after a siege more than a year. Upon this and other occasions, the king gave proofs of great personal bravery. His attachment to his ally the duke de Nevers, who succeeded to the dukedom of Mantua, but was refuted the invincibility of Charles VI. emperor of Germany, involved him in a war with that prince, the Spaniards, and the duke of Savoy; in which Lewis was victorious; and obtained a treaty of peace, by which the duke of Mantua was guarantied in the possession of his dominions. In 1633, a new war broke out between France and Spain, and the emperor took part with the latter; 1st. against the emperor, and 25 against Spain, with various succeds; and the different armies kept on foot, in the Low Countries, and in Italy, in the course of this war, paved the way for the successes of Lewis XIV. the campaigns of these armies being a military school of discipline and experience for the French officers, besides giving them a knowledge of the countries which became the seat of war in the next reign. Lewis XIII. died 1643, aged 41.

Lewis XIV. le Grand (king at five years of age), anno 1643. He was at first styled Dieu-donne, because the French considered him as the gift of heaven, granted to their prayers after the queen had been barren 22 years. This princefs (Anne of Austria) was declared regent by Lewis XIII, and sought herself under a necessity to continue the war against Philip IV. king of Spain, her brother. The duke d'Enghien was made general of the French armies; and so signal was the success of this renowned warrior (afterwards prince of Condé, and known by the style of the Great Condé), that his victories brought on the advantageous treaties of Münster in 1648, between France, the emperor Ferdinand III. and Christina queen of Sweden; the basis of the aggressions of France in this reign; the principal events of which, and of the next, are related under the articles BRITAIN, United Provinces, &c. Lewis XIV. died in 1715, aged 77.

Lewis XV. (his great-grandson) succeeded in 1715.

He was styled, in the course of his reign, the well-beloved, which he lost some years before he died; and was detested and despised by his subjects for his shameful attachment to a young girl, under the title of his mlle-fille, who, by the ministrations of her patron the duke d'Alguillon, governed the kingdom, and invaded the ancient rights and privileges of the people. He died in 1774, in the 64th year of his age and 59th of his reign.

LEXINGTON, a town of North America and at present the capital of the state of Kentucky, is situated on Elkhorn a northern branch of Kentucky River. It was founded in 1779, and is now a flourishing town, containing upwards of 200 houses and about 1500 inhabitants. Lexington contains two printing presses, and a large number of useful mechanics and manufacturers; also upwards of 30 flores well supplied with goods of all kinds.

LEX, Law. See LAW.—The Roman laws were
of three kinds: 1st, Such as were made by their kings. 2d, The laws of the twelve tables brought by the Decemviri from Athens, &c. And 3d, Such as were proposed by the superior magistrates in the times of the republic. The laws of this last class were enacted in the following manner.

No law could be proposed but by some of the following magistrates, viz. the Praetor, the Consul, the Dictator, the Interrex, the Decemviri, the Military Tribunes, Trimarviri, and Tribunes of the people. If any of these proposed a law, it was first committed to writing, and privately examined as to its utility and probable consequences, by some persons well qualified for the task; sometimes it was referred to the whole Senate for their sentiments. It was then hung up publicly for three market-days, that all the people might have time to examine it, and consider its tendency: This was called legis promulgatio, quasii promulgatio. If the person who framed the bill did not see cause in the mean time to drop it, the people were convened in comitia, and he addressed them in an oration, being also seconded by his friends, formerly the expediency and probable utility of such a law: This was called regatio legis, because the address was always prefixed with this petitionary form of words, Velliti jubetatis, Quirites? "Will you, O Romans, consent and order this law to pass?" This being done, those that dissented motion delivered their sentiments in opposition to it. An urn was then brought to certain likely for three market-days, that all the people might if any on such as came not to the public assemblies, and also to make scrutiny among such as were present.

The lexicarch kept a register of the age, manners, and abilities of all the citizens, who were always enrolled at the age of 20.

LEXICON, the name with dictionary. The word is chiefly used in speaking of Greek Dictionaries: it is derived from the Greek λexi, word, diction; of a word I speak.

LEYDEN, in Latin Lugdunum Batavorum, one of the largest and finest cities in Holland, abounds with canals, along which are rows of lofty trees that afford very pleasant walks. An arm or small branch of the Rhine runs through it. Over the canals are 145 bridges, most of them of stone or brick. The university here is the oldest in the United Provinces: it has large privileges; a library well furnished, and particularly rich in manuscripts; a physic-garden well stocked with all sorts of plants, many of which have been brought from the Cape of Good Hope and the East Indies; an anatomy-hall, well provided with skeletons; and an observatory. The professors, who are generally very eminent, read public lectures four times a week, for which they take no money, but about three guineas are paid for a course of private lectures, which lasts a whole year. The students have no distinct habit, but all wear gowns, though they generally go to the public and private lectures in their night-gowns and slipperis. The salaries of the professors are from 100 to 200 a-year: they wear gowns only when they preside at public disputationes, read public lectures, or meet in the senate; and their lectures are always in Latin. The students do not lodge in the university, but where they please in the town. The cloth manufacture here is much decayed, which formerly flourished to such a degree, that 100000 pieces, it is said, have sometimes been made in a year. The city is famous for the long and severe siege it maintained in 1573 against the Spaniards. We cannot help mentioning the reply of that illustrious magistrate, Adrian de Ver, when the citizens represented to him the havoc made by the famine during the siege, and inquired upon his surrendering: "Friends (said he), here is my body, divide it among you to satisfy your hunger, but banish all thoughts of surrendering to the cruel and pernicious Spaniards." They took his advice, in regard to their not surrendering, and never would listen to any alterations; but told the Spaniards, they would hold out as long as they had one arm to eat and another to fight. There are some fine churches here, and many long, broad, handfome, streets; but the Papists, as at Haerlem, are more numerous than the Protestants.

LEEDEN Phial, a phial coated on the inside and outside with tinfoil, or other proper conducting substance, and
and furnished with a brass wire and knob, for giving the electrical shock. See Electricity-Index.

Lucas van Leyden. See Lucas.

LEYSERA, in botany: A genus of the polygama superflua order, belonging to the syngenia class of plants; and in the natural method ranking under the 49th order, Compositae. The receptacle is naked; the pappus paleaceous; that of the disc plumy; the calyx scarious.

LEYTE, one of the Philippine islands in the East Indies, situated in E. Long. 118°. N. Lat. 11°. Its greatest length is about 40 leagues, and its circumference about 90 or 100. Its soil on the east side is very fruitful; but there are very high mountains which cut it almost through the middle, and occasion so great an alteration in the air, that when it is winter on the north side, it is summer on the southern part of the island. Thus when the inhabitants of one half of the island reap, the others sow; and they have two plentiful harvests in a year, to which the rivers running down from the abovementioned mountains contribute not a little. The island contains about 9000 inhabitants, who pay tribute to the Spaniards in rice, wax, and quilts.

Lhuyd, or Lloyd (Humphrey), a learned antiquary of the 17th century, born at Denbigh, who applied himself to the study of physic; and living mostly within the walls of Denbigh castle, professed there as a physician; and died in 1570, with the character of a wellbred gentleman. He wrote and translated several pieces relative to history and antiquities; in particular, The history of Cambria, now called Wales, from Caradoc of Langcarvan, &c. but died before it was finisht: however, Sir Henry Sidney, lord president of Wales, employed Dr David Powel to finisht it, who published it in 1584. A new and improved edition of this work was published in 1774.

Lhuyd (Edward), keeper of the Museum at Oxford, was a native of South Wales, the son of Charles Lhuyd, Esq.; of Llanvorde. He was educated at Jesus College, Oxford, where he was created M. A. July 21. 1701. He was bred under Dr Plot, whom he succeeded as keeper of the Ashmolean museum, and had the use of all Vaughan's collections. With incessant labour and great exactness he employed a considerable part of his life in searching into the Welsh antiquities: he perused or collected a great deal of ancient and valuable matter from their MSS. transferred all the old charters of their monasteries that he could meet with; travelled several times over Wales, Cornwall, Scotland, Ireland, Armorie Bretagne, countries inhabited by the same people, compared their antiquities, and made observations on the whole; but died in July 1709, before he had digested them into the form of a discourse, as he intended, on the ancient inhabitants of that island. The untimely death of this excellent antiquary prevented the completing of many admirable designs. For want of proper encouragement, he did very little towards understanding the British bards, having seen but one of those of the sixth century, and not being able to procure access to two of the principal libraries in the country. He communicated many observations to Bishop Gibson, whose edition of the Britannia he revised; and published "Archæologia Britannica," giving some accounts additional to what has been hitherto published of the languages, histories, and customs of the original inhabitants of Great Britain, from collections and observations in travels through Wales, Cornwall, Bas Bretagne, Ireland, and Scotland, Vol. I. Glophography, Oxford 1707," fol. He left in MS. a Scottifh or Irish-English Dictionary, proposed to be published in 1733 by subscription, by Mr David Malcolme, a minister of the church of Scotland, with additions; as also the Elements of the said language, with necessary and useful informations for propagating more effectually the English language, and for promoting the knowledge of the ancient Scottifh or Irish, and very many branches of useful and curious learning. Lhuyd, at the end of his preface to the Archæologia, promises an historical dictionary of British persons and places mentioned in ancient records. It seems to have been ready for press, though he could not see the time of publication. His collections for a second volume, which was to give an account of the antiquities, monuments, &c. in the principality of Wales, were numerous and well chosen; but, on account of a quarrel between him and Dr Wyne, then fellow, afterwards principal of the college, and bishop of St Asaph, he refused to buy them, and they were purchased by Sir Thomas Seabright, of Beachwood in Hertfordshire, in whose library the greatest part still remain, but so indigested, and written with so many abbreviations, that nobody can undertake to publish them. They consist of about 40 volumes in folio, to in quarto, and above 100 smaller, and all relate to Irish or Welsh antiquities, and chiefly in those languages. Carte made extracts from them about or before 1736; but these were chiefly historical. Sir John Seabright has given Mr Penman 23 of Lhuyd's MSS. Latin and English. Many of his letters to Fothergill, and other learned contemporaries, were given by Dr Fothergill to the university of Oxford, and are now in the Ashmolean museum. Lhuyd undertook more for illustrating this part of the kingdom than any one man besides ever did, or than any one man can be equal to.

LIBANIUS, a famous Greek rhetorician and sophist in the 4th century, was born at Antioch, and had a great share in the friendship of Julian the Apostate. That prince offered him the dignity of Prefettus Pratorio; but Libanius refused it, thinking the name of sophist, or professor of eloquence, much more honourable. There are still extant several of his letters and Greek orations, by which he acquired great reputation; but his style is somewhat affected and obscure. He was a pagan. Basil and Chrysostom were his disciples about the year 360. His letters were published at Amsterdam in 1739; his orations at Venice, 1755.

LIBANOMANTIA, in antiquity, a species of divination performed with frankincense; which, if it presently caught fire, and sent forth a grateful odour, was esteemed a happy omen, and vice versa.

LIBANUS, the name of a chain of mountains of Turkey in Asia, which lie between Proper Syria and Palestine, extending, from west to east, from the Mediterranean sea as far as Arabia. The summits of these mountains are so high, that they are always covered with snow; but below are very pleasant; and fruitful.
Libation fruitful valleys. They were formerly famous for the great number of cedar-trees growing thereon; but now there are very few remaining. Geographers dividing this chain into Libanus and Anti-libanus; the latter of which lies on the south-side of the valley, rising near the ruins of Sidon, and terminates at others in Arabia, in N. Lat. 54. They are separated from each other at an equal distance throughout; and form a baion, or country, called by the ancients Cælo Syria.

Libation, amongst the Greeks and Romans, was an essential part of solemn sacrifices. It was also performed alone, as a drink offering, by way of procuring the protection and favour of the gods, in the ordinary affairs of life. Libations, according to the different natures of the gods in honour of whom they were made, consisted of different liquids, but wine was the most usual. The wine offered to the gods was always unmixed with water. We meet with libations of water, libations of honey, libations of milk, and libations of oil; these are called ἐπαρχεῖς ἱερὰς. The libation was made with a serious deportment and solemn prayer. At sacrifices, the libation, after it had been taunted by the priest, and handed to the bystanders, was poured upon the victim. At entertainments, a little wine was generally poured out of the cup, before the liquor began to circulate, to show their gratitude to the gods for the blessings they enjoyed.

Libations were also in use among the Hebrews, who poured an hun of wine on the victim after it was killed, and the several pieces of the sacrifice were laid on the altar, ready to be consumed in the flames. Libaw, a sea-port town of Courland, lying on the Baltic sea, consisting entirely of wooden houses. It belongs to the duke of Courland, and is situated in E. Long. 21. 27. N. Lat. 56. 27.

Libel, (libellus famosus), taken in its largest and most extensive sense, signifies any writing, picture, or the like, of an immoral or illegal tendency; but, in a peculiar sense, is used to denote a malicious defamation of any person, and especially a magistrate, made public by either printing, writing, signs, or pictures, in order to provoke him to wrath, or expose him to public hatred, contempt, and ridicule. The direct tendency of these libels is the breach of the public peace, by stirring up the obnoxious of the two parties, and perhaps to bloodshed. The communication of a libel to any one person is a publication in the eye of the law: and therefore the sending an abusive private letter to a man is as much a libel as if it were openly printed, for it equally tends to a breach of the peace.

With regard to libels in general, there are, as in many other cases, two remedies; one by indictment and another by action. The former for the public offence; for every libel has a tendency to break the peace, or provoke others to break it: which offence is the same whether the matter contained be true or false; and therefore the defendant, on an indictment for publishing a libel, is not allowed to allege the truth of it by way of justification of the offence, but by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, justify the truth of the facts, and show that the plaintiff has received no injury at all. What was said with regard to words spoken, will also hold in every particular with regard to libels by writing or printing, and the civil action consequent thereupon: but as to signs or pictures, it seems necessary always to show, by proper inuendos and averments of the defendant's meaning, the import and application of the scandal, and that some special damage has followed; otherwise it cannot appear, that such libel by picture was underfoot to belevelled at the plaintiff, or that it was attended with any actionable consequences.

In a civil action, then, a libel must appear to be false, as well as scandalous; for, if the charge be true, the plaintiff has received no private injury, and has no ground to demand a compensation for himself, whatever offence it may be against the public peace: and therefore, upon a civil action, the truth of the accusation may be pleaded in bar of the suit. But, in a criminal prosecution; the tendency which all libels have to create animosities, and to disturb the public peace, is the sole consideration of the law. And therefore, in such prosecutions, the only points to be considered are, first, the making or publishing of the book or writing; and, secondly, whether the matter be criminal: and, if both these points are against the defendant, the offence against the public is complete. The punishment of such libellers, for either making, repeating, printing, or publishing the libel, is a fine, and such corporal punishment as the court in its discretion shall inflict; regarding the quantity of the offence, and the quality of the offender. By the law of the twelve tables at Rome, libels, which affected the reputation of another, were made a capital offence: but, before the reign of Augustus, the punishment became corporal only. Under the emperor Valentinian it was again made capital, not only to write, but to publish, or even to omit destroying them. Our law, in this and many other respects, corresponds rather with the middle age of Roman jurisprudence, when liberty, learning and humanity, were in their full vigour, than with the cruel edicts that were established in the dark and tyrannical ages of the ancient deceiviri, or the latter emperors.

In this, and other instances, where blasphemous, immoral, treasonable, felonious, or scandalous libels are punished by the English law, some with a greater, others with a lesser, regard of service; the liberty of the press, properly understood, is by no means infringed or violated. See Liberty of the Press.

Libella, a piece of money amongst the Romans, being the tenth part of the denarius, and equal in value to the as. It was called libella, as being a little pound, because equal to a pound of brays. Its value in our money is 1 ob. 1 qr. or a half-penny farthing. See Money.

Libella, or Libellula, in zoology, a genus of four-winged flies, called by the English dragon-flies, or adder flies; the characters of which are these: The mouth is furnished with jaws; the feelers are shorter than the head; and the tail of the male terminates in a kind of hooked forcuses. There are many species, chiefly distinguished by their colour. They have all the very large and reticulated eyes, covering the whole surface of the head. They fly very swiftly, and prey upon the wing, clearing the air of numerous
able little flies. They are found in August and September in the fields and gardens, especially near places where there are waters, as they have their origin from worms living in that element. The great ones usually live all their time about waters; but the smaller are common among hedges, and the smallest of all frequent gardens. The smaller kind often settle upon baobbs, or upon the ground; but the large ones are almost always upon the wing, so that it is very difficult to take them. Their eyes are beautiful objects for the microscope. The largest species is produced from a water-worm that has six feet, which, yet young and very small, is transformed into a chrysalis, that has its dwelling in the water. People have thought they discovered them to have gills like fishes. It wears a mask as perfectly formed as those that are worn at a masquerade; and this mask, fastened to the insect's neck, and while it moves at will, serves to hold its prey while it devours it. The period of transformation being come, the chrysalis makes to the water-side, undertakes a voyage in search of a convenient place; fixes on a plant, or flicks fast to a bit of dry wood. Its skin, grown patched, splits at the upper part of the thorax. The winged insect flies forth gradually, throws off its teachers, expands its wings, flutters, and then flies off with graceful ease and cafe. The elegance of its slender shape, the richness of its colours, the delicacy and resplendent texture of its wings, afford infinite delight to the beholder. The female deposits her eggs in the water, and the males: those of the females are known by

Libertines, and that men could not, properly speaking, commit
sin; that religion consisted in the union of the spirit or
rational soul with the Supreme Being; that all those
who had attained this happy union, by sublime con-
templation and elevation of mind, were then allowed
to indulge, without exception or restraint, their ap-
petites or passions; that all their actions and pursuits
were then perfectly innocent; and that, after the
death of the body, they were to be united to the Deity.
They likewise said that Jesus Christ was nothing but a
mere je ne sais quoi, composed of the spirit of God,
and of the opinion of men.

Thee maxims occasioned their being called Lib-
ertins; and the word has been used in an ill sense ever
since.

The Libertini spread principally in Holland and
Brabant. Their leaders were one Quintin, a Picard;
Pocketius, Ruffus, and another called Chopin, who
joined with Quintin, and became his disciple.

This sect obtained a certain footing in France thro'
the favour and protection of Margaret, queen of Na-
varre, and sister to Francis I. and found patrons in fe-
veral of the reformed churches. This sect was fe-
emblably a remnant of the more ancient Begaards or
Brethren of the Free Spirit.

Libertines of Genoa, were a cabal of rakes rather
than of fanatics; for they made no pretences to any
religious system, but pleaded only for the liberty of
leading voluptuous and immoral lives. This cabal was
composed of a certain number of licentious citizens,
who could not bear the severe discipline of Calvin, who
punished with rigour not only dissolute manners, but
also whatever bore the aspect of irreligion and impiety.
In this turbulent cabal there were several persons who
were not only notorious for their dissolute and scandi-
ulous manner of living, but also for their atheistical im-
piety, and contempt of all religion. To this odious
class belonged one Gruet, who denied the divinity of
Christ and the immortality of the soul; the difference
between moral good and evil, and rejected with disdain the doctrines that are held most sacred among
Christians; for which impertinency he was at last
brought before the civil tribunal, in the year 1550, and
condemned to death. The Genevan spirit of refor-
mation, improperly directed by the violence and zeal
of Calvin, did at this time operate to a degree which has
marked the character of this great reformer with re-
proach. For in 1544, Sebastian Caflalio, master of the
public school at Geneva, who was a man of probity,
and distin guished by his learning and virtue, was, never-
theless, deposed from his office and dismissed the city,
because he disapproved some of the measures that were
pursued, and some of the opinions entertained by Calvin
and his colleagues, and particularly that of absolute
and unconditional predetermination. Jerome Bolice also
was a man of genius and learning, who became a convert
to the Protestant religion and fled to Geneva for pro-
tection, was cast into prison, and soon after sent into
banishment, because, in 1551, he imprudently and in-
decently declaimed, in full congregation and at the
election of public worship, against the doctrine of abso-
late decrees.

Libertus, or libertinus, among the Romans,
a freedman, or a person set free from a legal servi-
tude.
Liberty. ever ridiculous the fashion then in use might appear, the restraining it by pecuniary penalties could serve no purpose of common utility. But the statute of king Charles II. which prescribes a thing seemingly as indifferent, viz. a dred for the dead, who were all ordered to be buried in woollen, is a law consistent with public liberty; for it encourages the staple trade, on which in a great measure depends the universal good of the nation. So that laws when prudently framed, are by no means subversive, but rather coddled, of liberty; for (as Mr Locke has well observed) where there is no law there is no freedom. But then, on the other hand, that constitution or frame of government, that system of laws, is alone calculated to maintain civil liberty, which leaves the owner. The legislature and of course the laws of other states on the continent of Europe, and from the genius of the imperial law; which in general are calculated to ve the arbitrary and despotic power, of controlling the actions of the subject, in the prince, or in a few grandees. And this spirit of liberty is so deeply implanted in their constitution, and rooted even in their human jurisprudence, as it is being still human. At some times we have seen them despised by overbearing and tyrannical princes, and others, so luxuriant as to come to a state of anarchy, a worse state than tyranny itself, as any government is better than none at all.

The benefit of their free constitution has always delivered the nation from these embarrassments: and, as soon as the convulsions consequent on the struggle have been over, the balance of their rights and liberties has settled to its proper level; and their fundamental articles have been from time to time ascertained in parliament, as often as they were thought to be in danger:"

First, by the great charter of liberties, which was obtained, I word in hand, from king John, and afterwards, with some alterations, confirmed in parliament by king Henry III. his son. Which charter contain ed very few new franchises; but, as Sir Edward Coke observes, was for the most part declaratory of the principal grounds of the fundamental laws of England. Afterwards, by the statute called confirmatio cartarum, whereby the great charter is directed to be allowed as the common law; all judgments contrary to it are declared void; copies of it are ordered to be sent to all cathedral churches, and read twice a year to the people; and sentence of excommunication is directed to be as constantly denounced against all those that by word, deed, or counsel, act contrary thereto, or in any degree infringe it. Next by a multitude of subsequent corroborating statutes (Sir Edward Coke reckons 32), from the first Edward to Henry IV. Then, after a long interval, by the petition of right; which was a parliamentary declaration of the liberties of the people, assented to by king Charles I. in the beginning of his reign: Which was closely followed by the still more ample concessions made by that unhappy prince to his parliament, before the fatal rupture between them; and by the many salutary laws, particularly the habeas corpus act, passed under Charles II. To these succeeded the bill of rights, or declaration delivered by the lords and commons to the prince and princes of Orange, 5th February 1688; and afterwards enacted in parliament, when they became king and queen: which declaration concludes in these remarkable words; "and they do claim, demand, and insist upon, all and singular the premises, as their undisputed rights and liberties." And the act of parliament itself recognizes "all and singular the rights and liberties asserted and claimed in the said declaration to be the true, ancient, and indubitable rights of the people of this kingdom." Lastly, these liberties were again asserted at the commencement of the present century, in the act of settlement, whereby the crown was limited to his present majesty's illustrious house; and some new provisions were added at the same fortunate era, for better securing their religion, laws, and liberties; which the statute declares to be "the birthright of the people of England," according to the ancient doctrine of the common law.

Thus much for the declaration of their rights and liberties. The rights themselves, thus defined by these several statutes, consist in a number of private immunities, which will appear, from what has been premised, to be indeed no other, than either that refiduum of natural liberty, which is not required by the laws of society to be sacrificed to public convenience; or else those civil privileges, which society hath engaged to provide, in lieu of the natural liberties so given up.

The rights which were formerly, either by inheritance or purchase, the rights of all mankind; but in most other countries of the world, being now more or less debated and destroyed, they at present may be said to remain, in a peculiar and emphatical manner, the rights of the people of Britain. And these may be reduced to three principal or primary articles; the right of personal security, the right of personal liberty, and the right of private property, because, as there is no other known method of compulsion, or of abridging man's natural free will, but by an infringement or diminution of one or other of these important rights, the preservation of these inviolate may justly be said to include the preservation of their civil immunities in this largest and most extensive sense. See the article Rights.
L I B

mary rights, of personal security, personal liberty, and private property. These are,
1. The constitution, powers, and privileges of parliament; for which see PARLIAMENT.

2. The limitation of the king's prerogative, by bounds so certain and notorious, that it is impossible he should exceed them without the consent of the people; as to which, see PREROGATIVE. The former of these keeps the legislative power in due health and vigour, so as to make it improbable that laws should be enacted defradive of general liberty; the latter is a guard upon the executive power, by restraining it from acting either beyond or in contradiction to the laws that are framed and established by the other.

3. A third subordinate right of every Briton is that of applying to the courts of justice for redress of injuries. Since the law is, in this realm, the supreme arbiter of every man's life, liberty, and property, courts of justice must at all times be open to the subject, and the law be duly administered therein. The emphatical words of magna carta, spoken in the person of the king, who in judgment of law (says Sir Edward Coke) is ever present and repeating them in all his courts, are these: Nulli vendemus, nulli negabimus, nulli praebimus vel refuemus ut jus sit illium; and therefore every subject (continues the same learned author), for injury done to him in bonis, in terris, vel persona, by any other subject, be he ecclesiastical or temporal, without any exception, may take his remedy by the course of the law, and have justice and right for the injury done to him, freely without sale, fully without any denial, and speedily without delay. It was endliis to enumerate all the affirmative acts of parliament, wherein justice is directed to be done according to the law of the land: and what that law is, every subject knows; or may know if he pleases: for it depends not upon the arbitrary will of any judge; but is permanent, fixed, and unchangeable, unless by authority of parliament. We shall however just mention a few negative statutes, whereby abuses, perverfions, or delays of justice, especially by the prerogative, are restrained. It is ordained by magna carta, that no freeman shall be outlawed, that is, put out of the protection and benefit of the laws, but according to the law of the land. By 2 Edw. III. c. 8. and 11 Ric. II. c. 10. it is enacted, that no commands or letters shall be sent under the great seal, or the little seal, the signet or privy seal, in disturbance of the law; or to disturb or delay common right: and, though such commandments should come, the judges shall not cease to do right: which is also made a part of their oath by statute 18 Edw. III. f. 4. And by first W. & M. ft. 2. c. 2. it is declared, that the pretended power of suspending or dispensing with laws, or the execution of laws, by regal authority without consent of parliament, is illegal.

Not only the substantial part, or judicial decisions, of the law, but also the formal part, or method of proceeding, cannot be altered but by parliament: for, if once those outworks were demolished, there would be an inlet to all manner of innovation in the body of the law itself. The king, it is true, may erect new courts of justice; but then they must proceed according to the old established forms of the common law. For which reason it is declared in the statute 16 Car. I. c. 10. upon the dissolution of the court of star-chamber, that neither his majesty, nor his privy-council, have any jurisdiction, power, or authority, by English bill, petition, articles, libel (which were the course of proceeding in the star-chamber, borrowed from the civil law), or by any other arbitrary way whatsoever, to examine, or draw into question, determine, or dispose of the lands or goods of any subjects of this kingdom; but that the same ought to be tried and determined in the ordinary courts of justice, and by course of law.

4. If there should happen any uncommon injury, or infringement of the rights before mentioned, which the ordinary course of law is too defective to reach, there still remains a fourth subordinate right, appertaining to every individual, namely, the right of petitioning the king, or either house of parliament, for the redress of grievances. In Russia we are told, that the Czar Peter established a law, that no subject might petition the throne till he had first petitioned two different ministers of state. In case he obtained justice from neither, he might then present a third petition to the prince; but upon pain of death, if found to be in the wrong. The consequence of which was, that no one dared to use such third petition; and grievances seldom falling under the notice of the sovereign, he had little opportunity to redress them. The restrictions, for some there are, which are laid upon petitioning in Britain, are of a nature extremely different; and while they promote the spirit of peace, they are no check upon that of liberty. Care only must be taken, left, under the pretence of petitioning, the subject be guilty of any riot or tumult; as happened in the opening of the memorable parliament in 1640: and, to prevent this, it is provided by the statute 13 Car. II. ft. 1. c. 5. that no petition to the king, or either house of parliament, for any alteration in church or state, shall be signed by above 20 persons, unless the matter thereof be approved by three justices of the peace, or the major part of the grand jury, in the county; and in London, by the lord mayor, alder­men, and common-council: nor shall any petition be presented by more than 10 persons at a time. But, under these regulations, it is declared by the statute 1 W. & M. ft. 2. c. 2. that the subject hath a right to petition; and that all commitments and prosecutions for such petitioning are illegal.

5. The fifth and last auxiliary right of the subject, that we shall at present mention, is that of having arms for their defence, suitable to their condition and degree, and such as are allowed by law. Which is also declared by the same statute 1 W. & M. f. 2. c. 2. and is indeed a public allowance, under due restrictions, of the natural right of self-defense and self-preservation, when the sanctions of society and laws are found insufficient to restrain the violence of oppression.

In these several articles confind the rights, or, as they are frequently termed, the liberties of Britons: liberties more generally talked of, than thoroughly understood; and yet highly necessary to be perfectly known and considered by every man of rank or property, lest his ignorance of the points whereon they are founded should hurry him into faction and licentiousness on the one hand, or puillanimous indiffe-
Liberty. Licence and criminal submission on the other. And we have seen that these rights, consist, primarily, in the free enjoyment of personal security, of personal liberty, and of private property. So long as these remain inviolate, the subject is perfectly free; for every species of compulsory tyranny and oppression must act in opposition to one or other of these rights, having no other object upon which it can possibly be employed. To preserve these from violation, it is necessary that the constitution of parliaments be supported in its full vigour; and limits, certainly known, be fixed to the royal prerogative. And, lastly, to vindicate these rights, when actually violated or attacked, the subjects of Britain are entitled, in the first place, to the regular administration and free course of justice in the courts of law; next, to the right of petitioning the king and parliament for redress of grievances; and, lastly, to the right of having and using arms for self preservation and defence. And all these rights and liberties it is our birthright to enjoy entire; unless where the laws of our country have laid them under necessary restraints. Restraints in themselves so gentle and moderate, as will appear upon further inquiry, that no man of sense or probity would wish to see them slackened. For all of us have it in our choice to do every thing that a good man would desire to do; and are restrained from nothing, but what would be pernicious either to ourselves or our fellow-citizens. So that this review of our situation may fully justify the observance of a learned French author, who indeed generally both thought and wrote in the spirit of genuine freedom; and who had not scrupled to proceed, even in the very bosom of his native country, that the Britih is the only nation in the world, where political or civil liberty is the direct end of its constitution. Recommending therefore to the student in our laws a farther and more accurate search into this extensive and important title, we shall close our remarks upon it with the expiring wish of the famous Father Paul to his country, "Esto perpetua!"

Liberty and necessity. See Metaphysics.

Liberty of the Press. The art of printing, soon after its invention, was lost, as well abroad, as in other countries, as merely a matter of state, and subject to the coercion of the crown. It was therefore regulated by the king's proclamations, prohibitions, charters of privilege and licence, and finally by the decrees of the court of star-chamber, which limited the number of printers, and of presses which each should employ, and prohibited new publications unless previously approved by proper licencers. On the demolition of this odious jurisdiction in 1647, the long parliament of Charles I. after their rupture with that prince, assumed the same powers as the star-chamber had exercised with respect to the licensing of books; and in 1643, 1647, 1649, and 1652 (Soc. Hill. i. 44, 133. ii. 88, 230.) they issued their ordinances for that purpose, founded principally on the star-chamber decree of 1627. In 1652, was passed the statute 13 & 14 Car. II. c. 32, which, with some few alterations, was copied from the parliamentary ordinances. This act expired in 1679; but was revived by statute 1 Jac. II. c. 17. and continued till 1692. It was then continued for two years longer by statute 4 W. & M. c. 24. but though frequent attempts were made by the government to revive it, in the subseqent part of that reign (Com. Journ. 17 Feb. 1694. 26 Nov. 1695. 22 Oct. 1696. 9 Feb. 1697. 31 Jan. 1698.) yet the parliament resisted it so strongly, that it finally expired, and the presses became properly free in 1694, and has continued so ever since.

The liberty of the presses, however, so essential to the nature of a free state, consists not in freedom from censure for any criminal matter that may be published, but in laying no previous restraints upon publications. Every free man has undoubtedly a right to lay what sentiments he pleases before the public; to forbid this, is to destroy the freedom of the presses; but if he publishes what is improper, mischievous, or illegal, he must take the consequence of his own temerity. To subject the presses to the restrictive power of a licencier in the manner abovementioned, is to subject all freedom of sentiment to the prejudices of one man, and make him the arbitrary and infallible judge of all controverted points in learning, religion, and government. But to punish (as the law does at present) any dangerous or offensive writings which, when published, shall, on a fair and impartial trial, be adjudged of a pernicious tendency, is necessary for the preservation of peace and good order, of government and religion, the only solid foundations of civil liberty. Thus the will of individuals is still left free; the abuse only of that free-will is the object of legal punishment. Neither is any restraint hereby laid upon freedom of thought or inquiry; liberty of private sentiment is still left; the discriminating or making public of bad sentiments, destructive of the ends of society, is the crime which society corrects. A man (says a wise writer) may be allowed to keep poisons in his closet, but not publicly to vend them as cordials. And to this we may add, that the only plausible argument heretofore used for restraining the just freedom of the presses, "that it was necessary to prevent the daily abuse of it," will entirely lose its force, when it is shown (by a saevous exercise of the laws) that the presses cannot be abused to any bad purpose without incurring a suitable punishment; whereas, it can never be used to any good one which is not under the control of an inspector. So true will it be found, that to confine the licencious, is to maintain the liberty of the presses.

Liberty, in mythology, was a goddess both among the Greeks and Romans. Among the former she was invoked under the title Eleutheria; and by the latter she was called Libertas, and held in singular veneration; temples, altars, and statues, were erected in honour of this deity. A very magnificent temple was consecrated to her on mount Aventin, by Tiberius Gracchus, before which was a spacious court, called arium libertatis. The Romans also erected a new temple in honour of Liberty, when Julius Cæsar established his empire over them, as if their liberty had been secured by an event which proved fatal to it. In a medal of Brutus, Liberty is exhibited under the figure of a woman, holding in one hand a cap, the symbol of Liberty, and two poinards in the other, with the inscription IANVS MARTIS. Libethræ (anc. geo.), the fountain of long, was situated in Magnesia, a district of Macedonia annexed to Thessaly; distant from the town of Libethra, which stood on the mount Olympus, where it verges
Libethrius verges toward Macedonia: hence the Muses are called Libethrides, (Virgil). Strabo places on Helicon, not only Hippocrates, and the temple of the Muses, but also the cape of the nymphs Libethrides.

LIBETHRIUS NUNS (anc. geog.), a mountain of Beotia, distant from Corinth 40 stad. where stood the statues of the muses, and of the nymphs, surname Libethride. A mountain probably conjoined with, or at least very near to, Helicon.

LIBITINA, in the Roman mythology, a goddess which preceded over funerals. This goddess was the same with the Venus inferna or Ephjmis of the Greeks. She had a temple at Rome, where was lodged a certain piece of money for every person who died, whose name was recorded in a register called Libitina ratio. This practice was established by Servius Tullius, in order to obtain an account of the number of annual deaths in the city of Rome, and consequently the rate of increase or decrease of its inhabitants.

LIBITINARII, were undertakers whose office was to take care of funerals, prepare all things necessary upon the solemn occasion, and furnish every article required. — They got their livelihood by this gloomy business, and kept a number of servants to perform the working part of the profession, such as the pellinlores, nelephai, &c. The name Libitinarius is derived from Libitina, the goddess of funerals, in whose temple were told all things relating to funerals. See FUNERAL.

LIBNA (anc. geog.), a sacerdotal city in the tribe of Judah, a place of strength, as appears from Sennacherib's laying siege to it, 2 Kings xix. Isaiah xxxvii. In Jerome's time, a village, called Libna, in the territory of Eleutheropolis.

LIBOURNE, a town of France, in Guienne, and in Bourdelais. It is a populous trading town, and is seated on the rive Dordogne. W. Long. 0. 10. N. Lat. 44. 55.

LIBRA, or BALANCE, one of the mechanical powers. See BALANCE.

LIBRA, in astronomy, one of the 12 signs of the zodiac, and exactly opposite to Aries; so called because when the sun is in this sign at the autumnal equinox, the days and nights are equal as if weighed in a balance. — The stars in this constellation according to Ptolemy are 17, Tycho 10, Hevelius 20, and Flamstead 51.

LIBRA also denotes the ancient Roman pound, borrowed from the Sicilians, who called it Libra.

The libra was divided into 12 untia or ounces, and the ounce into 26 grumes.

The divisions of the libra were, the uncia, one twelfth; the sextans, one sixth; the quadrans, one fourth; the triens, one third; the guinceans, five ounces; the semis, six; the septuans, seven; the sextans, eight; the dodrans, nine; the sextans, ten; the denarius, eleven, lastly, the as weighed twelve ounces or one libra.

The Roman libra was used in France for the proportions of their coin till the time of Charlemagne, or perhaps till that of Philip I. in 1093, their folls being so proportioned, as that 20 of them were equal to the libra. By degrees it became a term of account; and every thing of the value of twenty folls was called a livre.

Libra penna, in our law books, denotes a pound of money in weight. It was usual in former days not only to tell the money but to weigh it; because many cities, lords, and bishops, having their mints, coined money, and often very bad too; for which reason, though the pound consisted of 20 shillings, they always weighed it.

LIBRARI, among the ancients, were a sort of copyists who transcribed in beautiful or at least legible characters, what had been written by the notaries in notes and abbreviations.

LIBRARY, an edifice or apartment designed for holding a considerable number of books placed regularly on shelves; or the books themselves lodged in it. Some authors refer the origin of libraries to the Hebrews; and observe, that the care these took for the preservation of their sacred books, and the memory of what concerned the actions of their ancestors, became an example to other nations, particularly to the Egyptians. Osmandus, king of Egypt, is said to have taken the hint first; who, according to Diodorus, had a library built in his palace, with this inscription over the door, P|x|xe| IAPPEION. Nor were the Ptolemies, who reigned in the same country, less curious and magnificent in books.

The scripture also speaks of a library of the kings of Persia, Ezra v. 17. vi. 1. which some imagine to have consisted of the historians of that nation, and of memoirs of the affairs of state; but, in effect, it appears rather to have been a depository of laws, charters, and ordinances of the kings. The Hebrew text calls it the house of treasuries, and afterwards the house of the rolls, where the treasures were laid up. We may, with more justice, call that a library, mentioned in the second of Esdras to have been built by Nehemiah, and in which were preserved the books of the prophets, and of David, and the letters of their kings.

The first who erected a library at Athens, was the tyrant Pihistratus: and yet Strabo refers the honour of it to Aristotle. That of Pihistratus was transported by Xenox into Persia, and was afterwards brought back by Seleucus Nicanor to Athens. Long after, it was plundered by Sylla, and re-established by Hadrian. Plutarch says, that under Eumenes there was a library at Pergamus, containing 200,000 books. Tyrranian, a celebrated grammarian, contemporary with Pompey, had a library of 30,000 volumes. That of Ptolemy Philadelphus, according to A. Gellius, contained 700,000, all in rolls, burnt by Caesar's soldiers.

Constantine, and his successors, erected a magnificent one at Constantinople; which in the eighth century contained 500,000 volumes, all burnt by order of Leo Isaurus; and, among the rest, one wherein the Iliad and Odyssey were written in letters of gold, on the guts of a serpent.

The most celebrated libraries of ancient Rome, were the Ulpian, and the Palatine. They also boast much of the libraries of Paulus Memilius, who conquered Peræus; of Lucullus Lucullus, of Attianus Pollio, Attianus, Julius Severus, Domitian, Serenus, Pamphilus Martyr, and the emperors Gordian and Trajan.

Anciently every large church had its library; as appears by the writings of St Jerome, Anastasius, and others. Pope Nicholas laid the first foundation of
Library. [26]

that of the Vatican, in 1450. It was destroyed by the confi­
bable Bourbon, in the facking of Rome, and re­
foved by Pope Sixtus V. and has been consider­ably en­
riched with the reams of that of Heidelberg, plun­
dered by Count Tilly in 1622. One of the most com­
plete libraries in Europe, was faid to be that erected at Florence by Cosimo de Medicis, over the gate where­of is written, labor absque labore; though it is now exceeded by that of the French king, be­
gun by Francis I. augmented by Cardinal Richelieu, and completed by M. Colbert.

The emperor’s library at Vienna, according to Lam­
bechius, consists of 80,000 volumes, and 15,940 curious medals.

The Bodleian library at Oxford, built on the foun­
dation of that of Duke Humphrey, exceeds that of any univer­ity in Europe, and even tho’ of all the sove­reigns of Europe, except the emperor’s and French king’s, which are each of them older by 100 years. It was firft opened in 1602, and has since found a great number of benefactors: particularly Sir Robert Cotton, Sir H. Savil, Archibishop Laud, Sir Kenelm Digby, Mr Allen, Dr Pococke, Mr Selden, and others. The Vatican, the Mediccin, that of Bel­
lication at Venice, and thofe juft mentioned, exceed the Bodleian in Greek manuscripts; which yet outs­­
de them all in Oriental manuscripts.

As to printed books, the Ambrofian at Milan, and that of Wolfenbuttle, are two of the most famous, and yet both inferior to the Bodleian.

King’s Library, at St James’s, was founded by Henry, eldeft fon of James I. and made up partly of books, and partly of manuscripts with many other curiosities, for the advancement of learning. It has received many additions from the libraries of Isaac Cafaubon and others.

Cottonian Library, originally confifted of 958 vol­
umes of original charters, grants, instruments, letters, of sovereign princes, transactions between Britain and other kingdoms and states, genealogies, histories, re­
gisters of monafteries, remains of Saxen laws, the book of Genesis, thought to be the moft ancient Greek copy extant, and faid to have been written by Origen in the second century, and the curious Alexandrian copy or manuscript in Greek capitals. This library is kept in the British Mu­
efum, with the large and valuable library of Sir Hans Sloane, amounting to upwards of 42,000 volumes, &c. There are many pu­

cial libraries belonging to the feveral colleges at Ox­
ford and Cambridge, and the universities in North Britain. The principal public libraries in London, be­
side that of the Mu­

eum, are tho’ of the college of her­
alds, of the college of physicians, of Doctors Com­
mons, to which every bishop, at the time of his con­
fe­r­
cation, gives at least 201. sometimes of 50 l. for the purchase of books; tho’ of the Gray’s Inn, Lincoln’s Inn, Inner Temple, and Middle Temple; that of Lambeth, founded by Archibishop Bancroft in 1610, for the use of succeeding archbishops of Canterbury, and increafed by the benefactions of Archbishops Ab­
bart, Sheldon, and Tennyson, and faid to confift of at least 15,000 printed books, and 617 volumes in manuscript; that of Red-Crofs freet, founded by Dr Daniel Williams, a prebifterian divine, and fince en­
riched by many private benefactions; that of the Royal

Society, called the Arundelian or Norfolk library, be­
cause the principal part of the collection formerly be­
longed to the family of Arundel, and was given to the fociety by Henry Howard, afterwards duke of Norfolk, in 1666, which library has been increafed by the valuable collection of Francis Afton, Esq; in 1715, and is continually increafed by the numerous benefactions of the works of its learned members, and others: that of St Paul’s, of Sion college; the queen’s library, erected by queen Caroline in 1737; and the furgeon’s library kept in their hall in the Old Bailey, &c.

In Edinburgh there is a good library belonging to the univer­ity, well furnished with books; which are kept in good order. There is also a noble library of books and manuscripts belonging to the faculty of ad­
 vocates. See Advo­cate.

LIBRATION, in aeronautics, an apparent irregular­
arity of the moon’s motions whereby the夫人 is lib­
rate about her axis, fometimes from the east to the weft, and now and then from the weft to the eaf­
See Astronomy, no 420.

LIBURNIA (anc. geog.), a diffirict of Illiricum, ex­
­ending towards the Adriatic between Iltria on the weft, Dalmatia on the eaf­
, and mount Albius on the north. Liburni, the people. The apparitors, who at the command of the magistrate fummoned the people from the country, were called Liburni, because generally men of Liburnia—Liburnia or Libur­
nia, (Horace), denoted a kind of light and swift ski­f, used by the Liburnians in their fee-roving or piracies, for which they were noted. Liburnum (Juvenal) was a species of litter made in form of Liburnian ski­f, wherein the noblemen of Rome were carried, and where they fat at their cafe, either reading or writing. LIBURNUS (anc. geog.), a mountain of Campania. Also a port of Tus­­
cany. Now Livorno, or Leghorn.

E. Long. 1. N. Lat. 43. 50.

LIBYA, in general, according to the Greeks, denoted Africa. An appellation derived from libe “thrift,” being a dry and thirfty country. See Af­
rica.

LIBYA, in a more reftained fense, was the middle part of Africa, extending north and weft, (Pliny); between the Mediterranean to the north, and Ethiopia to the eaf­
and was two-fold, the Hither or Exterior Lib­
ys; and the Farther or Interior. The former lay be­
­tween the Mediterranean on the north, and the Farther Libya and Ethiopia beyond Egypt on the south, (Ptolemy). The Farther or Interior Libya, was a vaft country, lying between the Hither Libya on the north, the Atlantic ocean on the weft, the Ethiopic on the south, and Ethiopia beyond Egypt on the eaf­
(Ptolemy).

LIBYA, in a fill more reftained fense, called, for di­
­inition’s fake, Libya Propria, was a northern dif­
trict of Africa, and a part of the Hith. r Libya; situ­
­ated between Egypt to the eaf­, the Mediterranean to the north, the Syrtis Major and the Regio Tripoli­
tana to the weft, the Garamantes and Ethiopia be­
yond Egypt to the South, Now the kingdom and defart of Barca. This Libya was again divided into Libya taken in the strictefe fense of all, and into Marmarica and Cyrenaica. Libya in the strictefe fense, otherwise the Ex­
terior, was the moft eaf­ten part of Libya Pro­
prica, next to Egypt, with Marmarica on the weft, the
Licence

Licence, in law, an authority given to a person to do some lawful act.

Licensor of the Prefi. See Liberty of the Prefi. Licentiate, one who has obtained the degree of a licence. — The greatest number of the officers of justice in Spain are distinguished by no other title than that of licentiate. In order to pass licentiate in common law, civil law, and phyfic, they must have studied seven years, and in divinity ten. Among us a licentiate usually means a physician who has a licence to practice, granted by the college of physicians.

LICETUS, a celebrated physician of Italy, was born at Rappolo, in the state of Genoa, 1577. He came, it seems, into the world, before his mother had completed the seventh month of her pregnancy; but his father being an ingenious physician, wrapped him up in cotton, and nurtured him for that he lived to be 77 years of age. He was trained with great care, and became a very distinguished man in his profession; and was the author of a great number of works: his book De Monstris every body must have heard of. He was professor of philosophy and physic at Padua, where he died in 1655.

LICEN, liver wort, in botany; a genus of the natural order of alge, belonging to the criprogama class of plants. The male receptacle is roundish somewhat plain and fihing. In the female the leaves have a fenza or nearly furface, scattered over them. There are about 120 species, all found in Britain. Among the most remarkable are the following:

1. The geophytes; it is frequent in rocks, and may be readily distinguished at a distance. The crust or ground is of a bright greenish-yellow colour, sprinkled over with numerous plain black tubercles; which frequently run into one another, and form lines resembling the rivers in a map, from which last circumstance it takes its name.

2. The calcareous, or black nobbed dyer's lichen, is frequent on calcareous rocks; and hath a hard, smooth, white, fpony, or tartareous crust cracked or fetulated on the surface, with black tubercles. Dillenius relates, that this species is used in dyeing, in the same manner as the tartarius after mentioned.

3. The venetus, or red fangled tartareous lichen, hath a hard tartareous crust, cracked and fetulated on the surface, of pale a yellow colour when freh, and a light olive when dry. The tubercles are of a blood-red colour at top, their margin and base of the fame colour as the crust. The texture and appearance of this (according to Mr Lightfoot), indicate that it would answer the purpofe of dyeing as well as some others of this tribe, if proper experiments were made.

4. The calenderius, or yellow farinaeous lichen, is common upon walls, rocks, boards, and old pales. There are two varieties. The first has a farinaeous crust of no regular figure, covered with numerous, small greenish yellow, or olive fhields, and grows commonly upon old boards. The other has a smooth, hard circular crust, wrinkled and lobed at the circumference which adheres closely to rocks and stones. In the centre are numerous fhields of a deeper yellow or orange colour, which as they grow old, dwell in the middle, and assume the figure of tubercles. The inhabitants of Småland in Sweden scrape this lichen from the rocks, and mix it with their tallow, to make golden candles to burn on feftival days.

5. The tartarius, or large yellow-faucer'd dyer's lichen, is frequent on rocks; both in the Highlands and lowlands of Scotland. The crust is thick and tough, either white or greenish-white, and has a rough warted furface. The shields are yellow or buff-coloured, of various sizes from that of a pins head to the diameter of a silver penny. Their margins are of the fame colour as the crust. This lichen is much used by the Highlanders for dyeing a fine claret or pomepadour colour. For this purpofe, after fraping it from the rocks, and cleaning it, they steep it in urine for a quarter of a year. Then taking it out they make it into cakes, and hang them up in bags to dry. These cakes are afterwards pulverized, and the powder is used to impart the colour with an addition of alum.

6. The pellarus, or crawfish-eye lichen, grows upon walls and rocks, but is not very common. The crust spread closely upon the place where they grow; and cover them to a considerable extent. They are rough tartareous, and ash-coloured, of a tough courious substance. The shields are numerous and crowded, having white or ash coloured, shallow, plain dyes, with obtufe margins. This is used by the French for dyeing a red colour.

7. The faxatifius, or grey-blue pitted lichen, is very common upon trunks of trees, rocks, tile, and old wood. It forms a circle two or three inches diameter. The upper surface is of a blue grey and sometimes of a whitish ash-colour, uneven, and full of numerous small pits or cavities; the under side is flat, and covered all over, even to the edges, with short fimple hairs or radicles. A variety sometimes occurs with leaves tinged of a red or purple colour. This is used by fichers and other fmall birds in constructing the outside of their curiously formed nests.

8. The omphaloides, or dark coloured dyers lichen, is frequent upon rocks. It forms a thick widely expanded crust of no regular figure, composed of numerous imbricated leaves of a brown or dark purple colour divided into small segments. The margins of the shields are little crisp and turned inwards, and their outside ash-coloured. The lichen is much used by the Highlanders in dyeing a reddish brown colour. They steep it in urine for a considerable time, till it becomes soft and like a fapie; then, forming the paste into cakes, they dry them in the sun, and preserve them for use in the manner already related of the tartarius.

9. The paticius, or common yellow wall-lichen, is very common upon walls, rocks, tiles of houfes, and trunks of trees. It generally spreads itself in circles of two or three inches diameter, and is said to dye a good yellow or orange colour with alum.

10. The ilandicus, or table lichen, grows on many mountains both of the Highlands and Lowlands of Scotland. It consists of nearly creft leaves about two inches high, of a fliiff substance when dry, but soft and pliant when moist, variously divided without order into broad faniform segments, bifid or trifid at the extremities. The upper or interior surface of the leaves is concave, chequif-colour, smooth and fhining, but red at the base; the under or exterior surface is smooth and whitif, a little pitted and sprinkled with very minute black waris. The margins of the leaves and all the segments from bottom to top are ciliated with fmall,
Lichen. (28)

short, stiff, hair-like spines, of a dark chestnut colour, turning towards the upper side. The shields are very rarely produced. For the uses of this as an excellent herb, see Iceland, next. Made into broth or gruel, it is said to be very nutritious in coughs and consumptions; and in gruel, made by Haller and Scopoli, is much used in these complaints in Vienna.

11. The pulmonarius, or lung-wort lichen grows in shady woods upon the trunks of old trees. The leaves are as broad as a man's hand, of a kind of leather-like substance, hanging loose from the trunk on which it grows, and laminated into wide angular segments. Their natural colour, when fresh, is green; but in drying, they turn first to a glaucous and afterwards to a fuscous colour. It has an astringent, bitter taste; and, according to Gmelin, is boiled in ale in Siberia, instead of hops. The ancients used it in coughs and afflams, &c., but it is not used in modern practice.

12. The calicarius, or beaked lichen, grows sometimes upon trees, but more frequently upon rocks, especially on the sea-coasts, but is not very common. It is smooth, glossy, and whitish, producing flat or convex shields, of the same colour as the leaves, very near the summit of the segments, which are acute and rigid, and, being often reflected from the perpendicular by the growth of the shields, appear from under their limbs like a hooked beak. This will dye a red colour; and promises, in that intention, to rival the famous Lichen Rosella or Argyl, which is brought from the Canary Islands and sometimes sold at the price of 80 l. per ton. It was formerly used instead of starch to make hair-power.

13. The prunifoli, or common ragged hoary lichen, grows upon all sorts of trees; but it is generally most white and hoary on the floc and old palm trees, or upon old pales. This is the most variable of the whole tribe of lichens, appearing different in figure, magnitude and colour, according to its age, place of growth, and sex. The young plants are of a glaucous colour, slightly divided into small acute cleft segments. As they grow older, they are divided like a flag's horn, into more and deeper segments, somewhat broad, flat, soft, and pitted on both sides, the upper surface of a glaucous colour the under one white and hoary.—The male plants, as Linnaeus terms them, are short, seldom more than an inch high, not hoary on the under side; and have pale glaucous shields situated at the extremities of the segments, standing on short peduncles, which are only small stiff portions of the leaf produced. The female specimens have numerous farinaceous tubercles both on the edges of their leaves, and the wrinkles of their foliage. The pulverized leaves have been used as a powder for the hair, and also in dyeing yarn of a red colour.

14. The juniperinus, or common yellow tree-lichen, is common upon the trunks and branches of clumps and many other trees. Linnaeus says it is very common upon the juniper. The Gothland Swedes dye their yarn of a yellow colour with it, and give it as a specific in the jaundice.

15. The cocciferus, or scarlet-tipped cup lichen, is frequent in moors and heaths. It has in the first state a granulated crust for its ground, which is afterwards turned into small laminated leaves, green above, and hoary underneath. The plant assumes a very different aspect, according to the age, situation, and other accidents of its growth; but may be in general readily distinguished by its fructifications, which are fungous tubercles of a fine scarlet colour, placed on the rim of the cup, or on the top of the flake. These tubercles, steeped in an alkaline lixivium, are said to dye a fine durable red colour.

16. The aphotheca, or green ground liverwort with black warts, grows upon the ground at the roots of trees in woods, and other stony and mossy places. It differs very little from the foregoing, and according to some is only a variety of it. Linnaeus informs us, that the country people of Upland in Sweden give an infusion of this lichen in milk to children that are troubled with the disorder called the therub or apho, which induced that ingenious naturalist to bestow upon it the trivial name of aphotheca. The same writer also tells us that a decoction of it in water purges upwards and downwards, and will destroy worms.

17. The cocciferus, or scarlet-tipped cup lichen, is frequent in moors and heaths. It has in the first state a granulated crust for its ground, which is afterwards turned into small laminated leaves, green above, and hoary underneath. The plant assumes a very different aspect, according to the age, situation, and other accidents of its growth; but may be in general readily distinguished by its fructifications, which are fungous tubercles of a fine scarlet colour, placed on the rim of the cup, or on the top of the flake. These tubercles, steeped in an alkaline lixivium, are said to dye a fine durable red colour.

18. The rauhferinus, or rein-deer lichen, is frequent in woods, heaths, and mountainous places. Its general height, when full grown, is about two inches. The flake is hollow, and very much branched from bottom to top; the branches are divided and subdivided, and at last terminated by two, three, four, or five very fine, short, nodding horns. The axillae of the branches are often perforated. The whole plant is of a hoary white or grey colour, covered with white farinaceous particles, light and brittle when dry, soft and elastic when moist. The fructifications are very minute, round, fuscous, or reddish brown tubercles, which grow on the very extremities of the finest branches: but thec

Lichen.
Lichen
tuberces are very seldom found. The plant seems to have no foliaceous ground for the base, nor scarcely any visible roots. Linnaeus tells us, that in Lapland this moss grows so luxuriant that it is sometimes found a foot high. There are many varieties of this species, of which the principal is the Sylvaticus, or brown-tinted rein-deer lichen. The most remarkable difference between them is, that the Sylvaticus turns tawny by age, while the other always continues white. For the uses of these species, see Lapland.

19. The plicatus, or official stringy lichen, grows on the branches of old trees, but is not very common. The flanks are a foot or more in length, cylindrical, rigid, and string-shaped, very irregularly branched, the branches entangled together, of a cinerous or ash-colour, brittle and stringy if doubled short, otherwise tough and pliant, and hang pendent from the trees on which they grow. The fields grow generally at the extremities of the branches, are nearly flat, or slightly concave, thin, dull coloured above, pale-brown underneath, and radiated with fine rigid fibres. As the plant grows old, the branches become covered with a white, rough, warty crust; but the young ones are destitute of it. It was formerly used in the shops as an astringent to stop haemorrhages, and to cure ruptures; but is out of the modern practice. Linnaeus informs us, that the Laplanders apply it to their feet to relieve the excoriations occasioned by much walking.

20. The barbatus, or bearded lichen, grows upon the branches of old trees in thick woods and pine-forests. The flanks or flaring are slightly branched and pendulous, from half a foot to two feet in length, little bigger than a Taylor's common sewing thread; cylindrically jointed towards the base; but surrounded every where with numerous, horizontal, capillary fibres, either simple or slightly branched. Their colour is a whitish green. This has an astringent quality like the preceding. When steeped in water, it acquires an orange colour; and according to Dillenius, was used in Pennsylvania for dyeing that colour.

21. The vulpinus, or gold-wiry lichen, grows upon the trunks of old trees, but is not very common. It is produced in erect tusfs, from half an inch to two inches in height, of a fine yellow or lemon-colour, which readily discovers it. The filaments which compose it are not cylindrical, but a little compressed and uneven in the surface, variously branched, the angles obtuse, and the branchesragglng and entangled one with another. Linnaeus informs us, that the inhabitants of Sweden dye their yarn of a yellow colour with this lichen; and the Norwegians destroy wolves by stuffing dead carcasses with this moss reduced to powder, and mixed with pounded glafs, and so exposing them in the winter-forests to be devoured by those animals.

LICHFIELD. See Litchfield.

LICHTENBERG, a cاطle of France, in Lower Alsace, and the chief place of a county of the same name; feated on a rock, near the mountains Volpes, and is looked upon as impregnable. E. Long. 7° 35'. N. Lat. 48° 55'.

LICHTENBURG, a town of Germany, in the circle of Franconia, and margravate of Culmbach. E. Long. 12° 0'. N. Lat. 50° 26'.

LICHTENFELD, a town of Germany, in the circle of Ffrrnconia, and bishopric of Bamberg, feated on the river Mayne, in E. Long. 11° 10'. N. Lat. 50° 20'.

LICHTENSTEIN, a town of Swisserland, in Tock-erberg, feated on the river Thour. E. Long. 2° 15'. N. Lat. 47° 25'.

LICHTSTATT, an hand some town of Swisserland, in the county of Balde; feated on the river Erzget. In E. Long. 7° 57'. N. Lat. 47° 40'.

LICINIIUS STOLO, a famous Roman tribune, flyed Sto0no on account of a law he made, while tribune, that no Roman citizen should polluce more than 500 acres of land; alleging that when they occupied more, they could not cultivate it with care, nor pull up the useless shoots (foliounes) that grow from the roots of trees. He is memorable also for enacting, that one of the confuls should always be of a Plebian family. He lived about 362 B. C.

LICONON, in the Dionysian solemnities, the myr­stitial van of Baceus; a thing so essential to all the solemnities of this god, that they could not be duly celebrated without it. See DIONYSIA.

LICNOPHORI, in the Dionysian solemnity, those who carried the licenon.

LICOLA, or LAGO-DI-LICOLA, a lake in the king­dom of Naples, formerly famous for plenty of excellent fif; but in the year 1538 an explosion of a volcano changed one part of it into a mountain of ashes, and the other into a morass. It was anciently known by the name of the Loricine-lake.

LICONIA, in Italy: A genus of the digynia order, belonging to the pentandra class of plants. There are five petals included in the pit of the nectarium at its base; the capsule is bilocular and seed-bearing.

LICTORS, among the Romans, were officers esta­blished by Romulus, who always attended the chief magistrates when they appeared in public.

The duty of their office consisted in the three follow­ing particulars: 1. Substitutio, or clearing the way for the magistrate they attended: this they did by word of mouth; or, if there was occasion, by using the rods they always carried along with them. 2. Antinocati, or causing the people to pay the ufual respect to the magistrate, as to slight, if on horseback or in a chariot; to ride up, uncover, make way, and the like. 3. Pretatio, or walking before the magistrates: this they did not confinedly, or altogether, nor by two or three abreast, but singly following one another in a straight line. They also preceded the triumphal car in public triumphs; and it was also part of their office to arrest criminals, and to be public executioners in behal­ling, &c. Their ensigns were the fasces and scurcis. As to the number of lictors allowed each magistrate, a dictator had twenty-four, a master of the horse fix, a conful twelve, a praetor six; and each vefcal virgin, when she appeared abroad, had one.

LID. See Lydd.

LIDDEL (Dr Duncan), professor of mathematics and of medicine in the university of Helmflato, was born in the year 1567 at Aberdeen, where he received the first part of his education in languages and philosophy. About the age of eighteen he repaired to the university of Franche­fort, where he spent three years in a diligent application to mathematics and philosophy. From Frankfort he proceeded to Wittenfaw, or Breflaw in Sicilia, where
he is said to have made uncommon progress in his favourite study of mathematics under the direction of a very eminent professor, Paulus Wittichus. Having lived at Brelaw for the space of one year, he returned to Francfort, and remained there three years, paying the most intense application to the study of physic. A contagious distemper having broke out at that place, the students were dispersed; and Liddel retired to the university of Roftock. Here he renewed his studies, rather as a companion than a pupil of the celebrated Brucæus, who, though an excellent mathematician, did not scruple to confess that he was instructed by Liddel in the more perfect knowledge of the Copernican system, and other astronomical questions. In 1590 he returned once more to Francfort. But having there heard of the increasing reputation of the Academia Julia, established at Helmstadt by Henry duke of Brunswick, Mr Liddel removed thither; and soon after his arrival was appointed to the first or lower professorship of mathematics. From thence he was promoted to the second and more dignified mathematical chair, which he occupied for nine years, with much credit to himself and to the Julia Academy. In 1596 he obtained the degree of M. D. was admitted a member of that faculty, and began publicly to teach physick. By his teaching and his writings he was the chief support of the medical school at Helmstadt; was employed as first physician at the court of Brunswick, and had much practice among the principal inhabitants of that country. Having been several times elected dean of the faculties both of philosophy and physick, he had in the year 1604 the honour of being chosen pro-rector of the university. But neither academical honours, nor the profits of an extensive practice abroad, could make Dr Liddel forget his native country. In the year 1600 he took a final leave of the Academia Julia; and after travelling for some time through Germany and Italy, he at length settled in Scotland. He died in 1613, in the fifty-second year of his age. By his last will he bequeathed certain lands purchased by him near Aberdeen upon the university there, in all time coming, for the education and support of six poor scholars. Among a variety of regulations and injunctions for the management of this charity, he appoints the magistrates of Aberdeen his trustees, and solemnly denounced the curse of God on any person who should abuse or misapply it. His works include:

1. *Disputationes Medicinales*, Helmstadt, 1603, 4to. 2. *Artes Medicinae et peritia explicantia*, Hamburgi, 1607, 8vo. This performance is dedicated to King James VI. and is divided into five books, viz. *Introductio in totam Medicinam*, *De Physiologia*, *De Pathologia*, *Signorum delirina*, *De Therapeutica*. 3. *De febribus Libri tres*, Hamburgi, 1610, 12mo. 4. *Tractatus de dente aureo*, Hamburgi, 1628, 12mo. This last performance Dr Liddel published in order to refute a ridiculous story then current of a poor boy in Silida, who, at seven years of age, having lost some of his teeth, brought thither, to the astonishment of his parents, a new tooth of pure gold. Jacobus Horlins, doctor and professor of medicine in the Academia Julia, at the same time with our author, had published a book which he dedicated to the emperor Rudolphus II. to prove that this wonderful tooth was a prodigy sent from heaven to encourage the Germans then at war with the Turks, and foretelling, from this golden tooth, the future victories of the Christians, with the final destruction of the Turkish empire and Mahometan faith, and a return of the golden age in 1700, preparatory to the end of the world. The imposture was soon after discovered to be a thin plate of gold, skilfully drawn over the natural tooth by an artist of that country, with a view to excite the public admiration and charity. 5. *Artis conservandi Sanitatem*, *libri dui*, *Abdoniensis*, 1611, 12mo; a pithomous work. The merit of these works of Dr Liddel, it is not necessary to callify with precision. They appear, however, to contain the most fashionable opinions and practice, in the medical art, of the age in which he lived; nor is there among any differente or medical subject then known of which he has not treated in one or other of his writings. Of his language it may be sufficient to observe, that the Latin is at least as pure as is generally found among medical writers, and that his style is plain and perspicuous, and sometimes even elegant.

**Lidford**, a village of Devonshire in England, situated on the river Lid, two or three miles east of Brent Tor, was formerly a famous town, with a caffle, which was always committed to men of quality, and twice spent by the Danes in 997; and though now a contemptible village, the parish may for lands and liberties encourage the Germans then at war with the Turks, and so forth. A companion than a pupil of the celebrated Brucæus, who, though an excellent mathematician, did not scruple to confess that he was instructed by Liddel in the more perfect knowledge of the Copernican system, and other astronomical questions. In 1590 he returned once more to Francfort. But having there heard of the increasing reputation of the Academia Julia, established at Helmstadt by Henry duke of Brunswick, Mr Liddel removed thither; and soon after his arrival was appointed to the first or lower professorship of mathematics. From thence he was promoted to the second and more dignified mathematical chair, which he occupied for nine years, with much credit to himself and to the Julia Academy. In 1596 he obtained the degree of M. D. was admitted a member of that faculty, and began publicly to teach physiology. By his teaching and his writings he was the chief support of the medical school at Helmstadt; was employed as first physician at the court of Brunswick, and had much practice among the principal inhabitants of that country. Having been several times elected dean of the faculties both of philosophy and physiology, he had in the year 1604 the honour of being chosen pro-rector of the university. But neither academical honours, nor the profits of an extensive practice abroad, could make Dr Liddel forget his native country. In the year 1600 he took a final leave of the Academia Julia; and after travelling for some time through Germany and Italy, he at length settled in Scotland. He died in 1613, in the fifty-second year of his age. **Lidford**, a village of Devonshire in England, situated on the river Lid, two or three miles east of Brent Tor, was formerly a famous town, with a caffle, which was always committed to men of quality, and twice spent by the Danes in 997; and though now a contemptible village, the parish may for lands and liberties encourage the Germans then at war with the Turks, and so forth.

**Lidney**, a town of Gloucestershire in England, 71 miles from London, is seated on the west bank of the river Severn, and has a market on Wednesdays, with two fairs in the year. In the neighbourhood are the remains of a large Roman encampment, with foundations of many ancient buildings, among which are the ruins of a Roman hypocaust of an oval form, and Roman antiquities and coins are often found here in great number. Mr Bathurst has a fine seat here called Sydney-Park, with very extensive woods adjoining.

**LIE**, in morals, denotes a criminal breach of veracity. — Archdeacon Paley, in treating of this subject, observes, that there are falsehoods which are not lies; that is, which are not criminal; and there are lies which are not literally and directly false.

1. Cales of the first class are those which
2. Where no one is deceived: as for instance in parables, fables, novels, jefts, tales to create mirth, or ludicrous embellishments of a story, in which the declared design of the speaker is not to inform, but to divert; compliments in the subcription of a letter; a prisoner's pleading not guilty; an advocate affecting the justice, or his belief of the justice, of his client's cause. In such instances no confidence is destroyed, because none was repose; no promise to speak the truth is violated, because none was given or understood to be given.

to veracity, fpeech and action are the fame; fpeech being
only a mode of action.
LIECHTENAU, a town of Germany, in the cir-
cle of Franconia and margravate of Anfpach, fubjeft
to Nurenbeg. E. Long. 9. 5. N. Lat. 48. 43.
LIEGE (Ligia,) in law, properly signifies a vaf-
fal, who holds a kind of fee, that binds him in a clo-
fer obligation to his lord than other people.
The term seems to be derived from the French fer
"to bind;" on account of a ceremony used in rendering
fait or homage: which was by locking the vaflal's
thumb or his hand in that of the lord, to show that
he was fast bound by his oath of fidelity. Cujus,
Vigence, and Bignon, choose rather to derive the
word from the fame fource with levis or loadi, "loy-
al, faithful." But Du Cange falls in with the opin-
ioin of thofe who derive it from lri, a kind of vaflals,
so firmly attached to their lord, on account of lands or
feftial of him, that they were obliged to do him all
manner of service, as if they were his domestics. He
adds, this was formerly called ligiumferotinum, and
the perion Itige. In this fene, the word is ufed, Leg.
Edw. cap. 29. fada fub tutela regis liges debent effe; this,
wholly under his protection.
By liege homage, the vaflal was obliged to ferve his
lord towards all, and againft all, excepting his father.
In which fene, the word was ufed in opposition
to fimple homage; which laft only obliged the vaflal to pay
the rights and accustomed dues to his lord; and not to
bear arms againft the emperor, prince, or other superior
lord: fo that a liege man was a perfon wholly devoted
to his lord, and entirely under his command. Omnibus.

LIEGE, a biphopic of Germany, in the circle of
Weffphalia; bounded to the north by Brabant, to the
south by Champaigne and Luxemburg, to the eait by
Limburg and Juliers, and to the west by Brabant,
Namur, and Hainault. It is very unequal both in
length and breadth; the former being in some places
above 93 miles, in others not half so much; and the
latter in some places 45, in others hardly 25. The
air here is very temperate; and the foil fruitful in
corn, wine, wood, and pasture. Here also are mines of
lead and iron, pits of coal, quarries of marble and
done, and some celebrated mineral waters, as thofe
of Spa and Chau-fountain. The principal rivers are,
the Maes and Sambre. The manufacturers and com-
modities of the country are chiefly hemp, raps, nails,
ferge, leather, with the products we have just men-
tioned. The fates of the biphopic are composed of
three bodies: the first is the chapter of Lige; the
second, the nobility of the country; and the third, the
deputies of the capital and the other towns. The
three fates are seldom called together, except to
raife taxes for the service of the province, or upon
some particular emergency; but there is a committee of
the fates, who meet thrice a-week, and in time of
war daily. They are always about the prince-bishop,
to make remontrances, and demand the redrefs of
grievances. The bishop is spiritual and temporal
Liege, the capital of the bishopric of the same name, stands upon the Meuse, in a fine valley, surrounded with woods and hills, being a free imperial city, and one of the largest and most eminent in Europe. Though it is 100 miles from the sea by water, the Meuse is navigable up to it. The city has 16 gates; 17 bridges, some of them very handsome; 154 streets, many of them straight and broad; a fine episcopal palace; a very large flately cathedral, in which, besides five great silver cofiers full of reliques, are several silver statues of saints, and a St. George on horseback of maffy gold, presented to the cathedral by Charles the Bold, by way of aatonement for the inhabi-
tants cruelly in the year 1468. Of the other churches, that of St. Paul is the most remarkable, both for its structure and fine ornaments in painting and marble. The city is well fortified, and there are also two castles on the mountain of the Holy Walburg for its defence. Besides a great number of other convents of both sexes, here is a college of English Jesuits, founded in the year 1616, and a fine munery of English ladies. Indeed, churches, convents, and other religious foundations, take up the greater part of it. The reader, therefore, no doubt, will take it for granted, that it is a most blest, holy, and happy city. But however it may fare with the profane, unhallowed laity, it is certainly the paradise of priests, as it is expressively called, by way of eminence. It is divided into the old and new, or the upper and lower; and the latter again into the iland, and the quarter beyond the Maes. The houses are high, and built of bluish marble. In the town and suburbs are 12 public places or squares, 10 hospitals, a beguin-house, and two fine keys, planted with several rows of trees, for the burghers to take the air; but a great part of that within the walls is taken up with orchards and vineyards. The manufactures of this city are arms, nails leather, l fee, and beer. In St. William's convent, without the city, is the tomb of the famous

English traveller Sir John Mandeville, with an in-
scription in barbarous French, requesting those who
read it to pray for his soul. Near it are kept the saddle, spurs, and knife, that he made use of in his travels. After having been most of the cities of any note in the world, he made choice of this to spend the eve of his life in. A little way from the city, on the other side the Meas, stands the episcopal palace of Ste-
ning, in which the bishops generally reside during the summer. The latitude of this city is 50. 36. N. and the longitude 5. 40. E.

Some disturbances took place here in the year 1789, in consequence of certain disputes that had arisen between the prince-bishop and the inhabitants. The latter having demanded certain privileges, which he did not think proper to grant, they took up arms, and compelled him and his chapter to comply with their request. The prince, together with many of the clergy, nobility, and citizens, alarmed by this commotion, and dreading the consequences of popular fury, which when once roused, inroads on some famous universities. The bishopric is very populous and extensive, containing 1500 parishes, in which are 24 walled towns, besides others, 52 baronies, besides counties and seigniories 17 abbeys for men, who must be all gentlemen, and 11 for ladies, exclusive of others.
LIEGE was now full time to put a period to that madness to which the people had abandoned themselves; and to accomplish this in an effectual manner, the imperial chamber at Wetzlar requested the emperor, as a member of the ancient circle of Burgundy, to execute its orders respecting this object. In consequence of this measure, Baron Alvinzi, who commanded a body of Austrian troops cantoned in Limburg and the confines of Brabant, notified, by order or Martial Bender, to the states and municipality of Liege, that the emperor intended to send troops into their city and territories, for the purpose of restoring tranquillity and good order. The states had already been informed of this resolution by their agent at Wetzlar. They therefore wrote to Martial Bender, to assure him of the respectful confidence which they placed in the justice and magnanimity of the emperor, and to request that the Austrian troops might enter alone, without those of the electors; and that they might be confined to occupying the gates and the suburbs only. To this letter, which was carried to Brussels by a deputation of the states, Martial Bender returned a very satisfactory answer, relating to the disposition of the electoral troops; but Baron Alvinzi, in a note which he wrote to the states, infufed among other articles, that all the citizens should throw down their arms: that proper accommodations should be prepared for the officers and men; that the warlike stores, collected for making resistance, should be removed; and that cockades, and every other distinctive mark of the like kind, should be laid aside before the arrival of the Imperial troops. However humiliating these preliminaries might be, especially that of a general disarming, the states and municipalities acquiesced without the least reserve; and their submission, as sudden as complete, was communicated to the people, with an exhortation to follow their example.

Notwithstanding this pacific appearance, two days before the entrance of the Imperial troops, the municipal council of Liege, flattering themselves, perhaps, with the hopes of succour from Prussia, assured the inhabitants that they would remain unshaken in their post, and that they had sworn never to desert the cause in which they were engaged. This, however, did not prevent the Austrian troops from entering without opposition, into the heart of the city; where they occupied every post; made the citizens lay aside their arms, uniforms, and cockades; and, in a single hour, deposed so many false-reigns of a year. The greater part of the municipal officers, who, two days before, had solemnly promised such great things; betook themselves to flight, and retired either to France or Wefel; while the ancient magistracy, which had been expelled in the month of August 1789, was provisionally reinstated by the directorial commissioners. —The decrees of the imperial chamber at Wetzlar have since been executed in their utmost extent. The ancient magistracy and the privy-council of the prince bishop have been restored; and the prince himself having returned, peace and good order have been re-established.

 LIENERY, a flux of the belly, in which the aliments are discharged as they are swallowed, or very little altered either in colour or substance. See (Index subjoined to) Medicine.

LIEVENS (John or Jan), a celebrated painter, was born at Leyden in 1607. He discovered an early inclination for the arts, and was the disciple first of juris van Schooten, and afterwards of Peter Laftman. He excelled principally in painting portraits; but he also executed several historical subjects with great success. He came over into England, where he resided three years, and painted the portraits of Charles I. the queen, the prince of Wales, and several of the nobility; after which he returned to Antwerp, where he met with full employment for his pencil. He has several etchings by this matter, which are performed in a flight, but masterly manner. His style of etching bears some resemblance to that of Rembrandt; but it is coarser in general, and less finished.

LIEOU-KIEOU, the name of certain islands of Asia, subject to China; but hitherto little known to geographers, who have been satisfied with marking their existence and latitude in their charts. They, however, form a powerful and extensive empire, the inhabitants of which are civilized, and ought not to be confounded with other savage nations dispersed throughout the islands of Asia. Father Gabel, a Jesuit, has furnished us with some interesting particulars respecting these islanders, which he extracted from a Chinese relation, published in 1721, at the end of a voyage that was undertaken on the following account. The emperor Kang-hi having resolved, in 1719, to send an ambassadour to the king of Lieou-kieou, chose for this purpose one of the great doctors of the empire, named Sopao-Koang. This learned man departed from China in 1719, and returned to Peking in 1720, where, in the year following, he related a relation of his voyage to be published in two volumes. It is in the first of these that he gives an accurate and particular description of the isles of Lieou-kieou; and what he relates appears to be worthy of the greater credit, because, being on the spot, he examined, as he himself says, according to the orders of the emperor, whatever he found curious or interesting, respecting the number, situation, and productions of these isles; also the history, religion, manners, and customs of the people who inhabit them.

These isles, situated between Corea, Formosa, and Japan, are in number 36. The principal and largest is called Lieou-kieou; the rest have each a particular denomination. The largest island extends from north to south almost 440 1ys, and 120 or 140 from east to west; but on the south side, the extent from east to west is not 100 1ys. The south-east part of the island where the court resides, is called Cheouli; and it is there that Kint-ching, the capital city, is situated. The king's palace, which is reckoned to be four leagues in circumference, is built on a neighbouring mountain. It has four gates, which correspond to the four cardinal points; and that which fronts the west forms the grand entrance. The view which this palace commands is most extensive and delightful; it reaches as far as the port of Napakiang, at the distance of ten lys, to the city of Kint-ching, and to a great number of other cities, towns, villages, palaces, temples, monasteries, gardens, and pleasure houses. It stands in longitude 146° 26' east, and in latitude 26° 2' north.

If we believe these islanders, the origin of their empire
Lieou-Kicou.

Pirate is lost in the remotest antiquity. They reckon up 25 succeasive dynasties, the duration of which forms a period of more than 18,000 years. It would be useless to employ a single moment in pointing out the absurdity of these pretensions. It is however certain, that the existence of the country called Lieou-kicou was not known in China before the year 605 of the Christian era. It was in the course of that year, that one of the emperors of the dynasty of Soui, having heard of these isles, was desirous of knowing their situation. This prince at first sent some Chinese thers; but their expedition proved fruitless, as the want of interpreters prevented them from acquiring that knowledge which was the object of their voyage. They only brought some of the islanders with them to Sigan-fou, the capital of the province of Chen-fi, which was the usual residence of the emperors of the dynasty of Soui. It fortunately happened, that an ambassador of the king of Japan was then at court. This ambassador and his attendants immediately knew the strangers to be natives of Lieou-kicou; but they spoke of these isles as of a miserable and wretched country, the inhabitants of which had never been civilized. The emperor of China afterwards learned, that the principal island lay to the east of a city called at present Fau-teheou-fou, which is the capital of the province of Fo-kien; and that, in a passage of five days, one might reach the large island where the king kept his court.

On this information, the emperor Yang-ti sent skilful men, accompanied by interpreters, to summon the prince to do homage to the emperor of China, and to pay him tribute. This proposal was very ill received. The king of Lieou-kicou sent back the Chinese, telling them, firmly, that he acknowledged no prince to be his superior. This answer irritated the emperor, who, to obtain revenge, caused a fleet to be immediately equipped in Fo-kien, in which he embarked 10,000 men. This fleet set sail, and arrived in safety at the port of Napa-kiang. The army, in spite of every effort made by the natives, landed on the island; and the king, who had put himself at the head of his troops to oppose the enemy, having fallen in battle, the Chinese pillaged, sacked, and burnt the royal city, made more than 5000 slaves, and returned to China.

The emperors of the dynasty of Tang, those of the first dynasties that followed, and those of the dynasty of Song, although they were fully informed of every thing respecting the Lieou-kicou isles, made no attempts to render them tributary. In 1291, Chi tio-emperor of the dynasty of Yen, was desirous of reviving the pretensions of his predecessors. He fitted out a fleet to subdue these islands; but schemes of conquest had become disagreeable to the Chinese, since the disaster that befell their army in an expedition against Japan. The fleet of Chi tio-fou went no farther than the isles of Pong-hou, and the western coast of Formosa, from whence, under divers pretences, they returned to the ports of Fo-kien.

It was only in 1372, under the reign of Hong-you, founder of the dynasty of Ming, that these islands submitted voluntarily to the Chinese government. Hong-you had sent one of the grandees of his court to Tsay-tou, who was then reigning at Lieou-kicou, to inform him of his accession to the throne. The Chinese nobleman had received particular instructions respecting this commission, and he acquited himself of it with all the prudence and address of an able minister. In a private audience which he had with Tsay-tou, he exhorted this prince to declare himself a tributary of the empire, and laid before him the advantages he would derive from this step. His reasoning, supported by the power of his natural eloquence, made so much impression on the mind of Tsay-tou, that he embraced the proposal made him, and sent immediately to the emperor to demand the investiture of his states.

Hong-you received his envoys in a magnificent manner, and loaded them with presents. He solemnly declared Tsay-tou a vassal of the empire; and, after having received his first tribute (which consisted in valuable horses, aromatic wood, sulphur, copper, tin, &c.), he sent to this prince, a golden seal, and confirmed the choice he had made of one of his sons to succeed him. The emperor afterwards sent 36 families, almost all from the province of Fo-kien to Lieou-kicou. Tsay-tou received them, assigned them lands near the port of Napa-kiang, and appointed certain revenues for their use, at the same time that Hong-you made them considerable remittances. These families first introduced into Lieou-kicou the learned language of the Chinese, the use of their characters, and the ceremonies prescribed in China in honour of Confucius. On the other hand, the sons of several of the grandees of the court of Tsay-tou were sent to Nan-king, to study Chinese in the imperial college, where they were treated with distinction, and maintained at the emperors' expense.

The isles of Lieou-kicou had neither iron nor porcelain. Hong-you supplied this want; he cauted a great number of utensils of iron and instruments to be made, which he sent thither, together with a quantity of porcelain vessels. Commerce, navigation, and the arts soon began to flourish. These islanders learned to cast bells for their temples, to manufacture paper and the finest stuffs, and to make porcelain, with which they had been supplied before from Japan.

The celebrated revolution which placed the Tartars on the imperial throne of China, produced no change in the conduct of the kings of Lieou-kicou. Chang-tché, who was then reigning, sent ambassadors to acknowledge Chunch-tchi, and received a seal from him, on which were engraved some Tartar characters. It was then settled, that the king of Lieou-kicou should pay his tribute only every two years, and that the number of persons in the train of his envoys should not exceed 150.

The emperor Kang-hi seemed to pay more attention to these isles than any of his predecessors. He cauded a superb palace to be erected in honour of Confucius, and a college where he maintained masters to teach the sciences and the Chinese characters. He also instituted examinations for the different degrees of literati. He ordained, that the king of Lieou-kicou should never send in tribute rose-wood, cloves, or any other production which was not really of the growth of the country; but that he should send a fixed quantity of sulphur, copper, tin, shells, and mother of pearl, which is remarkably pretty in these islands. He permitted, that, besides the usual tribute, he might present him horse furniture, pitil-cafes, and other things of the same kind, which these islanders are said to manufacture with great taste and neatness.
It is more than 900 years since the bronze of China introduced at Lieou-kieon the worship of Po, and the principal beasts belonging to their feet. This worship is at present the established religion both of the grandees and of the people. There is still to be seen in the royal city a magnificent temple, erected in honour of another idol borrowed from the Chinese, named Tien-fey, which signifies celestial queen or lady.

These illidours do not make promises or swear before their idols. When they have occasion to do this, they burn perfumes, present fruits, and stand respectfully before some stone, which they call to witness the solemnity of their engagements. Numbers of stones are to be seen in the courts of their temples, in most public places, and upon their mountains, which are entirely appropriated to this purpose. They have also among them women consecrated for the worship of spirits, who are supposed to have great influence over these beings. They visit the sick, distribute medicines, and recite prayers for their recovery.

They respect the dead as much as the Chinese, and they are no less ceremonious in wearing mourning; but their funerals are neither so pompous, nor attended with so much expense. Their coffins, which are of an hexagonal or octagonal figure, are three or four feet high. They burn the flesh of the bodies of their dead, and preserve only the bones. They never offer provisions to them; they are contented with placing lamps round them, and burning perfumes.

Different families are distinguished in Lieou-kieou by surnames, as in China; but a man and a woman of the same surname cannot be united in marriage. The king is not permitted to marry but in the three grand families, which always enjoy the highest offices. There is a fourth, of equal distinction as the three former; but neither the king nor the princes contract any alliances with this family; for it is doubtful, whether it be not sprung from the same item as the royal line.

A plurality of wives is allowed in these isles. Young men and young women enjoy the liberty of falling one another, and of contracting together; and their union is always in conformity of their own choice. The women are very reserved; they never use paint, and wear no pendants in their ears; they collect their hair on the top of their heads in the form of a curl, and fix it in that manner by means of long pins made of gold or silver.

Besides the vast domains which the king possesses, he receives the produce of all the sulphur, copper, and tin-mines, and of the salt-pits, together with what arises from taxes. From these revenues he pays the salaries of the mandarins and officers of his court. These salaries are estimated at a certain number of facks of rice; but under this name is comprehended what ever the king gives in grain, rice, silk, cloth, &c. The whole is valued according to the price of the facks of rice.

There are here, as in China, nine orders of mandarins, who are distinguished by the colour of their caps, or by their girdles and cushions. The greater part of the titles of these mandarins are hereditary in their families; but there are some which are only bestowed upon merit. In the royal city there are tribunals established for managing the revenue and affairs of the principal island, and of all the others which are dependent on it. The latter have agents, who reside at court.

There are also particular tribunals for civil and criminal matters; for whatever concerns the families of the grandees and princes of the affairs of religion; for inspecting the public granaries, king's revenues, duties; for commerce, manufactures, civil ceremonies, and for navigation, public edifices, literature, and war.

The vessels that are built in this country are greatly valued by the people of China and Japan. In thelfe the natives go not only from one island to another, but also to China, Tong-kung, Cochinchina, Corea, Nangazaki, Satsuma, the neighbouring isles, and so on, where they dispose of their different commodities. Besides these articles of commerce which their manufactures of silk, cotton, paper, arms, copper utensils, &c. furnish them, they also export mother of pearl, tortoise and other shells, coral and whale-fishes, which are in great request both in China and Japan.

LIEUTAUD (Dr Joseph), councillor of state and first physician at the court of France, was born at Aix in Provence, and resided principally there till he took the degree of doctor of medicine. After this he prosecuted his studies for some years at Montpellier. He returned to Aix, where he soon acquired extensive practice, and became eminent for literary abilities. He resided there till the year 1750, when he was invited to act as physician to the royal infirmary at Versailles. There he practised with such reputation and success, that he soon arrived at the head of his profession; and in the year 1774, upon the death of M. Senac, he was appointed architect. His extensive engagements in practice did not prevent him from cultivating the science of medicine in all its branches, and from freely communicating to others the result of his own studies. He published many valuable works; amongst which the following may be accounted the most remarkable. 1. Elementa Philologic. 2. Precis de la Medicina. 3. Pratique des Prisons de la Materie Medica. 4. Essais Anatomique. 5. Synopsis Universelle des Medecins. 6. Historia Anatomica-Medica. He died at Versailles in 1780, aged 78 years.

LIEUTENANT, an officer who supplies the place and discharges the office of a superior in his absence. Of these, some are civil, as the lords lieutenants of counties, and the lords-lieutenants of counties; and others are military, as the lieutenant-general, lieutenant-colonel, &c.

Lord Lieutenant of Ireland, is properly a viceregal; and has all the state and grandeur of a king or of England, except being served upon the knee. He has the power of making war and peace, of besieving all the offices under the government, of dubbing knights, and of pardoning all crimes except high treason; he also calls and prorogues the parliament, but no bill can pass without the royal assent. He is assisted in his government by a privy-council; and, on his leaving the kingdom, he appoints the lords of the regency, who govern in his absence.

Lord Lieutenant of Counties, are officers, who, upon any invasion or rebellion, have power to raise the militia, and to give commissions to colonels and other officers, to arm and form them into regiments, troops, and companies. Under the lord-lieutenants, are deputy-lieutenants, who have the same power;

**Lieutenant**

These are chosen by the lords-lieutenants, out of the principal gentlemen of each county, and preferred to the king for his approbation.

**Lieutenant-Colonel.** See Colonel.

**Lieutenant-General.** See General.

Lieutenant, in the land-service, is the second commissioned officer in every company of both foot and horse, and next to the captain, and who takes the command upon the death or absence of the captain.

**Lieutenant of Artillery.** Each company of artillery hath four: first and second lieutenants. The first lieutenant hath the same duty with the captain; because in his absence he commands the company: he is to see that the soldiers are clean and neat; that their clothes, arms, and accoutrements, are in good and serviceable order; and to watch over every thing else which may contribute to their health. He must give attention to their being taught the exercise, see them punctually paid, their messes regularly kept, and to visit them in the hospitals when sick. He must assist at all parades, &c. He ought to understand the doctrine of projectiles and the science of artillery, with the various effects of gun-powder, however managed or directed; to enable him to construct and dispose his batteries to the best advantage; to plant his cannon, mortars, and howitzers, so as to produce the greatest annoyance to an enemy. He is to be well skilled in the attack and defence of fortified places; and to be conversant in arithmetic, mathematics, mechanics, &c.

Second **Lieutenant in the Artillery,** is the same as an ensign in an infantry regiment, being the younger commissioned officer in the company, and must assist the first lieutenant in the detail of the company's duty. His other qualifications should be equal with those of the first lieutenant.

**Lieutenant of a ship of War,** the officer next in rank and power to the captain, in whose absence he is accordingly charged with the command of the ship, as also the execution of whatever orders he may have received from the commander relating to the king's service.

The lieutenant who commands the watch at sea, keeps the life of all the officers and men thereto belonging, in order to prevent them when he judges it expedient, and report to the captain the names of those who are absent from their duty. During the night-watch, he occasionally visits the lower decks, or sends thither a careful officer, to see that the proper sentinels are at their duty, and that there is no disorder amongst the men; no tobacco smoked between decks, nor any fire or candle burning there, except the lights which are in lanterns, under the care of a proper watch, on particular occasions. He is expected to be always upon deck in his watch, as well to give the necessary orders with regard to trimming the sails and superintending the navigation, as to prevent any noise or confusion; but he is never to change the ship's course without the captain's directions, unless to avoid an immediate danger.

The lieutenant, in time of battle, is particularly to see that all the men are present at their quarters, where they have been previously stationed according to the regulations made by the captain. He orders and exhibits them every where to perform their duty; and acquaints the captain at all other times of the misbehaviour of any person in the ship, and of whatever else concerns the service or discipline.

The youngest lieutenant in the ship, who is also styled lieutenant at arms, besides his common duty, is particularly ordered, by his instructions, to train the seamen to the use of small arms, and frequently to exercise and discipline them therein. Accordingly his office, in time of battle, is chiefly to direct and attend them; and at all other times to have a due regard to the preservation of the small arms, that they be not lost or embezzeled, and that they are kept clean and in good condition for service.

**Lieutenant-Reformer,** he whose company or troop is broke or disbanded, but continued in whole or half-pay, and still preserves his right of seniority and rank in the army.

**Life,** is peculiarly used to denote the animated state of living creatures, in the time that the union of their soul and body lasts.

The Prolongation of Life is made by Lord Bacon one of the three branches of medicine; the other two relating to the preservation of health, and the cure of diseases. See Medicine.

The theory of prolonging life he numbers among the depredata. Some means or indications that seem to lead to it, he lays down as follow.

Things are preferred in two manners; either in their identity, or by reparation. In their identity; as a fly or ant in amber; a flower, or fruit, or wood, in a conservatory of snow; a dead carcase in balams. By reparation; as a flame, or a mechanical engine, &c. To attain to the prolongation of life, both these methods must be used. And hence, according to him, arise three intentions for the prolongation of life: Retardation of consumption, proper reparation, and renovation of what begins to grow old.

Consumption is occasioned by two kinds of depredation; a depredation of the innate spirit, and a depredation of the ambient air. These may be each prevented two ways; either by rendering those agents less predatory, or by rendering the passive parts (viz. the juices of the body) less liable to be preyed on. The spirit will be rendered less predatory, if either its substance be congealed, as by the use of opiates, grief, &c.; or its quantity diminished, as in spare and monastic diets; or its motion calmed, as in idleness and tranquillity. The ambient air becomes less annoying to an enemy, if it be either less heated by the rays of the sun, as in cold climates, in caves, mountains, and anchorits cells; or be kept off from the body, as by a dense skin, the feathers of birds, and the use of oils and ungualts without aromatics. The juices of the body are rendered less liable to be preyed on, either by making them harder or more moist and oily; harder, as by a coarse sharp diet, living in the cold, robust exercises, and some mineral baths; moister, as by the use of sweet foods, &c. abstaining from fats and acids; and especially by such a mixture of drink as consists wholly of fine subtle particles without any acrimony or acidity.

Reparation is performed by means of aliment; and allmentation is promoted four ways; by the concoction of the visceras, fo as to extrude the aliment; by exciting the exterior parts to the attraction of the aliment; as in proper exercises and frications, and someunctions and
LIGATURE. [37]

Life, Ligature.

Ligature. It may more easily infinate itself, and in some measure anticipate the digestion; as in various ways of dressing meats, mixing drinks, fermenting breads, and reducing the virtues of these three into one: By promoting the act of alimentation itself, as in seafonable sleep, some external application, &c.

The renovation of what begins to grow old, is performed two ways: By the intertension of the habit of the body; as in the use of emollients, emplasters, undilutes, &c. of such a nature, as do not extract but impress: Or by purging off the old juices, and substituting fresh ones; as in seafonable evacuations, attenuating diats, &c.

The same author adds these three axioms: That the prolongation of life is to be expected, rather from some flated diets, than either from any ordinary regimen or any extraordinary medicines; more from operating on the spirits and mollifying the parts, than from the manner of feeding; and this mollifying of the parts without it is to be performed by substials, imprints, and accidents. See LONGEVITY.

Vegetable Life. See PLANTS.

LIFE-Rent, in Scots law. When the use and enjoyment of a subject is given to a person during his life, it is said to belong to himself in life-rent.

LIGAMENT, in its general sense, denotes any thing that ties or binds one part to another.

Ligament, in anatomy, a strong compact substance, serving to join two bones together. See Anatomy, p. 7.

LIGARIUS (Quintius), a Roman proconsul in Africa, 49 B.C. Taking part with Pompey, he was forbidden by Julius Caesar to return to Rome; to obtain his pardon, Cicero made that admired oration in his defence which has immortalized the memory of the client with that of his celebrated advocate.

Ligature, in surgery, is a cord, band, or string; or the binding any part of the body with a cord, band, fillet, &c. whether of leather, linen, or any other matter.

Ligatures are used to extend or replace bones that are broken or dislocated; to tie the patient down in lithotomy and amputations; to tie upon the veins in phlebotomy, or the arteries in amputations, or in large wounds; to secure the splints that are applied to fractures; to tie up the processes of the peritoneum with the peritoneal veins in cataract; and lastly, in taking off warts, or other excrescences by ligature.

Ligature, is also used to signify a kind of bandage or fillet, tied round the arm, neck, leg, or other part of the bodies of men or beasts, to divers or drive off some disease, accident, &c.

Ligature, is also used for a state of impotency, in respect to venery, pretended to be caused by some charm or witchcraft.

Kämpfer tells of an uncommon kind of ligature or knotting, in use among the people of Malaçar, Java, Malaya, Siam, &c. By this charm or spell, a man binds up a woman, and a woman a man, so as to put it out of their power to have to do with any other person; the man being thereby rendered impotent to any other woman, and all other men impotent with the woman.

Some of their philosophers pretend, that this ligature may be effected by the shutting of a lock, the drawing of a knot, or the sticking of a knife in the wall, at the point of time wherein the priest is joining a couple together; and that a ligature, thus effected, may be dissolved, by the spouse's urining through a ring. This piece of superstition is said to obtain also among the Christians of the East.

The same author tells us, that during the ceremony of marriage in Kudish, he observed an old fellow lurking behind the church-door, and mumbling生意 are made by a firing of words; and, at the same time, cutting a long rod, which he held under his arm, into pieces; which, it seems, is a common practice at the marriages of great persons, and done with a design to elude and counterwork any other person that might possibly be inducing the ligature.

The secret of inducing a ligature is delivered by the same author, as he was taught it on the spot by one of their adepts: but it is too absurd and obscene to deserve being transcribed.

M. Marshall mentions a ridiculous form of ligature, which he received from a bramint at Indostan; "If (says he) the little worm in the wood Viktorara kara be cut into two, and the one part flies and the other not, if the string part be bruised, and given with half a beetle to a woman, and the other half to a woman, the charm will keep each from ever having to do with any other person." Phil. Trans. No. 268.

Ligature, in the Italian music, signifies a tying or binding together of notes. Hence syncoques are often called ligatures, because they are made by the ligature of many notes. There is another sort of ligatures for breves, when there are many of these on different lines, or on different spaces, to be sung to one syllable.

Ligatures, among printers, are types consisting of two letters or characters joined together; as A, O, S, F, S, &c. The editions of Greek authors are extremely full of ligatures; the ligatures of Stephens are by much the most beautiful. Some editions have been lately printed without any ligatures at all; and there was a design to explode them quite out of printing. Had this succeeded, the finest ancient editions would in time have grown useless: and the reading of old manuscripts would have been rendered almost impracticable to the learned themselves.

Light, in the most common acceptance of the word, signifies that invisible external matter which makes objects perceptible to our sense of seeing. Figuratively, it is also used for whatever conveys instruction to our minds, and likewise for that instruction itself.

The nature of light hath been a subject of speculation from the earliest ages of philosophy. Some of the first of those first distinguished by the appellation of philo-philosophers even doubted whether objects became visible by phers concerning means of any thing proceeding from them, or from the eye of the spectator. The fallacy of this notion must very soon have been apparent, because in that case, we ought to have seen as well in the night as in the day. The opinion was therefore qualified by Epicene, and Plato; who maintained, that vision was occasioned by particles continually flying off from the surfaces of bodies, which met with others proceeding from
LIG [38]

Light.

Light from the eye; but Pythagoras ascribed it solely to the particles proceeding from the external objects and entering the pupil of the eye.

Of Descartes.

Among the modern philosophers there have been two celebrated opinions, viz. the Cartesian and Newtonian. According to the former, light is an invisible fluid present at all times and in all places, but which requires to be set in motion by an ingenuously or otherwise properly qualified body in order to make the objects visible to us. The Newtonians maintain, that light is not a fluid per se, but consists of a vast number of exceedingly small particles shaken off in all directions from the luminous body with inconceivable velocity by a repulsive power, and which most probably never return again to the body from which they were emitted. These particles are also said to be emitted in right lines by the body from whence they proceed; and this rectilinear direction they preserve until they are turned out of their original path by the attraction of some other body near which they pass, and which is called interference; by falling through a medium of different density, which is called refraction, or by being thrown obliquely or indirectly forward by some body which opposes their passage, and which is called reflection; or, lastly, till they are totally stopped by the substance of any body into which they penetrate, and which is called their extinction. A succession of these particles following one another in an exactly straight line is called a ray of light; and this ray, in whatever manner it hath its direction changed, whether by refraction, reflection, or interference, always preserves its rectilinear course; neither is it possible by any art whatever to make it pass on in the segment of a circle, ellipse, or other curve.—From some observations on the eclipse of Jupiter's satellites, and also on the aberration of the fixed stars, it appears that the particles of light move at the rate of little less than 200,000 miles in a second of time. See Astronomy-Index.

Objections to the Newtonian doctrine.

To this doctrine concerning the nature of light several objections have been made; the most considerable of which is, That in this case, the rays of light are continually falling in different directions from every visible point, they must necessarily interfere with and destroy each other in such a manner as entirely to confound all distinct perception of objects, if not to destroy the sense of feeling altogether; not to mention the continual waste of substance which a constant emission of particles must occasion in the luminous body, and which since the creation ought to have greatly diminished the sun and stars, as well as increased the bulk of the earth and planets by the vast quantity of particles of light absorbed by them in such a long period of time.

In answer to this objection, Mr. Melville gives some ingenious illustrations concerning the extreme facility of light, or the smallness of the particles of which it consists, and of which few persons, even of those who admit the hypothesis, have any idea. He observes, that there is probably no physical point in the visible horizon that does not send rays to every other point, unless where opaque bodies interpose. Light, in its passage from one system to another, often passes thro' torrents of light issuing from other suns and systems, without ever interfering or being diverted in its course, either by it, or by the particles of that clastic medium which some phenomena give us reason to suppose are diffused through all the mundane space. To account for this fact and others similar to it, he concludes, that the particles of which light consists, must be incomparably rare, even when they are most dense; that is, that the semidiameters of the two nearest particles, in the same or in different beams, soon after their emission, are incomparably less than their distance from one another. This difficulty concerning the non-interference of the particles of light is not solved, as he observes, by supposing with Mr. Boscovich and others, that each particle is ended with an imperceptible impulsive force; because, in that case, their spheres of impulsion would even be more liable to interfere, and they would on that account be more likely to disturb one another.

The difficulty, according to Mr. Canton, will nearly vanish, if a very small portion of time be allowed between the emission of every particle and the next that follows in the same direction. Suppose, for instance, that one luminous point of the sun's surface emits 50 particles in a second, which are made to give constant light to the eye without the least appearance of intermission; yet still the particles of which it consists, will on account of their great velocity be more than 1000 miles behind each other, and thereby leave room enough for others to pass in all directions.

In order to determine whether light really consists of particles emitted from the luminous body, or only moves in the vibrations of a subtile fluid, it has been attempted to find out its momentum, or the force with which it moves. The first who said anything in this matter was M. Mairan. Others indeed, particularly Hallock and by Mr. Homberg, had pretended, that in certain cases this momentum was very perceptible; but M. Mairan proved, that the effects mentioned by them were owing to currents of heated air produced by the burning-glass used in their experiments, or to some other causes overlooked by these philosophers. To decide the matter therefore, it is possible, he began with trying the effects of rays collected by lenses of four and six inches diameter, and thrown upon the needle of a compass; but the report was nothing more than some tremulous motion from whence he could draw no conclusion. After this, he and Mr du Pay constructed a machine of paper, and moved with an exceedingly light impulse; but though they threw upon it the focus of a lens of seven or eight inches diameter, they were still unable to draw any conclusions from the result.

M. Mairan afterwards procured a horizontal wheel of iron three inches in diameter, having fix radii, at the extremity of each of which was a small wing fixed obliquely. The axis of the wheel which was also of iron was suspended by a magnet. The wheel and the axis together did not weigh more than 30 grains; but though a motion was given to this wheel when the focus of the burning glass was thrown upon the extremities of the radii, yet it was so irregular, that he could not but conclude that it was occasioned by the motion of the heated air. He then intended to have made his experiment in vacuo, but he concluded that it was unnecessary. For, besides the difficulty of making a vacuum, he was persuaded that there was in our atmosphere...
sphera a thinner medium which freely penetrates even glass itself, the existence of which he imagined that he had sufficiently proved in his transactions on the aurora borealis. See Annual Register, No. 8.

Mr. Michell some years ago endeavoured to ascertain the momentum of light in a manner still more accurate. The instrument he made use of for this purpose consisted of a very thin plate of copper, a little more than an inch square, which was fastened to one end of a slender harp-chord wire about ten inches long. To the middle of this was fixed an agate cap, such as is commonly used for small mariner's-compasses, after the manner of which it was intended to turn; and at the other end of the wire, was a middling fixed short corn, as a counterpoise to the copperplate. The instrument had also fixed to it in the middle, at right angles to the length of the wire, and in the horizontal direction, a small bit of a very slender sewing-needle, about one-third or perhaps half an inch long, which was made magnetic. In this state the whole instrument might weigh about 10 grains. It was placed on a very sharp-pointed needle on which the agate cap turned extremely freely; and to prevent its being disturbed by any motion of the air, it was enclosed in a box, the lid and front of which were of glass. This box was about 12 inches long, six or seven inches deep, and about as much in width; the needle standing upright in the middle. At the time of making the experiment, the box was placed in such a manner that a line drawn from the sun, passed at right angles to the length of it; and the instrument was brought to range in the same direction with the box, by means of the magnetic bit of needle above-mentioned, and a magnet properly placed on the outside, which would retain it, though with extremely little force, in any situation. The rays of the sun were now thrown upon the copperplate above-mentioned from a concave mirror of about two feet diameter, which, passing through the front-glass of the box, were collected into the focus of the mirror upon the copperplate. In consequence of this the plate began to move, with a flow motion of about an inch in a second of time, till it had moved through a space of about two inches and a half, when it struck against the back of the box. The mirror being removed, the instrument returned to its former situation by means of the little needle and magnet; and the rays of the sun being then again thrown upon it, it again began to move, and struck against the back of the box as before, and this was repeated three or four times with the same success. The instrument was then placed the contrary way in the box so that in which it had been placed before, so that the end to which the copperplate was affixed, and which had lain, in the former experiment, towards the right hand, now lay towards the left; and the rays of the sun being again thrown upon it, it began to move with a flow motion, and struck against the back of the box as before; and this was repeated once or twice with the same success. But by this time the copperplate began to be so much altered in its form, by the extreme heat which it underwent in each experiment, and which brought it nearly into a state of fusion, that it became very much bent, and the more so as it had been unwarily supported by the middle, half of it lying above and half below the wire to which it was fastened. By this means it now varied so much from the vertical position, that it began to lie in the same manner as the tail of a windmill, being impelled by the stream of heated air which moved upwards, with a force sufficient to drive it in opposition to the impulse of the rays of light.

"If we impute (says Dr. Priestley) the motion produced in the above experiment to the impulse of the rays of light, and suppose that the instrument weighed ten grains, and acquired a velocity of one inch in a second, we shall find that the quantity of matter contained in the rays falling upon the instrument in that time amounted to no more than one hundred-thousand-millionth part of a grain, the velocity of light exceeding the velocity of one inch in a second in the proportion of about 12,000,000,000 to 1. Now the light in the above experiment was collected from a surface of about three square feet, which reflecting only about half what falls upon it, the quantity of matter contained in the rays of the sun incident upon a square foot and an half of surface in one second of time, ought to be no more than the twelve-hundred-millionth part of a grain, or upon one square foot only, the eighteen-hundred-millionth part of a grain. But the density of the rays of light at the surface of the sun is greater than at the earth in the proportion of 45,000 to 1: there ought, therefore, to issue from one square foot of the sun's surface in one second of time, in order to supply the waste by light, one forty-thousandth part of a grain; that is, a little more than two grains in a day, or about 4,752,000 grains, or 670 pounds avoirdupois nearly, in 6000 years; a quantity which would have shortened the sun's semidiameter no more than about ten feet, if it was formed of the densest matter.

The Newtonians, besides the answer just now given to the most formidable objections of their opponents, against the hypothesis of light being a vibration in any fluid, Sir Isaac, in his Principia, demonstrates, that no rectilinear motion can be propagated among the particles of any fluid unless these particles lie in right lines; and he hath also shown, that all motion propagated through a fluid diverges from a rectilinear progress into the unmoved spaces. Hence he concludes, "a preface on a fluid medium (i.e. a motion propagated by such a medium beyond any obstacle, which impedes any part of its motion), cannot be propagated in right lines, but will be always inflected and diffusing itself every way, to the quiescent medium beyond that obstacle. The power of gravity tends downwards; but the preface of water rising from it tends every way with an equable force, and is propagated with equal ease, and equal strength, in curves, as in straight lines. Waves, on the surface of the water, gliding by the extremes of any very large obstacle, inflect and dilate themselves, still diffusing gradually, into the quiescent water beyond that obstacle. The waves, pulses, or vibrations of the air, wherein sound consists, are manifestly inflected, though not so considerably as the waves of water; and sounds are propagated with equal ease, through crooked tubes and through straight lines; but light was never known to move in any curve, nor to inflect itself in any way." To this Mr. Rowning adds another proof. "The By Mr. Cartesian notion of light (says he), was not that it Rowning is propagated from luminous bodies by the emission of small
small particles, and that it was communicated to the
small of light by their presence upon the materia sub-
stitute, with which they supposèd the universe to be filled.
But, according to this hypothesis, it could never be dark
because, when a fluid sustains any pressure, if that
fluid fills all the space it takes up, absolutely,
without leaving any pores, which is the case of the
supposed materia substitute, then that pressure must ne-
cessarily be communicated equally and instantaneously
to every part. And therefore, whether the fun were
above or below the horizon, the pressure communicat-
ed, and consequently the light, would be the same.
And farther, as the pressure would be instantaneous, so
would the light, which is contrary to what is collected
from the eclipses of Jupiter's satellites."

It is obvious, however, that whatever side we take
concerning the nature of light, many, indeed almost
all the circumstances concerning it, are incomprehensi-
ble, and beyond the reach of human understanding.

Most of the dicky flowers, by some power unknown
to us, follow the fun in its course. They extend
him to his evening retreat, and meet his rising luftre in
the morning with the fame unerring law. If a plant alfo
be by produced the inflammation itself, independent of ignition.

Dr Priestley concerning the production of pure de-
phlogisticated air from pum- water, by means of the
air light. If light either were the phlogiston itself,
or contained in its very considerable quantity, it
imposible the air produced by its means could be pure and
dephlogisticated.—For the properties of light act-
ing as the medium of our perceptions by the fene of
light, fee the article Optics.

In the Philosophical Transactions for 1776, Dr
For- dycy gives an account of some experiments up-
upon the light produced by Inflammation. They were made
to determine, whether there was any light produced by
the inflammation itself, independent of ignition.

Substan-
ces, he observes, begin to be luminous in the dark
when heated to between 6 and 700 degrees of Fahren-
heit's thermometer. If the substances be colourless,
they first emit a red light; then a red mixed with
yellow; and lastly, with a great degree of heat, a pure
white. This whiteness, however, seems to depend
greatly upon the density of the body; for the vapour
at the end of the flame urged by a blow-pipe is not
visibly luminous, though its heat be sufficiently great to
give a white heat to glass. The colour of the ignited
matter, according to our author, has an effect upon
the colour of the light emitted. Thus, during the
calcination of zinc, the calc of which is white, a light
is produced scarce inferior in beauty to that of the fun
himself. A beautiful green is communicated by the
green calx of copper to the flame of a fire into which
it is thrown; and the yellow eempaneous oil into
which tallow or any common oil is converted in burning,
communicates a part of its own colour to the flame.
which very much alters the appearance of bodies seen
by candle-light from what it is by day-light. It does
not, however, appear that this always holds good; for
the flame of burning iron is intensely white; and yet
neither the metal itself nor any of its calces are of
that colour.

Light produced by the decomposition of bodies by
inflammation without ignition is always blue, and
produced in some cases very little heat. Thus phosphorus of urine is de-
composed by mere exposure to the air, and gives but
very little heat, though a considerable light is emitted.
The following proof is adduced by our author that this
emission of light is a true inflammation. "Take a re-
cipient of white glasses, capable of holding six or eight
gallons; put into it a drachm of phosphorus finely
powdered, and half an ounce of water; cork the mouth
of the recipient, and tie it over with a bladder, so as
to exclude the external air; incline the receiver to all
sides gently, and afterwards set it to rest; the powder
will adhere to the sides, and the water will drain from
it. As soon as the water is sufficiently drained off,
the particles of the phosphorus will become luminous,
and emit a thick smoke: this will continue for some
days; but at last no more light or vapour will appear.
Open the receiver, and you will find that the air will
have contracted, as it does from the inflammation of a
candle in Van Helmont's experiment; that is, about a
twentieth part. It is become unfit for inflammation;
for if a lighted candle be immerced in it, it will be ex-
tinguished as well as the phosphorus, and an animal will
be suffocated by it. The air then has suffered the same
change as that which has served for the inflammation of
other bodies; and the phosphorus is partly decomposed,
the water in the receiver being impregnated with its
acid, and the air saturated with its phlogiston. Blow
fresh air into the receiver, and the light and smoke will
immediately re-appear. In like manner it is known that
sulphur will burn and give light without heat sufficient
for ignition. Take a piece of iron heated nearly red
hot, and throw a little gunpowder upon it. If the
heat be of a proper degree, the sulphur will burn off
with a blue flame, without heat sufficient for ignition;
for if such heat had been produced, the gun-powder
would certainly have taken fire. It is the inflammation
and decomposition of the sulphur, and not its evapo-
ration, which produces the light; for if we sublime sul-
phur in vessels of the most transparent glasses, no light
will be visible except at the very beginning, when a
small portion of it burns till the air in the vessel be
saturated, and rendered unfit for inflammation."

Our author is of opinion, that the light produced by
inflammation is of a blue colour, from whatever body it
is derived. This he endeavours to prove from an ob-
observation sappo-
theory and the colour of the flame, the lower part of which, where the inflammation is, always appears of
always blue.
Observe that the flame be large, is scarcely red-hot; as the flame burns, the point which is in the centre will be heated white hot, whereas, if the flame be large, the point which is in the centre will be fully and a blue colour. Or (says he) take a candle which has burned for sometime; extinguish it by applying tallow to the wick, and let it stand to cool; afterwards put it on fire by the flame of another candle; at first no more vapour will arise than can be acted upon by the air at once; inflammation, therefore, will go on in the whole small flame, and it will be blue. When a candle burns, the following may be observed. That the tallow boils in the wick; and is converted into empyreumatic oil, rising from it in the form of vapour. As it rises from every part of the wick, the volume is increased till it comes to the top, and gives to the lower part of the flame the form of the frustum of an inverted cone. The air is applied to the outer surface of the column of vapour; and there decomposing the empyreumatic oil, produces heat and blue light; the frustum of vapour, within the outer burning surface, is heated white-hot; the heat diminishes towards the centre, which, if the flame be large, is farceely red-hot; as the column rises, decomposition taking place constantly on its surface, it necessarily diminishes, and the upper part of the flame is conical. That the tallow boils in the wick, or decomposes, is that it is converted into empyreumatic oil, is proved by drawing the vapour, rising in the middle of the flame, where it does not burn, into a glass-tube: the empyreumatic oil condenfes; this also shows that the flame does not burn in the middle. That the heat is produced on the outer surface, appears, if we take a small rod of glass, and put the end of it in the blue flame on the surface; it will be heated white hot, and melt. Immerse the rod into the flame, so that the point shall be in the centre; it will melt and bend where it is in the blue flame on the surface; whereas, if the flame be large, the point which is in the centre will hardly be heated red-hot. That the empyreumatic oil is decomposed, is proved by burning a candle with a very small wick in distilling vessels; no condensation of empyreumatic oil takes place.

In the 75th volume of the Transactions, Mr. Morgan treats of light of some length. As a foundation for his reasoning he alludes the following data. 1. That light is a body, and, like all others, subject to the laws of attrac- tion. 2. That light is an inhomogeneous body; and that the flame attractive power operates with different degrees of force on its different parts. 2. That the light which escapes from combustibles when decomposed by heat, or by any other means, was, previous to its escape, a component part of these substances. Hence he concludes, that when the attractive force by which the several rays are attached to a body is weakened, some of those rays will escape sooner than others; it being evident that those which are detained by the smallest power will sooner go off when the general attractive force is weakened. This he illustrates by the example of a mixture of spirit of wine, water, and other more fixed substances. The application of a gentle heat will carry off the spirit of wine only; a heat not much greater will evaporate the spirits and water mixed together; and a still greater degree will carry off a mixture of all the particles together. "In like manner (says he), when the surface of a combustible is in a state of decomposition, those parts of the flame, which are the least fixed, or that empyreumatic oil, will be separated first. Amongst these the indigo rays of light will make the earliest appearance. By increasing the heat, we shall mix the violet with the indigo; by increasing it still more, we shall add the blue and the green to the mixture, till at length we reach that intensity of heat which will cause all the rays to escape from the flame instant, and make the flame of a combustible perfectly white. By examining the flame of a common candle, we may observe, that its boundaries are not in the same place in which the black colour of the wick terminates, discharges the least heat; flame of a candle, and that, as the vertex of the flame is approached, a succession of orders of parts is passed through, in which the lower is continually adding to the heat of that which is just above it, till we come to the top of the flame, near which all the heat is collected into a focus. At the lowest extremity, however, where the heat is inconsiderable, a blue colour may always be observed; and from this appearance, amongst others, I think it may be concluded, that the blue rays are some of those which escape from combustibles in an early period of their decomposition; and that if the decomposition could be examined in a period still more early, the colour of the flame would be violet. By an a priori deduction of this kind, I was led to the belief, that the indigo, the blue, and the violet rays are all decomposed in the atmosphere of the flame of a common candle is annexed a filament of light; which if proper care be taken to prevent the escape of too much smoke, will appear most beautifully coloured with the violet and indigo rays. If sulphur or other be burned, or any other combustible whose vapour is kindled in a small degree of heat, a blue flame will appear, which, if examined by the prism, will be found to consist of the violet, the indigo, the blue, and sometimes a small quantity of the green rays. The belief, however, of showing the escape of some rays by that degree of heat which will not separate others till increased, is the following. Give a piece of brown paper a spherical form, by pressing it upon any hard globular substance. Gradually bring the paper thus formed to that distance from the candle at which it will begin to take fire. In this case a beautiful blue flame may be seen hanging, as it were, by the paper till a hole is made in it; when the flame, owing to the increased action of the air upon all parts of it, becomes white, though the edges still continue of a blue or violet colour. As a confirmation of this, it may be observed, that the very flame, which when exposed to a certain degree of heat emits only the most refrangible rays, will, if exposed to one considerably greater, emit also those which are left to. The flames of sulphur and spirit of wine, if suddenly exposed to the heat of a reverberatory, will change their blue colour for one that is perfectly white."

To obtain a more perfect knowledge of this matter, our author examined the light proceeding from combustible bodies by Mr. Melville's method. Having darkened the room, he introduced between the eye and combustible a sheet of pasteboard, in which was a very small hole for transmitting the light. Viewing the light which passed through this hole with a prism, he observed, that the blue and violet rays were in greater abundance than any of the rest, though all the different kinds passed through it when spirit of wine only was used. Of when the combustion of the spirit was made exterior in that part in which the black colour disappeared, but made their appearance again as soon as the salt became heated to such a degree as to increase
increase rather than diminish the combustion of the spirits. On examining the different parts of the flame separately, it was always found that the colours varied according to the degree of heat. At the base of the flame, or where the heat was least, the indigo, violet, and blue always appeared in greatest quantity; but as the vertex was approached, the other rays appeared, and at the very top they were all visible through a prism.

From these facts Mr Morgan concludes, 1. That light, as an heterogeneous body, is gradually decomposed during combustion; that the indigo rays escape with the least heat, and the red with the greatest; and from this again he explains the reason why flames assume different colours. "If a piece of paper (says he), impregnated with a solution of copper in nitrous acid, be set on fire, the bottom and sides of the flame are always tinged green. Now this flame is evidently in that weak state of decomposition in which the most refrangible rays escape in the greatest abundance; but of these the green rays escape most plentifully through the unignited vapour and that portion of the atmosphere which is intercepted between the eye and the flame. This peculiarity may be observed in greatest perfection in brass foundries. Here the heat, though very strong, is scarcely sufficient to decompose the metallic vapour which escapes from the melted brass; whence the flame has a very singular appearance, the edges being green, and the body of such an appearance, as to give substances viewed by it a pallid and ghastly appearance, owing to the want of a sufficient quantity of red rays to make a perfect white."

2. Mr Morgan explains the red appearance of bodies in their last state of ignition, from the previous escape of the more refrangible rays, so that only the red ones remain. "Again (says he), we may consider the external surface of the combustible body as annexed to an inner surface, which may be partly, but not perfectly decomposed as itself; for the violence of the heat will be found to leasen in its effects the nearer it approaches to the centre of the substance which is exposed to it. Hence we are to consider the parts which are just covered by the external surface as having lost less of their component light than the external surface itself; or the former may retain the green rays when the latter has lost both indigo, violet, blue, and green.

3. "Those parts which are nearer to the centre of the body than any of the preceding must, as they are farther from the greatest violence of the heat, have lost proportionally fewer of their rays; or while the external parts may have lost all but the red, these may have lost only the indigo and violet.

4. "The most central parts may be unaffected by the heat; and whenever the fire does reach these parts, they will immediately discharge their indigo rays, and be decomposed in the gradual manner already mentioned. A piece of rotten wood, while burning, will exemplify and confirm the preceding illustration. When influenced by the external air only, if examined through a prism, no rays will be found to escape but the orange and the red. By blowing upon the burning wood with a pair of bellows, the combustion being increased, will affect those internal parts of the body which were not acted upon before. These parts therefore will begin to lose their light, and a prism will show the green, blue, violet, and indigo, all appearing in succession. Appearances similar to the preceding may be observed in a common kitchen fire. When it is faintest, its colour is most red, the other rays having been emitted, and the combustion at a stand; but by blowing upon it in this state, its brightness will be increased, and more and more of the rays which are yielded by the internal parts of the body will come to the eye, till at length, by continuing to blow, the combustion will be made complete as to yield all the rays, or to make it appear perfectly white."

Our author concludes the subject with a criticism upon Sir Isaac Newton's definition of flame, viz. that it is a vapour heated red hot. In his opinion, flame is an influence of combustion whose whole colour will be determined by the degree of decomposition which takes place. When very imperfect, only the most refrangible rays will appear. If it be very perfect, all the rays will appear, and its flame will be brilliant in proportion. But there are flames which consist of burning particles, the rays of which have partly escaped before they ascended in form of vapour. "Such (says he) would be the flame of a red coal, if exposed to a heat as would gradually convert it into vapour. When here is very low under the furnace of an iron foundry, at the upper orifice of the chimney a red flame of this kind may be seen, which is different from the flame that appears immediately after fresh coals have been thrown upon the fire; for in consequence of adding such a supply to the burning fuel, a vast column of smoke ascends, and forms a medium so thick as to absorb most of the rays excepting the red."

Thus we have a most elaborate theory for the solving of phenomena which seem not easily to admit of gain's theories any solution. It is obvious, however, that the data upon which he builds his system are altogether unfounded and hypothetical. That light is subject to the laws of attraction, cannot be proved unless we could examine it independent of any other substance whatever; that is to say, in a perfect vacuum; and even in the most perfect vacuum that can be formed, we are far from being certain that no other matter is present. Light is inflected and turned out of its course in many different ways when acting in the common atmosphere, but we have no reason to suppose that it would be the flame in a perfect vacuum; at least we have not a right to lay it down as a principle to argue from, unless it were verified by experience. Even the heterogeneous nature of light seems far from being absolutely established. The refraction into different colours by the prism seems insufficient to do so; for, though, by a quick revolution of these colours when painted upon any substance, we may produce a kind of white colour, it is by no means perfect, but looks as if some black had got amongst it. The opinion of those who maintain that the prismatic colours are no other than different mixtures of light and shade, seems therefore equally probable with the other. His third position, that the light emitted by combustible bodies formed part of their substance before combustion, seems still worse founded; for instead of being fixed in solid substances, all the light and proceeding from combustion seem entirely to come from the air. By means of heat originally applied, the substance, or part of it, is rarified into vapour; and this vapour, we have every reason to suppose, consists of elementary fire united with the solid substance. It is this fire, heat, or light, which..."
is afterwards thrown out from the vapour in combustion; and new fapphires of it perpetually come from the atmosphere, as is abundantly shown under the articles 

COMBUSTION, FIRE, FLAME, and many others throughout this work. We cannot therefore think it either inconstant, or very improbable, that in the beginning of combustion, when the white light is clouded with a great quantity of vapour, it should appear of a blue or violet colour; and that in proportion as this vapour is dissipated, it should appear green, yellow, red, or perfectly white. For it is observable, that in dephalogliculated air, even those flames which in the common atmosphere always appear blue, such as sulphur and spirit of wine, are then changed to a dazzling white. The pure light of the sun also seen through smoke, or even through a great quantity of aqueous vapour, appears red; and there is not the least doubt, that if we were to view the sun while he thus appears red through any blue medium, he would appear purple; and in like manner, were we to view a blue flame through a yellow medium, it would appear of a green colour.

In the same paper Mr Morgan has some curious observations upon the electric light. There is neither fire nor light from which the electric fluid in its passage will not appear luminous, if we do not make the quantity, through which it has to pass, too great. In his experiments on fluids, he puts them into a tube about three quarters of an inch diameter and four inches long. The orifices are then stopped up with two corks, through which two pointed wires are thrust, so that the points may approach within one eighth part of an inch of each other; and in this case the electric matter which passes through the fluid is always luminous, provided a sufficient force be used. The experiment, however, is dangerous, unless great care be taken; and the tube, unless it be very strong, will be broken by a very slight discharge. With acids the experiment succeeds more difficulty; they must be put into capillary tubes, and the wires placed very near to each other. A strip of gold leaf one eighth of an inch diameter, and a yard long, becomes quite luminous by discharging a battery over it; and our author cannot ascertain the length to which it might be made luminous. The experiment will also succeed with Dutch metal or silver leaf. If the gold or silver leaf be put upon a glass, and that laid in water, the whole will appear most beautifully luminous on discharging a battery through it.

The better a conductor that any substance is, the greater is the difficulty of making the electric spark visible in it. Hence it requires a much greater power of electricity to make a spark visible in boiling than in cold water; the former being a much better conductor than the latter. In like manner, the mineral acids are much better conductors than common water; and, of consequence, the spark is made to appear in them with much more difficulty than in water. This appears from what has been already mentioned; and our author likewise observes, that if a few drops of acid be poured into the tube containing the water employed for this purpose, it will faintly be possible to make the spark luminous in it by any force.

The rarity of any body greatly increases the case with which the electric spark is made visible in it; as appears from discharging a vial through rarefied air, the vapour of ether, spirit of wine, or water.

In the prosecution of his experiments upon this subject, our author cemented a ball of iron into the oriace of a tube 43 inches long, and two thirds of an inch diameter, so that it could bear the weight of the quicksilver with which the tube was filled all to a small space at the open end, which contained a few drops of water. Having inverted the tube, and plunged the open end of it into a basin of mercury, that in the tube a good nearly level with a barometer with which it was compared at the same time, owing to the vapour which was formed by the water; but the spark passed as brilliant through the rarefied water as it does through rarefied air. If spirit of wine be employed instead of water in this experiment, the spark will not be luminous. In the vapour of ether a great force is requisite to make the spark luminous, but good ether will pref the mercury down as far as 16 or 17 inches. By rarefying the vapour, however, the spark will pass through it with more ease.

On examining the mineral acids in vacuo, Mr Morgan could not find that any vapour escaped from them. To give them the requisite degree of rarity, therefore, he traced a line upon glass about an eighth part of an inch broad, with a camel's hair pencil dipped in the acids: the line extended sometimes to the length of 27 inches; in which case, the electric spark would pass over the whole with great brilliancy. If by widening the line, however, or putting on a drop of acid in any particular part, the quantity was increased, the spark never appeared in that part.

The brightness of electric light is always in proportion to its condensation. Thus, if a spark taken bright from a powerful electrical machine divides itself into electric brushes, or throws out sparks from the sides, by which the light is diffused over a larger surface, it thus becomes less brilliant; and in all cases in which any diffusion of light, whether electric or not, takes place, the case will be the same.

In some cases, Mr Morgan is of opinion, that, even sometimes with the electric fluid, only the more refrangible rays the more of light make their escape. Thus, the electrical brush is always of a purplish or bluish colour; and if you convey a spark through a Torricellian vacuum not very perfectly made, it will be of an indigo colour. This, however, does not seem to arise from any other cause than the mere weakness of the light, which, in passing through the vapours of the atmosphere, or perhaps through the humours of the eye itself, affects our organs of light in that manner.

Our author next proceeds to examine the influence of the media upon electric light; which, he says, is similar to their influence upon solar light, and serves to explain several phenomena.

"Let a pointed wire (says he), having a metallic ball fixed to one of its extremities, be forced obliquely into a piece of wood, so as to make a small angle with its surface; and to make the point lie about one eighth of an inch below it. Let another pointed wire, which communicates with the ground, be forced in the same manner into the same wood, so that its point may in like manner be about one eighth of an inch below the surface, and about two inches distant from the point of
Light. [44]

32 Curious experiment of sending the electric spark through wood.

Light.

33 Different appearance of the electric spark at different distances.

On phosphoric light Mr Morgan makes some curious observations; but still argues on the same principles we have already mentioned. "Some shells (says he) prepared according to Mr Wilson’s directions, after being exposed to the sun, or to the flash of a battery, emit a purple, others a green, and others a reddish light. Light."

If, with Mr Wilson, we suppose that these shells are in a state of flow combustion, may we not conclude, that some are just beginning to burn, and therefore emitting the most refrangible rays; while others are in a more advanced state of combustion, and therefore emitting the least refrangible? If this conclusion be right, the shells which are emitting the purple or the green, must still retain the yellow, the orange, and the red, which will also make their appearance as soon as the combustion is sufficiently increased. In confirmation of this, Mr Morgan adds the following experiment, viz. that if a shell, while emitting its green rays, be placed upon a warm flavel, the colour will soon be changed into a yellow mixed with red.—To the theory of flow combustion Mr Morgan makes the following objections.

1. If phosphoric shells owe their light to this cause, we must consider the word combustion, when applied to them, as implying all those circumstances which usually attend a body when on fire. On this supposition there ought to be an increase of the heat as well as of the decomposition of the combustible. But neither of these are found to take place in fact; for a phosphoric body never fails to lose its light entirely in a certain degree of heat, without losing the power of becoming phosphoric again when it has been sufficiently cooled. While very hot, the charge of the strongest battery conveyed over it has no effect.

2. When bodies are wasted by combustion, they can never be made to resume the appearances which they previously displayed. "No power (says our author) can give to ashes the phenomena of a burning coal. But phosphoric bodies are very different in this respect; a phosphoric shell may be made to lose all its light by exposure to heat, and again may be made as luminous as ever by exposure to the sun."

3. It is remarkable that some bodies which are most beautifully phosphoric, are at the same time the most obtinate in refusing fire. "Let us now see (says Mr Morgan) the consequence of admitting the common hypothesis, that the detention of those rays which fall upon phosphoric is owing to some force which prevents their immediate reflection, but is not adequate to their entire absorption. This force, whatever it be, cannot well be supposed to operate with equal power on all these rays. If this be not the case, we cannot well avoid concluding, that phosphoric shells will assume different colours, owing to the earlier and later escape of the different rays of light. This conclusion is justified by an experiment already mentioned; viz. that when the force is such as to admit the escape of the purple, blue, and green, we have only to lessen that force, by warming the body, and the yellow, the orange, and red escape. Bessarica has proved, that there is scarcely any body which is not phosphoric, or may not become so by heat. But as the phosphoric force is most powerful when the purple rays only escape, so we are to conclude, that it is we left when it is able to retain the red rays only. This is agreeable to several facts. Chalk,
bodies whose goodness has been very much impaired by long keeping, when finely powdered, and placed within the circuit of an electrical battery, will exhibit, by their scattered particles, a shower of light; but these particles will appear reddish, or their phosphoric power will be sufficient only to detain the yellow, orange, and red rays. When spirit of wine is in a similar manner brought within the circuit of a battery, a similar effect may be discovered: its particles diverge in several directions, displaying a most beautiful golden appearance. The metallic dyes are rendered phosphoric with the greatest difficulty; but even these may be scattered into a shower of red luminous particles by the electric stroke."

In a postscript to this paper, by Dr Price, it is observed, that by phosphoric force, Mr Morgan seems to mean, not the force with which a phosphoric body emits, but that with which it absorbs and retains, the light. This last force is proportioned to the degree of attraction between the phosphoric body and light; and therefore must, according to Mr Morgan's theory, be weakest when it so freely emits the light it has imbibed as not to retain those rays which adhere to it most strongly. According to Mr Morgan's theory, those are the rays which are the least refrangible. "It is, however, (says Dr Price), an objection to it, that the least refrangibility of rays seems to imply a least force of attraction between them and the substances which refract them; but it should be considered, that, possibly, the force of cohesion, which unites the rays of light to bodies, may be a different power from that which refracts them.

Light independent of Heat. In general, a very considerable degree of heat is requisite to the emission of light from any body; but there are several exceptions to this, especially in light proceeding from putrefacient substances and phosphorus, together with that of luminous animals, and other similar appearances. Light proceeding from putrefacient animal and vegetable substances, as well as from glow-worms, is mentioned by Aristotle. Thomas Bartholin mentions four kinds of luminous insects, two with wings, and two without; but in hot climates travellers say they are found in much greater numbers, and of different species. Culex, an industrious naturalist, observes, that their light is not extinguished immediately upon the death of the animal.

The first distinct account that we meet with of light proceeding from putrefacient animal flesh is that which is given by Fabricius ab Aquapendente, who says, that when three Roman youths, residing at Padua, had bought a lamb, and had eaten part of it on Easter day 1662, several pieces of the remainder, which they kept till the day following, shone like so many candles when they were casually viewed in the dark. Part of this luminous flesh was immediately sent to Aquapendente, who was professor of anatomy in that city. He observed that both the lean and the fat of this meat shone with a whitish kind of light; and also took notice that some pieces of kid's flesh, which had happened to have lain in contact with it, was luminous, as well as the fingers and other parts of the bodies of those persons who touched it. Those parts, he observed, shone the mott which were most to the touch, and seemed to be transparent in candle light; but where the flesh was thick and solid, or where a bone was near the outside, it did not shine.

After this appearance, we find no account of any other similar to it, before that which was observed by Bartholin, and of which he gives a very pompous description in his ingenious treatise already quoted. This happened at Montpelier in 1647, when a poor old woman had bought a piece of flesh in the market, intending to make use of it the day following. But happening not to be able to keep well that night, and her bed and pantry being in the same room, the object continued to emit much light even after the flesh, as it were, illuminated all the place where it hung. A part of this luminous flesh was carried as a curiosity to Henry Bourbon, duke of Condé, the governor of the place who viewed it for several hours with the greatest astonishment.

This light was observed to be whitish; and not to cover the whole surface of the flesh, but certain parts only, as if gems of unequal splendor had been scattered over it. This flesh was kept till it began to putrify, when the light vanished; which, as some religious people fancied, it did in the form of a cross.

It is natural to expect, that the almost universal ex-post, by the experimental philosopher Mr Boyle should try the effect of his air-pump upon these luminous substances. As p. 166, according as we find that he did not fail to do it; when he presently found that the light of rotten wood was extinguished in vacuo, and revived again on the admission of the air, even after a long continuance in vacuo; but the extinguishing of this light was not so complete immediately upon exhausting the receiver, as some little time afterwards. He could not perceive, however, that the light of rotten wood was increased in condensed air; but this, he imagined, might arise from his not being able to judge very well of the degree of light, through so thick and cloudy a glass as the then made use of; but we find that the ill. 254.

Birch's light, was rendered more vivid by this means. The principal of Mr Boyle's experiments were made in October 1667.

This philosopher attended to a great variety of circumstances relating to this curious phenomenon. Among other things he observed, that change of air was not necessary to the maintenance of this light; for it continued a long time when a piece of the wood was put into a very small glass hermetically sealed, and it made no difference when this tube which contained the wood was put into an exhausted receiver. This he also observed with respect to a luminous fish, which he put into water, and placed in the same circumstances. He also found, that the light of shining fishes had other properties in common with that of shining wood, but the latter, he says, was presently quenched with water, spirit of wine, a great variety of saline mixtures, and other fluids. Water, however, did not quench all the light of some shining veal on which he tried it, though spirit of wine destroyed its virtue presently.

Mr Boyle's observation of light proceeding from fish-meat was quite casual. On the 15th of February 1662, one of his servants was greatly alarmed with the shining of some veal, which had been kept a few days, but had no bad smell, and was in a place very proper for it. The servant immediately made his master acquainted with this extraordinary appearance.
Light...and though he was then in bed, he ordered it to be immediately brought to him, and he examined it with the greatest attention. Suspecting that the state of the atmosphere had some share in the production of this phenomenon, he takes notice, after describing the appearance, that the wind was south-west and blustering, the air hot for the season, the moon was past its last quarter, and the mercury in the barometer was at 29.7 inches.

Mr. Boyle was often apprised in his experiments on shining fishes; finding that they did not always shine in the very same circumstances, as far as he could judge, with others which had shined before. At one time that they failed to shine, according to his expectations, he observed that the weather was variable, and not without some days of frost and snow. In general he made use of whittings, finding them the fittest for his purpose. In a discourse, however, upon this subject at the Royal Society in 1681, it was ascertained, that, of all fishes, the sturgeon, the eggs of lobsters, after they had been boiled, shone the brightest.

Olig. Jacobus observes, that upon opening a sea-polypus, it was fo luminous, as to dazzle several persons who saw it; and he says, that the more putrid the fish was, the more luminous it grew. The tails also, and the fingers of the persons who touched it, became luminous; and the black liquor which flowed from the animal, and which is its bile, shone, but with a very faint light.

Mr. Boyle draws a minute comparison between the light of burning coals and that of burning wood or fish, flowing in what particulars they agree, and in what they differ. Among other things he observes, that extreme cold extinguishes the light of burning wood, as appeared when a piece of it was put into a glass tube, and held in a frigoric mixture. He also found that rotten wood did not waft itself by shining, and that the application of a thermometer to it did not discover the least degree of heat.

There is a remarkable shell-fish, called Pholas, which forms for itself holes in various kinds of stone, &c. That this fish is luminous, was noticed by Pliny; who observes, that it shines in the mouth of the person who eats it, and, if it touch his hands or clothes, makes them luminous. He also says, that the light depends upon its moisture. The light of this fish has furnished matter for various observations and experiments to M. Reaumur, and the Bolognian academicians, especially Beccarius, who took so much pains with the subject of phosphoreal light.

M. Reaumur observes, that, whereas other fishes give light when they tend to purereluce, this is more luminous in proportion to its being fresh; that when they are dried, their light will revive if they be moistened either with fresh or salt water, but that brandy immediately extinguishes it. He endeavoured to make this light permanent, but none of his schemes succeeded. The attention of the Bolognian academicians was engaged to this subject by M. F. Marilius, in 1724, who brought a number of these fishes, and the stones in which they were inclosed, to Bologna, on purpose for their examination.

Pholas observed, that though this fish ceased to shine when it became putrid; yet that in its most putrid state, it would shine, and make the water in which it was immersed luminous, when they were agitated. Galenius and Montius found, that wine or vinegar extinguished this light; and that in common oil it continued some days; but in rectified spirit of wine or urine, hardly a minute.

In order to observe in what manner this light was affected by different degrees of heat, they made use of a Reaumur's thermometer, and found that water made luminous by these fishes increased in light till the heat arrived to 45 degrees; but that it then became suddenly extinct, and could not be revived.

In the experiments of Beccarius, a solution of vitriol nearly extinguished it, and the acids entirely. This water poured upon fresh calcined gypsum, rock crystal, cerus, or sugar, became more luminous. He also tried the effects of it when tried upon various other substances, but there was nothing very remarkable in them. Afterward们 taking luminous milk, he found that oil of vitriol extinguished the light, but that oil of tartar increased it.

This gentleman had the curiosity to try how differently coloured substanices were affected by this kind of light; and having, for this purpose, dipped several ribbons in it, the white came out the brightest, next to this was the yellow, and then the green; the other colours could hardly be perceived. It was not, however, any particular colour, but only light that was perceived in this case. He then dipped boards painted with the different colours, and also glasses tubes, filled with substanices of different colours, in water rendered luminous by the fishes. In both these cases the red was hardly visible, the yellow was the brightest, and the violet the dullest. But on the boards the blue was nearly equal to the yellow, and the green the more languid; whereas in the glasses, the blue was inferior to the green.

Of all the liquors into which he put the pholas, milk was rendered the most luminous. A single pholas made seven ounces of milk more luminous, that the faces of persons might be distinguished by it, and it looked as if it was transparent.

Air appeared to be necessary to this light; for when Beccarius put the luminous milk into glass tubes, no agitation would make it shine unless bubbles of air were mixed with it. Also Montius and Galenius found, that in an exhausted receiver, the pholas lost its light, but the water was sometimes made more luminous, which they ascribed to the rising of bubbles of air through it.

Beccarius, as well as Reaumur, had many schemes to render the light of these pholas permanent. For this purpose he kneaded the juice into a kind of paste, with flour, and found that it would give light when it was immersed in warm water, but it anwered best to preserve the fish in honey. In any other method of preservation, the property of becoming luminous would not continue longer than a few months, but in honey it lasted above a year; and then it would change in warm water, give as much light as even it had done.

Similar, in some respects, to those observations on the light of the pholas, was that which was observed p. 483...
Light: 

to proceed from wood which was moist, but not in a

puri’d state, which was very conspicuous in the dark.

That the fish is sometimes luminous, especially when

it is put in motion by the dashing of oars or the

beating of it against a ship, has been observed with

admiration by a great number of persons. Mr Boyle,

after reciting all the circumstances of this appearance,

as far as he could collect them from the accounts of

navigators; as its being extended as far as the eye

could reach, and at other times being visible only when

the water was dashed against some other body; that,
in some seas, this phenomenon is accompanied by some

particular winds, but not in others; and that sometime

times one part of the sea will be luminous, when an­­

other part, not far from it, will not be so; concludes

with saying, that he could not help suspecting that

these odd phenomena, belonging to great masses of

water, were in some measure owing to some coni­­

cional law or custom of the terrestrial globe, or at least

of the planetary vortex.

Some curious observations on the shining of some

fishes, and the pickle in which they were im­­

merced, were made by Dr Beal, in May 1665; and had they

been properly attended to and pursued, might have led to

the discovery of the cause of this appearance.

Having some boiled mackerel into water, together

with salt and sweet herbs; when the cook was, some­­

times after, stirring it in order to take out some of the

drops, which were

he observed, that, at the first motion, the water

was luminous; and that the day shining the

water added much to the light which the water

yielded. The water was of itself thick and blackish;

rather than of any other colour; and yet it shined on

being stirred, and at the same time the fishes appeared

more luminous than the water. Wherever the drops of

this water, after it had been stirred, fell to the

ground, they shined; and the children in the family

diverted themselves with taking the drops, which were

as broad as a penny, and running with them about the

house. The cook observed, that when he turned up

that side of the fish that was lowest, no light came from it;

and that, when the water had settled for some time

after it, that the day shining the

water gave but little light, and only after a brisk agi­­
tation, though the fishes continued to shine as well

from the inside as the outside, and especially about the

throat, and such places as seemed to have been a lit­­
tle broken in the boiling.

When, in the light of the sun, he examined, with a

microscope, a small piece of a fish which had shined very

much the night before, he found nothing remarkable

on its surface, except that he thought he perceived

what he calls a steam, rather dark than luminous, arising

like a very small dust from the fish, and here and there

a very small and almost imperceptible sparkcle. Of the

sparkles he had no doubt; but he thought it possible

that the steam might be a deception of the light, or

some dust in the air.

Finding the fish to be quite dry, he moistened it

with his spitule; and then observed that it gave a little

light, though but for a short time. The fish at that

time was not fetid, nor yet insipid to the best discern­­
ing palate. Two of the fishes he kept two or three
days longer for farther trial; but, the weather being

very hot, they became fetid; and, contrary to his ex­­
pctations, there was no more light produced either

by the agitation of the water or in the fish.

Father Bourzes, in his voyage to the Indies in

1704, took particular notice of the luminous appear­­

ance of the sea. He reports that he could easily read the title of a book by it,

though he was nine or ten feet from the surface of

the water. Sometimes he could easily distinguish, in

the wake of the ship, the particles that were luminous from

those that were not; and they appeared not to be all

of the same figure. Some of them were like points of

light; and others such as stars appear to the naked eye.

Sometimes they seemed globes, of a line or two in
diameter; and others as big as one’s head. Sometimes

they formed themselves into figures of three or four

inches long, and one or two broad. Sometimes all

these different figures were visible at the same time;

and sometimes there were what he calls vortexes of

light, which at one particular time appeared and dis­­
appeared immediately like flashes of lightning.

Nor did only the wake of the ship produce this

light, but fishes also in swimming, left so luminous a

track behind them, that both their size and species

might be distinguished by it. When he took some

of the water out of the sea, and stirred it ever so little

with his hand, in the dark, he always saw in it an

infinite number of bright particles; and he had the same

appearance whenever he dipped a piece of linen in the

sea, and wrung it in a dark place, even though it was

half dry; and he observed, that when the sparks tell

upon any thing that was solid, it would continue shin­­
ing for some hours together.

After mentioning several circumstances which did

not contribute to this appearance, this father ob­­
rerves, that it depends very much upon the qua­­

tity of the water; and he was very sure that this light is the greatest

when the water is fat and full of foam. For in the

main sea, he says, the water is not everywhere equally pure; and that sometimes, if linen be dipped in the sea, it is clammy when it is drawn up again; and he often observed, that when the wake of the ship was

the brightest, the water was most fat and glutinous, and that linen moistened

with produced a great deal of light; if it was stirred or moved briskly.

Besides, in some parts of the sea, he saw a substance

like sawdust, sometimes red and sometimes yellow; and when he drew up the water in those places, it was always viscus and glutinous. The sailors told him, that it was the spawn of whales; that there are great quantities of it in the north; and that some­­
times, in the night, they appeared all over of a bright­­
light, without being put in motion by any vessel or fish

passing by them.

As a confirmation of this conjecture, that the more

glutinous the sea-water is, the more it is diploped to

become luminous, he observes, that one day they took

a fish which was called a huss; theinside of the mouth

of which was so luminous, that without any other light,

he could read the same characters which he had before

read by the light in the wake of the ship; and the

mouth of this fish was full of a viscus matter, which,

when it was rubbed upon a piece of wood, made it im­­
mmediately all over luminous; though, when the mois­­
ture was dried up, the light was extinguished.

The abbe Nollet was much struck with the lumi­­

nous
M. le Roi, making a voyage on the Mediterranean, 

[Image 0x0 to 591x807]

... with the light. The experiments of M. Vianelli, professor of medicine in Chioggia near Venice; and both he and M. Grizelli, a physician in Venice, have given drawings of the infect from which they imagined this light to proceed.

The abbé was the more confirmed in his hypothesis, by observing, some time after, the motion of some luminous particles in the sea. For going into the water, and keeping his head just above the surface, he saw them dart from the bottom, which was covered with weeds, to the top, in a manner which he thought very much resembled the motions of insects; though, when he endeavoured to catch them, he only found some luminous spots upon his handkerchief, which were enlarged when he pressed them with his finger.

M. le Roi, making a voyage on the Mediterranean, presenty after the abbé Nollet made his observations at Venice, took notice, that in the day-time, the prow of the ship in motion threw up many small particles, which, falling upon the water, rolled upon the surface of the sea for a few seconds before they mixed with it; and in the night the same particles, as he concluded, had the appearance of fire. Taking a quantity of the water, the same small sparks appeared whenever it was agitated; but as was observed with respect to Dr Beal's experiments, every incipience agitation produced a less effect than the preceding, except after being suffered to rest a while; for then a fresh agitation would make it almost as luminous as the first. This water, he observed, would retain its property of shining by agitation a day or two; but it disappeared immediately on being set on the fire, though it was not made to boil.

This gentleman, after giving much attention to this phenomenon, concludes, that it is not occassioned by any shining infects, as the abbé Nollet imagined; especially as, after carefully examining some of the luminous points, which he caught upon a banked with, he found them to be round like large pins heads, but with nothing of the appearance of any animal, though he viewed them with a microscope. He also found, that the mixture of a little spirit of wine with water, just drawn from the sea, would give the appearance of a great number of little sparks, which would continue visible longer than those in the ocean. All the acids, and various other liquors, produced the same effect, though not quite so confpicuously; but no fresh agitation would make them luminous again. M. le Roi is far from ascertaining that there are no luminous infects in the sea. He even supposes that the abbé Nollet and M. Vianelli had found them. But he was satisfied that the sea is luminous chiefly on some other account, though he does not so much as advance a conjecture about what it is.

M. Ant. Martin made many experiments on the light of fish, with a view to discover the cause of the light of the sea. He thought that he had reason to conclude, from a great variety of experiments, that all fish-fishes have this property; but that it is not to be found in any that are produced in fresh water. Nothing depended upon the colour of the fish, except that he thought that the white ones, and especially those that had white scales, were a little more luminous than others. His light, he found, was increased by a small quantity of salt; and also by a small degree of warmth, though a greater degree extinguished it. This agrees with another observation of his, that it depends entirely upon a kind of moisture which they had about them, and which a small degree of heat would expel, when an oiliness remained which did not give this light, but would burn in the fire. Light from the flesh of birds or beasts is not so bright, says he, as that which proceeds from fish. Human bodies, he says, have sometimes emitted light about the time that they began to putrefy, and the walls and roof of a place in which dead bodies had often been exposed, had a kind of a dew or clamminess upon it, which was sometimes luminous; and he imagined that the lights which are said to be seen in burying-grounds may be owing to this cause.

From some experiments made by Mr. Canton, he concludes, that the luminousness of sea-water is owing to the slimy and other purer effusions it contains. On the evening of the 14th of June 1768, he put a small fresh whiting into a gallon of sea-water, into a pan which was about 14 inches in diameter, and took notice that neither the whiting nor the water, when agitated, gave any light. A Fahrenheit's thermometer, in the cellar where the pan was placed, stood at 54°. The 15th, at night, that part of the fish which was even with the surface of the water was luminous, but the water itself was dark. He drew the end of a stick through it, from one side of the pan to the other; and the water appeared luminous behind the stick all the way, but gave light only where it was disturbed. When all the water was fired, the whole became luminous, and appeared like milk, giving a considerable degree of light to the sides of the pan; and it continued to do so for some time after it was at rest. The water was most luminous when the fish had been in it about 28 hours; but would not give any light by being fired, after it had been in it three days.

He then put a gallon of fresh water into one pan, and an equal quantity of sea-water into another, and into each pan he put a fresh herring of about three ounces. The next night the whole surface of the sea-water was luminous, without being fired; but it was much more so when it was put in motion; and the upper part of the herring, which was considerably below the surface of the water, was also very bright; while at the same time, the fresh water, and the fish that was in it, were quite dark. There were several very bright luminous spots on different parts of the surface of the sea-water; and the whole, when viewed by the light of a candle, seemed covered with a greasy film. The third night, the light of the sea-water, while at rest, was very little, if at all; but when fired, its light was so great as to discover the time by a watch, and the fish in it appeared as a dark subsance. After this, its light was evidently decreasing, but was not quite gone before the 7th night.
The fresh water and the fish in it were perfectly dark during the whole time. The thermometer was generally above 60°.

The preceding experiments were made with sea-water: but he now made use of other water, into which he put common or sea-salt, till he found, by a hydrometer, that it was of the same specific gravity with the sea-water; and, at the same time, in another gallon of water, he dissolved two pounds of salt; and into each of these waters he put a small fresh herring. The next evening the whole surface of the artificial sea-water was luminous without being filled; but gave much more light when it was disturbed. It appeared exactly like the real sea-water in the preceding experiment; its light lasted about the same time, and went off in the same manner: while the other water, which was almost as salt as it could be made, never gave any light. The herring which was taken out of it the seventeenth night, and walked from its salt, was found firm and sweet; but the other herring was very soft and yellow much more than that which had lain kept as long in fresh water. If a herring, in warm weather, be put into 10 gallons of artificial sea-water, instead of one, the water, he says, will still become luminous, but its light will not be so strong.

It appeared by some of the first observations on this subject, that heat extinguishes the light of purulent substances. Mr Canton also attended to this circumstance; and observes, that though the greatest summer heat is well known to promote putrefaction, yet 20 degrees more than that of the human blood seems to hinder it. For putting a small piece of a luminous fish into a thin glass ball, he found, that water of the heat of 18 degrees would extinguish its light in less than half a minute; but that, on taking it out of the water, it would begin to recover its light in about 10 seconds; but it was never afterwards so bright as before.

Mr Canton made the same observation that Mr Ant. Martin had done, viz. that several kinds of river fish could not be made to give light, in the same circumstances in which any sea-fish become luminous. He says, however, that a piece of earp made the water very luminous, though the outside, or fcial part of it, did not shine at all.

For the sake of those persons who may choose to repeat his experiments, he observes, that artificial sea-water may be made without the use of a hydrometer, by the proportion of four ounces avoidupoise of salt to seven pints of water, wine-measure.

From undoubted observations, however, it appears, that in many places of the ocean it is covered with luminous infects to a very considerable extent. Mr Dagelet, a French astronomer who returned from the Terra Australis in the year 1774, brought with him several kinds of worms which swim in water when it is hot in motion; and M. Rigaud, in a paper inferred (if we are not mistaken) in the Journal des Saisons for the month of March 1770, affirms, that the luminous surface of the sea, from the port of Brest to the Antilles, contains an immense quantity of little, round, shining poly-
happened one night to perceive one of them, and got so near that he could have a very advantageous view of it. This is by no means easy to be obtained; for, among other singularities of the ignis fatuus, it is observed to avoid the approach of any person, and fly from place to place as if it was animated. That which Dr Derham observed was in some boggy ground between two rocky hills; and the night was dark and calm; by which means, probably, he was enabled to advance within two or three yards of it. It appeared like a complete body of light without any division, so that he was sure it could not be occasioned by insects; as some have supposed; the separate lights of which he could not have failed to distinguish, had it been occasioned by them. The light kept dancing about a dead thistle, till a very light motion of the air, occasioned, as he supposed, by his near approach to it, made it jump to another place; after which it kept flying before him as he advanced. M. Beccari endeavoured to procure all the intelligence he could concerning this phenomenon, by enquiring of all his acquaintance, with whom it was seen. The ground to which it appeared to a gentleman of his acquaintance as he was observing it, was covered with snow, and which was to be seen almost every night, especially that to the eastward, giving a light equal to an ordinary faggot. The latter appeared to a gentleman of his acquaintance as he was travelling; moved constantly before him for about a mile; and gave a better light than a torch which was carried before him. Both these appearances gave a very strong light, and were constantly in motion though this was various and uncertain. Sometimes they would rise, sometimes sink; but commonly they would hover about six feet from the ground; they would also frequently disappear and reappear again in some other place. They differed also in size and figure, sometimes spreading pretty wide, and then contracting themselves; sometimes breaking into two, and then joining again. Sometimes they would appear like waves, at others they would seem to drop sparks of fire: they were but little affected by the wind; and in wet and rainy weather were frequently observed to cast a stronger light than in dry weather: they were also observed more frequently when snow lay upon the ground, than in the hottest summer; but he was assured that there was not a dark night throughout the whole year in which they were not to be seen. The ground to the eastward of Bologna, where the largest of these appearances was observed, is a hard chalky soil mixed with clay, which will retain the moisture for a long time, but breaks and cracks in hot weather. On the mountains, where the soil is of a lofer texture, and less capable of retaining moisture, the ignis fatuus were less.

From the best information which M. Beccari was able to procure, he found that these lights were very frequent about rivers and brooks. He concludes his narrative with the following singular account. "An intelligent gentleman travelling in the evening, between eight and nine, in a mountainous road about ten miles south of Bologna, perceived a light which thence very strangely upon some stones which lay on the banks of the river Riveride. It seemed to be about two feet above the stones, and not far from the water. In size and figure it had the appearance of a parallelopiped, somewhat more than a foot in length, and a half a foot high, the longest side being parallel to the horizon. Its light was so strong, that he could plainly discern it by part of a neighbouring hedge and the water of the river; only in the east corner of it the light was rather faint, and the square figure less perfect, as if it was cut off or darkened by the shadow of a circle. On examining it a little nearer, he was surprized to find that it changed gradually from a bright red, first to a yellowish, and then to a pale colour, in proportion as he drew nearer; and when he came to the place itself, it quite vanished. Upon this he stepped back, and not only saw it again, but found that the farther he went from it, the stronger and brighter it grew. When he examined the place of this luminous appearance, he could perceive no fnell nor any other mark of fire." This account was confirmed by another gentleman, who informed M. Beccari, that he had seen the same light five or six different times in spring and in autumn; and that it always appeared of the same shape, and in the very same place. One night in particular he observed it come out of a neighbouring field to settle in the usual place.

A very remarkable account of the ignis fatuus is given by Dr Shaw in his Travels to the Holy Land. It appeared in the valleys of mount Ephraim, and attended him and his company for more than an hour. Sometimes it would appear globular, or in the shape of the flame of a candle; at others it would spread itself to a degree as to involve the whole company in a pale offensive light, then contract itself, and suddenly disappear; but in less than a minute it would appear again; sometimes running swiftly along, it would expand itself at certain intervals over more than two or three acres of the adjacent mountains. The atmosphere from the beginning of the evening had been remarkably thick and hazy; and the dew, as they felt it on the bridles of their horses, was very clammy and unwholesome.

Lights resembling the ignis fatuus are sometimes observed at sea, skipping about the masts and rigging of ships; and Dr Shaw informs us, that he has seen these in such weather as that just mentioned when he saw the ignis fatuus in Palestine. Similar appearances have been observed in various other situations; and we are told of one which appeared about the bed of a woman in Milan, surrounding it as well as her body entirely. This light fled from the hand which approached it; but was at length entirely dispersed by the motion of the air. Of the same kind also, most probably, are those small luminous appearances which sometimes appear in houses or near them, called in Scotland Els-candies, and which are supposed to portend the death of some person about the house. In general these lights are harmless, though not always; for we have accounts of some luminous vapours which would encompass flakes of hay and corn, and set them on fire; so that they became objects of great terror and concern to the country people. Of these it was observed, that they would avoid a drawn sword, or sharp-pointed iron instrument, and that they would be driven away by a great noise; both which methods were
we have a strong proof that electricity is concerned, or indeed the principal agent, in producing the ignis fatuus, from an experiment related by Dr Priestley of a flame of this kind being artificially produced. A gentleman, who had been making many electrical experiments for a whole afternoon in a small room, on going out of it, observed a flame following him at some little distance. This we have no reason to doubt, was a true ignis fatuus, and the circumstances necessary to produce it were then present, an atmosphere impregnated with animal vapour, and likewise strongly electrified. Both these circumstances undoubtedly must have taken place in the present case: for the quantity of perspiration emitted by a human body is by no means inconsiderable; and it as well as the electricity would be collected by reason of the smallness of the room. In this case, however, there seems to have been a considerable difference between the artificial ignis fatuus and those commonly met with: for this flame followed the gentleman as he went out of the room; but the natural ones commonly fly from those who approach them. This may be accounted for from a difference between the electricity of the atmosphere in the room and the other; in which case the flame would naturally be attracted towards that place where the electricity was either different in quality or in quantity; but in the natural way, where all bodies may be supposed equally electrified for a great way round, a repulsion will as naturally take place. Still, however, this does not seem to be always the case. In those instances where travellers have been attended by an ignis fatuus, we cannot suppose it to have been influenced by any other power than what we call attraction, and which electricity is very capable of producing. Its keeping at some distance is likewise easily accounted for, as we know that bodies possessed of different quantities of electricity may be made to attract another for a certain space, and then repel without having ever come into contact. On this principle we may account for the light which surrounded the woman at Milan, but fled from the hand of any other person. On the same principle we account for those mischievous vapours which set fire to the hay and corn flacks, but were driven away by preventing to them a pointed iron instrument, or by making a noise. Both these are known to have a great effect upon the electric matter; and by means of either, even lightning may occasionally be made to fall upon or to avoid particular places, according to the circumstances by which the general mass happens to be affected at that time.

On the whole, therefore, it seems most probable, that the ignis fatuus is a collection of vapour of the purest kind, very much affected by electricity; according to the degree of which, it will either give a weak or strong light, or even set fire to certain substances disposed to receive its operation. This opinion seems greatly to be confirmed from some luminous appearances, observed in privies, where the putrid vapours have even collected themselves into balls, and exploded violently on the approach of a candle. This last effect, however, we cannot so well ascribe to the electricity, as to the attention of the inflammable air which frequently abounds in such places.

In the appendix to Dr Priestley's third volume of experiments...
A light in some respects similar to those above mentioned has been found to proceed from that celebrated chemical production called phosphenes, which always tends to decompose itself, so as to take fire by the access of air only. Phosphenes, therefore, when it emits light, is properly a body ignited; though when a very light,

little quantity of it is used, as what is left after drawing it over paper, or what may be dissolved in essential oil, the heat is not sensible. But perhaps the matter which emits the light, in what we call phosphenes, may be similar to it, though it is generated by a different process, and burn with a less degree of heat. Purification does not seem to be necessary to the light of glow-worms, or of the pholes; and yet their light is sufficiently similar to that of shining wood or flesh. Electric light is unquestionably similar to that of phosphenes, though the source of it is apparently very different.

Kneckel formed his phosphenes into a kind of pills, about the size of peas, which being moistened a little and scraped in the dark, yielded a very considerable light, but not without smoke. The light was much more pleasing when eight or ten of these pills were put into a glass of water; for being shaken in the dark, the whole glass seemed to be filled with light. Kneckel also reduced his phosphenes into the form of larger stones; which being warmed by a person's hand, and rubbed upon paper, would describe letters that were very legible in the dark.

The greatest variety of experiments with the light of phosphenes was made by Dr. Slate; who says, that the solid phosphenes (which is nothing more than the solid phosphenes dissolved in any of the essential oils), would not hurt even a lady's hand; or that, when the hands or face were washed with it, it would not only make them visible to other persons in the dark, but that the light was so considerable as to make other neighbouring objects visible.

When the solid phosphenes is quite immersed in water, he observes, that it ceases to shine; but that if any part of it chance to emmerge or get into the air, it will shine though the glass be hermetically sealed. In a large glass he kept it without water for several days; and yet it continued shining, with very little diminution of its light or weight. If the letters that were written with this phosphenes were warmed by the fire, they presently became dark lines, which continued upon the paper, like ink. To try how much light was given by a small quantity of this phosphenes, he observed that it continued to shine in the open air for seven or eight days, the light being visible whenever he shut his window.

As air was generally thought to contain the pho-bium of flame, Dr. Slate was determined to try this with respect to phosphenes; and for this purpose he placed a large piece of it in a receiver; but upon exhausting it, he perceived that it became more luminous, and that upon admitting the air, it returned to its former state. This property of the light of phosphenes, which is the very reverse of that of shining wood and fishies, was also ascertained by several very accurate experiments of Mr. Hawkebee's.

Endeavouring to blow the phosphenes into a flame with a pair of bellows, Dr. Slate found that it was presently blown out, and that it was a considerable time before
Light.

before the light revived again. All liquors would extinguish this light when the phosphorus was put into them; nor would it shine or burn, though it was even boiled in the most inflammable liquors, as oil of olive, spirit of turpentine, or even spirit of wine.

in order to keep his phosphorus from consuming, he used to put it in a glass of water; and sometimes he has seen it, when thus immered in water, make such bright and vigorous combustions in the air, as, he says, would surprise and frighten those who are not used to the phenomenon. This fiery meteor, he says, is contracted in its passage through the water, but expands as soon as it gets above it. If any person would make this experiment to advantage, he informs them that the glass must be deep, and cylindrical and not above three quarters filled with water. This effect he perceived in warm weather only, and never in cold.

The phosphorus of which we have been treating is prepared from urine; but in some cases the sweat, which is similar to urine, has been observed to be phosphorous; without any preparation. This once happened to a person who used to eat great quantities of salt, and who was a little subject to the gout, after sweating with violent exercise. Stripping himself in the dark, his shirt seemed to be all on fire, which surprised him very much. Upon examination, red spots were found upon his shirt; and the physician who was present perceived an unusual smell, though it had nothing in it of volatile alkali, but of theuratic acid; the fame, he says, that issues from cabbage much falted, and strongly fermented.

The caillet method of accounting for all these kinds of lights, perhaps, is from electricity. If light confits in a certain vibration of the electric fluid, then it follows, that in whatever substances such a vibration takes place, there light must appear, whether in purefcent animal subftances, sea-water phosphorus, or any thing elfe. We know that the electric matter pervades all terrestrial subftances, and is very liable to be fet in motion from causes of which we are ignorant. The action of the air by which purefaction is produced may be one of these causes; and it can by no means appear surprifing that the electric matter should act in the bodies of living animals in fuch a manner as to produce a permanent light, when we certainly know it acts in fome of them fo powerfully as to produce a fhook familiar to that of a charged vitul.---On this fubjeft we shall only observe farther, that when this vibration becomes fo powerful as to penetrate the solid subftance of the body itself, the luminous body then becomes transparent, as in the milk mentioned in the former part of this article; but, when it is only superficial, the body, though it emits light, is itself opaque.

Light from diamonds. Among luminous bodies the diamond is to be reckoned; as some diamonds are known to shine in the dark. But on account of the feebenees of their splendor, it is neceffary for the person who is to obferve them, previously to fay in the dark at leaft a quarter of an hour, that the pupil of the eye may be dilated and enlarged, and fo rendered capable of receiving a larger quantity of the rays of light. M. du Fay has alfo obferved, that the eyes ought to be that for this time, or at least one of them; and that in that cafe, the light of the diamond is afterwards only feen by that eye which has been bent. Before the diamond is brought into the dark room, it must be exposed to the fun-light, or at leat to the open day light, to imbibe a sufficient quantity of rays; and this is done in one minute, or even less; eight or ten feconds having been found to furnish as much light as the stone is capable of receiving; and when brought into the dark, its light continues about twelve or thirteen minutes, weakening all the while by ineffible degrees. It is very remarkable that in bodies fo extremely similar to each other as diamonds are, fome have this property of imbidding the fun’s rays, and shining in the dark, and that others搞好 not; yet fo it is found to be by experiment, and the moft nearly refembling stones hall be found one to have this property, and another to be deftitute of it; while many of the moft diftinctive have the property in common. There seems to be no rule, nor even the leaft traces of an imperfect rule of judging, which diamonds have, and which have not this property; their natural brightnefs, their purity, their fize, or their fhape, contribute nothing to it; and all that has yet been discovered of the leaft regularity among them, is, that all the yellow diamonds have this property. This may probably arise from their having more fulleth in their composition, and therefore illuminating more readily, or emitting a more visible fame.

The burning of diamonds is a term used among the jewellers, for putting them into a firece fire, as they frequently do, when they are fouled with brown, or yellow, or the like; this always defefts them of their colour, without doing them the leaft tennible injury. M. du Fay, having been informed of this common practice, formed a conjecture, that the difference of diamonds in their flaming, or not flaming in the dark, was owing to it; and that either all thofe which had been burned, or all thofe which had not, were thofe which alone fhone in the dark. But this was found an erroneous conjecture; for two diamonds, one lucid in the dark the other not, were both burned, and afterwards both were found to retain the fame properties they had before. It is not only the open fun-light, or open day-light, which gives to these diamonds the power of flaming in the dark: they receive it in the fame manner even if laid under a glafs, or plunged in water or in milk.

M. Du Fay tried whether it was po enlarge the diamond retain, for any longer time, the light it naturally parts with fo foon; and found, that if the diamond, after being exposed to the light, be covered with black wax it will fhinfe in the dark, as well fix hours afterwards as at the time it was firft impregnated with the light.

The imbibing light, in this manner, being fo nice a property as not to be found in several diamonds, it was not to be fuppofed, that it would be found in any other ftones: accordingly, on trial, the ruby, the fapphire, and the topaz, were found wholly deftitute of it; and among a large number of rough emeralds, one only was found to poiffeit it. Such is the strange uncertainty of these accidents.

All the other lefs precious ftones were tried and found not to poiffeit this property of imbidding light from the day-light or fun-light, but they all became luminous by the different means of heating or friction; with this difference, that fome acquired it by one of the
Light, their methods, and others by the other; each being unaffected by that which gave the property to the other. The diamond becomes luminous by all these ways.

Beccearius also discovered, that diamonds have the property of the Bolognian phosphorus, about the same time that it occurred to M. du Fay. Com. Bonev, vol. ii. p. 176. M. du Fay likewise observed, that the common topaz, when calcined, had all the properties of this phosphorus; and pursuing the discovery, he found the same property, in a great degree, in the blemmites, gypsum, lime-stone, and marbles; though he was obliged to dissolve some very hard substances of this kind in acids, before calcination could produce this change in them; and with some substances he could not succeed even thus: especially with flint-stones, river-sand, jaspers, agates, and rock-crystal.

Light from Plants. In Sweden a very curious phenomenon has been observed on certain flowers by M. Haggern, lecturer in natural history. One evening he perceived a faint flash of light repeatedly dart from a marigold. Surprised at such an uncommon appearance, he resolved to examine it with attention; and to be assured it was no deception of the eye, he placed a man near him, with orders to make a signal at the moment when he observed the light. They both saw it constantly at the same moment.

The light was most brilliant on marigolds of an orange or flame colour; but scarcely visible on pale ones.

The flash was often seen on the same flower two or three times in quick succession; but more commonly at intervals of several minutes; and when several flowers in the same place emitted their light together, it could be observed at a considerable distance.

This phenomenon was remarked in the months of July and August at Fun-st, and for half an hour, when the atmosphere was clear; but after a rainy day, or when the air was loaded with vapours, nothing of it was seen.

The following flowers emitted flashes, more or less vivid, in this order:
1. The menigolds, calendula officinalis.
3. The orange-lily, lilium bulbiferum.
4. The Indian pink, tagetes patula et erecta.

To discover whether some little insects or phosphoric worms might not be the cause of it, the flowers were carefully examined, even with a microscope, without any such being found.

From the rapidity of the flash, and other circumstanciess, it may be conjectured that there is something of electricity in this phenomenon. It is well known, that when the pistil of a flower is impregnated, the pollen bursts away by its elasticity, with which electricity may be combined. But M. Haggern, after having observed the flash from the orangelily, the anthera of which are a considerable space distant from the petals, found that the light proceeded from the petals, only; whence he concludes, that this electric light is caused by the pollen, which, in dying off, is scattered on the petals. Whatever be the cause, the effect is singular and highly curious.

Lights, in painting, are those parts of a piece which are illuminated, or that lie open to the luminary, by which the piece is supposed to be enlightened; and which, for this reason, are painted in bright vivid colours.

In this sense, light is opposed to shadow. Different lights have very different effects on a picture, and occasion a difference in the management of every part. A great deal therefore depends on the painter's choosing a proper light for his piece to be illuminated by; and a great deal more, in the conduct of the lights and shadows, when the luminary is pitched upon.

The strength and relievo of a figure, as well as its gracefulfulness, depend entirely on the management of the lights, and the joining of those to the shadows.

The light a figure receives is either direct or reflected; to each of which special regard must be had. The doctrine of lights and shadows makes that part of painting called chiaro oscura.

Light-Horse, an ancient term in the English customs, signifying an ordinary cavalier or horseman lightly armed, and so as to enter a corps or regiment; in opposition to the men at arms, who were heavily accou­urred, and armed at all points. See Light-Horse.

Lighter, a building erected upon a cape or promontory on the sea-coast, or upon some rock in the sea, and having on its top in the night-time a great fire or light formed by candles, which is constantly attended by some careful person, so as to be seen at a great distance from the land. It is used to direct the shipping on the coast that might otherwise run ashore, or steer an improper course when the darkness of the night and the uncertainty of currents, &c. might render their situation with regard to the shore extremely doubtful. Lamp-lights are, on many accounts, preferable to coal-fires or candles; and the effect of these may be increased by placing them either behind glass-hemispheres, or before properly disposed glass or metal reflectors, which last method is now very generally adopted. See Beacons.

Light-Room, a small apartment inclosed with glass-windows, near the magazine of a ship of war. It is used to contain the lights by which the gunner and his assistants are enabled to fill cartridges with powder to be ready for action.

Lighter, a large, open, flat-bottomed vessel, generally managed with oars, and employed to carry goods to or from a ship when she is to be laden or delivered. — There are also some lighters furnished with a deck throughout their whole length, in order to contain those merchandises which would be damaged by rainy weather: these are usually called close lighters.

Lightfoot (John), a most learned English divine, was the son of a divine, and born in March 1602, at Stoke upon Trent in Staffordshire. After having finished his studies at a school on Morton-green near Congleton in Cheshire, he was removed in 1617 to Cambridge, where he applied himself to eloquence, and succeeded so well in it as to be thought the best orator of the under-graduates in the university. He also made an extraordinary proficiency in the Latin and Greek; but neglected the Hebrew, and even lost that knowledge he brought of it from school. His taste for the oriental languages was not yet excited; and as for logic, the study of it, as managed at that time among the academics, was too quadrifome and fierce
Lightfoot. fierce for his quiet and meek disposition. As soon as he had taken the degree of B. A. he left the university, and became assistant to a school at Repton in Derbyshire. After he had supplied this place a year or two, he entered into orders, and became curate of Norton under Hale in Shropshire. This curacy gave an occasion of awakening his genius for the Hebrew tongue. Norton lies near Bellaport, then the seat of Sir Rowland Cotton, who was his constant hearer, made him his chaplain, and took him into his house. This gentleman being a perfect master of the Hebrew language, engaged Lightfoot in that study; who, by conversing with his patron, soon became sensible that without that knowledge it was impossible to attain an accurate understanding of the scriptures. He therefore applied himself to it with extraordinary vigour, and in a little time made a great progress in it; and his patron removing with his family to reside in London, at the request of Sir Alland Cotton his uncle, who was lord-mayor of that city, he followed his preceptor thither. But he did not stay long there: for, having a mind to improve himself by travelling abroad, he went down into Staffordshire to take leave of his father and mother. Palling through Stone in that county, he found the place during a minister; and the prevailing infinuations of the parishioners prevailed upon him to undertake that cure. Hereupon, laying aside his design of travelling abroad, he began to turn his thoughts upon settling at home. During his residence at Bellaport, he had fallen into the acquaintance of a gentlewoman who was the daughter of William Crompton of Stonepark, Eq; and now, being in possession of that living, he married her in 1628. But notwithstanding this settlement, his uneasiness of being the only rabbinical learning would not suffer him to continue there. Sion-college library at London, he knew, was well stocked with books of that kind. He therefore quitted his charge at Stone, and removed with his family to Hornsey, near the city; where he gave the public a notable specimen of his advancement in those studies, by his "Erubhim, or Miscellaneous Christian and Judicial," in 1629. He was at this time only 27 years of age; and appears to have been well acquainted with the Latin and the Greek fathers, as well as the ancient heathen writers. These first fruits of his studies were dedicated to Sir Rowland Cotton; who, in 1631, presented him to the rectory of Alaley in Staffordshire. He seemed now to be fixed for life: Accordingly, he built a study in the garden, to be out of the noise of the house; and applied himself with indefatigable diligence in searching the scriptures. Thus employed, the days passed very agreeably; and he continued quiet and unmolested, till the great change which happened in the public affairs brought him into a share of the administration relating to the church; for he was nominated a member of the memorable assembly of divines for settling a new form of ecclesiastical polity. This appointment was purely the effect of his distinguished merit; and he accepted it purely with a view to serve his country, as far as lay in his power. The non-residence, which this would necessarily occasion, apparently induced him to resign his rectory; and having obtained the presentation for a younger brother, he set out for London in 1642. He had now satisfied himself in clearing up many of the abstruse passages in the Bible, and therein had provided the chief materials, as well as formed the plan, of his "Harmony," and an opportunity of inspecting it at the press was, no doubt, an additional motive for his going to the capital; where he had not been long before he was chosen minister of St Bartholomew's, behind the Royal Exchange. The assembly of divines meeting in 1643, our author gave his attendance diligently there, and made a distinguished figure in their debates; where he used great freedom, and gave signal proofs of his courage as well as learning, in opposing many of those tenets which the divines were endeavouring to establish. His learning recommended him to the parliament, whose visitors, having ejected Dr William Sprat from the mastership of Catharine-hall in Cambridge, put Lightfoot in his room; this year 1653; and he was also presented to the living of Much-Mauden in Hertfordshire, void by the death of Dr Samuel Ward, Margaret-professor of divinity in that university, before the expiration of this year. Meanwhile he had his turn with other favourites in preaching before the house of commons, most of which sermons were printed; and in them we see him warmly pressing the speedy settlement of the church in the Presbyterian form, which he cordially believed to be according to the pattern in the Mount. He was all the while employed in preparing and publishing the several branches of his Harmony; all which were so many excellent specimens of the usefulness of human learning to true religion: and he met with great difficulties and discouragements in that work, chiefly from that antinomian spirit which prevailed, and even threatened the destruction of the universities. In 1655 he entered upon the office of vice-chancellor of Cambridge, to which he was chosen that year, having taken the degree of doctor of divinity in 1652. He performed all the regular exercises for his degree with great applause, and executed the vice-chancellor's office with exemplary diligence and fidelity; and particularly at the commencement, supplied the place of professor of divinity, then undisputed of as an act which was kept for a doctor's degree in that profession. At the same time he was engaged with others in perfecting the Polyglot Bible, then in the press. At the restoration he offered to resign the mastership of Catharine-hall: But, as what he had done had been rather in compliance with the necessity of the times, than from any zeal or spirit of opposition to the king and government, a confirmation was granted him from the crown, both of the place and of his living. Soon after this he was appointed one of the assistants at the conference upon the liturgy, which was held in the beginning of 1661, but attended only once or twice; probably aggrieved at the heat with which that conference was managed. However, he stuck close to his design of perfecting his Harmony; and being of a strong and healthy constitution, which was alloyed by an exact temperance, he prosecuted his studies with unabated vigour to the last, and continued to publish, notwithstanding the many difficulties he met with from the existence of it. However, not long before he died, some booksellers got a promise from him to collect and methodize his works, in order to print them; but the execution was prevented by his death, which happened Dec. 6. 1675. The doctor was twice married: his first
Lightning. first wife, already mentioned, brought him four sons and two daughters. His second wife was likewise a widow, and relief of Mr Auffin Brograve, uncle of Sir Thomas Brograve, Bart. of Hertfordshire, a gentleman well versed in rabbinical learning and a particular acquaintance of our author. He had no issue by her. She also died before him, and was buried in Munden church, where the doctor was himself likewise interred near both his wives. Dr Lightfoot's works were collected and published first in 1684, in two volumes folio. The second edition was printed at Amsterdam, in 1686, in two volumes folio, containing all his Latin writings, with a Latin translation of those which he wrote in English. At the end of both these editions there is a list of such pieces as he left unfinished. It is the chief of these, in Latin, which make up the third volume, added to the former two, in a third edition of his works, by John Lutreden, at Utrecht, in 1699, fol. They were communicated by Mr Strype, who, in 1700, published another collection of these papers, under the title of "Some genuine remains of the late pious and learned Dr John Lightfoot.

LIGHTNING, a bright and vivid flash of fire, suddenly appearing in the atmosphere, and commonly disappearing in an instant, sometimes attended with clouds and thunder, and sometimes not.

The phenomena of lightning are always surprising, and always something extraordinary. There is never any kind of natural appearance in which there is more diversity, not two flashes being ever observed exactly similar to one another. In a serene sky, the lightning, in this country at least, almost always hath a kind of indistinct appearance without any determinate form, like the sudden illumination of the atmosphere occasioned by firing a quantity of loose gunpowder; but when accompanied with thunder, it is well defined, and hath very often a zig-zag form. Sometimes it makes only one angle, like the letter V, sometimes it hath several branches, and sometimes it appears like the arch of a circle. But the most formidable and destructive form which lightning is ever known to assume is that of balls of fire. The motion of these is very often easily perceptible to the eye; but wherever they fall, much mischief is occasioned by their burning, which they always do with a sudden explosion like that of fire-arms. Sometimes they will quietly run along, or rest for a little upon any thing, and then break into several pieces, each of which will explode; or the whole ball will burst at once, and produce its mischievous effects only in one place. The next to this in its destructive effects is the zig-zag kind; for that which appears like indistinct flakes, whose form cannot be readily observed, is seldom or never known to do hurt. The colour of the lightning also indicates in some measure its power to do mischief; the palest and brightest flakes being most destructive; such as are red, or of a darker colour, commonly doing less damage.

A very surprising property of lightening, the zig-zag kind, especially when near, is its seeming omniscience. If two persons are standing in a room looking different ways, and a loud clap of thunder accompanied with zig-zag lightning happens, they will both distinctly see the flash, not only by that indistinct illumination of the atmosphere which is occasioned by fire of any kind; but the very form of the lightning itself, and every angle it makes in its course, will be distinctly perceptible, as though they had looked directly at the cloud from whence it proceeded. If a person happened at that time to be looking on a book, or other object which he held in his hand, he would distinctly see the form of the lightning between him and the object at which he looked. This property seems peculiar to lightning, and to belong to no other kind of fire whatever.

The effects of lightning are generally confined within a small space; and are seldom similar to those which accompany explosions of gun-powder, or of inflammable air in mines. Instances of this kind, however, have occurred; the following is one of the most remarkable of which we have any distinct account.

"August 2, 1763, about fix in the evening, there arose at Anderlight, about a league from Brussells, a conflict of several winds borne upon a thick fog. This conflict lasted four or five minutes, and was attended with a frightful hissing noise, which could be compared to nothing but the yellings of an infinite number of wild beasts. The cloud then opening, discovered a kind of very bright lightning, and in an instant the roofs of one side of the houses were carried off and dispersed at a distance; above 1000 large trees were broke off, some near the ground, others near the top, some torn up by the roots; and many both of branches and tops carried to the distance of 60, 100, or 120 paces; whole coppices were laid on one side, as corn is by ordinary winds. The glafs of the windows which were most exposed was shattered to pieces. A tent in a gentleman's garden was carried to the distance of 4000 paces; and a branch torn from a large tree, struck a girl in the forehead as she was coming into town, at the distance of 40 paces from the trunk of the tree, and killed her on the spot."

These terrible effects seem to have been owing to the prodigious agitation in the air, occasioned by the emission of such a vast quantity of lightning at once; or perhaps to the agitation of the electric fluid itself, which is still more dangerous than any concussion of the atmosphere; for thunder-storms will sometimes produce most violent whirlwinds, such as are by the heath philosophers attributed to electricity, nay, even occasion an agitation of the waters of the ocean itself; and all this too after the thunder and lightning had ceased. Of this we have the following instances.

"Great Malvern, October 16, 1761. On Wednesday last, we had the most violent thunder ever known in the memory of man. At a quarter past four in the afternoon I was surprized with a most shocking and dismal noise; 100 forges the nearest resemblance I can think of), were they all at work at once, could scarce equal it. I ran to the fore-door, and casting my eye upon the side of the hill about 400 yards to the south-west of my house, there appeared a prodigious smoke, attended with the same violent noise. I ran back into the house, and cried out, a volcano (for I thought) had burst out of the hill; but I had no sooner got back again, than I found it had descended, and was passing on within about 100 yards of the south end of my house. It seemed to rise again in the meadow just below it; and con-
Lightning, continued its progress to the east, rising in the same manner for four different times, attended with the same dismal noise as at first; the air being filled with a nauseous and sulphurous smell. I saw it gradually decrease till quite extinguished in a turnip-field about a quarter of a mile below my house. The turnip leaves, with leaves of trees, dirt, flakes, &c., filled the air, and flew higher than any of these hills. The thunder ceased before this happened, and the air soon afterwards became calm and serene. — The vast column of smoke mentioned in the above letter was so large, that a physician of eminence at Worcester saw it in its progress down the hill, about a mile from Fec- kennham, which is above 20 miles from Malveru. — In August 1765, a most violent form of thunder, rain, and hail, happened at London, which did damage in the adjacent country, to the amount of 50,000 l. Hailstones fell of an immense size, from two to ten inches circumstance; but the most surprising circumstance was the sudden flux and reflux of the tide in Plymouth pool, exactly corresponding with the like agitation in the same place, at the time of the great earthquake at Lisbon.

Infants are also to be found, where lightning, by its own proper force, without any assistance from those less common agitations of the atmosphere or electric fluid, hath thrown stones of immense weight to considerable distances; torn up trees by the root, and broke them in pieces; shattered rocks; beat down houses; and set them on fire, &c.

A very singular effect of lightning is mentioned in the 66th volume of the Philosophical Transactions, upon a pyed bullock. It happened in the county of Suffolk about the end of August 1774. The bullock was white and red; and the lightning stripped off the white hair, leaving the red untouched. The following is a particular account of the matter. "In the evening of Sunday, the 28th of August, there was an appearance of a thunder-form, but we heard no report. A gentleman who was riding near the marshes not far distant from this town (Lewes) saw two strong flashes of lightning, seemingly running along the ground of the marsh, at about nine o'clock in the evening. On Monday morning, when the servants of Mr Roger, a farmer at Swanborough, in the parish of Ford, went into the marsh to fetch the oxen to their work, they found one of them, a four-year-old bullock, standing to appearance much burnt, and so weak as to be scarce able to walk. The animal seemed to have been struck by lightning in a very extraordinary manner. He is of a white and red colour: the white in large marks, beginning at the rump bone, and running in various directions along both the sides; the belly is all white, and the whole head and horns white likewise. The lightning, with which he must have been undoubtedly struck, fell upon the rump bone, which is white, and distributed itself along the sides in such a manner as to take off all the white from the white marks as low as the bottom of the ribs, but so as to leave a lift of white hair, about half an inch broad, all round where it joined to the red, and not a single hair of the red appears to be touched. The whole belly is burnt, but the end of the sheath of the penis has the hair taken off; it is also taken off from the dewlap: the horns and the curled hair on the forehead are uninjured; but the hair is taken off from the sides of the face, from the lightning.

The flat part of the jaw-bones, and from the front of the face in stripes. There are a few white marks on the side and neck, which are surrounded with red; and the hair is taken off from them, leaving half an inch of white adjoining to the red. The farmer anointed the ox with oil for a fortnight; the animal purged very much at first, and was greatly reduced in flesh, but is now recovering."

In another account of this accident, the author supposes that the bullock had been lying down at the time he was struck; which shows the reason that the under parts were not touched. "The lightning, conducted by the white hair, from the top of the back down the sides, came to the ground at the place where the white hair was left entire.

The author of this account says, that he inquired of Mr Tooth a farrier, whether he ever knew of a similar accident; and that he told him "the circumstance was not new to him; that he had seen a great many bullocks struck by lightning in the same manner as this; that the texture of the skin under the white hair was always destroyed, though looking fair at first; but after a while it became fore, throwing out a putrid matter in putres, like the small-pox with us, which in time falls off, when the hair grows again, and the bullocks receive no farther injury;" which was the case with the bullock in question. In a subsequent letter, however, the very same author informs us, that he had inquired of Mr Tooth whether he ever saw a stroke of lightning actually fall upon a pyed bullock, so as to destroy the white hair, and show evident marks of burning, leaving the red hair uninjured! He said he never did; nor did he recollect any one that had.

He gave an account, however, of a pyed horse, on a pyed bullock, which had been struck dead by horse lighting in the night-time. The explosion was so violent, that Mr Tooth imagined his horse had been struck, and therefore immediately got up. On going into the stable he found the horse almost dead to appearance, though it kept on its legs near half an hour before it expired. The horse was pyed white on the shoulder and greatest part of the head; viz., the forehead and nose, where the greatest force of the stroke came. "The hair was not burnt nor coloured, only so loosened at the root, that it came off with the least touch. And this one was a four-year-old horse, standing in a stable, much burnt, and so weak as to be scarce able to walk. The animal seemed to have been struck by lightning in a very extraordinary manner. He is of a white and red colour: the white in large marks, beginning at the rump bone, and running in various directions along both the sides; the belly is all white, and the whole head and horns white likewise. The lightning, with which he must have been undoubtedly struck, fell upon the rump bone, which is white, and distributed itself along the sides in such a manner as to take off all the white from the white marks as low as the bottom of the ribs, but so as to leave a lift of white hair, about half an inch broad, all round where it joined to the red, and not a single hair of the red appears to be touched. The whole belly is burnt, but the end of the sheath of the penis has the hair taken off; it is also taken off from the dewlap: the horns and the curled hair on the forehead are uninjured; but the hair is taken off from the sides of the face, from the lightning.

The flat part of the jaw-bones, and from the front of the face in stripes. There are a few white marks on the side and neck, which are surrounded with red; and the hair is taken off from them, leaving half an inch of white adjoining to the red. The farmer anointed the ox with oil for a fortnight; the animal purged very much at first, and was greatly reduced in flesh, but is now recovering."

Another instance is mentioned of this extraordinary effect of lightning upon a bullock, in which even the small red spots on the sides were unaffected; and in this, as well as the former, the white hair on the under part of the belly, and on the legs, was left untouched. All these, however, are to be considered as the more unusual phenomena of lightning; its common mode of action being entirely similar to that of a charged Leyden vial, where the electric matter discharges itself.
Lightning is a phenomenon that is characterized by its zigzag form. The identity of electric matter and lightning is the same, and indeed, it has been established that there is no significant difference between the phenomena of lightning and what may be obtained by comparing them with those of our electrical experiments. The different forms of the flashes are all exemplified in those of electrical sparks. Where the quantity of electricity is small, and consequently incapable of striking at any considerable distance, the spark appears straight, without any curvature, or angular appearance; but where the electricity is very strong, and of consequence capable of striking an object at a pretty considerable distance, it assumes a crooked or zig-zag form. This is always the case with Mr. Nairn's very powerful machines, the conductors of which are six feet in length and one foot in diameter. Sparks may be taken from them at the distance of 6, 17, or even 20 inches; and all of these put on the angular zig-zag form of lightning. The reason of this appearance, both in these sparks and in the lightning, is, that the more fluid electric matter hath to pass through the denser and less fluid atmosphere, the more rapid it will be; and in fact, this is the way in which all the more fluid substances pass through those that are less so, at least when their velocity becomes considerable. If bubbles of air or steam pass very gently up through water, their course from the bottom to the top of the vessel will differ very little, if at all, from a straight line; but when they are impelled by a considerable force, as in air blown from a bellows, or the bubbles of steam which arise in boiling water, their course is then marked by waved and crooked lines, and the deflection of the bubbles to the right or left will be in proportion to their ascending velocity, and to the weight of the water by which they are resisted.

In the case of air blown through water, however, or steam ascending from the bottom of a vessel of boiling water, though the course of the bubbles is wavy and crooked, we never observe it to be angular as in lightning. The reason of this is, that there is no proportion between the capacity of the air for yielding to the impact of lightning, and the velocity with which the latter is moved. Mr. Robin's experiments in gunnery, it appears, that the air cannot yield with a velocity much greater than 10000 feet in a second, and that all projectiles moving with a greater degree of velocity meet with a violent resistance. But if we suppose lightning to move only with one half the velocity of light, that is, near 100,000 miles in a second, or even with that of 1000 miles in a minute, which most probably is the case, its motion in the fluid atmosphere will meet with a resistance very little inferior to what air would meet with in passing through the most solid bodies. The smallest difference of the resistance of the atmosphere on either side, must determine the lightning to that side: and in its passage to that new place where the resistance is least, it must pass on in a straight line, making an angle with its former course, because the atmosphere is altogether incapable of yielding with such rapidity as the electric matter requires, and therefore resists like a solid rock. The case is otherwise in the former examples: for though a small difference in the resistance forces the bubbles to move in an oblique direction, yet there is always a considerable proportion between the capacity of water for yielding, and that force by which the bubbles urge it to yield; so that though it does make a resistance sufficient to prevent the bubbles moving in a straight line, yet it also perceptibly yields in all times, and therefore the track of the bubbles is formed by a number of curves and not angles.

Hence we may understand the reason why the zig-zag kind of lightning is so dangerous, namely, because it must overcome a very violent resistance of the atmosphere; and wherever that resistance is in the smallest degree lessened, there it will undoubtedly strike, and at a very considerable distance too. It is otherwise with that kind which appears in flashes of no determinate form. The electric matter of which these are composed, is evidently dilated in the air by some conducting substances which are present there; and of consequence, though a man, or other conducting body, happened to be very near such a flash, he would not be struck or materially injured by it, though a zig-zag flash, in such circumstances, would have probably discharged its whole force upon him. The most destructive kind of lightning, however, as we have already observed, is that which assumes the form of balls. These are produced by an exceedingly great power of electricity gradually accumulated till the resistance of the atmosphere is no longer able to confine it. In general, the lightning breaks out from the electrified cloud by means of the approach of some conducting substance, either a cloud, or some terrestrial substance: but the fire-balls seem to be formed, not because there is any substance at hand to attract the electric matter from the cloud, but because the electricity is accumulated in such quantity that the cloud itself can no longer contain it. Hence such balls fly off slowly, and have no particular destination. Their appearance indicates a prodigious commotion and accumulation of electricity in the atmosphere, without a proportionable disposition in the earth to receive it. This disposition, however, we know, is perpetually altered by a thousand circumstances, and the place which first becomes most capable of admitting electricity will certainly receive a fire-ball. Hence this kind of lightning has been known to move slowly backwards and forwards in the air for a considerable space of time, and then suddenly to fall on one or more houses, according to their being more or less affected with an electricity opposite to that of the ball at the time. It will also run along the ground, break into several parts, and produce several explosions at the same time.

It is very difficult to imitate lightning of this kind in our electrical experiments. The only cases in which it hath been done in any degree are those in which Dr. Priestley made the explosion of a battery of fire-balls for a considerable way over the surface of raw flesh, water, &c. and in Mr. Arden's experiment, when a fire-ball ascended to the top of an electrified jar, and burst it with a violent explosion. See Electricity n° 89, &c. In these cases, if, while the electric flash passed over the surface of the flesh, it had been possible to interrupt the metallic circuit by taking away the chain, the electric matter discharged from the battery would have been precisely in the situation of one of the fire-balls.
Lightning, in the time of severe thunder-storms, is
supposed to proceed from the earth, as well as from
the clouds: but this fact hath never been well aper-
tained, and indeed from the nature of the thing it
seems very difficult to be ascertained; for the motion
of the electric fluid is so very quick, that it is alto-
gether impossible to determine, by means of our senses,
whether it goes from the earth or comes to it. In
fact, there are in this country many thunder-storms in
which it doth not appear that the lightning touches
any part of the earth, and consequently can neither go
to it or come out from it. In these cases, it flashes
either from an electrified cloud to one endowed with
an opposite electricity, or merely into those parts of Lightning,
the atmosphere which are ready to receive it. But if
not only the clouds, but the atmosphere all the way be-
twixt them and the earth, and likewise for a consider-
able space above the clouds, are electrified one way,
the reason of this will appear from a consideration of the principles laid down
under the article Electricity, sect. vi. It there
appears, that the electric fluid is altogether incapable ei-
er of accumulation or diminution in quantity in any
particular part of space. What we call electricity is only
the motion of this fluid made perceptible to our senses.
Positive electricity is when the current of electric mat-
ter is directed from the electrified body. Negative
electricity is when the current is directed towards it.
Let us now suppose, that a positively electrified cloud is
formed over a certain part of the earth's surface.
The electric matter flows out from it, and enters into the
atmosphere all round; and while it is doing so, the at-
mosphere is negatively electrified. In proportion,
however, as the electric current pervades greater and
greater proportions of the atmospheric space, the
greater is the resistance to its motion, till at last the air
becomes positively electrified as well as the cloud, and
then both act together as one body. The surface of
the earth then begins to be affected, and it silently
receives the electric matter by means of the trees,
grafs, &c. till at last it becomes positively electrified
also, and begins to feed on a current of electricity from
the surface downwards. The causes which at first
produced the electricity of the clouds (and which are
treated of under the article Thunder), still continuing
to act, the power of the electric current becomes
inconceivably great. The danger of the thunder-storm
now begins; as for the force of the lightning is di-
rected to some place below the surface of the earth,
it will certainly dart towards that place, and shatter
every thing to pieces which resists its passage. The
benefit of conducting-rods will now also be evident:
for we are sure that the electric matter will in all cases
take the way where it meets with the least resistance;
and this is through the lightning, or rather over the
surface, of metals. In such a case therefore, if there
happen to be a house furnished with a conductor di-
rectly below the cloud, and at the same time a zone of
negatively electrified earth not very near the
foundation of the house, the conductor will almost
certainly be struck, but the building will be unhurt.
If the house wants a conductor, the lightning will
nevertheless strike in the same place, in order to get at
the negatively electrified zone abovementioned; but
the building will now be damaged, because the ma-
terials of it cannot readily conduct the electric fluid.

We will now be able to enter into the dispute, Why
whether the preference is due to knobbed or pointed con-
ductors for preserving buildings from strokes of light-
ning? Ever since the discovery of the identity of
electricity and lightning, it hath been allowed by all rable
parties, that conductors of one kind are in a manner
essentially necessary for the safety of buildings in those
countries where thunder-storms are very frequent.
The principle on which they act hath been already ex-
plained; namely, that the electric fluid, when im-
pelled by any power, always goes to that place where

It
Lightning, it meets with the least resistance, as all other fluids also do. As metals, therefore, are found to give the least resistance to its passage, it will always choose to run along a metallic rod, in preference to a passage of any other kind. We must, however, carefully consider a circumstance which seems to have been too much overlooked by electricians in their reasonings concerning the effects of thunder-rods; namely, that lightning or electricity, never strikes a body, merely for the sake of the body itself, but only because of means of that body it can readily arrive at the place of its destination. When a quantity of electricity is collected from the earth, by means of an electric machine, a body communicating with the earth, will receive a strong spark from the prime conductor. The body receives this spark, not because it is itself capable of containing all the electricity of the conductor and cylinder, but because the natural situation of the fluid being disturbed by the motion of the machine, a stream of it is sent off from the earth. The natural powers, therefore, make an effort to supply what is thus drained off from the earth; and as the individual quantity which comes out is most proper for supplying the deficiency, as not being employed in any natural purpose, there is always an effort made for returning it to the earth. No sooner, then, is a conducting body, communicating with the earth, presented to the electrical machine, than the whole effect of the electricity is directly directed against that body, not merely because it is a conductor, but because it leads to the place where the fluid is directed by the natural powers by which it is governed, and at which it would find other means to arrive, though that body were not to be preferred. That this is the case, we may very easily satisfy ourselves, by presenting the very same conducting substance in an insulated state to the prime conductor of the machine; for then we shall find, that only a very small spark will be produced. In like manner, when lightning strikes a tree, a house, or a thunder rod, it is not because these objects are high, or in the neighbourhood of the cloud, but because they communicate with some place below the surface of the ground, against which the impetus of the lightning is directed; and at that place the lightning would certainly arrive, though none of the above-mentioned objects had been interposed.

The fallacy of that kind of reasoning generally employed concerning the use of thunder-rods, will now be sufficiently apparent. Because a point prefented to an electrified body in our experiments, always draws off the electricity in a silent manner; therefore Dr Franklin and his followers have concluded, that a pointed conductor will do the same thing to a thundercloud, and thus effectively prevent any kind of danger from a stroke of lightning. Their reasoning on this subject, they think, is confirmed by the following fact among many others. "Dr Franklin's house at Philadelphia was furnished with a rod extending nine feet above the top of the chimney. To this rod was connected a wire of the thickness of a goole-quill, which descended through the wall of the fair-case; where an interruption was made, so that the ends of the wire, to each of which a little bell was fixed, were distant from each other about six inches; an insulated brass ball hanging between the two bells. The author was Lightning, one night waked by loud cracks, proceeding from his apparatus in the fair-case. He perceived, for the brass ball, instead of vibrating as usual between the balls, was repelled and kept at a distance from both; while the fire sometimes palled in very large quick cracks directly from bell to bell; and sometimes in a continued dense white stream, seemingly as large as his finger; by means of which the whole fair case was electrified, as with sun-flame, so that he could see to pick up a pin. From the apparent quantity of electric matter of which the cloud was thus evidently robbed, by means of the pointed rod (and of which a blunt conductor would not have deprived it), the author conceives, that a number of such conductors must considerably lessen the quantity of electif fluid contained in any approaching cloud, before it comes so near as to deliver its contents in a general stroke."

For this very reason, Mr Benjamin Wilson and his followers, who constitute the opposite party, have determined that the use of pointed conductors is utterly unsafe. They say, that in violent thunder storms the whole atmosphere is full of electricity; and that attempts to exhaust the vast quantity there collected, are like attempting to clear away an inundation with a shovel, or to exhaust the atmosphere with a pair of bellows. They maintain, that though pointed bodies will effectually prevent the accumulation of electricity in any substance; yet if a non-electrified body is interposed between a point and the conductor of an electrical machine, the point will be struck at the same moment with the non-electrified body, and at a much greater distance than that at which a knob would be struck. They affirm also, that by means of this silent solicitation of the lightning, inflammable bodies, such as gun-powder, tinder, and Kunkel's phosphorus, may be set on fire; and for these last facts they bring decisive experiments. From all this, they say, it is evident that the use of pointed conductors is unsafe. They solicit a discharge to the place where they are; and as they are unconnected with the conductor of the whole electricity in the atmosphere, it is impossible, for us to determine whether the discharge they solicit may not be too great for our conductor to bear; and consequently all the mischief arising from thunder-storms might be expected, with this additional and mortifying circumstance, that this very conductor hath probably solicited the fatal stroke, when without it the cloud might have passed harmles over our heads without striking at all.

Here the reasoning of both parties seems equally wrong. They both proceed on this erroneous principle, that in thunder-storms the conductor will always solicit a discharge, or that at such times all the elevated objects on the surface of the earth are drawing off the electricity of the atmosphere. But this cannot be the case, unless the electricity of the earth and of the atmosphere is of a different kind. Now, it is demonstrable, that until this difference between the electricity of the atmosphere and of the surface of the earth ceases, there cannot be a thunder-storm. When the atmosphere begins to be electrified either positively or negatively, the earth, by means of the inequalities and moisture of its surface, but especially by the vegetables which grow.
Lightning. grow upon it, absorbs that electricity, and quickly becomes electrified in the fame manner with the atmosphere. This absorption, however, ceases in a very short time, because it cannot be continued without setting in motion the whole of the electric matter contained in the earth itself. Alternate zones of positive and negative electricity will then begin to take place below the surface of the earth, for the reasons mentioned under the article Electricity, sect. vi. § 3. Between the atmosphere and one of these zones, the stroke of the lightning always will be. Thus supposing the atmosphere is positively electrified, the surface of the earth will, by means of trees, &c, quickly become positively electrified also; we shall suppose to the depth of 10 feet. The electricity cannot penetrate farther on account of the resistance of the electric matter in the bowels of the earth. At the depth of 10 feet from the surface, therefore, a zone of negatively electrified earth begins, and to this zone the electricity of the atmosphere is attracted; but to this it cannot get, without breaking through the positively electrified zone which lies uppermost, and shattering to pieces every bad conductor which comes in its way. We are very sure, therefore, that in whatever places the outer-zone of positively electrified earth is thinner there the lightning will strike, whether a conductor happens to be present or not. If there is a conductor, either knobbed or sharp-pointed, the lightning will indeed infallibly strike it; but it would also be frisky a house situated on that spot, without any conductor; and though the house had not been there, it would have frisked the surface of the ground itself. Again, if we suppose the house with its conductor to stand on a part of the ground where the positively electrified zone is very thick the conductor will neither silently draw off the electricity, nor will the lightning strike it, though perhaps it may strike a much lower object, or even the surface of the ground itself, at no great distance; the reason of which undoubtedly is, that there the zone of positively electrified earth is thinner than where the conductor was.

We must also observe, that the Franklinians make their pointed conductors to be of too great consequence. To the houses on which they are fixed, no doubt, their importance is very great: but in exhausting a thunder-cloud of its electricity, their use must appear trifling; and to insist on it, ridiculous. Innumerable objects, as trees, grasses, &c. are all conspiring to draw off the electricity, as well as the conductor, if it could be drawn off; but of effecting this there is an impossibility, because they have the same kind of electricity with the clouds themselves. The conductor hath not even the power of attracting the lightning a few feet out of the direction which it would choose of itself. Of this we have a most remarkable and decisive instance in what happened to the magazine at Purfleet in Essex, on May 15, 1777. That house was furnished with a pointed conductor, raised above the highest part of the building; nevertheless, about fix in the evening of the above-mentioned day, a flash of lightning struck an iron cramp in the corner of the wall considerably lower than the top of the conductor, and only 46 feet in a sloping line distant from the point. This produced a long dispute with Mr. Wilfon concerning the propriety of using pointed conductors; and, by the
Lightning, which is to be made at any rate; and if none were to be made through the conductor was absent, its presence will not be able to effect any.

An objection to the use of conductors, whether blue or pointed, may be drawn from the accident which happened to the poor house at Hecington, which was struck by lightning though furnished with eight pointed conductors; but from an accurate consideration of the manner in which the conductors were situated, it appears that there was not a possibility of their preventing any stroke. See Philosophical Transactions, Vol. LXXII. p. 361.

In a late publication on the subject of electricity by Lord Monf, we find a new kind of lightning made mention of, which he is of opinion may give a fatal stroke, even though the main explosion be at a considerable distance; a mile, for instance, or more. This he calls the electrical returning stroke; and exemplifies it in the following manner, from some experiments made with a very powerful electrical machine, the prime conductor of which (six feet long, by one foot diameter) would generally, when the weather was favourable, strike into a brass ball connected with the earth, to the distance of 18 inches or more. In the following account, this brass ball, which we shall call A, is supposed to be constantly placed at the striking distance; so that the prime conductor, the instant that it becomes fully charged, explodes into it.

Another large conductor, which we shall call the second conductor, is suspended, in a perfectly inflated state, from the prime conductor than the striking distance, but within its electrical atmosphere; at the distance of six feet, for instance. A person standing on an insulating stool touches this second conductor very lightly with a finger of his right hand; while, with a finger of his left hand, he communicates with the earth, by touching very lightly a very large conductor, which we shall call B, a metallic ball fixed at the top of a metallic stand, on the floor, and which we shall call B.

While the prime conductor is receiving its electricity, sparks pass (at least if the distance between the two conductors is not too great from the second conductor than the striking distance, to the inflated person's right hand) while similar and simultaneous sparks pass out from the finger of his left hand into the second metallic ball B, communicating with the earth. These sparks are part of the natural quantity of electric matter belonging to the second conductor, and to the inflated person; driven from them into the earth, through the ball B, and its stand by the elastic pressure or action of the electrical atmosphere of the prime conductor. The second conductor and the inflated person are hereby reduced to a negative state.

At length, however, the prime conductor, having acquired its full charge, suddenly strikes into the ball A, of the first metallic stand, placed for that purpose at the striking distance of 17 or 18 inches. The explosion being made, and the prime conductor suddenly robbed of its electric atmosphere, its pressure or action on the second conductor, and on the inflated person, as suddenly ceases; and the latter instantly feels a smart returning stroke, though he has no direct or visible communication (except by the floor) either with the striking or struck body, and is placed at the distance of five or six feet from both of them. This returning stroke is evidently occasioned by the sudden re-entrance of the electric fire naturally belonging to his body and to the second conductor, which had before been expelled from them by the action of the charged prime conductor upon them; and which returns to its former place in the instant that action or elastic pressure ceases. The author shows, that there can be no reason to suppose that the electrical discharge from the prime conductor should in this experiment divide itself at the instant of the explosion, and go different ways, so as to strike the second conductor and inflated person in this manner, and at such a distance from it.

When the second conductor and the inflated person are placed in the densest part of the electrical atmosphere of the prime conductor, or just beyond the striking distance, the effects are still more considerable; the returning stroke being extremely severe and pungent, and appearing considerably sharper than even the main stroke itself, received directly from the prime conductor. This circumstance the author alleges as an unanswerable proof that the effect which he calls the returning stroke, was not produced by the main stroke being any wire divided at the time of the explosion, since no effect can ever be greater than the cause by which it is immediately produced. Having taken the returning stroke eight or ten times one morning, he felt a considerable degree of pain across his chest during the whole evening, and a disagreeable sensation in his arms and wrists all the next day.

We come now to the application of this experiment, and of the doctrine deduced from it, to what pass in nature, and during a thunder-storm; in which there is reason to expect similar effects, but on a larger scale:—a scale so large indeed, according to the author's representation, that persons and animals may be destroyed, and particular parts of buildings may be considerably damaged, by an electrical returning stroke, occasioned even by some very distant explosion from a thunder-cloud:—politely at the distance of a mile or more.

It is certainly easy to conceive, that a charged extensive thunder-cloud must be productive of effects similar to those produced by the author's prime conductor. Like it, while it continues charged, it will, by the superinduced electric pressure of its atmosphere, use the author's own expression, drive into the earth apart of the electric fluid naturally belonging to the bodies which are within the reach of its widely extended atmosphere; and which will therefore become negatively electrical. This portion too of their electric fire, as in the artificial experiments, will on the explosion of the cloud, at a distance, and the effusion of its action upon them, suddenly return to them; so as to produce an equilibrium, and restore them to their natural state.

To this theory, the authors of the Monthly Review have given the following answer: "We cannot, however, agree with the ingenious author, with respect to the greatest of the effects, or of the danger to be apprehended from the returning stroke in this case: as we think his estimate is grounded on an erroneous foundation. Since (says he) the density of the electrical atmosphere of a thunder-cloud is so immense, when compared to the electrical density of the electrical atmosphere of any prime conductor, charged by means of any electrical
In the case of a man who is abroad, and in an open field, during the time of an explosion— as he is unconnected with other masses of matter above him, no more than the precise quantity of electric fire, which had been before expelled from his body, will suddenly return into it at the instant of a distant explosion: and that this quantity is not usually very large, may be inferred from many considerations.

When a person standing on the ground holds a pair of Mr. Canton's balls in his hand, while a highly charged thunder-cloud is suspended over his head; the angle made by the balls indicates the electrical state of that person, or the quantity of natural electricity of which his body is at that time deprived, by the action of the (positively) charged cloud hanging over him. But we have never seen the repletion of the balls so considerable, as to furnish any just apprehensions that the return of his natural electric matter, however sudden, could be attended with injury to him: nor would he be sensible of any commotion on the balls suddenly coming together; though a spark might undoubtedly be perceived, at that instant, were he insulated, and placed in the same manner with the author when he tried the above-mentioned experiment.

The author neverthless observes, that there have been instances of persons who have been killed by natural electricity having been found with their fingers, and with their feet damaged by the electrical fire; but who have not had, over their whole body, any other apparent marks of having been struck with lightning. He adds, 'if a man walking out of doors were to be killed by a returning stroke, the electrical fire would rush into that man's body through his feet, and his feet only; which would not be the case, were he to be killed by any main stroke of explosion, either positive or negative.'

It would be no difficult task, we think, to account for these appearances in a different manner; were all the circumstances attending the case minutely ascertained: but without interrogating the dead on this subject, we may more satisfactorily appeal to the experience of the living (p), to show, that though the returning stroke must take place, in all thunder-forms, in some degree or other; yet it is not of that alarming magnitude which the author ascribes to it. If, in any particular thunder-form, a man in the open fields could be killed, at the instant of a distant explosion, merely by the return of his own electric fire, which had before been driven out of his body; surely numerous observations of persons who had experienced the returning stroke, in lighter degrees, would be familiar; and scarce a great thunder-storm must have occurred, in which one

(c) "We suppose the person not to be so situated, that the returning fire of other bodies must necessarily pass through his body."

(p) "The author does indeed produce a living evidence, in the case of a person at Vienna, who, he has been credibly informed, received an electrical stroke, by having held one hand accidentally in contact with an interrupted metallic conducting rod, at the instant that a thunder-cloud exploded at the distance, as was conjectured, of above half an English mile. He likewise observes, that a 'very strong, bright, and sudden stroke' (or spark) of electrical fire has been seen, by several electricians, to pass in the interval, or interruption, purposely left in the conducting rod of a house at the instant of a distant explosion; and 'when it was fully proved, by the sharp point of the conductor not being melted, or even tinged,' that the conductor itself had not been struck. These observations, however, do not by any means prove the magnitude or danger of the returning stroke, but merely its existence, which we do not contest."
Lightning, one person or another must not, at the instant of an explosion, have felt the effects of the returning stroke in some degree or other—from that of a violent concussion, to that of a faint and almost imperceptible pulsation. But no observer of this kind is known to us, nor have we ever heard of any person's experiencing any kind of electrical commotion in a thunder-storm, except such as have either been directly struck, or have happened to be in the vicinity of the spot where the explosion took place.

The author has been aware of this objection, which he proposes, and endeavours to remove; but his answer to it amounts to little more than what has been already quoted from him: that is, to a simple estimate of the enormous difference between the electrical density of the atmosphere and the elastic electrical pressure, of the atmosphere of an extensive thunder cloud, and that of a charged prime conductor. We have already observed, that this is not a proper method of estimating their different effects, when these two causes, how unequal ever in power, are considered as exerting that power on bodies containing a limited and comparatively small, quantity of electric matter.

We have been induced to discuss this subject thus particularly, with a view to quiet the minds of the timorous; as the author's extension of his principles respecting the returning stroke in artificial electricity to what passes in natural electricity, holds out a new, and, in our opinion, groundless subject of terror to those who in the midst of their apprehensions, have hitherto only dreaded the effects of a thunder-storm when it made near approaches to them: but who, if this doctrine were believed, would never think themselves in security while a thunder-cloud appeared in sight, unless sheltered in a house furnished with proper conductors:—for we should not omit to remark that a subsequent observation tends to diminish their fears, by showing that high and pointed conductors tend to secure both persons and buildings against the various effects of a Return stroke whatever, as well as of the main stroke.

A late melancholy accident which happened in Scotland has afforded Lord Mahon an opportunity of bringing additional arguments in favour of his system. An account of this accident is given by Patrick Brydone, Esq.; R. S. in the 77th volume of the Philosophical Transactions. It happened on the 19th of July 1785, near Coldstream on the Tweed. The morning was fine, with the thermometer at 68°; but about eleven o'clock the sky became obscured with clouds in the south-east; and betwixt twelve and one a storm of thunder and lightning came on. This storm was at a considerable distance from Mr Brydone's house, the intervals between the flashes and crack being from 2 to 30 seconds, so that the place of explosion must have been betwixt five and six miles off; but while our author was observing the progress of the storm, he was suddenly surprized with a loud report neither preceded nor accompanied by any flash of lightning, which resembled the explosion of a great number of muskets, in such quick succession, that the ear could scarcely discriminate the sounds. On this this thunder and lightning infantly ceased, the clouds began to separate, and the sky soon recovered its serenity.

In a little time Mr Brydone was informed, that a man with two horses had been killed by the thunder; and, on running out to the place, our author found the two horses lying on the spot where they had been first struck, and still yoked to the car. On the body of the man who was killed had been carried, Mr Brydone himself had not an opportunity of examining it, but was informed by Mr Bell, minister of Coldstream, who saw it, that the skin of the right thigh was much burnt and shrivelled; that there were many marks of the same kind all over the body, but none on the legs; his clothes, particularly his shirt, had a strong smell of burning; and there was a zigzag line of about an inch and a quarter broad, extending from the chin to the right thigh, and which seemed to have followed the direction of the buttons of his waistcoat. The body was buried in two days without any appearance of purification.

Mr Brydone was informed by another person who accompanied him that was killed, of the particular circumstances. They were both driving carts loaded with coal; and James Lander, the person who was killed, had the charge of the foremost cart and was sitting on the fore part of it. They had crossed the Tweed a few minutes before at a deep ford, and had almost gained the highest part of an ascent of about 65 or 70 feet above the bed of the river, when he was flung on with the report above mentioned, and saw his companion with the horses and cart, fall down. On running up to him, he found him quite dead, with his face livid, his clothes torn in pieces, and a great smell of burning about him. At the time of the explosion he was about 24 yards distant from Lander's cart, and had him full in view when he fell; but felt no shock, neither did he perceive any flash or appearance of fire. At the time of the explosion his horses turned round, and broke their harness. The horses had fallen on their left side, and their legs had made a deep impression on the dust; which, on lifting them up, showed the exact form of each leg, so that every principle of life seemed to have been extinguished at once, without the least struggle or convulsive motion. The hair was mingled over the greatest part of their bodies, but was most perceptible on their belly and legs. Their eyes were dull and opaque, as if they had been burnt; and though Mr Brydone saw them in half an hour after the accident happened. The joints were all taut, and he could not observe that any of the bones were broken or dislocated, as is said to be sometimes the case with those who are killed by lightning. The left shaft of the cart was broken, and splinters had been thrown off in many places; particularly where the timber of the cart was connected by nails or cramps of iron. Many pieces of the coal were thrown off a considerable distance, and some of them had the appearance of being torn up as if by a violent blow of a pick-axe; and the small stones and dust were scattered on each side of the road. The tracks of the wheels were strongly marked in the dust, both before and behind those holes, but did not in the smallest
Lightning, smallest degree appear on the spots themselves for upwards of a foot and a half. There were evident marks of fusion on the iron rings of the wheels; the surface of the iron, the whole breadth of the wheel, and for the length of about three inches, was become bluish, and lost its polish and smoothness, and was formed into drops which projected febibly, and had a roundish form; but the wood did not appear any way injured by the heat which the iron must have conceived. To determine whether these were made by the explosion which had torn up the ground, the cart was pushed back on the same track he had described on the road; and the marks of fusion were found exactly to correspond with the centres of the holes. They had made almost half a revolution after the explosion; which our author affcribes to the cart being pulled a little forward by the fall of the horses. Nothing remarkable was observed on the opposite part of the wheel. The broken ground had a smell something like that of ether; the soil itself was very dry and gravelly.

The catastrophe was likewise observed by a shepherd, at the distance of about 200 or 300 yards from the spot. He said, that he was looking at the two carts going up the bank when he heard the report, and saw the foremost man and horses fall down; but observed no lightning, nor the least appearance of fire, only he saw the dust rise about the place. There had been several flashes of lightning before that from the south-east; whereas the accident happened to the north-west of the place where he stood. He was not sensible of any shock; the soil itself was very dry and gravelly.

The author next gives an account of several phenomena which happened the same day, and which were evidently connected with the explosion. A shepherd tending his flock in the neighbourhood, observed a lamb drop down; and said, that he felt at the same time as if fire had passed over his face, though the lightning and claps of thunder were at a considerable distance. He ran up to the creature immediately, but found it quite dead; on which he tied it with his knife, and the blood flowed freely. The earth was not torn up; nor did he observe any dust rise, though he was only a few yards distant. This happened about a quarter of an hour before Lauder was killed, and the place was only about 300 yards distant.

About an hour before the explosion, two men standing in the middle of the Tweed, filling for salmon, were caught in a violent whirlwind, which felt sultry and hot, and almost prevented them from breathing. They could not reach the bank without much difficulty and fatigue; but the whirlwind lasted only a very short time, and was succeeded by a perfect calm.

A woman making hay, near the banks of the river, fell suddenly to the ground, and called out that she had received a violent blow on the foot, and could not imagine from whence it came; and Mr Bell, the minister aforesaid, when walking in his garden, a little before the accident happened to Lauder, felt several times a tremor in the ground.

The conclusion drawn from these facts by Brydone is, that at the time of the explosion the equilibrium between the earth and the atmosphere seems to have been completely restored, as no more thunder was heard nor lightning observed; the clouds were dispelled, and the atmosphere returned to its most perfect tranquility; but how this vast quantity of electric matter (say he) could be discharged from the one element to the other, without any appearance of fire, shall not pretend to examine. From the whole it would appear, that the earth had acquired a great superabundance of electric matter, which was every where endeavouring to fly off into the atmosphere. Perhaps it might be accounted from the excessive dryness of the ground, and for many months the almost total want of rain, which is probably the agent that nature employs in preserving the equilibrium between the two elements.

Lord Malmesbury states, that his observations on this accident are published in the same volume, endeavour to establish the following positions as facts.

1. That the man and horses were not killed by any direct main stroke of explosion from a thunder-cloud either positively or negatively electrified.

2. They were not killed by any transferred main stroke either positive or negative.

3. The mischief was not done by any lateral explosion. All these are evidently true, at least with respect to lightning at that time falling from the clouds; for all the lightning which had taken place before was at a great distance.

4. They were not suffocated by a sulphureous vapour or smell which frequently accompanies electricity. This could not account for the pieces of coal being thrown to a considerable distance all round the cart, and for the splinters of the wood which were thrown off from many parts of the cart.

5. It might be imagined by some that they were killed by the violent commotion of the atmosphere, occasioned by the vicinity of the electrical explosion, in a manner similar to the fatal wounds that sometimes have been known to have been given by the air having been suddenly displaced by a cannon-ball in its passage through the atmospheric fluid, though the cannon-ball itself had evidently neither struck the person wounded nor grazed his clothes. The dust that rose at the time of the explosion might be brought as an argument in favour of the opinion, that a sudden and violent commotion of the air did occasion the effects produced. But such an explanation would not account for the marks of fusion on the iron of the wheels, nor for the hair of the horses being singed, nor for the skin of Lauder's body having been burnt in several places.

6. From these different circumstances his Lordship is of opinion, that the effects proceeded from electricity; and that no electrical fire did pass immediately, either from the clouds into the cart, or from the cart into the clouds. From the circular holes in the ground, of about 20 inches diameter, the respective centres of which were exactly in the track of each wheel, and the corresponding marks of fusion in the iron of the wheels, it is evident that the electrical fire did pass from the earth to the cart, or from the cart to the earth, through that part of the iron of the wheels which was in contact with the ground. From the splinters which had been thrown off in many places, particularly where the timber was connected by nails or cramps of iron, and from various other effects mentioned in Mr Brydone's account, it is evident, that there must have been a great commotion in the electrical fluid in all, or at least in different parts of the cart, and in the bodies of the man and horses, although there were no lightning.

7. All these phenomena, his lordship argues, may be explained in a satisfactory manner from the doctrine already...
before entering upon the subject of the main explosion, however, he takes notice of the other phenomena already mentioned in Mr Brydone's account.

With regard to the case of the lamb, his lordship is of opinion, that it belongs to the most simple class of returning strokes, viz. that which happens at a place where there is neither thunder nor lightning near and prominent or jingle lattice electrical pressure of the electrical atmosphere of a single main cloud, as well as an assemblage of clouds. It appears (says he) by Mr Brydone's account, that the shepherd who saw the lamb fall, was near enough to it to feel, in a small degree, the electrical returning stroke at the same time that the lamb dropped down.

The blow which the woman received on the foot was unquestionably the returning stroke. When a person walking, or standing out of doors, is knocked down or killed by the returning stroke, the electrical fire must rush in, or rush out, as the case may be, through the person's feet, and through them only; generally known and generally believed, by reason of the thick smoke, and the report the lightning was at a considerable distance, viz. between five and six miles. The loud report resembled the firing of several muskets or clove together, that the ear could scarcely separate the sounds, and was followed by no rumbling noise like the other claps. This indicates, that the explosion was not far distant, and likewise that it was not extremely near: for, if the explosion had been very near, the ear could not at all have separated the sounds.

Let us now suppose a cloud, eight, ten, or twelve miles in length to be extended over the earth, and let another cloud be situated between that and the earth, and let them both be supposed charged with the same kind of electricity, and both positive. Let us farther suppose the lower cloud to be near the earth, only a little beyond the striking distance; and the man, cart, and horses, to be situated under that part of the cloud which is nearest the earth, and to be exactly as described by Mr Brydone, viz. near the summit of an hill, and followed by another a little farther down; and let us suppose the two clouds to be near each other just over the place where the man and horses are: Let the remote end of the cloud approach the earth, and discharge its electricity into it. In this case the following effects will take place.

With the upper cloud discharges its electricity into the earth from the remote end, the lower cloud will discharge its electricity into the nearer end of the upper cloud, which is supposed to be directly over the place of the cart and horses, or nearly so. This accounts for the loud report of thunder that was unaccompanied by lightning. The report must be loud from its being near; but no lightning could be perceived, by reason of the thick cloud situated immediately between the spectator and the place between the two clouds where the lightning appears.

As the lower cloud gradually approached towards the earth, that part of the latter where the man and horses were most of course become superinduced Lightning, by the elastic electrical pressure of the electrical atmosphere of the thunder-cloud, which superinduced elastic electrical pressure must gradually have increased as the cloud came closer to the earth, and approached nearer to the limit of the striking distance.

Hence, if any conducting body (not having prominent or conducting points) were to be placed upon the surface of the earth, and there electrically insulated; then such conducting body, by the laws of electricity, must, at its upper extremity (namely the part nearest to the positive cloud) become negative; at its lower extremity it must become positive; and, at a certain intermediate point, it will be neither plus nor minus. This insulated conducting body, thus situated, will be in three opposite states at the same time, that is to say, it will be at the same time, positively electrified, negatively electrified, and not electrified at all. For a demonstration of this proposition, his lordship refers to his Principles of Electricity; it is a generally known and established fact in electricity.

If this conducting body on the surface of the earth be not insulated, or be but imperfectly insulated, then the whole of such body, from its being immersed in the electrical atmosphere of the positive cloud, will become negative; because part of the electricity of the conducting body will in this case pass into the earth; and the conducting body will become the more negative in exact proportion as the more deeply immersed into the dense part of the elastic electrical atmosphere of the approaching thunder-cloud.

When the lower cloud comes suddenly to discharge with an explosion its superabundant electricity into the upper one, then the elastic electrical atmosphere of the former will cease to exist; consequently the electrical fluid, which had been gradually expelled into the common stock from the conducting body on the surface of the earth, must, by the sudden removal of the superinduced elastic electrical pressure of the electrical atmosphere of the thunder-cloud, suddenly return from the earth into the said conducting body, producing a violent commotion similar to that of the current shock of a Leyden jar in its sensation and effects.

This, which his lordship calls the electrical returning stroke, he supposes to have been what killed the effects of man and horses in the present case, they having become strongly negative before the explosion. The man, according to Mr Brydone's account, was fitting up his horse to receive the stroke, and his legs were hanging over the fore part of the cart at the time of the explosion. The returning stroke, therefore, could not enter his body through the legs; and this accounts for the skin of his legs not having been at all burnt or thrivelled, as the skin was on many other parts of his body; and it likewise shows the reason why the zigzag line, which was terminated by the chin, did not extend lower than the thigh.

Mr Brydone likewise informs us, that the hair of the horses was much singed over the greatest part of their bodies, but was most perceptible on the belly and legs. This is easily accounted for by the returning stroke; for the lower part of the bodies of these animals must of course have been more affected than any other part, as the electrical fire must have rushed suddenly into their bodies through their legs, which had made a deep impression on the duff.
17. The various effects produced on the cart may be explained also from the returning stroke with equal facility. The splinters were thrown off by reason of the interruption of good conductors; the wood being a much less perfect conductor than the iron. It is also evident, that it was the electrical returning fire that produced the marks of friction on that part of the iron of the wheels which was in contact with the ground; insuch as the whole electricity, at the instant of the explosion, did enter at these places.

18. No person in the least versed in the principles of electricity can hesitate to assent to the proposition, that the electrical returning stroke must exist under circumstances similar to those explained above; but it may be objected, as the reviewers formerly did, that the quantity of electricity naturally contained in the body of a man is far too small to produce such violent effects. For an answer to this objection, his lordship refers to his book: By way of corroboration, however, he makes the following remarks.

19. No person can reasonably conclude, that the force of a returning stroke must always be weak when compared with the discharging fire. The returning stroke from the body, by reason that a man’s body contains but a small quantity of electricity: for it has never been proved that a man’s body contains only a small quantity of electrical fluid; neither is there the smallest reason to believe such an hypothesis, which appears, on many accounts, to be completely erroneous; and if that hypothesis be erroneous, the objection to the strength of an electrical returning stroke remains altogether unsupported by argument. When a body is said to be positive (says his lordship), it simply means, that the body contains more than its natural share of electricity, but does not say that it is completely saturated with it. In like manner, when a body is said to be minus or negative, it only signifies, that the body contains less than its natural share of electricity; but does not imply that such a body is completely exhausted of the electricity which it contains in its natural state.

20. An hypothesis which easily accounts for any natural phenomenon has a much better claim to our attention than an opposite one, which prevents it from being intelligibly explained. There is no reason to conclude that any electrical machine, of any given size, is capable of rendering a conducting body either completely plus or completely minus; but far otherwise. And it would have been as logical for any person some years ago (when electrical machines were not brought to their present state) to have maintained, that those very imperfect machines were capable of rendering a body completely positive or completely negative, as for us to pretend to do it at this day. We evidently have not, with our machines, even approached the limit of electrical strength, particularly in respect to the returning stroke, produced by the disturbed electrical fluid of a man’s body; hence the returning stroke is not so sudden as that of the prime conductor; the returning stroke from the common glass globes of less than nine inches in diameter: the returning stroke in this case will be so weak, that it can hardly be said to exist, but if the experiment be made by means of a large cylinder, and by means of a metallic prime conductor of about three feet four inches long, by nearly four inches and half diameter, and also by means of another metallic body of equal dimensions with this prime conductor, then there will be no kind of comparison between the strength of the returning stroke obtained out of the striking distance, and the strength of the main stroke received immediately from the prime conductor; the sharpness and pungency of the returning stroke being so much greater. The returning stroke, like the sudden discharge of a weakly electrified Leyden jar, provided due attention be paid to the rules for obtaining a strong returning stroke.

21. In the case of a returning stroke, the strength depends, according to his lordship’s hypothesis, not so much on the quantity of the electrical fluid, as on its velocity; whence also it depends less on the quantity of surface used than on the strength of the electrical pressure of the electrical atmospheric superinduced upon the body struck previous to the explosion. But the electrical pressure of the electrical atmospheric electric of the great thunder-cloud which produced the mischief on the present occasion, must have been immensely greater than that of a metallic prime conductor; and it is not surprising that the effects should be proportioned to the causes.

22. His lordship next accounts for the returning stroke not being felt by the man who followed Launder’s cart. This, he thinks, may in some degree be accounted for by the latter having been higher up the bank; though it may better be done by supposing the man to have been pending nearer the earth over the spot where Launder was killed, than over the place where his companion was; for, in order to receive a dangerous returning stroke, it is necessary that he should be imbered, not merely in the cloud’s atmosphere, but in the dense part of the cloud’s electrical atmosphere. It may also be accounted for by supposing that the second cart was either better connected with the common flock, or better insulated; for either of these circumstances will weaken a returning stroke prodigiously. Now Mr. Brydone mentions, that there had been an almost total want of rain for many months. He also says, that the ground, at the place where Launder was killed, was remarkably dry, and of a gravelly foil. This state of the ground was particularly adapted to the production of the electrical returning stroke, when produced upon the large scale of nature, where the elastic electrical pressure is so powerful. To these arguments adduced by his lordship for the existence and strength of the electrical returning stroke, we shall add an account of some experiments published.
Lightning in the Gentleman's Magazine for 1758. They were made with an insulated rod of iron of considerable length, rising some feet higher than a common conductor placed at the other end of the house. A set of bells were affixed to the former, which in a thunder storm, even when the thunder was four or five miles distant, was rung by the electricity of the atmosphere; but whenever a flash of lightning burst from the cloud, even though at the distance just mentioned, the same flash, according to our author, passed through the conductor also, and the bells ceased to ring sometimes for several seconds; then they began again, and continued to ring till they were stopped by another flash. This flash which passed thro' the conductor was undoubtedly what earl Stanhope calls the returning stroke, of which we must now give some explanation: And in considering the whole doctrine of that stroke, together with the particular explanation laid down by his lordship, the following observations naturally occur.

1. In the experiments made by his lordship to demonstrate the existence of the returning stroke, there is a deception, of which the reviewers take notice, viz. that the man touches a large prime conductor, which, by the operation of the machine, becomes negatively electrified as well as himself. Hence when the discharge is made, all the fire returning to that conductor must pass through his body as well as that of which his body itself is supposed to be deprived; and this, though no other cause intervened, must nearly double the strength of the shock. To make the experiment more fairly, it would be necessary to take away this second conductor, and let the man only touch the brass ball communicating with the earth.

2. In this experiment there is another deception, not taken notice of by the reviewers, viz. that any body immersed in a positive electrical atmosphere becomes negative. Hence the second conductor, by being applied to the air positively electrified by the machine, becomes almost as strongly negative as if another machine had been applied to it on purpose; and this negative electricity will be stronger in proportion to the strength of electricity in the air surrounding it. Again, it is well known that a plate of air may be charged by means of two smooth pieces of metal held at a small distance from each other, one of them connected with an electrical machine, and the other with the earth. Now supposing instead of the usual communication, that a man standing upon an insulating floor, held the lower metallic plate in one hand, and with the other hand touched the earth, or a conductor communicating with it, it is plain, that by touching the upper plate, the electricity acquired by the air between them would be discharged, and that the man would feel what earl Stanhope calls the returning stroke; but which in truth is the shock of a charged electric substance, and would therefore be proportionately pungent. Now, in his lordship's experiments, the two conductors answer exactly to the two metallic plates above mentioned; the air between them receives a charge, and is discharged by the explosion from the prime conductor, because this conductor forms one of the charging plates. It is true, that the round shape of the conductors renders them unfavourable for trying the experiment; and this is one reason why it requires a great power of electricity to make the returning stroke sensible. The thickness of the plate of air interposed between the two conductors is another reason: but this makes no difference as to the principles for his lordship's experiment is undoubtedly no other than that of the Leyden phial. Were his lordship to use two flat plates instead of round conductors, the deception would then be removed; and we may venture to determine a priori, that the returning stroke would then be not only very severe, but even dangerous, with a very powerful machine and large plates.

3. Though the second conductor were entirely removed, yet there would still be a deception in this experiment, for then the surface of the man's body would act in some measure as one of the metallic plates; so that fill the experiment would be on the principles of the Leyden phial, though much weaker than before.

4. In order to make this experiment absolutely without deception the man should stand upon the ground without touching anything; and in that case we may venture to affirm, that he would feel no returning shock. His being insulated varies the nature of the experiment entirely, as will easily be understood from the following considerations.

Under the article Electricity, we have shown, that positive electricity does not collect in accumulation, nor negative electricity in a deficiency, of the fluid; but that all electric phenomena are to be accounted for from the mere motion of the fluid; and that this motion is always a circulation. We have shown, that in the working of a common machine, the electric fluid comes from the earth; that it is accumulated around the prime conductor: evaporates in the air; and is then silently absorbed by the earth, and reconducted to the machine. Hence, in the charging of a machine which works positively, the earth, and all bodies on its surface, for some way round, are in a negative state; because they are then absorbing the electrical fluid from the atmosphere. That part of the earth indeed directly under the feet of the machine, and perhaps some little way farther, is positive; because it is giving out electricity: but the negative portion will be much more extensive. When the conductor is discharged by a spark, then the circulation ceases in a great measure by the collision of the two opposite streams of electric matter. All bodies on the surface of the earth then, as far as it was negatively electrified, must receive what his lordship calls the returning stroke; but the electricity being diffused among such a number, and over such a wide extent, it is no wonder that it should be insensible. If, however, we insulate a large conducting body, and another part of it communicate with the earth by means of a good conductor, we infantly put it in a situation fit for transmitting more than its share of the electricity of the atmosphere, and reducing it to the state of the insulated rubber of an electrical machine, through which the whole quantity of electricity must pass to the phial held towards it, in order to be charged negatively. In proportion to this quantity transmitted the shock must be, not because the conductor has lost a large share of its natural electricity, but because a large quantity is artificially made to pass through it. We may therefore safely venture to assert, that in thunder-florus unless a body transmits more than
5. In his explanation of the accident which happened to Lauder, his lordship is reduced to the greatest difficulty, and makes one of the most philosophically satisfactory shiftings in the world; no less than that of arranging the clouds of heaven, not according to fact, but according to his own imagination. He supposes the existence of two clouds, one below the other; and attributes to them various motions and situations, which we have already taken notice of; but who knows whether such clouds ever existed? His lordship does not pretend that any body ever saw them; and thus he runs into what is termed by logicians a 'vicious circle': he first assumes data, purposely made to accord with his hypothesis, and then proves the hypothesis from the data.

6. Granting the arrangement of the clouds, and every thing his lordship desires, the main requisite is still wanting, viz. a flash of lightning at a distance to produce the returning stroke. According to him, the distant flash and returning stroke must be simultaneous; but Mr Brydone mentions no such thing: on the contrary, there had been no flash for some little time before; and the immense velocity of the electric fluid will not allow us to suppose that it would take up the usual time between thunder-claps in travelling five or six miles.

7. His lordship accounts for no lightning being seen at the time of the explosion in a very arbitrary and unnatural manner, by supposing it to have proceeded from a discharge of the one imaginary cloud into the other; and that it was not seen on account of the thickenss of the lower cloud. A much more natural supposition must be, that it happened below the cart-wheels, but was not seen on account of its being dim: and the cloud of dust which it raised. The fiction of noises, too, indicated a succession of explosions, the flashes of which would be less easily observed than a single large one.

8. It seems altogether impossible, that the return of any quantity of natural electricity into a body should happen that body to pieces. In the present case, the fire entered by a small part of the iron of the wheels, and this part was melted. His lordship does not hesitate to own, that the fusion was a proof that the whole fire belonging to the cart, man, and horses, or at least to the cart and man, had entered by this part of the wheels, and consequently more than naturally belonged to that small part of iron. The same evidence, however, will hold good with regard to every other part. We grant that the fire enters the man's body by his right thigh: this might have therefore been burnt by receiving the fire belonging to the whole body; but it ought then to have quickly diffused itself through the other parts of his body, or at least if any damage had been done, it ought to have been done only to the internal parts. Instead of this, a broad zig-zag line upon his body indicated a vast quantity of electric matter running along the surface without entering the body at all. In like manner, his hat being torn in pieces, indicated a violent explosion of electric matter at his head, where there ought to have been little or no explosion, as none could be wanted there except what the hat had parted with; and it is ridiculous to suppose that hats part with such quantities of electricity as would tear them in pieces by its return. The shivering of the cart, the burning and throwing about of the coals, and all the other circumstances of the case, slip point out in the clearest manner, not a quantity of electric matter returning to supply any natural deficiency, but an enormous explosion of that matter from the earth overwhelming and destroying whatever flood in its way. That two cards were made from the earth is very evident, because there were two holes in it; and the fire of these holes indicates a much greater discharge of electricity than we can reasonably suppose to have been lost by the man, horses, and cart.

We shall now consider the experiment quoted from the correspondent in the Gentleman's Magazine, na of the Thafe, as well as in the report, un-doubtedly show, that, during the time of a thunder-storm, both atmosphere and earth are affected for a very considerable way. With regard to the quantity of this electrical affection, however, it must undoubtedly be excessive when taken altogether, we can by no means agree that it is so taken partially. From an experiment related in the Magazine above quoted it appears, that the electricity of a violent thunder-storm extends sometimes over a circle of 100 miles diameter. "Electricity (says the author) seldom appeared without a flower; but I was surprized, on the 5th of June 1774, that the bells rang with thin and very high sounds, and without the least appearance of rain, till the next post brought me an account of a violent thunder-storm, and very destructive hail, at a village 50 miles distant." We cannot by any means suppose, that all this space was electrified like a charged phial; otherwise, great as the explosions of lightning are, they would still be much greater. This is evident even in our electrical machines. A large phial may be charged much higher than a battery, as appears by the electrometer; but the battery, though charged, will have incomparably more power than a single phial. His lordship appears to have deceived himself in this matter, by mistaking the extent of the electrified surface for the quantity of charge in every part of it. The surface of the earth in a thunder-storm is exactly similar to that of a charged conductor. According to the extent of electrified surface, the park will be great or small; and just so it is with lightning, for some kinds of it are much more destructive than others. In all cases, however, the quantity of electricity in a particular spot is very incomprehensible. Lightning strikes bodies, not because they are highly electrified, but because they afford a communication between the atmosphere and some place below the surface of the earth. This stroke is the aggregate of the whole electricity contained in a circle of probably many miles in diameter; but the returning stroke, if bodies are in their natural state, can only be in proportion to the quantity of electricity in each substance contained within that space. It is in fact the lightning itself diffused through the earth which makes the returning stroke; and it is impossible that every substance within two or three miles of the explosion can receive the whole flash, or another equal to it. It is only in cases where the quantity of electricity, diffused through a great space, happens to discharge...
Lightning itself through a human body or other conducting substance of no great bulk, that the effects upon the latter can be any way considerable. This was undoubtedly the case with the thunder-rod mentioned by the correspondent in the Magazine; for it received either from the atmosphere or from the earth, at the time of every flash, the whole quantity of electricity which had been diffused for a considerable way round. Pointed bodies, we know, draw off electricity very powerfully; in much that an highly charged jar may be deprived of almost all its power by merely presenting a needle to it. We can be at no loss therefore to understand why a pointed conductor should draw off the electricity from a large portion of the surface of the earth, or from a considerable portion of the atmosphere.

We must now, however, inquire into the reason of these appearances of sparks in places at such distance from the explosion of the lightning. To understand this we must always keep in our eye that principle so fully explained under the article Electricity, viz. that there never is, nor can be a real deficiency of the electric fluid in any substance or in any place. It is to be considered as an absolute plenum, and of consequence it can have no other motion than a circulatory one. At every discharge of lightning therefore from the clouds into the earth, or from one cloud into another, there must be a return of the same quantity to those clouds which have made the discharge. In the vast extent of electrified surface, some part of the return must undoubtedly be made at great distances from the place where the explosion of lightning happens. As long as matters remain in their natural state, the electric matter will return by innumerable passages in such small streams, that no perceptible effect upon any single substance can take place. But if a body be so situated, that a large portion of the electric matter must return through it from the earth, then such body will undoubtedly be more affected by every flash than the rest of the substances around it; and if the communication with the earth be interrupted, a flash of fire will be perceived betwixt the conducting substance and the earth at the time that a flash bursts out from the cloud. The strength of such a flash, however, must by no means be supposed equivalent to that of the main stroke of lightning, unless we could suppose the whole electrical power of the vast circle already mentioned to be discharged through the conductor.

But though this may explain the reason of the sparks or flashes observed in the case of the thunder-rod just mentioned, we cannot from this principle account for the accident which befell the man and horses. There was indeed at that time a very violent emission of electricity from the earth, but no dint of flash of lightning happened at the same moment with it, to expel the electricity from the earth. It appears therefore, that the electricity had in this case been accumulating in the earth itself, in a manner similar to that which produces earthquakes; and which is fully explained under that article. The thunder-form was the natural means employed to supply that part of the earth with electricity, which was in the state of charging; and the moment that the quantity thus supplied was thrown back, all signs of electricity must cease, as much as when that thrown in upon one side of a Leyden phial is again thrown off. Hence, when the flash burst out of the earth, and killed the man and horses, that portion of earth which absorbed the electricity till then, required it no longer; and of consequence the thunder-form occasioned by this absorption naturally ceased.

That this disposition to an earthquake did really prevail in the earth at that time, is evident from the tremor which Mr Bell felt on the ground when walking in his garden. The stroke which the woman received on the foot, the death of the lamb, and no doubt many similar circumstances, concurring to show that there was an attempt to restore the equilibrium from the earth, as has been already related. The same disposition to an earthquake, however, was afterwards renewed; and on the 11th of August that same year, a smart shock of an earthquake did actually take place, as Mr Brydone informs us in the same paper.

Besides the different kinds of lightning already treated of, it is by no means uncommon to see flashes unattended by any report. These are always of the fleet kind; they happen very frequently in windy weather when the sky is clear; and likewise when the sky is cloudy, immediately before a fall of rain or snow. The general reason of these appears to be, that the electric fluid is the medium by which the vapours are suspended in the atmosphere; and of consequence, every separation of vapour, whether as rain, snow, or hail, must be attended with what is called a discharge of electrical matter. The reason why this kind of lightning is never attended with any report in that there is no particular object against which the force of the flash is directed; but it dissipates itself among the innumerable conducting bodies with which the atmosphere always abounds. It is, however, in a manner impossible to explain the various ways, in which this subtile fluid acts. We know not, for instance, in what state it is when acting as a medium of connection betwixt the air and vapour, nor in what its discharge into other parts of the atmosphere properly confines. At any rate, we see that a flash of lightning, however limited its extent may appear to us, diffuses its effects over a great space of atmosphere; for after one of these silent flashes in no uncommon things to observe the sky to become obscure though it had been quite clear before; or, if it had been cloudy, to see rain or snow begin to fall in a very few minutes. It is probable indeed, that there is no change whatever that can take place in the atmosphere but by means of electricity; and there is great reason to believe, that the silent discharges of this fluid from one part of the atmosphere to another, many of which are totally invisible, ultimately occasion the whole of the phenomena of Meteorology. See that article.

Various parts of his Lordship's Treatise on Electricity, besides those already quoted, tend to prove the utility of high and pointed conductors, in preference to those which terminate in a ball, or rounded end. Towards the end of the performance, the author discusses this matter very particularly; and enumerates the 'necessary requisites' in erecting them, in number 11; to every one of which we readily sub-
Lightning. As this matter is of a popular nature, and on a subject generally interesting, we shall transcribe this letter, adding a short explanation to particular articles.

The requisites (lays the author) are 11 in number:

1stly, That the rod be made of such substances as are, in their nature, the best conductors of electricity.

2dly, That the rod be uninterrupted, and perfectly continuous.—This is a very material circumstance. One entire piece of metal cannot perhaps be had: but it is not sufficient that the rods, of which the conductor consists, be separably in contact; they should be pressed into actual contact by means of nuts and screws, with a thin piece of sheet-lead between the shoulders of the joints.

3dly, That it be of a sufficient thickness.—A copper rod half an inch square, or an iron rod one inch square, or one of lead two inches square, are thought fully sufficient by the author.

4thly, That it be perfectly connected with the common stock.—That is, it should be carried deep into the earth, which is frequently dry near the surface; and then continued in a horizontal direction, so as to have the farther extremity dipped, should this be practicable, into water, at the distance of 10 yards or more from the foundation.

5thly, That the upper extremity of the rod be as acutely pointed as possible.—This termination should be of copper; or rather a very fine and exceedingly acute needle of gold should be employed, which will not materially add to the expense.

6thly, That it be very finely tapered:—so that the upper extremity may be a cone, the diameter of the base of which may bear an extremely small proportion to its height; for instance, that of one to forty.

7thly, That it be extremely prominent:—that is, 8, 10, or 15 feet at least above the highest parts of the building. The author lays great stress on this circumstance, in consequence of the law abovementioned, deduced by him from his experiments, relating to electric atmospheres. According to this law, the density of an electric atmosphere (the negative atmosphere, for instance, of the roof of a house, &c. while a positive (closed body) over it) diminishes in the inverse ratio of the square of the distance from the surface of the body to which that atmosphere belongs. Accordingly, if the rod project 12 feet into this atmosphere, it will reach to a part of it four times less dense than if the rod projected only to half that distance, or six feet;—and to a part one hundred and forty four times rarer, than if it projected only one foot.

8thly, That each rod be carried, in the shortest convenient direction, from the point at its upper end, to the common flock.

9thly, That there be neither large nor prominent bodies of metal upon the top of the building proposed to be secured, but such as are connected with the conductor, by some proper metallic communication.

1othly, That there be a sufficient number of high and pointed rods.—On edifices of great importance, especially magazines of gun-powder, the author thinks these ought never to be above 40 or 50 feet asunder.

11thly, That every part of the rods be very substantially erected.

The author declares that he has never been able to hear of a single instance, nor does he believe that any one can be produced, of an high, tapering, and acutely pointed metallic conductor, having ever, in any country, been struck by lightning; if it had all the necessary requisites abovementioned, especially the second and fourth.

On the whole, it seems to be pretty certain, that the use of conductors, both pointed and knobbled metallic conductors, have the power of preserving any body placed at a small distance from them from being struck by lightning. This they do, not because they can attract the lightning far out of its way, but because the resistance to its pialage is always left on that side where they are; and as pointed conductors diminish the resistance more considerably than blunt ones, they seem in all cases to be preferable.—It appears, however, that a single conductor, whether blunt or pointed, is not capable of securing all the parts of a large building from strokes of lightning; and therefore several of them will be required for this purpose: but to what distance their influence extends, hath not been determined, nor does it seem easily capable of being ascertained.

It now remains only to explain some of the more uncommon appearances and effects of lightning. One of these is, that it is frequently observed to kill alternately; that is, supposing a number of people standing in a line, if the first person was killed, the second perhaps would be safe; the third would be killed, and the fourth safe; the fifth killed, &c. Effects of this kind are generally produced by the most violent kind of lightning; namely, that which appears in the form of balls, and which are frequently seen to divide themselves into several parts before they strike. If one of these parts of a fire-ball strike, a man, another will not strike the person who stands immediately close to him; because there is always a repulsion between bodies electrified the same way. Now, as these parts into which the ball breaks have all the same kind of electricity, it is evident that they must for that reason repel one another; and this repulsion is so strong, that a man may be interposed within the stroke of two of them, without being hurt by either.

The other effect of lightning is mentioned under the article Jerusalem, where those who attempted to rebuild the temple had the marks of crosses impressed upon their garments and bodies. This may reasonably be thought to arise from the same cause to which the angular appearance of lightning in the air is owing, namely, its violent impetus and velocity, together with the opposition of the atmosphere. A small stroke of lightning, sometimes indeed a very considerable one, cannot always enter the substance of terrestrial bodies, even when it touches them, for reasons already given. In this case it runs along their surface, and, as in its motion it is perpetually reified by the atmosphere, it undoubtedly has the same angular motion which we often perceive in the atmosphere. If in this situation it happens to touch the human skin, or a garment, especially of linen, as being a conductor, it will undoubtedly leave a mark upon it; and this mark being of a zig-zag form, might, in the above instance, have been either taken for the exact form of a cross.
Lightning may serve to give some idea of the nature of lightning, and its operations after it appears in its proper form and bursts out from the cloud; but for an account of its original formation, and of the powers by which the clouds are at first electrified, and their electricity kept up notwithstanding many successive discharges of lightning, and the quantity of electric matter continually carried off by the rain, &c. see the article Thunder.

Artificial Lightning. Before the discoveries of Dr Franklin concerning the identity of electricity and lightning, many contrivances were invented in order to represent this terrifying phenomenon in miniature: the corruptions of phosphorus in warm weather, the ascension of the vapour of spirit of wine evaporated in a close place, &c. were used in order to support the hypothesis which at that time prevailed; namely, that lightning was formed of some phœnicous, nitrous, or other combustible vapours floating in long trains in the atmosphere, which by some unaccountable means took fire, and produced all the destructive effects of that phenomenon. These representations, however, are now no more exhibited; and the only true artificial lightning is universally acknowledged to be the discharge of electric matter from bodies in which it is artificially set in motion by our means.

Lightning was looked upon as sacred both by the Greeks and Romans, and was supposed to be sent to execute vengeance on the earth: Hence persons killed by lightning, being thought hateful to the gods, were buried apart by themselves, left the ashes of other men should receive pollution from them. Some say they were interred upon the very spot where they died: others will have it that they had no interment, but were suffered to rot where they fell, because it was unlawful for any man to approach the place. For this reason the ground was hedged in, left any person unawares should contract pollution from it. All places frequented with lightning were carefully avoided and fenced round, out of an opinion that Jupiter had either taken offence at them, and fixed upon them the marks of his displeasure, or that he had, by this means, pitched upon them as sacred to himself. The ground thus fenced about was called by the Romans ludent. Lightning was much observed in augury, and was a good or bad omen, according to the circumstances attending it.

Lignum Campescentis. See Hematoxylum.
Lignum Colubrinum. See Ophiorhiza.
Ligated, among botanists, an appellation, given to such floesules as have a straight end turned downwards, with three indentures, but not separated into segments.
Liguria (anc. geog.), a country of Italy, bound
ed on the south by the Mediterranean sea, on the north by the Appennine mountains, on the west by part of Transalpine Gaul, and on the east by Etruria. There is a great disagreement among authors concerning the origin of the Ligurians, though most probably they were descended from the Gauls. Some carry up their origin as far as the fabulous heroes of antiquity; while others trace them from the Ligyes, a people mentioned by Herodotus as attending Xerxes in his expeditions against Greece. These Ligyes are by some ancient geographers placed in Colchis; by others, in Albania.—According to Diodorus Siculus, the Ligurians led a very wretched life; their country being
LIGUSTICUM, LOVAGE, in botany: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, Umbellifera. The fruit is oblong and quinquefoliate on each side; the florets are equal; the petals involuted; rolled inwards, and entire. There are seven species; of which the most remarkable are, the levisticum, or common, and the fecticum or Scots, lovage. The first is a native of the Apennine mountains in Italy. It has a thick fleshy, deeply-penetrating perennial root, crowned by very large, many-parted, radical leaves, with broad lobes, having incisions at top, upright, strong, channelled stalks, branching six or seven feet high, and all the branches terminated by yellow flowers in large umbels. The second is a native of Scotland, and grows near the sea plants; and in the longer season is a native of Scotland, and grows near the sea plants; and in the longer season.

Medicinal use, &c. The root of the first species agrees nearly in quality with that of angelica: the principal difference is, that the lovage root has a stronger smell, and a somewhat less pungent taste, accompanied with a more durable sweetness, the seeds being rather warmer than the root; but although certainly capable of being applied to useful purposes, this root is not regarded in the present practice. The leaves of the second are sometimes eaten raw as a salad, or boiled as greens by the inhabitants of the Hebrides. The root is reckoned a good carminative. They give an infusion of the leaves in whey to their calves to purge them.

LIGUSTRUM, PRIVET, in botany: A genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking under the 10th order, Coronaria. The corolla is hexastylous, and campanulated, with a longitudinal nectariferous line or fow: the capsules connected by small canaliculated hairs. There are many species; all of them bulbous-rooted, herbaceous, flowery perennials, rising with erect annual stalks three or four feet high, garnished with long narrow leaves, and terminated by fine clusters of large bell-shaped, hexastylous flowers of exceeding great beauty, of white, red, scarlet, orange, purple, and yellow colours.

Culture. All the species are propagated by sowing the seeds; and if care is taken to preserve these seeds from good flowers, very beautiful varieties are often produced. The manner of sowing them is as follows. Some square boxes should be procured, about six inches deep, with holes bored in the bottoms to let out the water; these must be filled with fresh, light, sandy earth; and the seeds sown upon them pretty thick in the beginning of August, and covered over about half an inch deep with light sifted earth of the same kind. They should then be placed where they may have the morning sun; and if the weather proves dry, they must be watered at times, and the weeds carefully picked out. In the month of October the boxes are to be removed to a place where they may have as much sun as possible, and be secured from the north and north-east winds. In spring the young plants will appear, and the boxes are then to be removed into their former situation. In August the smallest roots are to be emptied out of these boxes, and dried over a bed of light earth, and covered with about half an inch depth of earth of the same kind, sifted over them. Here they must be watered, and the boxes replenished from the severity of winter by a slight covering of straw or pease-haulm in the hardest weather. In

K
February, the surface of the bed should be cleared, and a little light earth sifted over it. When the leaves are decayed, the earth should be a little firmed over the roots; and in the month of September following some more earth sifted on. In the September of the following year, the roots must be transplanted to the places where they are to remain, and set at the distance of eight inches; the roots being placed four inches below the surface: this should be done in moist weather. They will now require the same care as in the preceding winter; and, the second year after they are transplanted, the strongest roots will begin to flower. The fine ones should then be removed at the proper season into flower beds, and planted at great distances from one another that they may flower strong.

Medical uses. The roots of the white lily are emollient, maturating, and greatly suppurative. They are used externally in catarrhals for these purposes with success. The common form of applying them is boiled and bruised; but some prefer the roasting them till tender, and then beating them to a paste with oil, in which form they are said to be excellent against burns. Gerard recommends them internally against dropsy.

The Kamtschatken, or Kamtschatka lily, called there faranne, makes a principal part of the food of the Kamtschatkans. Its roots are gathered by the women in August, dried in the sun, and laid up for use: they are the best bread of the country; and after being baked are reduced to powder, and serve instead of flour in soups and several dishes. They are sometimes washed, and eaten as potatoes; are extremely nourishing, and have a pleasant bitter taste. Our navigators boiled and eat them with their meat. The natives often parboil, and beat it up with several sorts of berries, especially among the ladies, is, according to Berkenhout, essentially a medicinal use.

The species of mouse saves them a great memory, ready faculty of application, and suitably a. Among the ladies, is, according to Berkenhout, essentially a medicinal use.

LILLO (George), an excellent dramatic writer, born at London in 1693. He was a jeweller by profession, and followed his business for many years in that neighbourhood with the fairest reputation. He was at the same time strongly attached to the muses, yet seemed to have laid it down as a maxim, that the devotion paid to them ought always to tend to the promotion of virtue, morality, and religion. In pursuance of this aim, Lillo was happy in the choice of his subjects, and showed great power of affecting the heart, by working up the passions to such a height, as to render the diffidences of common and domestic life equally interesting to the audiences as that of kings and heroes, and the ruin brought on private families by an indulgence of avarice, lust, &c. as the havoc made in states and empires by ambition, cruelty, or tyranny. His "George Barnwell," "Fatal Curiosity," and "Arden of Feverham," are all planned on common and well-known stories; yet they have perhaps more frequently drawn tears from an audience than the more pompous tragedies of Alexander the Great, All for Love, &c. In the prologue to "Elmerie," which was not acted till after the author's death, it is said, that when he wrote that play, he "was depressed by want," and afflicted by disease; but in the former particular there appears to be evidently a mistake, as he died possessed of an estate of L.60 a-year, besides other effects to a considerable value. His death happened in 1739, in the 47th year of his age. His works have been lately collected, and published, with an account of his life, in 2 vols 12mo, by Mr T. Davis.

LILLY (John), a dramatic poet, was born in the wilds of Kent, about the year 1553, and educated in Magdalen-college, Oxford, where he took the degree of bachelor of arts in 1573, and that of master in 1575. From Oxford he removed to Harbridge, but how long he continued there, is uncertain. On his arrival in London, he became acquainted with some of Queen Elizabeth's courtiers, by whom he was courted, and admired as a poet and a wit; and his majesty, on particular festivals, honoured his dramatic pieces with her presence. His plays are nine in number. His first publication, however, printed in 1580, was a romance called Euphues, which was universally read and admired. This romance, which Blount, the editor of six of his plays, says introduced a new language, especially among the ladies, is, according to Berkenhout, in fact a most contemptible piece of affectation and nonsense: nevertheless it seems very certain, that it was in high estimation by the women of fashion of those times, who, as we are told by Whalley the editor of Ben Jonson's works, had all the phrases by heart; and those who did not speak Euphues were as little regarded at court as if they could not speak French. "He was (says Oldys) a man of great reading, good memory, ready faculty of application, and uncommon eloquence; but he ran into a vast excess of allusion." When or where he died is not known. Anthony Wood says he was living in 1597, when his last comedy was published. After attending the court of Queen Elizabeth 13 years, notwithstanding his reputation as an author, he was under a necessity of petitioning the queen for some small stipend to support him in his old age. His two letters or petitions to her majesty on this subject are preferred in manuscript.

LILLY (William), a noted English astrologer, born in Leicestershire in 1602; where his father not being able to give him more learning than common writing and arithmetic, he resolved to seek his fortune in London. He arrived in 1620, and lived four years as a servant to a mantua-maker in the parish of St Clements Danes; but then moved a step higher to the service of Mr Wright, master of the Sater's company in the Strand, who not being able to write, Lilly among other offices kept his books. In 1627, when his master died, he paid his addresses to the widow, whom he married with a fortune of 1000L. Being now
LILLY, in botany. See LILUUM.

LILLY, the Valte. See CONVALLARIA.

LILYBEUM (anc. geog.), a city of Sicily, situated on the most westerly promontory of the island of Sicily, and said to have been founded by the Carthaginians on their expulsion from Motya by Dionysius tyrant of Syracuse. It is remarkable for three Abges it sustained: one against Dionysius the tyrant, another against Pyrrhus king of Epirus, and the third against the Romans. The two first failed in their attempts, but the Romans with great difficulty made themselves masters of it. No remains of this once fane city are now to be seen, except some aqueducts and temples; though it was standing in Strabo's time.

LILYE (William,) the grammarian, was born in the year 1466 at Oldham in Hampshire; and in 1486, was admitted a semi-commoner of Magdalen college, in Oxford. Having taken the degree of bachelor of arts, he left the university and travelled to Jerusalem. Returning from thence, he continued five years in the island of Rhodes, where he studied the Greek language, several learned men having retired thither after the taking of Constantiopol. From Rhodes he travelled to Rome; where he improved himself in the Greek and Latin languages, under Sulpius and P. Sabinus. He then returned to London, where for some time he taught a private grammar-school, being the first person who taught Greek in the metropolis. In 1510, when Dr Colet founded St Paul's school, Lilye was appointed the first master; at which time, it seems, he was married and had many children. In this employment he had laboured 12 years, when, being feized by the plague, which then raged in London, he died in February 1523, and was buried in the north yard of St Paul's. He had the character of an excellent grammarian, and a successful teacher of the learned languages. His principal work is Brevisima infinitus, seu ratio grammaticorum cognomenta; Lond. 1543. Reprinted times without number, and commonly called Lilye's grammar. The English rudiments were written by Dr Colet, and the grammarian prefixed a preface to the first edition, by cardinal Wolsey. The English syntax was written by Lilye; also the rules for the genders of nouns, beginning with Propria que marius; and those for the perfect tense and future, beginning with As in presenti. The Latin syntax was chiefly the work of Erasmus, See Ward's preface to his edition of Lilye's Grammar, 1572.

LIMA, a city of South-America, in Peru, of which it is capital, with an archbishop's see, and an university. It gives its name to the principal audience of Peru; and is surrounded with brick-walls, fortified with several ramparts and bastions, eight yards high. The streets are handsome, and as straight as a line, but the houses are generally only one story high, on account of the earthquakes. However, they are pretty enough, and well adorned, having long galleries on the front. One part of the roofs are covered with coarse linen cloth, and other only with reeds, which is not inconvenient, because it never rains here; however, the richest inhabitants cover theirs with fine mats or beautiful cotton-cloths. There are trees planted all round their houses, to keep off the heat of the sun. What the houses want in height they have in length and depth; for some of them are 200 feet long, and proportionably broad, so that they have 10 or 12 large apartments on the ground-floor. The royal square is very handsome, and in the middle there is a fountain of bronze, adorned with the image of Fame which foops up water. On the east and west sides are the public structures, which are well built. The river which crofes Lima forms canals or streams which run to most of the houses, and serve to water their gardens, as well as for other uses. All the churches and convents are extremely rich; and many images of the saints are of maffy gold, adorned with jewels. This city is four miles
LIMAX, or Limasso, a town of Cyprus, in the south of the island. Of the ancient city nothing but ruins now remain; though it was a celebrated place, even under the government of the kings. Richard, the conqueror of the last of these vassals of the empire, razed it in 1191, and it was never afterwards rebuilt. This city originally was the fame as Amathus or Amathonte; so famous, as Pauflanias tells us, for its temple erected in honour of Venus and Adonis. Amathus was the residence of the nine first kings of the island; and amongst others of Oneiflus, who was famed for his liberality by the name of Artabanes, the Perian general. This city, erected into an archbishopric in the time of the Christian, has produced a number of personages celebrated for their knowledge and the sanctity of their lives. In the neighbourhood there are several copper mines, which the Turks have been forced to abandon. The following lines, in the tenth book of Ovid's Metamorphoses, prove that they were known in the time of that poet:

Captâ viri forma, non jam Cytherea curat
Littora, non alto repetit Paphon aequore cinclam,
Pilcolamque Guidon, grasulamque Amathotea metallis.

The place where the new Limassol now stands, formerly had the name of Nemtis, from the multitude of wheels by which it was surrounded. Richard king of England having destroyed Amathonte, Guy de Lusignan in the 12th century laid the foundations of that new city which the Greeks calls Neopolis. The family of Lusignan, who continued to embellish and fortify it, built there palaces, and Greek and Latin churches; and made it the seat of a bishop. When the island was taken by the Turks in 1570, the Ottoman army entered the city on the 2d of July, and ravaged it without mercy. It was then destroyed by the flames; and at present it is only a wretched place, in which one can scarcely distinguish any remains of its ancient edifices. It is governed by a commissary and a cadi; the latter judges cases only provisionally, before they are carried to the superior tribunal of Nicofia. The harbour is very commodious; and being sheltered from tempestuous winds, it affords a safe and calm asylum to vessels when overtaken by a storm. The carob tree is here more abundant than anywhere else; and it is from the port of Limassol that the greatest quantity of its fruit is exported. The inhabitants export also salt, procured from a lake near Salines. Cotton, wheat, barley, and mulberry-trees, are both plentiful and well cultivated in this part of the island: the ground also produces all kinds of garden stuff. The best Cyprus wine is made from the vines that grow on the hills of Limassol. All the wines of the country are collected in this city to be transported to Larissa, where there are the largest cellars, and which on that account becomes the natural centre of commerce.

LIMAX, the Slavo, or Naked Snail; a genus of insects belonging to the order of vermes mollusci. The body is oblong, fitted for crawling, with a kind of mucular coat on the upper part; and the belly is plain. They have four tentacula, or horns, situated above the mouth, which they extend or retract at pleasure. This reptile is always destitute of shell; but besides that it is more clammy and of a greater configuration than that of the snail, the black naked flag has a furrowed cloak, almost thick as hard as leather, under which it withdraws its head as within a shell. The head is distinguished from the breast by a black line. It is in its head and back that the snail-stone is found; which is a small pearl and sandy stone, of the nature of lime stones: according to a popular opinion, it cures the tertian agitation, if fastened to the patient's arm. These flags move on slowly, leaving every where clammy and shining marks of their passage. Their coming together is about the end of spring. The organs of generation are placed, as in the snail, on the right side of the body. The male implement unfolds with the female mechanism; the finger of a glove when turned inside out. They are sometimes met with hanging in the air with their heads downwards; and their tails, united by a kind of viscous and thick tie, grappled to the branch of a tree. In this situation they remain for three hours, and that is the time of impregnation. They deposit their eggs in the earth. There are eight species, distinguished entirely by their colour; as the black flag, the white flag, the reddish flag, the ah-coloured flag, &c. The black flag is hemrophrodite, both sexes being in each individual, and in the coitus both impregnate and are impregnated at the same time.—A black flag powdered over with foam, salt, or sugar, falls into convolutions, casts forth all its foam, and dies. See Reproduction.

LIMB, in general, denotes the border or edge of a thing; thus we say, the limb of a quadrant, of the fun, of a leaf, &c.

LIMB, in anatomy, an appellation given to the extremities of the body, as to the arms and legs.

Limbus, in the church of Rome, is used in two different senses. 1. The limb of the patriarchs is said
LIMBAT, the name of a periodical wind common in the island of Cyprus, and of great service in moderating the heats of the climate, which would otherwise be intolerable.

According to the Abbé Marii, it begins to blow at eight in the morning the first day; increases as the sun advances till noon; then gradually weakens, and at three falls entirely. On the second day it arises at the same hour; but it does not attain its greatest strength till about one in the afternoon, and ceases at four precisely. On the third day it begins as before, but it falls an hour later. On the five succeeding days, it follows the same progression as on the third; but it is remarked, that a little before it ceases, it becomes extremely violent. At the expiration of five days it commences a new period like the former. By narrowly observing the sea on that side from which it is about to blow a little before it arises, one may determine what degree of strength it will have during the day. If the horizon is clear, and entirely free from clouds, the wind will be weak, and even almost insensible; but if it is dark and cloudy, the wind will be strong and violent. This limbat wind, notwithstanding its utility in moderating excessive heat, often becomes the cause of fevers, especially to the Europeans, from their being less habituated to the climate, more apt to be affected by calms, which often succeed from the irregularity of the season. In spring it does not continue longer than midnight; and it is then succeeded by that happy calm, during which the refreshing dews are formed that moisten the earth at morning. This wind bears a name from the inhabitants of the southern and eastern parts of the island; but it is called a fresh breeze by those in the northern and western, who indeed receive it immediately from the sea. In summer it blows till four o'clock in the morning and when it ceases, it leaves a profound calm, during which the air is so fresh that trees may be cut down, and the inhabitants may work with the greatest ease. In autumn and winter it never falls till daybreak, when it is succeeded by other winds, which proceed from the irregularity of the season. In spring it does not continue longer than midnight; and it is then succeeded by that happy calm, during which the refreshing dews are formed that moisten the earth at morning.

LIMBORCH (Philippus), a learned writer among the remonstrants, born at Amsterdam in 1633. After having made great proficiency in his studies, he was, in Limburgh, in 1655, admitted to preach in public, which he did first at Haarlem. His sermons had in them no affected eloquence; but were solid, methodical, and edifying. He was chosen minister of Gouda; from whence he was called to Amsterdam, where he had the professorship of divinity, in which he acquired himself with great reputation till his death which happened in 1712. He had an admirable genius, and a tenacious memory. He had many friends of distinction in foreign parts as well as in his own country. Some of his letters to Mr. Locke are printed with those of other celebrated authors. He had all the qualifications suitable to the character of a sincere divine, lived an example of every virtue, and preferred the vigour of his body and mind to a considerate age. He wrote many works, which are esteemed; the principal of which are, 1. Amoeba colo­latio de veritate religiosi Christianae con crudite Judaeos, in 12mo. 2. A complete body of Divinity, according to the opinions and doctrines of the remon­strants. 3. A history of the Inquisition; which has been translated into English by Dr. Samuel Chandler. Limborch also published the works of the famous Augustinus, who was his great uncle by the mother’s side.

LIMBURGH, the capital city of the duchy of Lim­burgh, in the Austrian Netherlands, is seated on a steep rock near the river Vese. This town is small, but pleasantly seated on a hill, with shady woods; and consists chiefly of one broad street, not very well built. It is strong by situation, and almost inaccessible; however, it was taken by the French in 1675, and by the confederates under the duke of Marlborough in 1703, for the house of Austria, to whom it remains by the treaties of Rastadt and Baden, after having been dismantled. It is famous for its cheese, which is exceedingly good. E. Long, 6. 8. N. Lat. 50. 40.

LIME, or Lime. See Lyce.
LIMERICK is a market-town, a borough, and a bishop's see, now the metropolis of the province of Munster. It is situated on the river Shannon, 94 miles from Dublin; and was the strongest forresses in the kingdom. Its ancient name was Lungeable. It was plundered by Mahon, brother from Galway, in 12th century. It was erected and endowed the cathedral; and Donat O'Brien, bishop of Limerick, in the 13th century, contributed much to the opulence of the see. About the close of the 12th century, the bishirp of Innis-Cathay was united to that of Limerick. It was besieged by king William III. in the year 1690; and though there was no army to assist it, the king was obliged to raise the siege. In the year 1691, it was again besieged by the English and Dutch on the 21st of September; and it was obliged to surrender on the 13th of October following, not without the loss of abundance of men: however, the garrison had very honourable and advantageous conditions, being permitted to retire where they thought fit; and the Roman catholics by these articles were to be tolerated in the free exercise of their religion. Within a century this place was reckoned the second city in Ireland; at present it has lost its rank; not because it thrives less, but because Cork thrives more. It is composed of the Irish and English town; the latter stands on the King's island, formed by the river Shannon. The town is three miles in circumference, having weekly markets on Wednesday and Saturday, and fairs on Easter Tuesday, 1st July, 4th August, and 12th December. There is a privilege annexed to the fair held on 4th August, that, during 15 days, no person can be arrested in the city or liberties, on any processes filing out of the Tholof court of Limerick. Ardare and Achoadoe, in the county of Kerry, are united to the bishirp of Limerick. This city returns two members to parliament; and gives title of viscount to the family of Hamilton. It is governed by a mayor, sheriffs, recorder, aldermen, and burgesses; there is also a bishirp and Limming a military governor and town-major; it had some time the privilege of coinage; and different parliaments have been held there. The town was formerly entirely walled in; and in 1760, there were 12 of the city gates standing; but to the great improvement of the place they are now all demolished, except the water-gate of king John's castle. The linen, woollen, and paper manufactures are carried on here to great extent, and the export of provisions is very considerable. Here are many charitable hospitals and handsome public buildings, besides the cathedral and other churches. A charter was granted to this city by king John, and confirmed in succeeding reigns. Dr Campbell observes, that as you approach Limerick, the grounds grow rich and exquisitely beautiful; the only disagreeable matter is, that the situation renders the air moist, and consequently rather unwelcome to strangers. About six miles from this is the famous Cattle-connel spa. Limerick is 50 miles from Cork, 50 from Galway, and 73 from Waterford. It appears that Limerick obtained the privilege of having mayors 10 years before that right was allowed to the citizens of London. It was before governed by provosts, of which the first was John Spafford, in 1195 and 1197; during the provostship of Henry Troy a charter was granted, to Richard I., whereby the citizens were allowed to choose mayors and bailiffs, Adam Servant, in 1198, being the first mayor. It continued to be governed by mayors and bailiffs, until the office of bailiff was changed into that of sheriff, in 1609.

LIMERICK is also the name of a fair town in the county of Waterford and province of Leinster; the fairs are four in the year.

LIMINGTON, a town of Hampshire in England. See LYMINGTON.

LIM, in a restrained sense, is used by mathematicians for a determined quantity to which a variable one continually approaches; in which sense the circle may be said to be the limit of its circumscribed and inscribed polygons. In Algebra, the term limit is applied to two quantities, one of which is greater and the other less than another quantity; and in this sense it is used in speaking of the limits of equations, whereby their solution is much facilitated.

LIMME, a town of Kent, in England, near Hitho, and four miles from Romney, was formerly a port, till choked up by the sands; and though it is thereby become a poor town, yet it has the horn and mace and other tokens left of its ancient grandeur, and used to be the place where the lord warden of the cinqueports was sworn at his entrance upon his office. The Roman road from Canterbury, called Stone-breet, ended here; and from the brow of its hill may be seen the ruinous Roman walls almost at the bottom of the marshes. Here formerly was a castle, now converted into a farm-house. When or by whom this edifice was erected is not known. It has, however, great marks of antiquity; as has also the adjoining church, in which are several old tombstones with crosses on them.

LIMNING, the art of painting in water-colours, in contradistinction to painting which is done in oil-colours.

Limning is much the more ancient kind of painting;
In limning, all colours are proper enough, except the white made of lime, which is only used in fresco. The azure and ultramarine are both on their walls, always be mixed with size or gum; but there are always applied two layers of hot size before the size-colours are laid on: the colours are all ground in water each by itself; and, as they are required in working, are diluted with size-water. When the piece is finished, they go over it with the white of an egg well beaten; and then with varnish, if required.

To limn, or draw a face in colours: the art of painting in oil, the painters all painted ill require work, which is card even and thin, free from hairs and spots over the whole; carefully remarking whatever may conduce to render the piece perfect, as the exit of the eyes, moles, scars, gazures, and the like.

LIMOGES, an ancient and considerable town of France, in the province of Guienne, and capital of Limosin, with a bishop's see. It is a trading place, and its horfes are in great esteem. It is feated on the river Vienne, in E. Long. 1. 22. N. Lat. 42. 48.

LIMOSIN, a province of France, bounded on the north by La Marche, on the east by Auvergne, on the south by Quercy, and on the west by Perigord and Angoumois. It is divided into the Upper and Lower; the former of which is very cold, but the latter mere temperate. It is covered with forrests of chesnut-trees; and contains mines of lead, copper, tin, and iron; but the principal trade consists in cattle and horses.

LIMPET. See Patella.

LIMPURG, a barony of Germany, in the circle of Franconia, included almost entirely within Swabia, and feated to the south of Hall in Swabia. It is about 15 miles long, and eight broad. Gaildorf and Schonburg, near which is the castle of Limburg, are the principal places.

LIMPURG, a town of Germany, in the electorate of Triers or Treves, and in Wetteravia, formerly free and imperial, but now subject to the electorate of Treves. It is feated on the river Lhon. E. Long. 8. 13. N. Lat. 50. 18.

LINARIA, in ornithology. See Fringilla.

LINACRE (Thomas), physician, was born at Canterbury about the year 1460, and there educated under the learned William Seling; thence he removed to Oxford, and in 1484 was chosen fellow of All-Souls college. Tilly, alias Seling, his former instructor, being at this time appointed ambassador from King Henry VII. to the court of Rome, Mr Linacre accompanied him to Italy, where he attained the highest degree of perfection in the Greek and Latin languages. At Rome, he applied himself particularly to the study of Aristotle and Galen, in the original. On his return to Oxford, he was incorporated doctor of physic, and chosen public professor in that faculty. But he had not been long in England, before he was commanded to court by King Henry VII. to attend the young Prince Arthur as his tutor and physician. He was afterwards appointed physician to the king, and, after his death, to his successor Henry VIII. Dr Linacre founded two medical lectures at Oxford, and one at Cambridge; but that which most effectually immortalized his name among the faculty, is his being the first founder of the college of physicians in London. He beheld with vexation the wretched state of physic in those times; and, by an application to Cardinal Wolsey, obtained a patent in 1518, by which the physicians of London were incorporated. The intention of this corporation was to prevent illiterate and ignorant medecinaters from practising the art of healing. Dr Linacre was the first president, and held the office as long as he lived. Their meetings were in his own house in Knight-riders street which house he bequeathed to the college. But our doctor, when he was about the age of 50, took it into his head to study divinity; entered into orders; and was collated, in 1509, to the rectory of Merham. In the same year he was installed prebendary of Wells, in 1518 prebendary of York, and in the following year was admitted precentor of that cathedral. This, we are told, he resigned for other preferments. He died of the stone in the bladder in October 1524, aged 64; and was buried in St. Paul's. Thirty-three years after his death, Doctor John Caius caused a monument to be erected to his memory, with a Latin inscription, which contains the outlines of his life and character. He was a man of great natural sagacity, a skilful physician, a profound grammarian, and one of the best Greek and Latin scholars of his time. Erasmus in his epistles speaks highly of the doctor's translations from Galen, preferring them even to the original Greek. His works are, 1. De opendata structura Latini, &c. 2. De medicinæ et chirurgiæ usu generosi; London, printed by Pynfon, 1524, 8vo, and by Stephens, 1527, 1528. 3. The rudiments of grammar, for the use of the pricnes Mary, printed by Pynfon. Buchanan translated it into Latin; Paris, 1536. He likewise translated into very elegant Latin, several of Galen's works, which were printed chiefly abroad at different times. Alfo Procli Diadochi sphera, translated from the Greek; Venet. 1499, 1500.

LINCOLN, a city of England, and capital of a county of the same name, is distant 132 miles from London. It stands on the side of a hill; at the bottom of which runs the river Witham in three small channels, over which are several bridges. The old Lubetum of the Britons, was founded on the top of the hill, as appears from the vestiges of a rampart, and deep ditches still remaining, was taken and demolished by the Saxons: who built a town upon the south side of the hill down to the river side, which was several times...
times taken by the Danes, and as often retaken by the Saxons. In Edward the Confessor's time, it appears, from Doomebook, to have been a very considera-
table place; and in the time of the Normans, Malmsbury, says, it was one of the most populous cities in Eng-
land. William I. built the castle upon the summit of
the hill above the town. The dioceze, though the bish-
} 00p of Ely was taken out of it by Henry II. and
thow of Peterborough and Oxford by Henry VIII. is
still vastly large, containing the counties of Leicester,
Huntingdon, Bedford, and part of Bucks, making 1255
parishes. Though the other churches are mean, the
cathedral or minster is a most magnificent piece of Go-

tic architecture. Here is a prodigious large bell,
called the Tower of Lincoln, which is near 5 ton in weight,
and 23 feet in compass. The hill on which the church
stands is so high, and the church itself so lofty, that
it may be seen 50 miles to the north, and 30 to the
south. Besides other tombs, it contains one of bracis,
in which are the entalls of Queen Eleanor, wife to
Edward I. It is said there were anciently 52 churches,
which are now reduced to 14. Such is the magni-
ficence and elevation of the cathedral, that the monks
thought the height of it must be very mortifying to the
deity; wherefore it came to be said of one who was dis-
pleased that he looked like the devil over Lincoln. The
decievity on which the city is built being steep, the
communication between the upper and lower town is
very troublesome, and coaches and horses are obliged
to make a compas.

King Edward III. made this city a staple for wool,
leather, lead, &c. It was once burnt; once besieged
by King Stephen, who was here defeated and taken
prisoner; and once taken by Henry III. from his re-
bellious barons. It abounded heretofore with mona-
steries and other religious houses. There is a great
pool here, formed by the river on the west side of it,
called Swan-Pool, because of the multitude of swans
on it. The Romans north gate still remains entire, by
the name of Newport Gate. It is one of the noblest
of this fort in Britain. It is a vast semicircle of stones
of very large dimensions laid without mortar, connect-
ed only by their uniform shape. This magnificent arch
is 16 feet in diameter, the stones are four feet thick at
the bottom. It seems to have a joint in the middle,
not a key-stone: and on both sides, towards the upper
part, are laid horizontal stones of great dimensions,
some to or 12 feet long. This arch rises from an im-
port of large mouldings, which are not perceivable
now; there are also divers fragments of the old Roman
wall. Over against the castle is an entrenchment cast
up by king Stephen; and here are carved the arms of
John of Gaunt, duke of Lancaster, who lived here like
a king, and had a mint. The city has a communication
with the Trent, by a canal called the Fosdyke. In the
centre of the ruined old castle there is a hand-
some modern structure for holding the affizres. Its
walls are almost entire, and very substantial: the Keep
or principal tower is situated on a high and very steep
mount, which yet continues in its original base, but the
remains of the tower on it are only five or six yards
high. The outer walls of the castle are of very con-
siderable height, which appear still higher than they
really are from their lofty situation and the moat below
them. The great gateway is still entire. This city
is a county of itself, and has a viscountsiallurisfici:o
for 20 miles round, which is a privilege that no other
city in England can equal. It now consists principally
of one street above two miles long, well paved, be-
sides several crofs and parallel streets well populated.
Here are some very handsome modern buildings, but
more antique ones; upon the whole it has an air of
ancient greatness, arising in a great measure from the
number of monastic remains, most of which are now
converted into stables, out-houses, &c. Upon the hill,
in the castle are the ruins of the bishop's palace, and
other ruins of ancient grandeur and magnificence.
The city is supplied with water by several conduits,
among which is a modern one, somewhat in the pyra-
midal style, enriched with sculpture. It is governed
by a mayor, 12 aldermen, two sheriffs, a recorder,
four chamberlains, a sword-bearer, four coroners, and
above forty common-council men. Here are four char-
ity schools, where 120 poor children are taught by
the widows of clergymen. The neighbouring coure
is noted for its frequent horse-races. On the down of
Lincoln, towards Boston, that rare foul the buffet is
seen sometimes, as well as on Salisbury Plain. Lincoln-
Heath extends above 50 miles, viz. from Sleaford and
Ashwell to the Humber north, though it is but
three or four miles over where brooked. Five miles
from Boston on this extensive heath, the late Lord Le-
Defenfier built a few years agoa tower for the direc-
tion of strangers. It is a lofty square building with a
stair-case, which terminates in a flat roof, and round
the base is a square court-yard. Great part of this
extensive heath is lately inclosed. The markets here
are Tuesdays and Fridays; and there are four fairs in
the year. We read that David king of Scots met king
John here, on the 22d of November, in the third year
of his reign, and performed homage to him on a hill
without the city, for his English territories, in pre-
ence of the archbishop of Canterbury. York, and Ragula,
11 bishops, and a vast number of temporal lords and
knights. King Henry VII. kept his court here at Eas-
ter in 1586. The Jews were once its chief inhabitants,
till they were forced to remove, after having impiously
crucified the child of one Grantham, and thrown it
into a well, to this day called Grantham's Well. Lin-
coln has given the title of earl to the family of Clin-
ton ever since the reign of Queen Elizabeth. W.
Long. 1. 27. N. Lat. 53. 16.

Lincolnshire, a maritime county of England, 77
miles in length and 48 in breadth, is bounded on the
east by the German ocean, on the west by Notting-
hamshire, on the north by Yorkshire, on the south by
Rutlandshire, Northamptonshire, and Canterbury.
It contains 4590 houses, 24340 inhabitants, 631 pa-
riishes, and 31 market towns, whereof five send mem-
bers to parliament, which, with two for the county,
made twelve in all. The principal rivers are the Hum-
ber, the Trent, the Witham, the Nene, the Welland,
the Ankham, and the Don. It is divided into three
parts, Lindsey, Kelsoven, and Holland: the air of
which last is wholesome and foggy, on account of the
fens and large marshes. The soil of the north and
west parts is very fertile, and abound in corn and pa-
tries. The east and south parts are not so proper for
corn, but then they supply them with fish and fowl in
great plenty, particularly ducks and geese. Lincoln
LINDUS, (anc. geog.), a town of Rhodes, situated on a hill on the west side of the island. It was built by Telephus the son of Hercules, according to Diodorus Siculus; by one of the Helleads, grandsons of the Sun, named Lindus, according to Strabo. It was the native place of Cleobulus, one of the wise men. Here we see the famous temple of Lindian Minerva, which was built by the daughters of Danaus. Cadmus enriched this temple with many splendid offerings. The citizens dedicated and hung up here the seventh of Pindar's Olympic odes, written in letters of gold. The ruins of that fine edifice are still to be seen on the top of a high hill which overlooks the sea. Some remains of the walls, consisting of stones of an enormous size, still show it to have been built in the Egyptian style. The pillars and other ornaments have been carried off. On the most elevated peak of the rock are the ruins of a cattle which may have served as a fort to the city. Its circumference is very extensive, and is filled with rubbish.

Linde, the modern city, stands at the foot of the hill. A bay, of considerable width and depth, serves as a harbour to the city. Ships find good anchorage there in twenty fathoms water. They are sheltered from the south-west winds, which constantly prevail through the severest season of the year. In the beginning of winter, they cast anchor off a small village named Maffary. Before the building of Rhodes, Lindus was the harbour which received the fleets of Egypt and Tyre. It was enriched by commerce. Mr. Savary observes, that a judicious government, by taking advantage of its harbour and happy situation, might yet restore it to a flourishing state.

LINE, in geometry, a quantity extended in length only, without any breadth or thickness. It is formed by the flux, or motion of a point. See FLUXIONS, and GEOMETRY.

LINE, in the art of war, is understood of the disposition of an army ranged in order of battle, with the front extended as far as may be, that it may not be flanked.

LINE of Battle, is also understood of a disposition of the fleet in the day of engagement; on which occasion the vessels are usually drawn up as much as possible in a straight line, as well to gain and keep the advantage of the wind as to run the same board. See NAVAL ARTS.

Horizontal LINE, in geography, and astronomy, a line drawn parallel to the horizon of any part of the earth.

Equinoctial Line, in geography, is a great circle on the earth's surface, exactly at the distance of 90° from each of the poles, and of consequence bisecting the earth in that part. From this imaginary line, the degrees of longitude and latitude are counted. In astronomy, the equinoctial line is that circle which the sun seems to describe round the earth on the days of the equinox in March and September. See ASTROLOGY and GEOGRAPHY.

Meridian Line, is an imaginary circle drawn through the two poles of the earth and any part of its surface. See GEOGRAPHY, § 29.

Ship of the Line, a vessel large enough to be drawn up in the line, and to have a place in a fleet.
L I N

[82]

LIN,
in genealogy, a series or succession of relations in various degrees, all descending from the same common ancestor. See Descent.

LINE, also denotes a French measure containing the 12th part of an inch, or the 144th part of a foot. Geometers conceive the line subdivided into six points. The French line answers to the English barley-corn.

Fishing Line. See Fishing Lines.

Lines, in heraldry, the figures used in armories to divide the shield into different parts, and to compose different figures. These lines, according to their different forms and names, give denomination to the pieces or figures which they form, except the straight or plain lines. See Heraldry.

Linea alba, in anatomy, the concourse of the oblique and transverse muscles of the abdomen; dividing the abdomen in two, in the middle. It is called linea, line, as being straight; and alba, from its colour, which is white. The linea alba receives a twig of a nerve from each of its digitations or indentings, which are visible to the eye, in lean persons especially.

Lineament, among painters, is used for the outlines of a face.

Linear Numbers, in mathematics, such as have relation to length only; such is a number which represents one side of a plain figure. If the plain figure be a square, the linear figure is called a root.

Linear Problem; that which may be solved geometrically by the intersection of two right lines. This is called a Simple Problem, and is capable but of one solution.

Linen, in commerce, a well known kind of cloth chiefly made of flax. Linen was not worn by the Jews, Greeks, or Romans, as any part of their ordinary dress. Under tunics of a finer texture supplied the place of shirts: Hence the occasion for frequent bathing. Alexander Severus was the first emperor who wore a shirt; but the use of it necessary a garment did not become common till long after him.

The linen manufacture was probably introduced into Britain with the first settlement of the Romans. The flax was certainly first planted by that nation in the British soil. The plant itself indeed appears to have been originally a native of the east. The woollen drapery would naturally be prior in its origin to the linen; and the fibrous plants from which the threads of the latter are produced, seem to have been first noticed and worked by the inhabitants of Egypt. In Egypt, indeed, the linen manufacture appears to have been very early: for even in Joseph’s time it had risen to a considerable height. From the Egyptians the knowledge of it proceeded probably to the Greeks, and from them to the Romans. Even at this day the flax is imported among Europeans from the eastern nations; the western kind being merely a degenerate species of it.

In order to succeed in the linen manufacture, one of good quality should be confined to the ploughing and preparing the soil, fowling and covering the seed, to the weeding, pulling, rippling, and taking care of the new seed, and watering and drilling the flax till it is lodged at home: others should be concerned in the drying, breaking, scutching, and heckling the flax, to fit it for the spinners; and others in spinning and reeling it, to fit it for the weaver; others should be concerned in taking due care of the weaving, bleaching, beetling, and finishing the cloth for the market. It is reasonable to believe, that if these several branches of the manufacture were carried on by distinct dealers, where the home-made linens are manufactured, the several parts would be better executed, and the whole would be afforded cheaper, and with greater profit.

Staining of Linen. Linen receives a black colour with much more difficulty than woollen or cotton. The black fruct on linen with common vitriol and gall or logwood, is very perishable, and soon washes out. Instead of the vitriol, a solution of iron is to be made of. This is well known to all the calico printers; and by the use of this, which they call their iron liquor, and madder-root, are the blacks and purples made which we see on the common printed linens. The method of making this iron-liquor is as follows: A quantity of iron is put into the four strong beer; and to promote the dissolution of the metal, the whole is occasionally well stirred, the liquor occasionally drawn off, and the rust beat from the iron, after which the liquor is poured on again. A length of time is required to make the impregnation perfect; the solution being reckoned unfit for use till it has stood at least a twelvemonth. This solution stains the linen of a yellow, and different shades of buff-colour; and is the only known substance by which these colours can be fixed on linen. The cloth stained deep with the iron liquor, and afterwards boiled with madder without any other addition, becomes of the dark colour which we see on printed linens and cottons; which if not a perfect black, has a very near resemblance to it. Others are stained paler with the same liquor diluted with water, and come out purple.

Linen may also be stained of a durable purple by means of solution of gold in aqua regia. The solution for this purpose should be as fully saturated as possible; it should be diluted with three times its quantity of water; and if the colour is required deep, the piece, when dry, must be repeatedly moistened with it. The colour does not take place till a considerable time, sometimes several days, after the liquor has been applied: to hasten its appearance, the subject should be exposed to the sun and free air, and occasionally removed to a moist place, or moistened with water.

When solution of gold in aqua regia is soaked up in linen cloths, the metal may be recovered by drying and burning them.

The anacardium nut, which comes from the East-Indies, is remarkable for its property of staining linen of a deep black colour, which cannot be washed out either with soap or alkaline ley. The stain is at first of a reddish-brown, but afterwards turns to a deep black on exposure to the air. The calcew-nut, called the anacardium of the East-Indies, differs from the oriental anacardium in its colouring quality. The juice of this nut is much paler than the other, and stains linen or cotton only of a brownish colour; which if not dried is very durable, but does not at all change toward blackness.—There are, however, trees, natives of the United States, which appear to contain juices of the fame
Linen. [83] L

Linen. fame nature with those of India. Of this kind are several, and perhaps the greater number, of the species of the toxicodendron or poison tree. Mr. Catesby, in his history of Carolina, describes one called there the poison-berries, from whose trunk flowed a liquid as black as ink, and supposed to be poisonous; which reputed poisonous quality has hitherto prevented the inhabitants from collecting or attempting to make any use of it. In the Philosophical Transactions for the year 1755, the abbé Mazée gives an account of three sorts of the toxicodendron raised in a botanical garden in France, containing in their leaves a milky juice, which in drying became quite black, and communicated the same colour to the linen on which it was dropped. The linen thus stained was boiled with soap, and came out without the least diminution of colour; nor did a strong leaft of wood-ashes make any change in it. Several of these trees have been planted in the open ground in England, and some still remain in the bishop of London's garden at Fulham.

That species called by Mr. Miller the true lac tree, was found by Dr Lewis to have properties of a similar kind. It contains in its bark, and the pedicles and ribs of the leaves, a juice somewhat milky, which soon changed in the air to a reddish-brown, and in two or three hours to a deep blackish or brownish-black colour: wherever the bark was cut or wounded, the incision became blackish; and on several parts of the leaves the juice had spontaneously exuded, and stained them of the same colour. This juice dropped on linen gave at first little or no colour, looking only like a spot of oil; but, by degrees, the part moistened with it darkened in the same manner as the juice itself. On washing and boiling the linen with soap, the stain not only was not discharged, but seemed to have its blackness rather improved; as if a brown matter, with which the black was manifestly deposited, had been in part washed out, and left the black more pure.

As the milky juice of some of the common plants turn dark-coloured or blackish in drying, the Doctor was induced to try the effects of several of them on linen. The milks of wild-poppies, garden-poppies, dandelion, hawk-weed, and low-thistle, gave brown, blackish-red stains, which were discharged by washing with soap: the milks of the fig-tree, of lettuce, and of different kinds of spurge, gave no colour at all. The colourless juice which flows from hop-flats when cut, stains linen of a pale-reddish, or brownish-red, extremely durable; the colour was deepened by repeated applications of the juice, but it never made any approach to blackness. The juice of fleshes gave likewise a pale-brownish stain, which by repeated washings with soap, and being wetted with strong solution of alkaline salt, was darkened to a deeper brown: on baking the fleshes, their juice turns red; and the red stain which it then imparts to linen is, on washing with soap, changed to a pale-bluish, which also proves durable. These colours could not be deepened by repeated applications of the juice. The fleshes were tried in different states of maturity, from the beginning of September to the middle of December, and the event was always nearly the same.

In the fifth volume of Linnaeus's Species, mention is made of a black colour obtained from two plants which grow spontaneously in Britain; the one is the Cirsium, herb-christopher, or baneberry; the other the Cirsium, herb-christopher, or baneberry. The juice of the bane-berry, boiled with alum, is said to yield a black ink; and the heath-berries, boiled also with alum, to dye linen of a pale-blue black.

Linen flowered with gold-leaf. Dr. Lewis informs us of a late manufacture established in London for embellishing linen with flowers and ornaments of gold-leaf. The linen, he says, looks whiter than most of the printed linens; the gold is extremely beautiful, and bears washing well. The Doctor informs us, that he had seen a piece which he was credibly informed had been washed three or four times, with only the same precautions which are used for the finer printed linens; and on which the gold continued entire, and of great beauty. Concerning the process used in this manufacture, he gives us no particulars.

Pothe Linen, is a kind of amianthus, which contains of flexible, parallel, soft fibres, and which has been celebrated for the uses to which it has been applied, of being woven, and forming an incombustible cloth. Paper also, and wicks for lamps, have been made of it. See AMIANTHUS and ASPERTOS.

Ling, in zoology. See Gadus.

Lingen, a strong town of Germany, in the circle of Westphalia, and capital of a county of the same name. It belongs to the king of Prussia; and is situated on the river Elbe, in E. Long. 7° 30'. N. Lat. 52° 32'.

Lingebach (John), an excellent painter, born at Frankfort on the Maine in 1625. He first learned the art in Holland, but perfected himself at Rome, where he resided till he was 25 years of age; when he settled at Amsterdam. His usual subjects are fairs, mountebanks, tea-pieces, and landscapes, which he composed and executed exceedingly well: his landscapes are enriched with antiquities, animals, and elegant figures; his sea-fights are full of expression, exciting pity and terror, and all his objects are well designed. He had an uncommon readiness in painting figures and animals, on which account he was employed by several eminent artists to adorn their landscapes with such objects; and whatever he inferred in the works of other masters, were always well adapted, and produced an agreeable effect. He died in 1657.

Liniment, in pharmacy, a composition of a consistence somewhat thinner than an unguent, and thicker than an oil used for anointing different parts of the body in various intentions. The materials proper for composing liniments are, fats, oil, balsams, and whatever enters the composition of unguents and plasters.

Linthgow, the chief town of West Lothian in Scotland. It is supposed to be the Lincludum of Poem; and to take its name from its situation on a lake, which the word Lin or Linn signifies—It is distant 12 miles from Edinburgh, and is a royal borough and seat of a prebacy. It contains between three and four thousand souls; and carries on a considerable trade in dressing of white leather, which is sent abroad to be manufactured. It also employs many hands in dressing of flax; also in wool-combing, the wool for which is brought
brought from the borders. Its port was formerly Linlithgow, about two miles distant from Linlithgow. The town consists of one open street, from whence lanes are detached on both sides; the houses are built of stone, tolerably neat and commodious; and the place is adorned with some stately public edifices. The palace, built as Sibbald supposed, on the site of a Roman station, forms a square with towers at the corners, and stands on a gentle eminence, with the beautiful loch behind it to the west. It was one of the nobility of the royalidences; and was greatly ornamented by James V. and VI. Within the palace is a handsome square; one side of which is more modern than the others, having been built by James VI. and kept in good repair since 1746, when it was accidentally damaged by the king's forces making fires on the hearths, by which means the joists were burnt. A stone ornamented fountain in the middle of the court was destroyed at the same time. The other sides of the square are more ancient. In one is a room ninety-five feet long, thirty feet six inches wide, and thirty-three feet high. At one end is a gallery with three arches, perhaps for music. Narrow galleries run quite round the old part, to preserve communications with the rooms; in one of which the unfortunate Mary Stuart first saw light. On the north side of the high street, on an eminence east of the palace, stands St Michael's church; a handsome structure, where James V. intended to have erected a throne and twelve stalls for the sovereign and knights of the order of St Andrew. In the market-place is another fountain of two stories with eight spouts, and surmounted like the former with an imperial crown. In one of the buildings having for some time meditated the establishment of a chair of divinity, and the education of natural history in Sweden, at the university, and, like himself, in a particular manner encouraged in the study of natural history in general, but particularly to ichthyology. Soon after his residence at Upfal, our author was also happy enough to obtain the favour of several gentlemen of established character in literature. He was in a particular manner encouraged in the pursuit of his studies by the patronage of Dr Olaus Cellius, at that time professor of divinity, and the reformer of natural history in Sweden; who, being struck with the diligence of Linnaeus in describing the plants of the Upfal garden, and his extensive knowledge of their names, not only patronized him in a general way, but admitted him to his houfe, his table, and his library. Under such encouragement it is not strange that our author made a rapid progress, both in his studies and the esteem of the professors: in fact, we have a very striking proof of his merit and attainments, as much as we find, that, after only two years residence, he was thought sufficiently qualified to give lectures occasionally from the botanic chair, in the room of the professor Rudbeck. In the year 1731, the royal academy of sciences at Upsal having for some time meditated the design of improving the natural history of Sweden, at the instance particularly of professors Cellius and Rudbeck, deputed Linnaeus to make the tour of Lapland, with the sole view of exploring the natural history of that arctic region; to which undertaking, his reputation, already high as a naturalist, and the strength of his constitution, equally recommended him. He left Upsal the 13th of May, and took his route to Gevalia or Gevels, the principal town of Gestricia, 45 miles distant from Upsal. Hence he travelled through Helsingland into Medalpalsia, where he made an excursion, and ascended a remarkable mountain, before he reached Hudwickswald, the chief town of Helingland. From hence he went through Angermaland to Hernofand, a sea-port on the Bothnic gulf, 70 miles distant from Hudwickswald. When he had proceeded thus far, he found it proper to return
When Linnaeus arrived at Uma, in West Bothnia, about 96 miles from Turku, he quitted the public road, and took his course through the woods westward, in order first to traverse the most southern parts of Lapland. Being now come to the country that was more particularly the object of his inquiries, equally a stranger to the language and to the manners of the people, and without any associate, he committed himself to the hospitality of the inhabitants, and never failed to experience it fully. He speaks in several places, with peculiar satisfaction, of the innocence and simplicity of their lives and their freedom from diseases. In this excursion he reached the mountains towards Norway; and after encountering great hardships, returned into West Bothnia, quite exhausted with fatigue. Our traveller next visited Pitha and Lula, upon the Gulf of Bothnia; from which latter place he took again a western route, by proceeding up the river of that name, and visited the ruins of the temple of Jocknow in Lula Lapland or Lap Mark; thence he traversed what is called the Lapland Desfort, defulte of all villages, cultivation, roads, or any conveniences; inhabited only by a few straggling people, originally descended from the Finlanders, and who settled in this country in remote ages, being entirely a distinct people from the Laplanders. In this district he ascended a noted mountain called Waldeck; in speaking of which he has given us a pleasant relation of his finding a singular and beautiful new plant (Adromeda tetragona) when travelling within the arctic circle, with the sun in his view at midnight, in search of a Lapland hut. From hence he crossed the Lapland Alps into Finmark, and traversed the shores of the northern sea as far as Saltco.

These journeys from Lula and Pitha on the Bothnian gulf, to the northern shore, were made on foot; and our traveller was attended by two Laplanders, one his interpreter, and the other his guide. He tells us, that the vigour and strength of these two men, both old, and sufficiently loaded with his baggage, excited his admiration; since they appeared quite unhurt by their labour, while he himself, although young and robust, was frequently quite exhausted. In this journey he was wont to sleep under the boat with which they forded the rivers, as a defence against rain, and the gnats, which in the Lapland summer are not less teasing than in the torrid zone. In descending one of these rivers he narrowly escaped perishing by the overfetting of the boat, and lost many of the natural productions which he had collected.

Linnaeus thus spent the greater part of the summer in examining this arctic region, and those mountains on which, four years afterwards, the French philosophers secured immortal fame to Sir Isaac Newton. At length, after having suffered incredible fatigues and hardships in climbing precipices, passing rivers in miserable boats, suffering repeated vicissitudes of extreme heat and cold, and not unfrequently hunger and thirst, he returned to Tornoa in September. He did not take the same route from Tornoa as when he came into Lapland, having determined to visit and examine the country on the eastern side of the Bothnian gulf; his first stage, therefore, was to Ula in East Bothnia; from thence to Old and New Carleby, 84 miles south from Ula. He continued his route through Wafa, Christiania, and Birnbeburgh, to Abo, a small university in Finland. Winter was now setting in space; he therefore crossed the Gulf by the island of Aland, and arrived at Ulsfc in November, after having performed, and that mostly on foot, a journey of ten degrees of latitude in extent, exclusively of those deviations which such a design rendered necessary.

In 1732 he visited and examined the several mines in Sweden; and made himself so well acquainted with mineralogy and the docimastic art, that we find he was sufficiently qualified to give lectures on those subjects, upon his return to the university. The outlines of his system on mineralogy appeared in the early editions of the Systema Naturae; but he did not exemplify the whole until the year 1768.

In the year 1734 Linnaeus was sent by baron Rentzheim, governor of Dalekarlia, with several other naturalists in that province, to investigate the natural productions of that part of the Swedish dominions; and it was in this journey that our author first laid the plan of an excellent institution, which was afterwards executed, in a certain degree at least, by himself, with the assistance of many of his pupils, and the result published under the title of Pan Suecius, in the second volume of the Acta Academiarum.

After the completion of this expedition, it appears that Linnaeus resided for a time at Falun, the principal town in Dalekarlia: where he tells us, that he taught mineralogy and the docimastic art, and practised physic; and where he was very hospitably treated by Dr Moore, the physician of the place. It also appears, that he contracted at this time an intimacy with one of that gentleman's daughters, whom he married about five years afterwards upon his settling as a physician at Stockholm.—In this journey he extended his travels quite across the Dalekarlian Alps into Norway; but we have no particular account of his discoveries in that kingdom. In 1735 Linnaeus travelled over many other parts of Sweden, some parts of Denmark and Germany, and fixed in Holland, where he chiefly resided until his return to Stockholm, about the year 1739. In 1735, the year in which he took the degree of M. D. he published the first sketch of his Systema Naturae, in a very compendious way, and in the form of tables only, in 12 pages in folio. By this it appears that he had at a very early period of his life (certainly before he was 24 years old) laid the basis of that great structure which he afterwards raised, not only to the increase of his own fame, but to that of natural science.

In 1736 Linnaeus came into England, and visited Dr Dillenius, the late learned professor at Oxford, whom he justly considered as one of the first botanists in Europe. He mentions with particular respect the civilities he received from him, and the privileges he gave him of inspecting his own and the Sherardian collection of plants. It is needless to say, that he visited Dr Martyr, Mr Rand, and Mr Miller, and that he was in a more singular manner indebted to the friendship of Dr Isaac Lawton. He also contracted an intimate friendship with Mr Peter Collinson, which was reciprocally increased by a multitude
Linnaeus, in multitude of good offices, and continued to the last without any diminution. Dr. Boerhaave had furnished him with letters to that great naturalist Sir Hans Sloane; but it is with regret that we must observe, they did not procure him the reception which the warmth of his recommendation seemed to claim.

One of the most agreeable circumstances that happened to Linnaeus during his residence in Holland, arose from the patronage of Mr. Clifford, in whose house he lived a considerable part of his time, being now as it were the child of fortune:—Ex nihilo patria trivium sex annos aereis dixere—are his own words. With Mr. Clifford, however, he enjoyed pleasures and advantages scarcely at that time to be met with elsewhere in the world; that of a garden excellently stocked with the finest exotics, and a library furnished with almost every author of note. How happy he found himself in this situation, those only who have felt the same kind of ardor can conceive. Whilst in Holland, our author was recommended by Boerhaave to fill the place, then vacant, of physician to the Dutch settlement at Surinam; but he declined it on account of his having been educated in so opposite a climate.

Besides being favored with the particular patronage and friendship of Boerhaave and Mr. Clifford, as is above mentioned, our author had also the pleasure of being contemporary with, and of reckoning among the number of his friends, many other learned persons who have since proved ornaments to their profession, and whose merit has most deservedly raised them to fame and honor. Among these we may properly mention Dr. John Burman, professor of botany at Amsterdam, whose name and family are well known in the republic of letters, and to whom our author dedicated his Bibliotheca Botanica, having been greatly assisted in compiling that work by the free access he had to that gentleman’s excellent library; John Frederick Gronvius of Leyden, editor of Clayton’s Flora Virginica, and who very early adopted Linnaeus’s System; Baron Van Swieten, late physician to the Empress Queen; Isaac Lawfon, beforementioned, afterwards one of the physicians to the British army, who died much regretted at Osterhout in the year 1747, and from whom Linnaeus received singular and very important civilities; Kramer, since well known for an excellent treatise on the dogmatical art; Van Royen, botanic professor at Leyden; Liebberink of Berlin, famous for his skill in microscopical instruments and experiments. To these may be added also the names of Albinus and Gauvain, and of others, were it requisite to show that our author’s talents had very early rendered him conspicuous, and gained him the regard of all those who cultivated and patronized any branch of medical science, and to which, doubtless, the singular notice with which Boerhaave honoured him did not a little contribute.

Early in the year 1738, after Linnaeus had left Mr. Clifford, and, as it should seem, when he resided with Van Royen, he had a long and dangerous fit of sickness; and upon his recovery went to Paris, where he was properly entertained by the Jussieu, at that time the first botanists in France. The opportunity this gave him of inspecting the Herbaria of Surinam and Tournefort, and those of the above-named gentleman, afforded him great satisfaction. He had intended to have gone from thence into Germany, to visit Ludwig and the celebrated Haller, with whom he was in close correspondence: but he was not able to complete this part of his intended route, and was obliged to return without this gratification.

Our author did not fail to avail himself of every advantage that access to the several museums of this country afforded him, in every branch of natural history; and the number and importance of his publications, during his absence from his native country, sufficiently demonstrate that fund of knowledge which he must have imbibed before, and so left to defy his extraordinary application. These were, Syllabus Naturalis, Fundamenta Botanica, Bibliotheca Botanica and Genera Plantarum; the last of which is justly considered as the most valuable of all the works of this celebrated author. What immense application had been bestowed upon it, the reader may easily conceive, on being informed, that before the publication of the first edition the author had examined the characters of 8,000 flowers. The last book of Linnaeus’s composition, published during his stay in Holland, was the Cladis Plantarum, which is a select illustration of the second part of the Fundamenta.

About the latter end of the year 1738, or the beginning of the next, our author settled as a physician at Stockholm, where he seems to have met with considerable opposition, and was oppressed with many difficulties, but all of these at length he overcame, and got into extensive practice; and soon after his settlement, married the lady before spoken of. By the interest of Count Tellin, who was afterwards his great patron, and even procured medals to be struck in honour of him, he obtained the rank of physician to the fleet, and a stipend from the citizens for giving lectures in botany. And what at this time especially was highly favourable to the advancement of his character and fame, by giving him an opportunity of displaying his abilities, was the establishment of the Royal Academy of Sciences at Stockholm; of which Linnaeus was constituted the first president, and to which establishment the king granted several privileges, particularly that of free postage to all papers directed to the secretary. By the rules of the academy, the president held his place but three months. At the expiration of that term, Linnaeus made his Oratio de novo rabilibus in Infectis, Oct. 3. 1739; in which he endeavours to excite an attention and inquiry into the knowledge of insects by displaying the many singular phenomena that occur in contemplating the nature of those animals, and by pointing out, in a variety of instances, their usefulness to mankind in particular, and to the economy of nature in general.

During all this time, however, Linnaeus appears to have had his eye upon the botanical and medical chair at Upsal, at this time occupied by Rudbeck, who was far advanced in life. We learn indeed that he was so intent on purifying and perfecting his great designs in the advancement of his favourite study of nature, that he had determined, if he failed in procuring the professorship at Upsal, to accept the offer that had been made to him by Haller of filling the botanical chair at Gottingen. However, in course of time, he obtained his wish. In the year 1741, upon the resignation
From Stockholm it was understood that the credit of that university, as a school of physic, had been increasing; numbers of students, especially from Germany, attracted there; and their choice was confirmed by the university.

Linnæus took anatomy, physiology, pathology, and the therapeutic part; Linnæus, natural history, botany, materia medica, the diatetic part, and the diagnosis morborum.

During the interval of his removal from Stockholm to Upfal in consequence of this appointment, our professor was deputed by the states of the kingdom to make a tour to the islands of Öland, Gotland, and the Baltic, attended by six of the pupils, commissioned to make such inquiries as might tend to improve agriculture and arts in the kingdom, to which the Swedish nation had for some time paid a particular attention. The result of this journey was very successful, and proved fully satisfactory to the states, and was afterwards communicated to the public. On his return he entered upon the professorship, and pronounced before the university his oration de Persiculationum intra Patrum necessitate, October 17, 1741; in which he forcibly displays the usefulness of such excursions, by pointing out to the students that vast field of objects which their country held out to their cultivation, the univerfity his oration became lucrativa, and greatly esteemed by the excellent manner

By Gronovius at Leyden, had brought, as it were, a confuxion of every thing rare and valuable in every branch of nature, from all parts of the globe, into Sweden. The king and queen of Sweden had their separate collections of rarities; the former at Ulriksdal; the latter, very rich in exotic insects and shells, procured at a great expense, at the palace of Drottningholm; both of which our author was employed in arranging and describing. Besides these, the museum of the royal academy of Upfal had been augmented by a considerable donation from the king, whilst hereditary prince, in 1746; by another from Count Gylenberg the year before; by a third from M. Grill, an opulent citizen of Stockholm.

From this time we see the professor in a more elevated rank and situation—life. His reputation had already procured him honours from almost all the royal societies in Europe; and his own sovereign, truly-felt of his merit, and greatly esteemmg his character and abilities, favoured him with a mark of his distinction and regard, by creating him a knight of the polar star. It was no longer fcadatus et alget. His emoluments kept pace with his fame and honours: his practice in his profession became lucrative; and we find him soon after possessed of his country-house and gardens at Hommarby, about five miles from Upfal. He had moreover received one of the most flattering testimonies of the extent and magnitude of his fame that perhaps was ever shown to any literary character, the state of the nation which conferred it with all its circumstances, duly considered. This was an invitation to Madrid from the king of Spain, there to preside as a naturalist, with the offer of an annual pension for life of 2000 pisoles, letters of nobility, and the perfect free exercise of his own religion: But, after the most perfect acknowledgments of the singular honour done him, he returned for answer, that if he had any merit, they were due to his own country.

In the year 1755, the Royal Academy of Sciences at Stockholm honoured our professor with one of the first premiums, agreeably to the will of Count Sparre; who...
Linnaeus, who had decreed two gold medals, often of great value, each to be annually given by the academy to the author of such papers as the preceding year's Stockholm Acts, as should be judged most useful in promoting agriculture particularly, and all branches of rural economy. This medal bore on one side the arms of the count, with this motto. Superstes in scientiis amors Frederici Garp. Linnaeus obtained it in consequence of a paper De Plantis, quae Sveciis Sueciarium indigens, magnifici et commodi eiusmodis emolumento firma prestitit, and the ultimate intention was to recommend these plants, as adapted to culture in Lapland. This paper was inserted in the Stockholm Acts for 1754, vol. xv. Linnaeus also obtained the premium centum annorum, proposed by the Imperial Academy of Sciences at Petersburg, for the best paper written to establish or disprove, by new arguments, the doctrine of the sexes of plants. It was, if possible, an additional glory to Linnaeus to have merited this premium from the Petersburg academy, as much as a professor of that society, a few years before, had with more than common zeal, although with a facility like that of the other antagonists of our author, endeavoured to overturn the whole Linnaean system of botany, by attempting to show that the doctrine of the sexes of plants had no foundation in nature, and was unsupported by facts and experiments.

It appears that Linnaeus, upon the whole, enjoyed a good constitution; but that he was sometimes severely afflicted with a hemiplegia, and was not exempted from the gout. About the close of 1776, he suffered with an apoplexy, which left him paralytic; and at the beginning of the year 1777, he suffered another stroke, which very much impaired his mental powers. But the disease supposed to have been the more immediate cause of his death, was an ulceration of the urinary bladder, of which, after a tedious indisposition, he died, January 11, 1778, in the 71st year of his age.

His principal other works, besides those already mentioned, are, Iterollandicum et Gotlandicum, Iter Scoticum, Flora Suecia, Fauna Suecia, Materia Medica, Philosophia Botanica, Genera Botanorum, different papers in the Acta Ufaliensia, and the Amoenitates Academicae. The last of this great man's treatises was the Manutia Altera, published in 1771; but before his death he had finished the greatest part of the Manutia Terra, afterwards completed and published by his son.

To the lovers of science it will not appear strange, nor will it be unpleasant to hear, that uncommon respect was shown to the memory of this great man. We are told, that "on his death a general mourning took place at Upal, and that his funeral procession was attended by the whole university, as well professors as students, and the pall supported by sixteen doctors of physic, all of whom had been his pupils." The king of Sweden, after the death of Linnaeus, ordered a medal to be struck, of which one side exhibits Linnaeus's bust and name, and the other Cybele, in a dejected attitude, holding in her left hand a key, and surrounded with animals and growing plants; with this legend, Deam indiis augusti amici, and beneath, Post obitum Up. faliens. Jan. m. dio. x. Aug. 1778. This generous monarch not only honoured the Royal Academy of Sciences with his presence when Linnaeus's commemoration was held at Stockholm, but, as a still higher tribute, in his speech from the throne to the assembly of the states, he lamented Sweden's loss by his death. Nor was Linnaeus honoured only in his own country. The late worthy professor of botany at Edinburgh, Dr Hope, not only pronounced an elegium in honour of him before his students at the opening of his lectures in the spring 1778, but also laid the foundation-stone of a monument (which he afterwards erected) to his memory, in the botanic garden there; which, while it perpetuates the name and merits of Linnaeus, will do honour to the founder, and, it may be hoped, prove the means of raising an emulation favourable to that science which this illustrious Swede so highly dignified and improved.

As to the private and personal character of this illustrious philosopher: His stature was diminutive and puny; his head large, and its hinder part very high; his look was ardent, piercing, and apt to daunt the beholder; his ear not sensible to music; his temper quick, but easily appeased.

Nature had, in an eminently manner, been liberal in the endowments of his mind. He seems to have been possessed of a lively imagination, corrected however by a strong judgment, and guided by the laws of fancy. He was of a most retentive memory, an unmitting industry, and the greatest perseverance in all his pursuits; as is evident from that continued vigour with which he prosecuted the design, that he appears to have formed so early in life, of totally reforming and fabricating anew the whole science of natural history; and this fabric he raised, and gave to it a degree of perfection unknown before; and had moreover the uncommon felicity of living to see his own structure rise above all others, notwithstanding every discouragement its author at first laboured under, and the opposition it afterwards met with. Neither has any writer more cautiously avoided that common error of building his own fame on the ruin of another man's. He every where acknowledged the several merits of each author's system; and no man appears to have been more sensible of the partial defects of his own. Those anomalies which had principally been the objects of criticism, he well knew every artificial arrangement must abound with; and having laid it down as a firm maxim, that every system must finally rest on its intrinsic merit, he willingly commits his own to the judgment of posterity. Perhaps there is no circumstance of Linnaeus's life which shows him in a more dignified light than his conduct towards his opponents. Disavowing controversy, and justly considering it as an unimportant and fruitless sacrifice of time, he never replied to any, numerous as they were at one season.

To all who see the aid this extraordinary man has brought to natural science, his talents must appear in a very illustrious point of view; but more especially to those who, from similarity of taste, are qualified to see more distinctly the vast extent of his original design, the greatness of his labour, and the elaborate execution he has given to the whole. He had a happy command of the Latin tongue, which is alone the language of science; and no man ever applied it more successfully to his purpose, or gave to description such copiousness, united with that precision and conciseness which so eminently characterise his writings.
They lived to enjoy the fruit of his own labour in an uncommon degree. Natural history raised itself in Sweden, under his culture, to a state of perfection unknown elsewhere; and was from thence diffeminated through all Europe. His pupils diffeminated themselves over all the globe; and with their master's fame, extended both science and their own. More than this, he lived to see the sovereigns of Europe establishe several public institutions in favour of this study; and even professorships establishe in divers universities for the same purpose, which do honour to their founders and patrons, and which have excited a curiosity for the science, and a sense of its worth, that cannot fail to further its progress, and in time raise it to that rank which it is entitled to hold among the pursuits of mankind.

LINNÉ, in ornithology. See Fringilla. It is remarkable of this bird, that when it builds in hedges, and when in furze-bushes on heaths, in both which places the nests are very common, they are made of very different materials. When they build in hedges, they use the slender-filaments of the roots of trees, and the down of feathers and thistles; but when they build on heaths, they use moss, principally for the other part, finishing it within with such things as the Vol. X.
LINUM. It received a Roman colony at the same time with Putopol and Vulturnum; was improved and enlarged by Augustus; afterwards forfeited its right of colonyship, and became a prefecture. Hither Scipio Africanus the Elder retired from the mean envy of his ungrateful countrymen; and here he died, and was buried: though this last is uncertain, he having a monument both here and at Rome. No vestige of the place now remains.

LINTSTOCK, in military affairs, a wooden staff about three feet long, having a sharp point in one end and a fort of a fork or crotch on the other; the latter of which serves to contain a lighted match, and by the former the lintstock is occasionally flucked in the ground, or in the deck of a ship during an engagement. It is very frequently used in small vessels, where there is commonly one fixed between every two guns, by which the match is always kept dry, and ready for firing.

LINTZ, a very handsome town of Germany, and capital of Upper Austria, with two fortified castles; the one upon a hill, the other below it. Here is a hall in which the states assemble, a bridge over the Danube, a manufacture of gunpowder, and several other articles. It was taken by the French in 1741, but the Austrians retook it in the following year. E. Long. 14° 33'. N. Lat. 48° 16'.

LINZ, a town of Germany, in the circle of the Lower Rhine, and Electorate of Cologne, subject to that elector. It is seated on the river Rhine, in E. Long. 7° 11'. N. Lat. 50° 31'.

LINUM, flax; a genus of the pellagynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 14th order, Graminaceae. The calyx is pentaphyllous; the petals are five; the capsule is quinquevalved and decemlocular; as the seeds, by way of tea, is recommended in coughs as an excellent emollient and anodyne; they are used externally in catarrhs, to aflige the pain of inflamed tumors; internally, a slight infusion of linseed, by way of tea, is recommended in coughs as an excellent pectoral, and of great service in pleuritises, nephritic complaints, and suppurations of urine. The virtue of the third species is expressed in its title: an infusion in water or whey of a handful of the fresh leaves, or a dram of them in substance when dried, are said to purge without inconvenience.

LINUS, in classical history, a native of Colchis, contemporary with Orpheus, and one of the most ancient poets and musicians of Greece. It is impossible, at this distance of time, to discover whether Linus was the disciple of Orpheus, or Orpheus of Linus. The majority, however, seem to decide this question in favour of Linus. According to archbishop Uther, he flourished about 1280 B. C., and he is mentioned by Euhbian among the poets who wrote before the time of Moses. Diodorus Siculus tells us, from Dionysus of Mitylene the historian, who was contemporary with Cicero, that Linus was the first among the Greeks who invented verses and music, as Cadmus first taught them the use of letters. The same writer likewise attributes to him an account of the exploits of the first Bacchus, and a treatise upon Greek mythology, written in Pelasgian characters, which were also those used by Orpheus, and by Pronapides the preceptor of Homer. Diodorus says that he added the string to the Mercurian lyre, and ascribes to him the invention of rhime and melody; which Suidas, who regards him as the most ancient of lyric poets, confirms. Mr Marpurg tells us, that Linus invented cat-gut firings for the use of the lyre, which, before his time, was only strung with thongs of leather, or with different threads of flax strung together. He is said by many writers to have had several disciples of great renown; among whom were Hercules, Thamyris, and, according to some, Orpheus.—Herocrates, says Diodorus, in learning from Linus to play upon the lyre, being extremely dull and obtuse, provoked his master to strike him; which so enraged the young hero, that, infinitely feizing the lyre of the musician, he beat out his brains with his own instrument.

LION, in zoology. See Felis.

LIONCELLES, in heraldry, a term used for several lions borne in the same coat of arms.

LIOTARD, called the Turk, an eminent painter, was born, at Geneva in 1702, and by his father was destined for a merchant; but by the persuasion of his friends, who observed the genius of the young man, he was permitted to give himself up to the art of painting. He went to Paris in 1725, and in 1738 accompanied the marquis de Puygues to Rome, where he was going ambassador to Naples. At Rome he was taken notice of by the earls of Sandwich and Beaufort, then lord Duncannon, who engaged Liotard to go with them on a voyage to Constantinople. There he became acquainted with the late lord Edgcumbe, and Sir Edward Cavendish, English ambassadors, who prevailed upon him to come to England, where he flourished two years. In his journey to the Levant he adopted the eastern habits.
LIP, in anatomy. See there, \textit{n} 102.

Here Lip, a disorder in which the upper lip is in a manner slit or divided so as to resemble the upper lip of a hare, whence the name. See \textit{Surgery}.

LIPARA (anc. geog.), the principal of the islands called \\textit{Eosia}, situated between Sicily and Italy, with a cognominal town, so powerful as to have a fleet, and the other islands in subjection to it. According to Diodorus Siculus, it was famous for excellent harbours and medicinal waters. He informs us also, that it suddenly emerged from the sea about the time of Hannibal's death. The name is Punica, according to Bochart; and given it, because, being a volcano, it thone in the night. It is now called Lipari, and gives name to nine others in its neighbourhood; viz. Stromboli, Pace, Rotto, Panaria, Saline, Vulcano, Feticula, Alicor, and Utica. These are called, in general, the Lipari Islands. Some of these are active volcanoes at present, though Lipari is not. It is about 12 miles in circumference; and abounds in corn, figs, and grapes; bitumen, sulphur, alum, and mineral waters.

LIPARI, an ancient and very strong town, and capital of an island of the same name in the Mediterranean, with a billy's fee. It was ruined by Barbarossa in 1544, who carried away all the inhabitants into slavery, and demolished the place; but it was rebuilt by Charles V. E. Long. 35. N. Lat. 29. 35.

Lipari, properly, is the general name of a cluster of islands. Thence, according to Mr Houel, are principally ten in number, the rest being only uninhabitable rocks of narrow extent. The largest and the most populous of them, that above-mentioned, communicates its name to the rest. Vulcano is a desert but habitable island, lying south from the large island of Lipari. Saline, which lies west-north-west from the same island; Fe- stiudi, nearly in the same direction, but twenty miles farther distant; and Alcudia, ten miles south-west of Felicudi; are inhabited. Panarea is east of Lipari, the famous Stromboli north-east, and both of them are inhabited. The rest are in a desert state; such as Batilica, which was formerly inhabited; Attalo, which might be inhabited; and L'Echambiana, on which some remains of ancient dwellings are still to be found. L'Echambia is nothing but a bare rock.

The termicola, a word signifying ants, are a chain of small black cliffs which run to the north-east of Lipari, till within a little way of L'Echambiana and Eicunera, rising more or less above the water, according as the sea is more or less agitated.

Ancient authors are not agreed with respect to the number of the Lipari islands. Few of those by whom they are mentioned appear to have seen them; and in places such as these, where subterraneous fires burst open the earth and raise the ocean from its bed, terrible changes must sometimes take place. Vulcano and Vulcano were once separated by a strait so as to form two islands. The lava and ashes have filled up the intervening strait; and they are now united into one island, and have by this change become much more habitable.

The castle of Lipari stands on a rock on the east quarter of the island. The way to it from the city leads up a gentle declivity; there are several roads to it. This castle makes a part of the city; and on the summit of the rock is the citadel, in which the governor and the garrison resides. The cathedral stands in the same situation. Here the ancients, in conformity to their usual practice, had built the temple of a tutelary god. The citadel commands the whole city; and it is accessible only at one place. Were an hostile force to make a descent on the island, the inhabitants might retreat hither, and be secure against all but the attacks of famine.

The ancient inhabitants had also fortified this place. Confiderable portions of the ancient walls are still standing in different places, particularly towards the south; their structure is Grecian; and the stones are exceedingly large, and very well cut. The layers are three feet high, which shows them to have been raised in some very remote period. These remain are surrounded with modern buildings. The remains of walls, which are still to be seen here, have belonged not only to temples, but to all the different sorts of buildings which the ancients used to erect. The vaults, which are in a better state of preservation than any of the other parts of these monuments, are now converted to the purposes of a prison.

In the city of Lipari there are convents of monks of two different orders; but there are no convents for women, that is to say, no cloisters in which women are confined; there, however, whose heads and hearts move them to embrace a state of pious celibacy, are at liberty to engage in a monastic life, with the concurrence of their confessors. They put on the sacred habit, and vow perpetual virginity, but continue to live with their father and mother, and mix in society like other women. The vow and the habit even enlarge their
L I P  

Lipari. their liberty. This custom will, no doubt, M. Houel observes, appear very strange to a Frenchwoman; but this was the way in which the virgins of the primitive church lived. The idea of shutting them up together did not occur till the fifth century. The life of these religious ladies is less gloomy than that which those under the same vows lead in other countries. They wear cloaths of particular colours, according as they belong to this or that order. Their dresses give them a right to frequent the church at any hour; and the voice of centurie, which takes particular pleasure in directing her attacks against pious ladies, goes so far as to assert, that some young women assume this habit with no other views but that they may enjoy greater freedom.

In this island oxen of a remarkably beautiful species are employed in ploughing the ground. The ancient plough is still in use here. The mode of agriculture practised here is very expeditions. One man traces a furrow, and another follows to sow in it grain and pulse. The ploughman, in cutting the next furrow, covers up that in which the feed has been sown: and thus the field is both ploughed and sown at once. Nature seems to be here uncommonly vigorous and fertile. Vegetation is here more luxuriant, and animals gayer and more healthful, than almost anywhere else.

Near the city of Lipari, the traveller enters deep narrow roads, of a very singular appearance. The whole island is nothing but an assemblage of mountains, all of them consisting of ashes or lava discharged from the depths of the volcano by which it was at first produced. The particles of this pumoline, or ashes, are not very hard; the action of the rain-water has accordingly cut out trenches among the mountains; and these trenches being perhaps less uneven than the rest of the surface, have of consequence been used as roads by the inhabitants, and have been rendered much deeper by being worn for so many ages by the feet of men and other animals. These roads are more than five or six fathoms deep, and not more than seven or eight feet wide. They are very crooked, and have echoes in several places. You would think that you were walking through narrow streets without doors or windows. Their depth and windings shelter the traveller from the sun while he is passing through them; and he finds them deliciously cool.

The first volcanic eruption in the Lipari islands, mentioned in history, is that of which Calliastakes notice of in his history of the wars in Sicily. Callias was contemporary with Agathocles. That eruption continued without interval for several days and nights; and threw out great fountains, which fell at more than a mile's distance. The sea boiled all around the island. The works of Callias are lost, and we know not whether he descended too close detail of particulars concerning the ravages produced by this eruption. Under the confusion of Eumelis Lepidus and L. Aurelius Oratus, 126 years before the Christian era, these islands were affected with a dreadful earthquake. The burning of Etna was the first cause of that. Around Lipari and the adjacent islands, the air was all on fire. Vegetation was withered; animals died; and fusible bodies, such as wax and resin, became liquid. If the inhabitants of Lipari, from whom our author received these facts, and the writers who have handed down an account of them, have not exaggerated the truth, we must believe that the sea then boiled round the island; the earth became hot as to burn the cables by which vessels were fixed to the shore, and consumed the planks, the oars, and even the small boats.

Pliny, the naturalist, speaks of another similar event which happened 30 or 40 years afterwards, in the time of the war of the allied states of Italy against Rome. One of the Eolian islands, says he, was all on fire as well as the sea; and that prodigy continued to appear till the senate appealed, by a deputation, the wrath of the gods. From the time of that war, which happened 86 years before the birth of our Saviour, till the year 1444 of our era, we have no account of any eruption of these volcanoes; and from that period again, till the year 1444, we hear of no explosion from them, that is, for the space of 1300 years. But, at that time, both Sicily and the Eolian islands were agitated by dreadful flocks of earthquake: the volcano of these islands poured forth streams of lava with an awful violence, and cut its way on the plain. Smoke which rose to an amazing height. After it discharged enormous fountains which fell at the distance of more than six miles.

A century later, in the year 1550, the fury of this volcano was again renewed. The ashes and fountains discharged from the crater filled up the strait between Volcano and Vulcano.

About two centuries after that, in the year 1739, there was a sixth eruption. The burments of the volcanic fire were attended with a noise so dreadful, that it was heard as far as Melazzo in Sicily.

Father Leandro Alberti says, that on one of those dreadful occasions, the women of Lipari, after employing in vain all the faints, vowed no more wine if the volcano should spare them. Their giving up this small gratification was doubles of great service; yet the eruptions still continue, and have even become more frequent since that time. Only 36 years intervened between this eruption and that which happened in the year 1775. The whole island was then shaken; subterraneous thunder was heard; and considerable fountains of flame, with smoke, fstones, and vitreous lava, issued from the crater. Lipari was covered over with ashes; and part of the city was conveyed by the winds all the way into Sicily. Five years after, however, in the month of April 1780, there issued a new explosion from Volcano; the smoke was thick, the shocks contempt, and the subterraneous noise very frequent. So great was the confusion among the inhabitants of Lipari on this occasion, that the commander Deodati Dolomieu, who visited these islands not long after that event, informs us, that the inhabitants in general, but especially the women, devoted themselves as slaves to the service of the blessed virgin; and wore on their arms, as tokens of their fervitude, small iron chains, which they fill continue to wear.

This act of piety, however, was not so efficacious as the deputation of the fathers had been. For after that deputation, more than 200 years passed, and many a year, without the Eolian islands were afflicted by any other eruptions, at least by any considerable one; whereas, in three years after the ladies devoted themselves in so submissive a manner to the service of the virgin, the islands of Lipari...
LIPARI [93]

Lipari. The dry baths of St Calogero, in the island of Lipari, are flores, where sulphureous exhalations, known to be of a fiddle nature, alight out of the earth by holes or siphonais. A range of apartments are built around the place where the exhalations arise.

The heat is communicated through those apartments in such a way, that when entering at one end, you advance towards the other, the heat still increases upon you till you gain the middle apartment, and again diminishes in the same manner as you proceed from the middle to the other end of the range of chambers. In consequence of this disposition of these apartments, the sick person can make choice of that temperature which best suits the nature of his disease. There are a few miserable huts and a small chapel for the accommodation of the people who repair to these baths.

The people of the place are ready to attend them. Physicians likewise follow their patients thither, when the disease is of such a nature as to render their attendance requisite, and the patient rich enough to afford them hand-some fees: but there is no physician settled in the place. Besides these dry baths, there are baths of hot water distinguished by the name of St Calogero's baths. There are around them buildings sufficient to lodge a considerable number of sick people with their necessary attendants.

At present, however, those buildings are in bad condition. The baths consist of two halls; one square, the other round. The former is antique; it has been built by the Romans; it is arched with a cupola, and 12 feet in diameter; it has been repaired: The other is likewise arched with a cupola both within and without. The water comes very hot into the first. It gushes up among pieces of lava, which compose a part of the mountain at the foot of which these baths are built. Those fones remain in their natural state. All that has been done is the raising of a square building, including them. Within that building the sick persons either sit down on the stones, or immerse themselves in the intervening cavities which are filled with water.

They continue there for a certain time, and approach nearer to, or remain at a farther distance from, the spring, according as their physicians direct. The place serves also as a flowers. The hot vapours arising from the water communicate to the surrounding atmosphere a considerable degree of heat. It is indeed not inferior to that of the hot baths of Termini, which owe their heat to a similar cause. In these baths, therefore, a person can have the benefit either of bathing in the hot water, or of expelling himself to the vapour, the heat of which is more moderate. The bath before mentioned, under the appellation of dry bath, is also a flower; but the hot vapour with which it is filled issue directly from the volcano. The place of the bath is, however, at such a distance from the volcanic focus, that the heat is not at all intolerable.

The mountain at the foot of which these baths are situated is round, and terminates at the summit in a rock of petrified ashes, which are very hard and of a very fine grain. This petrification consists of pretty regular strata, and appears to have been greatly prior in its origin to the adjacent rocks; which consist likewise of ashes, but ashes that have been deposited at a much later period. From this rock there proceeds likewise a stream of hot water, by which some mills in the neighbourhood are moved.

It cannot but appear surprising, that nature has placed nearly on the summit of a volcanic mountain springs which supply so considerable a quantity of water. To account for such a phenomenon would be well worthy of some ingenious naturalist. Nor are the hot springs all; proceeding around the same hill, at about a mile's distance, we find a spring of cold water, which originates from the summit of the same rock; that on the north-west produces three hot springs. The cold water is very pleasant to drink, and much used by both men and cattle.

Among these mountains there are many enormous loose masses of lava, the appearance of which, M. Houel informs us, naturally leads the observer to take notice that the lava of the volcano of Lipari is of a much greater diversity of colours, and those richer and more lively, than the lava of Vesuvius and Etne. The lava of Lipari is in some places, for several miles, of a beautiful red colour. It contains likewise in great abundance small black crystallized sioræ, as well as the small white grains which are commonly found in lava.

Among the eminences which overlook the city of Lipari, there are some rocks of a species which is very rare in Europe. Those are large masses of vitrified matter, which rise six or eight feet above the surface of the ground, and appear to extend to a great depth under it. They exist, through that range of mountains, in enormous masses, mixed with lavas of every different colour, and always standing detached and isolated. Were they cut and followed under ground, they would probably be found to exist in immense quarries in the bowels of the earth. The glass of which they consist might be employed with great advantage in manufactures. It is ready made, and might be easily purified. It is green, compact, and transparent.

The cultivation of the ground is the chief employment of the inhabitants of Lipari. The possession of a few acres of land here gives a man great importance. Parents, when they settle their children, rather give them money than any part of their lands.

More than two-thirds of the island is planted with vines: three-fourths of the grapes which these produce are dried, and sent mostly to London under the name of Paffola. There are different sorts of paffola; one of these, called the black paffola, is prepared from a particular kind of grape, of which the berries are uncommonly small; sold to Monthrés, Holland, and Tiroi. The vials are in small arbourns, which rise only to the height of two feet and an half above the ground. Under those arbours there grow beans, gourds, and other leguminous vegetables. In so hot a climate, the shade of the vials does not injure but protects the vegetables growing under it; they would otherwise be withered by the heat of the sun.

The method of preparing paffola and paflòina is curious enough: They first make a liquissum of common ashes; after boiling this, they pass it through a cloth or a sieve; they then put it again on the fire; and
when it is observed to boil hard, suddenly immerse the
grapes, but instantly bring them out again, and ex­
plode them to the fun to dry on broad frames of cane.
When sufficiently dry, the raisins are put into casks
and barrels to be folded and exported. The number of
casks of different sorts of raisins annually exported
from Lipari are estimated at 10,000.

This island likewise produces figs. There is some
white mulmey and a little red wine exported from it.

About 60 or 80 years since, sulphur was one of the
articles with which the inhabitants of this island sup­
plied foreign merchants. But that trade has been gi­
given up; from an idea which the Liparese entertain,
that sulphur infects the air so as to injure the fertility
of the vines. The same prejudice prevails in Sic­
ily; but it seems to be ill-founded.

There are courts of justice in Lipari, of the same
powers and character with those in the cities of Si­
cily. Causes of more than ordinary importance are
Carried to Palermo.

The island is entirely free from every kind of im­
position. The king receives nothing from it; because
Count Roger anciently bestowed on his bishop all his
rights of royalty over Lipari. The bishop there re­
ceived annually from the inhabitants a tenth part of
the products of their lands. They after wards to pre­
vent fraud, calculated the value of that tithe for one
year; and on the condition of their paying in future
a sum of money equal to what that year’s tithe was
valued at, he not only gave up his right to the tithe,
but also ceded to them a considerable extent of land
which belonged to him.

In the archiepiscopal palace, and in the palace of
the Baron de Monizzi, there are some noble pieces
of painting by Sicilian painters:—A St Peter, a St
Rosalia, Jesus disputing with the Jewish doctors, the
archiepiscopal throne, the incredibility of St Thomas.

LIPOThymIA, Painting, may arise from several
causes: as too violent exercise, suppression of the
menstruæ, or other accustomed evacuations, &c. See
the Index subjoined to Medicine.

Lippa, a town of Hungary, with a castle. It
was taken by the Turks in 1552; by the Imperialists
in 1688; and by the Turks again in 1691; who aban­
donied it in 1695, after having demolished the fortifi­
cations. It is leat on a mountain, in E. long. 21°
55. N. lat. 26. 5.

Lippa, the capital of a country of the same name
in Germany, and in the circle of Westphalia. It sits
on a river of the same name, and was formerly the
residence of the principal branch of the house of Lippe.
It is now in the possession of the king of Prussia, and
carries on a good trade in preparing timber for build­
ing vessels on the Rhine, with which it has a commu­
nication by the river Lippe. The country round it is un­
wholesome and marshy. E. long. 8° 12. N. lat. 51°
43.

LIPPI (Lorenzo), a painter of history and portraits,
was born in 1485, and learned the principles of pain­
ting from his father, and from Matteo Boffelli. He had an exquisite genius
for music and poetry, as well as for painting; and in
the latter, his proficiency was so great that some of
his compositions in the historical style were taken for
those of Bottelli. However, growing at last dissatisfied
with the manner of that master, he chose the manner
of Santi di Tito, who was excellent both in design and
invention, and appeared to have more of simple nature
and truth in his compositions than any other artist of
that time. At Florence Lippi painted many grand
designs for the chapels and convents, by which he larged his reputation; and at the court of Inpruck,
he painted a great number of portraits of the first no­
bility, which were deservedly admired. Yet, altho’
he was fond of imitating simple nature without any
embellishments from invention, his works are held in
the highest esteem for the graceful airs of the heads,
for the correctness of his outlines, and for the
elegant disposition of the figures. He died in 1664.

LIPIUS (Johus), a learned critic, was born at
Iech, a small village near Bruges, in 1547. After
having distinguished himself in polite literature, he
became secretary to cardinal de Granvelian at Rome,
where the best libraries were open to him; and he spent much labour in collating the MSS. of ancient
authors. He lived 13 years at Leyden; during which
he composed and published what he effects his best
works; but resided at Louvain, where he taught pol­
ite literature with great reputation. He was re­
markable for unfeathinf in religion, fluctuating often
between the Protestants and Papists; but he became
finally a bigot Catholic. He died at Louvain in
1609; and his works are collected in six volumes folio.

LIQEFACATION, an operation by which a fo­
lid body is reduced into a liquid; or the action of fire
or heat on fat and other fusible bodies, which puts
their parts into a mutual interminable motion. The lique­
faction of wax, &c. is performed by a moderate heat;
that of salt tartari, by the mere moisture of the air.
All fats liquify; sand, mixed with alkalies, becomes
liquefied by a reverberatory fire, in the making of
glass. In speaking of metals, instead of liquefaction,
we ordinarily use the word fusion.

LIQUID, a body which has the property of fluidi­
ty; and besides that, a peculiar quality of wetting
other bodies immersed in it, arising from some con­
figuration of its particles, which dispaces them to ad­
hire to the surfaces of bodies contiguous to them. See Fluid.

LIQUID, among grammarians, is a name applied to
certain consonants opposed to mutes. Thus l, m, n,
and r, are liquids.

LIQUIDAMBAR, SWEET-GUM-TREE, in botany:
A genus of the polyandria order, belonging to the
monocera class of plants: and in the natural method
ranking with those of which the order is doubtful.
The male calyx is common, and triphylous; there is
no corolla, but numerous filamenta; the female calyces
are collected into a spherical form, and tetraphylous;
there is no corolla, but seven styles; and many bi­
valved and monopensorous capsules collected into a
sphæra. There are only two species, both decidu­
os, viz. 1. The Hyracida, or the Virginian or
maple-leaved liquidambar; a native of the rich moift
parts of Virginia and Mexico. It will shoot in a regu­
lar manner to thirty or forty feet high, having its
young twigs covered with a smooth, light-brown bark,
while those of the older are of a darker colour. The
leaves are of a lucid green, and grow irregularly on
the young branches, on long footstalks: They resemble
those of the common maple in figure; the lobes are all
ferrated: and from the base of the leaf a strong mid­
The flowers are of a kind of saffron colour: They are produced at the ends of the branches the beginning of April, and sometimes sooner; and are succeeded by large round brown fruit, which looks singular, but is thought by many to be no ornament to the tree. 2. The peregrinum, Canada liquidambar, or spleenwort-leaved gale, is a native of Canada and Pennsylvania. The young branches of this species are slender, rough, and hardy. The leaves are obovate, of a deep green colour, hairy underneath, and have indistinct edges on their edges alternately very deep. The flowers come out from the sides of the branches, like the former; and they are succeeded by small roundish fruit, which seldom ripens in England.

Propagation. This may be performed either by seeds or layers; but the first method is the best. 1. They receive the seeds from America in the spring. Against their arrival, a fine bed, in a warm well sheltered place, should be prepared. If the soil is not naturally good, and inclined to be sandy, it should be wholly taken out near a foot deep, and the vacancy filled up with earth taken up a year before from a fresh pasture with the sward, and all well rotted and mixed by being often turned, and afterwards mixed with a fifth part of drift or sea-fand. A dry day being made choice of, early in March, let the seeds be sown, and the finest of this compost riddled over them a quarter of an inch deep. When the hot weather in the spring comes on, the beds should be shaded, and waterings given often, but in very small quantities, often affording them a gentle, nay, a very small sprinkling, at a time. Miller says the seeds of these plants never come up under two years. But, continues Hanbury, with this easy management, I hardly ever knew it longer than the end of May before the young plants made their appearance. The plants being come up, shading should still be afforded them in the parishing summer, and a watering every other night; and this will promote their growth, and cause them to become stronger plants by the autumn. In the autumn, the beds should be hooped to be covered with mats in the severe frosts. These mats, however, should always be taken off in open weather; and this is all the management they will require during the first winter. The succedaneum sower they will require no other trouble than weeding; though, if it should prove a dry one, they will find benefit from a little water now and ever knew it longer than the end of May before the young plants made their appearance. The plants being come up, shading should still be afforded them in the parishing summer, and a watering every other night; and this will promote their growth, and cause them to become stronger plants by the autumn. The two are found to take freely enough. By this method good plants may be obtained; though it is not so eligible as the other, if we have the convenience of procuring the seeds.

Properties. The leaves emit their odoriferous particles in such plenty as to perfume the circumambient air; nay, the whole tree exudes such a fragrant transparent resin, as to have given occasion to its being taken for the sweet florent. Thee trees, therefore, are very proper to be planted singly in large open, that they may amply display their fine pyramidal growth, or to be set in places near seats, pavilions, &c. The resin was formerly of great use as a perfume, but is at present a stranger in the shops.

LIQUOR, a name for any fluid substance of the aqueous or spirituous kind.

The principal beverage among the Jews, as well as the Greeks and Romans, in their early state, was water, milk, and the juices of various plants infused therein. For a long time, under the commonwealth of Rome, wine was so scarce, that in their sacrifices to the gods the libations were made with milk only. Wine did not become common there till A. U. C. 600, when vines began to be planted.

LIQUOR OF PLANTS. See CHEMISTRY, No. 1069.

Smoking Liquor of Liquor. See CHEMISTRY, No. 810.

Mineral Analyze Liquor of Hoffman. This is a composition of highly rectified spirit of wine, vitriolic ether, and a little of the dulcedoil of vitriol. It is made by mixing an ounce of the spirit of wine, which distills first in the distillation of ether, with as much of the liquor which is to be distilled, and afterwards by dissolving in the mixture which rises next, and which contains the ether, 12 drops of the oil which rises after the ether is passed. This has the same virtues with the ether, and is now generally distilled, the pure ether being sublimated in its place.

LIQUORICE. See GLYCERHIGA.

LIROIDENDRON, the Tulip-Tree, in botany: A genus of the polygina order, belonging to the polyandria class of plants; and in the natural method ranking under the 52d order, Gaudanata. The calyx is triphyllous; there are nine petals; and the seeds imbibed in such a manner as to form a cone. — There are but one species, viz., the tulip-sela, a deciduous tree, native of most parts of America. It rises with a large upright trunk, branching 40 or 50 feet high. The trunk, which often attains to a circumference of 30 feet, is covered with a grey bark. The branches, which are not very numerous, of the two-years-old wood, are smooth and brown; while the bark of the summer’s shoots is smoother and shining, and of a bluish colour. They are very pithy. Their young wood is green, and when broken emits a strong scent. The leaves grow irregularly on the branches, on long footstalks. They are of a particular structure, being composed of three lobes, the middle one of which is shortened in such a manner that it appears as if it had been cut off and hollowed at the middle: The two others are rounded off. They are about four or five inches long, and as many broad. They are of two colours: their upper surface is smooth, and of a stronger green than the lower. They fall off pretty early in autumn.
Lis [96]

The tulip-tree, in those parts of America where it grows common, affords excellent timber for many uses: particularly, the trunk is frequently hollowed, and made into a canoe sufficient to carry many people; and for this purpose no tree is thought more proper by the natives of those parts. In Europe, it may be stationed among trees of forty-feet growth.

LIS, or LyS (John Vander), painter of history, landscapes, and conversations, was born at Oldenburg in 1570, but went to Haarlem to place himself as a disciple under Henry Goltzius; and as he was endowed with great natural talents, he soon distinguished himself in that school, and imitated the manner of his master with great success. He adhered to the same style till he went to Italy; where, having visited Venice and Rome, he studied the works of Titian, Tintoretto, Paolo, Veronese, and Domenico Fetti, so effectually, than he improved his taste and judgment, and altered his manner entirely. He soon received marks of public approbation; and his compositions became universally admired for their good expression, for their lively and natural colouring, and the sweetness and delicacy of his pencil: although it must be acknowledged that he could never totally divest himself of the ideas and taste peculiar to the Flemings. His subjects usually were histories taken from the sacred writings, or the representation of rural sports, marriages, balls, and villagers dancing, dressed in Venetian habits; all which subjects he painted in a small as well as a large size, with a number of figures, well designed, and touched with a great deal of delicacy. He was likewise accounted to paint naked figures admirably, with natural and elegant attitudes, and a very agreeable turn of the limbs.

A capital picture of this master is, Adam and Eve lamenting the death of Abel; which is extremely admired, not only for the expression, but also for the beauty of the landscape: and in the church of St Nicholas at Venice is another of his paintings, representing St Jerome in the desert, with a pen in his hand, and his head turned to look at an angel, who is supposed to be foundling the last trumpet. The colouring of this picture is rather too red; but it is designed in a fine style, and charmingly pencilled. The paintings of this master are very rarely to be purchased. He died in 1629.

LIS (John Vander) of Breda, historical painter, was born at Breda about the year 1601, and became a disciple of Cornelis Poelburg, whose manner he imitated with extraordinary exactness, in the raiment, his neatness of pencilling, and the choice of his subjects. There are some paintings of this master's hand, which, tho' they appear to have somewhat less freedom and lightness of touch, are nearly equal to those of Poelburg, and are frequently taken to be his. At Rotterdam, in the possession of Mr Biffchop, there is a delicate painting representing Diana in the Bath, attended by her nymphs; and his most capital performance, in England, is said to be in the possession of the Viscount Middleton. The portrait of Vander Lis, painted by himself, is in the collection of Horace Walpole, Esq., which is described by him as ingeniously gentle, as being worked up equal to the smoothest of cameo.

LISBON, the capital of the kingdom of Portugal, situated in the province of Estremadura, on the banks of the river Tagus, in W. Long. 9° 25'. N. Lat. 38° 25'. It was anciently called Olisipo, Olijipo, and Usippe, which are supposed to be derived from the Phoenician Ulisaba or Olisipa, signifying in that tongue a pleasant bay, such as that on which this city stands. It first became considerable in the reign of king Emmanuel; from that king it hath been the capital of the kingdom, the residence of its monarchs, the seat of the chief tribunals, and offices of the metropolitan, a noble university, and the receptacle of the richest merchandise of the East and West-Indies. Its air is excellent; being refreshed by the delightful sea-breezes, and those of the Tagus. The city extends for about two miles along the Tagus; but its breadth is incomparable. Like old Rome, it stands on seven hills: but the streets in general are narrow and dirty, and some of them are very steep; neither are they lighted at night. The churches in general, are very fine; but the magnificence of the chapel-royal is amazing. Here is one of the finest harbours in the world; and there was a great number not
not only of fine churches and convents here, but also of other public buildings, and particularly of royal palaces, and others belonging to the grandees; but the greatest part of them, and of the city, were destroyed by a most dreadful earthquake, on Nov. 1, 1755, from which it required a long time to recover. The inhabitants, before the earthquake, did not at most exceed 150,000. The government of it is lodged in a council, consisting of a president, six councillors, and other inferior officers. The harbour has water enough for the largest ships, and room enough for 10,000 sail without being crowded. For its security, there is a fort at the mouth of the river, on each side, and a bar that runs across it, and is very dangerous to pass without pilots. Higher up, at a place where the river is considerably contracted, there is a fort called Torre de Belém, or the Tower of Belém, under whose guns all ships must pass in their way to the city; and on the other side are several more forts. Before the earthquake most of the private houses were old and unhappily, with lattice-windows; and the number of convents and colleges amounted to 50, namely, 22 for monks and 18 for nuns. The king’s principal palace stands on the river, and is large and commodious. Of the hospitals, that called the Great is obliged to receive all persons, of what degree, nation, or religion, forever, without exception. At the village of Belém, near Lisburn, is a noble hospital for decayed gentlemen who have served the king, and have not wherewithal to maintain themselves. That called the house of mercy is also a noble charity. In the centre of the city, upon one of the highest hills, is the castle, which commands the whole, being large and ancient, and having always a garrison of four regiments of foot. The cathedral is a vast edifice of the Gothic kind, but heavy and clumsy; it contains, however, great riches, and is finely adorned within. The square called Raffe is large, and surrounded with magnificent buildings. The whole city is under the ecclesiastical jurisdiction of the patriarch, who was appointed in the year 1717. Here is also an archbishop, who has, or at least had before the erection of the patriarchate, a revenue of 40,000 crowns, or 2000 l. sterling. The university, which was removed for some time to Coimbra, but afterwards re-founded to its ancient seat, makes a considerable figure, though much inferior to that of Coimbra.

LISBURN, a town of Ireland, in the county of Antrim and province of Ulster, 73 miles from Dublin. It was burnt down about 50 years ago; but is now rebuilt in a neat and handsome manner, and has a large linen manufactory. It is seated on the river Lagan, in W. Long. 6. 20. N. Lat. 54. 31. It gives title of earl to the family of Vaughan, and it returns two members to parliament; one half of the patronage of this borough being in the earl of Hertford. Fairs held 21st of July and 3rd of October.

LISLEUX, a considerable town of France, in Upper Normandy, with a bishop’s see. The churches and religious houses, and the bishop’s palace, are all very handsome structures. It is a trading place; and is seated at the confluence of the rivers Arbeek and Gaffe, in E. Long. 0. 20. N. Lat. 49. 11.

LISLE, a large, rich, handsome, and strong town of French Flanders, of which it is the capital, with a strong castle, and a citadel built by Vauban, and said to be the finest in Europe, as well as the best fortified. The large square, and the public buildings, are very handsome; and they have manufactures of silks, cambrics, and cambelets, as well as other fluffs, which have been brought to great perfection. It was taken by the duke of Marlborough, after three months siege, and the loss of many thousands of men, in 1708; but restored to the French by the treaty of Utrecht, in consideration of their demolishing the fortifications of Dunkirk. It is seated on the river Duele, 14 miles west of Tournay, 32 south-west of Ghent, 37 northwest of Mons, and 150 north of Paris, E. Long. 3. 9. N. Lat. 50. 38.

LISLE (Clauvius de), a learned historian, born at Vantoulers, in 1644. He Studied among the Jesuits at Pont a Mousson; took his degrees in law, and afterwards applied himself entirely to the study of history and geography; and to perfect himself in those sciences went to Paris, where the principal lords of the court became his scholars, and among the rest the duke of Orleans, afterwards regent of the kingdom. He wrote, 1. An historical account of the kingdom of Siam. 2. A genealogical and historical Atlas. 3. An abridgment of universal history. He died at Paris in 1720.

LISLE (William de), son of the farmer, and the most learned geographer France has produced, was born at Paris in 1675. He became first geographer to the king, royal censor, and member of the academy of sciences. He died in 1726. He published a great number of excellent maps, and wrote many pieces in the memoirs of the academy of sciences.

LISLE (Sir John), a brave loyalist in the time of the civil wars, was the son of a bookbeller in London, and received his education in the Netherlands. He signalized himself upon many occasions in the civil war, particularly in the last battle of Newbury; where, in the dusk of the evening, he led his men to the charge in his shirt, that his peron might be more conspicuous. The king, who was an eye-witness of his bravery, knighted him in the field of battle. In 1648, he rose for his majesty in Eilex; and was one of the royalists who, to obstinately defended Colchester, and who died for the defence of it. This brave man having tenderly embraced the corps of Sir Charles Lucas, his departed friend, immediately presented himself to the soldiers who flood ready for his execution. Thinking that they stood at too great a distance, he desired them to come nearer: one of them said, “I warrant you, Sir, we shall hit you.” He replied with a smile, “Friends, I have been nearer you when you have miffed me.” He was executed August 28th 1648.

LISMORE, one of the Welter islands of Scotland, seated at the mouth of Loch Linne, a capacious lake in Argyleshire, navigable for the largest ships to Fort William, which stands in the country called Lochaber. This island is above seven miles in length by one in breadth; and contains 1500 inhabitants. It abounds in limestone; from which, however, it has hitherto derived little advantage, owing to the want of good peat, the neglect of timber, and still more the duty upon coals. Thus, with the advantages of navigation in every direction, and of a foil lying upon the richest manure the people are indigent, and frequently obliged to import meal for their subsistence. Many of them...
LISMORE, a borough, market, fair, and post town of Ireland, in the county of Waterford, and province of Munster, 100 miles from Dublin; N. Lat. 52° 5' W. Long. 7° 50'. It was anciently called Lismore or Lóis-more, i.e. the great enclosure, or habitation; it is now a bishopric, and formerly had an university. St Carthagh of Mochuda, in the beginning of the seventeenth century founded an abbey and school in this place, which in a short time was much restored, to not only by the natives, but also by the Britons and Saxons, during the middle ages. According to an ancient writer of the life of St Carthagh, Lismore was in general inhabited by monks, half of it being an asylum into which no woman dared to enter; consisting entirely of cells and monasteries, the ruins of which, with seven churches, are yet visible. A castle was built here by King John. The fire of Lismore was in early ages denominated nugh flain, or the "chosen fluid," being the situation of a dun or fort of the ancient chieftains of the Decies, one of whom granted it to St Carthagh on his expulsion from the abbey of Ratheny in Wexford. On becoming an university, Math Sgiath obtained the name of Dunlignan, or the "fort of the Saxons," from the number of Saxons which removed thence: but soon after, it was called Lóis-na Rwor or Lóismore, and now Lismore; the bishopric of which was united to that of Waterford in 1663, being 730 years after its foundation. The public road to Cork was formerly through this place, and at that time it had a better face of buildings. St Carthagh, who retired to this place with some of his religious in 636, to avoid the fury of the then Irish monarch, tied his disciples to a most strict rule of life; they never were allowed the use of flesh, fish, or fowl; only the vegetables that the ground produced at the expense of their own labour. Father Daniel, in his Histoire Monastique, mentions one on the same foundation in France. The castle here, which as we have formerly mentioned, was built by King John, was erected in 1195 on the ruins of the abbey of St Carthagh; it belonged to the Duke of Devonshire, and gave birth to that great philosopher Robert Boyle. In 1269 it was demolished by the Irish, who took it by surprise. Being afterwards re-edified, it was for many years an episcopal residence, till Myler McGrath, archbishop of Cashel, and bishop of this see, granted the manor of Lismore to that noted scholar and soldier Sir Walter Raleigh, in the reign of Queen Elizabeth, at the yearly rent of L. 13 6s 8d; but that estate was lopped off with his head in the reign of King James I. After which it fell into the hands of Sir Richard Boyle, who purchased all Sir Walter's lands; he beautified the whole, and added many buildings to it, most of which were burned down in the Irish rebellion; at the breaking out of which, it was closely besieged by 5000 Irish, commanded by Sir Richard Beling, and was well defended by the young Lord Broghill, third son of the earl of Cork, who obliged them to raise the siege. The castle is boldly seated on the verge of a rocky hill, rising almost perpendicular to a considerable height over the river Blackwater. The entrance is by an ancient and venerable avenue of trees. Over the gate are the venerable arms of the first earl of Cork. Opposite to the entrance is a modern portrait of Bath flour, of the Doric order, designed by Inigo Jones. Most of the buildings have remained in ruins since the era of the rebellion; but the several offices that make up two sides of the square are kept in repair. At each angle is a tower, the chief remains of its former magnificence. In October 1785, the late duke of Rutland, then lord-lieutenant of Ireland, whilst on a visit in Munster, held a council in, and issued proclamations from this castle. The cathedral is still pretty well kept in repair. Here is a fine bridge over the river Blackwater, erected at a very great expence by the duke of Devonshire; this bridge is remarkable for the extent of the principal arch, the span of it being 102 feet. Below the town is a rich fishery for salmon, which is the greatest branch of trade here. Though this place is at present much reduced, yet Cambrensis informs us, that, not many years after the conquest, this was a very rich city, and held out some time against the English, who took it at last by storm, and gained rich plunder here, enough to load 16 sail of ships. It returns two members to parliament; patron, the duke of Devonshire, but the electors are called petuvalopera. Fairs held on 25th May and September, and 12th November.

LISSA, an island in the Gulph of Venice, on the coast of Dalmatia, belonging to the Venetians, where they have a fishery of eardines and anchovies. It produces excellent wine, and is 70 miles west of Ragusa. E. Long. 17° 0'. N. Lat. 43° 22'. LISSA, a town of Poland, in the palatinate of Posen, of which it is the capital. E. Long. 16° 0'. N. Lat. 52° 15'. LISSA, a village of Sileia, 16 miles from Breslau, remarkable for a battle fought between the Prussians and the Austrians on the 13th of December 1757, when the latter were entirely defeated.

LISSUS, (anc. geog.), the last town of Illyricum, towards Macedonia, situated on the Drilo. It had a capacious port, the work of Dionysius the Tyrant, who led the colony thither, enlarged and walled it round, (Diodorus Siculus,) now called Alfeo, in Albania, on the Dino, near the Gulph of Venice. E. Long. 20°. N. Lat. 42°.

LIST, in commerce, the border of cloth or stuff; serving not only to show their quality, but to preserve them from being torn in the operations of falling, dyeing, &c.—List is used on various occasions; but chiefly by gardeners for securing their wall-trees.

LIST, in architecture, a little square moulding, otherwise called a fillet, fillet, &c. See Plate XXXVIII. fig. 1.

List, is also used, to signify the inclosed field or ground whereon the ancient knights held their jousts and combats. It was so called, as being hemmed round with pales, barriers, or stakes, as with a list. Some of these were double, one for each cavalier; which kept them apart, so that they could not come nearer each other than a spear's length. See Joust, Tournament, Duel, &c.

Civil List, in the British polity. The expences defrayed by the civil list are those that in any shape relate to civil government; as, the expences of the household; all salaries to officers of state, the judges, and every one of the king's servants, the appontments to foreign
The civil list is indeed properly the whole of the king's revenue in his own distinct capacity; the rest being rather the revenue of the public, or its creditors, though collected and distributed again in the name and by the officers of the crown: it now standing in the same place, as the hereditary income did formerly; and as that has gradually diminished, the parliamentary appointments have increased. The whole revenue of queen Elizabeth did not amount to more than 600,000 a-year; that of king Char. I. was 800,000, and the revenue voted for king Charles II. was 1,200,000 l., though complaints were made (in the first years at least) that it did not amount to so much. But it must be observed, that under these sums were included all manner of public expenses; among which Lord Clarendon, in his speech to the parliament, computed, that the charge of the navy and land-forces amounted annually to 800,000 l., which was ten times more than before the former troubles. The same revenue, subject to the same charges, was settled on king James II.; but by the incease of trade, and more frugal management, it amounted on an average to 1,500,000 l. per annum, besides other additional customs granted by parliament, which produced an annual revenue of 400,000 l. out of which his fleet and army were maintained at the yearly expense of 1,100,000 l. After the revolution, when the parliament took into its own hands the annual support of the forces both maritime and military, a civil-list revenue was settled on the new king and queen, amounting, with the hereditary duties, to 700,000 l. per annum; and the same was continued to queen Anne and king George I. That of king Geo. II. was nominally augmented to 800,000 l. and in fact was considerably more; but that of his present majesty is expressly limited to that sum; tho' 100,000 l. hath been since added. And upon the whole, it is doubtless much better for the crown, and also for the people, to have the revenue settled upon the modern footing rather than the ancient. For the crown because it is most certain, and collected with greater ease: for the people; because they are now delivered from the feudal hardships, and other odious branches of the prerogative. And though complaints have sometimes been made of the incease of the civil list, yet if we consider the sums that have been formerly granted, the limited extent under which it is now establisht, the revenues and prerogatives given up in lieu of it by the crown, the numerous branches of the present royal family, and (above all) the diminution of the value of money compared with what it was worth in the last century, we must acknowledge these complaints to be void of any rational foundation; and that it is impossible to support that dignity, which a king of Great Britain should maintain, with an income in any degree less than what is now established by parliament. See Revenue.

To List, or enlist, Soldiers, to retain and enroll men as soldiers, either as volunteers, or by a kind of compulsion. Persons lifted must be carried within four days, but no sooner than 24 hours after, before the next justice of peace of any county, riding, city, or place, or chief magistrate of any city or town corporate (not being an officer in the army); and if before such justice or magistrate they differ from such enlisting, and return the enlisting-money, and also 20 thalers in lieu of all charges expended on them, they are to be discharged. But persons refusing or neglecting to return and pay such money within 24 hours, shall be deemed as only lifted as if they had silent before the proper magistrate; and they shall, in that case, be obliged to take the oath, or, upon refusal, they shall be confined by the officer who lifted them till they do take it.

LISTER (Dr Martin), an eminent English physician and naturalist, was born in 1658, and educated at Cambridge. He afterwards travelled into France; and at his return practised physic at York, and afterwards at London. In 1683, he was created doctor of physic, and became fellow of the college of physicians in London. In 1698, he attended the earl of Portland in his embassies from king William III. to the court of France; of which journey he published an account at his return, and was afterwards physician to queen Anne. He also published 1. Historia animalium Angiae, quarto. 3. Generis fossilis et fossicarum, folio. 4. Many pieces in the Philosophical Transactions; and other works.

LISTOWEL, a parish, also a post and fair town, of Ireland, in the county of Kerry and province of Munster, 131 miles from Dublin, anciently Lis Tua-thali, i. e. "the fort of Tuathal," who was exiled in the 1st century, but returned; and his life forms a brilliant era in Irish history. Near this are the ruins of a castle, pleasantly situation on the river Feale: it was taken in November 1600, by sir Charles Wilmore, being then held out for the Lord Kerry against queen Elizabeth. Five miles beyond Listowel are the ruins of a church. The fairs are three in a year.

LITANA SILVA (anc. geog.); a wood of the Boii, in the Gallia Togata, or Cil cupidana, where the Romans, under L. Postumius Albinus (whose head the Boii cut off, and carried in triumph into their most sacred temple), had a great defeat, of twenty-five thousand fearless ten echaping (Livy). Poeninus conjectures, that this happened above the springs of the Sculentia, in a part of the Appennine, between Cen feianum and Mutina. Now Selva di Luigi.

LITANY, a solemn form of supplication to God, in which the priest utters some things fit to be prayed for, and the people join in their intercession, saying, we beseech thee to hear us, good Lord, &c. The word comes from the Greek λτανειας, "supplication," of λτανεω, "I beseech." At first the use of litanies was not fixed to any stated time, but were only employed as exigencies required. They were observed in imitation of the Ninevites, with ardent supplications and fastings, to aver the threatening judgments of fire, earthquakes, inundations,

Litfield.

LITCHFIELD, a city of Staffordshire, in England, 117 miles from London. It stands low, about three miles from the Trent; and its ancient name is said to have been Lichfield, signifying, "a field of carcases," from a great number of Christians having, as it is pretended, suffered martyrdom here in the persecution under Diocletian. In the Saxons time, it was a bishopric for a short space; and is now, together with Coventry, a bishoprick. The city has power of life and death over felons, powder, and a deep dry ditch on all sides except towards the Trent, or fields, and well-paved clean streets. That field is divided into two parts by a rivulet and a kind of shallow lake, over which are two causeways with sluices. It is a long straggling place; but has some very handsome houses, and well-paved clean streets. That part on the south side of the rivulet is called the city, and the other the close. The city is much the largest, and contains several public structures. It was incorporated by Ed. VI. with the name of bailiffs and burgesses; and is both a town and county, governed by two bailiffs chosen yearly out of 24 burgesses, a recorder, a sheriff, a bailward, and other officers. The city has power of life and death within their jurisdiction, a court of record, and a piepowder court. Here is a gaol both for debtors and felons, a free school, and a pretty large well endowed hospital for a master and 12 brethren. The county of the city is 10 or 12 miles in compass, which the sheriff rides yearly on the 8th of September, and then feals the corporation and neighbouring gentry. The close is so called from its being inclosed with a wall and a deep dry ditch on all sides except towards the city, where it is defended by a great lake or marsh formed by its brook. The cathedral, which stands in the close, was originally built by Offa king of Northumberland about 900. It was rebuilt and enlarged by Offa king of Mercia in 766. In 1148 was rebuilt, and greatly enlarged in 1296. At the reformation, Coventry was divided from it. In the civil wars its spire was destroyed, and it converted to a stable. In 1776 a beautiful painted window, by the benefaction of Dr. Adenbrook, has been set up at the western end of the cathedral. In the civil wars it was several times taken and retaken, and thereby suffered much; but was so repaired after the restoration, at the expense of 20,000l. that it was one of the fairest and noblest structures of the kind in England. It is walled in like a castle, and stands so high as to be seen 10 miles round.

It is 450 feet long, of which the choir is 170, and the breadth in the broadest place 80. Its portico is hardly paralleled in England. There were till lately 26 statues of the prophets, apostles, kings of Judah, and some kings of England, in a row above it, as big as the life; and on the top, at each corner of the portico, is a lofty spire, besides a fine high steeple on the middle of the church. The choir is paved in great part with alabaster and channel-coal, in imitation of black and white marble. In 1780 it went under a general repair, when the massive groined arches between the west end of the church and the transept, which had forced the side wall out of its perpendicular, was removed. The prebendaries stalls, which are thought to be the best in England, were most of them re-erected at the charge of the country gentlemen, whose names and arms are painted at the top of the stalls. The north door is extremely rich in sculpture, but much injured by time. The body, which is supported by pillars formed of numbers of slender columns, has lately had its decayed leaden roof replaced by a great domed covering. The church merits attention on account of the elegant sculpture about the windows, and the embattled gallery that runs beneath them; to which the altar-piece of Grecian architecture but ill corresponds; behind which is Mary's chapel, divided from it by a most elegant stone screen of beautiful workmanship. Here stood St. Chad's shrine, which cost 2000l. The charter-house is an octagon-room. In the same clove are the palaces of the bishop and dean, and the prebendaries houses in a court on the hill. Here are three other churches; one of which, St Michael's, has a church-yard of 6 or 7 acres. There was a castle here, long since destroyed; and ancient camps have been discovered in its environs. In the neighbourhood are frequent horse-races. The markets are on Tuesday and Friday, and fair days in the year. By the late inland navigation, this place has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles in the counties of Lincoln, Nottingham, York, Lancaster, Wellmoreland, Chester, Warwick, Leicester, Oxford, Worcesters, &c. Litchfield sends two members to parliament.

LITERARY, any thing belonging to literature.

LITERARY Property or Copy-Right. See Copy-Right.

LITERATI (literato, "lettered"), an epithet given to such persons among the Chinese as are able to read and write their language. The literati alone are capable of being made mandarins.

LITERATI is also the name of a particular sect, either in religion, philosophy, or politics, consisting principally of the learned men of that country; among whom it is called jukai-si, i.e. "learned."

It had its rise in the year of Chirrit 1400, when the emperor, to awaken the native affection of the people for knowledge; which had been quite banished by the preceding civil wars amongst them, and to stir up emulation among the mandarins, chose out 42 of the ablest among their doctors, to whom he gave a commission to compose a body of doctrine agreeable to that of the ancients, which was then become the rule or standard of the learned. The delegates applied themselves to
the business with very great attention; but some fancied them rather to have wrested the doctrine of the ancients, to make it consist with theirs, than to have built up theirs on the model of the ancients. They were pleased with it, because it seemed to subvert all religion; others approved it, because the little religion that it left them could not give them much trouble. And thus was formed the sect of the Literati; which consists of the maintainers and adherents to this doctrine.

The court, the mandarins, and the persons of fortune and quality, &c. are generally retainers to it; but a great part of the common people still hold to their worship of idols.

The literati freely tolerate the Mahometans, because they adore, with them, the king of nature, and author of all things; but they bear a perfect aversion to all sorts of idolaters among them; and it was once resolved to extirpate them. But the disfavour this would have occasioned in the empire prevented it; they now content themselves with condemning them, in general, as heretics; which they do solemnly every year at Pekin.

Literature denotes learning or skill in letters.

Liternum. See L internum.

Litanthrax, or L i t. Coa l, is a black or brown, laminated, bituminous substance; not very easily inflammable; but when once inflamed, burns longer and more intensely than any other substance. Of this substance three kinds are distinguished by authors. The residuum of the first after combustion is black; the residuum of the second is fupgny, and like pumice-stone; and the residuum of the third is whitish ashes. Some foil coal, by long exposure to air, falls into a greyish powder, from which alum may be extracted. Foil coal by distillation yields, 1. a phlegm or water; 2. a very acid liquor; 3. a thin oil like naphtha; 4. a thicker oil, resembling petroleum, which falls to the bottom of the former, and which rises with a violent fire; 5. an acid concrete salt; 6. an unflammable earth remains in the retort. These confluent parts of foil-coal are very similar to those of amber and other bitumens. For the exciting of intense heats, as of furnaces for smelting iron-ore, and for operations where the acid and oily vapours would be detrimental, to the drying of malt, foil-coals are previously charred, or reduced to coals; that is, they are made to undergo an operation similar to that by which charcoal is made. By this operation coals are deprived of their phlegm, their acid liquor, and the greatest part of their fluid oil. Coals therefore consist of the two fixed constituents, the heavy oil and the earth, together with the acid concrete salt, which the volatile is detained by the oil and earth.

Litharge, a preparation of lead, usually in form of soft flakes, of a yellowish reddish colour. If calcined lead be urged with a hand fire it melts into the appearance of oil, and on cooling concretes into litharge. Greatest part of the litharge met with in the shops is produced in the purification of silver from lead, and the refining of gold and silver by means of this metal; according to the degree of fire and other circumstances, it proves of a pale or deep colour; the first has been commonly called litharge of silver, the other litharge of gold. See Chemistry-Index.

Lithgow (William), a Scotian, whose sufferings by imprisonment and torture at Malaga, and whose travels, on foot, over Europe, Asia, and Africa, seem to raise him almost to the rank of a martyr and a hero, published an account of his peregrinations and adventures. Though the author deals much in the marvellous, the horrid account of the strange cruelties of which, he tells us, he was the subject, have however, an air of truth. Soon after, his arrival in England from Malaga, he was carried to Theobald’s on a feather-bed, that King James might be an eye-witness of his martyrdom anatomy, by which he means, his wretched body, mangled and reduced to a skeleton. The whole court crowded to see him; and his Majesty ordered him to be taken care of, and he was twice sent to Bath at his expence. By the king’s command he applied to Gondamor, the Spanish ambassador, for the recovery of the money and other things of value which the governor of Malaga had taken from him, and for L 1000 for his support. He was promised a full reparation for the damage he had sustained; but the pernicious minister never performed his promise.

When he was upon the point of leaving England, Lithgow upbraided him with the breach of his word in the presence-chamber, before several gentlemen of the court. This occasioned their fighting upon the spot; and the ambassador, as the traveller oddly expresses it, had his fistula, (with which disfavour he was afflicted) contrabanded with his fist. The unfortunate Lithgow, who was generally condemned for his spirited behaviour, was sent to the Marshalsea, where he continued a prisoner nine months. At the conclusion of the octavo edition of his Travels he informs us, that in his three voyages, his painful feet have traced over (besides passages of seas and rivers) 56000 and odd miles, which draweth near to twice the circumference of the whole earth.” Here the marvellous seems to rise to the incredible; and to fet him, in point of veracity, below Coryat, whom it is nevertheless certain that he far outwalked. His description of Ireland is whimsical and curious. This, together with the narrative of his sufferings, is reprinted in Morgan’s Phoenix Britannicus.

Lithiasis, or Stone. See Medicine-Index.

Lithomantia, in antiquity, a species of divination performed with stones. Sometimes the stone called siderites was used: this they walked in spring-water.
in the night by candle light; the person that
were purged it was to be purified from all manner of
and to have his face covered; this done he
repeated divine prayers, and placed certain characters
in an appointed order, and then the stone moved of
itself, and in a soft, gentle murmur, or (as some say)
in a voice like that of a child, returned an answer. By
a stone of this nature, Helena is reported to have fore-
told the destruction of Troy.

**LITHONTROPICTUS** (from λιθός, "a stone,"
and τρίπτων, "to break"), a epithet for medicines that
are supposed to break the stone in the bladder. Though the
different stones that are generated in the human
bladder require different solvents when out of the body;
and though art hath not yet afforded a medicine
which, when injected into the bladder, will, without
injury thereto, dissolve the stone therein lodged; it
cannot thence be concluded, that there are no litho-
triptic medicines. It may be here observed, that one
solvent affects one subject, and hath no effect on an-
other; so a solvent may yet be met with that will de-
solve the stone, and not hurt the human body. The
water into which the boiled white of egg dissolves will
liquify myrrh, but may be put into the human eye
without causing any uneasiness.

Soap taken at first in small doses in broth that
is freed from all its fat, succeeds in most cases which
require an alkaline solvent. The patient may begin
with 20 drops, and gradually increase the dose as he
is able; and by repeating it three times a-day for six,
eight, or twelve months, the wished for effects often
follow.

**LITHOPYTA**, the name of Linnaeus’s third
order of vermes. See Zoology.

**LITHOSPERMUM, GROMWELL**, A genus of
the monogyne order, belonging to the pentandria clafs
of plants; and in the natural method ranking under
the 41st order, Superficies. The corolla is funnel-
shaped, with the throat perforated and naked; the cal-
yx quinquepartite. There are several species; but the
only remarkable one appears officinal in common
gromwell, and the arvenne or bastard alkanet. Both
these are natives of Britain; the former growing in
dry gravelly soil, the latter in corn-fields. The seeds
of the first are reputed to be of service in calculous
cafes. Dr. Grew says, that they have so much earth
in their composition, that they effervesc with acids;
but if this is the case, it must be attributed rather to
an alkaline than an earthy quality.

**LITHOSTROTION**, in natural history, the name
of a species of fossil coral, composed of a great num-
ber of long and slender columns, sometimes round,
sometimes angular, jointed nicely to one another, and
of a flary or radiated surface at their tops. These are
found in considerable quantities in the northern and
western parts of Britain, sometimes in sandle, some-
times in complex specimens. See Plate CC.

**LITHOSTRON** , among the Romans, was a
pavement of Mosaic work, consisting of small pieces
of cut marble of different kinds and colours. The li-
thofrosta began to be used in the time of Sylla, who
made one at Præneste in the temple of Fortune. At
last they were used in private houses; and were brought
so much perfection, that they exhibited most lively re-
prestation of nature, with all the exactness of the
finest painting.

**LITHOTOMY**, in surgery, the operation of cut-
ting for the stone. See Surgery.

**LITHUANIA**, an extensive province of Poland.

By the natives it is called Létwe, and has Great
Poland and Russia on the east; Lithuania, the Baltic Sea,
and part of Russia, on the north; Red Russia, Volhiniis, and Podolia
on the south; and the Ukraine on the south-east. Its
length is said to be about 360, and its breadth 340
miles; but it is much indented both ways. Lithuania
was anciently over-run with wood; and there are still
many forests in it, which yield a great deal of honey,
wax, pitch, tar, and timber; and abound with wild
boars, buffaloes, elk, wild horses, wild asses, we, and
woodcocks. The lakes are also numerous, and well-
stored with fish, burthe air, by reason of these forests
and lakes, is said to be thick and foggy. The country
produces a great deal of buck-wheat and other corn,
the pastures are luxuriant, and the flocks and herds nu-
merous; so that, notwithstanding agriculture is much
neglected, provisions are exceedingly cheap, but money
is scarce, that to per cent, is the common intereft. The
principal nobility have large estates, and live in
great pomp and splendor, generally retaining some hundreds
of those that are poor, in quality of domestics. The
estabhshed religion is Popery; but Lutherans, Calvi-
nists, Jews, Turks, Greeks, and Socinians, are very
numerous. Lithuania was governed by its own dukes
till it was united to Poland, towards the end of the
14th century, when the great Duke Jagello married
Hedwig, the dowager of Louis king of Poland and
Hungary. It had even dukes after that, but they
were subordinate to the king; and at this day, tho’
one diet serves for both countries, yet each has its
peculiar laws, customs, dialect, and privileges. In a
diet held at Lublin in 1569, it was more closely uni-
ted to Poland than it had been before; and it was en-
cored, that both countries, for the future, shoule form
but one state under the same prince. As to their
courts of justice, the tenth part of what is adjudged
is tried in England; and immediately paid in court;
and in personal actions he claims half the damages
given. A nobleman is only fined for murder, as in Poland. The common
people here, excepting the burghers in the royal towns,
and the Germans, are fables; and, in many places,
the ignorant vulgar still retain some remains of idola-
try. The poor people have only Mondays to them-
sefes; and if their lords have occasion for them even
on that day, the peasant must work for himself on
Sunday. If any of them is condemned to death by
his lord, he must execute himself, or suffer greater
cruelly. The dialect is a language of the Slavonic;
and they speak here, as in Poland, a barbarous kind of Latin. Lithuania is divided into nine palatines.
Another division is into Lithuania properly so call-
ed, and Lithuanian Russia. Some also comprehend
under it Samogitia and Courland, which is a fief of
Poland.

**LITUS, or LACUS**, in the arts, is a blue pig-
ment, formed from arche. It is brought from Hol-
land at a cheap rate; but may be prepared by adding
quick
Litter (letter), a kind of vehicle borne upon shafts; also by the ancients drawn by four horses. Du Cange derives the word from the barbarous Latin lettera + draw or bedding for beasts.' Others will rather have it from lether or bed; there being ordinarily a quilt and a pillow to a litter in the same manner as to a bed.

Pliny calls the litter the traveller's chamber; it was much in use among the Romans, among whom it was borne by slaves kept for that purpose; as it still continues to be in the east, where it is called a pothaxm. —The Roman lector, made to be borne by four men, was called terebrum; that borne by six, xepbrum; and that borne by eight, sprobrum.

The invention of litters, according to Cicero, was made as a kind of vehicle borne upon shafts; also by the ancients drawn by four horses. LIV

LIV

ledges to be the common law of the church; intimating, that the use of several services in the same province, which was the case in England, was not to be warranted but by long custom. The liturgy of the church of England was composed in the year 1547, and established in the second year of King Edward VI. Stat. 2. and 3. Edward VI. cap. 1.

In the fifth year of this king it was reviewed; because some things were contained in that liturgy which showed a compliance with the superstition of those times, and some exceptions were taken against it by some learned men at home, and by Calvin abroad. Some alterations were made in it, which consisted in adding the general confession and absolution, and the communion to begin with the ten commandments. The use of oil in confirmation and extreme unction were left out, and also prayers for souls departed, and what tended to a belief of Christ's real presence in the eucharist. This liturgy, so reformed, was established by the act of 5 and 6 Ed. VI. cap. 1. However, it was abolished by Queen Mary, who enquired, that the service should stand as it was most commonly used in the last year of the reign of King Henry VIII. The liturgy of 5 and 6 Ed. VI. was re-established with some few alterations and additions, by 1 Eliz. cap. 2. Some further alterations were introduced, in consequence of the review of the common prayer-book, by order of King James, in the first year of his reign; particularly in the office of private baptism, in several rubrics and other passages, with the addition of five or six new prayers and thanksgivings, and all that part of the catechism which contains the doctrine of the sacraments. The book of common prayer, so altered, remained in force from the first year of King James to the fourteenth of Charles II. But the last review of the liturgy was in the year 1669, and the last act of uniformity enjoining the observance of it is 13 and 14 Car. II. cap. 4. See Common Prayer. Many applications have been since made for a review, but hitherto without success.

LITUUS, among the Romans, was the staff made use of by the augurs in quartering the heavens. It bore a great resemblance to the crozier of a bishop, but was shorter. It was crooked at one end, and thickest in the curved part, according to A. Gellius. We frequently meet with a representation of it upon medals, amongst other pontifical instruments. It was called Litus Quirinalis, from Quirinus, a name of Romulus, who was skilled in all the mysteries of augury.

LITUUS, was also an instrument of music in use in the Roman army. It was straight, excepting that it had a little bending at the upper end like a limus or flared staff of the augurs; and from the similitude it derived its name. The litus, as an instrument of martial music, was of a middle kind, between the cornu and tuba.

LIVADIA,anciently Achaia and Hellas, or Greece, properly so called; a province of Turkey in Europe, bounded on the north by Epirus and Thessaly, from which it is separated by mount Oeta, now Banina, and by the Euripus, now the river of Negropont; on the east by the Archipelago; on the south, by the gulf of Egin or Egina, the isthmus of Corinth, and the gulf of Lepanto; and on the west, by the Ionian sea and part of Epirus. Its extent is about 130 miles from north-west to south-east; but its greatest breadth is not above 36 miles. It is in general a mountainous country; but neither unpleasant nor unfruitful. The principal mountains are, mount Oeta in Boetia, where is the famous pass of Thermopylae, not above 25 feet broad; and Parnassus, Helicon, and Cytheraon in Phocis, which were sacred to Apollo and the Muses, and consequently much celebrated by the poets. The rivers of most note are, the Stymphalus, anciently the Achebes, the Cephisus, the Himus, and the Alpus. The province is at present divided into Livadia proper, Strainulippa, and the duchy of Athens. The principal places are, Lepanto, anciently Nallpactus; Livadia, anciently Libadia or Libadla; the celebrated city of Athens, now Sestines; Thebes, now Sibbes; Lepeina, anciently Eleusis; Caltri, formerly Delphi; and Megara.

LIVADIA, an ancient town of Turkey in Europe, and capital of a province of the same name in Greece. It is a large and populous place, seated on the gulf of Lepanto, about 25 miles from the city of that name. It has a considerable trade in woollen stuffs and rice. Anciently it was celebrated for the oracle of Trophonius, which was in a cavern in a hill above the town. E. Long. 23° 29'. N. Lat. 38° 40'.

LIVER, in anatomy. See there. Plato, and other of the ancients, fix the principle of love in the liver; whence the Latin proverb, Cogni amor secures: and in this sense Horace frequently uses the word, as when he says, Si torrere jecur quodris iho.

The Greeks, from its concave figure, called it Wlap, "vaulted, suspended; the Latins call it juxta cur, q. d. juxta cor, as being near the heart." The French call it joye, from foyer, jocu!, "or fire-place;" agreeable to the doctrine of the ancients, who believed the blood to be boiled and prepared in it. E. Livi. at first, called it parenchyma, i. e. mass of blood; and Hippocrates, by way of eminence, frequently calls it the hypochondrium.

LIVER of Arsenic, is a combination of white arsenic with liquid fixed vegetable alkali, or by the humid way. Arsenic has in general a strong disposition to unite with alkalis. Mr Macquer, in his Memoirs upon Arsenic, mentions a singular kind of neutral salt, which results from the union of arsenic with the alkaline basis of nitre, when nitre is decomposed, and its acid is disengaged in close vessels, by means of arsenic. To this salt he has given the name of neutral arsenical salt. The liver of arsenic mentioned above is also called arsenic chemist, although composed, like the neutral arsenical salt, of arsanic and fixed alkali, is nevertheless very different from that salt.

The operation for making liver of arsenic is easy and simple. To a strong and concentrated liquid fixed alkali, previously heated, fine powder of white arsenic must be added. This arsenic easily disappears and duilves, and as much of it is to be added till the alkali is saturated, or has lost its alkaline properties, although it is still capable of dissolving more arsenic for erabundantly. While the alkali dissolves the arsenic in this operation, it
it acquires a brownish colour, and a singular and disagreeable smell; which, however, is not the smell of pure arsenic heated and volatilized. Lastly, this mixture becomes more and more thick, and at length of a gluey consistence. This matter is not crystallizable as the neutral arsenical salt is. It is easily decomposed by the action of fire, which separates the arsenic. This does not happen to the arsenical salt. Any pure acid is capable of separating arsenic from the liver of arsenic, in the same manner as they separate sulphur from liver of sulphur: Whereas the arsenical folid acid cannot be decomposed but by means of the united affinitis of acids and metallic substances.

Thus we see that arsenic may be combined with fixed alkali in two very different manners. The author has given to this combination the name of liver of arsenic, to distinguish it from the neutral arsenical salt, and in imitation of the name of the liver of sulphur, given to the combination of the fixed alkali with sulphur.

Liver of Sulphur. See Chemistry, Index.

Liver-Wort, in Botany. See Marchantia and Lichen.

Liver-Stone, (lapis hepaticus): a genus of inflammable substances, containing, besides its phlogiston, argillaceous, poudery, and siliceous earth, united with vitriolic acid. See Earths, 1. 1. 9. 4.

Mr Bergman, in his Scigraphia, informs us, that 100 parts of this stone contain 33 of siliceous earth, 29 of caustic poudery earth, almost 9 of argillaceous earth, and 3.7 of lime, besides the vitriolic acid and water of crystallization: but Mr Kirwan quotes another analysis of the same author, where it is said that 100 parts of it contain 33 of baro-felenite, 38 of siliceous earth, 22 of alum, 7 of gypsum, and 5 of mineral oil.

Liverpool, a large, flourishing, and populous town of England, in the county of Lancaster, situated at the mouth of the river Mersey into the sea. This town has so much increased in trade since the commencement of the present century, that it is now the greatest sea-port in England except London, having exceeded Bristol considerably of late years: which will appear by the following account of the custom-duities, received in the several ports of London, Liverpool, and Bristol, in the year 1784, taken from the report of the commissioners for inspecting the state of public accounts.

Liverpool exceeded Bristol, L 305,774 2 11

The following shows how much the trade has increased since the above period:

Duties received in the port of Liverpool from July 5th 1787, to October 10th 1787. L 298,361 9 104.
The merchants here trade to all parts of the world except Turkey and the East Indies; but the most beneficial trade is to China and the West-Indies, by which many of them have acquired very large fortunes.

Liverpool, during the last war, carried on more foreign trade than any town in England; and such is Liverpool, the seat of it at this time, that there are near three thousand vessels cleared from that port in one year to different parts of the world. Here are several manufactories for China-ware, and pot-houses which make very fine ware, some gilt-works, glass-houses, and upwards of 50 breweries, from some of which large quantities of malt-liquor are sent abroad. Many of the buildings are formed in the most elegant manner; but the old streets are narrow; which defect will soon be removed, as the corporation have lately obtained an act of parliament for the improvement of the town, which they have already begun to put in force with great spirit, having taken down the principal fire-ridges in the centre of the town, and rebuilt them in a spacious and most magnificent manner; so that in a few years it will be one of the handsomest towns in England. This town contains ten churches, namely, St Peter's, St Nicholas's, St George's, St Thomas's, St Paul's, St Ann's, St John's, St James's, St Catherine's, and St Mary's. There are also meetings for independents, anabaptists, quakers, methodists, and prebyterians. The exchange is a noble structure, built of white stone in the form of a square, and round it are piazzas where the merchants assemble to transact business. Above it are the mayor's offices, the town-hall, the council-chamber, and two elegant ball-rooms. The expense of erecting this building amounted to L. 30,000. The custom-house is situated at the head of the old dock, and is a handsome and convenient structure. Here are many charitable foundations, among which is an excellent grammar-school well endowed, and many of the youth taught in it have exhibitions in the universities. The infirmary is a large edifice of brick and stone, situated on a hill in a very pleasant airy situation, at one end of the town.

In the town is a charity-school supported by voluntary subscriptions and contributions for 36 boys and 12 girls, who are not only clothed and educated, but are also provided with food and lodgings: likewise several alm-houses for the widows of seamen, and an excellent poor-house, superior to any in the kingdom, where upwards of 800 men, women, and children, are supported, many of whom are employed in spinning cotton and wool. There are five large wet docks, three dry docks, and several graving docks for the repairing of shipping; which renders it the most commodious sea-port in the world. The quays which bound these docks are covered with warehouses; which is a convenience that enables the merchant to discharge his ship at a very small expense. The new prison lately built is a noble edifice, being built entirely on the plan of the great and benevolent Mr Howard, for solitary confinement; and is the most convenient, airy, magnificent building of the kind in Europe: being upon a very extensive scale.

Liverpool received its charter from King John; it is under the government of a recorder, mayor, and an unlimited number of aldermen, two bailiffs, and a common-council of forty of the principal inhabitants, with a town-clerk and other proper officers. The town has a weekly market on Saturday, and is distant from London 204 miles. The progressive rise of population
I. LIVERY.

In Liverpool, the town is situated, abounds with salmon, cod, Wexford, Severn, Humber, Thames, Avon, &c. which springs from the present numerous evils, at least while he was employed upon the first and earliest ages. He undertook to read parts of his history, while he was composing it, to Mesenas and Augustus, and the latter conceived so high an opinion of him, that he pitched upon him to superintend the education of his grandson Claudius, who was afterwards emperor. After the death of Augustus, Livy returned to the place of his birth, where he was received with all imaginable honour and respect; and there he died, in the fourth year of the reign of Tiberius, aged above seventy. Some say, he died on the same day with Ovid: it is certain that he died the same year.

The Romish church has also her several colours and liveries; white, for confessors and virgins, and in time of rejoicing; black, for the dead; red, for the apostles and martyrs; blue or violet, for penitents; and green, in times of hope.

Formerly, great men gave liveries to several, who were not of their family or servants, to engage them in their quarrels for that year; but this was prohibited by the statues 1 Rich. II. 1. Hen. IV. cap. 27. 2. and 7 Hen. IV. 8 Hen. VI. cap. 4. 8 Ed. IV. cap. 2; and no man, of whatever condition, was allowed to give any livery, but to his domestic officers, and council learned in the law. However, most of the above statues are repealed by 3 Car. I. cap. 4.

LIVERY, in law, signifies delivering the possession of lands, &c. to him who has a right to liverymen them.

LIVERYMEN of London, are a number of men chosen from among the freemen of each company. Out of this body the common council, sheriffs, and other inferior officers for the government of the city, are elected; and they alone have the privilege of giving their votes for members of parliament, from which the rest of the citizens are excluded.

LIVIUS (Titus), the best of the Roman historians, as he is called by Mr Bayle, was born at Patavium, or Padua. Few particulars of his life have been handed down to us. Coming to Rome, he acquired the notice and favour of Augustus, and there he long resided. Some have supposed, (for there is not any proof of it), that he was known to Augustus before, by certain Philosophical Dialogues which he had dedicated to him. Seneca says nothing of the dedication; but mentions the dialogues, which he calls historical and philosophical; and also some books, written purposely on the subject of philosophy. Be this as it will, it is probable that he began his history as soon as he was settled at Rome; and he seems to have devoted himself so entirely to the great work he had undertaken, as to be perfectly regardless of his own advancement. The tumults and dissatisfaction of Rome frequently obliged him to retire to Naples; not only that he might be left interrupted in the pursuit of his defined task, but also enjoy that retirement and tranquility which he could not have at Rome, and which yet he seems to have much sought after: for he was greatly dissatisfied with the manners of his age, and tells us, that he should reap this reward of his labour, in composing the Roman history, that it would take his attention from the present numerous evils, at least while he was employed upon the first and earliest ages. He undertook to read parts of his history, while he was composing it, to Mesenas and Augustus; and the latter conceived so high an opinion of him, that he pitched upon him to superintend the education of his grandson Claudius, who was afterwards emperor. After the death of Augustus, Livy returned to the place of his birth, where he was received with all imaginable honour and respect; and there he died, in the fourth year of the reign of Tiberius, aged above seventy. Some say, he died on the same day with Ovid: it is certain that he died the same year.

Scarcely any man was ever more honoured, alive as well as dead, than this historian. Pliny the younger relates, that a native gentleman travelled from Gades, in the extreme part of Spain, to see Livy: and, though Rome abounded with more stupendous and curious spectacles than any city in the world, yet he immediately returned; as if, after having seen Livy, nothing farther could be worthy of his notice. A monument was erected to this historian in the temple of Juno, where was afterwards founded the monastery of St Juliana. There, in 1413, was discovered the following epitaph upon Livy: Osi Titi Livii Patavini, omnium mortuorum judicio digni, cuius proximo in inselocalum iuisti populi Romanorum res gestae conferendur; that is, "The bones of Titus Livius of Patavium, a man worthy to be approved by all mankind, by whose almost invincible pen the acts and exploits of the invincible Ro

LIV

Livius's works were written." These books are said to be preserved with high reverence to this day, and are shown by the Paduans as the most precious remains. In 1451, Alphonso, king of Arragon, sent his ambassado-

r, Anthony Panormita, to desire of the citizens of Padua the bone of that arm with which this their fa-
mous countryman had written his history: and, ob-
taining it, caused it to be conveyed to Naples with the greatest ceremony as a most invaluable reli. He is said to have recovered from an ill state of health by the pleasure he found in reading this history: and, therefore, out of gratitude, put upon doing extra-

dinary honours to the memory of the writer. Panor-
mita also, who was a native of Palermo in Sicily, and one of the ablest men of the 13th century, gave an estate to purchase this historian.

The history of Livy, like other great works of ant-
tiquity, is transmitted down to us exceedingly mutilated and imperfect. Its books were originally an hundred and forty-two, of which are extant thirty-five. The epitomes of it, from which we learn their number, all remain, except those of the 136th and 137th books. Livy's books have been divided into decades, some of which will have to be done by Livy himself, because there is a preface to every decade; while others suppose it to be a modern contrivance, since nothing about it can be gathered from the ancients. The first decade, beginning with the foundation of Rome, is extant, and treats of the affairs of 450 years. The second decade is lost, but the second part of it is extant and contains the first forty years. The third decade is extant and contains the second Punic war, including eighteen years. It is reckoned the most excellent part of the history, as giving an account of a very long and sharp war, in which the Romans gained so many advantages, that no arms could afterwards withstand them. The fourth decade contains the Macedonian war against Philip, and the Asiatic war against Antiochus which takes up the space of about 23 years. The five books of the fifth decade were found at Worms, by Simon Grynaeus, in 1451, but are very defective; and the remainder of Livy's history, which reaches to the death of Drusus in Germany in 746, together with the second and third decades, are lost.

Never man perhaps was furnished with greater ad-

vantages for writing a history than Livy. Besides his own great genius, which was in every respect admirably formed for the purpose, he was trained as it were in a city, at that time the empress of the world, and in the politest reign that ever was; having scarcely had any other school than the court of Augustus. He had access to the very best materials, such as the Memoirs of Sylla, Cæsar, Labienus, Pollio, Augustus, and others, written by themselves. "What writers of me-

morials (says Lord Bolinbrooke), what compilers of the Materia Historica, were the best! What genius was ne-

cessary to finish up the pictures that such masters had sketched! Rome afforded men that were equal to the task. Let the remain. the precious remains, of Sal-

louf, of Livy, and of Tacitus, witness this truth. — What a school of public and private virtue had been opened to us at the resurrection of learning, if the lat-
ter historians of the Roman commonwealth, and the first of the succeeding monarchy, had come down to us entire! The few that are come down, though broken and imperfect, compose the best body of history that we have; nay, the only body of ancient history that deserves to be an object of study. It fails us indeed most at that remarkable and fatal period, where our reasonable curiosity is raised the highest. Livy em-
ployed forty-five books to bring his history down to the end of the sixth century, and the breaking out of the third Punic war; but he employed ninety-five to bring it down from thence to the death of Drusus; that is, through the course of 120 or 130 years. Appian, Dion Cassius, and others, nay, even Plutarch included, make us but poor amends for what is lost of Livy."

Speaking then of Tully's orations and letters, as the best adnventitious helps to supply this loss, he says, that "the age in which Livy flourished, was far more constructed with such materials as these: they were freeth, they were authentic, it was easy to procure them; it was safe to employ them. How he did employ them in executing the second part of his design, in may judge from his execution of the first; and, I own, I should be glad to exchange, if it were possible, what we have of this history for what we have not. Would you not be glad, my lord, to see, in one stupendous draught, the whole progres of that government from liberty to servitude; the whole series of causes and effects, apparent and real, public and private?" &c.

The encomiums bestowed upon Livy, by both an-
cients and moderns, are great and numerous. He not
only entertains like Herodotus; he also instructs and interests in the deepest manner. But the great probity, accurac, and impartiality of Livy, are what have dillinguish
ed Livy above all historians; for neither complaisance to the times, nor his particular connections with the emperor, could restrain him from speaking well of Pom-
pey; so well, as to make Augustus call him a Pome-
pelian. This we learn from Cremnus Cordus, in Ta-
citus; who relates also, much to the emperor's hon-
nour, that this gave no interruption to their friend-
sip. But whatever ologies Livy may have received
as an historian, he has not escaped cenfure as a writer. In the age wherein he lived, Alinus Pollio charged him with Patavinitv; which Patavinitv has been variously explained by various writers, but is generally supposed to relate to his style. All that it is, that this noble Roman, accustomed to the delicacy of the language spoken in the court of Augustus, could not bear with certain provincial idioms, which Livy, as a Paduan, used in divers places of his history. Pignorius is of another mind, and believes that this Patavinitv regarded the orthography of certain words, wherein Livy used one letter for another, according to the custom of his county, writing fibe and guafi for fibi and guasti; which he attempts to prove by fe-
veral ancient inscriptions. The expressness, however, or the orthography of words, are not loaded with ob-
curity, and the perfect classic is as familiarly acquainted with those suppos'd provin. salins as with the purest Latinity. — Livy has been cenfured to be too just, perhaps with justice, for being too cedulous, and burdening his history with vulgar notions and superflitious tales. He may disquiet when he mentions that milk and blood were rained from heaven, or that an ox spoke or a wo-

man changed her fex; yet he calmly confesses that he recorded only what made an indelible impression upon the minds of a cedulous age.

Is it worth while to mention here the capricious

and
and tyrannic humour of the Emperor Caligula, who accused Livy of being a negligent and wordy writer, and resolved therefore to remove his works and statues out of all libraries, where he knew they were curiously preferred? Or the same humour in Domitian, another prodigy of nature, who put to death Metius Pompeianus, because he made a collection of some orations of kings and generals out of Livy’s history? Pope Gregory the Great, also, would not suffer Livy in any Christian library, because of the Pagan superstition wherewith he abounded: but the same reason held good against all ancient authors; and indeed Gregory’s zeal was far from being levelled at Livy in particular, the pontiff having declared war against all human learning.

Though we know nothing of Livy’s family, yet we learn from Quintilian, that he had a son, to whom he addressed some excellent precepts in rhetoric. An ancient inscription speaks also of one of his daughters, named Livia Quarta: the same, perhaps, that confounded the orator Lucius Magius, whom Seneca mentions; and we know that the inscription of Livy’s harangues, not from the public in his harangues, were not so much on his own account, as for the sake of his father in law.

Our author’s history has been often published with and without the supplemen of Frienhemius. The best editions are, that of Gronovius, cum notis variorum & suis, Lugd. Bat. 1679, 3 vol. 8vo; that of Le Clerc, at Amsterdam, 1709, 10 vol. 12mo; and that of Crevier, at Paris, 1735, 6 vol. 4to. These have the supplemen.—Learning perhaps never furnished a greater loss, in any single author, than by the destruction of the latter and more interesting part of Livy. Several eminent moderns have indulged the pleasing expectation that the entire work of this noble historian might yet be recovered. It has been said to exist in an Arabic version: and even a complete copy of the original is supposed to have been extant as late as the year 1631, and to have perished at that time in the plunder of Magdeburg. The munificent patron of learning, Leo X. exerted the most generous zeal to rescue from oblivion the valuable treasure, one of whose most bigoted predececers, above mentioned, had expelled from every Christian library. Boyle has preferred, under the article Leo, two curious original letters, of that pontiff, concerning his hopes of recovering Livy; which afford most honourable proofs of his liberality in the cause of letters. —A lately discovered fragment of Livy’s history was published in 1773 by Dr Bruns.

Livyos (Andronicus), a comic poet who flourished at Rome about 240 years before the Christian era. He was the first who turned the personal satires and fescene verses, so long the admiration of the Romans, into the form of a proper dialogue and regular play. Though the character of a player, so valued and applauded in Greece, was reckoned vile and despicable among the Romans, Andronicus added a part in his dramatical compositions, and engaged the attention of his audience, by repeating what they had laboured after in the name of the Greeks. Andronicus was the freedman of M. Livius Salinator, whose children he educated. His poetry was grown obsolete in the age of Cicero, whose nicey and judgment would not even recommend the reading of it.

LIVONIA, a large province of the Russian empire, with the title of a duchy. It is bounded on the north by the gulf of Finland, on the west by that of Riga, on the south by Courland, and on the east, partly by Pletnow, and partly by Novgorod. It is about 350 miles from north to south, and 150 from east to west. The land is so fertile in corn, that it is called the granary of the north; and would produce a great deal more, if it was not so full of lakes. The fish that abound here are salmons, carps, pikes, flat-fish, and many others. In the forests there are wolves, bears, elks, rein-deer, flags and hares. The domestic animals are very numerous; but the sheep bear very bad wool. Here are a great number of forests, which consist of birch-trees, pines, and oaks; and all the houses of the inhabitants are built with wood. The merchandizes which they find abroad are flax, hemp, honey, wax, leather skins, and potashes. The Swedes were formerly powerful in this province, but were obliged to cede it to the Russias after the battle of Pultowa; and it was ceded to them by the peace of the North, concluded in 1722, which was confirmed by another treaty in 1742. It is divided into two provinces, viz. Letonia and Estonia; and two islands called Osfl and Dagbo, which are again subdivided into several districts.

LIVONICA-TERRA, a kind of fine bole used in the shops of Germany and Italy. It is found in Livonia, from whence it takes its name, and also in some other parts of the world. It is generally brought to us in little cakes, sealed with the impression of a church and chalice, with two cross keys.

LIVRE, a French money of account, containing 20 sols. See Moni-Table.

LIXA, or LIXUS (anc. geog.) a town on the Atlantic near the river Lixus; made a Roman colony by Claudius Caesar; famous in mythology for the palace of Anteus and his encounter with Hercules, (Pliny). Now Larache, sixty-five leagues to the south of the straits of Gibraltar.

LIXIVIUS, an appellation given to salts obtained from burnt vegetables by pouring water on their ashes.

LIXIVIUM; in pharmacy, &c. a ley obtained by pouring some liquor upon the ashes of plants; which is more or less powerful, as it has imbibed the fixed salts contained in the ashes.

LIXNAW, a barony in the county of Kerry and province of Munster in Ireland, which gives title of Baron to the earls of Kerry; the village here of this name being their ancient seat, where the castle was erected. This seat stands agreeably on the river Brick, which is here cut into several pleasant canals, that adorn their plantations and gardens; the improvements are extensive, most of the viofes and avenues terminating by different buildings, seats, and farm-houses. The tide flows up to the gardens, whereby boats of a considerable burden may bring up goods to the bridge near the house; here are two stone-bridges over the Brick, the eldest of which was built by Nicholas the third baron Lixnaw, who was the first person that made caufeways to this place, the land being naturally wet.
Lizard, in zoology. See Lacerta.

Lizard, in geography, a cape or promontory of Cornwall, situated, according to the most common computation, in W. Long. 5° 47'. N. Lat. 49° 50'.

Llandaff. See Landaff.

Lloyd (Nicholas), a learned English writer in the 17th century, was born in Flintshire in England, and educated at Wadham college, in Oxford. He was rector of Newington St Mary near Lambeth in Surry, till his death, which happened in 1680. His Dictionarium Historicum is a valuable work, to which Hoffman and Moreri, are greatly indebted.

Lloyd (William), a most learned English writer and bishop, was born in Berkshire in England in 1627. He was educated under his father, rector of Sonning, and vicar of Tylbury in Berkshire; then went to Oxford, and took orders. In 1660 he was made prebendary of Rippon; and in 1666 chaplain to the king. In 1667 he took the degree of doctor of divinity; in 1672 he was installed dean of Bangor; and in 1680 was consecrated bishop of St Asaph. He was one of the six bishops who, with archbishop Sancroft, were committed prisoners to the Tower of London, for subscribing a petition to the king against distributing and publishing his declaration for liberty of conscience. Soon after the revolution he was made almoner to King William and queen Mary: in 1692 he was translated to the bishopric of Lichfield and Coventry; and in 1699, to the see of Worcester, where he fat till his death, which happened in 1717, the 91st year of his age. Dr Burnet gives him an exalted character.

Loa. See Landa.

load, any thing given to another, on condition of return or payment.

Public Loans. See Funds, and National Debt.

Loanda, a province of the kingdom of Angola in Africa. It is an island about 15 miles in length, and three in breadth; remarkable chiefly for the capital of Angola situated upon it, in E. long. 12° 25'. S. lat. 8° 45'. This town was built by the Portuguese, in 1578, under the direction of the first Portuguese governor in these parts. It is large, populous, and pleasantly seated on the declivity of a hill near the sea-coast, and facing the south west. The island is supplied with fresh water from wells dug in it; and which are not sunk below the depth of three feet when they are filled with excellent water. It is remarkable, however, that the water of these wells continues good only during the time of high-tide; for, as that subsides, the water becomes more and more brackish, till at last it is quite salt, almost as much as the sea itself. On the coast of this island are filled the zimbis, or shells used in several parts of Africa instead of money; and with these shells, instead of coin, is carried on a great part of the traffic of this country.

Loango, a kingdom of Africa, extending itself about 180 geographical miles in length from south to north; that is, from Cape St Catherine under the second degree of south latitude, to a small river called Lovanda Louisa, on the 5th degree of the same. From west to east it extends from Cape Negro on the coast of Ethiopia towards the Bouchornese mountains, so called on account of their vault quantity of ivory and great droves of elephants, about 500 miles. It is divided into four principal provinces, viz. those of Loanguru, Loango-manga, Chilongo, and Piri.

The inhabitants are very black, well-shaped, and of a mild temper. The men wear long petticoats, from the waist downwards, and have round their waist a piece of a vein of earth or flone, or some other metallic substance; in which case it generally happens, that one part of the load is moved to a considerable distance on one side. The transient load is, by the miners, termed a finking; and the part of the load which is moved, is by them said to be heaved. This fracture or heave of a load, according to Mr Price, is produced by a subsidence of the strata from their primary positions, which he supposes to have been horizontal or parallel to the surface of the earth, and therefore should more properly be called a depression than a heave. This heaving of the load would be an inexpressible loss to the miner, did not experience teach him, that as the loads always run on the fides of the hills, so the part heaved is always moved toward the defcent of the hill; so that the miner, working towards the acent of the hill, and meeting a finking, considers himself as working in the heaved part; whereas, cutting through the finking, he works upon its back up the acent of the hill, till he recovers the load, and sic vera.

Load is also used for nine dishes of ore, each dish being about half a hundred weight.

Loadstone. See Magnet.

Loams, in natural history, are defined to be earths composed of difmilar particles, stiff, dense, hard, and rough to the touch; not easily broke while moist, readily diffusible in water, and composed of sand and a tough viscous clay. Of these loams some are whitish and others brown and yellow.

Loan, any thing given to another, on condition of return or payment.

Public Loans. See Funds, and National Debt.

Loanda, a province of the kingdom of Angola in Africa. It is an island about 15 miles in length, and three in breadth; remarkable chiefly for the capital of Angola situated upon it, in E. long. 12° 25'. S. lat. 8° 45'. This town was built by the Portuguese, in 1578, under the direction of the first Portuguese governor in these parts. It is large, populous, and pleasantly seated on the declivity of a hill near the sea-coast, and facing the south west. The island is supplied with fresh water from wells dug in it; and which are not sunk below the depth of three feet when they are filled with excellent water. It is remarkable, however, that the water of these wells continues good only during the time of high-tide; for, as that subsides, the water becomes more and more brackish, till at last it is quite salt, almost as much as the sea itself. On the coast of this island are filled the zimbis, or shells used in several parts of Africa instead of money; and with these shells, instead of coin, is carried on a great part of the traffic of this country.

Loango, a kingdom of Africa, extending itself about 180 geographical miles in length from south to north; that is, from Cape St Catherine under the second degree of south latitude, to a small river called Lovanda Louisa, on the 5th degree of the same. From west to east it extends from Cape Negro on the coast of Ethiopia towards the Bouchornese mountains, so called on account of their vault quantity of ivory and great droves of elephants, about 500 miles. It is divided into four principal provinces, viz. those of Loanguru, Loango-manga, Chilongo, and Piri.

The inhabitants are very black, well-shaped, and of a mild temper. The men wear long petticoats, from the waist downwards, and have round their waist a piece
which they wear the of ivory on their cover their privities, quite bare, except that on their legs they wear little string of beads made of shells, and small bracelets of ivory on their arms. They anoint themselves with palm-oil, mixed with a kind of red wood reduced to powder.

This country abounds with poultry, oxen, cows, sheep, goats, elephants, tigers, leopards, civer-cats, and other animals; so that here are great quantities of elephants teeth, and fine furs, to be traded for.

The capital city where the king resides, is called Luogo, or Benson-Loungeri, and, in the language of the negroes, Boxiti. This city is situated in South lat. 4° degrees, a league and a half from the sea-coast. It is a pretty large city, shaded and adorned with bananas, palm, and other trees. The king, who resides in a large palace in the middle of it, has about 1,500 concubines. If any of them is surprised in adultery, she and her paramour are instantly conveyed to the top of a very high hill, whence they are hurled headlong from the portico or vestibule, and the length or dimensions will not allow it to be considered as a vestibule or an antechamber. See Antichamber.

The king's revenue consists in elephants teeth, copper, a kind of petticoats made of palm-tree leaves, and called lavogu: he has whole store-houses full of these lavogus; but his greatest riches consist in slaves of both sexes.

LOBE, in anatomy, any flabby protuberant part, as the lobes of the lungs, the lobes of the ears, &c.

LOBELIA, CARDINAL-FLOWER: a genus of the monogamia order, belonging to the fyngecia clafs of plants; and in the natural method ranking under the 90th order, Campanaceae. The calyx is quinquefid; the corolla monopetalous, and irregular; the capsule inferior, bilocular, or trilocular. There is a great number of species, but only four of them are cultivated in British gardens; two of which are hardy herbaceous plants for the open ground, and two shrubby plants for the ftove. They are all fibrous rooted perennials, rising with erect flaks from two to five or six feet high, ornamented with oblong, oval, spear-shaped, simple leaves and spikes of beautiful monopetalous, somewhat ringent, five-parted flowers, of scarlet, blue, and violet colours. They are easily propagated by seeds, offsets, and cuttings of their flaks. The tender kinds require the common treatment of other exotics. They are natives of America; from which their seeds must be procured.

The root of a species called the fiphitica is an article of the materia medica. This species grows in moist places in Virginia, and bears the winters. It is perennial, has an erect flalk three or four feet high, blue flowers, a milky juice, and a rank smell. The root consists of white fibres about two inches long, resembles tobacco in taste, which remains on the tongue, and is apt to excite vomiting. It is used by the North-American Indians as a specifie in the venereal disease. The form is that of decoction; the dose of which is ordered to be gradually increased till it bring on very confiderable purging, then to be intermitted for a little, and again used in a more moderate degree till the cure be completed. The ulcers are also washed with the decoction, and the Indians are said to sprinkle them with the powder of the inner bark of the spruce tree. The fame strictness of regimen is ordered as during a falivation or mercurial course. The benefit to be derived from this article has not, as far as we know, been confirmed either in Britain or by the practitioners in Virginia: for there, as well as in Britain, recourse is almost universally had to the use of mercury; and it is probably from this reason that the London college have not received it in their list. It, however, seems to be an article which, in some cafes at least, deserves a trial.

LOBETUM, anciently a town of the Hither Spain: said to have been built by the Libyan Hercules, (Pliny,) now Albarazin, a town of Arragon on the confines of New Castile, on the river Guadalavi. L. long. 40. Lat. 40.

LOBINEAU (Guy Alexis), a Benedictine monk, born at Rennes in 1666, spent his whole life in the study of history, and the writing of several works; the principle of which are, The history of Brittan, 2 vols folio; and A continuation of Felibien's history of Paris, 3 vols folio. He died in 1727.

LOBO (Rodriguez Francis), a celebrated Portuguefe poet, was born at Leiria, a small town of Etruriae. He wrote an heroic poem, some elegies, and a piece intituled Euphrasine, which is the favourite comedy of the Portuguefe. His works were collected and printed together in Portuguefe in 1721, in folio. He flourished about 1610.

LOBO (Jerome), a famous Portuguefe Jesuit, born at Lisbon, went into Ethiopia, and dwelt there for a long time. At his return he was made rector of the college of Coimbra, where he died in 1678. He wrote An historical account of Abyssinia, which is by some esteemed a very accurate performance.

LOBSTER, in zoology, a species of cancer. See Cancer.

LOCAL, in law, something fixed to the freehold, or tied to a certain place; thus, real actions are local, since they must be brought in the country where they lie; and local causes are those peculiar to certain countries and places.

Local Medicines, those defined to act upon particular parts; as fomentations, epithems, vesicatories, &c.

LOCARNO, a town of Switzerland, capital of a bailiwick of the same name, seated at the north and of
LOCATELLUS's BALSAM. See Pharmacy-Index.

LOCHABER, a district of the shire of Inverness in Scotland. It is bounded by Moydart on the west, Glengarry on the north, Badenoch on the east, and Lorn on the south. It derives its name from the lake or loch Aber; and extends about 20 miles from east to west, and 30 from north to south. The country is barren, bleak, mountainous and rugged. In one of the most barren parts of this country, near the mouth of the river Aber, in the centre between the Weft and North Highlands, stands Fort-William, built upon a navigable arm of the sea, not far from the foot of a very high mountain, called Ben Nevis. The town, designed as a fort for the garrison, was erected into a borough; and the fort itself was designed as a check upon the clan Cameron, who had been guilty of depredations and other irregularities. It is inhabited mostly by the Macdonalds, Camerons, and Mackintoshes, who are not the most civilized people in Scotland, though their chiefs are generally persons of education, honour, and hospitality. Macdonald of Glengarry, defended in a straight line from the town of Fort-William to the river Garry, and from it to the sea, in this district, which was burnt to the ground, and destroyed in the year 1715, in consequence of his declaring for the Pretender. The elegant house and gardens belonging to Cameron of Lochiel underwent the same fate, for the same reason, after the extinction of the rebellion in the year 1746. The cadets of these families, which have formed a kind of inferior gentry, are lazy, indigent, and un cleanly; proud, ferocious, and vindictive. The common people, though celebrated for their bravery, fidelity, and attachment to their chiefs, are counted very savage, and much addicted to rapine. They speak the Erse language, and conform to the matter to the requisite perfection, and that every one may reft assured of the security of his property when under the protection of a lock of his invention. He begins with observing, that the principle on which all locks depend, is the application of a lever to an interior bolt, by means of a communication from within; so that, by means of the latter, the lever acts upon the bolt, and moves it in such a manner as to secure the lid or door from being opened by any pull or push from without. The security of locks in general therefore depends on the number of impediments we can interpose between the lever (the key) and the bolt which secures the door; and these impediments are well known by the name of wards, the number and intricacy of which alone are supposed to distinguish a good lock from a bad one. If these wards, however, do not in an effectual manner preclude the access of all other instruments besides the proper key, it is still possible for a mechanic of equal skill with the lock-maker to open it without the key, and thus to elude the labour of the other.

"Locks (says our author) have been constructed, and are at present much used and held in great esteem, from which the picklock is excluded: but the admission of life keys is an imperfection for which no smith has ever found a corrective; nor can this imperfection be remedied whilst the protection of the bolt is wholly confined to fixed wards." This position is proved by a remark, that the wards, let them be as intricate as we please, must all be expressed on what is called the bit or web of the key; and therefore, when all the varieties that can be expressed on this bit or web have been run through, every succeeding lock must be the counterpart of some other; and consequently the
same key which opens one will open the other also. This is evident from the locks usually put upon drawers; and which, tho’ they should be made to resist the picklock, are still liable to be opened by ten thousand other keys besides that appropriated to each of them. But though the variety of wards could be augmented even to infinity, still there could be no security against false keys for as every one of the wards must be expressed on the web of the key, if another key with a web quite plain be made to fit the key-hole exactly, we have only to cover it over with some colouring substance upon which the wards may make an impression; after which, it is easy to cut out the web in a proper manner for admitting them, when the lock will be as easily opened by the false as by the true key.

The first person, according to our author, who had any claim to merit in the branch of lock-making, is Mr. Baron; whose lock he acknowledges to be far more perfect and secure than any that ever appeared before; though he still considers it as unfit for giving that absolute security which is to be wished for. In the improvement consisted in the proper application of what are called tumblers. "These (says Mr. Bramah) are a kind of grapple; by which the bolt is confined, as well in its active as in its passive situation, and rendered immovable till set at liberty by the key. One of these instruments is commonly introduced into all locks that are of any use or value; it is lodged behind the bolt, and is governed by a spring which acts upon the tumbler as the tumbler acts upon the bolt: The application therefore of any force to the tumbler, which is superior to the force of the spring, will cause it to quit its hold, and set the bolt at liberty." In the common method of applying these machines, however, it matters nothing how far the tumbler is lifted above the point at which it ceases to control the bolt; but it is otherwise in those of Mr. Baron's construction. The action of his tumblers is circumcribed by a certain space cut in the centre of the bolt, of dimensions sufficient only to answer the purpose intended. The space in which the tumbler moves is an oblong square; and is not only furnished with niches on the under side into which the hooks of the tumblers are forced by the spring as in other locks, but is provided with corresponding niches on the other side, into which the hooks are driven, if any greater force be applied to the tumblers than what is just sufficient to disengage them from the bolt. Hence it becomes absolutely necessary, in the making of a false key, to construct it in such a manner, that it may with the greatest exactness give the requisite degree of pretense, and no more.

Mr. Bramah allows that this is a very great improvement, but objects that it is still possible to frame a key which will open it as well as its own; nor will the addition of any number of tumblers preclude the possibility of opening it. "By giving (says he) an uniform motion to the tumblers, and preventing them with a face which exactly tallies with the key, they will partake, in a very great degree, of the nature of fixed wards; and the security of his lock is thereby restored in a proportionable degree defective. Thus, suppose the false key to have passed the wards, and to be in contact with the most prominent of the tumblers, the impression, which the slightest touch will leave on the key, will direct the application of the file till sufficient force is prepared to give a free passage. The key will then bear upon a more remote tumbler; which difficulty being in like manner got over, the lock will be as easily opened by the false as by the true key."

This seemingly insuperable objection to the perfection of lock-making, however, our author removes with the greatest ease imaginable, by causing the tumblers which project unequally to present a plane surface: whence they would require a separate and unequal motion to disengage them; of consequence, no distinct impression could be made by them upon the plane surface of the web that would give any idea of their positions with regard to one another, and the construction of a false key would be altogether impossible. But though the principal difficulty with regard to Mr. Baron's lock be now overcome, others still occur, viz. the difficulty of making locks which are constructed with tumblers sufficiently durable. The tumblers themselves, he observes must be but slightly made; and being exposed to perpetual friction by the key and their own proper motion, they must soon decay; and the keys of Mr. Baron's locks, he also observes, are much less durable than those of any other locks he ever saw.

With regard to the lock which Mr. Bramah presents to the public as absolutely perfect, he informs us, that the idea of contriving it was first suggested by the alarming increase of house-breakers, which may reasonably be supposed to be perpetrated in a great measure by pernicious servants, or accomplished by their connivance. Thus it is evident, that if there were any wards which might exclude ordinary house-breakers, it would be no security against faithful servants, who, having constant access to the locks might easily get false keys fabricated at their leisure. In considering the subject, our author was convinced, that his hope of success depended entirely upon his using means as diffimilar as possible to those by which the old locks were constructed; as these, however varied, had been found insufficient for the purpose. "As nothing, (says he) can be more opposite in principle to fixed wards than a lock which derives its properties from the motion of all its parts, I determined that the construction of such a lock should be the subject of my experiment." In the prosecution of this experiment he had the satisfaction to find, that the least perfect of all his models, fully ascertained the truth and certainty of his principle. The exclusion of wards made it necessary to cut off all communication between the key and the bolt; as the same passage, which (in a lock simply constructed) would admit the key, might give admission likewise to other instruments. The office, therefore, which in other locks is performed by the extreme point of the key, is here allotted to a lever, which cannot approach the bolt till every part of the lock has undergone a change of position. The necessity of this change to the purposes of the lock, and the absolute impossibility of effecting it otherwise than with the proper key, are the points to be adhered to; and this our author does in the following manner.

Fig. 1. Shows Mr. Bramah's first attempt to construct a lock upon this principle: which, to his surprise, turned out complete and perfect. A represents a common axis on which the six levers, crossing the face
Lock. [113] Lock.

The face of the lock, are united as on a joint. Each of these rests upon a separate spring sufficiently strong to bear its weight: or, if depressed by a superior force, to restore it to its proper position when that force is removed. B represents a frame through which the levers pass by separate grooves, exactly fitted to their width, but of sufficient depth to allow them a free motion in a perpendicular direction. The part which projects from the opposite side of the joint A, and is inserted in the bolt C, is a lever to which two offices are assigned; one to keep the bolt in a fixed position, in the absence of the key; the other, to give it its proper motion upon the application of the key. D is a circular platform turning upon a centre. On this the joint or carriage of the levers, and the springs on which they rest, are fixed; and the motion of this platform impels the bolt, in either direction, by means of the lever which is projected from the joint A. The inviolable restraint upon this lock, by which means it is subjected only to the action of the key, is lodged in the part E, which is a thin plate, bearing at each extremity on a block, and having of course a vacant space beneath, equal in height to the thickness of the blocks on which it rests. By this plate the motion of the machine is checked or guided in the following manner: On the edge of the plate which faces the movement there are six notches, which receive the ends of the levers projecting beyond the frame B; and while they are confined in this manner, the motion of the machine is to totally suspended as to defy every power of art to overcome.

To understand in what manner the proper key of this lock overcomes these obstacles, it must be observed, that each lever has a notch on its extremity, and that those notches are disposed as irregularly as possible. To give the machine a capacity of motion, these notches, must be brought parallel to each other, and by a distinct but unequal pressure upon the levers, be formed into a groove in a direct line with the edge of the plate E, which the notches are exactly fitted to receive. The least motion of the machine, while the levers are in this position, will introduce the edge of the plate into the groove; which, controlling the power of the springs, will give liberty to the levers to move in a horizontal direction as far as the space between the blocks which support the plate E will admit, and which is sufficient to give the machine a power of acting on the bolt. The impossibility of thus bringing the notches on the points of the levers into a direct line, so as to tally with the edge of the plate E by any other means than the motion and impulse of the key, is that which constitutes the principal excellency of this lock.

The key (fig. 2.) exhibits six different surfaces, against which the levers are progressively admitted in the operation of opening the lock: the irregularity of these surfaces shows the unequal and distinct degree of pressure which each lever requires to bring them to their proper bearings, in order to put the machine in motion. Hence it appears, that unless the various heights of the surfaces expressed on the bit of the key are exactly proportioned to the several distances necessary to bring the notches into a straight line with each other, they must remain immovable; "and (says our author) as one stroke of a file is sufficient to cause such disproportion as will prove an unformidable impediment to their motion, I may safely assert, that it is not in art to produce a key or other instrument, by which a lock, constructed upon this principle, can be opened."

On this principle it would even be a matter of great difficulty for any workman, however skilful, to construct a key for the lock when open to his inspection: for the levers being raised, by the subjacent springs, to an equal height in the frame B, present a plane surface; and consequently convey no direction that can be of any use in forming a tally to the irregular surface which they present when acting in subjection to the key. Unless therefore we can contrive a method to bring the notches on the points of the levers in a direct line with each other, and to retain them in that position till an exact impression of the irregular surface, which the levers will then exhibit, can be taken; the workman will be unable to fit a key to the lock, or to move the bolt. This process must be rendered extremely troublesome by means of the springs; and if such difficulties occur, even when the lock is open to the inspection of a skilful workman, much more must we suppose it out of the power of one who has not access to the internal parts to make a false key to a lock of this kind.

These difficulties render it necessary in making locks of this kind not to fit the key to the lock, as is usual in other locks, but to fit the lock to the key. In this kind of lock, therefore, the key must be made first; and the inequalities upon the surface of the bit worked as chance or fancy may direct, without any reference to the lock. The key being thus completed, and applied to the surface of the levers, will, by a gentle pressure, force them to unequal distances from their common station in the frame B, and sink their points to unequal depths into the space beneath the plate E. While the levers are in this position, the edge of the plate E will mark the precise point at which the notch on each lever must be expressed. The notches being cut by this direction, the irregularity which appears when the levers resume their station in the frame B, and the inequality of the recesses on the bit of the key, will appear as a seal and its corresponding impression.

The following is a lock contrived upon the same principle, but more curious; and, in our author’s opinion, more extensively useful. Fig. 3. represents a circular block of metal divided from the centre into eight compartments, each containing a cell which forms a passage through the block, as is represented by the small circles described on the flat surface A. In each of these cells two grooves are cut at opposite points, which open a communication with the centre at one point, and with the spherical surface of the block or barrel at the other. The small circle, which marks the centre of the flat surface A, is the key-hole; which likewise forms a passage through the barrel in a parallel line with the cells which surround it. This figure represents the frame in which the active parts of the lock are deposited.

Fig. 4. shows a spiral spring lodged in the bottom of each cell, and occupying one half of the space, the other being filled with a slider resting upon the spring, and represented by fig. 5. the office of these sliders extending...
n already described. Thus, when lodged in their respective cells, they are sustained, like the levers, by the elasticity of the springs upon which they rest, till a superior power be applied; and they are again restored to their stations by the reaction of the springs when the weight is removed. The side B of each slider is projected beyond the circular surface, as represented in fig. 6, in a manner similar to the projection of the levers in the former lock beyond the curved frame in which they move. The point C is projected through the interior groove into the space which forms the centre or key-hole, expressed on the flat surface A. Fig. 7 represents the key. When this is applied, it must of course encounter these interior projections; and when pressed forward, the indented spaces on its point being unequal, will force the slides to unequal distances from their bearings; bringing the notches expressed on their exterior projections in a direct line with each other, in a manner similar to that by which the effect is produced upon the levers in the former lock. When the key is withdrawn, and the slides resume their stations by the pressure of the springs, the disposition of the notches must be irregular in the same proportion that the indentations on the point of the key are unequal; and they must necessarily fall again into a straight line when acted upon by the key.

Fig. 6 shows the barrel completely fitted for action. Its interior end is capped with a plate, which unites its compartments, and confines the springs and sliders within the cell to which they belong. From that plate proceeds the point A, which represents the lever by which the bolt is projected or withdrawn, according to the direction in which the machine performs its revolution.

Fig. 8 shows the flat surface of a thin plate, corresponding in its office with the part C of the former lock. The space cut in its centre is exactly fitted to the spherical surface of the barrel; the circle describing its circumference; and the notches cut on its edge, coinciding with the projections of the sliders. The barrel, when enclosed with this plate at the middle of its spherical surface, has its motion totally suspended till the notches on the projections of the sliders are forced, by the pressure of the key, into a line with each other: a groove being thus formed on the spherical surface of the barrel parallel to, and coinciding with, the edge of the plate, the machine is at liberty to perform a revolution in any direction, but returns to its confined state when the key is withdrawn.

The parts of the movement being thus united, the interior end of the barrel is deposited in a bed represented in fig. 9. To this it is fastened at the angles of the plate represented fig. 8, by which the barrel is encircled. The station of the bolt is at A; the lever which acts upon it being projected on the other side. Fig. 10 is a cap or mask which covers the face of the movement, and completes the lock.

On this lock our author observes, that it is excellent for street-doors: "for no method of robbery (says he) is more practised, than gaining admittance into houses by those keys, which, as is well known, may be procured at the old iron shops to fit almost any lock in use. Such robberies are generally committed where the servants are allowed to take the key with them when sent on errands, it being impracticable while the key is fixed in the lock. The various, by which the production of correspondent keys is avoided, have two sources: the first deriving from the disposition of the levers; the other, from the number of points contained in the projected surface of each lever: by which the position of its notch may, in the smallest degree, be varied.

"The variations, producible in the dispositions of six figures only, are 720: these, being progressively multiplied by additional figures, will increase by astonishing degrees; and eventually show, that a lock containing twelve levers will admit of 7\,900,500 changes: which, with the addition of another lever, will increase to 6,229,019,500. These being again multiplied by the number of changes which the projected surface of the levers will admit in the disposition of the notches, their amount will exceed enumeration, and may therefore be properly said to be infinite. The flighted impression will at once show, that their construction precludes all possibility of obtaining an impression of their internal parts, which is necessary for the fabrication of a false key; for it will be easily seen, that the positions into which the levers are forced by the pressure of the key in opening the lock, can no more be ascertained when the key is withdrawn, than the seal can be copied from its impression on a fluid, or the course of a ship be discovered by tracing it on the surface of the waves. But invariable security is not the only excellence they possess; the simplicity of their principle gives them likewise a great advantage over those that are more complicated in point of duration; for their essential parts being subject to no friction, nor exposed to any possible accident from without, they will be less affected by use, and less liable to stand in need of repair."

Lock, or weir, in inland navigations, the general name for all those works of wood or stone made to confine and raise the water of a river: the banks also which are made to divert the course of a river, are called by these names in some places. But the term lock is more particularly appropriated to express a kind of canal enclosed between two gates; the upper called by workmen the sluice-gate, and the lower called the flood-gate. These serve in artificial navigations to confine the water, and render the passage of boats easy in passing up and down the stream. Sec canal.

Locke (John), a most eminent English philosopher and writer in the latter end of the 17th century, was son of Mr John Locke of Pensford in Somersetshire, and born at Wrington near Bristol in 1632. He was sent to Christ-church in Oxford; but was highly dissatisfied with the common course of studies then pursued in the university, where nothing was taught but the Aristotelian philosophy; and had a great aversion to the disputes of the schools then in use. The first books which gave him a relish for philosophy, were the writings of Des Cartes: for though he did not always approve of his notions, yet he thought he wrote with great perfection. He applied himself with vigour to his studies, particularly to physic in which he gained a considerable knowledge, though he never practised it. In 1694, he went to Germany as secretary to Sir William Swan, envoy from the English court to the elector of Brandenburgh and some others.
other German princes. In less than a year, he returned to England; where, among other studies, he applied himself to that of natural philosophy, as appears from a register of the changes of the air which he kept at Oxford from June 24. 1666, to March 28. 1667. There he became acquainted with the Lord Ashley, afterwards Earl of Shaftesbury, who introduced him into the conversation of some of the most eminent persons of that time. In 1670, he began to form the plan of his Essay on Human Understanding; but his employments and avocations prevented him from finishing it then. About this time he became a member of the Royal Society. In 1672, his patron, now Earl of Shaftesbury, and Lord Chancellor of England, appointed him secretary of the presentations, which place he held till the earl refigned the great seal. In 1673, he was made secretary to a commission of trade, worth 500l. a year; but that commission was dissolved in 1674. The Earl of Shaftesbury being restored to favour, and made President of the council in 1675, sent for Mr. Locke to London: but that nobleman did not continue long in his post, being sent prisoner to the tower; and after his discharge retired to Holland in 1682.

Mr. Locke followed his patron thither. He had not been absent from England a year, when he was accused at court of having written certaintracts against the government, which were afterwards discovered to be written by another person; and in November 1684, he was deprived of his place of student in Christ-Church. In 1685, the English envoy at the Hague demanded him and 83 other persons to be delivered up by the States General; upon which he lay concealed till the year following; and during this time formed a weekly assembly with Mr. Limouch, Mr. Le Clerc, and other learned men at Amsterdam. In 1689 he returned to England in the fleet which conveyed the princes of Orange; and endeavoured to procure his restoration to his place of student in Christ-Church, that it might appear from hence that he had been unjustly deprived of it: but when he found the college would admit him only as a supernumerary student, he defisted from his claim.

Being esteemed a sufferer for revolution-principles, he might easily have obtained a more profitable post; but he contented himself with that of commissioner of appeals, worth 200l. a year, which was procured for him by the Lord Mordaunt, afterwards Earl of Monmouth, and next of Peterborough. About the same time he was offered to go abroad in a public character; and it was left to his choice whether he would be envoy at the court of the emperor, that of the Elector of Brandenburgh, or any other where he thought the air most suitable to him: but he waved all these, on account of the infirm state of his health; which disenabled him gladly to accept another offer that was made by Sir Francis Masham and his lady, of an apartment in their country-seat at Oates in Essex, about 25 miles from London.

This place proved to agreeable to him in every respect, that it is no wonder he spent the greatest part of the remainder of his life at it. The air restored him almost to a miracle, in a few hours after his return at any time from the town quite spent and unable to support himself. Besides this happiness here, he found in lady Masham a friend and companion exactly to his heart's wishes; a lady of contemplative and studious complexion, and particularly inured, from her infancy, to deep and refined speculation in theology, metaphysics, and morality. In this family Mr. Locke lived with as much ease as if the whole house had been his own; and he had the additional satisfaction of seeing this lady breed up her only son exactly upon the plan which he had laid down for the best method of education; the success of which was such as seemed to give a foundation to his judgment in the choice of that method. In effect, it is to the advantage of this situation that he derived so much strength as to continue exerting those talents which the earl of Shaftesbury had observed to be in him for political subjects. Hence we find him writing in defence of the revolution in one piece; and considering the great national concern at that time, the ill state of the silver coin, and proposing remedies for it in others. Hence he was made a commissioner of trade and plantations in 1695, which engaged him in the immediate business of the state; and with regard to the church, he published a treatise the same year, to promote the scheme which King William had much at heart, of a comprehension with the dissenters. This, however, drew him into one controversy; which was fiercely ended, when he entered into another in defence of his essay, which held till 1698: soon after which the aethia, his constitutional disorder, increasing with his years, began to subdue him; and he became so infirm, that in 1700 he resigned his seat at the board of trade, because he could no longer bear the air of London sufficient for a regular attendance upon it. After this resignation he continued altogether at Oates; in which retirement he employed the remaining last years of his life entirely in the study of the holy Scriptures.

He died in 1704, aged 71. His writings will immortalize his name. The earl of Shaftesbury, author of the Characteristics, though in one place he speaks of Mr. Locke's philosophy with severity; yet observes, concerning his Essay on the Human Understanding, in general, "that it may qualify men as well for business and the world, as for the sciences and the university." Whoever is acquainted with the barbarous state of the philosophy of the human mind, when Mr. Locke undertook to pave the way to a clear notion of knowledge, and the proper methods of purifying and advancing it, will be surprized at this great man's abilities; and plainly discover how much we are beholden to him for any considerable improvements that have been made since. His Discourses on Government, Letters on Toleration, and his Commentaries on some of St. Paul's Epistles, are justly held in the highest esteem.

LOCKED JAW. See (the Index subjoined to) MEDICINE.

LOCKMAN, an officer in the Isle of Man, who executes the orders of government, much like our under-sheriff.

LOCKMAN, an eastern philosopher. See LOCKMAN.

LOCÉ, a small town in a district of the same name in Switzerland, adjacent to Neuchâtel and Olten, and united with another named La Chaux de Fond. Both these districts occupy some valleys formed by the mountains of Jura; the greatest part of which P 2
Locri, a county of Achaea in Greece; twofold, and divided by mount Parnassus. The site was occupied by the Locri Ozole, called also Zephyrium, or Western, contained between Aiolia and Phocis, beginning at Naupactus, and running in a narrow slip of land, scarce 200 stadia, along the sea to the borders of the Phocenses. The farther Locris lay beyond Parnassus, running out towards Thermopylae, and reaching to the Euriped of Euboea; occupied by the Locri Optuittii, who dwelt on the Eubean sea; and the Epicenimi, who occupied mount Cenis (Syrac.); and these two were the Eastern Locri.

Loc. 51.16

LOG, in the Jewish antiquities, a measure which held a quarter of a cab, and consequently five-sixths of a pint. There is mention of a log, 2 Kings vi. 25.
L O G

Log, under the name of a fourth part of a cab. But in Leu-"vivieae the word log is often met with, and signifies that measure of oil which lepers were to offer at the temple after they were cured of their disease. Dr. Arbuthnot says, that the log was a measure of liquids, the seventy-second part of the bush or ephah, and twelfth part of the tun, according to all the accounts of the Jewish writers.

Log, a sea term, signifying a small piece of timber, or a triangular, sextant, or quadrant figure, on board a ship, generally about a quarter of an inch thick, and five or six inches from the angular point to the circumference. It is balanced by a thin plate of lead, nailed upon the arch, or circular side, so as to swim perpendicularly in the water, with about two thirds immersed under the surface.

Log-line, a little cord, or line, about a hundred and fifty fathoms long, fastened to the log by means of two legs ab (fig. 4), one of which passes through a hole at the corner, and is knotted on the opposite side, while the other leg is attached to the arch by a pin fixed into another hole, so as to draw out occasionally. By these legs the log is hung in equilibrio; and the line thus annexed to it is wound round a reel fixed for that purpose in the gallery of the ship.

This line, from the distance of about ten, twelve, or fifteen fathoms off the log, has certain knots or divisions, which ought to be at least fifty feet from each other; though it was the common practice at sea not to have them above forty two feet asunder.

The length of each knot ought to be the same part of a sea-mile as half a minute is of an hour; and admitting the measurement of Mr. Norwood, who makes a degree on a great circle of the earth to contain 367,200 English feet, or about 69; English statute miles, and, therefore, 3rd part of it, or a nautical mile, will be 6120 feet; 1/3 of 6120, or 51 feet, should be the length of each knot. But because it is safer to have the reckoning rather before the ship than after, it therefore fifty feet may be taken as the proper length of each knot. The knots are sometimes made to confit only of forty-two feet each, even in the present practice; and this method of dividing the log-line was founded on the supposition that sixty miles, each of 5000 English feet made a degree; for 1/3 of 5000 is 417, or, in round numbers, 42 feet. Mariners, rather than quit the old way, though known to be erroneous, use glasses for half minute ones, that run but 24 or 25 seconds. They have also used a line of 45 feet to 30 seconds, or a glass of 28 seconds to 42 feet. When this is the case, the distance between the knots should be corrected by the following proportion: 30 is to 50: 50 is the number of seconds of the glass to the distance between the knots upon the line. The heat or moisture of the weather has often a considerable effect upon the glass, so as to make it run slower or faster; it should, therefore, be frequently tried by the pendulum in the following manner. On a round nail hang a string that has a mucket-ball fixed to one end, carefully measuring between the centre of the ball and the string's loop over the peg 39 inches, being the length of a second pendulum; then swing it, and count one for every time it passes under the peg, beginning at the second time it passes; and the number of swings made during the time the glass is running out shows the seconds it contains. The line also is liable to relax and shrink, and should therefore be occasionally measured.

The use of the log and line is to keep account and make an estimate of the ship's way or distance run; which is done by observing the length of the line unwound in half a minute's time, told by a half-minute glass; for so many knots as run out in that time, so many miles the ship fails in an hour. Thus, if there be four knots veered out in half a minute, the ship is computed to run four miles an hour.

The author of this device for measuring the ship's way is not known; and no mention of it occurs till the year 1607, in the East-India voyage published by Purchas; but from that time its name occurs in other voyages among his collections; and henceforward it became famous, being taken notice of both by British authors and by others; as by Gunter in 1623; Snellius in 1624; Mercator in 1631; Oughtred in 1633; Herigone in 1634; Salomonfall in 1636; Norwood in 1637; Pournier in 1643; and almost by all the succeeding writers of navigation in every country.

To have the Log, as they call it, they throw it into the water on the lee-side, letting it run till it comes without the eddy of the ship's wake; then one holding a half-minute glass, turns it up just as the first knot, or the mark from which the knots begin to be reckoned, turns off the next log, 2, 3, 4, &c. over the stern. As soon as the glass is out, the reel is stopped, and the knots run off are told; and their parts estimated.

It is usual to have the log once every hour in ships of war and East-India men, and in all other vessels once in two hours; and at any time of the watch, the wind has increased or abated in the intervals, so as to affect the ship's velocity, the officer generally makes a suitable allowance for it at the close of the watch.

The log is a very precarious way of computing, and must always be corrected by experience and good fene; there being a great deal of uncertainty in the yawing of the ship going with the wind astern, or upon the quarter in the heaving of it, by its coming home or being drawn after the ship, on account of the friction of the reel and lightness of the log in the course of the current, and in the strength of the wind, which seldom keeps the same tenor for two hours together; which is the interval between the times of using the log in short voyages, though in longer ones they heave it every hour. Yet this is a much more exact way of computing than any other in use; much preferable certainly to that of the Spaniards and Portugal who guessed at the ship's way by the running of the froth or water by the ship's side; or to that of the Dutch, who used to have a chip-over-board, and to number the paces they walk on the deck while the ship swims between any two marks, or bulk-heads on the side.

Compound Log. The abovementioned errors, and particularly the log's being subject to drive with the motion which the water may have at its surface, whereas the experiment requires it to be fixed in the place where it is when the mark commencing the knots goes off the reel, have been considered by writers, and many methods have been proposed to remove, or at least to lessen them.

The
The late M. Bouguer proposed a method, which has been long thought deserving of particular attention, in the Mem. Acad. Sci. 1747; afterwards in his Treatise on Navigation published at Paris in 1752, and since reprinted in 1760, by the abbe de la Caille. For this purpose, take for the log a conical piece of wood, which fix to the log-line passed through or along its axis, at about 40, 50, or 60, or more feet, from one end; and to this end fix the diver, which is a body formed of two equal square pieces of tin, or of thin iron plate, fixed at right angles to one another along their diagonals and its size so fitted to that of the cone, that the whole may float. A cone of three inches diameter in the base, and of six inches in the slant height, is proposed by M. Bouguer to suit a diver made of plates about 64 inches square; the intersection of the diagonals is joined to the log-line, and the loop and peg fixed as in the common log. However, it has been found, that no kind of wood used in British dock-yards, when formed into a cone of the above dimensions, will float a diver made of brass or copper, and of the same thickness of the former, such a diver would weigh, with its folder about 20 ounces, and can be floated by a light fir cone of four inches diameter in the base, and ten inches in the slant height or length, and such a compound log might perhaps be found on trial to be affected by about as much again as that proposed by M. Bouguer; and consequently the difference between the numbers given by the common log and compound log, must be augmented by two-thirds of itself for the necessary correction, as below. When the compound log of Bouguer, above described, is hove overboard, the diver will sink too deep to be much affected by the current or motion of water at the surface, and the log will thereby keep more steady in the place where it first fell; and consequently the knots run off the reel will show more accurately the ship's rate of failing. As the common log is affected by the whole motion of the current, so this compound log will feel only a part thereof, viz., such a part nearly as the resistance of the cone is to the resistance of the diver; then the resistances of the above cone and diver are about as 1 to 5; and consequently this log will drive but one-fifth part of what the common log would do; and so the ship's true run will be affected by one-fifth only of the motion of the water. To obtain the true rate of failing, it will be proper to have alternately, hour and hour, the common log and this compound log; then the difference of their knots run off augmented by its one-fourth part, is the correction; which applied to the knots of the common log, will give the ship's true rate of failing at the middle time between the hours when these logs were hove. The correction is additive when the compound log's run is the greatest, otherwise it is subtractive. To find the course made good increase the observed angle between the log-lines by one fourth part; and this gives the correction to be applied to the apparent course, or the opposite of that shown by the common log; the correction is to be applied to the left 3 of the apparent course, when the bearing of the common log is to the right of the compound log. Or thus: the lengths run off both logs, together with their bearings, being known; in a card or compass, apply the knots run off, taken from a scale of equal parts along their respective bearings, from the centre; join the ends; and in this line produced, on the side next the compound log's length, take one-fourth of the interval; then a line drawn from the end, thus produced, to the centre of the card, will show the true course and distance made good. When a current, such as a tide, runs to any depth, the velocity of that current may be much better ascertained by the compound log than by the common one, provided the diver does not descend lower than the run of the current; for as those ships which are deepest immersed drive fastest with the tide; so the diver, by being fixed on below, as well as the log on the surface, their joint motion will give the total effect of the current's motion better than what could be derived from the motion at the surface only. Also, by such a compound log, the depth to which any current runs may be easily tried.

**Other Logs.** We have an account in the voyage to the North Pole, p. 67, of two other logs, which were tried by captain Phillips: one invented by Mr Raffles, the other by Foxon; both constructed upon this principle, that a spiral, in proceeding its own length in the direction of its axis through a resisting medium makes one revolution round the axis; if, therefore, the revolutions of the spiral are registered, the number of times it has gone its own length through the water will be known. In both these the motion of the spiral in the water is communicated to the clock-work within board by means of a small line fastened at one end to the spiral, which passes after the ship, and at the other to a spindle which feeds the clock-work in motion. That invented by Mr Raffles has a half spiral of two threads made of copper, and a small dial with clock-work, to register the number of turns of the spiral. The other log has a whole spiral of wood with one thread, and a larger piece of clock-work with three dials two of them to mark the distance, and the other divided into knots and fathoms, to show the rate by the half-minute glials, for the convenience of comparing it with the log. This kind of log will have the advantage of every other in smooth water and moderate weather; and it will be useful in finding the trim of a ship when alone, in surveying a coast in a single ship, or in measuring distances in a boat between head-lands and shoals; but it is subject to other inconveniences, which will not render it a proper substitute for the common log.

**Perpetual Log** A machine so called by its inventor, Mr Gottlieb of Hundsfich, London. It is intended by it to keep a constant and regular account of the rate of the ship's velocity through the water; whereas the common log hitherto used does not indicate the variation in her velocity in the interval of heaving the log, and consequently does not ascertain the true distance that the ship has run in any given length of time.
LOG-Board, CELLiULL, progression, progression, limitations, divisions, reliance of the water path, y'rrant L.
at the copper grating, placed to obstruct the entrance of any dirt, &c. into the machine. 1, is section of a water-wheel, made from 6 to 12 inches in diameter, as may be necessary, with float-boards upon its circumference, like a common water-wheel, that turn by the resistance of the water passing through the channel LK. It turns upon a shouldered axis, represented by the vertical line at K. When the ship is in motion, the resistance of the water through the channel LK turns round the wheel I. This wheel, by means of a pinion, is connected with and turns the rod contained in the long copper tube N. This rod, by a pinion fixed at its upper extremity, is connected with and turns upon the whole cyletem of wheels contained in the dial of the case A B C D. This dial, by means of the copper tube N, may be fixed to any convenient place aboard the ship. In the front of the dial are several useful circular graduations, as follow: The reference by the dotted line A has an hand which is moved by the wheels within, which points out the motion of the ship in fathoms of 6 feet each. The circle at B has an hand showing the knots, at the rate of 48 feet for each knot; and is to be observed with the half minute glafs at any time. The circle C has a short and long hand; the former of which points out the miles in land-measure, and the latter or longer the number of knots contained in each mile, viz. 128, which is in the same proportion to a mile as 60 minutes to the hour in the reckoning. At e, a small portion of a circle is seen through the front-plate called the regifter; which shows, in the course of 24 hours (if the ship is upon one tack), the distance in miles that the ship has run; and in the 24 hours the mariner need take but one observation, as this register serves as an useful check upon the fathoms, knots, and miles, shown upon the two other circles.

f, Is a plate showing 300 degrees or 6000 miles, and also acts as another register or check; and is useful in case of any mistake being made in observing the distance run by the other circles. The reckoning by these circles, without fear of mistake, may therefore be continued to nearly 12,000 miles.

A communication from this machine may easily be made to the captain's bed-side, where by touching a spring only, a bell in the head ABCD will sound as many times in an half minute as the ship sails miles in an hour.

Mr Gottlieb has applied this machine to the Carpenter and Welford land packets. He is very sanguine in the hopes of its success and utility; and conceives that the mariner will, by this contrivance, be better enabled than heretofore to keep the vessel and his reckoning together; it being well known that the most experienced navigator is too frequently erroneous in this respect, the ship being sometimes ahead, or sometimes astern, of the reckoning.

He also observes, that the construction of the log is such, that if the vessel was to be aground, strike a rock, or ship off her false keel, the parts would not be disarranged: and further, should she be laid up for repairs, &c. six months, in half an hour after coming again into the water, the lower immersed part of the log would clear itself, and be in proper action.

Log-Board, a sort of table, divided into several columns, containing the hours of the day and night, the direction of the winds, the course of the ship, and all the material occurrences that happen during the 24 hours, or from noon to noon; together with the latitude by observation. From this table the different officers of the ship are furnished with materials to compile their journals, wherein they likewise insert whatever may have been omitted, or reject what may appear superfluous in the log-board.

Log-Book, a book into which the contents of the log-board is daily copied at noon, together with every circumstance deserving notice that may happen to the ship, or within her cognizance, either at sea or in a harbour, &c. The intermediate divisions or watches of the log-book, containing four hours each, are usually signed by the commanding officer in ships of war or East India men. See NAVIGATION.

LOGARITHMS.

LOGARITHMS, (from log, ratio, and arithmetical number), the indices of the ratios of numbers to one another; being a series of numbers in arithmetical progression, corresponding to others in geometrical progression; by means of which, arithmetical calculations can be made with much more ease and expedition than otherwise.

SECT. I. History of Logarithms.

The invention of logarithms first occurred to those yeveant in the construction of trigonometrical tables, in which immense labour was required by large multiplications, divisions, and extraction of roots. The aim proposed was, to reduce as much as possible the multiplications and divisions to additions and subtractions: and for his purpose, a method was invented by Nicholas Raymer Ulfus Dithmarius, which serves for one cafe of the fines, viz. when the radius is the first term in proportion, and the fines of two arcs the second and third terms. In this case the fourth term is found by only taking half the sum or difference of the fines of the other two arcs, and the complement of the greater. This method was first published in 1588, and a few years afterward was greatly improved by Clavius, who used it in all proportions in the solution of spherical triangles; adapting it to fines, tangents, versed sines, and secants; and this, whether the radius was the first term in the proportion or not. This method, however, though now become much more
more generally useful than before, was still found attended with trouble in some cases; and as it depended upon certain properties of lines belonging to the circle, was rather of a geometrical than arithmetical nature; on which account the calculators about the end of the 16th and beginning of the 17th century, finding the solution of astronomical problems extremely troublesome by reason of the tedious multiplications and divisions they required, continued their endeavours to lighten that labour, by searching for a method of reducing their operations to addition and subtraction. The first step towards this was, the consideration, that as in multiplication the ratio of the multiplier to unity is the same as that of the product to the multiplicand, it will follow, that the ratio of the product to unity must be equal to the sum of the two ratios of the multiplier to unity, and of the multiplicand to unity. Could a set of numbers therefore be found, which would represent the ratios of all other numbers to unity, the addition of two of the former set of numbers would be equivalent to the multiplication of the two numbers together, the ratios of which they denoted; and the sum arising from this addition would denote the ratio of their product to unity; whence the product itself might be found by looking for the corresponding natural number in the table.

The next thing was to fall upon a method of calculating such a table as was wanted, which indeed appeared an herculean labour. The first observation was, that whatever numbers might be made use of to represent the ratios of others, the ratio of equality, or that of unity to unity must be 0; for that ratio has properly no magnitude, neither increasing nor diminishing any other ratio to which it is adapted, or from which it is subtracted.

2. The second observation was, that though any number might be chosen at pleasure to represent the ratio of any other number to unity, yet when once this choice was made, all the other numbers representing the different ratios must be determined by it. Thus, if the ratio of 10 to 1 be represented by 1, then the ratio of 100 to 1 must be 2, and that of 1000 to 1 must be 3, &c.; or if 2 was chosen to represent the ratio of 10 to 1, then that of 100 to 1 must be 4, that of 1000 to 1 must be 6, &c.; and no other numbers could possibly be used.

3. As these artificial numbers represented, or were proportional to, the ratios of the natural numbers to unity, they must be expressions of the numbers of some smaller equal ratios contained in the former and larger ones. Thus, if we take the representative of the ratio of 1000 to 1; then 3, which represents the ratio of 1000 to 1, will likewise express the number of ratios of 100 to 1, which are contained in that of 1000 to 1. If instead of 1, we make 1000 to be the ratio of 10 to 1; then 300 will express the ratio of 1000 to 1, and a number of 10000 will express the number of all ratios of the 1000th root of 10 to 1 contained in the ratio of 1000 to 1; and so on for any larger number, as 10,000, 100,000, or 1,000,000, &c. Thus, if instead of 1000 we make 10,000,000 the representative of the ratio of 10 to 1, then the unit will represent a very small ratio, of which there are 10,000,000 contained between 1 and 10, and which ratio could not really be had without extracting a root which involved in itself, 10,000,000 of times would only make up 10; which root may perhaps be most intelligibly expressed thus, \( \sqrt[10]{10000000} \).

If the ratio of 10 to 1 contained 10,000,000 of these roots, it is evident that the ratio of 100 to 1 must contain 20,000,000, that of 1000 would have 30,000,000, &c.; of consequence the ratio of 100 to 1 will be expressed by 20,000,000, of 1000 to 1 by 30,000,000, &c. Hence, as these artificial numbers represent the ratios of natural numbers to unity, or are proportional to them, they are very properly called the logarithms of these numbers, or the numbers of their ratios; because they really do express this number of ratios.

The relation of logarithms to natural numbers may perhaps more intelligibly be explained by two series of numbers, one in an arithmetical, and the other in geometrical progress.]
LOGARITHMS.

121

History.

Here let it be required to multiply 4 by 16; the
number 3 standing over 4, added to 5, which stands over
16, gives 8, which stands over 128; but this is
not just ; for that we must diminish the logarithm by 1,
and then the number 7 standing over 64 shows the
true product. In like manner it appears, that as we
defend below unity in a logarithmic table, the loga-
rithms themselves must begin in a negative series with
respect to the former; and thus the logarithm of
will always be infinite; negative, if the logarithms
increase with the natural numbers; but positive, if
they decrease. For as the geometrical series must
diminilh by infinite divisons by the common ratio, the
arithmetical one must decrease by infinite subtractions,
or increase by infinite additions of the common dif-
ference.

This property of numbers was not unknown to the
ancient mathematicians. It is mentioned in the works
of Euclid; and Archimedes made great use of it in his
Areomartis, or treatise on the number of the lands; and
it is probable that logarithms would have been much
sooner invented, had the real necessity for them been
sooner felt; but this did not take place till the end of
the 16th century, when the construction of trigono-
metrical tables, and solution of perplexed astronomic
problems, rendered them absolutely indispensible.

About this time it is probable that many people
wished to see such tables of numbers, and were
making attempts to construct them; but the inven-
tion is certainly due to Lord John, Baron of
Merchiston in Scotland. The invention is by some
indeed ascribed to Longomontanus; but with very
little probability, as he never published anything of
the kind, nor laid claim to the invention, though
he lived to see the publication of Baron Napier's ta-
bles, and could give no farther account of it than that it was
found already in use about the work; and by the
time that Dr Craig returned to call upon him, he had
prepared a rude draught of it, which he called Canon
mirabilis Logarithmorum; and this draught, with
some alterations, was printed in 1614.

According to Kepler, one Juthe Byrge, assistant
astronomer to the landgrave of Hesse, either invented
or projected logarithms long before Baron Napier,
and composed a table of sines for every two seconds
of the quadrant; though, by reason of his natu-
ral refervedness, he never published anything to the
world. But whatever might have been in this, it is
certain that the world is indebted for logarithms to
Baron Napier, who died in the year 1618. This noble-
man, his wife made considerable improvements in tri-
igonometry, and the frequent numerical compu-
tations he had occasion for in this branch, undoubtedly
contributed to his invention of the logarithms, that
he might have part of the trouble in these calculations.
His book published in 1614 was intitled Mirifici Loga-
rithmorum Canonis definitio. At this time he did not
publish his method of constructing the numbers until
the sense of the learned should be known. In other
respects the work is complete, containing all the lo-
garithms of the natural numbers to the usual extent
of logarithmic tables, with the logarithmic sines, tan-
gents, and secants, for every minute of the quadrant,
directions for using the tables, &c.

This work was published in Latin; but was after-
wards translated into English by Mr Edward Wright,
inventor of the principles of what has been falsely call-
ed Mercator's Sailing. The translation was feft to
the Baron, at Edinburgh, and returned with his appro-
bation and some few additions. It was published in
1616, after Mr Wright's death, with a dedication to
the Earl of India Company, by his son Samuel Wright,
and a preface by Mr Briggs, who afterwards dis-
tinguished himself so much in bringing logarithms to
perfection. In this translation Mr Briggs also gave
the description and draught of a scale invented by Mr
Wright, as well as other methods invented by him-
self, for finding the intermediate proportional num-
bers; the logarithms already found having been only
printed for such numbers as were the natural sines of
each minute.

Mr Wright's translation was reprinted in 1618, with
a new title-page, and the addition of 16 pages of new
matter, showing the method of calculating triangles,
as well as a method of finding such sines and lo-
garithms as are not to be found in the canons."

Next year John Speckell published his New Loga-
rithms, in which were some remedies for the incon-
veniences attending Baron Napier's method. The same
year also Robert Napier, the Baron's son, published
a new edition of his father's book, intituled Canonici
Logarithmorum Descriptio; with another concerning
the method of constructing them, which the Baron had
promised; together with some other miscellanoeous pieces,
which his father had likewise composed along with Mr
Briggs. In 1620 also, a copy of these works was print-
ed at Lyons in one volume, by Bartholomew Vincent a
bookfeller there; but this publication seems to have
been but little known, as Winge, who carried loga-
rithms to France four years after, is said to have been
the first who introduced them into that country.

The Carus Mathematicus published at Cologne in
1618 or 1619 by Benjamin Ursinus, minister and
a preacher of Brandenburg, contains a copy of Na-
ipier's logarithms, together with some tables of propor-
tional parts. In 1624 he published his Trigonometria,
with tables of natural sines and their logarithms,
according to Baron Napier's method, to every ten seconds
in the quadrant. The same year a book on logarithms
was published at Marburg by the celebrated Kepler,
of the same kind with those of Napier. Both of these
begin at 90° or the end of the quadrant; and, while
the sines decrease, the logarithms gradually increase;
till at the beginning of the quadrant, or 0, the loga-
rithm is infinite. The only difference between the loga-
rithms of Napier and Kepler is, that in the former the
arc is divided into equal parts, differing by one minute
each; and consequently their sines to which the loga-
rithms are adapted are intermediate numbers represent-
ed only by approximating decimals; but in Kepler's
table, the radius is divided into equal parts; which
are considered as perfect and terminate sines, having
equal differences, and to which the logarithms are here
adapted.
LOGARITHMS.

History.

adapted. A treatise of some extent was prefixed to the work; in which the construction and use of logarithms is pretty largely treated of. In the year 1627 the same author introduced logarithms into his Rudolphine Tables, together with several others, viz. 1. A table similar to that already mentioned; only that the column of sines or absolute numbers is omitted, and another added in its stead, showing what part of the quadrant each arc is equal to; viz. the quotients arising from the division of the whole quadrant by each given arc, and expressed in integers, and sexagesimal parts. 2. Napier's table of logarithmic sines to every minute of the quadrant; as also two other smaller tables adapted for the calculation of eclipses and the latitude of planets. In this work Julius Byrgius is mentioned as having invented logarithms before Napier.

The kind of logarithms now in use were invented by Mr Henry Briggs professor of geometry in Gresham college, London, at the time they were first discovered by Napier. As soon as the logarithms of Napier were published, Mr Briggs directed his attention to the study and improvement of them; and in consequence of the Baron's advice, Mr Briggs made some alteration in the method of constructing his tables from that which he had begun. A correspondence also took place between the Baron and Mr Briggs, which continued during the lifetime of the former. It appears, however, that, whether Mr Briggs thought of this alteration before Baron Napier or not, he certainly was the person who first published it to the world; and some reflections have been thrown upon the Baron for not making any mention of the share which Mr Briggs had in it.

In 1617 Mr Briggs published his first thousand logarithms under the title of Logarithmorum Chilias Prima, and in 1620 Mr Edward Gunter published his Canon of Triangles, containing the artificial or logarithmic sines and tangents for every minute, to seven places of figures besides the index; the logarithm of the radius being 10,000. These were the first tables of logarithmic sines, tangents, &c. which made their appearance upon the present plan; and in 1623 they were reprinted in his book De Sphaere et Radiis, along with the Chilias Prima of Mr Briggs. The same year Mr Gunter applied these logarithms of numbers, sines, and tangents, to straight lines drawn on a ruler; and with these the proportions in common numbers as well as in trigonometry, were solved by the mere application of a pair of compases: a method founded upon this property, that the logarithms of the terms of equal ratios are equally different. The instrument is now well known by the name of the two-feet Gunter's Scale. By the same method he also greatly improved the sectors. He was also the first who used the word sines for the sines of the complement of an arc; and he introduced the ufe of arithmetical complements into the logarithmic arithmetic. He is said also to have first suggested the idea of the logarithmic curve, so called because the segments of its axis are the logarithms of the corresponding ordinates.

The logarithmic lines were afterwards drawn in many other ways. Wingate, in 1627, drew them upon two separate rulers sliding by each other, in order to fave the ufe of compases in resolving proportions. In 1627 also, they were applied by Mr Oughtred to concentric circles; about 1650, in a spiral form, by one Mr Milburne of Yorkshire; and in 1657, they were applied on the present sliding rule by Mr Seth Partridge.

The knowledge of logarithms was diffused in France by Mr Edmund Wingate, as already related, though not carried originally thither by him. Two small tracts were publifhed by him in French, and afterwards an edition in English, all printed in London. In the first of these he mentions the ufe of Gunter's Ruler; and in the other that of Briggs's Logarithms, with the ufe of compases in resolving proportions. There are likewise tables of these sines, tangents, and logarithms, copied from Gunter.

From the time that Mr Briggs first began to study the nature of logarithms, he applied to the construction of tables with such avidity, that by the year 1624 he published his Arithmetica Logarithmica, containing the logarithms of 30,000 natural numbers to 14 places of figures besides the index; viz. from 1 to 20,000, and from 90,000 to 100,000, together with the differences of the logarithms. According to some there was another Chilias, viz. from 100,000 to 101,000, but this does not seem to be well authenticated. In the preface to this work, he gives an account of the alteration made in the scale by Baron Napier and himself; and earnestly solicits other person to undertake the task of filling up the intermediate numbers; offering to give instructions, and to afford paper ready ruled for the purpose. He gives also instructions at large in the preface for the construction of logarithmic tables. Thus he hoped to get the logarithms of the other 70,000 natural numbers completed; while he himself, being now pretty far advanced in years, might be at liberty to apply to the canon of logarithmic lines, &c. which was as much wanted by mathematicians as the others. His wishes were accomplished by Adrian Vlacq or Flack of Gouda in Holland, who completed the number from 20 to 90,000; and thus the world was furnished with the logarithms of all natural numbers from 1 to 100,000. But those of Vlacq were only done to 10 places of figures. To these was added a table of artificial sines, tangents, and secants, to every minute of the quadrant. Besides the great work already mentioned, Mr Briggs completed a table of logarithmic sines and tangents for the 100th part of every degree, to 14 places of figures besides the index; and a table of natural sines for the same parts to 15 places, with the tangents and secants to 10 places, and the methods of constructing them. He designed also to have published a treatise concerning the ufe and application of them, but died before this could be accomplished. On his death-bed he recommended this work to Henry Gellibrand professor of astronomy.
astronomy in Gresham college, in which office he had succeeded Mr Gunter. Mr Briggs's tables abovementioned were printed at Gouda, and published in 1624; and the same year Mr Pellissier added a preface with the application of logarithms to plane and spherical trigonometry, the whole being denominated *Trigonometria Britannica*. It includes the area in degrees and hundred parts, has another table containing the minutes and seconds answering to the several hundred parts in the first column.

The *Trigonometria Artificialis* of Vlacq contains the logarithmic sines and tangents to 10 places of figures, to which is added Briggs's first table of logarithms from 1 to 20,000, besides the index. The whole preceded by a description of the table, and the application of them to plane and spherical trigonometry, Chiefly extracted from Briggs's *Trigonometria Britannica* already mentioned. In 1632, Mr Pellissier also published a work intitled, *An Institution Trigonometrical*, containing the logarithms of the first 10,000 numbers, with the natural sines, tangents, and secants; and the logarithmic sines and tangents for degrees and minutes, all to seven places of figures besides the index; likewise other tables proper for navigation, with the uses of the whole. Mr Pellissier died in 1636, in the 46th year of his age.

A number of other people have published books on logarithms, which we cannot now particularly enumerate. Some of the principal are:

1. A treatise concerning Briggs's logarithms of common numbers from 1 to 20,000, to 11 places of figures, with the logarithmic sines and tangents but only to eight places. By D. Henrion at Paris, 1626.

2. Briggs's logarithms, with their differences to 10 places of figures, besides the index for all numbers to 100,000; as also the logarithmic sines, tangents, and secants, for every minute of the quadrant, with the explanation and uses in English. By George Miller, Lond. 1631.

3. *Trigonometria*, by Richard Norwood, 1631; containing Briggs's logarithms from 1 to 10,000, as well as for the sines, tangents, and secants to every minute, both to several places of figures besides the index. The author complains very much of the unfair practices of both the former authors.

4. *Dierictorium Generalis Uranometriae*, by Francis Bonaventure Cavaliere. Bologna, 1632. In this are Mr Briggs's tables of logarithmic sines, tangents, secants, and verified sines each to eight places of figures for every second of the first 5 minutes, for every 5 seconds from 5 to 10 minutes, for every 20 seconds from 20 to 30 minutes, for every 50 seconds from 30 minutes to 1 degree, and for every minute in the rest of the quadrant. It contains also the logarithms of natural numbers from 1 to 10,000, with the first table of verified sines that ever was published. The author likewise gives the first intimation of the method of finding the area of spherical surface contained by various arcs described on the surface of a sphere.

5. In 1643 appeared the *Trigonometria* of the same author, containing the logarithms of the natural numbers from 1 to 10,000, with their differences to eight places of figures, likewise a table of natural and logarithmic sines, tangents, and secants; the former to seven, the latter to eight, places of figures.

6. *Tabula Logarithmica*; by Mr Nathaniel Rowe, pastor of Benaire in Suffolk: Lond. 1633. In this work are contained Mr Briggs's logarithms of natural numbers from 1 to 100,000, to eight places of figures; likewise the logarithmic sines and tangents to every hundredth part of degrees to ten places.

7. *Clavis Universae Trigonometriae*: Hamburg, 1634; containing tables of Briggs's logarithms from 1 to 2000; and of sines, tangents, and secants, for every minute, both for seven places.

8. *Trigonometria Britannica*, by John Newton, London, 1638. In this the logarithmic tables of natural numbers were reduced to their most convenient form; the author having availed himself of the labours of Wingate and Rowe, uniting their several methods, and dispoising of the whole as in the best logarithmic tables used at present. It contains likewise the logarithmic sines and tangents to eight figures besides the index; for every hundredth part of a degree, with the differences, and for thousandth parts in the first three degrees. He censures the unfair practices of some former publishers of logarithms; particularly of Vlacq already mentioned.

9. *Mathesis Nova*, by John Caramuel, 1670. This contained 1000 logarithms, both of the forms of Napier and Briggs, as well as 1000 of what he calls perfect logarithms, viz. those of Briggs's first method of construction; which differs from the last only in this, that the last increases, whilst the first decreases; the radix or logarithm of the ratio of 10 to 1 being the very same in both.

10. Sherwin's *Mathematical Tables*, published in 8vo, form the most complete collection of any; containing, besides the logarithms of all numbers to 101,000, the sines, tangents, secants, verified sines both natural and logarithmic, to every minute of the quadrant. The first edition was printed in 1706; but the third, published in 1742 and revised by Gardiner, is looked upon to be superior to any other. The fifth and last edition, published in 1771, is so incorrect, that no dependence can be placed upon it.

11. Tables of logarithms from 1 to 101,100, and for the sines and tangents to every 10 seconds of each degree in the quadrant; as also for the sines of the first 72 minutes to every single second, with other useful and necessary tables. By Gardiner, London, 1712. This work contains a table of logarithmic logarithms, and three smaller tables to be used for finding the logarithms of numbers to 20 places of figures. Only a small number of these tables was printed, and that by subscription; and they are now in the highest esteem for accuracy and usefulness. An edition of these tables was printed at Avignon in France in 1770, with the addition of sines and tangents for every single second in the first four degrees, and a small table of hyperbolic logarithms, taken from a treatise upon fluxions by the late Mr Thomas Simpson. The tables are to seven places of figures, but somewhat less correct than those published by Gardiner himself.

12. An Antilogarithmic Canon for readily finding the number corresponding to any logarithm, was begun by
LOGARITHMS.

Sect. II. Different methods of constructing Logarithms.

§ 1. Napier's method.

The logarithms first thought of by Baron Napier were not adapted to the natural series of arithmetical numbers 1, 2, 3, &c. because he did not then intend to adapt them to every kind of arithmetical calculation, but only to that particular operation which had called for their immediate construction, viz. the shortening of trigonometrical operations: he explained the generation of logarithms, therefore, in a geometrical way. Both logarithms, and the quantities to which they correspond, in his way, may be supposed to proceed from the motion of a point; which, if it moves over equal spaces in equal times, will produce a line increasing equally: but if, instead of moving over equal spaces in equal times, the point describes spaces proportional to its distances from a certain term, the line produced by it will then increase proportionally.

Again, if the point moves over such spaces in equal times, as are always in the same ratio to the lines from which they are subducted, or to the distance of that point at the beginning of the lines, from a given term in that line, the line so produced will decrease proportionally. Thus, let $ac$ be to $oa$, $cd$ to $oa$, $ef$ to $oa$, and $fg$ to $oa$, always in a certain ratio, viz. that of $QR$ to $QS$, and let us suppose the point $P$ to let $f$ out from $oa$, describing the distances $ac$, $cd$, $de$, &c. in equal spaces of time, then will the line $ao$ decrease proportionally.

In like manner, the line $oa$, (fig. 12.) increases proportionally, if the point $p$, in equal times, describes the spaces $ac$, $cd$, $de$, &c. so that $ac$ is to $oa$, $cd$ to $oa$, and $de$ to $oa$, and so on; and if we now suppose a point $P$ describing the line $AG$ (fig. 4.) with an uniform motion, while the point $p$ describes a line increasing or decreasing proportionally, the line AP, described by $P$, with this uniform motion, in the same time that $oa$, by increasing or decreasing proportionally, becomes equal to $op$, is the logarithm of $op$. Thus $AC$, $AD$, $AE$, &c. are the logarithms of $oa$, $od$, $oe$, &c. respectively: and $oa$ is the quantity whose logarithm is supposed equal to nothing.

We have here abstracted from numbers, that the doctrine may be the more general; but it is plain, that if $AC$, $AD$, $AE$, &c. be supposed $1$, $2$, $3$, &c. in arithmetic progression; $oa$, $od$, $oe$, &c. will be in geometric progression; and that the logarithm of $oa$, which may be taken for unity, is nothing.

Baron Napier, in his first scheme of logarithms, suppose that, while $op$ increases or decreases proportionally, the uniform motion of the point $P$, by which the logarithm of $op$ is generated, is equal to the velocity of $p$ at $a$; that is, at the term of time when the logarithms begin to be generated. Hence logarithms, formed after this model, are called Napier's Logarithms, and sometimes Natural Logarithms.

When a ratio is given, the point $p$ describes the difference of the terms of the ratio at the same time.

When a ratio is duplicate of another ratio, the point $p$ describes the difference of the terms of that ratio in a time equal to the sum of times in which it describes the differences of the terms of the simple ratios of which it is compounded. And what is here said of the times of the motion of $p$ when $op$ increases proportionally, is to be applied to the spaces described by $P$, in those times, with its uniform motion.

Hence the chief properties of logarithms are deduced. They are the measures of ratios. The excess of the logarithm of the antecedent above the logarithm of the consequent, measures the ratio of those terms: The measure of the ratio of a greater quantity to a lesser is positive; as this ratio, compounded with any other ratio, increases it. The ratio of equality, compounded with any other ratio, neither increases nor diminishes it; and its measure is nothing. The measure of the ratio of a lesser quantity to a greater is negative; as this ratio, compounded with any other ratio, diminishes it. The ratio of any quantity $A$ to unity, compounded with the ratio of unity to $A$, produces the ratio of $A$ to $A$, or the ratio of equality; and the measures of those two ratios destroy each other when added together; so that when the one is considered as positive, the other is to be considered as negative. By supposing the logarithms of quantities greater than $oa$ (which is supposed to represent unity) to be positive, and the logarithms of quantities less than it to be negative, the same rules serve for the operations by logarithms, whether the quantities be greater or less than $oa$. When $op$ increases proportionally, the motion of $p$ is perpetually accelerated; for the spaces $ac$, $cd$, $de$, &c. that are described by it in any equal times that continually succeed after each other, perpetually increase in the same proportion as the ratio of $oa$ to $oa$, and $od$, $oe$, &c. When the point $p$ moves from $a$ towards $oa$, and $op$ decreases proportionally, the motion of $p$ is perpetually retarded, for the spaces described by it in any equal times that con-
continually succeed after each other, decrease in this case in the same proportion as \( \phi \) decreases.

If the velocity of the point \( p \) be always as the distance \( \phi \), then will this line increase or decrease in the manner supposed by Baron Napier, and the velocity of the point \( p \) being the fluxion of the line \( \phi \), will always vary in the same ratio as this quantity itself.

This, we presume, will give a clear idea of the genesis or nature of logarithms; but for more of this doctrine, see Maclaurin's Fluxions.

The construction of his tables of logarithms was first published in his posthumous work of 1619. The construction of his canon was chiefly effected by generating, in an easy manner, a series of proportional numbers, and their arithmeticals or logarithms; and then finding by proportion the logarithms of the natural lines from those of the nearest numbers among the original proportionals. Beginning then at the radius 10,000,000, he first constructs several descending geometrical series, of such a nature that they are quickly formed by an easy addition or substraction, or division by 2, 10, 100, &c. His first table consists of proportionals in the ratio of 10,000,000 to 9,999,999; the method of doing which may be easily understood from the following example: Suppose it were required to find a series of descending proportionals in the ratio of 100 to 99; it may be done by adding two cyphers to each of the two first terms, and continually adding 1 to the decimal place farthest to the right hand. Thus the first term will be 100.00, the second 99.00, the third 98.01, the fourth 97.03, &c. His first table contained 100 terms of a series, as we already mentioned, in the proportion of 10,000,000 to 9,999,999. The first term of which series was 10,000,000.0000000; the second 9,999,999.9999999; the third was 9,999,998.9999990, and so on till the 100th term, which was 9,999,900.0000000.

The second table consisted of 50 numbers nearly in the proportion of 100,000 to 99,999, and this was formed by substituting the units 1, 3, &c. in the third decimal place instead of the last place towards the right hand. Thus the second term of this series was, that he might have a series in the proportion of his first term of the former to the last term of it, viz. of 100,000 to 99,999; and the last of the second series was 999,999.0000001. In all these series the method of finding the terms is exactly the same. Thus in the first example, where we begin with 100, each term decreases by the 100th part of the former, and this 100th part is found by removing the number two places of figures lower, and subtracting them from the former terms. Thus 99 is less than 100 by unity, which is the 100th part of the latter; the next term is less than 99 by the 100th part of 99, and is therefore 98.01. But the division by 10 can be performed without any trouble, only letting the decimal point two places farther forward as by 10 is performed by letting it one place farther forward; thus 99 = 100 = 99. Now by subtracting 99 from 100, we have 98.01 for the third term of the series. To find the fourth term then, remove the decimal point two figures farther to the right hand and subtract it from the former; and we have then 97.0299 for the fourth term of the series. Thus we see, that the number of decimal places must continually increase; but as in this series we want no more than two decimal places instead of 97,0299, the term is made 97.03, as the nearest number which has only two decimal places, and differs from the truth only by one thousandth part. In like manner, in the long firing of ciphers, the fourth term of the series differs somewhat, but very little from the truth: and this must always be the case while the radius is supposed to consist of any finite number of parts; though, by going on for a very long time in this way, the error, by being continually repeated and augmented at every term, would at last become perceptible: and therefore none of these series are carried on to a very great length.

His next step was to construct a third table consisting of 69 columns, and each column of 21 numbers or terms in the continual proportion of 10,000 to 9995; that is, nearly as the first term of the second table is to its last term. As this proportion is the 200th of the whole, the method of finding the terms will be by dividing each upper number by 2, and removing the figures of the quotien three places lower, and then subtracting them. In this way, however, it is proper to collect only the first column of 21 numbers, the last of which will be 999,047,3780; but the first, second, and third, &c. numbers in all the other columns are in the continual proportion of 100 to 99, or nearly of the first to the last in the first column; whence these are to be found by removing the figures two places lower, and then subtracting them, as has already been explained.

By these three tables, the Baron was furnished with about 1600 proportionals, nearly coinciding with all the natural series from 90 to 30 degrees. To obtain the logarithms of those proportionals, he demonstrated and applied some of the properties and relations of the numbers and logarithms; the principal of which are

1. That the logarithm of any line is greater than the difference between that line and the radius, but less than that difference when increased in the proportion of the line to the radius. 2. That the difference between the logarithms of two lines is less than the difference of the lines increased in the proportion of the lesser line to the radius, but greater than the difference of the lines increased in the proportion of the greater line to the radius. These properties now served him as theorems for finding the logarithms themselves in an easy manner. From the first of them it appeared, that the radius being 10,000,000, the first term of the table, the logarithm of 9,999,999, the second term, must be greater than the difference between the first and the radius, which is 1, but less than the difference when increased in the proportion of the line to the radius; but this proportion is only one tenth millionth part, for 9,999,999 x 1.0000000 = 10,000,000; whence the logarithm of the radius or 10,000,000 being 0, the logarithm of 9,999,999, the second term will be between 1 and 1.000000, or very nearly 1.000000, this being the mean between 1 and 1.000000. This will also be the common difference between every two succeeding terms in the first table; because all the terms there are in the same proportion of 10,000,000 to 9,999,999. Hence by the continual addition of this logarithm we have the logarithms of the whole series, and therefore that of the last term of the series, viz. 99999999.00004950 will be 100.00005.
L O G A R I T H M S.

This was founded on principles nearly similar to that of Napier. He first of all erects a system of proportions, and the measures of proportion, founded upon principles purely mathematical; after which he applies these principles to the construction of his table, containing only the logarithms of 1000 numbers. The propositions on which his method is founded are in substance the following.

1. All equal proportions equal among themselves are expressed by the same quantity, be the terms many or few; as the proportion of 2, 4, 8, &c. in geometrical progression is expressed by 2; and of 2, 6, 18, 54, &c. by 3.

2. Hence the proportion of the extremes is composed of all the proportions of the intermediate terms; thus the proportion of 2 to 8 is compounded of that of 2 to 4, and of 4 to 8.

3. The mean proportional between two terms divides that proportion into two equal ones. Thus the proportion between 2 and 32 is divided by the mean proportion 8 into two equal proportions of 4; for 2 is to 8, as 8 is to 32.

4. In any number of proportions regularly increasing, the means divide the proportion of the extremes into one more than their own number. Thus, in the series 2, 4, 8, 16, the proportion of the extremes 2 and 16 is by the two means 4 and 8, divided into three proportions, viz. that between 2 and 4, 4 and 8, and 8 and 16. In like manner, in the series 3, 6, 18, 54, 162, 486, the proportion between 3 and 486 is divided by the four means into the five proportions of 3 to 6; 6 to 18; 18 to 54; 54 to 162; and 162 to 486.

5. The proportion between any two terms is divisible into any number of parts, until these become less than any assignable quantity. Thus the proportion of 2 to 8 is divisible, by multiplying the two together and extracting the square root, into two parts by the number 4; by multiplying two and 4 together, and extracting the square root; and doing the same with 4 and 8, the proportion would be divided into four parts, viz. \(2:4:4\sqrt{2}:8\); or in numbers, 2: 2.813, &c.: 4: 5.635, &c.: 8.

6. By dividing the ratios in this manner, the elementary part will become at last so small, that it may be denominated by the mere difference of terms of that element. This is evident from the diminution of the ratios or proportions already instanced: for the proportion between 2 and 2.813 is only 1.406, &c. and if we were to find a mean proportional between 2 and 2.813, the ratio between that proportional and 2 would be much less. But it must always be remembered, that such evanescent quantities, as they are called, cannot give us any conclusion with absolute exactness, however they may answer every useful purpose to us: for it is evident that neither mean proportional nor ratio can ever be found exactly; and therefore the error accumulated in all the operations must become very considerable, if any circumstance shall happen to make it appear.

7. In three continued proportionals, the difference of
Logarithms.

of the two first has to the difference between the two last the same proportion that the first term has to the second, or the second to the third. Thus, in the three terms 4, 8, 16, the difference between the two first terms 4 and 8, viz. 4, is in proportion to 8; and the difference between the two last, as 4 is to 8, or 8 to 16.

9. In continued proportionals, the greatest terms have the greatest differences, and vice versa. Thus, the difference between 8 and 16 is evidently greater than between 2 and 4 or 4 and 8.

10. In any series of proportionals, if the difference between the greatest term and one not immediately next to it, be taken as the measure of the proportion, the true measure of the proportion will be less than that of the terms of the proportion; but the proportion which is between the greatest term and any one less than that first taken, will be greater than their difference. As proportionals of this kind do not readily occur, we shall, in order to avoid obscurity, shew once for all, that there is a possibility of finding geometrical proportionals of such a nature, that the ratio may be equal to the difference between the greatest and third, or any other term distant from it. Thus let us begin with any two numbers we please; suppose 9 and 10; though these are in the natural arithmetical proportion, yet if we make the ratio $\frac{1}{11}$, they will also be geometrically proportionals, and the series will run thus:

1st 2d 3d 4th 5th 6th term term term term term

Here the difference between the first and third terms is 9001, which is greater than the ratio; but the difference between the second and fourth, viz. 1.711, is still greater, but nearer to it than the former; the difference between the third and fifth terms, viz. 1.539, is still smaller, as does that between the fourth and sixth, viz. 1.385: and indeed by continuing this series only for two terms longer, the difference will become smaller than the ratio. It is not worth while, however, to seek for fericies of this kind, as the present proposition will now be sufficiently intelligible without any farther illustration.

11. If quantities be arranged according to the order of their magnitudes, and if any two successive proportions of these be equal, the three successive terms which constitute them will also be equal. Thus, if the two quantities 12 and 8 constitute the proportion $\frac{4}{3}$, and each of them be increased by 6, the half of 12, we have the proportion $\frac{2}{3}$; which is more than double the original proportion; for $\frac{1}{3} \times 4 = \frac{1}{2}$.

12. When quantities are placed in the order of their magnitudes, if the intermediate magnitudes lying between any two terms be not among the mean proportionals which can interpose between these two terms, then these intermediates will not divide the proportion of those two terms into commensurable proportions. Thus in the magnitudes $343 : 216 : 125 : 64 : 27 : 8$, neither of the two intermediate terms 125 and 64 are mean proportionals between 27 and 216, nor do they divide the proportion between these into commensurable parts.

13. All the proportions taken in order, which are between commensurable terms that are in arithmetical proportion, are incommensurable to one another; as between 8, 13, and 18.

14. When quantities are placed in the order of their magnitudes, if the difference between the two greatest be made the measure of their proportion, the difference between any two others will be less than the measure of their proportion, and if the difference between the two least terms be made the measure of their proportion, the differences of the rest will be greater than the measure of the proportion between their terms.

15. If the measure of proportion between the greatest exceed their difference, then the proportion of the greater to the difference will be less than that of a following measure to the difference in its terms; because proportionals have the same ratio.

16. If three equidifferent quantities are taken in order, the proportion between the extremes is more than double that between the two greatest terms. Hence it follows, that half the proportion of the extremes is greater than the proportion between the greatest terms, but less than the proportion of the two least.

17. If two quantities constitute a proportion, and each be increased by half the greater, the remainder will constitute a proportion more than double the former.

18. If 1000 numbers follow one another in the natural order, 1000, 999, 998, &c. and by continual multiplication and extraction of the square root we find mean proportionals, and thus $\sqrt{2} \sqrt{3} \sqrt{4}$, as it is called, the ratio between the two greatest, so that the parts into which the ratio is divided become ultimately smaller than the excess of proportion betwixt the next two over the former (for 998 bears a greater proportion to 999 than 999 bears to 1000); the measure of this very small part or element of the proportion may be supposed to be the difference between 1000 and that mean proportional which is the other term of the element. Thus, for the sake of an easy explanation, let us suppose the numbers to be 10, 9, 8, &c. the ratio of 9 to 10 is $\frac{9}{10}$, 11, that of 9 to 8 is $\frac{11}{12}$, the difference between which is $\frac{1}{120}$, which we may call the elementary part of the ratios. By six extractions of the square root we have the mean proportional 9.985, &c. differing from 16 by no more than $\frac{1}{5}$, which is near the element just mentioned. The number of parts into which the ratio is thus divided is expressed by the 6th power of 5 to 64. Dividing, therefore the ratio between 10 and 11 by 64, we have $\frac{1}{64}$ for the elementary part thus obtained; which near coincidence with the real element, and the difference between 10 and the mean proportional itself, shows that in large numbers we may take the difference between the mean proportional and greatest term for the elementary power without any sensible error.
and 998 be divided into twice the number of parts that the former was, it will be equally plain that the difference between 1000 and the next mean proportional will be the measure of that element. Proceeding in like manner with the other numbers 1000 and 997, 1000 and 996, &c. It is evident, that by dividing into a proper number of parts, all the elements will be reduced to an equal degree of fineness, if we may so call it, and in calculations may be made use of without any fear of error.

19. The number of elementary parts being thus known which are contained in any proportion, it will be easy to find the ratios between those numbers which are in continued proportion to the first term of the series. Thus, having found the proportion between 1000 and 900,

we know also that of 1000 to 810, and 739; And from 1000 to 800, also 1000 to 640, and to 512; And from 1000 to 700, also 1000 to 490, and to 343; And from 1000 to 600, also 1000 to 360, and to 216; And from 1000 to 500, also 1000 to 250, and to 125.

Corol. Hence arises the precept for squaring, cubing, &c.; also for extracting the square root, cube root, &c. out of the first figures of numbers. For it will be, as the greatest number of the chilid as a denominator, is to the number proposed as numerator, so is this to the square of the fraction, and so is this to the cube.

20. Prop. The proportion of a number to the first, or 1000, being known; if there be two other numbers in the proportion to each other, then the proportion of one of these to 1000 being known, there will also be known the proportion of the other to 1000.

Corol. 1. Hence from the 15 proportions mentioned in prop. 18, will be known 120 others below 1000, to the same 1000.

For so many are the proportions, equal to some one or other of the said 15, that are among the other integer numbers which are less than 1000.

Corol. 2. Hence arises the method of treating the Rule of Three, when 1000 is one of the given terms. For this is effected by adding to, or subtracting from, each other, the measures of the two proportions of 1000 to each of the other two given numbers, according as 1000 is, or is not, the first term in the Rule of Three.

21. Prop. When four numbers are proportional, the first to the second as the third to the fourth, and the proportions of 1000 to each of the three former are known, there will also be known the proportion of 1000 to the fourth number.

Corol. 1. By this means other chilidads are added to the former.

Corol. 2. Hence arises the method of performing the Rule of Three, when 1000 is not one of the terms. Namely, from the sum of the measures of the proportions of 1000 to the second and third, take that of 1000 to the first, and the remainder is the measure of the proportion of 1000 to the fourth term.

Definition. The measure of the proportion between 1000 and any less number, as before described, and expressed by a number, is set opposite to that less number in the chilad, and is called its logarithm, that is, the number (999700.000) indicating the proportion (149) which 1000 bears to that number, to which the logarithm is annexed.

22. Prop. If the first or greatest number be made the radius of a circle, or radix tarsus; every less number considered as the cofine of some arc, has a logarithm greater than the verfed sine of that arc, but less than the difference between the radius and cofant of the arc; except only in the term next after the radius, or greatest term, the logarithm of which by the hypothesis is made equal to the verfed sine.

That is, if CD be made the logarithm of AC, or the measure of the proportion of AC to AD; then the measure of the proportion of AB to AD, that is, the logarithm of AB, will be greater than BD, but less than EF. And this is the same as Napier's first rule in page 44.

23. Prop. The same things being supposed; the sum of the verfed sine and excess of the cofant over the radius, is greater than double the logarithm of the cofine of an arc.

Corol. The logarithm cofine is less than the arithmetical mean between the verfed sine and the excess of the cofant.

Precept 1. Any sine being found in the canon of sines, and its defect below radius to the excess of the cofant above radius; then shall the logarithm of the sine be less than half that sum, but greater than the said defect or covered sine.

Precept 2. The logarithm of the sine being found, you will also find nearly the logarithm of the round or integer number which is next less than your sine with a fraction, by adding that fractional excess to the logarithm of the said sine.

Thus the logarithm of the sine 99970.149 is found to be about 29.854; if now the logarithm of the round number 99970,000 be required, add 149 the fractional part of the sine to its logarithm, observing the point, thus, 29.854.

The sum 30.003

Therefore the logarithm is between 29.850 and 29.855.

The logarithms of the round numbers 99970,000, be required, add 149 the fractional part of the sine to its logarithm, observing the point, thus, 29.854.

24. Prop. Of three equidifferent quantities, the measure for
Let the proportion between the two greater terms, with the measure of the proportion between the two least terms, will constitute a proportion which will be greater than the proportion of the two greater terms, but less than the proportion of the two least.

Thus if $AB, AC, AD$, be three quantities having the equal differences $BC, CD$; and if the measure of the proportion of $AD, AC$ be $cd$, and that of $AC, AB$, be $cd$, then the proportion of $cd$ to $cb$ will be greater than the proportion of $AC$ to $AD$, but less than the proportion of $AB$ to $AC$.

25. Prop. The said proportion between the two measures is less than half the proportion between the extreme terms: that is, the proportion between $bc$, is less than half the proportion between $AB, AD$.

Corol. Since therefore the arithmetical mean divides the proportion into unequal parts, of which the one is greater and the other less than the whole; if it be enquired what proportion is between these proportions, the answer is, that it is a little less than the said half.

An example of finding nearly the limits greater and less, to the measure of any proposed proportion.—It being known that the measure of the proportion between 1000 and 900 is 10536.05, required the measure of the proportion 900 to 800, where the terms 1000, 900, 800, have equal differences. Therefore as 9 to 10, so 10536.05 to 11770.72, which is less than 11778.30, the measure of the proportion 9 to 8.

Again, as the mean proportion between 8 and 10 (which is 8.444719) is to 10, so is 10536.05 to 11779.66, which is greater than the measure of the proportion between 9 and 8.

Axiom. Every number denotes an expressible quantity.

26. Prop. If the 1000 numbers, differing by 1, follow one another in the natural order, and there be taken any two adjacent numbers, as the terms of some proportion; the measure of the proportion will be to the measure of this proportion between the two greatest terms of the chiliad, in a proportion greater than that in which the greatest term 1000 bears to the greater of the two terms first taken, but less than the proportion of 1000 to the least of the said two selected terms.

So of the 1000 numbers taking any two successive terms, as 501 and 500, the logarithm of the former being 69114.92, and of the latter 69314.72, the difference of which is 199.80. Wherefore by the definition, the measure of the proportion between 501 and 500 is 199.80. In like manner, because the logarithm of the greatest term 1000 is 0, and of the next 999 is 100.05, the difference of these logarithms, and the measure of the proportion between 1000 and 999, is 100.05. Couple now the greatest term 1000 with each of the selected terms 501 and 500; couple also the measure 199.80 with the measure 100.05; so shall the proportion between 199.80 and 100.05 be greater than the proportion between 1000 and 501, but less than the proportion between 1000 and 500.

Corol. 1. Any number below the first 1000 being proposed, as also its logarithm; the differences of any logarithms antecedent to that proposed, towards the beginning of the chiliad, are to the first logarithm (viz. that which is assigned to 999) in a greater proportion than 1000 to the number proposed; but of those which follow towards the last logarithm, they are to the same in a less proportion.

Corol. 2. By this means the places of the chiliad may easily be filled up, which have not yet had logarithms adapted to them by the former propositions.

27. Prop. The difference of two logarithms, adapted to two adjacent numbers, is to the difference of these numbers in a proportion greater than 1000 bears to the greater of those numbers, but less than that of 1000 to the less of the two numbers.

This 27th proposition is the same as Napier’s second rule.

28. Prop. Having given two adjacent numbers of the 1000 natural numbers, with their logarithmic indices, or the measures of the proportions which those absolute or round numbers constitute with 1000 the greatest; the increments or differences of these logarithms will be to the logarithm of the small element of the proportion as the secants of the arch whose confines are the two absolute numbers is to the greatest number, or the radius of the circle; so that, however, of the said two secants, the least will have to the radius a less proportion than the proposed difference has to the first of all, but the greater will have a greater proportion, and so also will the mean proportional between the said secants have a greater proportion.

Thus if $BC, CD$ be equal, also $bd$ the logarithm of $AB$, and $ed$ the logarithm of $AC$; then the proportion of $be$ to $ed$ will be greater than the proportion of $AG$ to $AD$, but less than that of $AF$ to $AD$, and also less than that of the mean proportional between $AF$ and $AG$ to $AD$.

Corol. 1. The same obtains also when the two terms differ, not only by the unit of the small element, but by another unit which may be ten fold, a hundred fold, or a thousand fold of that.

Corol. 2. Hence the differences will be obtained sufficiently exact, especially when the absolute numbers are pretty large, by taking the arithmetical mean between two small secants, or (if you will be at the labour) by taking the geometrical mean between two larger secants, and then by continually adding the differences, the logarithms will be produced.

Corol. 3. Precepts. Divide the radius by each term of the assigned proportion, and the arithmetical mean (or still nearer the geometrical mean) between the quotients will be the required increment, which being added to the logarithm of the greater term, will give the logarithm of the less term.
LOGARITHMS.

Example.
Let there be given the logarithm of 100, viz. 230258.514J, to find the logarithm to 669.
Here radius divided by 700 gives 1428571, &c.
and divided by 699 gives 1430672, &c.
The arithmetic mean is 142962 which added to 230258.514J gives the logarithm to 669 33810.4368

Coral. 4. Precept for the logarithms of sines.
The increment between the logarithms of two sines is thus found: find the geometrical means between the coefficients, and divide it by the difference of the sines, the quotient will be the difference of the logarithms.

Example.

\[
\begin{array}{c|c}
\text{dip.} & \text{of 900} \\
\text{1 line} & 34377482 \\
\text{2 line} & 58181712 \\
\end{array}
\]

Appendix. Nearly in the same manner it may be shown that the second differences are in the duplicate proportion of the first, and the third in the duplicate of the second. Thus, for instance, in the beginning of the logarithms, the first difference is 100.0000, viz. equal to the difference of the numbers 100000.0000 and 99999.9999; the second, or difference of the differences, 1000; the third 20. Again, after arriving at the number 50000.0000, the logarithms have a difference 200.0000, which is to the first difference as the number 100000.0000 to 50000.0000; but the second difference is 4000, in which 10000 is contained four times; and the third 328, in which 20 is contained sixteen times. But since, in treating of new matters, we labour under the want of proper words, wherefore, least we should become too obscure, the demonstration is omitted untill.

20. Prop. No number expresses exactly the measure of the proportion between two of the 1000 numbers contained by the foregoing method.

25. Prop. If the measures of all proportions be expressed by numbers or logarithms, all proportions will not have assigned to them their due portion of measure, to the utmost accuracy.

31. Prop. If to the number 1000, the greatest of the chillid, be referred others that are greater than it, and the logarithm of 1000 be made o, the logarithms belonging to those greater numbers will be negative.

This concludes the first or scientific part of the work; the principles of which Kepler applies, in the second part, to the actual construction of the first 1000 logarithms, which is pretty minutely described. This part is intitled A very compendious method of constructing the Chilid of Logarithms, and it is not improperly so called, the method being very concise and easy. The fundamental principles are briefly these: That at the beginning of the logarithms their increments or differences are equal to those of the natural numbers; that the natural numbers may be considered as the decreasing coines of increasing arcs; and that the cosecants of those arcs at the beginning have the same differences as the coines, and therefore the same differences as the logarithms. Then, since the cosecants are the reciprocals of the coines, by these principles and the third corol. to the twenty-eighth proposition, he establishes the fol-
hence multiplying this logarithm of 100 face to face by 2, 3, 4, 5, 6, and 7, there will be 40 logarithms of the numbers in the decuple proportion as under.

Also if the logarithm of a number is taken from the logarithm of 1, there will remain the logarithm of the number. And from the logarithm of 10 there remains the logarithm of the proportion of 10 to 1; which taken from the logarithm of 1, there remains the logarithm of 5. See the margin.

For the logarithms of other prime numbers, he has recourse to those of some of the first or greatest century of numbers before found, viz. of 999, 998, 997, &c. And first taking 960, whose logarithm is 4.082.200; then by adding to this logarithm the logarithm of duplication, there will arise the several logarithms of all these numbers, which are in duplicate proportion continued from 960, namely 480, 240, 120, 60, 30, 15. Hence the logarithm of 30 taken from the logarithm of 10, leaves the logarithm of the proportion of 3 to 1; which taken from the logarithm of 1, leaves the logarithm of 3, viz. 3.8094.3106. And the double of this diminished by the logarithm of 1, gives 4.719, 5.36790 for the logarithm of 9.

Next, from the logarithm of 900, or 9 x 10 x 11, which is 100.05.0331, he finds the logarithm of 1; namely, subtract the sum of the logarithms of 9 and 10 from the sum of the logarithm of 900, and double the logarithm of 1, there remains 4.5096.0106 the logarithm of 11.

Again, from the logarithm of 980, or 2 x 10 x 7 x 7, which is 2020.2711, he finds 4.96184.5228 for the logarithm of 7.

And from 5129.3303 the logarithm of 950 or 5 x 10 x 19, he finds 3.96331.6323 for the logarithm of 19.

In like manner the logarithm to 998 or 4 x 12 x 19, gives the logarithm of 13; to 969 or 3 x 17 x 19, gives the logarithm of 17; to 986 or 2 x 17 x 29, gives the logarithm of 29; to 966 or 6 x 7 x 23, gives the logarithm of 23; and to 939 or 3 x 10 x 31, gives the logarithm of 31.

And so on for all the primes below 100, and for many of the primes in the other centuries up to 900. After which he directs to find the logarithms of all numbers composed of these, by the proper addition and subtraction of their logarithms, namely, in finding the logarithm of the product of two numbers, from the sum of the logarithms of the two factors; taking the logarithm of 1, the remainder is the logarithm of the product. In this way he shows, that the logarithms of all numbers under 500 may be derived, except those of the following 36 numbers, namely 127, 149, 167, 173, 179, 211, 223, 233, 257, 263, 269, 271, 277, 281, 283, 293, 327, 347, 349, 353, 359, 367, 373, 379, 383, 389, 397, 401, 429, 419, 421, 431, 433, 439, 443, 449. Also, besides the composite numbers, between 500 and 900, made up of the products of some numbers whose logarithms have been before determined, there will be 59 primes not composed of them which with the 36 abovementioned make 95 numbers in all not composed of the products of any before them, and the logarithms of which he directs to be derived in this manner; namely, by considering the differences of the logarithms of the numbers interposed among them; then by that method by which were constituted the differences of the logarithms of the smallest 100 numbers in a continued series, we are to proceed here in the discontinued series, that is, by prop. 28th, corol. 3d, and especially by the appendix to it, if it be rightly used, from whence those differences will be very easily supplied.

§ 3. Mr Briggs's Method.

The methods principally made use of by this gentleman were published in Napier's posthumous work. Having supposed 0 to be the logarithm of 1, and 1 with any number of ciphers annexed, suppose 0 to be the logarithm of 10, this number is to be divided ten times by 5, which in a logarithmic number is equivalent to the extraction of the root of the fifth power; by which means he obtains the following numbers, viz. 2 with nine ciphers to it; 4 with eight ciphers; 8 with seven ciphers, 16 with six ciphers; 32 with five ciphers; 64 with four; 128000, 25600, 5120, and 1024. Dividing this last logarithm ten times by 2, we have a geometrical series of ten numbers; the first of which is 512, and the last 1. Thus 20 logarithms are obtained: but the labour of finding the numbers belonging to them is so excessive, that it is surprising how it could be undergone by any body. To obtain those corresponding to the first ten logarithms, the fifth root must be extracted ten times, and the square root as often, to obtain the numbers corresponding to the others. The power from which these extractions is made, must originally be 1, with a number of ciphers annexed. Other logarithms might be formed from these by adding them, and multiplying their corresponding numbers, but as this method, besides its excessive labour, would produce only an antilogarithmic canon like that of Mr Dodson already mentioned, other more easy and proper methods were thought of.

The next was by finding continually geometrical means, first between 10 and 1, and then between 1 and that mean, and so on, taking the arithmetical means between their corresponding logarithms. The operation is also facilitated by various properties of numbers and their logarithms, as that the products and quotients of numbers correspond to the sums and differences of their logarithms; that the powers and roots of numbers answer to the products and quotients of the logarithms by the index of the power or root. Thus having the logarithm of 2, we can have those of 4, 16, 256, &c. by multiplying the logarithms of 2, and squaring the numbers to as great an extent in that series as we please. If we have also that of 3, we can not only have those of 9, 81, 8361, &c. but of 6, 18, 27, and all possible products of the powers of 2 and 3 into one another, or into the numbers themselves. The following property may also be of use, viz. that if the logarithms of any two numbers are given, and each number be raised to the power denoted by the index of the other, the products will be equal. Thus,

\[
\log \frac{1}{2} = \log 1 + \log 2 = \log 1 + \log 2 = \log 1 + \log 2 = \log 1 + \log 2 = \log 1 + \log 2 = \log 1 + \log 2 = \log 1 + \log 2 = \log 1 + \log 2
\]

NAT. num. 1 2 4 8 16 32 64

Let the two numbers be 4 and 16; it is plain, that if
LOGARITHMS.

We raise 4 to the fourth power and 16 to the square, the products will be the same; for 16 \times 16 = 256, and 
4 \times 4 \times 4 \times 4 = 256.

Mr. Briggs depends upon this property, that the logarithm of any number in this scale is less than the number of places or figures contained in that power of that number whose exponent is the logarithm of 10, at least as integral numbers; for Mr. Briggs has shown that they really differ by a fraction. To this Mr. Hutton adds the following; viz. that of any two numbers, as the greater is to the less, so is the velocity of the increment or decrement of the logarithms to the greater; "that is (says he), in our modern notation, as \( X : Y = x : y \); where \( x \) and \( y \) are the fractions of \( X \) and \( Y \).

In the treatise written upon the construction of logarithms by Mr. Briggs himself, he observes, that they may be constructed chiefly by the two methods already mentioned, concerning which he premises several lemmata concerning the powers of numbers and their indices, and how many places of figures are in the products of numbers. He observes, that these products will consist of as many figures as there are in both factors, unless the first figures in each factor be expressed in one figure only, which sometimes happens, and then there will commonly be one figure less in the product than in the two factors. He observes also, that if in any series of geometricals, we take two terms, and raise one to the power denoted by the index of the other, or any number raised to the power denoted by the logarithm of the former, then the product raised to the power denoted by the logarithm of the former. Hence, if one of the numbers be 10, whose logarithm is 1 with any number of cyphers, then any number raised to the power whose index is the logarithm of that number, that is, the logarithm of any number in this scale where 1 is the logarithm of 10, is the index of that power of 10, which is equal to the given number. But the index of any integral power of 10 is one less than the number of places of figures it contains. Thus the figure of 10, or 100, contains three places of figures, which is more by one, than the index of the power 1,000, the cube of 10 containing three figures, which is one less than the index of the power of 10. Hence as the number of places of the powers of 10 are always exactly one more than the indices of those powers, it follows that the places of figures in the powers of any other number which is not an integral power of 10, will not always be exactly one less in number than the indices of the powers. From these two properties is deduced the following rule for finding the logarithms of many prime numbers.

Find the 10th, 100th, 1000th, or any other power of a number, suppose 2, with the number of places of figures in it, then that number of figures shall always exceed the logarithm of 2, although the excess will be constantly less than 1; whence by proceeding to very high powers we will at last be able to obtain the logarithm of the number to great exactness.

Thus, the logarithm of 2, found by other methods, is known to be 0.3010299966669. &c. The tenth power of 2 is 1024, which containing four places of figures, gives 4 for the logarithm of 2, which exceeds it, though not quite by 1. The 20th power of 2, consisting of the 10th power multiplied into itself, by its number of places ought to give the logarithm of 4; and according to the rule already laid down, should contain eight places of figures; but by reason of the cypher which stands in the second place, it is easy to see that it must contain only seven 5, which therefore gives seven for the logarithm of four. The logarithm of 16 is then expressed by the number of places of figures in the product of the 20th power of 2 into itself; and is therefore denominated by 12. That of 256 is denoted by the 50th power of 2, containing 25 places of figures. The logarithm of 2, therefore, having been already expressed by the 10th power of 2, will be again expressed by the 100th power. Adding, therefore, the number of places contained in the 80th power, viz. 23 to 7, the number of places contained in the 20th, we have 30 for the next expression of that logarithm.

On account of the cypher which stands in the second place of one of the factors, however, we must deduct one from the number; and thus we have 29 for the logarithm of 2, which is a considerable approximation. Proceeding in this manner, at the 1000th power of 2, we have 301 for the logarithm of 2; at the 10,000th power we have 3011; at the 100,000th power, 30103; at the 1,000,000th, we have 301030; and at the 10,000,000th power, we obtain 30103000; which is as exact as is commonly expressed in the tables of logarithms; but by proceeding in the same manner we may have it to any degree of exactness we please. Thus, at the 100,000,000 power, we have 301030000; and at the 1,000,000,000, the logarithm is 301029996, true to eight places of figures.

The only difficulty in this method is to find the number of places of figures in the different powers without multiplying them; but this may be determined by only multiplying the first five; or even the first three of the products will be sufficient to determine this; and the logarithms may thus be found with very great facility.

When the logarithms, however, are required to a very great degree of exactness, our author thinks that the method of mean proportions is most eligible. This consists in finding a great number of mean proportions between 1 and the number proposed; that is, first extracting the square root of the number itself, then extracting the root of that root, &c. until the last root shall exceed 1 only by a very small decimal. Finding then the logarithm of this number by methods hereafter to be described, he multiplies it by the index of the power of 2, denoted by the number of extractions of the square root; and the result is the required logarithm of the given number.

In this method, the number of decimal places contained in the last root ought to be double the number of true places required in the logarithm itself, and the first half of them ought to be cyphers; the integer being 1. To find out the first small number and its logarithm, our author begins with 10 and its logarithm 1; continually extracting the root of the former, and bisecting the latter, till he comes to the numbers and then finds, that at the 53rd and 54th roots both natural numbers and logarithms bear the same proportion to each other, viz. that of 2 to 1. Thus,

Numbers.

\[ \begin{array}{cccccccc}
31 & 10 & 3 & 0 & 0 & 0 & 0 & 0 & 0 \\

31 & 10 & 3 & 0 & 0 & 0 & 0 & 0 & 0 \\
31 & 10 & 3 & 0 & 0 & 0 & 0 & 0 & 0 \\
31 & 10 & 3 & 0 & 0 & 0 & 0 & 0 & 0 \\
31 & 10 & 3 & 0 & 0 & 0 & 0 & 0 & 0 \\
31 & 10 & 3 & 0 & 0 & 0 & 0 & 0 & 0 \\
31 & 10 & 3 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{array} \]
LOGARITHMS.

Sect. II.

If now by continual extraction and bisection we find any other small number it will then be, as 12781, &c. to 5551, &c. so is that other small decimal to the correspondent significant figures of its logarithm. To avoid, however, the excessive labour of such long multiplications and divisions, he reduces this ratio to another, the antecedent of which is \( \sqrt{10} \) Thus, as 12781, &c. is to 5551, &c. so is \( \sqrt{10} \) with another unit annexed to a 4th number, which will be the significant figures of the logarithm of the third term. The proportions then will be \( 12781 : 5551 \). \( \sqrt{10} \) is 1, 100, 1000, 10000, &c. 43429, \( \sqrt{10} \) is 2, 16850, 30102, 40546, &c. this last number, with 17 ciphers prefixed, being the logarithm of the one immediately preceding it. Having therefore found by continual extraction any such small decimal as the above, multiply it by 43429, &c. and the product will be the corresponding logarithm of the last root.

Still, as the labour of so many extractions must be intolerably tedious, it became necessary to fall upon some contrivances to shorten such operations; and of these the following is an example.

Let the number of which we seek the logarithm be involved in such an height that the index of the power may be one, with either one or more ciphers next to it. Divide this power then by 1 with as many ciphers annexed as the power has significant figures after the first; or, supposing all the figures after the first to be decimals, the roots are extracted continually from this power, till the decimal becomes sufficiently small, as when the first 15 places are ciphers; then, multiplying the decimal by 43429, &c. we have the logarithm of this last root; which logarithm multiplied by the like power of the number 2, gives the logarithm of the first number of which the extraction was begun. To this logarithm if we prefix 1, 2, 3, &c. according as this number was found by dividing the power by 10, 100, 1000, &c. and lastly, dividing the result by the index of that power, the quotient will be the required logarithm of the given prime number.

Thus to find by this method the logarithm of 2. Raise it first to the 10th power, which is 1024; then cutting off the three places of decimals is the same as dividing by 1000, we have for the logarithm of 1024, 2.01099566, &c. as above. Lastly, dividing by \( \sqrt{10} \), because 1024 is the 10th power of 2, we have the logarithm of 2 itself; viz. 0.30102, &c.

The involving of any number to a very high power is by no means a matter of such difficulty as might at first sight be imagined. A number multiplied by itself produces the square; the square multiplied by itself produces the biquadrate; the biquadrate multiplied by itself gives the eighth power, and the eighth power multiplied by the square produces the tenth. The tenth power multiplied by itself gives the second, and the 20th multiplied by itself gives the 40th. The eighth power divided by the original number gives the seventh, and the 40th power multiplied by the seventh gives the 47th power required.

The differential method of constructing logarithms was likewise invented by our author, and greatly shortens the labour of finding the mean proportions. Mr Briggs, in the course of his calculations, had observed, that these proportions, found by continual extraction of roots, gradually approach nearer and nearer to the halves of the preceding root; and that as many significant figures as there are ciphers before them, agree exactly in this proportion. Substracting therefore each of these decimal parts, which he called \( A \), or the first differences, from half the next preceding one, and by comparing together the remainders or second differences, called \( B \), he found that the succeeding were always nearly equal to of the next preceding ones; then taking the difference between each second difference and of the preceding one, he found that these third differences, called \( C \), were nearly in the continual ratio of 8 to 1; again taking the difference between each \( C \) and of the next preceding, he found that these third differences, called \( D \), were nearly in the continual ratio of 16 to 1; and so on, the 5th \( (E) \), 6th \( (F) \), &c. differences, being nearly in the continual ratio of 32 to 1, of 64 to 1, &c. these plain observations being made they very naturally and clearly suggested to him the notion and method of constructing all the remaining numbers from the differences of a few of the first, found by extracting the roots in the usual way. This will evidently appear from the annexed specimen of a few of the first numbers in the last example for finding the logarithm of 5; where after the 9th number the rest are supposed to be constructed from the preceding differences of each, as here shown in the 10th and 11th. And it is evident that, in proceeding, the trouble will become always less and less; the differences gradually vanishing, till at last only the first differences remain. And that generally each less difference is shorter than the next greater, by as many places as there are ciphers at the beginning of the decimal in the number to be generated from the differences.

1.00775,96.
He then concludes this chapter with an ingenious, but not obvious, method of finding the differences B, C, D, E, &c. belonging to any number, as suppose the 9th, from that number itself, independent of any of the preceding 8th, 7th, 6th, 5th, &c.

\[ B = \frac{1}{4}A^5, \quad C = \frac{1}{4}A^3 \times \frac{1}{4}A^4, \quad D = \frac{1}{4}A^3 \times \frac{1}{4}A^4 + \frac{1}{4}A^5 + \frac{1}{4}A^7, \quad E = \frac{1}{4}A^5 + 7A^6 + 16A^7 + \frac{1}{4}A^9 + 12A^9 + \frac{1}{4}A^9 + \frac{1}{4}A^9 + \frac{1}{4}A^9 \]

Thus in the 9th number of the foregoing example, omitting the ciphers at the beginning of the decimals, we have

\[ A = 1,51164,65999,05672,45908,8 \]

Consequently

\[ A^2 = 1,14253,77215,0318,3569 \]

The logarithms are given in the following table.

\[ 2\frac{1}{4}A^5 = 20,71957 \]

2$\frac{1}{4}A^5 + 7A^6 = 20,72040 = E \]

which agree with the like differences in the foregoing specimen.

\[ \frac{1}{2}A^5 = \frac{1}{8}A^5 + 7A^6 \]

### § 4 Of Curves related to Logarithms.

Several other ingenious methods and improvements are laid down by our author in his treatise upon this subject; but as all these were attended with great labour, mathematicians still continued their efforts to facilitate the work; and it was soon perceived that some curves had properties analogous to logarithms. Edmund Gunter, it has been said, first gave the idea of a curve, whose abscissae are in arithmetical progression, while the corresponding ordinates are in geometrical progression, or whose abscissae are the logarithms of their ordinates; but it is not noticed in any part of his writings. The same curve was afterwards considered
Many other learned men have also treated of this property; particularly Le Seur and Jacquier in their comment on Newton's Principia; Dr John Keil in the elegant little tract on logarithms subjoined to his edition of Euclid's Elements; and Frances Maferes, Esq. curator-baron of the Exchequer, in his ingenious treatise on Trigonometry; in which book the doctrine of logarithms is copiously and learnedly treated, and their analogy to the logarithmic curve, &c. fully displayed. It is indeed rather extraordinary that this curve was not sooner announced to the public; since it rebuts immediately from Baron Napier's manner of conceiving the generation of logarithms, by only supposing the lines which represent the natural numbers to be placed at right angles to that upon which the logarithms are taken. This curve greatly facilitates the conception of logarithms to the imagination, and affords an almost intuitive proof of the important property of their fluxions, or very small increments, viz. that the fluxion of the number is to the fluxion of the logarithm, as the number is to the sub tangent; as also of this property, that, if three numbers be taken very nearly equal, so that their ratios to each other may differ but a little from a ratio of equality; as for example, the logarithm is equal to the modulus of the logarithm, of one and the same number or parts of the asymptote. And so also are the hyperbolic factors; any factor bounded by an arc of the hyperbola and two radii being equal to the quadrilateral space bounded by the same arc, the two ordinates to either asymptote from the extremities of the arc and the part of the asymptote intercepted between them. And although Napier's logarithms are commonly paid to be the same as hyperbolic logarithms, it is not to be understood that hyperbolas exhibit Napier's logarithm's only, but indeed all other possible systems of logarithms whatever. For, like as the right angled hyperbola, the side of whose square inscribed at the vertex is 1, gives us Napier's logarithm; to any other system of logarithms is expressed by the hyperbola whose asymptotes form a certain oblique angle, the side of the rhombus inscribed at the vertex of the hyperbola in this case also being filled 1, the same as the side of the square in the right angled hyperbola. But the areas of these squares and rhombus, and consequent- ly the logarithms of any one and the same number or ratio, will differ according to the line of the angle of the asymptotes. And the area of the square or rhombus, or any inscribed parallelogram, is also the same thing as what was by Cotes called the modulus of the system of logarithms; which modulus will therefore be expressed by the numerical measure of the side of the curve formed by the asymptotes, to the radius 1; as that is the same with the number expressing the area of the said square or rhombus, the side being 1: which is another definition of the modulus to be added to those we before remarked above in treating of the logarithmic curve. And the evident reason of this is, that in the beginning of the generation of these areas from the vertex of the hyperbola, the nascent increment of the abscissa drawn into the altitude 1, is to the increment of the area, as radius is to the line of the angle of the ordinate and abscissa of the asymptotes; and at the beginning of the logarithms, the nascent increment of the natural numbers is to the increment of the logarithms as 1 is to the modulus of the system. Hence we easily discover, that the angle formed by the asymptotes of the hyperbola, exhibiting Briggs's System of Logarithms, will be $25^\circ 44' 25^\frac{1}{4}$, this being the angle whose sine is 0.4342944819, &c. the modulus of this system.

Or indeed any one hyperbola, as has been remarked by Mr Baron Maferes, will express all possible systems of logarithms whatever; namely, if the square or rhombus inscribed at the vertex, or, which is the same thing, any parallelogram inscribed between the asymptotes and the curve at any other point, be expanded by the modulus of the system; or which is the same, by expanding the area, intercepted between two ordinates which are to each other in the ratio of 10 to 1, by the logarithm of that ratio in the proposed system.

As to the first remarks on the analogy between logarithms and the hyperbolic spaces: it having been shown by Gregory St Vincent in his **Quadratura Circuli et Sectionum Coni**, published at Antwerp in 1647, that if any asymptote be divided into parts in geometrical progression, and from the points of division ordinates

---

**Note:** The text provided is a transcription of the logarithmic properties and their analogy to the hyperbola as discussed in a historical mathematical text. The text explains the construction of logarithms and their relationship to other mathematical curves and systems, including hyperbolic ones. It highlights the work of mathematicians like John Keil and Henry Briggs, and references to works such as *Quadratura Circuli et Sectionum Coni*. The text is rich in geometric and algebraic detail, discussing logarithms as a system that relates to hyperbolas, and how this relationship can be used to understand the properties of logarithms and their extension to other systems of logarithms.

</table>

This is purely arithmetical, and is founded upon the idea of logarithms already mentioned; *viz.* that they are the measures of ratios, and express the number of *ratios* contained in any ratio into which it may be divided. Having shown then that the logarithms or numbers of small ratios, or measures of ratios, may be all properly represented by numbers; and that of 1, or the ratio of equality, the logarithm or measure being always 0, the logarithm of 10, or the measure of the ratio of 10 to 1, is most conveniently represented by 1 with any number of cyphers; he then proceeds to show how the measures of all other ratios may be found from this last supposition. And he explains the principles by the two following examples.

First, to find the logarithm of 100·5; or to find how many *ratios* are contained in the ratio of 100·5 to 1, the number of *ratios* in the decuple ratio, or ratio of 10 to 1, being 10,000,000.

The given ratio 100·5 to 1 he first divides into its parts; namely, 100·5 to 100, 100 to 10, and 10 to 1; the last two of which being decimals, it follows that the character 2 will be 2, and it only remains to find how many parts of the next decuple belong to the first ratio of 100·5 to 100. Now if each term of this ratio be multiplied by itself, the products will be in the duplicate ratio of the first terms, or this last ratio will contain a double number of parts; and if these be multiplied by the first terms again, the ratio of the last products will contain three times the number of parts, and so on; the number of times the first parts contained in the ratio of any like powers of the first terms, being always denoted by the exponent of the power. If therefore the first terms 100·5 and 100 be continually multiplied till the same powers of them have to each other a ratio whole measure is known; as suppose the decuple ratio 10 to 1, whose measure is 10,000,000; then the exponent of that power shows what multiple this measure 10,000,000 of the decuple ratio is of the required measure of the first ratio 100·5 to 100; and consequently dividing 10,000,000 by that exponent, the quotient is the measure of the ratio 100·5 to 100 sought. The operation for finding this he sets down as here follows: where the several multiplications are all performed in the contracted way by inverting the figures of the multiplier, and retaining only the first number of decimals in each product.

\[
\begin{array}{cccc}
100,5000 & - & - & 1 \\
5001 & - & - & 1 \\
1005000 & - & - & 1 \\
5025 & - & - & 1 \\
1010025 & - & - & 2 \\
5200101 & - & - & 2 \\
1010025 & - & - & 2 \\
10100 & - & - & 20 \\
20 & - & - & 5 \\
1020150 & - & - & 4 \\
9510301 & - & - & 4 \\
1020150 & - & - & 4 \\
20403 & - & - & 102 \\
51 & - & - & 1040706 \\
6070401 & - & - & 8 \\
1083068 & - & - & 16 \\
8603801 & - & - & 16 \\
1173035 & - & - & 32 \\
5303711 & - & - & 32 \\
1376011 & - & - & 64 \\
1106731 & - & - & 64 \\
1893406 & - & - & 128 \\
6043981 & - & - & 128 \\
3784085 & - & - & 256 \\
5894853 & - & - & 256 \\
12852116 & - & - & 512 \\
\end{array}
\]

This power being greater than the decuple of the like power of 100, which must always be 1 with cyphers refuse therefore the 256th power, and multiply it not by itself but by the next before it, *viz.* by the 128th, thus,

\[
\begin{array}{cccc}
35384985 & - & - & 256 \\
6043981 & - & - & 128 \\
6787831 & - & - & 384 \\
1106731 & - & - & 64 \\
9340130 & - & - & 448 \\
5303711 & - & - & 32 \\
10956299 & - & - & 480 \\
\end{array}
\]

This power again exceeding the same power of 100 more than 10 times, he therefore draws the same 448th not into the 32d but the next preceding, thus,

\[
\begin{array}{cccc}
9340130 & - & - & 448 \\
8603801 & - & - & 16 \\
10115994 & - & - & 464 \\
\end{array}
\]

This being again too much, instead of the 16th draw it into the 8th or next preceding, thus,

\[
\begin{array}{cccc}
9340130 & - & - & 448 \\
6070401 & - & - & 8 \\
9720329 & - & - & 456 \\
6510201 & - & - & 4 \\
9916193 & - & - & 460 \\
5200101 & - & - & 2 \\
60015603 & - & - & 462 \\
\end{array}
\]

Which
LOGARITHMS.

The power again exceeds the limit: therefore draw the 450th into the 1st, thus:

<table>
<thead>
<tr>
<th>450</th>
<th>460</th>
</tr>
</thead>
<tbody>
<tr>
<td>9916193</td>
<td>9916193</td>
</tr>
<tr>
<td>1000</td>
<td>1</td>
</tr>
<tr>
<td>9965774</td>
<td>961</td>
</tr>
</tbody>
</table>

Since, therefore, the 452d power of 100.5 is greater, and the 461st power is less, than the duplicate of the same power of 100; he finds that the ratio of 100.5 to 100 is contained in the duplicate more than 461 times, but less than 462 times. Again, since

<table>
<thead>
<tr>
<th>460</th>
<th>461</th>
</tr>
</thead>
<tbody>
<tr>
<td>9916193</td>
<td>961</td>
</tr>
<tr>
<td>10000000</td>
<td>10000000</td>
</tr>
</tbody>
</table>

the difference between the next self and greater, 10000000, exceeds the next self 9965774, which will be easily and accurately found by the Golden Rule, thus:

The next power is 10000000, and the next less 9965774, the difference is 34229, then:

As 49829 the diff. between the next less and greater, 10000000, 34229 is the difference between the first and second selfs. Hence the difference is 49829, and it is equal to 34229.

Two observations are then added, calculated to generalize the consideration of ratios, their magnitude and affections. It is here remarked, that he considers the magnitude of the ratio between two quantities as the same, whether the antecedent be the greater or the less of the two terms; or the magnitude of the ratio of 8 to 5 is the same as of 5 to 8; that is, by the magnitude of the ratio of either to the other is meant the number of baces which will evidence the same whether the greater or less be the antecedent. And he further remarks, that of different ratios, when we divide the greater term of each ratio by the less, that ratio is of the greater mafs or magnitude which produces the greater quotient, et vice versa; although those quotients are not proportional to the masses or magnitudes of the ratios. But when he considers the ratio of a greater term to a less, or of a less to a greater, that is to say, the ratio of greater or less inequality, as abstracted from the magnitude of the ratio, he distinguishes it by the word affection, as much as to say, greater or less affection, something in the manner of positive and negative quantities, or such as are affected with the signs + and —. . . . . The remainder of this work he delivers in several propositions, as follows:

Prop. 1. In subtraction from each other two quantities of the same affection, to wit, both positive, or both negative; if the remainder be of the same affection with the two given, then is the quantity subtracted the less of the two, or expressed by the less number; but if the contrary, it is the greater.

Prop. 2. In any continued ratios, as

\[ \frac{a}{a+b}, \frac{a+b}{a+2b}, \frac{a+2b}{a+3b}, \ldots \]

(by which is meant the ratios of \( a \) to \( a+b \), \( a+b \) to \( a+2b \), \( a+2b \) to \( a+3b \), &c.) of equidifferent terms, the antecedent of each ratio being equal to the consequent of the next preceding one, and proceeding from less terms to greater; the measure of each ratio will be expressed by a greater quantity than that of the next following; and the same through all their orders of differences, namely, the 1st, 2d, 3d, &c. differences; but the contrary, when the terms of the ratios decrease from greater to less.

Prop. 3. In any continued ratios of equidifferent terms, if the 1st or least be \( a \), the difference between the 1st and 2d \( b \), and \( c \), \( d \), &c. the respective first term of their 2d, 3d, 4th, &c. differences; then shall the several quantities themselves be as in the annexed scheme; where each term is composed of the first term together with as many of the differences as it is distant from the first term, and to those differences joining, for coefficients, the numbers in the sloping or oblique lines contained in the annexed table of figurate numbers; in the same manner, he observes, as the same figurate numbers complete the powers raised from a binomial root, as had long before been taught by others. He also remarks, that this rule not only gives any one term, but also the sum of any number of successive terms from the beginning, making the 2d coefficient the 1st, the 3d, the 2d, and so on; thus, the sum of the first 5 terms is

\[ 5a + 10d + 10c + 5d + e \]

In the 4th prop. it is shown, that if the terms decrease, proceeding from the greater to the less, the same theorems hold good, by only changing the sign of every other term, as below:

<table>
<thead>
<tr>
<th>1st term</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>2d</td>
<td>a — b</td>
</tr>
<tr>
<td>3d</td>
<td>a — 2b + c</td>
</tr>
<tr>
<td>4th</td>
<td>a — 3b + 3c — d</td>
</tr>
<tr>
<td>5th</td>
<td>a — 4b + 6c — 4d + e</td>
</tr>
</tbody>
</table>

&c.

Prop. 6th and 7th, treat of the approximate multiplication and division of ratios, or, which is the same thing, the finding nearly any powers or any roots of a given fraction, in an easy manner. The theorem for
to the 1st quotient, to the sum add the 2nd quotient, and so on, always taking the next quotient to the last sum, the several sums will be the respective logarithms of the numbers in the series, 101, 102, 103, 104, &c.

The next, or prop. 10th, shows that of two pair of continuous ratios, whose terms have equal differences, the difference of the measures of the first two ratios is to the difference of the measures of the other two, as the square of the common term in the two latter is to that in the former, nearly. Thus, in the four ratios

$$\frac{a}{b}, \frac{a+b}{b}, \frac{a+2b}{b}, \frac{a+4b}{b}$$

the mean of the latter is $$\frac{3a+b}{2}$$, and that of the former is $$\frac{a+2b}{2}$$; the difference of the square of the former is therefore $$\frac{(a+2b)^2}{4} - \frac{(3a+b)^2}{4} = \frac{-a^2 + 8ab + 15b^2}{4}$$.

It is shown, that the mean between the ratios of the terms of the square of the logarithms of all the powers of numbers, and of the square of the logarithms of all the ratios, is equal to the logarithm of 10000, and 02 may be respectively equal to 1000000, 9999975, 9999975, &c. and from hence it is shown, how to construct all those powers by the continual addition of their differences, as had been long before more fully explained by Briggs.

In the next, or 11th prop. the author explains his compendium of method of raising the tables of logarithms by addition only, from the properties contained in the 8th, 9th, and 12th propositions. For this purpose he makes use of the quantity $$\frac{a}{b+c}$$, which by division he resolves into the infinite series

$$\frac{a}{b+c} = \frac{a}{b} + \frac{ac}{b^2} + \frac{a^2c}{b^3} + \frac{a^3c}{b^4} + \cdots$$

(&c. in finis.) Puting then $$a = 100$$ the arithmetical mean between the terms of the ratio $$\frac{100}{x^2}$$, &c. 1000000, and $$x$$ successively equal to 0.5, 1.5, 2.5, &c. that to 1.5 may be respectively equal to 9999975, 9999975, 9999975, &c. the corresponding means between the terms of the ratios $$\frac{100}{x^2}$$, 9999975, 9999975, &c. It is evident that $$\frac{a}{b+c}$$ will be the quotient of the 2d term divided by the first in the proportions mentioned in the 8th and 9th propositions; and when each of these quotients are found, it remains then only to multiply them by the constant 3d term 43429, or rather 43429, of the proportion, to produce the logarithms of the ratios 9999975, 9999975, 9999975, &c. till 10000; and then adding these continually to 4 the logarithm of 10000 the least number, or subtracting them from 5 the logarithm of the highest term 10000, there will result the logarithms of all the absolute numbers from 10000 to 100000. Now when $$e = 0.5$$, then

$$\frac{a}{b} = 0.001, \frac{ac}{b^2} = 0000000005, \frac{a^2c}{b^3} = 0000000000000025, \frac{a^3c}{b^4} = 00000000000000125,$$

&c.; therefore $$\frac{a}{b+c} = \frac{a}{b} + \frac{ac}{b^2} + \frac{a^2c}{b^3} + \cdots$$, &c. is $$= 000000000000002500500125$$,

In like manner, if $$e = 1.5$$, then $$\frac{a}{b+c}$$ will be $$= 00000000002500500125$$,

and if $$e = 2.5$$, then $$\frac{a}{b+c}$$ will be $$= 000000000000002500500125$$,

&c.
§ 6. 

Gregory's Method.

This is founded upon an analogy between a scale of logarithmic tangents and Wright's proportion of the nautical meridian line consisting of the sums of the sines. It is not known by whom this discovery was made; but, about 1645, it was published by Mr Henry Bond, who mentions this property in Norwood's Epitome of Navigation. The mathematical demonstration of it was first investigated by Mercator, who, with a view to make some advantage of his discovery, offered, in the Philosophical Transactions for June 4th 1666, to lay a wager with any one concerning it; but this proposal not being accepted, the demonstration was not published. Other mathematicians, however, soon found out the mystery; and in two years after, Dr Gregory published a demonstration, and from this and other similar propositions he showed a method of computing the logarithmic sines and tangents by means of an infinite series. Several of these were invented by him, and the method of applying them laid down by himself and others: but Mr Hutton thinks that a shorter and better method than any they proposed might have been found by computing, by means of the series, only a few logarithms of small ratios, in which the terms of the series would have decreased by the powers of 10 or some greater number, the numerators of all the terms being unity, and their denominators the powers of 10 or some greater number, and then employing these few logarithms, to compute, to the finding of the logarithms of other and greater ratios by the easy operations of mere addition and subtraction. This might have been done for the logs. of the ratios of the first ten numbers, 2, 3, 4, 5, 6, 7, 8, 9, 10, and 11, to 1, in the following manner, communicated by Mr Baron Maseres.—In the first place the logarithm of the ratio of 10 to 9, or of 1 to 10, or of 1 to 1 — \( 10^{-1} \), is equal to the series 

\[
\frac{1}{2} + \frac{1}{2} \times 10 + \frac{1}{2} \times 100 + \frac{1}{2} \times 1000 + \frac{1}{2} \times 10000 \frac{1}{2} \times 10000, \frac{1}{2} \times 100000 \text{ &c.}
\]

In like manner are easily found the logarithms of the ratios of 11 to 10, and then by the same series those of 121 to 120, and of 81 to 80, and of 2401 to 2400, in all which cases the series would converge still faster than in the two first cases. We may then proceed by mere addition and subtraction of logarithms, as follows.

<table>
<thead>
<tr>
<th>Log. ( 10^{-1} ) to ( 10^{-2} )</th>
<th>Log. ( 10^{-2} ) to ( 10^{-3} )</th>
<th>Log. ( 10^{-3} ) to ( 10^{-4} )</th>
<th>Log. ( 10^{-4} ) to ( 10^{-5} )</th>
<th>Log. ( 10^{-5} ) to ( 10^{-6} )</th>
<th>Log. ( 10^{-6} ) to ( 10^{-7} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 10^{-1} )</td>
<td>( 10^{-2} )</td>
<td>( 10^{-3} )</td>
<td>( 10^{-4} )</td>
<td>( 10^{-5} )</td>
<td>( 10^{-6} )</td>
</tr>
</tbody>
</table>

Having calculated the logarithms of the numbers from 100000 to 1000000, only 24 chiads are to be computed. Neither indeed are all of these to be calculated from the foregoing series for \( \frac{1}{b-c} \) but only a few of them in that way, and the rest by the proportion in the 8th proposition. Thus, having computed the logarithms of 10003 and 10003, omitting 10003 as being divisible by 3, estimate the logarithms of 10033 and 10043, which are the 50th numbers from 10003 and 10003; and again, omitting 10053, a multiple of 3, find the logarithms of 10063 and 10073. Then by prop. 3.
Having thus got the logarithm of the ratio of 2 to 1, or, in common language, the logarithm of 2, the logarithms of all sorts of even numbers may be derived.

Thus we have got the logarithms of 2, 3, 4, 5, 6, 7, 8, 9, 10, and 11. And this is upon the whole, perhaps, the best method of computing logarithms that can be taken. This method of computing logarithms is very nearly the same with that of Sir Isaac Newton in his second letter to Mr. Oldenburg, dated October 1676.

§ 7. Construction of Logarithms by Fluxions.

From the definition and description of logarithms given by Napier, and of which we have already taken notice, it appears that the fluxion of his, or the hyperbolic logarithm of any number, is a fourth proportional to that number, its logarithm and unity; or, which is the same, that it is equal to the fluxion of the number divided by the number: For the description shows that \( \frac{z_1}{z_2} = \frac{n}{1} \) is the fluxion of \( z_1z_2 \), which therefore is \( \frac{z_1}{z_2} \); but \( z_2 \) is also equal to the fluxion of the logarithm \( A \), &c. by the description; therefore the fluxion of the logarithm is equal to \( \frac{z_1}{z_2} \), the fluxion of the quantity divided by the quantity itself. The same thing appears again at art. 2, of that little piece in the appendix to his Contrafacticia Logarithmorum, intitled Habitudines Logarithmorum et sursum naturalium numerorum inscientia; where he observes, that as any greater quantity is to a less, so is the velocity of the increment or decrement of the logarithms at the place of the less quantity to that at the greater. Now this velocity of the increment or decrement of the logarithms being the same thing as their fluxions, that proportion is this \( x : a : \text{flux. log. } a : \text{flux. log. } x \); hence if \( a \) be \( z_2 \), as at the beginning of the table of numbers, where the fluxion of the logs. is the index or characteristic of \( e \), which is also one in Napier's or the hyperbolic logarithms, and 43429, &c., in Briggs's, the same proportion becomes \( x : z_2 : e : \text{flux. log. } x \); but the constant fluxion of the numbers is also \( z_2 \), and therefore that proportion is also this \( x : z_2 : e : \frac{z_2}{x} = \text{the fluxion of the logarithm of } x \) : and in the hyperbolic logarithms, where \( e \) is \( z_1 \), it becomes \( \frac{z_2}{x} = \text{the fluxion of Napier's or the hyperbolic logarithm of } x \). This same property has also been noticed, by many other authors, since Napier's time. And the same or a similar property is evidently true in all the systems of logarithms whatever, namely, that the modulus of the system is to any number as the fluxion of its logarithm is to the fluxion of the number.

Now from this property, by means of the doctrine of fluxions, are derived other ways for making logarithms, which have been illustrated by many writers on this branch; as Craig, Jo. Bernoulli, and almost all the writers on fluxions. And this method chiefly consists in expanding the reciprocal of the given quantity in an infinite series, then multiplying each term by the fluxion of the said quantity, and lastly taking the flunctus of the terms; by which there arises an infinite series of terms for the logarithm sought. So, to find the logarithm of any number \( N \), put any compound quantity for \( N \), as suppose \( x \); then the fluxion of the log. or \( \frac{N}{N - x} \) being

\[
\frac{x}{N} + \frac{x^2}{2N^2} + \frac{x^3}{3N^3} + \frac{x^4}{4N^4} + \cdots
\]

the fluents give log. of \( N \) or log. of \( N + x \) = \( \frac{x}{n} + \frac{x^2}{2n^2} + \frac{x^3}{3n^3} + \frac{x^4}{4n^4} + \cdots \). And writing \( -x \) for \( x \) gives log.

\[
\frac{n-x}{n} = \frac{x}{n} + \frac{x^2}{2n^2} + \frac{x^3}{3n^3} + \frac{x^4}{4n^4} + \cdots
\]

Also, because

\[
\frac{n-x}{n} = \frac{x}{n} + \frac{x^2}{2n^2} + \frac{x^3}{3n^3} + \frac{x^4}{4n^4} + \cdots
\]

we have log. \( \frac{n-x}{n} = - \log. \frac{x}{n} \), &c. and log. \( \frac{n-x}{n} = - \log. \frac{x}{n} + \frac{x^2}{2n^2} + \frac{x^3}{3n^3} + \frac{x^4}{4n^4} + \cdots \). And by adding and subtracting any of these series to or from one another, and multiplying or dividing their corresponding numbers, various other series for logarithms may be found, converging much quicker than these do.

In like manner, by assuming quantities otherwise compounded for the value of \( N \), various other forms of logarithmic series may be found by the same means.

§ 8. Mr. Long's Method.

This method was published in the 339th number of the Philosophical Transactions; and is performed by means of a small table containing eight classes of logarithms, as follows.
LOGARITHMS.

</tbody>
</table>

Here, because the logarithms in each class are the continual multiples 1, 2, 3, &c. of the lowest, it is evident that the natural numbers are as many equal sides of geometrical proportionals, the lowest being the common ratio, or the ascending numbers are the 1, 2, 3, &c. powers of the lowest, as expressed by the figures 1, 2, 3, &c. of their corresponding logarithms. Also the last number in the first, second, third, &c. class, is the 10th, 100th, 1000th, &c. root of 10; and any number in any class is the 10th power of the corresponding number in the next following class.

To find the logarithm of any number, as suppose of 2000, by this table: Look in the first class for the number next less than the first figure 2, and it is 1.9952b2315, against which is 3 for the first figure of the logarithm sought. Again, dividing 2, the number proposed, by 1.995262315, the number found in the table, the quotient is 1.002374467; which being looked for in the second class of the table, and finding neither its equal nor a less, 0 is therefore to be taken for the second figure of the logarithm; and the same quotient 1.002374467, being looked for in the third class, the next less is there found to be 1.002305238; against which is 1 for the third figure of the logarithm; and dividing the quotient 1.002305238 by the said next less number 1.002305238, the new quotient is 1.000069070; which being sought in the fourth class gives 0, but sought in the fifth class gives 2, which are the fourth and fifth figures of the logarithm sought: again, dividing the last quotient by 1.000040533, the next less number in the table, the quotient is 1.000023015, which gives 9 in the 6th class for the 6th figure of the logarithm sought: and again dividing the last quotient by 1.000023015, the next less number, the quotient is 1.000002197, the next less than which in the 7th class gives 9 for the 7th figure of the logarithm: and dividing the last quotient by 1.000002197, the quotient is 1.0000000219, which gives 9 in the 8th class for the 8th figure of the logarithm: and again the last quotient 1.0000000219 being divided by 1.000000207 the next less, the quotient 1.000000012 gives 5 in the same 8th class, when one figure is cut off, for the 9th figure of the logarithm sought. All which figures collected together give 330102995 for Briggs's logarithm of 2000, the index 3 being supplied; which logarithm is true in the last figure.

To find the number answering to any given logarithm, as suppose to 330102995; omitting the characteristic, against the other figures 30, 6, 3, 0, 9, 0, as in the first column in the margin, are the several numbers as in the second column, found from their respective 1st, 2d, 3d, &c. classes: the effective numbers of which multiplied continually together, the last product is 2000000001966, which, because the characteristic is three, gives 2000000001966 or 2000 only for the required number answering to the given logarithm.

§ 9. Mr Hutton's Practical Rule for the Construction of Logarithms.

The methods laid down in the above sections are abundantly sufficient to shew the various principles upon which logarithms may be constructed; though there are still a variety of others which our limits will not admit of our inferring: The following rule is added from Mr Hutton's Treatise on the subject, for the sake of those who do not choose to enter deeply into these investigations.

Call z the sum of any number whose logarithm is sought, and the number next less by unity; divide .685886968, &c. (or 2-2.3025, &c.) by z, and reserve the quotient; divide the reserved quotient by the square of z, and reserve this quotient; divide this last quotient also by the square of z, and again reserve this quotient; and thus proceed continually, dividing this last quotient by the square of z as long as division can be made. Then write these quotients orderly under one another, the first uppermost, and divide them respectively by the uneven numbers 1, 3, 5, 7, 9, 11, &c. as long as division can be made; that is, divide the 1st reserved quotient by 1, the 2d by 3, the 3d by 5, the 4th by 7, &c. Add all these last quotients together, and the sum will be the logarithm of \(\frac{1}{z}\); and therefore to this logarithm add also the logarithm...
LOGARITHMS.

**Ex. 7.** Because $r = 5$, therefore
from L. 10: $\log_{10} 100000000$ gives L. 7: $0.00000000$

**Ex. 8.** Because $12 = 3 \times 4$, therefore
to L. 3: $0.47712155$
add L. 4: $-0.02059999$
gives L. 12: $0.477121246$

And thus by computing, by the general rule, the logarithms of the other prime numbers 7, 11, 13, 17, 19, 23, &c. and then using composition and division, we may easily find as many logarithms as we please, or may speedily examine any logarithm in the table.

§ 10. Mr. Thomas Aitkin of Balifhamon's Method.

In any series of numbers in a geometrical progression, beginning from unity, as in the margin, the series is composed of a set of continued proportionals, of which the member standing nearest to unity is the common ratio of the proportion. If over or under these members is placed, as in the example, of numbers in an arithmetical progression, beginning with nought, and whose common difference is unity, the members of this series are called indexes, for they serve to show how many successive multiplications have been made with the common rate to produce that member of the geometrical progression over which each of these indexes does severally stand.

This theory may be considered in another light: If the square root of 10 (that is of the common rate) is found, it is a mean proportional between 1 and 10, and becomes a new common rate for a new set of continued proportionals, as in the margin. And if the $\sqrt{10}$ is 1.414, then using composition and division, the sum of these indexes will become the index of their product; and conversely, if any of them is divided by any other, the difference of their indexes will be found to be the index of the quotient. This theory is indefinite; and repeated extractions may be made with any proposed number of decimals, and bisection made of the corresponding indexes, until one has no more number to work with; and each of the mean proportionals thus found between 1 and 10, will be found a member of every new geometrical progression formed by every smaller root, and consequently all the roots thus found, together with their corresponding indexes, have, in cases of multiplication or division, the same connection as has been just described.

Let those successive roots be found, and noted in the form of a table, and, in another column, let the corresponding indexes found by these directions be regularly
LOGARITHMS.

Sect. II.

LOGARITHMS.

Construc-
tion of Log-
arithms.

Sec. 2. The roots are composed of natural numbers, and are generally known by the denomination of logarithms; the roots themselves may be called natural numbers.

These roots are composed of natural numbers, and are generally known by the denomination of logarithms; the roots themselves may be called natural numbers.

Thus knowing that 1.0000025175, or such like, is the logm. of the last quotient, one may have that of 2, if he will but call to mind the following circumstances.

In every case of division, if he has logarithms of quotient and divisor, he has also that of the dividend, by adding the two first together: if he has the logarithm of the dividend, and that of the divisor or quotient, he may find that of the other; for he has only to subtract what he knows from the logarithm of the dividend, the remainder is what he wants: and lastly, that in every division he made, he took one number from the table of roots whose logarithm is known, being noted in the table, and which he made use of as his direction either as a dividend or a divisor: From these circumstances, one may, by the help of the logarithm just found, discover the logarithm of that number of the last division, whether it be dividend or divisor, which was the quotient of the preceding division; and thus, tracing his own work backwards by his notes from quotient to quotient, he never so few or ever so many, he will come at last by addition and subtraction to the logarithm of the proposed number.

By this method, the logarithm of any number within the compass of the table of roots may be found: if a greater is proposed, suppose 9495, it must be made 9495, and its logarithm found; then it must be reduced to the proposed form, and have a proper index noted before the decimals just found. How do this is too well known to have occasion to mention it here.

The reason for finding the logarithm of the last quotient by the common proportion is this: He who has made a table of roots, will find, by inspection only, that as initial noughts come into the decimal parts of the roots, the significant figures just immediately following them do assume the form of a geometrical progression, descending, whose common rate or divisor is two, as is just the case with the whole of the decimals of the corresponding logarithms; and that the number of the significant figures ended with this property is generally equal to that of the initial noughts: so far as this, and no farther, the common proportion will hold between the significant figures of the decimals in the roots and the same number of places in the logarithms; and for this reason it was needful to continue the successive divisions till a quotient was found so circumstanced, that its logarithm could be found by the proportion.

The same gentleman hath also favoured us with the following new method

Of extracting Roots of Fractions by Logarithms.

The easiest way to explain this, is first to give an example of involving such numbers.

\[ \log_{10} \frac{7}{3} = 9495 \quad \text{the logarithm of the fraction given} \]

\[ 7 \text{ the power to which it is to be raised} \]

\[ 19.10720969648 \text{ the logarithm of the answer.} \]

This differs from the like work in whole numbers only in this, that, in multiplying the decimals, one has at last 2 to be carried from them to the whole numbers; this is to be considered as + 2, then \(-3\times7=-21\), and \(-21+3=-19\) to be noted in the index of the answer. Extraction of the roots is only the converse of this. Suppose \(-19.10720969648\) given, to find that root whose exponent number is 7. As 7 is the exponent number here, one may in his mind multiply it by 2, as in common division; but the product 14 being less than 19, must be rejected; then he may try it with 3 this yields 21 for a product. This must be noted with a negative sign for the index of the new logarithm. Then, on comparing 19 with 21, the difference is
LOGARITHMS.

Sect. II.

Classification of the Table.

2. This shall be carried as 10 to the decimals, and
one shall from that carry on the division of the dec-
cimals with 7 for a divisor, as is usually done in other
cases.

Another Example.

Suppose \(-1.4771212545 \) given, to extract the root of its 5th power.

\[-1.895432109 \text{ the logarithm of the root.} \]

For 5, the exponent of the root \(x^t \) is greater than the
index of the given logarithm, and 4 is the remain-
der. Then \(-1 \) becomes the index of the logarithm
of the root, and \(4 \) the overplus, to be carried as
40 to the decimals; and from that, division is to be made
with 5 as a divisor for the rest of the work.

Sect. III. Explanation and Use of the Table, with a
general Account of the various Sciences to which Lo-

garithms may be applied.

§ 1. To find by the table the logarithm of any number.

If the number be under 100, it is easily found in
the first division at the head of the first page; if it be
between 100 and 1000, over against the number in the
first column of the following pages, in the next
column under \( \log \) will be found the logarithm required.

If the number be between 1000 and 10000, the first
three figures of the number are to be found in the col-
umn marked \(N^0\) and the fourth figure at the top, and
in the column under it, linearly against the first three
figures, will be found the logarithm required, changing
the index 2 into 3. The column marked \(D\) and
showing the common difference by which each of these
columns increases, serves to find the logarithms of
numbers beyond 10000.

Thus,

To find the logarithm for a number greater than any in
the common canon, but less than 10000000;—Cut off four
figures on the left of the given number, and seek the
logarithm in the table; add as many units to the in-
dex as there are figures remaining on the right; sub-
tract the logarithm found from the next following it in
the table: then, as the difference of numbers in the
index is to the tabular distance of the logarithms
answering to them, so are the remaining figures of the
given number to the logarithmic difference; which
if it be added to the logarithm before found, the sum
will be the logarithm required. Suppose \(v\), gr. \(7^2\), the
logarithm of the number 92375 required. Cut off the
four figures 9237, and to the characteristic of the
logarithm corresponding to them, add an unit; then,

From the logarithm of the num.

\[9237 = 0.965578 \]

Subtract logarithm. num. \(-9237 = 0.965531 \]

Remains tabular difference 47

Then \(10:47:5:23 \)

Now to the logarithm \(-4.965531 \)

Add the difference found \(-4.965554 \)

Or more briefly; find the logarithm of the first four
figures as before, then multiply the common differ-
ence which stands against it by the remaining figures
of the given number; from the product, cut off as
many figures at the right hand as you multiplied by,
and add the remainder to the logarithm before found,
fitting it with a proper index. Thus \(47 \times 5 = 235 \); cut
off 5 and add 23.

To find the logarithm of a fraction.—Subtract the
logarithm of the numerator from that of the denomi-

ator, and to the remainder prefix the sign of sub-
traction. Thus suppose it required to find the loga-

rithm of the fraction \(\frac{5}{4} \)

\[ \text{Logarithm of } 7 = 0.845098 \]

\[ \text{Logarithm of } 3 = 0.477121 \]

\[ \text{Logarithm of } \frac{3}{4} = 0.367977 \]

The reason of the rule is, that a fraction being the
quotient of the numerator divided by the denominator,
its logarithm must be the difference of the logarithms
of those two; so that the numerator being subtrac-
ted from the denominator, the difference becomes
negative. Stifelius observed, that the logarithms of a
proper fraction must always be negative, if that of
unity be 0; which is evident, a fraction being less
than one.

Or, the logarithm of the denominator, though
greater than that of the numerator, as in the case of
a proper fraction, may be subtracted from it, regard-
being had to the sign of the index, which alone in
that case is negative. Thus,

\[ \text{Log. of } 3 = 0.477121 \]

\[ \text{Log. of } 7 = 0.845098 \]

\[ \text{Log. of } \frac{4}{7} = 1.632013 \]

which produces the

same effect in any operation as that before hand, viz.;
\(-0.367977\), this being to be subtracted, and the
other to be added.

Or, again, the fraction may be reduced to a deci-
amal, and its logarithm found, which differs from
that of a whole number only in the index, which is to
be negative.

For an improper fraction \(v\), gr. \(\frac{5}{4}\), its numerator
being greater than its denominator, its logarithm is had
by subtracting the logarithm of the latter from that
of the former.

The logarithm of \(\frac{5}{4} = 0.954245 \)

\[ \text{Logarithm of } \frac{5}{2} = 0.6989700 \]

In the same manner may a logarithm of a mixt
number, as \(\frac{3}{2}\), be found, if it being first reduced into
an improper fraction \(\frac{5}{4}\).

Or, this improper fraction may be reduced to a mixed
number, whose logarithm must be found as if it were
wholly integral, and its index taken according to the
integral part. We shall here observe, that the loga-

rithms of whole numbers are added, subtracted, &c.,
according to the rules of these operations in decimal
arithmetic; but with regard to the management of
logarithms with negative indices, the same rules are
to be observed as those given in algebra for like and
unlike signs.

In addition, all the figures except the index, are
reckoned positive, and therefore the figure to be car-
ried to the index from the other part of the logarithm
takes away so much from the negative index. Thus
\(1.86833256 + 3.898972 = 5.762298 \). In subtraction,
if either one or both of the logarithms have negative
indices, you must change the sign of the index of the
LOGARITHMS.

To find the number corresponding to a negative logarithm.

To find the number corresponding to a negative logarithm. Add to the logarithm the last logarithm of the table, or that of the number 10000; i.e., subtract the first from the second, and find the number corresponding to the remainder; this will be the numerator of the fraction, whose denominator will be 10000; e.g., suppose it to be required to find the fraction corresponding to the negative logarithm 0.3679776. Subtract this from 4.0000000.

The remainder is 3.6320233, the number corresponding to which is 4285761. The reason of the rule is, that as a fraction is the quotient, arising on the division of the numerator by the denominator, unity will be to the fraction as the denominator to the numerator; but as unity is to the fraction corresponding to the given negative logarithm, so is 10000 to the number corresponding to the remainder; therefore, if 10000 be taken for the denominator, the number will be the numerator of the fraction required.

The negative logarithm -0.367977 is equal to the logarithm 1.632023, and the number answering to it, found in the manner already directed, will be 4285761.

The sines, tangents, &c. of any arch are easily found by seeking the degree at the top, if the arch be less than 45°, and the minutes at the side, beginning from the top, and by seeking the degree, &c. at the bottom, if the arch is greater than 45°. If a given logarithmic sine or tangent falls between those in the tables, then the corresponding degrees and minutes may be reckoned ½, ½, or ½, minutes more than those belonging to the nearest less logarithm in the tables, according as its difference from the given one is ½, or ½, or ½, &c. of the difference between the logarithm next greater and next less than the given log.

§ 2. Of the various Sciences to which Logarithms may be applied.

As these artificial numbers constitute a new species of arithmetic capable of performing every thing which can be done in the old way, it is plain that its use must be equally extensive, and that in every science in which common arithmetic can be useful, the logarithmic arithmetic must be much more so, by reason of its being more easily performed. Though the general principles of logarithmic arithmetic have been already laid down, we shall here, in order to render the subject still more plain, subjoin the following practical rules.

I. Multiplication by Logarithms.

Add together the logarithms of all the factors, and the sum is a logarithm, the natural number corresponding to which will be the product required.

Observing to add, to the sum of the affirmative indices, what is carried from the sum of the decimal parts of the logarithms.

And that the difference between the affirmative and negative indices is to be taken for the index to the logarithm of the product.
LOGARITHMS

Division by Logarithms.

Ex. 1. To multiply 23'14 by 5'062.

\[23'14 \times \log 1'3645934 \]

\[5'062 \times \log 0'7043221 \]

Product 117'1347 - 2'0686855

Ex. 2. To multiply 2'589196 by 3'457291.

\[2'589196 \times \log 0'314728 \]

\[3'457291 \times \log 0'387359 \]

Prod. 8'92647 - 0'9506797

Ex. 3. To multiply 3'902, and 597'16, and 0'314728 all together.

\[3'902 \times \log 0'5912873 \]

\[597'16 - 2'7770097 \]

\[0'314728 - 2'4979333 \]

Prod. 7'333533 - 1'8653133

The 2 cancels the 2, and the 1 to carry from the decimals is set down.

Ex. 4. To multiply 3'586, and 2'1046, and 0'8372, and 0'0294 all together.

\[3'586 \times \log 0'5345103 \]

\[2'1046 - 0'3351696 \]

\[0'8372 - 7'922892 \]

\[0'0294 - 3'457343 \]

Prod. 1'897618 - 1'0689564

Here the 2 to carry cancels the 2, and there remain the 1, to set down.

II. Division by Logarithms.

From the logarithm of the dividend subtract the logarithm of the divisor, the remainder is a logarithm whose corresponding number will be the quotient required.

But first observe to change the sign of the index of the logarithm of the divisor, viz. from negative to affirmative, or from affirmative to negative; then take the sum of the indices if they be of the same kind, or the remainder will be the logarithm of the quotient.

And when 1 is borrowed in the left-hand place of the decimal part of the logarithm, add it to the index of the logarithm of the divisor when that logarithm is affirmative, but subtract it when negative; then let the index thus found be changed and worked with as before.

Ex. 1. To divide 24'163 by 45'67.

Divide 24'163 its log. 4'3831509

Divid. 45'67 - 3'6596310

Quot. 5'290782 - 0'7235199

Ex. 2. To divide 37'149 by 52'76.

Divid. 37'149 its log. 1'3609491

Divid. 52'76 - 2'7191323

Quot. 0'07002752 - 2'8508148

Ex. 3. To divide 0'6314 by 0'07241.

Divid. 0'6314 its log. 2'3603046

Divid. 0'07241 - 3'8597995

Quot. 8'719792 - 0'9405061

Rule of Three by Logarithms.

Here 1 carried from the decimals to the 3 makes it become 2, which taken from the other 2, leaves 0 remaining.

Ex. 4. To divide 7'438 by 12'9476.

Divid. 7'438 its log. 1'8714562

Divid. 12'9476 - 2'3712193

Quot. 0'5744694 - 2'9592669

Here the 1 taken from the 1 makes it become 2 to set down.

III. The Rule of Three, or Proportion.

Add the logarithms of the 2nd and 3rd terms together, and from their sum subtract the logarithm of the 1st by the foregoing rules; the remainder will be the logarithm of the 4th term required.

Or in any compound proportion whatever, add together the logarithms of all the terms that are to be multiplied, and from that sum take the sum of the others; the remainder will be the logarithm of the term sought.

But instead of subtracting any logarithm, we may add its complement, and the result will be the same. By the complement is meant the logarithm of the reciprocal of the given number or the remainder by taking the given logarithm from 0, or from 10, changing the radix from 0 to 10; the easiest method of doing which, is to begin at the left hand, and subtract each figure from 9, except the last significant figure on the right hand, which must be subtracted from 10. But when the index is negative, add it to 9, and subtract the result as before. And for every complement that is added, subtract 10 from the last sum of the indices.

Ex. 1. To find a 4th proportional to 72'34, and 2'519, and 357'4862.

As 72'34 - comp. log. 8'1406215

To 2'519 - - 0'4012282

So 357'4862 - - 2'5532592

To 12'44827 - - 1'0051089

Ex. 2. To find a 3d proportional to 12'796 and 3'24718.

As 12'796 - comp. log. 8'9292528

To 3'24718 - 0'4515064

So 3'24718 - 0'4515064

To 8'240216 - 1'9179286

Ex. 3. To find a number in proportion to 3'79145 as 8'5132 is to 0'649.

As 0'649 - comp. log. 11'787753

To 8'5132 - 2'7191323

So 3'79145 - 1'5788054

To 4'973401 - 0'6966535

Ex. 4. If the interest of 10£. for a year or 365 days be 4£., what will be the interest of 279'25£. for 274 days?

As \[\frac{100}{365} \text{ comp. log.} \quad \frac{80000000}{17'23377071} \]

To \[\frac{279'25}{274} \quad - \quad 2'4459932 \]

So \[4'5 \quad - \quad 0'6532125 \]

To \[9'433296 \quad - \quad 0'9746634 \]
IV. *Involution, or raising of Powers.*

Multiply the Logarithm of the number given by the proposed index of the power, and the product will be the logarithm of the power sought.

*Note.* In multiplying a logarithm with a negative index by any affirmative number, the product will be negative. But what is to be carried from the decimal part of the logarithm will be affirmative. Therefore the difference will be the index of the product; and is to be accounted of the same kind with the greater.

Ex. 1. To find the 2d power of 2.5791.

Root 2.5791 its log. 0.4114682
index index

Power 6.651756 - 0.8229364

Ex. 2. To find the cube of 3.07146.

Root 3.07146 its log. 0.4873449
index index

Power 28.97575 - 1.4520347

Ex. 3. To find the 4th power of 0.9163.

Root 0.9163 its log. - 2.9620377
index index

Power 0.0000704938 - 5.8481508
Here 4 times the negative index being 8, and 3 to carry, the difference 5 is the index of the product.

Ex. 4. To find the 365th power of 1.0045.

Root 1.0045 its log. 0.0019499
index index

Power 5.148888 - 0.7117135

V. *Evolution, or Extraction of Roots.*

Divide the logarithm of the power or given number by its index, and the quotient will be the logarithm of the root required.

*Note.* When the index of the logarithm is negative, and the divisor is not exactly contained in it without a remainder, increase it by such a number as will make it exactly divisible; and carry the units borrowed, as so many tens, to the left-hand place of the decimal part of the logarithm; then divide the results by the index of the root.

Ex. 1. To find the square root of 365.

Power 365 - 2)3.5622929
Root 19.10498 - 1.2811465

Ex. 2. To find the cube root of 12345.

Power 12345 - 3)4.0914911
Root 23.11162 - 1.3638304

Ex. 3. To find the 10th root of 2.

Power 2 - 10)0.3010300
Root 1.071773 - 0.0301030

Ex. 4. To find the 365th root of 1045.

Power 1045 - 365)0.0191163
Root 1.000121 - 0.0000524

Ex. 5. To find the square root of 0.93.

Power 0.93 - 2)0.9684829

Root 0.04959 - 1.4842415
Here the divisor 2 is contained exactly once in 2 the negative index; therefore the index of the quotient is 1.

Ex. 6. To find the cube root of 0.00048.

Power - - 3)0.6812412
Root 0.07829735 - 2.8937471
Here the divisor 3 not being exactly contained in 4, augment it by 2, to make it become 6, in which the divisor is contained just 2 times; and the 2 borrowed being carried to the other figures 6, &c. makes 2.6812412, which divided by 3 gives .8937471.

In trigonometry, the use of logarithmical sines, tangents, &c. are used as well as the common arithmetical logarithms; and by using them according to the rules above laid down, the operations are shortened to a degree altogether incredible to persons unacquainted with this invention. With equal facility are the problems in astronomy and navigation solved by their means, as well as those of the higher geometry, fluxions, and in short every thing which requires deep and laborious calculation. For the particular application of them to the different sciences, see the articles Navigation, Trigonometry, &c.

**Notes:**

- Logarithms are important in mathematics for simplifying multiplication and division operations.
- The table provides logarithms for numbers ranging from 1 to 10,000.
- Logarithms are used in various scientific and engineering applications.

**Notes:**

- The table lists the sine and tangent values for various degrees, ranging from 0° to 90°.
- Each row contains the sine value, then the tangent value, followed by the sine complement and its tangent complement.
- The values are rounded to four decimal places.

#### Plate.

**LOGARITHMIC CURVE.** If on the line $AN$, both ways indefinitely extended, be taken $AC$, $CE$, $EG$, $GI$, $IL$, on the right hand; and also $Ag$, $gF$, $Eg$, $gG$, $kH$, $kL$, $mL$, be equal to one another; and if at the points $P$, $A$, $C$, $E$, $G$, $I$, $L$, be erected to the point $A$ the perpendiculars $PS, gH, EK, mK$, let be continually proportional, and represent numbers, viz. $AB$, $AC$, $CD$, $EF$, $HI$, $KL$, $LM$, which let be continually proportional, and represent numbers, viz. $AB$, $AC$, $CD$, $EF$, $HI$, $KL$, $LM$, and so on. Then we have two progressions of lines, arithmetical and geometrical: for the lines $AC$, $AE$, $AG$, &c. are in arithmetical progression, and $AB$, $AC$, $CD$, $EF$, &c. do correspond. For since $AG$ is triple of the first line $AC$, the number $GH$ shall be in the third place from unity, if $CD$ be in the first; so likewise shall $LM$ be in the fifth place, since $AL = 5 AC$. If the extremities of the proportions $d, D, d', D'$, &c. be joined by right lines, the figures $ABLM$ will become a polygon, consisting of more or less sides, according as there are more or less terms in the progression.

If the parts $AC$, $CE$, $EG$, &c. be bisected in the points $a, c, e, g, x$, &c. and there be again raised the perpendiculars $ad, eg, gh, ik, lm$, which are mean proportionals between $AB, AC, CD, CD$, &c. then there will arise a new series of proportionals, whose terms, beginning from that which immediately follows, are double of those in the first series, and the logarithm of the difference of the terms is become less, and approach nearer to a ratio of equality than before. Likewise, in this new series, the right lines $AL$, $Ag$, express the differences of the terms $LM$, &c. from unity, viz. figure $AL$ is ten times greater than $AC$, $LM$ shall be the tenth term of the series from unity; and because $AC$ is three times greater than $Ag$, $ef$ will be the third term of the series $if e$ be the first, and there shall be two mean proportionals between $AB$ and $ef$, and between $AB$ and $LM$ there will be nine mean proportionals. And if the extremities of the lines $Bd$, $Df$, $Fh$, &c. be joined by right lines, there will be a new polygon made, consisting of more but shorter sides than the last.

If, in this manner, mean proportionals be continually placed between every two terms, the number of terms at last will be made so great, as also the number of the sides of the polygon, as to be greater than any given number, or to be infinite; and every side of the polygon so increased, as to become less than any given right line; and consequently the polygon will be changed into a curve-lined figure; for any curve-lined figure may be conceived as a polygon, whose sides are infinitely small and infinite in number. A curve described after this manner is called logarithmic.

It is manifest from this description of the logarithmic curve, that all numbers at equal distances are continually,
LOG [ 188 ] LOG

Logarithmic Lines. For many mechanical purposes it is convenient to have the logarithms of numbers laid down on scales, as well as the logarithmic lines and tangents; by which means, computations may be carried on by mere menurilation with companies. Lines of this kind are always put on the common Gunter's scale; but as these instriments must be extended to a very great length, in order to contain any considerable quantity of numbers, it becomes an object of importance to shorten them. Such an improvement has been made by Mr William Nicholson, and published in the 77th volume of the Philosophical Transactions. The principles on which the construction of his instruments depends are as follow:

1. If two geometrical series of numbers, having the same common ratio, be placed in order with the terms opposite to each other, the ratio between any term in one series and its opposite in the other will be constant: Thus,

\[
\begin{align*}
2 & : 6 : 18 : 54 : 162, & c. \\
\end{align*}
\]

Then,

\[
\begin{align*}
\end{align*}
\]

where it is evident, that each of the terms in the upper series is exactly two-thirds of the corresponding one in the lower.

2. The ratio of any two terms in one series will be the same with that between those which have an equal distance in the other.

3. In all such geometrical series as have the same ratio, the property abovementioned takes place, tho' we compare the terms of any series with those of another: Thus,

\[
\begin{align*}
2 & : 4 : 8 : 16 : 32 : 64, & c. \\
3 & : 6 : 12 : 24 : 48 : 96, & c. \\
4 & : 8 : 16 : 32 : 64 : 128, & c. \\
5 & : 10 : 20 : 40 : 80 : 160, & c. \\
\end{align*}
\]

where it is plain that 2, 3, 4, 5; also 2, 4, 8, and 2, 4, 8, 16; &c. have the same ratio with that of each series.

4. If the differences of the logarithms of the numbers be laid in order upon equidistant parallel right lines, in such a manner that a right line drawn across whole shall intersect it at divisons denoting numbers of geometrical progression; then, from the condition of the arrangement, and the property of this logarithmic line, it follows, 1st. That every right line to drawn will, by its intersections, indicate a geometrical series of numbers; 2dly. That such series as are indicated by these right lines will have the same common ratio; and, 3dly. That the series thus indicated by two parallel right lines, supposing to move laterally, without changing either their mutual distance or parallelism to themselves, will have each the same ratio, and in all series indicated by such two lines, the ratio between an antecedent and consequent, the former taken upon one line, and the latter upon another, will be also the same. The 2d proposition is proved in the fol. Pltate bowing manner. Let the lines A B, C D, E F, represent the parts of the logarithmic line arranged according to the proportion already mentioned; and let GH be a right line passing through the points c, c, c, denoting numbers in geometrical progression; then will any other line IK, drawn across the arrangement, likewise pass through three points f, d, b, in geometrical progression.

From one of the points of intersection F in the last mentioned line IK, draw the line f g parallel to GH, and intersecting the arrangement in the points f, b; and the ratios of the numbers c, f, c, i, will be equal, as well as a, b; because the intervals on the logarithmic line, or differences of the logarithms of those numbers, are equal. Again, the point F, the line i d, and the line b b, are in arithmetical progression denoting the differences between the logarithms of the numbers themselves, whence the quotients of the numbers are in geometrical progression.

The 3d proposition arises from the parallelism of the lines to their former situation; by which means they indicate numbers in a geometrical series, having the same common ratio as before; their distance on the logarithmic line also remains unchanged; whence the differences between the logarithms of the opposite numbers, and of consequence their ratios, will always be constant.

Supposing now an antecedent and consequent to be given in any geometrical series, it will always be possible to find them, provided the line be of unlimited length. Drawing two parallel lines, then, through each of the numbers, and supposing the lines to move without changing their direction or parallel situation, they will continually describe new antecedents and consequents in the same geometrical series as before.

6. Though the logarithmic line contain no greater range of numbers than from 1 to 10, it will not be found necessary for the purposes of computation to repeat it. The only thing requisite is to have a slide or beam with two fixed points at the distance of the interval between 1 and 10, and a moveable point be made to range between them always to indicate the antecedent; then, if the consequent fixed point fall without the rule, the other fixed point will always denote the division on which it would have fallen had the rule been prolonged; and this contrivance may easily be adapted to any arrangement of parallel lines whatever. The arrangement of right lines, however, ought always to be disposed in such a manner as to occupy a
LOGIC is the art of thinking and reasoning justly; or, it may be defined the science or history of the human mind, inasmuch as it traces the progress of our knowledge from our first and most simple conceptions through all their different combinations, and all those numerous deductions that result from variously comparing them one with another.

The precise business of logic therefore is, to explain the nature of the human mind, and the proper manner of conducting its several powers, in order to the attainment of truth and knowledge. It lays open those errors and mistakes we are apt, through inattention, to run into; and teaches us how to distinguish between truth, and what only carries the appearance of it. By these means we grow acquainted with the nature and force of the understanding; see what things lie within its reach;
LOGIC. Part I.

PART I. OF PERCEPTION.

We find ourselves surrounded with a variety of objects, which acting differently upon our senses, convey distinct impressions into the mind, and thereby rouse the attention and notice of the understanding. By reflecting too on what passes within us, we become sensible of the operations of our own minds, and attend to them as a new set of impressions. But in all this there is only bare consciousness. The mind, without proceeding any farther, takes notice of the impressions that are made upon it, and views things in order, as they present themselves one after another. This attention of the understanding to the object acting upon it, whereby it becomes sensible of the impressions they make, is called by logicians perception and the notices themselves, as they still in the mind, and are there treasured up to be the materials of thinking and knowledge, are distinguished by the name of ideas. In the article Metaphysics it shall be shown at large, how the mind, being furnished with ideas, contrives to diversify and enlarge its stock: we have here chiefly to consider the means of making known our thoughts to others; that we may not only understand how knowledge is acquired, but also in what manner it may be communicated with the greatest certainty and advantage.

CHAP. I. Of Words, considered as the Signs of our Ideas.

I. Our ideas, though manifold and various, are nevertheless all within our own breasts, invisible to others, nor can of themselves be made appear. But God, designing us for society, and to have fellowship with those of our kind, has provided us with organs fitted to frame articulate sounds, and given us also a capacity of using those sounds as signs of internal conceptions. Hence spring words and language: for, having once pitched upon any found to stand as the mark of an idea in the mind, custom by degrees establishes such a connection between them, that the appearance of the idea in the understanding always brings to our remembrance the found or name by which it is expressed; as in like manner the hearing of the found never fails to excite the idea for which it is made to stand. And thus it is easy to conceive how a man may record his own thoughts, and bring them again into view in any succeeding period of life. For this connection being once fet:ted, as the same sounds will always serve to excite the same ideas; if he can but contrive to register his words in the order and disposition in which the present train of his thoughts present themselves to his imagination, it is evident he will be able to recall these thoughts at pleasure, and that too in the very manner of their first appearance. Accordingly we find, that the inventions of writing and printing, by enabling us to fix and perpetuate such perishable things as sounds, have also furnished us with the means of giving a kind of permanency to the tran:formations of the mind, infomuch that they may be in the same manner subjected to our review as any other objects of nature.

II. But, besides the ability of recording our own thoughts, there is this farther advantage in the use of and, of the external signs, that they enable us to communicate mutual information of what passes in their breasts. For any number of men, having agreed to establish the same sounds as signs of the same ideas, it is apparent that the repetition of these sounds must excite the like perceptions in each, and create a perfect correspondence of thoughts. When, for instance, any train of ideas succeed one another in my mind, if the names by which I cannot express them have been annexed by those with whom I converse to the very same set of ideas, nothing is more evident, than that, by repeating those names according to the tenor of my present conceptions, I shall raise in their minds the same course of thought as has taken possession of my own. For by merely attending to what passes within themselves upon hearing the sounds which I repeat, they will also become acquainted with the ideas in my understanding, and have them in a manner laid before their view. So that we hereby clearly perceive how a man may communicate his sentiments, knowledge, and discoveries to others, if the language in which he converses, be extensive enough to mark all the ideas and transformations of his mind. But as this is not always the case, and men are often obliged to invent terms of their own to express new views and conceptions of things: it may be asked, how in these circumstances we can become acquainted with the thoughts of another, when he makes use of words, to which we have never annexed any ideas, and that of course can raise no perceptions in our minds? In order to unveil this mystery, and give some light into the foundation, growth, and improvement of language, the following observations will be found of considerable moment.

III. First, that no word can be to any man the sign of an idea, till that idea comes to have a real existence in his mind. For names, being only so far intelligible as they denote known internal conceptions, where they have none such to answer them, there they are plainly founds without significations, and of words, or names, or any denomination are the ideas to which they belong raised in the understanding, than, finding it easy to connect them with the established names, we can join in any agreement of this kind made by others, and thereby enjoy the benefit of their discoveries. The first thing therefore to be considered is, how these ideas may be conveyed into the mind; that being there, we may learn to con-
Part I.

LOGIC.

The names of objects, the only channel of sensation of ideas, and marking the order and manner in which the ideas are made have already got admittance into the understanding, and the names by which they are known are sufficiently known to him. Thus, were any one to ask the meaning of the word "apple," we should tell him it stood for the same idea as "drole" in Latin, or "blanc" in French; or, if we thought him a stranger to these languages, we might appeal to an object producing the idea, by saying it denoted the colour we observe in snow or milk. But this is by no means a definition of the word, exciting a new idea in his understanding; but merely a contrivance to remind him of a known idea, and teach him its connection with the established name. For if the ideas after which he inquires have never yet been raised in his mind; as suppose one who had seen no other colours than black and white, should ask the meaning of the word "fauteuil;" it is easy to perceive, that it would be no more possible to make him comprehend it by words, or a definition, than to introduce the same perception into the imagination of a man born blind. The only method in this case is, to present some object, by looking at which the perception itself may be excited; and thus he will learn both the name and the idea together.

V. But how comes it to pass that men agree in the name of their simple ideas, seeing they cannot view the perceptions in one another's minds, nor make known these perceptions by words to others? The effect is produced by experience and observation. Thus finding, for instance, that the name of "heat" is annexed to the sensation which men feel when they approach the fire, I make it also the sign of the sensation excited in me by such an approach, nor have any doubt but it denotes the same perception in my mind as in theirs. For we are naturally led to imagine, that the same objects operate alike upon the organs of the human body, and produce an uniformity of sensation. No man imagines, that the idea raised in him by the taste of sugar, and which he calls "sweetness," differs from that excited in another by the like means; or that "vermilion," to whose relish he has given the epithet "bitter," produces in another the sensation which he denotes by the word "fauteuil." Presuming therefore upon this conformity of perceptions, when they arise from the same objects, we easily agree as to the names of our simple ideas: and if at any time, by a more narrow scrutiny into things, new ideas of this class come in our way, which we choose to express by terms of our own invention; these names are explained, not by a definition, but by referring to the objects whence the ideas themselves may be obtained.

VI. Being in this manner furnished with simple ideas, and the names by which they are expressed; the meaning of terms that stand for complex ideas is easily got, because the ideas themselves answering to these terms may be conveyed into the mind by definitions. For our complex notions are only certain combinations of simple ideas. When therefore these are enumerated, and the manner in which they are united into one conception explained, nothing more is wanting to raise that conception in the understanding; and thus the term denoting it comes of course to be understood. And here it is worth while to reflect a little upon the wise contrivance of nature, in thus furnishing us with the very aptest means of communicating our thoughts. For were it not so ordered, that,

The names of objects, the only channel of sensation of ideas, and marking the order and manner in which the ideas are made have already got admittance into the understanding, and the names by which they are known are sufficiently known to him. Thus, were any one to ask the meaning of the word "apple," we should tell him it stood for the same idea as "drole" in Latin, or "blanc" in French; or, if we thought him a stranger to these languages, we might appeal to an object producing the idea, by saying it denoted the colour we observe in snow or milk. But this is by no means a definition of the word, exciting a new idea in his understanding; but merely a contrivance to remind him of a known idea, and teach him its connection with the established name. For if the ideas after which he inquires have never yet been raised in his mind; as suppose one who had seen no other colours than black and white, should ask the meaning of the word "fauteuil;" it is easy to perceive, that it would be no more possible to make him comprehend it by words, or a definition, than to introduce the same perception into the imagination of a man born blind. The only method in this case is, to present some object, by looking at which the perception itself may be excited; and thus he will learn both the name and the idea together.

V. But how comes it to pass that men agree in the name of their simple ideas, seeing they cannot view the perceptions in one another's minds, nor make known these perceptions by words to others? The effect is produced by experience and observation. Thus finding, for instance, that the name of "heat" is annexed to the sensation which men feel when they approach the fire, I make it also the sign of the sensation excited in me by such an approach, nor have any doubt but it denotes the same perception in my mind as in theirs. For we are naturally led to imagine, that the same objects operate alike upon the organs of the human body, and produce an uniformity of sensation. No man imagines, that the idea raised in him by the taste of sugar, and which he calls "sweetness," differs from that excited in another by the like means; or that "vermilion," to whose relish he has given the epithet "bitter," produces in another the sensation which he denotes by the word "fauteuil." Presuming therefore upon this conformity of perceptions, when they arise from the same objects, we easily agree as to the names of our simple ideas: and if at any time, by a more narrow scrutiny into things, new ideas of this class come in our way, which we choose to express by terms of our own invention; these names are explained, not by a definition, but by referring to the objects whence the ideas themselves may be obtained.

VI. Being in this manner furnished with simple ideas, and the names by which they are expressed; the meaning of terms that stand for complex ideas is easily got, because the ideas themselves answering to these terms may be conveyed into the mind by definitions. For our complex notions are only certain combinations of simple ideas. When therefore these are enumerated, and the manner in which they are united into one conception explained, nothing more is wanting to raise that conception in the understanding; and thus the term denoting it comes of course to be understood. And here it is worth while to reflect a little upon the wise contrivance of nature, in thus furnishing us with the very aptest means of communicating our thoughts. For were it not so ordered, that,
that we could thus convey our complex ideas from one to another by definitions, it would in many cases be impossible to make them known at all. This is apparent in those ideas which are the proper work of the mind. For as they exist only in the understandings, and have no real objects in nature in conformity with which they are framed, if we could not make them known by description, they must lie for ever hid within our own breasts, and be confined to the narrow acquaintance of a single mind. All the fine scenes that arise from time to time in the poet's fancy, and by his lively painting give such entertainment to his readers; were he destitute of this faculty of laying them open to the view of others by words and description, could not extend their influence beyond his own imagination, or give joy to any but the original inventor.

VII. There is this further advantage in the ability we enjoy of communicating our complex notions by definitions; that as these make by far the largest classes of our ideas, and most frequently occur in the progress and improvement of knowledge, so they are by these means imparted with the greatest readiness, than which nothing would tend more to the increase and spreading of science; for a definition is soon perused; and if the terms of it are well understood, the idea itself finds an easy admission into the mind. Whereas in simple perceptions, where we are referred to the objects producing them, if these cannot be come at, as is sometimes the case, the names by which they are expressed must remain empty sounds. But new ideas of this class occurring very rarely in the sciences, they seldom create any great obfuscation. It is otherwise with our complex notions; for every step we take leading us into new combinations and views of things, it becomes necessary to explain these to others, before they can be made acquainted with our discoveries; and as the manner of definitions is easy, requiring no apparatus but that of words, which are always ready, and at hand; hence we can with the less difficulty remove such obstacles as might arise from terms of our own invention, when they are made to stand for new complex ideas suggested to the mind by some preexistent train of thinking. And thus at least we are let into the mystery hinted at in the beginning of this chapter, viz. how we may become acquainted with the thoughts of another, when he makes use of words to which we have as yet joined no ideas. The answer is obvious from what has been already said. If the terms denote simple perceptions, he must refer us to these objects of nature whence the perceptions themselves are to be obtained; but, if they stand for complex ideas, their meaning may be explained by a definition.

CHAP. II. OF DEFINITIONS.

I. A Definition is the unfolding of some conception of the mind, answering to the word or term made use of as the sign of it. Now as, in exhibiting any idea to another, it is necessary that the description be such as may excite that precise idea in his mind; hence it is plain that definitions, properly speaking, are not arbitrary, but confined to the representation of certain determinate settled notions, such as are annexed by the speaker or writer to the words he uses. As never-
be connected with any term, according to the good pleasure of him that uses it; in like manner may different descriptions be applied to the term, suitable to the ideas so connected. But this connection being settled, and the term considered as the sign of some fixed idea in the understanding, we are no longer left to arbitrary explications, but must study such a description as corresponds with that precise idea. Now this alone, according to what has been before laid down, ought to be accounted a definition. What seems to have occasioned no small confusion in this matter, is, that many explanations of words, where no idea is unfolded, but merely the connection between some word and idea asserted, have yet been dignified with the name of definitions. Thus, when we say that a clock is an instrument by which we measure time; that is by some called a definition; and yet it is plain that we are beforehand supposed to have an idea of this instrument, and only taught that the word clock serves in common language to denote that idea. By this rule all explications of words in our dictionaries will be definitions, nay, the names of even simple ideas may be thus defined. White, we may say, is the color we observe in snow or milk; heat the sensation produced by approaching the fire; and so in innumerable other instances. But these, and all others of the like kind, are by no means definitions, exciting new ideas, in the understanding, but merely contributions to remind us of known ideas, and teach their connection with the established names.

V. But now in definitions properly so called, we first consider the term we use, as the sign of some inward conception, either annexed to it by custom, or our own free choice; and then the business of the definition is to unfold and explicate that idea. As therefore the whole art lies in giving just and true copies of our ideas; a definition is then said to be made perfect, when it serves distinctly to excite the idea described in the mind of another, even supposing him before wholly unacquainted with it. This point decided, we next inquire what ideas are which are capable of being thus unfolded? And in the first place it is evident, that all our simple ideas are necessarily included. We have seen already that experience alone is to be consulted here, inasmuch that if either the objects whence they are derived come not in our way, or the avenues appointed by nature for their reception, are wanting, no description is sufficient to convey them into the mind. But where the understanding is already supplied with these original and primitive conceptions, as they may be united together in an infinity of different forms, so may all their several combinations be distinctly laid open, by enumerating the simple ideas contained in the various collections, and tracing the order and manner in which they are related one to another. Now these combinations of simple notices constitute what we call our complex notions; whence it is evident, that complex ideas, and these alone, admit of that kind of description which goes by the name of a definition.

VI. Definitions, then, are pictures or representations of our ideas; and as these representations are then only possible when the ideas themselves are complex, it is obvious to remark, that definitions cannot have place but where we make use of terms standing for such complex ideas. But our complex ideas, being as we have said, nothing more than different combinations of simple ideas; we then know and comprehend them perfectly, when we know the several simple ideas of which they consist, and can so put them together in our minds as may be necessary towards the framing of that peculiar connection which gives every idea its distinct and proper appearance.

VII. Two things are therefore required in every definition: first, That all the original ideas, out of which the complex one is formed, be distinctly enumerated; and, secondly, That the order and manner of combining them into one conception be clearly explained. Where a definition has these requisites, nothing is wanting to its perfection; because every one who reads it and understands the terms, feeling at once their combinations, can at pleasure form in his own mind the complex conception answering to the term defined. Let us, for instance, suppose the word square to stand for that idea by which we represent to ourselves a figure whose sides subtend quadrants of a circumscribed circle. The parts of this idea are the sides bounding the figure. These must be four in number, and all equal among themselves, because they are each to subtend a fourth part of the fame circle. But, besides these component parts, we must also take notice of the manner of putting them together. If we should exhibit the precise idea from which the word square here stands for four equal right lines, any how joined, will not subtend quadrants of a circumscribed circle. A figure with this property must have its sides standing also at right angles. Taking in therefore this last consideration respecting the manner of combining the parts, the idea is fully described, and the definition thereof rendered complete. For a figure bounded by four equal sides, joined together at right angles, has the property required; and is moreover the only right lined figure to which that property belongs.

VIII. It will now be obvious to every one, in what manner we ought to proceed, in order to arrive at just and adequate definitions. First, we are to take an exact view of the idea to be described, trace it to its original principles, and mark the several simple perceptions that enter into the composition of it. Secondly, we are to consider the particular manner in which these elementary ideas are combined, in order to the forming of that precise conception for which the term we make use of stands. When this is done, and the idea wholly unraveled, we have nothing more to do than fairly transcribe the appearance it makes to our own minds. Such a description, by distinctly exhibiting the order and number of our primitive conceptions, cannot fail to excite at the same time in the mind of every one that reads it, the complex idea resulting from them; and therefore attains the true and proper end of a definition.

Chap. II. Of the Composition and Resolutions of our Ideas, and the Rule of Definition thereupon arising.

I. The rule laid down in the foregoing chapter is general; extending to all possible cases: and is indeed that to which alone we can have recourse, where any doubt
though or difficulty arises. It is not, however, necessary
that we should practice it in every particular instance.
Many of our ideas are extremely complicated, infor
much that to enumerate all the simple perceptions out
of which they are formed, would be a very troublesome
and tedious work. For this reason logicians have eshablished certain compendious rules of defining,
of which it may not be amiss here to give some ac
count. But in order to the better understanding of
what follows, it will be necessary to observe, that
there is a certain gradation in the composition of our
ideas. The mind of man is very limited in its views,
and cannot take in a great number of objects at once.
We are therefore taught to proceed by steps, and make
our first advances subordinating to those which follow.
Thus, in forming our complex notions, we begin at
first with but a few simple ideas, such as we can man
age with ease, and unite them together into one con
ception. When we are provided with a sufficient
stock of these, and have by habit and use rendered
them familiar to our minds, they become the com
ponent parts of other ideas still more complicated, and
form what we may call a second order of compound
notions. This process, as is evident, may be con
tinued to any degree of composition we please, mount
ning from one stage to another, and enlarging the num
ber of combinations.

II. But now in a series of this kind, whoever would
equal himself perfectly with the last and highest
order of ideas, finds it much the most expeditious meth
od to proceed gradually through all the interme
diate steps. For, were he to take any very compound
idea to pieces, and, without regard to the several
classes of simple perceptions that have already been for
med into different combinations, break it at once into its
original principles the number, would be too great as per
fectly to confound the imagination; and overcome the
utmost reach and capacity of the mind. When we see
a prodigious multitude of men jumbled together in
crowds, without order or any regular position, we find
it impossible to arrive at an exact knowledge of their
number. But if they are formed into separate batta
lions, and so flattened as to fall within the leisure
survey of the eye; by viewing them successively and in
order, we come to an easy and certain deter
mination. It is the same in our complex ideas. When
the original perceptions, out of which they are framed,
are very numerous, it is not enough that we take a
view of them in loose and scattered bodies; we must
form them into distinct classes, and unite these classes
in a just and orderly manner, before we can arrive at a
true knowledge of the compound notions resulting
from them.

III. This gradual progress of the mind to its com
pound notions, through a variety of intermediate steps
plainly points out the manner of conducting the de
nitions by which these notions are conveyed into the
minds of others. For as the series begins with simple
and easy combinations, and advances through a for
cession of different orders, rising one above another in
the degree of composition, it is evident, that, in a train of
definitions expressing these ideas, a like gradation is to be observed. Thus the complex ideas of the
lowest order can no otherwise be described than by enumerating the simple ideas out of which they are made, and explaining the manner of their union. But

then in the second, or any other succeeding order, as
they are formed out of those gradual combinations,
and constitute the inferior classes, it is not necessary,
in describing them to mention one by one all the sim
ple ideas of which they consist. They may be more dif
tinctly and briefly unfolded, by enumerating the
compound ideas of a lower order, from whose union
they result, and which are all supposed to be already
known in conformance of previous definitions. Here
then it is that the logical method of defining takes
place; which, that it may be the better understood,
we shall explain somewhat more particularly the sev
eral steps and gradations of the mind in compound
ing its ideas, and hence deduce that peculiar form of
a definition which logicians have thought fit to es	ablish.

IV. All the ideas we receive from the several ob
jects of nature that surround us, represent distinct in
dividuals. These individuals, when compared to
gether, are found in certain particulars to resemble each
other. Hence, by collecting the resembling particulars
into one conception, we form the notion of a species,
general to these ideas. And here let it be observed, that this last idea is less complicated than that by which we represent any of the particular objects contained under it. For the idea of the species excludes the peculiarities of the several
individuals, and retains only such properties as are
common to them all. Again, by comparing several
species together, and observing their resemblance, we
form the idea of a genus; where, in the same manner
as before, the composition is lightened, because we
leave out what is peculiar to the several species com
pared, and retain only the particulars wherein they
agree. It is easy to conceive the mind proceeding
thus from one step to another and advancing through
its several classes of general notions, until at last it
comes to the highest genus of all, denoted by the word
being, where the bare idea of existence is only con
cerned.

V. In this procedure we see the mind unravelling
the complex idea, and tracing in the ascending scale, dust of the
from greater or less degrees of composition, until it mind in
terminates in one simple perception. If now we take
the species the contrary way, and, beginning with the
lowest or highest genus, carry our view downwards
advances through all the inferior genera and species, quite to the
the individuals, we shall thereby arrive at a distinct and
different apprehension of the conduct of the understanding in orders of
compound ideas. For in the several classes of
our preceptions, the highest in the scale is for the
most part made up of but a few simple ideas, such as
the mind can take in at a time with ease. This first
general notion, when branched out into the different
subdivisions contained under it, has in every one of
them something peculiar, by which they are dis	in
guished among themselves; insomuch that, in de
scending from the genus to the species, we always
superadd some new idea, and thereby increase the
degree of composition. Thus the idea denoted by
the word figure is of a very general nature, and compo
sed of but few simple perceptions, as implying no
more than space every where bounded. But if we
descend farther, and consider the boundaries of this
space, as that they may be either lines or surfaces, we
fall into the several species of figure. For where the
space is bounded by one or more surfaces, we give the
name
Part I.  
LOGIC.

name of a solid figure; but where the boundaries are lines, it is called a plain figure (a).

VI. In this view of things it is evident, that the species is formed by superadding a new idea to the genus. Here, for instance, the genus is circumscribed space. If now to this we superadd the idea of a circumscription by lines, we frame the notion of that species of figures which are called plural; but if we conceive the circumscriptio to be by surfaces, we have the species of solid figures. This superadded idea is called the specific difference, not only as it serves to divide the species from the genus, but because, being different in all the several subdivisions, we thereby also distinguish the species one from another. And as it is likewise that conception, which, by being joined to the general idea, completes the notion of the species; hence it is plain, that the genus and specific difference are to be considered as the proper and constitutional parts of the species. If we trace the progress of the mind still farther, and consider it advancing through the inferior species, we shall find its manner of proceeding to be always the same. For every lower

(a) This account of the composition and resolution of our ideas is agreeable to the common doctrine of logicians on the subject. Into the truth of the doctrine itself we shall inquire afterwards under the article METAPHYSICS: but to prevent mistakes, it may be proper to observe here, that though every writer of logic has treated largely of general and specific ideas, there is in reality nothing general in the matter but the terms of language. When we utter, for instance, the word triangle, that general term does not, as has been often said, suggest to the mind the general idea of a triangle, which is neither obtuse nor rectilinear, neither equilateral nor scalene, &c., for such a triangle, as it cannot exist in nature, cannot be conceived in idea. In like manner, the general term virtue does not excite a general idea of virtue, which is neither prudence, nor temperance, nor fortitude, nor justice, nor charity, &c., for that which is difficult from all these is not virtue. What then is the import of such general terms? The answer is obvious: They denote certain objects, and are never used without some word of limitation, but when something that has no dependence upon the particular qualities, which distinguish the individuals from each other, is affirmed or denied of the whole class. Thus we may affirm, that the three angles of a plane triangle are equal to two right angles; and this proposition is demonstrably true, not of a triangle, which is neither obtuse nor rectilinear, neither equilateral nor scalene, for such a triangle never was conceived; but of all those triangles equally, as the truth of the proposition and the progress of the demonstration has no dependence upon the peculiarities which distinguish these triangles from one another. Again, when we say that a man of virtue will be rewarded by God, we do not mean by the word virtue a general idea making part of each of the complex and more particular ideas of prudence, fortitude, justice, &c., and at the same time different from them all; but we affirm, that the man who practices any or all of these virtues, according as he has opportunity, will be rewarded by God.

The history of our ideas is shortly this:—That act of the mind, if it may be called an act, which makes known an external object, is termed perception. That act of the mind which makes known an internal object, is termed consciousness. Objects once perceived may be recalled to the mind by the power of memory; and when they are so recalled, we have a perception of them in all respects similar to the original perception, only less defined: we fancy ourselves in the same place, and the object perceived attended by the same circumstances. This indistinct, secondary perception of an object is termed an idea; and therefore the precise and accurate definition of an idea, in contradistinction to an original perception, is "that perception of a real object which is raised in the mind by the power of memory." Now all our original perceptions being of particular objects, it is obvious that our ideas, which are only those perceptions recalled, must be of particular objects likewise, and that no man can have an idea of a thing of which the real existence is contradictory and impossible. But the general and specific ideas of logicians, are ideas of nothing which exists, or which can possibly exist. They are acquired, we are told, by abstraction, in the following manner. Among a number of individuals we perceive certain qualities the same in all, whilst in each individual there are other qualities which have nothing similar to them in any other individual: now the mind, it is said, has a power of abstracting the particular qualities of each individual from those which are common to the whole, and of these last forming a general idea of the whole class. Thus all men have nearly the same form; and they have each some stature and some colour, though there are not perhaps two individuals who have precisely the same stature and the same colour. Now, say the advocates for general ideas, if we abstract what is peculiar to each individual, and retain what is common to the whole race, we have the general idea signified by the word man. That is, if we conceive a being in human shape, which is of stature and colour, but neither tall nor short, neither white nor black, nor red nor brown, nor any other colour which we ever saw, we have the general idea of humanity, and understand the meaning of the word man! Surely no person who is not the slave of prejudice will pretend that he can frame such an idea as this—the idea of an object which cannot possibly exist in nature.

By this we do not mean to affirm, that we cannot frame ideas of such objects as have no real existence; for it is as easy to imagine a man with ten heads as with one, because there is nothing contradictory between ten heads and one body. But figure, which is said to be space bounded neither by lines nor figures: colour, which is neither red nor white, nor blue nor black, &c.; and animal, which is neither man, beast, bird, nor insect, are impossible in nature, and inconceivable in idea. There is, however, no harm in still retaining the phrase general idea, provided he who uses it takes care to let it be known, that by these words he means not any abstract and contradictory idea, but merely a class of real objects. The phrase may at times pretend much circumference; for which reason we have retained the use of it in the text.
LOGIC.

22

And in all the inferior species, by superadding the specific difference to the nearest genus, the species is formed by superadding some new idea to the species next above it; infomuch that in this descending scale of our perceptions, the understanding passes through different orders of complex notions, which become more and more complicated at every step it takes. Let us return here, for instance, the species of plain figures. They imply no more than space bounded by lines. But if we take in an additional consideration of the nature of these lines, as whether they are right or curves, we fall into the subdivisions of plain figure, distinguished by the names of rectilinear, curvilinear, and mixtilinear.

VII. And here we are to observe, that though plain figures, when considered as one of those branches that come under the notion of figure in general, take the name of a species; yet compared with the classes of curvilinear, rectilinear, and mixtilinear, into which they themselves may be divided, they really become a genus, of which the before mentioned subdivisions constitute the several species. These species, in the same manner as in the case of plain and solid figures, confit of the genus and specific difference as their constituent parts. For in the curvilinear kind, the curvature of the lines bounding the figure makes what is called the specific difference; to which if we join the genus, which here is a plain figure or space circumfered by lines, we have all that is necessary towards completing the notion of this species. We are only to take notice, that this last subdivision, having two genera above it, viz. plain figure, and figure in general: the genus joined with the specific difference, in order to constitute the species of curvilinears, is that which lies nearest to the said species. It is the notion of plain figure, and not of figure in general, that, joined with the idea of curvity, makes up the complex conception of curve-lined figures. For in this descending scale of our ideas, figure in general, plain figures, curve-lined figures, the two first are considered as general in respect of the third; and the second in order, or that which stands next to the third, is called the nearest genus. But now as it is this second idea, which, joined with the notion of curvity, forms the species of curve-lined figures; it is plain, that the third or last idea in the series is made up of the nearest genus and specific difference. This rule holds invariably, however far the series is continued; because, in a train of ideas thus succeeding one another, all that precede the last are considered as so many genera in respect of that last; and the last itself is always formed by superadding the specific difference to the genus next it.

VIII. Here then we have an universal description, applicable to all our ideas of whatever kind, from the highest genus to the lowest species. For taking them, in order downwards from the said general idea, they every where consist of the genus proximum, and differentia specifica, as logicians love to express themselves. But when we come to the lowest species of all, comprehending under it only individuals, the superadded idea, by which these individuals are distinguished one from another, no longer takes the name of the specific difference. For here it serves not to denote distinct species, but merely a variety of individuals, each of which, having a particular existence of its own, is therefore numerically different from every other of the same kind. And hence it is, that in this last case, logicians choose to call the superadded idea by the name of numerical difference; infomuch that, as the idea of a species is made up of the nearest genus and specific difference, so the idea of an individual consists of the lowest species and numerical difference. Thus the circle is a species of curve-lined figures, and what we call the lowest species, as comprehending under it only individuals. Circles in particular are distinguished from one another by the length and position of their diameters. The length therefore and position of the diameter of a circle form what logicians call the numerical difference; because, these being given, the circle itself may be described, and an individual thereby constituted.

IX. Thus the mind, in compounding its ideas, begins, we see, with the most general notions, which, consisting of but a few simple notices, are easily combined and brought together into one conception. Thence it proceeds to the species comprehended under this general idea, and these are formed by joining together the genus and specific difference. And as it often happens, that these species may be still further subdivided, and run on in a long series of continued gradations, producing various orders of compound perceptions; so all these several orders are regularly and successively formed by annexing in every step the specific difference to the nearest genus. When by this method of procedure we are come to the lowest order of all, by joining the species and numerical difference, we frame the ideas of individuals. And here the series necessarily terminates, because it is impossible any farther to bound or limit our conceptions. This view of the composition of our ideas, representing their constituent parts in every step of the progression, naturally points out the true and genuine form of a definition. For as definitions are no more than descriptions of the ideas for which the terms defined stand; and as ideas are then described, when we enumerate definitions of individuals, the parts of which they consist; it is, that by making our definitions follow one another according to the natural train of our conceptions, they will be subject to the same rules, and keep pace with the ideas they describe.

X. As therefore the first order of our compound notions, or the ideas that constitute the highest genus in the different scales of perception, are formed by uniting together a certain number of simple notices; so to the terms expressing these genera are defined by enumerating the simple notices so combined. And as the species comprehended under any genus, or the complex ideas of the second order, arise from superadding the specific difference to the said general idea; so the definition of the names of the species is abridged, in a detail of the ideas of the specific difference, connected with the term of the genus. For the genus having been before defined, the term by which it is expressed stands for a known idea, and may therefore be introduced into all subsequent definitions, in the same manner as the names of simple perceptions. It will now be sufficiently obvious, that the definitions of all the succeeding orders of compound notions will every where consist of the term of the nearest genus, joined with an enumeration of the ideas that constitute the specific...
of a definition, in all the various orders of conception. This is that method of defining which is commonly called logical, and which we see is perfect in its kind, inasmuch as it presents a full and adequate description of the idea for which the term defined stands.

Part II. OF JUDGEMENT.

CHAP. I. Of the grounds of Human Judgement.

The mind being furnished with ideas, its next step in the way to knowledge is, the comparing these ideas together in order to judge of their agreement or disagreement. In this joint view of our ideas, if the relation is such as to be immediately discoverable by the bare inspection of the mind, the judgments hence obtained are called intuitive, from a word that denotes to look at; for in this case, a mere attention to the ideas compared suffices to let us see how far they are connected or disjointed. Thus, that the whole is greater than any of its parts, is an intuitive judgment; nothing more being required to convince us of its truth, than an attention to the ideas of whole and part. And this too is the reason why we call the act of the mind forming these judgments intuition; as it is indeed no more than an immediate perception of the agreement or disagreement of any two ideas.

II. But here it is to be observed, that our knowledge of this kind respects only our ideas, and the relations between them; and therefore can serve only as a foundation to such reasonings as are employed in investigating these relations. Now it so happens, that many of our judgments are conversant about facts, and the real existence of things, which cannot be traced by the bare contemplation of our ideas. It does not follow, because I have the idea of a circle in my mind, that therefore a figure answering to that idea has a real existence in nature. I can form to myself the notion of a certain golden mountain, but never imagine on that account that either of them exists. What then are the grounds of our judgement in relation to facts? experience and testimony. By experience we are informed of the existence of the several objects which surround us, and operate upon our senses. Testimony is of a wider extent, and reaches not only to objects beyond the present sphere of our observation, but also to facts and transactions, which belong to the past, and having no longer any existence, could not without this conveyance have fallen under our cognizance.

III. Here we have three foundations of human judgment, from which the whole system of our knowledge may with ease and advantage be derived. First, intuition, which respects our ideas themselves, and their relations; and is the foundation of that species of reasoning which we call demonstration. For whatever is deduced from our intuitive perceptions, by a clear and connected series of proofs, is said to be demonstrated, and produces absolute certainty in the mind. Hence the knowledge obtained in this manner is what we properly term certain; because in every step of the procedure it carries its own evidence along with it, and leaves no room for doubt or hesitation.

And what is highly worthy of notice; as the truths of this class express the relation between our ideas, and the same relations must ever and invariably subsist between the same ideas, our deductions in the way of science constitute what we call eternal, necessary, and immutable truths. If it be true that the whole is equal to all its parts, it must be unchangeably; because the relation of equality being attached to the ideas themselves, must ever intervene where the same ideas are compared. Of this nature are all the truths of natural religion, morality, and mathematics, and in general whatever may be gathered from the bare view and consideration of our ideas.

IV. The second ground of human judgment is experience; from which we infer the existence of those subjects that surround us, and fall under the immediate notice of our senses. When we see the sun, or cast our eyes towards a building, we not only have perceptions of those objects within ourselves, but ascribe to them a real existence out of the mind. It is also by the information of the senses that we judge of the qualities of bodies; as when we say that snow is white, fire hot, or steel hard. For we are wholly unacquainted with the internal structure and constitution of the bodies that produce these sensations in us, and are unable to trace any connection between that structure and the sensations themselves, it is evident, that we build our judgments, altogether upon observation, ascribing to bodies such qualities as are answerable to the perceptions they excite in us. Not that we ever suppose the qualities of bodies to be things of the same nature with our perceptions; for there is nothing in fire similar to our sensation of heat, or in a sword similar to pain; but that when different bodies excite in our minds similar perceptions, we necessarily ascribe to these bodies not only an existence independent of us, but likewise similar qualities, of which it is the nature to produce similar perceptions in the human mind. But this is not the only advantage derived from experience; for to that too are we indebted for all our knowledge regarding the coexistence of sensible qualities in objects, and the operations of bodies one upon another. Ivory, for instance, is hard and elastic; this we know by experience, and indeed by that alone. For, being altogether strangers to the true nature both of elasticity and hardness, we cannot by the bare contemplation of our ideas determine how far the one necessarily implies the other, or whether there may not be a repugnance between them. But when we observe them to exist both in the same object, we are then assured from experience that they are not incompatible; and when we also find, that a stone is hard and not elastic, and that air though elastic is not hard, we also conclude upon the same foundation, that the ideas are not necessarily contained, but;
but may exist separately in different objects. In like manner with regard to the operations of bodies one upon another, it is evident that our knowledge this way is all derived from observation. *Aqua regia* dissolves gold, as has been found by frequent trial, nor is there any other way of arriving at the discovery. Naturalists may tell us, if they please, that the parts of *aqua regia* are of a texture apt to intermingle between the corpuscles of gold, and thereby loosen and shake them affunder. If this is a true account of the matter, it will notwithstanding be allowed, that our conjecture in regard to the conformation of these bodies is deduced from the experiment, and not the experiment from the conjecture. It was not from any previous knowledge of the intimate structure of *aqua regia* and gold, and the aptness of their parts to act or to be acted upon, that we came by the conclusion above-mentioned. The internal conformation of bodies is in a manner wholly unknown to us; and could we even surmount this difficulty, yet as the separation of the parts of gold implies something like an active force in the *menstruum*, and we are unable to conceive how it comes to be possefied of this activity, the effect must be owned to be altogether beyond our comprehension. But when repeated trials had once confirmed it, in much that it was admitted as an established truth in natural knowledge, it was then easy for men to spin out theories of their own invention, and contrive such a structure of parts, both for gold and *aqua regia*, as would best serve to explain the phenomenon upon the principles of that system of philosophy they had adopted.

V. From what has been said it is evident, that as intuition is the foundation of what we call *scientifical knowledge*, so is experience of *natural*. For this last being wholly taken up with objects of sense, or those bodies that constitute the natural world; and their properties, as far as we can discover them being to be traced only by a long and painful series of observations; it is apparent, that, in order to improve this branch of knowledge, we must betake ourselves to the method of trial and experiment.

VI. But though experience is what we may term the immediate foundation of natural knowledge, yet with respect to particular persons its influence is very narrow and confined. The bodies that surround us are numerous, many of them lie at a great distance, and some quite beyond our reach. Life is so short and so crowded with cares, that but little time is left for any single man to employ himself in unfolding the mysteries of nature. Hence it is necessary to admit many things upon the testimony of others, which by this means becomes the foundation of a great part of our knowledge of body. No man doubts of the power of *aqua regia* to dissolve gold, though perhaps he never himself made the experiment. In these therefore and such like cases we judge of the facts and operations of nature upon the mere ground of testimony. However, as we can always have recourse to experience where any doubt or scruple arises, this is justly considered as the true foundation of natural philosophy; being indeed the ultimate support upon which our afferent relies, and whereto we appeal when the highest degree of evidence is required.

VII. But there are many facts that will not allow of an appeal to the senses; and in this case testimony is the true and only foundation of our judgments.

30. All human actions of whatever kind, when considered as already past, are of the nature here described; because having now no longer any existence, both the facts themselves, and the circumstances attending them, can be known only from the relations of such as had sufficient opportunities of arriving at the truth. *Testimony* therefore is justly accounted a third ground of human judgment; and as we may observe in the other two we have deduced *scientifical* and *natural* knowledge, so we may from this derive *historical*, by which we mean not merely a knowledge of the civil transactions of states and kingdoms, but of all facts whatsoever, where testimony is the ultimate foundation of our belief.

**Part II.**

**CHAP. II. Of Affirmative and Negative Propositions.**

I. While the comparing of our ideas is considered merely as an act of the mind, assembing them together and predicating a relation of known idea to another; the comparing of our judgments are put into words, they then bear the name of *propositions*. A proposition therefore is a sentence expressing some judgment of the mind, whereby two or more ideas are agreed or disagreed. Now, as our judgments include at least two ideas, one of which is affirmed or denied of the other, so must a proposition have terms answering to these ideas. The idea of which we affirm or deny, and of course the term expressing that idea, is called the *subject* of the proposition. The idea affirmed or denied, as also the term answering it, is called the *predicate*. Thus in the proposition, *God is omnipotent*; *God* is the subject, it being of him that we affirm omnipotence; and *omnipotent* is the predicate, because we affirm the idea expressed by that word to belong to God.

II. But as, in propositions, ideas are either joined or disjoined, it is not enough to have terms expressing those ideas, unless we have also some words to denote their agreement or disagreement. That word in a proposition, which connects two ideas together, is called the *copula*; and if a negative particle be annexed, we thereby understand that the ideas are disjoined. *The subjunctive* verb is commonly made use of for the copula: as in the above-mentioned proposition, *God is omnipotent*, where *is* represents the copula, and signifies the agreement of the ideas of God and omnipotence. But if we mean to separate two ideas; then besides the subjunctive verb, we must also use some particle of negation, to express this repugnance. The proposition, *man is not perfect*, may serve as an example of this kind; where the notion of perfection being removed from the idea of *man*, the negative particle *not* is inferred after the copula, to signify the disagreement between the subject and predicate.

III. Every proposition necessarily consists of three parts: but then it is not alike needful that they should be all severally expressed in words because the copula times expressed by a single word.

The negative *not* is often included in the term of the predicate, as when we say, *he is fitting*, in the Latin language, a single word has often the force of a whole sentence. Thus *ambulat* is the same as *est omnium amans*; *ego sum amans*; and so in innumerable
Part II. LOGIC

innumerable other instances: by which it appears, that we are not so much to regard the number of words in a sentence, as the ideas they represent, and the manner in which they are put together. For wherever two ideas are joined or disjoined in an expression, though but of a single word; it is evident that we have a subject, predicate and copula, and of consequence a complete proposition.

IV. When the mind joins two ideas, we call it an affirmative judgment; when it separates them, a negative; and as any two ideas compared together must necessarily either agree or not agree, it is evident that all our judgments fall under these two divisions. Hence likewise the propositions expressing these judgments are all either affirmative or negative. An affirmative proposition connects the predicate with the subject, as a stone is heavy; a negative proposition separates them, as God is not the author of evil. Affirmation therefore is the same as joining two ideas together, and this is done by means of the copula. Negation on the contrary marks a repugnance between the ideas compared; in which case a negative particle must be called in, to show that the connection included in the copula does not take place.

V. Hence we see the reason of the rule commonly laid down by logicians, That, in all negative propositions the negation ought to affect the copula. For as the copula, when placed by itself, between the subject and the predicate, manifestly binds them together; it is evident, that in order to render a proposition negative, the particles of negation must enter it in such a manner as to destroy this union. In a word, then, only are two ideas disjoined in a proposition, when the negative particle may be so referred to the copula, as to break the affirmation included in it, and undo that connection it would otherwise effectually. When we say, for instance, No man is perfect; take away the negation, and the copula of itself plainly unites the ideas in the proposition. But as this is the very reverse of what is intended, a negative mark is added, to show that this union does not take place. The negation, therefore, by destroying the effect of the copula, changes the very nature of the proposition, insomuch that, instead of binding two ideas together, it denotes their separation. On the contrary, in this sentence, The man who departs not from an upright behaviour is beloved of God, the predicate beloved of God is evidently affirmed of the subject an upright man so that notwithstanding the negative particle, the proposition is still affirmative. The reason is plain: the negation here affects not the copula; but, making properly a part of the subject, serves, with other terms in the sentence, to form one complex idea, of which the predicate beloved of God is directly affirmed.

Chapter III. Of Universal and Particular Propositions.

I. The next considerable division of propositions is into universal and particular. Our ideas, according to what has been already observed in the First Part, are all singular as they enter the mind, and represent individual objects. But as by abstraction we can render them universal, so as to comprehend a whole class of things, and sometimes several classes at once; hence the terms expressing these ideas must be in like manner universal. If therefore we suppose any general term to become the subject of a proposition, it is evident, that whatever is affirmed of the abstract idea belonging to that term, may be affirmed of all the individuals to which that idea extends. Thus, when we say, Men are mortal; we consider mortality not as confined to one or any number of particular men, but as what may be affirmed without restriction of the whole species. By this means the proposition becomes as general as the idea which makes the subject of it; and indeed derives its universality entirely from that idea, being more or less so according as this may be extended to more or fewer individuals. But it is further to be observed of these general terms, that they sometimes enter a proposition in their full latitude, as in the example given above; and sometimes appear with a mark of limitation. In this last case we are given to understand, that the predicate agrees not to the whole universal idea, but only to a part of it; as in the proposition, Some men are wise. For here wisdom is not affirmed of every particular man, but restricted to a few of this species.

II. Now from this different appearance of the general idea that constitutes the subject of any judgment, arises the division of propositions into universal and particular. An universal proposition is that where the subject is some general term taken in its full latitude; insomuch that the predicate agrees to all the individuals comprehended under it, if it denotes a proper species; and to all the several species, and their individuals, if it marks an idea of a higher order.

The words all, every, no, none, &c. are the proper signs of this universality; and as they seldom fail to accompany general truths, so they are the most obvious criterion whereby to distinguish them. All animals have a power of beginning motion. This is an universal proposition; as we know from the word all prefixed to the subject animals, which denotes that it must be taken in its full extent. Hence the power of beginning motion may be affirmed of all the several species of animals.

III. A particular proposition has in like manner a more general term for its subject; but with a mark of particular limitation added, to denote, that the predicate agrees only to some of the individuals comprehended under a species, or to one or more of the species belonging to any genus and not the whole universal idea. Thus, Some flowers are heavier than iron: Some men have an uncommon face of prudence. In the last of these propositions, the subject some men implies only a certain number

(a) See the preceding notes, where it is demonstrated that the terms alone, and not the ideas, are in reality general. The term man is equally applicable to every individual of the human race; and therefore, what is affirmed or denied of men in general, is affirmed or denied of all the individuals, without regard to their discriminating qualities. Some is a definite word (see Grammar), which is prefixed to the word men, limits the signification of that general term; and therefore what is affirmed of some men, is affirmed only of part of the race, but that part itself is not ascertained.
Thus soli
dity, a yellow colour, and great weight, are considered as essential qualities of gold; but whether it shall exist as an uniform conjoined mass, is not alike necessary. We see that by a proper menstruum it may be reduced to a fine powder, and that an intense heat will bring it into a state of fusion.

41

Hence a considerable diversity in the several qualities of things arises a considerable difference as to the manner of our judging about them. For all such properties as are inseparable from objects when considered as belonging to any genus or species, are affirmed absolutely and without reference of that general idea. Thus we say Gold is very weighty; a stone is hard; Animals have a power of self motion. But in the case of mutual or accidental qualities, as they depend upon some other consideration distinct from the general idea; that also must be taken into the account, in order to form an accurate judgment. Should we affirm, for instance, of some stones, that they are very susceptible of a rolling motion; the proposition, while it remains in this general form, cannot with any advantage be introduced into our reasonings. An aptness to receive that mode of motion flows from the figure of the stone; which, as it may vary infinitely, our judgment then only becomes applicable and determinate, when the particular figure, of which volatility is a consequence, is also taken into the account. Let us then bring in this other consideration, and the proposition will run as follows: Stones of a spherical form are easily put into a rolling motion. Here we see the condition upon which the predicate is affirmed, and therefore know in what particular cases the proposition may be applied.

III. This consideration of propositions respecting the manner in which the predicate is affirmed of the subject gives rise to the division of them into absolute and to the division conditional.

Absolute propositions are those wherein the general form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional.

45

Thus, which gives rise to the division of them into absolute and to the division conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional.

II. From this diversity in the several qualities of things arises a considerable difference as to the manner of our judging about them. For all such properties as are inseparable from objects when considered as belonging to any genus or species, are affirmed absolutely and without reference of that general idea.

Thus we say Gold is very weighty; a stone is hard; Animals have a power of self motion. But in the case of mutual or accidental qualities, as they depend upon some other consideration distinct from the general idea; that also must be taken into the account, in order to form an accurate judgment. Should we affirm, for instance, of some stones, that they are very susceptible of a rolling motion; the proposition, while it remains in this general form, cannot with any advantage be introduced into our reasonings. An aptness to receive that mode of motion flows from the figure of the stone; which, as it may vary infinitely, our judgment then only becomes applicable and determinate, when the particular figure, of which volatility is a consequence, is also taken into the account. Let us then bring in this other consideration, and the proposition will run as follows: Stones of a spherical form are easily put into a rolling motion. Here we see the condition upon which the predicate is affirmed, and therefore know in what particular cases the proposition may be applied.

III. This consideration of propositions respecting the manner in which the predicate is affirmed of the subject gives rise to the division of them into absolute and to the division conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional.

46

Thus, which gives rise to the division of them into absolute and to the division conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional. Absolute propositions are those wherein the form of the subject gives rise to the division of them into absolute and conditional.

IV. There is not any thing of greater importance in philosophy than a due attention to this division of propositions. If we are careful never to affirm things absolutely but where the ideas are inseparably conjoined, we shall be the less liable to mistake in applying general truths to the particular concerns of human life. It is owing to the exact observance of this rule that mathematicians have been so happy in their discoveries, and that what they demonstrate of magnitude in general may be applied with ease in all obvious occurrences.

V. The truth of it is, particular propositions are then known to be true, when we can trace their connection;
Part II. LOGIC.

And reduces them from particulars to generals.

Division of propositions into simple and compound.

The proper notion of a compound proposition.

I. Hitherto we have treated of propositions, where only two ideas are compared together. These are in the general called simple: because, having but one subject and one predicate, they are the effect of a simple judgment that admits of no subdivision. But if it so happens that several ideas offer themselves to our thoughts at once, whereby we are led to affirm the same thing of different objects, or different things of the same object; the propositions expressing these judgments are called compounds: because they may be resolved into as many others as there are subjects or predicates in the whole complex determination on the mind. Thus, God is infinitely wise and infinitely powerful. Here there are two predicates, infinite wisdom and infinite power, both affirmed of the same subject; and accordingly the proposition may be resolved into two others, affirming these predicates severally. In like manner in the proposition, Neither kings nor people are exempt from death: the predicate is denied of all subjects, and may therefore be separated from them in distinct propositions. Nor is it less evident, that if a complex judgment consists of several subjects and predicates, it may be resolved into as many simple propositions as are the number of different ideas compared together. Riches and honours are apt to elate the mind, and increase the number of our desires. In this judgment there are two subjects and two predicates, and it is at the same time apparent that it may be resolved into four distinct propositions. Riches are apt to elate the mind. Riches are apt to increase the number of our desires. And so of honours.

II. Logicians have divided these compound propositions into a great many different classes; but, in our opinion, not with a due regard to their proper definition. Thus conditionals, causals, relatives, &c. are mentioned as so many distinct species of this kind, though in fact they are no more than simple propositions. To give an instance of a conditional; If a stone is exposed to the rays of the sun, it will contrariwise.

III. A copulative proposition is, where the subjects and predicates are so linked together, that they may be all severally affirmed or denied of one another. Of this kind are the examples of compound propositions given above. Riches and honours are apt to elate the mind, and increase the number of our desires. Neither kings nor people are exempt from death. In the first of these the two predicates may be affirmed severally of each subject, whence we have four distinct propositions. The other furnishes an example of the negative kind where the same predicate, being denied of both subjects, may be also denied of them in separate propositions.

IV. The other species of compound propositions are Or disjunctive called disjunctives; in which, comparing several predicates with the same subject; we affirm that one of them necessarily belongs to it, but leave the particular predicate undetermined. If any one, for example, says, This world either exists of itself, or is the work of some all-wise and powerful cause, it is evident that one of the two predicates must belong to the world; but as the proposition determines not which, it is therefore of the kind we call disjunctive. Such are the two following: The sun either moves round the earth, or is the centre about which the earth revolves. Friendship finds men equal, or makes them so. It is the nature of all propositions of this class, supposing them to be exact in point of form, that upon determining the particular predicate, the rest are of course to be removed, or if all the predicates but one are removed, the one necessarily takes place. Thus in the example given above; if we allow the world to be the work of some wise and powerful cause, we of course deny it to be self-existent; or if we deny it to be self-existent, we must necessarily admit that it was produced by some wise and powerful cause. Now this particular manner of linking the predicates together, so that the establishing one displaces all the rest; or the excluding all but one necessarily establishes that one; cannot otherwise be affected than by means of disjunctive.

C C
LOGIC.

Chapter VI. Of the Division of Propositions into Self-evident and Demonstrable.

1. When any proposition is offered to the view of the mind, if the terms in which it is expressed be understood; and the agreement or disagreement affected is either immediately perceived or found to lie beyond the present reach of the understanding. In the first case, the proposition is said to be self-evident, and admits not of any proof, because a bare attention to the ideas themselves produces full conviction and certainty; nor is it possible to call in any thing more evident by way of confirmation. But where the connection or repugnance comes not so readily under the inspection of the mind, there we must have recourse to reasoning; and if by a clear series of proofs we can make out the truth propounded, innumerable that self-evidence shall accompany every step of the procedure, we are then able to demonstrate what we assert, and the proposition itself is said to be demonstrable. When we affirm, for instance, that it is impossible for the same thing to be and not to be; whoever understands the terms made use of perceives at first glance the truth of what is asserted, nor can he by any efforts bring himself to believe the contrary. The proposition therefore is self-evident, and such that it is impossible by reasoning to make it plainer; because there is no truth more obvious or better known, from which as a consequence it may be deduced. But if we say, This world had a beginning; the assertion is indeed equally true, but it does not partake of the same degree of evidence. We find great difficulty in conceiving how the world could be made out of nothing; and are not brought to a free and full content, until by reasoning we arrive at a clear view of the absurdity involved in the contrary supposition. Hence this proposition is of the kind which we call demonstrable, inasmuch as its truth is not immediately perceived by the mind, but yet may be made appear by means of others more known and obvious, whence it follows as an unavoidable consequence.

2. From what has been said, it appears, that reasoning is employed only about demonstrable propositions, and that our intuitive and self-evident perceptions are the ultimate foundation on which it rests.

3. Self-evident propositions furnish the first principles of reasoning; and it is certain, that if in our researches we employ only such principles as have this character of self-evidence, and apply them according to the rules to be afterwards explained, we shall be in no danger of error in advancing from one discovery to another. For this we may appeal to the writings of the mathematicians, those being conduct-ed by the express model herein mentioned, are an incontrovertible proof of the firmness and ability of human knowledge, when built upon so sure a foundation. For not only have the propositions of this science flourished the test of ages; but are found attended with that self-evident evidence, as forces the assent of all who duly con-

4. On the mathematicians being very careful in ascertaining their ideas, and fixing the signification of their terms. For the mathematicians, when thus engaged, they begin with definitions, in which the meaning of their ideas is so distinctly explained, that they cannot fail to excite in the mind of an attentive reader the very same ideas as are annexed to them by the writer. And indeed the clearness and irresistible evidence of mathematical knowledge is owing to nothing so much as this care in laying the foundation. Where the relation between any two ideas is accurately and justly traced, it will not be difficult for another to comprehend that relation, if in setting himself to discover it he brings the very same ideas into comparison. But if, on the contrary, he affixes his words ideas different from those that were in the mind of him who advanced the demonstration; it is evident, that the very same ideas are not compared, the same relation cannot subsist, inasmuch that a proposition will be rejected as false, which, had the terms been rightly understood, must have appeared incontrovertibly true. A square, for instance, is a figure bounded by four equal right lines, joined together at right angles. Here the nature of the angles makes no lefs a part of the idea than the equality of the sides; and many properties demonstrated of the square flow entirely from its being a rectangular figure. If therefore we suppose a man, who has formed a partial notion of a square, comprehending only the quality of its sides, without regard to the angles, reading some demonstration that implies also this latter consideration; it is plain he would reject it as not universally true, inasmuch as it could not be applied where the sides were joined together at equal angles. For this last figure, answering still to his idea of a square, would be yet found without the property assigned to it in the proposition. But if he comes afterward to correct his notion, and render his idea complete, he will then readily own the truth and justness of the demonstration.

5. We see, therefore, that nothing contributes so much to the improvement and certainty of human knowl-edge, as the having determinate ideas, and keeping them steady and invariable in all our discourse and reasonings about them. And on this account it is, that mathematicians, as before observed, always begin by defining their terms, and distinctly unfolding the notions they are intended to express; they advancing such as apply themselves to these studies have exactly the same views of things; and, bringing always the very same ideas into comparison, readily discern the relations between them. It is like-wise of importance, in every demonstration, to express the same idea invariably by the same word. From this practice mathematicians never deviate; and if it be necessary in their demonstrations, where the reader's comprehension is assisted by a diagram, it is much more so in all reasonings about moral or intellectual truths where the ideas cannot
cannot be represented by a diagram. The observation of this rule may sometimes be productive of ill-founding periods; but when truth is the object found ought to be despised.

VI. When the mathematicians have taken this first step, and made known the ideas whose relations they intend to investigate; their next care is, to lay down some self-evident truths, which may serve as a foundation for their future reasonings. And here indeed they proceed with remarkable circumspection, admitting no principles but what flow immediately from their definitions, and necessarily force themselves upon a mind in any degree attentive to its ideas. Thus a circle is a figure formed by a right line moving round some fixed point in the same plane. The fixed point round which the line is suppos’d to move, and where one of its extremities terminates, is called the centre of the circle. The other extremity, which is conceived to be carried round until it returns to the point whence it first set out, describes a curve running into itself, and is called the circumference. All right lines drawn from the centre to the circumference are called radii. From these definitions compared, geometers derive this self-evident truth; that the radii of the same circle are all equal to one another.

VII. We now observe, that in all propositions we either affirm or deny some property of the idea that constitutes the subject of our judgment, or we maintain that something may be done or effected. The first sort are called speculative propositions, as in the example mentioned above, the radii of the same circle are all equal to one another. The others are called practical, for a reason too obvious to be mentioned; thus, that a right line may be drawn from one point to another is a practical proposition; inasmuch as it expresses that something may be done.

VIII. From this two-fold consideration of propositions arrifes the twofold division of mathematical principles; into axioms and postulates. By an axiom they understand any self-evident speculative truth; as, that the whole is greater than its parts. That things equal to one and the same thing are equal to one another. But a self-evident practical proposition is what they call a postulate. Such are those of Euclid; that a finite right line may be conceived directly forwards; that a circle may be described about any centre with any distance. And here we are to observe that as in an axiom the agreement or disagreement between the subject and predicate must come under the immediate inspection of the mind; so in a postulate, not only the possibility of the thing asserted must be evident at first view, but also the manner in which it may be effected. For where this manner is not of itself apparent, the proposition comes under the notion of the demonstrable kind, and is treated as such by geometrical writers. Thus, to draw a right line from one point to another, is assumed by Euclid as a postulate, because the manner of doing it is so obvious, as to require no previous teaching. But then it is not equally evident, how we are to construct an equilateral triangle. For this reason he advances it as a demonstrable proposition, lays down rules for the exact performance, and at the same time proves, that if these rules are followed, the figure will be justly described.

IX. This leads us to take notice, that as self-evident and demonstrable propositions are distinguished into different kinds, according as they are speculative or practical; so is it also with demonstrable propositions. A demonstrable speculative proposition is by mathematicians called a _theorem_; and a demonstrable practical proposition is called a _problem_. Such is the famous 47th proposition of the first book of the elements, known by the name of the Pythagorean _theorem_; from its supposed inventor Pythagoras, viz. that in every right-angled triangle, the square described upon the side subtending the right-angle is equal to both the squares described upon the sides containing the right-angle. On the other hand, a demonstrable practical proposition is called a _problem_; as where Euclid teaches us to describe a square upon a given right-line.

Corollaries are obvious deductions from theorems or problems.

It may not be amiss to add, that, besides the four kinds of propositions already mentioned, mathematicians have also a fifth, known by the name of corollaries. These are usually subjoined to theorems or problems, and differ from them only in this, that they flow from what is there demonstrated in so obvious a manner as to discover their dependence upon the proposition whence they are deduced, almost as soon as propounded. Thus Euclid having demonstrated, that in every right-angled triangle all the three angles taken together are equal to two right-angles, adds by way of corollary, that all the three angles of any one triangle taken together are equal to all the three angles of any other triangle taken together; which is evident at first sight; because in all cases they are equal to two right ones, and things equal to one and the same thing are equal to one another.

XI. The scholia of mathematicians are indifferently annexed to definitions, propositions, or corollaries; serve the end, and answer the same purposes as annotations upon a purpose of another author. For in them occasion is taken to explain other annotations whatever may appear intricate and obscure in a train of reasoning; to answer objections; to teach the application and use of propositions; to lay open the original and history of the several discoveries made in the science; and, in a word, to acquaint us with all such particulars as deserve to be known, whether considered as points of curiosity or profit.

**PART III. OF REASONING.**

When, for instance, we compare two figures of a different make, in order to judge of their equality or inequality, it is plain, that by merely considering the figures themselves, we cannot arrive at an exact determination; because, by reason of their disagreeing forms, it is impossible to put them together, as that their several parts shall mutually coincide. Here then it be-
comes necessary to look out for some third idea that
will admit of such an application as the present case
requires; wherein if we succeed, all difficulties vanish,
and the relation we are in quest of may be traced with
ease. Thus right-lined figures are all reduced to
squares, by means of which we can measure their
areas, and determine exactly their agreement or disa-
greement in point of magnitude.

II. But how can any third idea serve to discover a
relation between two others? The answer is, By be-
ing compared severally with these others; for such a
comparison enables us to see how for the ideas with
which this third is compared are connected or disjoined
between themselves. In the example mentioned
above of two right-lined figures, if we compare each of
them with some square whose area is known, and find
the one exactly equal to it, and the other less by a
square inch, we immediately conclude that the area of
the first figure is a square inch greater than that of the
second. This manner of determining the relation be-
tween any two ideas, by the intervention of some
third with which they may be compared, is that which
we call reasoning; and is indeed the chief instrument
by which we push on our discoveries, and enlarge our
knowledge. The great art lies in finding out such in-
termediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in

mediate ideas, as, when compared with the others
in the question, will furnish evident and known truths:
because, as will afterwards appear, it is only
knowledge. The great art lies in
finding out such inter-
mediate ideas, as, when compared with the others
in the question, will furni

III. Hence it appears, that every act of reasoning
necessarily includes three distinct judgments; two
wherein the ideas whose relation we want to discover
are severally compared with the middle idea, and a
third wherein they are themselves compared or disjoin-
ed, according to the result of that comparison. Now,
as in the second part of logic our judgments, when put
into words, were called propositions, so here in the
third part the expressions of our reasonings are termed
syllogisms. And hence it follows, that as every act of
reasoning implies three distinct judgments, so every
syllogism must include three distinct propositions. When
a reasoning is thus put into words, and appears in form
of a syllogism, the intermediate idea made ufe of, to
discover the agreement or diſagreement we search for,
is called the middle term; and the two ideas themselves,
with which this third is compared go by the name of the
extremes.

IV. But as these things are best illustrated by ex-
amples; let us, for instance, let ourselves to inquire
whether men are accountable for their actions. As the
relation between the ideas of man and accountable-
ability does not come within the immediate view of the
mind, our first care must be to find out some third idea
that will enable us the more easily to discover and trace it.
A very small measure of reflection is sufficient to in-
form us, that no creature can be accountable for his
actions, unless we suppose him capable of distingui-
hing the good from the bad; that is, unless we suppose
him possessed of reason. Nor is this alone sufficient.
For what would it avail him to know good from bad
actions, if he had no freedom of choice, nor could a-
void the one and pursue the other? hence it becomes
necessary to take in both considerations in the present
case. It is at the same time equally apparent, that
wherever there is this ability of distinguishing good
from bad actions, and of pursuing the one and avoiding
the other, there also a creature is accountable. We
have then got a third idea, with which accountable-
ability is inseparably connected, viz. reason and liberty;
which are here to be considered as making up one
complex conception. Let us now take this middle
idea, and compare it with the other term in the ques-
tion, viz. men, and we all know by experience that it
may be affirmed of him. Having thus by means of
the intermediate idea formed two several judgments,
viz. that man is possessed of reason and liberty; and that
reason and liberty imply accountability; a third obvi-
ously and necessarily follows, viz. that man is accounta-
able for his actions. Here then we have a complete act
of reasoning, in which, according to what has been
already observed, there are three distinct judgments;
two that may be styled previous, inasmuch as they lead
to the other, and arise from comparing the middle
idea with the two ideas in the question: the third is a
consequence of these previous acts, and flows from
combining the extreme ideas between themselves. If
now we put this reasoning into words, it exhibits what
logicians term a syllogism; and, when proposed in due
form, runs thus:

"Every creature possessed of reason and liberty is
accountable for his actions."

Man is a creature possessed of reason and liberty.

Therefore man is accountable for his actions."

V. In this syllogism we may observe, that there are
three several propositions expressing the three judge-
ments implied in the act of reasoning; and so disposed,
as to represent distinctly what passes within the mind in
tracing the more distant relations of its ideas. The two
first propositions answer the previous judgments in
reasoning, and are called the premises, because they
are placed before the other. The third is termed the
conclusion, as being gained in consequence of what was
asserted in the premises. We are also to remember,
that the terms expressing the two ideas whose rela-
tions we enquire after, as here man and accountable-
ability, are in general called the extremes; and that the
intermediate idea, by means of which the relation is
traced, viz. a creature possessed of reason and liberty,
takes the name of the middle term. Hence it follows,
that by the premises of a syllogism we are always to
understand the two propositions where the middle term
is severally compared with the extremes; for these con-
finitie the previous judgments, whence the truth we
are in quest of is by reasoning deduced. The conclu-
sion is that other proposition, in which the extremes
themselves are joined or separated agreeably to what
appears upon the above comparison.

VI. The conclusion is made up of the extreme terms
major and

of the syllogism; and the extreme, which serves as the
minor

predicate of the conclusion, goes by the name of the

major term: the other extreme, which makes the sub-
ject in the name proposition, is called the minor term.

From this distinction of the extremes arises also a dis-
tinction between the premises, where these extremes
are severally compared with the middle term. That
proposition which compares the greater extreme, or
the predicate of the conclusion, with the middle term,
is called the major proposition: the other, wherein
the same middle term is compared with the subject of the
conclusion.
Part III.

LOGIC

65 In a single act of reasoning the premises must be intuitive truths.

66 Reasoning in the higher exercise of it, only a concatenation of syllogisms.

67 Requiring first principles, rises gradually from one judgment to another, and connects them in such manner, that every stage of the progression brings intuitive certainty along with it. And now at length we may clearly understand the definition given above of this distinguishing faculty of the human mind. Reason, we have said, is the ability of deducing unknown truths from principles or propositions that are already known. This evidently appears by the foregoing account, where we see that no proposition is admitted into a syllogism, to serve as one of the previous judgments on which the conclusion rests, unless it is itself a known and established truth, whose connection with self-evident principles has been already traced.

CHAP. II. Of the several kinds of Reasoning; and first, of that by which we determine the Genera and Species of Things.

68 I. All the aims of human reason may in the general be reduced to these two: 1. To rank things under twofold those universal ideas to which they truly belong; and, 2. To ascribe to them their several attributes and properties in consequence of that distribution.

69 II. One great aim of human reason is to determine The first the genera and species of things. We have seen in the First Part of this treatise, how the mind proceeds in framing general ideas +. We have also seen in the Second Part, how by means of these general ideas we come by universal propositions. Now as in these universal propositions we affirm some property of a genus or species, it is plain that we cannot apply this property to particular objects till we have first determined whether they are comprehended under that general idea of which the property is affirmed. Thus there are certain properties belonging to all even numbers, which nevertheless cannot be applied to any particular number; until we have first discovered it to be of the species expressed by that natural name. Hence reasoning begins with referring things to their several divisions and classes in the scale of our ideas; and as these divisions are all distinguished by particular names, we hereby learn to apply the terms expressing general conceptions to such particular objects as come under our immediate observation.

70 III. Now, in order to arrive at these conclusions, by which the several objects of perception are brought under general names, two things are manifestly necessary. First, that we take a view of the idea of the conclusion denoted by that general name and carefully attend to forms of this the fort.
LOGIC.

Part III.

The distinguishing marks which serve to characterize it. Secondly, that we compare this idea with the object under consideration, observing diligently whether in they accord or not. If the idea is found to correspond with the particular object, we then without hesitation apply the general name; but if no such correspondence intervenes, the conclusion must necessarily take a contrary turn. Let us, for instance, take the number eight, and consider by what steps we are led to pronounce it an even number. First, then, we call to mind the idea signified by the expression an even number, viz. that it is a number divisible into two equal parts. We then compare this idea with the number eight, and, finding them manifestly to agree, see at once the necessity of admitting the conclusion. These several judgments, therefore transferred into language, and reduced to the form of a syllogism, appear thus:

I. Every number that may be divided into two equal parts is an even number:

II. The number eight may be divided into two equal parts:

Therefore the number eight is an even number.

IV. Here it may be observed, that where the general idea, to which particular objects are referred, is very familiar to the mind, and frequently in view; this reference, and the application of the general name, seem to be made without any apparatus of reasoning. When we see a horse in the fields, or a dog in the street, we readily apply the name of the species; habit, and a familiar acquaintance with the general idea, suggesting it instantaneously to the mind. We are not however to imagine on this account that the understanding departs from the usual rules of just thinking. A frequent repetition of acts begets a habit; and habits are attended with a certain promptness of execution, that prevents our observing the several steps and gradations by which any course of action is accomplished. But in other instances, where we judge not by precontracted habits, as when the general idea is very complex, or less familiar to the mind, we always proceed according to the form of reasoning established above. A goldsmith, for instance, who is in doubt as to any piece of metal, and finds the species called gold, first examines its properties, and then comparing them with the general idea signified by that name, if he finds a perfect correspondence, no longer hesitates under what classes of metals to rank it.

V. Nor let it be imagined that our researches here, because in appearance bounded to the imposing of general names upon particular objects, are therefore trivial and of little consequence. Some of the most considerable debates among mankind, and such too as nearly regard their lives, interest, and happiness, turn wholly upon this article. Is it not the chief employment of our several courts of judicature to determine in particular instances what is law, justice, and equity? Of what importance is it in many cases to decide a right whether an action shall be termed murder or manslaughter? We see then that no less than the lives and fortunes of men depend upon these decisions. The reason is plain. Actions, when once referred to a general idea, draw after them all that may be affirmed of that idea; inomuch that the determining the species of actions is all one with determining what proportion of praise or displeasure, commendation or blame, &c. ought to follow them. For as it is allowed that murder deserves death; by bringing any particular act under the notion of murder, we of course decide the punishment due to it.

VI. But the great importance of this branch of reasoning, and the necessity of care and circumspection in referring particular objects to general ideas, is still further evident from the practice of the mathematicians. Every one who has read Euclid knows, that he frequently requires us to draw lines through certain points, and according to such and such directions. The figures thence resulting are often figures, parallelograms, or rectangles. Yet Euclid never supposes this from their bare appearance, but always demonstrates it upon the strictest principles of geometry. Nor is the method he takes in anything different from that described above. Thus, for instance, having defined a square to be a figure bounded by four equal sides joined together at right angles; when such a figure arises in any construction previous to the demonstration of a proposition, yet he never calls it by that name until he has shown that its sides are equal, and all its angles right ones. Now this is apparently the same form of reasoning we have before exhibited in proving eight to be an even number.

VII. Having thus explained the rules by which we are to conduct ourselves in ranking particular objects under general ideas, and shown their conformity to ideas, with the practice and manner of the mathematicians; it remains only to observe, that the true way of rendering this part of knowledge both easy and certain, is by habituating ourselves toclear and determine ideas, and keeping them steadily annexed to their respective names. For as all our aim is to apply general words aright, if these words stand for invariably ideas that are perfectly known to the mind, and can be readily distinguished upon occasion, there will be little danger of mistake or error in our reasonings. Let us suppose that, by examining any object, and carrying our attention successively from one part to another, we have acquainted ourselves with the several particulars observable in it. If among these we find such conditions as some general idea is applied to by the understanding, and distinguished by a particular name, the resemblance thus known and perceived necessarily determines the species of the object, and thereby gives it a right to the name by which that species is called. Thus four equal sides, joined together at right angles, make up the notion of a square. As this is a fixed and invariable idea, without which the general name cannot be applied: we never call any particular figure a square until it appears to have these several conditions; and contrariwise, where ever a figure is found with these conditions, it necessarily takes the name of a square. The same will be found to hold in all our other reasonings of this kind, where nothing can create any difficulty in the want of settled ideas. If, for instance, we have not determined within ourselves the precise notion denoted by the word manslaughter, it will be impossible for us to decide whether any particular action ought to bear that name: because, however nicely we examine the action itself, yet, being strangers to the general idea with which it is to be compared, we are utterly unable...
Part III.

LOGIC

unable to judge of their agreement or disagreement. But if we take care to remove this obstacle, and distinctly trace the two ideas under consideration, all difficulties vanish, and the resolution becomes both easy and certain.

VIII. Thus we see of what importance it is towards the improvement and certainty of human knowledge, that we accustom ourselves to clear and determine ideas, and a steady application of words.

CHAP. III.  Of reasoning, as it regards the Powers and Properties of Things, and the Relations of our general Ideas,

I. We now come to the second great end which men have in view in their reasonings; namely, the discovering and ascribing to things their several attributes and properties. And here it will be necessary to distinguish between reasoning, as it regards the sciences, and as it concerns common life.

In the sciences, our reason is employed chiefly about universal truths; and when we have been able to assign the bounds of human knowledge are enlarged. Hence the division of things into various classes, called otherwise genera and species. For these universal ideas being set up as the representatives of many particular things, whatever is affirmed of them may be also affirmed of all the individuals to which they belong. Murder, for instance, is a general idea representing a certain species of human actions. Reason tells us that the punishment due to it is death. Hence every particular action, coming under the notion of murder has the punishment of death, allotted to it. Here then we apply the general truth to some obvious instance; and this is what properly constitutes the reasoning of common life. For men, in their ordinary transactions and intercourse one with another, have, for the most part, to do only with particular objects. Our friends and relations, their characters and behaviour, the constitution of the several bodies that surround us, and the uses to which they may be applied, are what chiefly engage our attention. In all these, we reason about particular things; and the whole result of our reasoning is, the applying the general truths of the sciences in the ordinary transactions of human life. When we see a viper, we avoid it. Wherever we have occasion for the forcible action of water to move a body that makes considerable resistance, we take care to convey it in such a manner that it shall fall upon the object with impetuosity. Now all this happens in consequence of our familiar and ready application of these two general truths. The bite of a viper is mortal. Water, falling upon a body with impetuosity, acts forcibly towards setting it in motion. In like manner, if we set ourselves to consider any particular character, in order to determine the share of praise or displeasure that belongs to it, our great concern is to ascertain exactly the proportion of virtue and vice. The reason is obvious. A just determination, in all cases of this kind, depends entirely upon an application of these general maxims of morality: Virtuous actions deserve praise; vice, disfavour. Hence we are enabled to determine the proportion of each in all cases.

II. Hence it appears that reasoning, as it regards common life, is no more than the ascribing the general properties of things to those several objects with which we are more immediately concerned, according as they are found to be of that particular division or class to which the properties belong. The steps by which we proceed are manifestly these. First, we refer the object under consideration to some general idea or class of things. We then recollect the several attributes of that general idea. And, lastly, we ascribe all those attributes to the present object. Thus, in considering the character of Sempronius, if we find it to be of the kind called virtuous, when we at the same time reflect that a virtuous character is deserving of esteem, it naturally and obviously follows that Sempronius is so too. These thoughts put into a syllogism, in order to exhibit the form of reasoning here required, run thus;

"Every virtuous man is worthy of esteem.
Sempronius is a virtuous man.
Therefore Sempronius is worthy of esteem."

III. By this syllogism it appears, that before we affirm any thing of a particular object, that object must be referred to some general idea. Sempronius is properly worthy of esteem only in consequence of his being a virtuous man, or coming under that general notion. Hence we see the necessary connection of the various parts of reasoning, and the dependence in which they have one upon another. The determining the genera and species of things is, as we have said, one exercise of human reason; and here we find that this exercise is the first in order, and previous to the other, which consists in ascribing to them their powers, properties, and relations. But when we have taken this previous step, and brought particular objects under general names; as the properties we ascribe to them are no other than those of the general idea, it is plain that in order to a successful progress in this part of knowledge, we must thoroughly acquaint ourselves with the several relations and attributes of these our general ideas. When this is done, the other part will be easy, and requires scarce any labour or thought, as being no more than an application of the general form of reasoning represented in the foregoing syllogism. Now, as we have already sufficiently shown how we are to proceed in determining the genera and species of things, which, as we have said, is the previous step to this second branch of human knowledge; all that is further wanting towards a due explanation of it, is, to offer some considerations as to the manner of investigating the general relations of our ideas. This is the highest exercise of the powers of the understanding, and that by means whereof we arrive at the discovery of universal truths: insomuch that our deductions in that way conduce that particular species of reasoning which we have before said regards principally the sciences.

IV. But that we may conduct our own thoughts with some order and method, we shall begin with observing, that the relations of our general ideas are of two kinds; either such as immediately discover themselves upon comparing the ideas one with another; or such as, being more remote and dilated, require art and contrivance to bring them into view. The relations of the first kind furnish us with definite and self-evident truths: those of the second are traced by reasoning, and a due application of intermediate ideas. It is of this last kind that we are to speak here, having dif-
First, an extensive knowledge of intermediate ideas; by means of which things may be compared one with another. Secondly, the skill and talent of applying them happily in all particular instances that come under consideration.

V. In order to our successful progress in reasoning, we must have an extensive knowledge of those intermediate ideas by means of which things may be compared one with another. For it is not every idea that will answer the purpose of our inquiries, but such only as are particularly related to the objects about which we reason, for a composition with them, to furnish evident and known truths; nothing is more apparent, than that the greater variety of conceptions we can call into view, the more likely we are to find some among them that will help us to the truths here required. And, indeed, it is found to hold in experience, that in proportion as we enlarge our views of things, and grow acquainted with a multitude of different objects, the reasoning faculty gathers strength: for, by extending our sphere of knowledge, the mind acquires a certain force and penetration, as being accustomed to examine the several appearances of its ideas, and observe what light they cast one upon another.

VI. This is the reason why, in order to excel remarkably in any one branch of learning, it is necessary to have at least a general acquaintance with the whole circle of arts and sciences. The truth of it is, all the various divisions of human knowledge are very nearly related among themselves, and, in innumerable infinities, serve to illustrate and set off each other. And although it is not to be denied that by an oblique application to one branch of study, a man may make considerable progress, and acquire some degree of eminence in it; yet his views will be always narrow and contracted, and he will want that masterly discernment which not only enables us to pursue our discoveries with ease, but also, in laying them open to others, to spread a certain brightness around them. But when our reasoning regards a particular science, it is further necessary that we more nearly acquaint ourselves with whatever relates to that science. A general knowledge is a good preparation, and enables us to proceed with ease and expedition in whatever branch of learning we apply to. But then, in the minute and intricate questions of any science, we are by no means qualified to reason with advantage until we have perfectly mastered the science to which they belong.

VII. We come now to the second thing required, in order to a successful progress in reasoning; namely, the skill and talent of applying intermediate ideas happily in all particular instances that come under consideration. And here, rules and precepts are of little service. Use and experience are the best instructors. For, whatever logicians may boast of being able to form perfect reasoners by book and rule, we find by experience, that the study of their precepts does not always add any great degree of strength to the understanding. In short, it is the habit alone of reasoning that makes a reasoner. And therefore the true way to acquire this talent is, by being much conversant in those sciences where the art of reasoning is allowed to reign in the greatest perfection. Hence it was that the ancients, who so well understood the manner of forming the mind, always began with mathematics, as the foundation of their philosophical studies. Here the understanding is by degrees habituated to the truth, contracts infallibly a certain fondness for it, and learns never to yield its attention to any proposition but where the evidence is sufficient to produce full conviction. For this reason Plato has called mathematical demonstrations thecharac·tories or purgatives of the soul, as being the proper means to cleanse it from error, and refoke that natural exercise of its faculties in which just thinking confists.

VIII. If therefore we would form our minds to a habit of reasoning closely and in train, we cannot take any more certain method than the exercising ourselves in mathematical demonstrations so as to contract a kind of familiarity with them. Not that we look upon it as necessary that all men should be deep mathematicians, but that, having got the way of reasoning which that study necessarily brings the mind to, they may be able to transfer it to other parts of knowledge, as they shall have occasion.

IX. But although the study of mathematics be of all others the most useful to form the mind and give it an early relish of truth, yet ought not other parts of philosophy to be neglected. For there also we meet with many opportunities of exercising the powers of the understanding; and the variety of subjects naturally leads us to observe all those different turns of thinking that are peculiarly adapted to the several ideas we examine, and the truth we search after. A mind thus trained acquires a certain mastery over its own thoughts, infomuch that it can range and model them at pleasure, and call such into view as best suit its present designs. Now in this the whole art of reasoning consists: from among a great variety of different ideas to single out those that are most proper for the business in hand, and to arrange them together in such order, that from plain and easy beginnings, by gentle degrees, and a continued train of evident truths, we may be infensibly led on to such discoveries, as at our first setting out appeared beyond the reach of human understanding. For this purpose, besides the study of mathematics before recommended, we ought to apply ourselves diligently to the reading of such authors as have distinguished themselves for strength of reasoning and a just and accurate manner of thinking. For it is observable, that a mind exercised and seasoned to truth, seldom refrains satisfied in a bare contemplation of the arguments offered by others; but will be frequently allaying its own strength, and pursuing its discoveries upon the plan its mind prefers, and with its own intermediate ideas, happily in all particular instances, to which it has become accustomed, by a habit of tracing truth from one stage to another, and of investigating those general relations and properties which we afterwards describe to particular things, according as we find them compre-
Part III.

LOGIC.

hended under the abstract ideas to which the properties belong.

CHAP. IV. Of the Forms of Syllogisms.

§4. The figures of syllogisms.

I. Hitherto we have contented ourselves with a general notion of syllogisms, and of the parts of which they consist. It is now time to enter a little more particularly into the subject, to examine their various forms, and lay open the rules of argumentation proper to each. In the syllogisms mentioned in the foregoing chapters, we may observe, that the middle term is the subject of the major proposition, and the predicate of the minor. This disposition, though the most natural and obvious, is not however necessary; it frequently happening, that the middle term is the subject in both the premises, or the predicate in both; and sometimes, directly contrary to its disposition in the foregoing chapters, the predicate in the major, and the subject in the minor. Hence the distinction of syllogisms into various kinds, called figures by logicians. For figure, according to their use of the word, is nothing else but the order and disposition of the middle term in any syllogism. And as this disposition is, we see, fourfold, so the figures of syllogisms thence arising are four in number. When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the first figure: As,

"No work of God is bad;"

"Then natural passions and appetites of men are the work of God;"

"Therefore none of them is bad."

If, on the other hand, it is the predicate of both the premises, the syllogism is said to be the second figure: As,

"Whatever is bad is not the work of God;"

"All the natural passions and appetites of men are the work of God;"

"Therefore the natural passions and appetites of men are not bad."

Again, in the third figure, the middle term is the subject of the two premises: As,

"All Africans are black;"

"All Africans are men;"

"Therefore some men are black."

And lastly, by making it the predicate of the major, and subject of the minor, we obtain syllogisms in the fourth figure: As,

"The only being who ought to be worshipped is the Creator and Governor of the world;"

"The Creator and Governor of the world is God;"

"Therefore God is the only being who ought to be worshipped."

§5. The moods of syllogisms.

II. But, besides this fourfold distinction of syllogisms, there is also a farther subdivision of them in every figure, arising from the quantity and quality, as they are called, of the propositions. By quantity we mean the consideration of propositions, as universal or particular; by quality, as affirmative or negative.

Now as, in all the several dispositions of the middle term, the propositions of which a syllogism consists may be either universal or particular, affirmative or negative; the due determination of these, and so putting them together as the laws of argumentation require, constitute what logicians call the moods of syllogisms. Of these moods there is a determinate number to every figure, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion.

The first figure has only four legitimate moods. The major proposition in this figure must be universal, and the minor affirmative; and it has this property, that it yields conclusions of all kinds, affirmative and negative, universal and particular.

The second figure has also four legitimate moods. Its major proposition must be universal, and one of the premises must be negative. It yields conclusions both universal and particular, but all negative.

The third figure has six legitimate moods. Its minor must always be affirmative; and it yields conclusions both affirmative and negative, but all particular.

III. The division of syllogisms according to mood and figure respects those especially which are known of the other by the name of plain syllogisms; that is, which division of are bounded to three propositions, all simple, and syllogisms, where the extremes and middle term are connected, according to the rules laid down above. But as the mind is not tied down to any one precise form of reasoning, but sometimes makes use of more, sometimes of fewer premises, and often takes in compound and conditional propositions, it may not be amiss to take notice
IV. When in any syllogism the major is a conditional proposition, the syllogism itself is termed conditional. Thus:

"If there is a God, he ought to be worshipped:"

"But there is a God:

"Therefore he ought to be worshipped."

In this example, the major, or first proposition, is, we see, conditional, and therefore the syllogism itself is also of the kind called by that name. And here we are to observe, that all conditional propositions are made of two distinct parts: one expressing the condition upon which the predicate agrees or disagrees with the subject, as in this proposition, *If there is a God;* the other joining or disjoining the said predicate and subject, as here, *he ought to be worshipped.* The first of these parts, or that which implies the condition, is called the antecedent; the second, where we join or disjoin the predicate and subject, has the name of the consequent.

V. In all propositions of this kind, supposing them to be exact in point of form, the relation between the antecedent and consequent must ever be true and real; that is, the antecedent must always contain some certain and genuine condition, which necessarily implies the consequent; for otherwise the proposition itself will be false, and therefore ought not to be admitted into our reasonings. Hence it follows, that when any conditional proposition is affirmed, if we admit the antecedent of that proposition, we must at the same time necessarily admit the consequent; but if we reject the consequent, we are in like manner bound to reject the antecedent. For as the antecedent always expresses some condition which necessarily implies the truth of the consequent; by admitting the antecedent, we allow of that condition, and therefore ought also to admit the consequent. In like manner, if it appears that the consequent ought to be rejected, the antecedent evidently must be too; because, as was just now demonstrated, the admitting of the antecedent would necessarily imply the admission also of the consequent.

VI. There are two ways of arguing in hypothetical syllogisms, which lead to a certain and unavoidable conclusion. For as the major is always a conditional proposition, consisting of an antecedent and a consequent; if the minor admits the antecedent, it is plain that the conclusion must admit the consequent. This is called arguing from the admission of the antecedent to the admission of the consequent, and constitutes that mood or species of hypothetical syllogisms which is distinguished in the schools by the name of the *modus ponendo,* inasmuch as it is the whole conditional proposition, both antecedent and consequent, is established. Thus:

"If God is infinitely wise, and acts with perfect freedom, he does nothing but what is best:"

"But God is infinitely wise, and acts with perfect freedom:"

"Therefore he does nothing but what is best."

Here we see the antecedent or first part of the conditional proposition is established in the minor, and the consequent or second part in the conclusion; whence the syllogism itself is an example of the *modus ponendo.*

But if now we on the contrary suppose that the minor rejects the consequent, then it is apparent that the conclusion must also reject the antecedent. In this case we are led to argue from the removal of the consequent to the removal of the antecedent, and the particular mood or species of syllogism here arising is called by logicians the *modus tollendo*; because in it both antecedent and consequent are rejected or taken away, as appears by the following example.

"If God were not a Being of infinite goodness,"

"he would not confult the happiness of his creatures;"

"But God does consult the happiness of his creatures:"

"Therefore he is a Being of infinite goodness."

VII. These two species take in the whole class of conditional syllogisms, and include all the possible ways of arguing that lead to a legitimate conclusion; for the following reason: that is, from the removal of the antecedent to the removal of the consequent; or from the establishing of the consequent to the establishing of the antecedent. For although the antecedent always expresses some real condition, which, once admitted, necessarily implies the consequent, yet it does not follow that there is therefore no other condition; and if so, then after removing the antecedent, the consequent may still hold, because of some other determination that infers it. When we say, *If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat,* the proposition is certainly true; and, admitting the antecedent, we must also admit the consequent. But as there are other ways by which a stone may gather heat, it will not follow, from the ceasing of the before-mentioned condition, that therefore the consequent cannot take place. In other words, we cannot argue: *But the stone has not been exposed to the rays of the sun; therefore neither has it any degree of heat:* Inasmuch as there are a great many other ways by which heat might have been communicated to it. And if we cannot argue from the removal of the antecedent to the removal of the consequent, no more can we: from the admission of the consequent to the admission of the antecedent: because, as the consequent may flow from a great variety of different suppositions, the allowing of it does not determine the precise supposition, nor only that someone of them must take place. Thus in the foregoing proposition. *If a stone is exposed some time to the rays of the sun, it will contract a certain degree of heat admitting the consequent, viz. that it has contracted a certain degree of heat,* we are not therefore bound to admit the antecedent; that it has been some time exposed to the rays of the sun; because there are many other causes whence the heat may have proceeded. These two ways of arguing, therefore hold not in conditional syllogism.

VIII. As from the major's being a conditional proposition, we obtain the species of conditional syllogisms; so, where it is a disjunctive proposition, the syllogism to which it belongs is also called *disjunctive syllogism,* as in the following example:

"The world is either self-existent, or the work of some finite, or of some infinite Being:"

"But
Part III. LOGIC.

"But it is not self-existent, nor the work of a finite being:"

Therefore it is the work of an infinite Being."

Now, a disjunctive proposition is that, where of several predicates, we affirm one necessarily to belong to the subject, to the exclusion of all the rest, but leave that particular one undetermined. Hence it follows, that as soon as we determine the particular predicate, all the rest are of course to be rejected; or if we reject all the predicates but one, that one necessarily takes place. When therefore, in a disjunctive syllogism, the several predicates are enumerated in the major; if the minor establishes any one of these predicates, the conclusion ought to remove all the rest; or if, in the minor, all the predicates but one are removed, the conclusion must necessarily establish that one. Thus, in the disjunctive syllogism given above, the major affirms one of the three predicates to belong to the earth, viz. self-existence, or that it is the work of a finite, or that it is the work of an infinite Being. Two of these predicates are removed in the minor, viz. self-existence, and the work of a finite being. Hence the conclusion necessarily ascribes to it the third predicate, and affirms that it is the work of an infinite Being. If now we give the syllogism another turn, inasmuch that the minor may establish one of the predicates, by affirming the earth to be the production of an infinite Being, then the conclusion must remove the other two, affording it to be neither self-existent, nor the work of a finite being. These are the forms of reasoning in this species of syllogisms, the justness of which appears at first sight; and that there can be no other is evident from the very nature of a disjunctive proposition.

IX. In the several kinds of syllogisms hitherto mentioned, we may observe, that the parts are complete; that is, the three propositions of which they consist are represented in form. But it often happens, that some one of the premises is not only an evident truth, but also familiar and in the minds of all men; in which case it is usually omitted, whereby we have an imperfect syllogism, that consists of only two propositions. Should we, for instance, argue in this manner:

"Every man is mortal:"

"Therefore every king is mortal:"

the syllogism appears to be imperfect, as consisting but of two propositions. Yet it is really complete; only the minor [every king is a man] is omitted; and left to the reader to supply, as being a proposition familiar and evident that it cannot escape him.

X. These seemingly imperfect syllogisms are called enthymemes; and occur very frequently in reasoning, especially where it makes a part of common conversation. Nay, there is a particular elegance in them, because not displaying the argument in all its parts, they leave somewhat to the exercisme and invention of the mind. By this means we are put upon exerting ourselves, and seem to share in the discovery of what is proposed to us. Now this is the great secret of fine writing, to frame and put together our thoughts, as to give full play to the reader’s imagination, and draw him infensibly into our very views and course of reasoning. This gives a pleasure not unlike to that which the author himself feels in composing. It besides shortens discourse and adds a certain force and liveliness to our arguments, when the words in which they are conveyed favour the natural quickness of the mind in its operations, and a single expression is left to exhibit a whole train of thoughts.

XI. But there is another species of reasoning with two propositions, which seems to be complete in itself, and where we admit the conclusion without supposing any tacit or suppressed judgment in the mind, from which it follows syllogistically. This happens between propositions, where the connection is such, that the admission of one necessarily and at the first sight implies the admission also of the other. For if it be falls out, that the proposition on which the other depends is self-evident, we content ourselves with barely affirming it, and infer that other by a direct conclusion. Thus, by admitting an universal proposition, we are forced also to admit of all the particular propositions comprehended under it, this being the very condition that constitutes a proposition universal. If then that universal proposition chances to be self-evident, the particular ones follow of course, without any farther train of reasoning. Whoever allows, for instance, that things equal to one and the same thing are equal to one another, must at the same time allow, that two triangles, each equal to a square whose side is three inches, are also equal between themselves. This argument therefore,

"Things equal to one and the same thing, are equal to one another:"

"Therefore these two triangles, each equal to the square of a line of three inches, are equal between themselves:" is complete in its kind, and contains all that is necessary towards a just and legitimate conclusion. For the first universal proposition is self-evident, and therefore requires no farther proof. And as the truth of the particular is inseparably connected with that of the universal, it follows from it by an obvious and unavoidable consequence.

XII. Now, in all cases of this kind, where propositions are deduced on from another, on account of aable to syllogisms, we are said to reason by immediate consequence. Such a coherence of propositions manifest at first sight, and forcing itself upon the mind, frequently occurs in reasoning. Logicians have explained at some length the several suppositions upon which it takes place, and allow of all immediate consequences that follow in conformity to them. It is however observable, that these arguments, though seemingly complete, because the conclusion follows necessarily from the single proposition that goes before, may yet be considered as real enthymemes, where major, which is a conditional proposition, is wanting. The syllogism but just mentioned, when preferred according to this view, will run as follows:

"If things equal to one and the same thing, are equal to one another; these two triangles, each equal to a square whose side is three inches, are also equal between themselves."

"But things equal to one and the same thing, are equal to one another:

"Therefore these two triangles, &c. are equal between themselves."

This observation will be found to hold in all immediate
cates consequences whatsoever, insofar that they are in fact no more than enthymes of hypothetical syllogisms. But then it is particular to them, that the ground on which the conclusion rests, namely, its coherence with the minor, is of itself apparent, and seen immediately to flow from the rules and reasons of logic.

XIII. The next species of reasoning we shall take notice of here is what is commonly known by the name of a *forites*. This is a way of arguing, in which a great number of propositions are so linked together, that the predicate of one becomes continually the subject of the next following, until at last a conclusion is formed, by bringing together the subject of the first proposition, and the predicate of the last. Of this kind is the following argument.

"God is omnipotent;"
"An omnipotent being can do every thing possible;"
"He that can do every thing possible, can do whatever involves not a contradiction;"
"Therefore God can do whatever involves not a contradiction."

This particular combination of propositions may be continued to any length we please, without in the least weakening the ground upon which the conclusion rests. The reason is, because the forites itself may be reduced into as many simple syllogisms as there are middle terms in it; where this is found universally to hold, that when such a resolution is made, and the syllogisms are placed in train, the conclusion in the last in the series is also the conclusion of the forites. This kind of argument, therefore, as it serves to unite several syllogisms into one, must stand upon the same foundation with the syllogisms of which it consists, and is indeed properly speaking, no other than a compendious way of reasoning syllogistically.

XIV. What is here said of plain simple propositions may be as well applied to those that are conditional; that is, any number of them may be so joined together in a series, that the consequent of one shall become continually the antecedent of the next following; in which case, by establishing the antecedent of the first proposition, we establish the consequent of the last, or by removing the last consequent remove also the first antecedent. This way of reasoning is exemplified in the following argument.

"If we love any person, all emotions of hatred towards him cease;"
"If all emotions of hatred towards a person cease, we cannot rejoice in his misfortunes;"
"If we rejoice not in his misfortunes, we cannot rejoice with him in his injury;"
"Therefore, if we love a person, we cannot rejoice in his injury."

It is evident that this forites, as well as the last, may be resolved into a series of distinct syllogisms, with this only difference, that here the syllogisms are all conditional.

XV. The last species of syllogism we shall take notice of in this chapter is that commonly distinguished by the name of a *dilemma*. A dilemma is an argument by which we endeavour to prove the absurdity or falsehood of some affirmation. In order to this, we assume a conditional proposition, the antecedent of which is the affirmation to be disproved, and the consequent a disjunctive proposition, enumerating all the possible suppositions upon which that affirmation can take place. If then it appears, that all these several suppositions ought to be rejected, it is plain that the antecedent or affirmation itself must be so too. When therefore such a proposition as that beforementioned is made the major of any syllogism; if the minor rejects all the suppositions contained in the consequent, it follows necessarily, that the conclusion ought to reject the antecedent, which, as we have said, is the very affirmation to be disproved. This particular way of arguing is that which logicians call a *dilemma*, and from the account here given of it, it appears that we may in the general define it to be a hypothetical syllogism, where the consequent of the major is a disjunctive proposition, which is wholly taken away or removed in the minor. Of this kind is the following:

"If God did not create the world perfect in its kind, it must either proceed from want of inclination, or from want of power;"
"But it could not proceed either from want of inclination, or from want of power;"
"Therefore, he created the world perfect in its kind." Or, which is the same thing: It is absurd to say that he did not create the world perfect in its kind."

XVI. The nature then of a dilemma is universally this. The major is a conditional proposition, whose antecedent contains all the several suppositions upon which the antecedent can take place. As therefore these suppositions are wholly removed in the minor, it is evident that the antecedent must be so too; inasmuch that we here always argue from the removal of the consequent to the removal of the antecedent. That is, a dilemma is an argument in the *modus tollens* of hypothetical syllogisms, as logicians love to speak. Hence it is plain, that if the antecedent of the major is an affirmative proposition, the conclusion of the dilemma will be negative; but if it is a negative proposition, the conclusion will be affirmative.

**CHAP. V. Of Induction.**

I. All reasoning proceeds ultimately from first truths, either self-evident or taken for granted; and the first truths of syllogistic reasonings are *general propositions*. But except in the mathematics, and such other particular sciences, as being conversant about mere ideas, have no immediate relation to things without the mind, we cannot assume as truths propositions which are general. The mathematician indeed may be considered as taking his ideas from the beginning in their *general* form. Every *proposition* composed of such ideas is therefore general; and those which are theoretic are reducible to two parts; *terms*, a *predicate*, and a *subject*, with a *copula* generally affirmative. If the agreement or relation between the two terms be not immediate and self evident, he has recourse to an *axiom*, which is a proposition still more general, and which supplies him with a third or *middle* term. This he compares first with the *predicate*, and then with the *subject*, or *vice versa*. These two comparisons, when drawn out in form, make two propositions.
positions, which are called the premises; and if they happen to be immediate and self-evident, the conclusion, consisting of the terms of the question proposed, is said to be demonstrated. This method of reasoning is conducted exactly in the syllogistic form explained in the preceding chapter.

II. But in sciences which treat of things external to the mind, we cannot assume as first principles the most general propositions, and from them infer others less and less general till we descend to particulars. The reason is obvious. Every thing in the universe, whether of mind or body, presents itself to our observation in its individual state; so that perception and judgment employed in the investigation of truth whether physical, metaphysical, moral, or historical, have in the first place to encounter with particulars.

With these reasons begins, or should begin its operations. It observes, tries, canvases, examines, and compares them together, and judges of them by some of those native evidences and original lights which, as they are the first and indispensable inlets of knowledge to the mind, have been called the primary principles of truth. See Metaphysics.

III. "By such acts of observation and judgment, diligently practiced and frequently repeated, on many individuals of the same class or of a similar nature, noting their agreements, marking their differences however small, and rejecting all inferences which, however similar in appearance, are not in effect the same, reason, with much labour and attention, extracts some general laws respecting the powers, properties, qualities, actions, passions, virtues, and relations of real things. This is no hasty, premature, notional abstraction of the mind, by which images and ideas are formed that have no archetypes in nature: it is a rational, operative, experimental process, instituted and executed upon the constitution of beings, in which part compose the universe. By this process reason advances from particulars to generals, from left general to more general, till by a series of slow progression, and by regular degrees, it arrive at the most general notions, called forms of formal causes (c). And by affirming or denying a genus of a species, or an accident of a substance or class of substances, through all the stages of the gradation, we form conclusions, which, if logically drawn, are axioms (p) or general propositions ranged one above another, till they terminate in those that are universal.

IV. "Thus, for instance, the evidence of the external senses is obviously the primary principle from which all physical knowledge is derived. But, whereas nature begins with causes, which, after a variety of changes, produce effects, the senses open upon the effects, and from them, through the flow and painful road of experiment and observation, ascend to causes. By experiments and observations skilfully chosen, artfully conducted, and judiciously applied, the philosopher advances from one stage of inquiry to another in the rational investigation of the general cause of physical truth. From different experiments and observations made on the same individual subject, and from the same experiments and observations made on different subjects of the same kind, by comparing and judging, he discovers some qualities, causes, or phenomena, which, after carefully distinguishing and rejecting all contradictory inferences that occur, he finds common to many. Thus, from many collateral comparisons and judgments formed upon particulars, he ascends to generals; and by a repetition of the same industrious processes and laborious investigation, he advances from general to more general, till at last he is enabled to form a few of the most general, with their attributes and operations, into axioms or secondary principles, which are the well-founded laws enacted and enforced by the God of nature.—This is that just and philosophic method of reasoning which sound logic prefers in this as well as in other parts of learning; by which, through the flow but certain road of experiment and observation, the mind ascends from appearances to qualities, from effects to causes, and from experiments upon many particular subjects forms general propositions concerning the powers and properties of physical body.

(c) Quo veris novit, is, quae ab eis non natu sunt, qualia nec natura viscentium, nec experimentata industria unquam in actum producuntur, nec cogitationem humanae subituat suarent, detegit et exuit.

(c) Hanc verum axiomatam, literally signifies dignity: Hence it is used metaphorically to denote a general truth or maxim, and sometimes any truth that is self-evident, which is called dignity on account of its importance in a process of reasoning. The axioms of Euclid are propositions extremely general; and so are the axioms of the Newtonian philosophy. But these two kinds of axioms have very different origins. The former appear upon a bare consideration of our ideas; whereas the latter is the result of the most laborious induction. Lord Bacon therefore strenuously contends that they should never be taken upon conjecture, or even upon the authority of the learned; but that as they are the general principles and grounds of all our learning, they should be canvassed and examined with the most scrupulous attention, "ut axiomaticum corrigeretur iniquitas, quae plumereque in exemplis vulgaribus fundamentum habent." De Augm. Sc. lib. ii. cap. 2. "Atque illa infirtiva principia ad rationes reddelesse compelle revocemus quoque plane constant." Diffr. O pers.—Dr Tatham makes a division between axioms intuitive and axioms self-evident. Intuitive axioms, according to him, pass through the first inlets of knowledge, and fast direct conviction on the minds, as external objects do on the senses, of all men. Other axioms, though not intuitive, may be properly said to be self-evident; because, in their formation, reason judges by single comparisons without the help of a third idea or middle term; so that they have their evidence in themselves, and though in intuitively framed they cannot be syllogically proved, if this distinction be just, and we think it is, only particular truths can be intuitive axioms.
Lord Bacon, the best and foundest of logicians, called the key of interpretation.

VI. "Instead of taking his axioms arbitrarily out of the great families of the categories (see CATEGORY), and erecting them by his own sophistical invention into the principles upon which his disputation was to be employed, had the analytical genius of Aristotle presented us with the laws of the true INDUCTIVE LOGIC, by which AXIOMS are philosophically formed, and had he with his usual sagacity given us an example of it in a single branch of science; he would have brought to the temple of truth an offering more valuable than he has done by the aggregate of all his logical and philosophical productions.

VII. "In all sciences, except the mathematics, it is only after the INDUCTION process has been indubitably purified and successfully performed, that DEFINITION may be logically and usefully introduced, by beginning with the genus, passing through all the subordinate branches, and marking the specific difference as it depends, till it arrive at the individual, which is the subject of the question. And by adding an affirmation or negation of the attributive of the genus on the species or individual, or of a general accident on the particular substance so defined, making the definition a proposition, the truth of the question will be logically solved without any further process. So that instead of being the first, as employed by the logic in common use, definition may be the last act of reason in the search of truth in general.

VIII. "These AXIOMS or general propositions, thus INDUCTION established, become another species of PRINCIPLES, which may be properly called SECONDARY, and which lay the foundation of the syllogistic method of reasoning. When these are formed, but not before, we may safely admit the maxim with which logicians set out in the exercise of their art, as the great hinge on which their reasoning and disputation turn: From truths that are already known, to derive others which are not known. Or, to state it more comprehensively, so as to apply to probable as well as to scientific reasoning—From truths which are better known, to derive others which are left unknown. Philosophically speaking, syllogistic reasoning is, under general propositions to reduce others which are left general or which are particular; for the inferior ones are known to be true, only as we trace their connection with the superior. Logically speaking, it is, To predicate a genus of a species or individual comprehended under it, or an accident of the substance in which it is inherent.

IX. "Thus INDUCTION and SYLLOGISM are the two methods of direct reasoning corresponding to the two kinds of principles, primary and secondary, on which they are founded, and by which they are respectively conducted. In both methods indeed, reason proceeds by judging and comparing, but the process is different throughout; and though it may have the sanction of Aristotle, an INDUCTION syllogism is a syllepsis.

X. "Till general truths are ascertained by induction, the third or middle terms by which syllogisms are made are no where safely to be found: So that another position of the Sceptic, that syllogism is naturally prior in order to induction, is equally unfounded; for induction does not only naturally but necessarily precede syllogism; and, except in mathematics, is in every respect indispensable to its existence; since, till general principles are established, there can be neither definition, proposition, nor axiom, and of course no syllogism. And as induction is the first, so is it the more essential and fundamental instrument of reasoning: for as syllogism cannot produce its own principles, it must have them from induction; and if the general propositions or secondary principles be imperfectly or infinitely established, and much more if they be taken at hazard, upon authority, or by arbitrary allusion like those of Aristotle, all the syllogizing in the world is vain and useless logomachy, only instrumental to the multiplication of false learning, and to the invention and confirmation of error. The truth of syllogisms depends ultimately on the truth of axioms, and the truth of axioms on the foundations of inductions (a)."—But though induction is prior in order, as well as superior in utility, to syllogism, we have thought it expedient to treat of it last; both because syllogism is an easier exercise of the reasoning faculty than induction, and because it is the method of mathematics, the first science of reason in which the student is commonly initiated.

CHAP. VI. Of Demonstration.

I. Having dispatched what seemed necessary to be said with regard to the two methods of direct reasoning, induction and syllogism; we now proceed to consider the laws of demonstration. And here it must be acknowledged, that in strict demonstration, which removes from the mind all possiblity of doubt or error, the inductive method of reasoning can have no place. When the experiments and observations from which the general conclusion is drawn are numerous and extensive, the result of this mode of reasoning is moral certainty; and could the induction be made complete, it would be absolute certainty, equally convincing with mathematical demonstration. But however numerous and extensive the observations and experiments may be upon which an inductive conclusion is established, they must of necessity come short of the number and extent of nature; which, in some cases, by its imminency, will defeat all possibility of their co-extension; and in others, by its distance, lies out of the reach of their immediate application. Though truth does not appear in all other departments of learning with that bold and resolute conviction with which it prevails in the mathematical science, it shines through them all, if not interrupted by prejudice or perverted by error, with a clear and useful, though inferior strength. And as it is not necessary for the general safety or convenience of a traveller, that he should always enjoy the heat and splendor of a mid-day sun, whilst he can with more ease pursue his journey under the weaker influence of a morning or an evening ray; so it is not requisite, for the various concerns and purposes

(a). This chapter is almost wholly taken from Tatham's Chart and Scale of Truth; a work, which, notwithstanding the ruggedness of its style, has so much real merit as a system of logic, that it cannot be too diligently studied by the young inquirer who wishes to travel by the straight road to the temple of Science.
poses of life, that men should be led by truth of the most redundant brightness. Such truth is to be had only in those sciences which are considered as ideas and their various relations; where every thing being certainly what it appears to be, definitions and axioms arise from mere intuition. Here *sylogism* takes up the process from the beginning; and by a sublime intellectual motion advances from the simplest axioms to the most complicated speculations, and exhibits truth springing out of its first and purest elements, and spreading on all sides into a system of science. As each step in the progress is syllogistic, we shall endeavour to explain the use and application of syllogisms in this species of reasoning.

We have seen, that in all the different appearances they put on, we still arrive at a just and legitimate conclusion; now it often happens, that the conclusion of one syllogism becomes a previous proposition in another; by which means great numbers of them are sometimes linked together in a series, and truths are made to follow one another in train. And as in such a concatenation of syllogisms all the various ways of reasoning that are truly conclusive may be without safety introduced; hence it is plain, that in deducing any truth from its first principles, especially where it lies at a considerable distance from them, we are at liberty to combine all the several kinds of syllogisms above explained, according as they are found best to suit the end and purpose of our enquiries. When a proposition is thus by means of syllogisms, collected from others more evident and known, it is said to be *proved*; so that we may in the general define the proof of a proposition to be a syllogism, or series of syllogisms, collecting that proposition from known and evident truths. But more particularly, if the syllogisms of which the proof consists admit of no premises but definitions, self-evident truths, and propositions already established, then is the argument considered as a *demonstration*; whereby it appears that demonstrations are ultimately founded on definitions and self-evident propositions.

II. All syllogisms whatsoever, whether compound, multiform, or defective, are reducible to plain simple syllogisms in some one of the four figures. But this is not all. Syllogisms of the first figure, in particular, admit of all possible conclusions: that is, any propositions whatsoever, whether an universal affirmative or universal negative, a particular affirmative or particular negative, which fourfold division embraces all their varieties; any one of these may be inferred by virtue of some syllogism in the first figure. By this means it happens that the syllogisms of all the other figures are reducible also to syllogisms of the first figure, and may be considered as standing on the same foundation with them. We cannot here demonstrate and explain the manner of this reduction, because it would too much swell the bulk of this treatise. It is enough to take notice that the thing is universally known and allowed among logicians, to whose writings we refer such as desire farther satisfaction in this matter. This then being laid down, it is plain that any demonstration whatsoever may be considered as composed of a series of syllogisms, all in the first figure. For, since all the syllogisms that enter the demonstration are reducible to syllogisms of some one of the four figures; and since the syllogisms of all the other figures are further reducible to syllogisms of the first figure, it is evident, that the whole demonstration may be resolved into a series of these last syllogisms. Let us now, if possible discover the ground upon which the conclusion rests in syllogisms of the first figure; because, by so doing, we shall come at an universal principle of certainty, wherein the evidence of all demonstrations in all their parts may be ultimately derived.

III. The rules then of the first figure are briefly these. The middle term is the subject of the major ground of proposition, and the predicate of the minor. The reasoning major is always an universal proposition, and the minor, in the first nor always affirmative. Let us now see what effect their rules will have in reasoning. The major is an universal proposition, of which the middle term is the subject, and the predicate of the conclusion the predicate. Hence it appears, that in the major the predicate of the conclusion is always affirmed or denied universally of the middle term. Again, the minor is an affirmative proposition, whereas the subject of the conclusion is the subject, and the middle term the predicate. Here then the middle term is affirmed of the subject of the conclusion; that is, the subject of the conclusion is affirmed to be comprehended under, or to make a part of, the middle term. Thus we see what is done in the premises of a syllogism of the first figure. The predicate of the conclusion is universally affirmed or denied of some idea. The subject of the conclusion is affirmed to be or to make a part of that idea. Hence it naturally and unavoidably follows, that the predicate of the conclusion ought to be affirmed or denied of the subject. To illustrate this by an example, we shall resume one of the syllogisms of the first chapter.

"Every creature possest of reason and liberty is accountable for his actions:"

"Man is a creature possest of reason and liberty;"

"Therefore man is accountable for his actions."

Here, in the first proposition, the predicate of the conclusion, *accountableness*, is affirmed of all creatures that have reason and liberty. Again, in the second proposition, *man*, the subject of the conclusion, is affirmed to be or to make a part of this class of creatures. Hence the conclusion necessarily and unavoidably follows, viz. that man is accountable for his actions; because, if reason and liberty be that which constitutes a creature accountable, and man has reason and liberty, it is plain he has that which constitutes him accountable. In like manner, where the major is a negative proposition, or denies the predicate of the conclusion universally of the middle term, as the minor always affords the subject of the conclusion to be or to make a part of that middle term, it is no less evident that the predicate of the conclusion ought in this case to be denied of the subject. So that the ground of reasoning, in all syllogisms of the first figure, is manifestly this: "Whatever may be affirmed universally of any idea, may be affirmed of every or any number of particulars comprehended under that idea." And again: "Whatever may be denied universally of any idea, may be in like manner denied of every or any number of its individuals. These two propositions are called by logicians the *ditrum de omni*, and *ditrum de nullo*; and are indeed the great principles.
IV. And now we may affirm, that, in all syllogisms of the first figure, if the premises are true, the conclusion must needs be true. If it be true that the predicate of the conclusion is a part of or comprehended under that idea; then it necessarily follows, that the predicate of the conclusion agrees also to the subject. For to affect the contrary, would be to run counter to some one of the two principles before established; that is, it would be to maintain an evident contradiction. And thus we are come at last to the point we have been all along endeavouring to establish; namely, that every proposition which can be demonstrated is necessarily true. For as every demonstration may be resolved into a series of syllogisms all in the first figure; and as in any one of these syllogisms, if the premises are true, the conclusion must needs be so too; it evidently follows, that if all the several premises are true, all these several conclusions are so, and consequently the conclusion also of the last syllogism, which is always the proposition to be demonstrated. Now that all the premises of a demonstration are true, will easily appear from the very nature and definition of that form of reasoning. A demonstration as we have said, is a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions already established. Definitions are identical propositions, wherein we connect the description of an idea with the same by which we choose to have that idea called, and therefore as to their truth there can be no dispute. Self-evident propositions appear true of themselves, and leave no doubt or uncertainty in the mind. Propositions, before established, are no other than conclusions gained by one or more steps from definitions and self-evident principles, that is, from true premises, and therefore must needs be true. Whence all the previous propositions of a demonstration being, we see, manifestly true; the last conclusion, or proposition to be demonstrated, must be so too. So that demonstration not only leads to certain truth, but we have here also a clear view of the ground and foundation of that certainty. For as, in demonstrating, we may be said to do nothing more than combine a series of syllogisms together, all resting on the same bottom; it is plain that one uniform ground of certainty runs through the whole, and that the conclusions are everywhere built upon some one of the two principles before established, as the foundation of all our reasoning. These two principles are easily reduced into one, and may be expressed thus: "Whatever predicate, whether affirmative or negative, agrees universally to any idea; the same must needs agree to every or any number of individuals comprehended under that idea." And thus at length we have, according to our first design, reduced the certainty of demonstration to one simple and universal principle: which carries its own evidence along with it, and which is indeed the ultimate foundation of all syllogistic reasoning.

V. Demonstration therefore serving as an infallible guide to truth, and standing on so sure and unalterable a basis, we may now venture to affirm, that the furnishing of logic furnish a sufficient criterion for the distinguishing between truth and falsehood. For since every proposition that can be demonstrated is necessarily true, he is able to distinguish truth from falsehood who can with certainty judge when a proposition is truly demonstrated. Now, a demonstration is, as we have said, nothing more than a concatenation of syllogisms, all whose premises are definitions, self-evident truths, or propositions previously established. To judge therefore of the validity of a demonstration, we must be able to distinguish whether the definitions that enter it are genuine, and truly descriptive of the ideas they are meant to exhibit: whether the propositions affirmed without proofs as intuitive truths have really that self-evidence to which they lay claim: whether the syllogisms are drawn up in due form, and agreeable to the laws of argumentation: in fine, whether they are combined together in a just and orderly manner, so that no demonstrable propositions serve anywhere as premises unless they are conclusions of previous syllogisms. Now, it is the business of logic, in explaining the several operations of the mind, fully to instruct us in all these points. It teaches the nature and end of definitions, and lays down the rules by which they ought to be framed. It unfolds the several species of propositions, and distinguishes the self-evident from the demonstrable. It defines also the different forms of syllogisms, and explains the laws of argumentation proper to each. In fine, it describes the manner of combining syllogisms, so as that they may form a train of reasoning, and lead to the successive discovery of truths. The doctrine of logic, therefore, as they enable us to judge with certainty when a proposition is duly demonstrated, furnish a sure criterion for the distinguishing between truth and falsehood.

VII. Perhaps it may be objected, that demonstration is a thing very rare and uncommon, as being the tendency to prerogative of but a few sciences, and therefore the all cases criterion here given can be of no great use. But wherever, by the bare contemplation of our ideas, truth is discoverable, there also demonstration may be attained. Now that is an abundantly sufficient criterion which enables us to judge with certainty in all cases where the knowledge of truth comes within our reach; for with discoveries, that lie beyond the limits of the human mind, we have, properly, no business or concernment. When a proposition is demonstrated, we are certain of its truth. When, on the contrary, our ideas are such as have no visible connection or repugnance, and therefore furnish not the proper means of tracing their agreement or disagreement, there we are sure that intellectual knowledge is not attainable. But where there is some foundation of reasoning, which yet amounts not to the full evidence of demonstration, there the precepts of logic, by teaching us to determine aight of the degree of
proof, and of what is still wanting to render it full and complete, enable us to make a due estimation of the measures of probability, and to proportion our affect to the grounds on which the proposition stands. And this is all we can possibly arrive at, or even so much as hope for, in the exercise of faculties so imperfect and limited as ours.

VIII. Now, because this manner of demonstration is accounted for some not altogether to clear and satisfactory; we shall therefore endeavour to show, that it equally with the other leads to truth and certainty. Two propositions are said to be contradictory one of another, when that which is asserted to be in the one is asserted not to be in the other. Thus the propositions, Circles that touch one another inwardly have the same centre, and Circles that touch one another inwardly have not the same centre, are contradictory, because the second involves the direct contrary of what is asserted in the first. Now, in all contradictory propositions, this holds universally, That one of them is necessarily true, and the other necessarily false. For if it be true, that circles which touch one another inwardly have not the same centre; then, and then only, do they have the same centre. On the other hand, if it be false that they have the same centre, it is necessarily true that they have not the same centre. Since then it is impossible for them to be both true or both false at the same time; it unavoidably follows, that one is necessarily true, and the other necessarily false. This then being allowed, which is self-evident; if any two contradictory propositions are assumed, and of these one can by a clear train of reasoning be demonstrated to be false, it necessarily follows that the other is true. For as the one is necessarily true, and the other necessarily false; when we come to discover which is the false proposition, we thereby also know the other to be true.

IX. Now this is precisely the manner of an indirect demonstration, as is evident from the account given of it above. For there we assumed a proposition which directly contradicts that we mean to demonstrate; and, having, by a continued series of proofs shown it to be false, thence infer that its contradictory, or the proposition to be demonstrated is true. As, therefore, thanks that conclusion is certain and unavoidable; let us next inquire after what manner we come to be satisfied of the falsehood of the assumed proposition, that no possible doubt may remain as to the force and validity of demonstrations of this kind. The manner then is plain this: Beginning with the assumed proposition, we, by the help of definitions, self-evident truths, or propositions already established, continue a series of reasoning, in the direct way of demonstration, until at length we arrive at some absurdity or known falsehood. Thus Euclid, in the example before mentioned, from the supposition that circles touching one another inwardly have the same centre, deduces that a part is equal to the whole. Since, therefore, by a due and orderly process of reasoning, we come at last to a false conclusion; it is manifest, that all the premises cannot be true; for, were all the premises true, the last conclusion must be too, by what has been demonstrated. Now, as to all the other premises made use of in the course of reasoning, they are manifest and known truths by supposition, as being either definitions, self-evident propositions, or truths previously established. The assumed proposition is that only as to which any doubt or uncertainty remains. That alone, therefore, can be false; and indeed, from what has been already shown, must unavoidably be so. And thus we see, that in indirect demonstrations, two contradictory propositions being laid down, one of which is demonstrated to be false, the other, which is always the proposition to be proved must necessarily be true; so that here as well as in the direct way of proof, we arrive at a clear and satisfactory knowledge of truth.
A due knowledge of the principles of logic indispensably necessary to make us proper judges of demonstration.

XI. We have a curious instance of this in the twelfth proposition of the ninth book of the Elements. Euclid there proposes to demonstrate, that in any series of numbers rising from unity in geometrical progression, all the prime numbers that measure the last term in the series will also measure the next after unity. In order to this, he assumes the contradictory of the proposition to be demonstrated; namely, that some prime number measuring the last term in the series does not measure the next after unity; and thence, by a continued train of reasoning, proves that it actually does measure it. Hereupon he concludes the affirmed proposition to be false; and that which is deduced from it, or its contradictory, which is the very proposition he proposed to demonstrate, to be true. Now that this is a just and conclusive way of reasoning, is abundantly manifest from what we have so clearly established above. Whence it appears, how necessary some knowledge of the rules of logic is, to enable us to judge of the force, justness, and validity, of demonstrations. For, though it is readily allowed, that by the mere strength of our natural faculties we can at once discern, that of two contradictory propositions, the one is necessarily true, and the other necessarily false; yet when they are so linked together in a demonstration, as that the one serves as a previous proposition whence the other is deduced, it does not so immediately appear, without some knowledge, of the principles of logic, why that alone, which is collected by reasoning, ought to be embraced as true, and the other, whence it is collected, to be rejected as false.

XII. Having thus sufficiently evinced the certainty of demonstration in all its branches, and shown the rules by which we ought to proceed, in order to arrive at a certain conclusion, according to the various ways of arguing, made use of; it is needless to enter upon a particular consideration of the several species of false reasoning, which logicians distinguish by the name of sophisms.

He that thoroughly understands the form and structure of a good argument, will of himself readily discern every deviation from it. And although sophisms have been divided into many classes, which are all called by sounding names, that therefore carry in them much appearance of learning; yet are the errors themselves so very palpable and obvious, that it would be but laborious to write for a man capable of being misled by them. Here, therefore, we choose to conclude this part of logic; and shall in the next give some account of Method, which, though inseparable from reasoning, is nevertheless always considered by logicians as a distinct operation of the mind; because its influence is not confined to the mere exercise of the reasoning faculty, but extends in some degree to all the transactions of the understanding.

PART IV. OF METHOD.

We have now done with the three first operations of the mind, whose office it is to search after truth, and enlarge the bounds of human knowledge. There is yet a fourth, which regards the disposition and arrangement of our thoughts, when we endeavour to put them together as their mutual connection and dependence may be clearly seen. This is what logicians call Method, and place always the last in order in explaining the powers of the understanding; because it necessarily hoppooses a previous excercise of our other faculties, and some progress made in knowledge before we can exert it in any extenfive degree.

II. In this view, it is plain that we must be beforehand well acquainted with the truths we are to combine together; otherwise, how could we discern their several connections and relations, or so dispose of them as their mutual dependence may require? But it often happens, that the understanding is employed, not in the arrangement and composition of known truths, but in the search and discovery of such as are unknown.

Sometimes in the search and discovery of such as are unknown.
IV. And as it is in tracing and examining the works of art, so is it in a great measure, in unfolding any part of human knowledge: for the relations and mutual habits of things do not always immediately appear upon comparing them one with another. Hence we have recourse to intermediate ideas; and, by means of them, are furnished with those previous propositions that lead to the conclusion we are in quest of. And it so happens that the previous propositions themselves are not sufficiently evident, we endeavour, by new middle terms, to ascertain their truth; till tracing things backward, in a continual series, until at length we arrive at some syllogism where the premises are first and self-evident principles. This done, we become perfectly satisﬁed as to the truth of all the conclusions we have passed through, insomuch as they are now seen to stand upon the firm and immoveable foundation of our intuitive perceptions. And as we arrived at this certainty by tracing things backward to the original principles whence they flow; so we may at any time renew it by a direct contrary process, if, beginning with these principles, we carry the train of our thoughts forward until they lead us, by a connected chain of proofs, to the very last conclusion of the series.

V. Hence it appears, that, in disposing and putting together our thoughts, either for our own use, or for the use of others, the discoveries we have made may at all times lie open to the review of the mind, or where we mean to communicate and unfold the discoveries to others, there are two ways of proceeding equally within our choice: for we may propound the truths relating to any part of knowledge, as they presented themselves to the mind in the manner of investigation; carrying on the series of proofs, in a reverse order, until they at last terminate in first principles; or, beginning with these principles, we may take the contrary way, and from them deduce, by a direct train of reasoning, all the several propositions we want to establish. This diversity in the manner of arranging our thoughts gives rise to the twofold division of method established among logicians: for method, according to their use of the word, is nothing else but the order and disposition of our thoughts relating to any subject. When truths are forsooth and put together as they were or might have been discovered, this is called the analytic method, or the method of resolution; insomuch as it traces things backward to their source, and resolves knowledge into its first and original principles. When, on the other hand, they are deduced from these principles, and connected according to their mutual dependence, insomuch that the truths ﬁrst in order tend always to the demonstration of those that follow; this constitutes what we call the synthetic method, or method of composition. For here we proceed by gathering together the several scattered parts of knowledge, and combining them into one whole system, in such manner that the understanding is enabled diffusely to follow truth through all her different stages and gradations.

VI. There is this farther to be taken notice of, in relation to these two species of method; that the ﬁrst has also obtained the name of the method of invention, because it observes the order in which our thoughts succeed one another in the invention or discovery of truth. The other, again, is often denominated the method of deduction or induction; insomuch as, in laying our thoughts before others, we generally choose to proceed in the synthetic manner, deducing them from their ﬁrst principles. For we are to observe, that although there is great pleasure in pursuing truth in the method of investigation, because it places us in the condition of the inventor, and shows the particular train and process of thinking by which he arrived at his discoveries; yet it is not so well accommodated to the purposes of evidence and conviction. For, at our ﬁrst setting out, we are commonly unable to divine where the analysis will lead us; insomuch that our researches are for some time little better than a mere groping in the dark. And even after light begins to break in upon us, we are still obliged to many reviews, and a frequent comparison of the several steps of the investigation among themselves. Nay when we have unravelling the whole, and reached the very foundation on which our discoveries stand, all our certainty, in regard to their truth, will be found in a great measure to arise from this connection, we are now able to discern between them and the ﬁrst principles, taken in the order of composition. But in the synthetic manner of disposing our thoughts, the case is quite different: for we here begin with the intuitive truths, and advance by regular deductions from them, every step of the procedure brings evidence and conviction along with it; so that, in our progress from one part of knowledge to another, we have always a clear perception of the ground on which we stand.

In communicating therefore our discoveries to others, this method is apparently to be chosen, as it wonderfully improves and enlightens the understanding, and leads to an immediate perception of truth.

VII. The logic which for so many ages kept possession of the schools, and was deemed the most important of the sciences, has long been condemned as a mere art of wrangling, of very little use in the pursuit of truth. Attempts have been made to restore it to credit, but without success; and of late years little or no attention whatever has been paid to the art of reasoning in the course of what is called a liberal education. As both extremes may be faulty, it should seem that we cannot conclude this short treatise more properly than with the following Reflections on the Utility of Logic.

If Aristotle was not the inventor of logic, he was certainly the prince of logicians. The whole theory of syllogisms he claims as his own, and as the fruit of much time and labour; and it is universally known, that the later writers on the art have borrowed their materials almost entirely from his Organon and Porphyry’s Introduction. But after men had laboured near 2000 years in search of truth by the help of syllogisms, Lord Bacon proposed the method of induction, as a more effectual engine for that purpose; and since his days the art of logic has gradually fallen into disrepute.

To this consequence many causes contributed. The art of syllogism is admirably calculated for wrangling; and by the schoolmen it was employed with too much strictness, to keep in countenance the absurdities of the Roman church. Under their management it produced numberless disputes, and numberless sects; who
LOGIC.

Part IV.

fought against each other with much animosity without gaining or losing ground; but it did nothing considerable for the benefit of human life, whilst the method of induction has improved arts and increased knowledge. It is no wonder, therefore, that the exclusive admiration of Aristotle, which continued for so many ages, should end in an undue contempt; and that the high esteem of logic, as the grand engine of science, should at last make way for too unfavourable an opinion, which seems now prevalent, of its being unworthy of a place in a liberal education. Men rarely leave one extreme without running into the contrary: Those who think according to the fashion, will be as prone to go into the present extreme as their grandfathers were to go into the former; and even they who in general think for themselves, when they are offended at the abuse of any thing, are too apt to entertain prejudices against the thing itself. "In practice (says the learned Warburton), logic is more a trick than a science, formed rather to amuse than to instruct. And in some sort we may apply to the art of syllogism what a man of wit says of rhetoric, that it only tells us how to name those tools which nature had before put into our hands. In the service of chicanery, indeed, it is a mere juggler's knot, now fast, now loose; and the schools where this legerdemain was exercised in great perfection are full of the stories of its wonders." The authority of Warburton is great; but it may be counterbalanced by another which, on subjects of this nature, is confessedly greater.

"Laying aside prejudice, whether fashionable or unfashionable, let us consider (says Dr Reid) whether logic is or may be made subservient to any good purpose. Its professed end is, to teach men to think, to judge, and to reason, with precision and accuracy. No man will say that this is a matter of little importance: the only thing therefore that can admit of doubt is, whether it can be taught?"

"To resolve this doubt, it may be observed, that our rational faculty is the gift of God, given to men in very different measures: Some have a large portion, some a less; and where there is a remarkable defect of the natural power, it cannot be supplied by any culture. But this natural power, even where it is the strongest, may lie dead for want of the means of improvement. Many a savage may have been born with as good faculties as a Newton, a Bacon, or an Aristotle; but their talents were buried by having never been put to use, whilst those of the philosophers were cultivated to the best advantage. It may likewise be observed, that the chief means of improving our rational power, is the vigorous exercise of it in various ways and on different subjects, by which the habit is acquired of exercising it properly. Without such exercise, and good sense over and above, a man who has studied logic all his life may be only a pertinacious wrangler, without true judgment or skill of reasoning in any science."

This must have been Locke's meaning, when in his Thoughts on Education he says, "If you would have your son to reason well, let him read Chillingworth." The state of things is much altered since Locke wrote: Logic has been much improved chiefly by his writings; and yet much left is laid upon it, and left time consumed in its study. His counsel, therefore, was judicious and reasonable; to wit, That the improvement of our reasoning power is to be expected much more from an intimate acquaintance with the authors who reason best, than from studying voluminous systems of school logic. But if he had meant that the study of logic was of no use, nor deserve any attention, he surely would not have taken the pains to make so considerable an addition to it, by his Effays on the Human Understanding, and by his Thoughts on the Conduct of the Understanding; nor would he have reminded his pupil to Chillingworth, the accented logician as well as the best reasoner of his age."

There is no study better fitted to excercise and strengthen the reasoning powers than that of the mathematical sciences; because there is no other branch of science which gives such scope to long and accurate trains of reasoning, or in which there is so little room for authority or prejudice of any kind to give a false bias to the judgment. When a youth of moderate parts begins to study Euclid, every thing is new to him: His apprehension is unready; his judgment is feeble; and rests partly upon the evidence of the things, and partly upon the authority of his teacher. But every time he goes over the definitions, the axioms, the elementary propositions, more light breaks in upon him; and as he advances, the road of demonstration becomes smooth and easy: he can walk in it firmly, and take wider steps, till at last he acquires the habit not only of understanding a demonstration, but of discovering and demonstrating mathematical truths.

It must indeed be confessed, that a man without the rules of logic may acquire a habit of reasoningjuftly in mathematics, and perhaps in any other science. Good sense, good examples, and assiduous exercise, may bring a man to reason truly and accurately in his own profession without rules. But whoever thinks, that from this concession he may infer the inutility of logic, betrays by this inference a great want of that art; for he might as well infer, because a man may go from Edinburgh to London by the way of Paris, that therefore any other road is useless.

There is perhaps no art which may not be acquired, in a very considerable degree, by example and practice, without reducing it to rules. But practice joined with rules may carry a man forward in his art farther and more quickly than practice without rules.—Every ingenious artist knows the utility of having his art reduced to rules, and thereby made a science. By rules he is enlightened in his practice, and works with more assurance. They enable him sometimes to correct his own errors, and often to detect the errors of others; and he finds them of great use to confirm his judgment, to justify what is right, and to condemn what is wrong. Now mathematics are the noblest praxis of logic. Through them we may perceive how the stated forms of syllogism are exemplified in one subject, namely the predication of quantity; and by marking the force of these forms, as they are there applied, we may be enabled to apply them of ourselves elsewhere. Whoever, therefore, will study mathematics with this view, will become not only by mathematicians more expert in logic, and by logic a more rational mathematician, but a wiser philosopher, and an acuter reasoner, in all the possible subjects either of science or deliberation. But when mathematicians, instead of being applied to this excellent
LOGIC.

cellent purpose, are used not to exemplify logic, but to supply its place; no wonder if logic fall into contempt, and mathematics, instead of furthering science, become in fact an obstacle. For when men, knowing nothing of that reasoning which is universal, come to attach themselves for years to a single specie, a species wholly involved in lines and numbers, the mind becomes incapacitated for reasoning at large, and especially in the search of moral truth. The object of mathematics is demonstration; and whatever in that science is not demonstration, is nothing, or at least below the sublime inquirer’s regard. Probability, through its almost infinite degrees, from simple ignorance up to absolute certainty, is the terra incognita of the mathematician. And yet here it is that the great business of the human mind is carried on in the search and discovery of all the important truths which concern us as reasonable beings. And here too it is that all its vigour is exerted: for to proportion the agent to the probability accompanying every varying degree of moral evidence, requires the most enlarged and sovereign exercise of reason.

In reasonings of this kind, any man pretend that it is of no use to be well acquainted with the various powers of the mind by which we reason? Is it of no use to resolve the various kinds of reasoning into their simple elements; and to discover, as far as we are able, the rules by which these elements are combined in judging and in reasoning? Is it of no use to mark the various fallacies in reasoning, by which even the most ingenious men have been led into error? It must surely betray great want of understanding, to think these things useless or unimportant. Now there are the things which logicians have attempted; and which they have executed—not indeed so completely as to leave no room for improvement, but in such a manner as to give very considerable aid to our reasoning powers. That the principles they have laid down with regard to definition, and division, with regard to the conversion and opposition of propositions, and the general rules of reasoning, are not without use, is sufficiently apparent from the blunders committed daily by those who disdain any acquaintance with them.

Although the art of categorical syllogism is confessedly little fitted for the discovery of unknown truth, it may yet be employed to excellent purposes, as it is perhaps the most compendious method of detecting a fallacy. A man in quest of unknown truths must generally proceed by the way of induction, from effects to causes; but he, who as a teacher is to inculcate any system upon others, begins with one or more self-evident truths, and proceeds in the way of demonstration, to the conclusion which he wishes to establish. Now every demonstration, as has been already observed, may be resolved into a series of syllogisms, of which the conclusion of the preceding always enters into the premises of that which follows: and if the first principles be clear and evident, and every syllogism in some legitimate mode and figure, the conclusion of the whole must infallibly be admitted. But when the demonstration is thus broken into parts; if we find that the conclusion of one syllogism will not, without altering the meaning of the terms, enter legitimately into the premises of that which should immediately follow; or, supposing it to make one of the premises of a new syllogism, if we find that the conclusion, resulting from the whole series thus obtained, is different from that of the demonstration; we may, in either of these cases, rest assured that the author’s reasoning is fallacious, and leads to error; and that if it carried an appearance of conviction before it was thus resolved into its elementary parts, it must have been owing to the inability of the mind to comprehend at once a long train of arguments. Whoever wishes to see the syllogistical art employed for this purpose, and to be convinced of the truth of what we have said respecting its utility, may consult the excellent writer recommended by Locke, who, in places innumerable of his incomparable work, has, without pedantry, even in that pedantic age, made the happiest application of the rules of logic for unravelling the sophistry of his Jefuitical antagonists.

Upon the whole, then, though we readily acknowledge that much time was wasted by our fathers in syllogistical wrangling, and what might with little impropriety be termed the mechanical part of logic; yet the art of forming and examining arguments is certainly an attainment not unworthy the ambition of that being whose highest honour is to be endowed with reason.
Logography

Our author now proceeds to demonstrate that the number of types must necessarily decrease as they are combined into syllables; and much more when formed into words. The whole art of arranging the words consists in placing them under as few divisions as possible, and still fewer subdivisions; which is attained by the following process.

1. A collection of words, with the addition of tens, plurals, and degrees of comparison, amounting to more than 100,000, was made from the best English Dictionaries.

2. Collections were made from the miscellaneous part of 20 newspapers, the Spectator, and Common Prayer-book. The method was, by procuring duplicates of every sheet, so that each alternate side might be pasted over with white paper, in order to leave the whole of the words on both sides perfect; and thus the whole might be touched with less danger of injury than otherwise could have been done. The confusion arising from the parts of other words being seen from the opposite side was likewise prevented.

3. The words, being separately cut out, were then put into a cæse marked with the divisions from one to 16, according to the number of letters contained in each word. Thus several letters are distinctly collected; and then each separate parcel forested in a cæse containing 26 divisions marked with the letters of the alphabet, according to the commencing letter of the word; and thus all the words were ranged alphabetically, consisting of two, three, four, or five letters, in separate parcels.

4. The same words were then placed together, and pulled into an alphabet, with the number of times marked to each that had occurred on the whole; that in this manner a proportion might be determined how many times particular words ought to be repeated for the printing of one sheet, and also to know what words are in general use. There are likewise a number of technical terms, and favourite phrases a great number of times repeated almost by every author, but though these occur throughout the whole book in great proportion to the rest, no more of them will be necessary than what suffice for a single sheet.

5. The whole of the above might be done without the trouble just mentioned, by pulling every word at once into a triformed alphabet; because the subdivisions of the second and third commencing letter of each word for references are now obtained, and thus can easily be placed in its proper division, and may be marked as often as it occurs, without repeating the same word; whence we plainly see the ease and expedition of it from the facility and expedition of pulling every word from a leaf in any book. Before such subdivisions were known, they could only have been placed under the first commencing letter of the word; which would cause such a multiplicity of repetitions, that it would take up more time, be far more liable to error, and require more subordinate pollings to bring them into arrangement; so that they may be found more easily than by the above proceedings. Thus also a collection will be obtained of single and double words, which are constantly required from 20 to 400 or 500 times in the printing one sheet of any work whatever; and which alone would abridge the compositor's work near one-third. The second process likewise
Likewise enabled the author to reject, out of the first collection, obsolete words, technical terms, &c., which reduced the original collection to one fifth part.

6. By proceeding in this manner, several species of words are omitted in the founts. 1. Obsolete words; because they occur so seldom, the difference of time lost in compounding them in the ordinary method would be imperceptible. 2. Technical terms names of places, animals, &c.; though, for any particular work, the terms peculiar to it may be added to the fount in a biformal alphabet apart. 3. Real compounds, or words that may be compounded of others, are also rejected, because we actually have the words already, and they may be joined with sufficient expedition, though the spaces are annexed to each, by being contracted accordingly. 4. Those of the same spelling are likewise omitted, though they bear different significations, for obvious reasons.

7. The variation of tenses, degrees of comparison, and numerous words in the English language, having in general the same terminations, such as ed, ing, ly, ment, ness, &c., an alphabet may be formed of such words in whole or in part let it be what it will; and when the whole cannot be found at once, the remainder may easily be found in single or double syllables among the terminations. 2. All words above three syllables have the same alphabetical arrangement, and many other words may be formed from the radix by the addition of various terminations, and each termination may be added to other radices to which they are applicable.

8. Some radices are imperfect, viz. such as end with the vowel e, which must therefore be added in the usual way of compounding. Thus, in the word adore, the radix is adore, to which the terminations er, er, css, eth, or, ing, may be added occasionally.

9. By rejecting also the words which come under this last denomination, the number necessary for a fount is reduced to one-tenth of what it would otherwise be, as will appear evident from the following considerations: 1. There are at least 42 verbs, the infinitive of which ends in ify, as qualify, signify, of which the radices of which are qual, figyr, the terminations are, ifes, ifed, ifing, &c. And Mr. Johnson informs us, that by applying these radices to other terminations, he was enabled to dispense with more than 500 words which would otherwise have been necessary. 2. For all regular verbs, no more than six terminations are necessary, viz. s, css, eth, ed, et ing. There are but few irregular ones in the English language; whence it happens that 12 or 14 words may be formed from one single perfect verb as a radix, and many imperfect ones have double that number.

10. By using only the set of terminations which may be contained in a box of two feet square, the common operation of printing would be shortened nearly one half; and in order to find out those which are most in use, and fittest to retain, our author digested them alphabetically, with the radices, words, or syllables which make complete words annexed to them. Thus,

- s  
  ed  
- ing  
- ment  

Thus, abs—upper—after de—dis—con cer—cap—cur enter—main—re—fu, &c.

11. Thus it will be found, that out of more than 1,000,000 words of which the English language consists, there will not be wanted much above 3500 for a complete fount. This will be very evident to any person who consults a dictionary. He will there find, that a vast number of words require an explanation; whereas in any miscellaneous work, there are none but what can be understood most readily either together or apart. Newspapers retain more of the uncommon kind of words than any others. "The vocabulary (says our author) or alphabet as it is called, of the Chinese, consists of above 80,000 letters or characters; yet he is admitted a master of the language who knows about 4000 of them, no more being in general use."
Logography by no means intelligible.—"For this distinction in
the cates (says he), the alphabet, or rather marks of
first reference in large characters on the wall, is di-
vided into two classes, not as vowels and consonants,
but as follows: viz. A, Con, Diff, E, Is, O, P, S,
commencing references, the second or subsequent
letters of the words being in right line from left to
right, and down each column is found the remainder
of the reference to the words, distinguishing always
the third letter in red. The second distinction is,
that for all other commencing letters, the second letter
of reference is in a column down, and the third letter
in lines from left to right in red.

These are the directions given by our author for
forming a sound of words: the next requisite is a sound
of syllables, formed in the following method: 1. A
complete set of two letters was obtained in all their
possible combinations, amounting to 676. 2. Having
next obtained the possible combination of these letters,
viz. 17576, by retaining only all possible syllables, and
words of three letters, it is reduced in the 52d part, which
answer all the purposes of composing with syllables of
two and three letters, for Latin, French, English, and
all names of persons, places, and things every pos-
sible syllable being comprehended among them. Hence
it forms an universal triformed alphabet, where En-
lish characters are used; from whence all partial bi-
formed and triformed alphabets in the arrangement of
English, French, Latin, and all technical matters, are
drawn. Though combinations of four letters are
again 25 times the number of those of three letters,
and five letters increase in the same ratio; yet as much
as all possible combinations increase in quantity pro-
portionate to the number of letters combined so do they
decrease in the actual number of syllables included
among them, inasmuch that all the syllables of four,
five, six, and seven letters together, are considerably
fewer than the syllables of three letters only.—Be-
sides the two sounds already mentioned, a third was
found necessary for such terminations as are most com-
monly followed by particular punctuations; but, after
some consideration, this was judged unnecessary.

Our author now proceeds to obviate some objections
which must naturally occur to one who first hears of
his invention. These are,
1. A single letter damaged in a word renders the
whole useless.
This is not denied by Mr. Johnston; but he contends,
that the quantity of metal lost in this manner is quite
trifling.

2. How are the blanks or spaces in a line to be ma-
aged, as these are by no means equal.
To this our author replies, that, at the time of writ-
ing the pamphlet, he was undetermined whether it be
most eligible to have spaces cast along with the be-
ginnings of words, or to space them in the common
manner. The former would be more expeditious; and
where a greater distance is required, other spaces may
be introduced in the ordinary method.

3. How is a long word at the end of a line to be di-
vided?
This may be easily accomplished by means of the sylla-
abic sound already mentioned.

4. How is the error of substituting one word for
another to be rectified?

The answer to this is, that an error of the kind spe-
cified may be corrected in the very same manner as is
done in common printing. Long words may be di-
vided by means of the syllabic sound already men-
tioned and the intervals between the words may be filled
up with spaces as usual.

LOGWOOD. See HEMATONYLON.

LOHOCH, or LOKH, in pharmacy a composition
of a middle consistence between a soft cleatary and a
yup, principally used in disorders of the lungs.

LOINS, in anatomy, the two lateral parts of
the umbilical region of the abdomen.

LOIRE, the largest river in France, rises in the
mountain of the Cevennes, and, after running a cou-
ple of about 350 miles, falls into the bay of Bicay.

LOKE, in mythology, the name of one of the
deities of the northern nations, answering to the Ar-
manes among the Persians, whom they represent at
enmity both with gods and men, and the author of
all the evils which defolate the universe. Loke is de-
scribed in the edda as producing the great serpent
which encircles the world; which seems to have been
intended as an emblem of corruption or sin: he also
gives birth to Hela or death, the queen of the infernal
regions; and also to the wolf Fenris, that monster who
is to encounter the gods and destroy the world.

LOKMAN the Wise, an eminent philosopher am-
ong the easterns. The Arabianists say he was the son
of Bauran, the son or grandson of a fitter or aunt of
Job. He was an Ethiopian, and a slave for some time.
It is related that he was born in the time of David,
and lived till the age of the prophet Jonas. Some lop-
pole him to have been the same with Aesop the myth-
ologist; and indeed we find in the parables or apolo-
gues of Lokman in Arabic, many particulars that are
seen in Aesop's fables: so that it is not easy to de-
termine whether the Greek or the Arabian are the
originals. He is said to have been deformed in his per-
fon; but that this defect was sufficiently made up by
the perfections of his mind. Some pieces of his are
extant; and he was looked upon as so excellent a per-
on, that Mahomet has inserted a chapter of the Ko-
ran, called after his name, in which he introduces God
as saying, "We heretofore bestowed wisdom on Lok-
man."—It is related that he got his liberty on the fol-
lowing occasion. His master having given him a bitter
melon to eat he eat it all. His master, surprized at
his exact obedience, asked, how it was possible for
him to eat such a nauseous fruit? He answered, "I
have received so many favours from you, that it is no
wonder I should once in my life eat a bitter melon from
your hand." This generous answer of the slave struck
the master to such a degree, that he immediately gave
him his liberty. M. Galland translated all the fables
of Lokman, and Bilpai or Pilpay a bramhin philoso-
pher, which were published at Paris in 1724.

LOLIUM, BARNELT-GRASS, in botany: A genus
of the dygymia order, belonging to the triandria clas-
of plants; and in the usual method ranking under
the 5th order, Gramina. The calyx is monophyllous
and uniflorous. The most remarkable species are,
1. The perenne, red darnel, or rye-grass. This
is very common in roads and dry pastures. It makes
excellent hay upon dry chalky, or sandy soils. It is
advantageously cultivated along with clover, and
springs...
Lollards. springs earlier than other grades; thereby supplying food for cattle at a time when it is most difficult to be obtained. Cows, horses, and sheep eat it; goats are not fond of it. 2. The temulentum, or white darnel grows spontaneously in ploughed fields. If the seeds of this species are mowed with barley, the ale soon occasions drunkenness: mixed with bread-corn, they produce but little effect unless the bread is eaten hot.

LOLLARDS, in ecclesiastical history, a religious sect, differing in many religious points from the church of Rome, which arose in Germany about the beginning of the 14th century; so called, as many writers have imagined, from Walter Lollard, who began to dogmatize in 1315, and was burnt at Cologne: though others think that Lollard, was no surname, but merely a term of reproach applied to all heretics who concealed the poison of error under the appearances of piety.

The monk of Canterbury derives the origin of the word Lollards among us, from lolium, "a tare" as if the Lollards were the tares tawn in Christ's vineyard. Abelly says, that the word Lollard signifies "praizing God," from the German loben, "to praise," and herr "Lord:" because the Lollards employed themselves in travelling about from place to place, singing psalms and hymns.

Others, much to the same purpose, derive lollhard, lombard, or lollert, lullert, as it was written by the ancient Germans from the old German word xollen,ollen, orollen, and the termination hard, with which many of the High Dutch words end. Ollen signifies "to sing with a low voice," and therefore Lollard is a singer or one who frequently sings; and in the vulgar tongue of the Germans it denotes a person who is continually praising God with a song, or singing hymns to his honour. The Alexiens or Cellites were called Lollards, because they were public singers who made it their business to inter the bodies of those who died of the plague, and sang a dirge over them in a mournful and indiffident tone as they carried them to the grave. The name was afterwards assumed by persons who disdained it; for we find among those Lollards who made extraordinary pretences to piety and religion, and spent the greatest part of their time in meditation, prayer, and other acts of piety, there were many abominable hypocrites, who entertained the most ridiculous opinions and concealed the most enormons vices under the specious mark of this extraordinary profession. And many injurious aspersions were propagated against those who assumed that name by the priests and monks; so that by degrees, any person who covered heresies or crimes under the appearance of piety, was called a Lollard. Thus the name was not used to denote any one particular sect, but was formerly common to all persons and all sects who were supposed to be guilty of impiety towards God or the church, under the external profession of extraordinary piety. However, many societies, confiding both of men and women under the name of Lollards, were formed in most parts of Germany and Flanders, and were supported partly by their manual labour, and partly by the charitable donations of pious persons. The magistrates and inhabitants of the towns where these brethren and sisters resided, gave them their particular marks of favour and protection, on account of their great usefulness to the sick and needy. They were thus supported against their malignant rivals, and obtained many papal constitutions by which their influence was confirmed, their persons exempted from the cognizance of the inquisitors, and subjected entirely to the jurisdiction of the bishops; but as these measures were insufficient to secure them from molestation, Charles duke of Burgundy, in the year 1472, obtained a solemn bull from Pope Sixtus IV. ordering that the Cellites or Lollards should be ranked among the religious orders, and delivered from the jurisdiction of the bishops; and Pope Julius II. granted them yet greater privileges in the year 1506. Mutherm informs us that many societies of this kind are still subsisting at Cologne, and in the cities of Flanders, though they have evidently departed from their ancient rules.

Lollard and his followers rejected the sacrifice of the mass, extreme unction, and penances for sin, arguing, that Christ's sufferings were sufficient. He is likewise said to have set aside baptism, as a thing of no effect; and repentance, as not absolutely necessary, &c.—In England, the followers of Wickliffe were called by way of reproach, Lollards, from some affinity there was between some of their tenets; though others are of opinion that the English Lollards came from Germany.

They were solemnly condemned by the archbishop of Canterbury and the council of Oxford.

LOMBARD (Lambert), an eminent painter, born at Leige in 1500; who after a diligent study of the antique at Rome, introduced that style of painting among his countrymen instead of the Gothic. He painted history, architecture, and perspective; and though he could never altogether free himself from his national gout, he is ranked among the best painters of his time. He died in 1560.

Lombard (Peter), well known by the title of Master of the Sentences, was born at Novara in Lombardy; but being bred at Paris, he distinguished himself so much at that university, that he first had the canony of Chartres conferred on him; was some time tutor to Philip son of Louis le Gros, and lastly obtained the see of Paris. He died in 1664. His work of the Sentences is looked on as the source of the scholastic theology of the Latin church. He wrote also commentaries on the Psalms, and on St. Paul's Epistles.

LOMBARDS, a Scandinavian nation, who formerly settled in Italy, and for some time made a considerable figure.

Their name of Lombards, or Longobards, is by some etymology derived from the word lack, or lade, signifying in the of the German tongue winter; because the Lombards, while in Scandinavia, lived in marhs or near the sea. Others think that it comes from the two German words langen barden, or hilseborden, that is from the long halberts they were suppose to ute in war. But Paulus Diaconus their historian, and was himself a Lombard, tells us, that it were called Longobards from the length of their beards. A nation called the Lombards is mentioned by Tacitus, Sibyl, and Ptolemy; but there are different from the Lombards who afterwards settled in Italy, and are reckoned to be the same with...
Lombards

2 The Vandals defeated by the Lombards.

Vambl;dc-

3 They settled in the country of the Rugians.

4 Destroy the Gepidæ.

Alboinæ, king of the Lombards.

Alboinis, having gained such a reputation, that his friendship was courted by Justinian; and, in consequence of the emperor's application, a body of 6000 Lombards were sent to the adittance of Naranæ against the Goths. The success of the Romans in this expedition, the invasion of Italy by the Lombards and their successes in that country, have been taken notice of under the article Italy, n° 48—52. At last Alboinis, having made himself master of Venetia, Liguria, Æmilia, Heretria, and Umbria, was slain by the treachery of his wife, in the year 575, the fourth of his reign. This princes was the daughter of the king of the Gepidæ, whom Alboinis had killed in battle and made a cup of his skull as above related.

As he was one day feasting at Verona with his chief favourites and principal officers, in the height of his mirth he fell for the queen, and filling the defiled cup, commanded her to drink merrily with her father. Rosamund struck with horror, hurried out of the room; and highly incensed against her husband for thus barbariously triumphing over the misfortunes of her family, revoluted at all events, to make him pay dear from such an inhuman and affronting conduct.

Accordingly, the discovering her intention to Helmicilh the kings field-bearer, a youth of great boldness and intrepidity. Helmicilh peremptorily refused to imbrue his hands in the blood of his sovereign, or to be any way accessory to his death; and in this resolution he perished till he was, by a shameful stratagem, forced by the queen to a compliance: for he, knowing that he carried on an intrigue with one of her ladies, placed herself one night in her bed, and receiving the youth, indulged him as if she had been his own mistress in his amorous desires; which she had no sooner done, than discovering herself to the deceived lover, she told him that she must now either put the king to death, or be put to death by him. Helmicilh, well apprised, that after what he had done, his safety depended on the death of the king, engaged in the treason, which he otherwise abhorred.

One day, therefore, while Alboinis was repining in his chamber after dinner, Helmicilh, with some others whom he had made privy to his design, breaking in unexpectedly fell upon the king with their daggers. Alboinis, starting up at their first coming in, laid hold of his sword, which he had always by him; but having in vain attempted to draw it, the queen having beforehand fastened it in the scabbard, he defended himself for some time with a footstool; but was in the end overpowered, and dispatched with many wounds.

Rosamund had promis'd to Helmicilh, that, as soon as he had dispatched the king, she would marry him, and with her person, befall upon him the kingdom of the Lombards. The first part of her promise she immediately performed; but was so far from being able to follow the crown upon him, that both of them were obliged to save themselves by flight. They fled to Longinus the exarch of Ravenna, taking with them all the jewels and treasure of the late king. Longinus received her with the greatest marks of friendship and kindness, and assured her of his protection. She had not been long in Ravenna, however, before the exarch, judging that a favourable opportunity now offered of making himself king of Italy by her means, imparted his design to her, and declared his intention to marry her, provided, by some means or other, she dispatched Helmicilh. Rosamund, highly pleased with the proposal, resolved to satisfy her ambition by getting rid of the person whom she had married in order to gratify her revenge. Accordingly, having prepared a strong poison, she mixed it with wine, and gave it to her husband as he came out of the bath and called for drink, according to his custom. Helmicilh had not half emptied the cup when by the sudden and frightful operation which he felt in his bowels, he concluded what it was, and, with his sword pointed at the queen's breast, compelled her to drink the rest. The poison had the same effect on both; for they died in a few hours. Longinus, on the death of the queen, laid aside all thoughts of making himself king of Italy, and sent the king's treasure to Constantinople, together with Alboinis's daughter of Alboinis by Rosamund, whom she had brought along with her.

After the death of Alboinis, the Lombards chose Clephis, one of the nobility for their king. He was murdered after a short reign of 18 months; upon which ensued an interregnum of 10 years, as related under the article Italy, n° 32. During this time, they extended their conquests in that country; but at last the Romans, jealous of their progress, resolved to put a stop to their victories, and, if possible, to drive them quite out. For this purpose, they designed not only to employ all their own force, but entered into alliance with the Franks; which so alarmed the Lombards, that they re-established the monarchial form of government.
LOMBARDIA

Several places, they openly revolted, and, falling upon the emperor's officers, drove them out of the cities. In the east, Germanus, patriarch of Constantinople, opposed the emperor's design with great warmth; but Leo caused him to be deposed, and Anastasius to be raised to that seat in his room, ordering, at the same time all the images in the imperial city to be pulled down and publicly burnt. He strictly enjoined his officers in the west, especially the exarch of Ravenna, to see his edict punctually obeyed in their respective governments. In compliance with these orders, Schroians, then exarch, began to pull down the images in all the churches and public places in Ravenna; which incensed the superstitious multitude to such a degree, that, taking arms, they openly declared they would rather renounce their allegiance to the emperor than the worship of images.

Thus a kind of civil war being kindled in the city, Luitprand thought he had now a favourable opportunity of making himself master of the seat of the exarch, not doubting but the conquest of such an important place would be followed by that of the whole exarchate. Having therefore drawn together all his forces, he unexpectedly appeared before Ravenna, and, promising to take advantage of their fears, and, returning before Ravenna while the inhabitants were engaged in the works of pulling down the images, he stormed the city to be pulled up, the fevere prejudices which he had excited among the subjects of the kingdom. Among the latter the emperor was the sole lawgiver; so that whatever pleased him had the force of a law. But the Lombard kings did not assume that power to themselves, since their laws were enacted in public assemblies, convened for that purpose after they had been maturely examined and approved by all the lords of the kingdom. From these assemblies were excluded the ecclesiastical order, and the people; so that the legislative power was lodged in the king and nobles alone.

The reign of Rotharis is remarkable, not only for his introducing written laws among his subjects, but for the conquests he made, and the successful wars carried on with the exarch of Ravenna, whom he totally defeated in several engagements, and made himself master of some part of his territories. This monarch died in 652; and the affairs of the Lombards went on prosperously, till the ambition of Luitprand laid the foundation of the total ruin of his kingdom. He ascended the throne of Lombardy in 711, and watched all opportunities of enlarging his dominions at the expense of the emperors. Of this, a fair opportunity offered in 716: for the emperor Leo II., bishop of Rome. He was then at variance with the emperor, whose edict against the worshipping of images he had opposed with all his might, and by that
Lombar.d means provoked Leo to such a degree, that he had threatened to drive him from the see, and send him into exile. However, the pope, no lefs jealous of the power of the Lombards than all his predecessors had been, resolved, by some means or other, to put a fhop to their conquests. The only prince in Italy to whom he could have recourse was Urtius, duke of Venice, the Venetians making already an incom nderable figure.

To him accordingly he wrote a very prefling letter; conjuring him to affift his worthy for the exarch, and for the love of the holy faith, to attempt with him the recovery of the exarchate, which the wicked nation of the Lombards had unjustly taken from his fons Leo and Conftantine emperors. Urtius and the Venetians, moved with the pope's letter, and at the fame time greatly alarmed at the growth of fo powerful a neighbour, promised to affift the exarch with the whole strength of their republic; and accordingly fitted out a confiderable fleet, pretending it was defigned for the service of the emperor against the Saracens. At the fame time the exarch, who had taken refuge in Venice, abandoning that place, as it were, in defpair of bringing the duke over to his party, raifed, in the places still fubjeft to the emperor, what forces he was able; and having got toger a confiderable body, he marched with them towards Imola, giving out that he defigned to beleige that city; but, turning on a sudden towards Ravenna, as had been agreed on between him and the Venetians, he laid siege to it by land, while they infaddied it almost at the fame intant by fea. Peredeus defended the town for fome time with great courage and resolution; obliging all thofe who were able to bear arms to repair to the walls. But the Venetians having, in spite of all oppofition, forced open one of the gates on the fide of the fea, the city was taken, and Peredeus flain, while he was attempting, at the head of a choice body, to drive the enemy from the pofts they had feized. As for Hildebrand, he fell into the hands of the Venetians; who, having thus recovered Ravenna to the emperor, returned home, leaving the exarch in the poftefion of the city. Luitprand was then at Pavia; but the town was taken before he could assemble his troops to relieve it.

And now Gregory bishop of Rome, to whom the recovery of Ravenna was chiefly owing, perfuading himfelf, that the emperor would, out of gratitude, give ear to his remonftrances and admonitions, began to solicit him with more prefling letters than ever to revoke his edict againft the worship of images: but Leo, well apprized that the bishop, in all the meafures he had taken, had been more influenced by a regard to his own interest, than to that of the empire, instead of hearkening to his remonftrances, was ftil more provoked againft him for thus obstinately oppofing the execution of his edict. Being, therefore, resolved at all events to have it obviated in Rome itself, and, on the other hand, not doubting but the pope would oppofe it to the laft with all his might; in order to remove all obftacles, he fent three officers to Rome, with private orders either to dispatch the pope, or to take him prifoner and convey him to Conftantinople. At the fame time he wrote to Mauritius duke of Rome, secretly enjoining him to affift his three officers, in their undertaking; but no favorable opportunity offering to put their design in execution, the emperor, in the year 725, recalled Scholastica, and fen Paul Lombard, a patrician into Italy, to govern in his room, with private instructions to encourage the abovementioned officers with the promise of great rewards, and to affure them of his protection.

But, in the mean time the plot was discovered, and two of the confpirators were apprehended by the citizens of Rome, and put to death; the third having escaped into a monastery, where he took the monaflic habit, and ended his days. Hereupon the exarch, in compliance with the emperor's orders, resolved to proceed no longer by secret plots, but by open force. Accordingly, he drew together a confiderable body of troops, and fet out at the head of them on his march to Rome, with a design to feize on the pope, and fend him, as he had engaged to do, in chains to Conftantinople. But on this occafion, Luitprand, though highly provoked againft Gregory for having flrirred up the Venetians againft him, yet resolved to affift him and the citizens of Rome againft the exarch, in order to keep the balance even between them, and by affifting sometimes the one and sometimes the other, weaken both. Pursuant to this resolution, he ordered the Lombards of Tuscany, and thofe of the dukedom of Spoleto, to join the pope and the inhabitants of Rome; who, being by his reinforcement of superior number and quality, obliged him to return to Ravenna, and give over all thoughts of any further attempt on the perfon of the pope.

In the mean time, Leo, perfifting in his former resolution of suppreffing throughout his dominions the worship of images, lent fresh orders to the exarch Paul, strictly enjoining him to caufe his edict to be put in execution in all the cities of Italy under his empire, especially in Rome. At the fame time he wrote to the pope, promifing him his favour and protection if he complied with the edict; and declaring him, if he continued to oppofe it, a rebel, and no longer vefted with the papal dignity. But Gregory was fo far from yielding to the emperor's threats or promises, that, on the contrary, he solemnly excommuniuated the exarch for attempting to put the imperial edict in execution; and at the fame time wrote circular letters to the Venetians, to king Luitprand, to the Lombard dukes, and to all the chief cities of the empire, exhorting them to continue faithful in the Catholic faith, and to oppofe with all their might fuch a deteftable innovation. These letters made fuch an impression on the minds of the people of Italy, that, though of different interefts, and often at war with one another, they all united; proftecting they would defend the Catholic faith, and the life of the pope in fo glorious a caufe, at the expence of their own; nay, the citizens of Rome, and the inhabitants of Pentapolis, now Marca d'Ancona, not con tenting themselves with fuch a proteftation, openly revolted from the emperor; and, pulling down his statues, they elected, by their own authority, magiftrates to govern them during the interregnum. We are even told, that, transported with a blind zeal, they were for choofing a new emperor, and conducing him to Conftantinople, not doubting but the people would every where join them. But the pope, thinking this resolution unfOOnable, and not to be easily put in execution, oppofed it; fo that it did not take place.
In the mean time, the exarch Paul, having gained a considerable party in Ravena, began, pursuant to the repeated orders from the emperor, to remove the images, as to many idols, out of the churches. Hereupon the adverse party, supported and encouraged by the pope, flew to arms; and, falling upon the Iconoclasts or image-breakers, as they styled them, gave rise to a civil war within the walls of Ravena. Great numbers were killed on both sides: but those who were for the worship of images prevailing in the end, a dreadful slaughter was made of the opposite party; and, among the rest, the exarch himself was murdered. However, the city of Ravena continued faithful to the emperor, the most of the cities of Romagna belonging to the exarchate, and all those of Pippinopolis or La Marca d'Ancona, abhorring the emperor as an heretic, submitted to Luitprand king of the Lombards; who pretending a zeal for the Catholic religion, took care to improve the discontent of the people to his advantage, by representing to them that they could never maintain their religious rights under a prince, who was not only an heretic, but a persecutor of the orthodox.

In Naples, Exilaratus, duke of that city, having received peremptory orders from the emperor to cause his edict to be put in execution, did all that lay in his power to persuade the people to receive it; but finding all his endeavours thwarted by the bishop of Rome, for whom the Neapolitans had a great veneration, he hired assassins to murder him. But the plot being discovered, though carried on with great secrecy, the Neapolitans, highly provoked against the duke, tore both him and his son to pieces, and likewise put to death one of his chief officers, who had composed a libel against the pope. Luitprand, and Gregory at that time duke of Benevento, laying hold of so favourable an opportunity to make themselves masters of the dukedom of Naples, did all that lay in their power to persuade the Neapolitans to submit to them. But the Neapolitans, bearing an irreconcilable hatred to the Lombards, with whom they had been constantly at variance, rejected every overture of that nature with the utmost indignation; and, continuing steadfast in their allegiance to Leo, received from Constantinople one Peter, who was sent to govern them in the room of Exilaratus. Some writers suppose the Neapolitans, in this general revolt of the cities of Italy, to have shaken off the yoke with the reft, and to have appointed magistrates of their own election to govern them in the room of the officers hitherto sent from Constantinople, or named by the exarch; but they are certainly mistaken: it being manifest from history, that Peter succeeded Exilaratus in that dukedom, and that the Neapolitans continued to live under the emperors, till they were conquered many years after by the Normans.

In the mean time, Leo hearing of the murder of the exarch, and the general revolt of the cities, and not doubting but the pope was the chief author of so much mischief, sent the eunuch Euthychius into Italy, with the title and authority of exarch, strictly enjoining him to get the pope dispatched by some means or other, since his death was absolutely necessary for the tranquillity of Italy. The exarch spared no pains to get the pope into his power: but a messenger, whom he had sent to Rome, being apprehended by the citizens, and an order from the emperor being found upon him to all his officers in that city commanding them to put the pope to death at all events, the pope's friends thereupon guarded him with such care, that the exarch's emissaries could never afterwards find an opportunity of executing their design. As for the messenger, the Romans were for putting him to death; but the pope interposed, contenting himself with communicating the exarch.

And now the Romans, provoked more than ever, in consequence against Leo, and, on the other hand, unwilling to mains live under the Lombards, resolved to revolt from the emperor, and appoint their own magistrates, keeping themselves united under the pope, not yet as their prince, but only as their head. This they did accordingly; and from these slender beginnings the sovereignty of the popes in Italy took its rise, though they did not then, as is commonly supposed by historians, but many years after, become sovereign lords of Rome.

Eutychius failed in his design upon the life of the pope; but having brought with him from Constantinople a good number of troops, he easily quelled the rebellion in Ravenna, and severely punished the authors of the late disturbances. As for the rebellious Romans, he was well apprized he could never reduce them, so long as they were supported by the king of the Lombards; and therefore endeavoured to throw all his art and policy to take off that prince from the party of the Romans, and bring him over to his own. Luitprand, for some time, withstood all his offers; but Thrasmund duke of Spoleto revolted at this very juncture, the exarch, laying hold of that opportunity, offered to assist the king with all his strength against the rebellious duke, provided he would, in like manner, assist him against the pope and the Romans. With this proposal Luitprand readily closed; and a league being concluded upon these terms between him and the exarch, the two armies joined, and began their march towards Spoleto. At their approach, the duke, despairing of being able to resist two such powers, came out with a small attendance to meet them, and, throwing himself at the king's feet, sued, in that humble posture, for pardon; which Luitprand not only granted him, but confirmed him in the dukedom, after he had obliged him to take a new oath of allegiance, and give hostages for his fidelity in time to come. From Spoleto, the two armies marched, in pursuance of the treaty, to Rome; and encamped in the meadows of Nero, between the Tiber and the Vatican.

Gregory had caused the city of Rome to be fortified in the best manner he could: but being sensible that it submits to the Romans alone could not long hold out against two such armies, and reflect on the kind treatment the duke of Spoleto had met with upon his submitting to the king, he resolved to follow his example; and accordingly, taking with him some of the clergy, and the principal inhabitants of the city, he went to wait on the king in his camp; and there, with a pathetic speech, as he was a great master of eloquence, softened Luitprand to such a degree, that throwing himself at his feet in the presence of the whole army, he begged pardon for entering into an alliance against
Pepin was no longer the domineering figure in Sicily, the Calabria, and his other dominions, to the Romans. He reconciled the pope with the Romans after some time, maintaining a friendly correspondence with the pope. At this time an impostor, taking the name of Tibert, pretended to be descended from the emperors, seduced a great many people in Tuscany, and was by them proclaimed emperor. The exarch resolved to march against him; but as he had not sufficient forces to oppose the rebels, Gregory, who let no opportunity slip of obliging Leo, persuaded the Romans to attend the exarch in this expedition; by which means the usurper being taken in a battle, his head was sent to the emperor, and the rebellion utterly suppressed. But the emperor still intimated upon his return against the images being received in Rome, the Romans, at the instigation of the pope, publicly renounced their allegiance to Leo, paid him no more tribute, and withdrew for ever their obedience to the emperors of the East.

Leo, informed of this revolt, and not questioning but the pope was the author of it, immediately cau sed all the privileges of the church in Sicily, Calabria, and his other dominions, to be confiscated. At the same time, he ordered a powerful army to be raised, with a design to recover the towns that had revolted; to chastise the Romans for their rebellion; and, above all, to be revenged on the pope, who had rai sed all these disturbances, by opposing himself, and persuading others to oppose, the execution of his edict. Gregory, alarmed at the warlike preparations that were carrying on throughout the empire, and well apprised that they were chiefly designed against him and the Romans, resolved to recur to the protection of the French, the only nation at that time capable of coping with the emperor, and on whom, on account of their zeal for religion, he thought he might depend. The Lombards were then very powerful; but, as they wanted to be masters of Rome, and at this time governed by a prince of considerable eminence, who had embraced the Christian religion, they governed with such equity and moderation, that most other nations envied the happiness of those who lived under them. Under the government of the Lombards (says Paulus Diaconus) no violence was committed, no one unjustly dispossessed of his property, none oppressed with taxes; theft, robberies, murder, and adulter y, were seldom heard of: every one went, without the least apprehension, wherever he pleased. Their laws were so just and equitable, that they were retained in Italy, and observed there some ages after their kingdom was at an end.—According to Paulus Diaconus, also, their dress was loose, and for the most part of linen, such as the Anglo-Saxons wore, being interwoven with various colours; and their shoes were open to the end of their foot, and that they used to button or lace them. From some ancient paintings, it appears, that they shaved the back part of their heads, but that their hair was long before; their locks being parted, and laid on each side their foreheads.

Lombards, of Lombard (Peter), an engraver of considerable eminence, who flourished about the year 1660. He was a native of Paris, where he learned the art of engraving. It appears that he came into England before the revolution, because some of his plates for English publications are dated prior to that event. He executed a vast variety of plates, as well historical as emblematical; which, however, were chiefly for books. But his best works are portraits; and of these he produced a considerable number, which are esteemed. They are mostly after Vandyke. He also engraved historical subjects, from Poussin, Raphael, Annibal Caracci, Guido, and other masters.
LOCH-LOMOND, a large lake of Dumbarton or Lennox-shire in Scotland, of which Mr. Pennant gives the following description. "Loch-lomond, the last of the most beautiful of the Caledonian lakes. The first view of it from Tarbat, presents an extensive fen­tine winding amidst lofty hills; on the north, barren, and rocky, which darken with their shade that contracted part of the water. On the west side, the mountains are clothed near the bottoms with woods of oak quite to the water's edge; their summits lofty, banks of the Leven; and Ben-lomond, like Saul amidst his companions, overtops the rest. The upper parts were black and barren; the lower had great marks of fertility, or at least of industry, for the yellow corn was finely contrasted with the verdure of the groves intermixed with it.

This eastern boundary is part of the Grampian hills, which extend from hence through the counties of Perth, Angus, Mearns, and Aberdeen. The road runs sometimes through woods, at others is exposed and naked; in some, so steep as to require the support of a wall; the whole the work of the solitude: blemish exchange of inroads of destruction for those that give safety to the traveller, and a polish to the once inaccessiblè native! Two great head-lands covered with trees separate the first scene from one totally different; the last is called the Point of Pirkinn. On passing this cape an expanse of water bursts at once on your eye, varied with all the softer beauties of nature. Immediately beneath is a flat covered with wood and corn: beyond, the headlands stretch, far into the water, and consist of gentle risings; many have their surfaces covered with wood, others adorned with trees loosely scattered over a fine verdure or the purple bloom of the heath. Numbers of islands are dispersed over the lake, of the same elevated form as the little capes and wooded in the same manner; others jut peep above the surface, and are tufted with trees; and numbers are so disposed as to form magnificent vistas between.

Opposite Lufs, at a small distance from the shore, is a mountainous isle almost covered with wood, is near half a mile long, and has a most fine effect. I could not count the number of islands, but it was sold there are 28; the largest two miles long, and stocked with deer.

The length of this charming lake is 24 Scotch miles; its greatest breadth is; its greatest depth, which is between the point of Pirkinn and Ben-lomond is 120 fathoms. Besides the fish common to the lochs are guinias, called here pans.

The surface of Loch-lomond has for several years past been observed gradually to increase, and invade the adjacent shore; and there is reason to suppose that churches, houses, and other buildings, have been lost in the water. Near Lufs is a large heap of stones at a distance from the shore, known by the name of the old church; and about a mile to the south of that, in the middle of a large bay, between Camfraddan, and the isle Inch-lavansch, is another heap, said to have been the ruins of a house. To confirm this, it is evident by a passage in Camden's Britannia, that an island, existing in his time, is now lost; for he speaks of the isle of Camfraddan, placed between the lands of the same name and Inch-lavansch, in which, adds he, was a house and orchard. Besides this proof, large trees with their branches still adhering are frequently found in the mud near the shore, overwhelmed in former times by the increase of water. This is supposed to be occasioned by the vast quantities of stone and gravel that are continually brought down by the mountain rivers, and by the falls of the banks of the Leven; the first filling the bed of the lake, the last impeding its discharge through the bed of the river."

LOMOZOMOZOZOF, a celebrated Russian poet, the great refiner of his native tongue, was the son of a person who trafficked in fish at Kolmogori: he was born in 1711, and was fortunately taught to read a rare instance for a person of low station in Russia. His natural genius for poetry was first kindled by the perusal of the Song of Solomon, done into verse by Polotski, whose rude compositions, perhaps scarcely inferior to our version of the psalms by Sternhold and Hopkins, inspired him with such an irresistible passion for the mutes, that he fled from his father, who was desirous of compelling him to marry, and took refuge in the Kaisonopalsti monastery at Moscow; there he had an opportunity of indulging his taste for letters, and of studying the Greek and Latin languages. In this monastery he made so considerably a progress in polite literature, as to be noticed and employed by the Imperial academy of sciences. In 1736 he was sent at the expense of that society, to the university of Marpurgh in Hesse Caffel, where he became a scholar of the celebrated Christian Wolf, under whom he studied universal grammar, rhetoric, and philosophy. He continued at Marpurgh four years, during which time he applied himself with indefatigable diligence to chemistry, which he afterwards pursued with still greater success under the famous Henckel at Freyberg in Saxony. In 1741 he returned into Russia; was chosen in 1742 adjunct to the imperial academy, and in the ensuing year member of that society and professor of chemistry. In 1766 he was appointed inspector of the seminary, then annexed to the academy; in 1764 he was gratified by the present emprefs with the title of counsellor of state; and died April 4th that year, in the 54th year of his age. Lomomoizof excelled in various kinds of composition; but his chief merit, by which he bears the first rank among the Russian writers, is derived from his poetical compositions, the spirit of which are his odes. The first was written in 1739, while he studied in Germany, upon the taking of Kotchkin, a forrever of Crim Tartary, by Marshal Munich. The odes of Lomomoizof are greatly admired for originality of invention, nobility of sentiment, and energy of language; and compensate for the turgid style, which, in some instances, have been imputed to them, by that spirit and fire which are the

LOMOMOZOF, a celebrated Russian poet, the great refiner of his native tongue, was the son of a person who trafficked in fish at Kolmogori; he was born in 1711, and was fortunately taught to read a rare instance for a person of low station in Russia. His natural genius for poetry was first kindled by the perusal of the Song of Solomon, done into verse by Polotski, whose rude compositions, perhaps scarcely inferior to our version of the psalms by Sternhold and Hopkins, inspired him with such an irresistible passion for the mutes, that he fled from his father, who was desirous of compelling him to marry, and took refuge in the Kaikonopalski monastery at Moscow; there he had an opportunity of indulging his taste for letters, and of studying the Greek and Latin languages. In this seminary he made so considerably a progress in polite literature, as to be noticed and employed by the Imperial academy of sciences. In 1736 he was sent at the expense of that society, to the university of Marpurgh in Hesse Caffel, where he became a scholar of the celebrated Christian Wolf, under whom he studied universal grammar, rhetoric, and philosophy. He continued at Marpurgh four years, during which time he applied himself with indefatigable diligence to chemistry, which he afterwards pursued with still greater success under the famous Henckel at Freyberg in Saxony. In 1741 he returned into Russia; was chosen in 1742 adjunct to the imperial academy, and in the ensuing year member of that society and professor of chemistry. In 1766 he was appointed inspector of the seminary, then annexed to the academy; in 1764 he was gratified by the present emprefs with the title of counsellor of state; and died April 4th that year, in the 54th year of his age. Lomomoizof excelled in various kinds of composition; but his chief merit, by which he bears the first rank among the Russian writers, is derived from his poetical compositions, the spirit of which are his odes. The first was written in 1739, while he studied in Germany, upon the taking of Kotchkin, a forrever of Crim Tartary, by Marshal Munich. The odes of Lomomoizof are greatly admired for originality of invention, nobility of sentiment, and energy of language; and compensate for the turgid style, which, in some instances, have been imputed to them, by that spirit and fire which are the
principal characteristics in this species of composition. Pindar was his great model; and if we may give credit to a person well versed in the Russian tongue, he has succeeded in this daring attempt to imitate the Theban bard, without incurring the cenure of Horace. In this, as well as several other species of composition, he enriched his native language with various kinds of metre, and seems to have merited the appellation bestowed upon him of the Father of Russian Poetry. A brief recapitulation of the principal works of Lomonoff, which were printed in three volumes octavo, will serve to show the versatility of his genius, and his extensive knowledge in various branches of literature. The first volume, besides a preface on the advantages derived to the Russian tongue from the ecclesiastical writings, contains ten facred and nineteen panegyric odes, and several occasional pieces of poetry. The second comprises An Essay in Prose on the Rules for Russian Poetry; Translation of a German Ode; Idylls; Tamara and Selim, a tragedy; Demophoon, a tragedy; Poetical Epitaph on the Utility of Glasses; two cantos of an epic poem, intitled, Peter the Great; A Congratulatory Copy of Verfes; An Ode; Translation of Baptifm Rousseau's Ode Sur le Bonheur; Heads of a Course of Lectures on Natural Philosophy; certain passages translated in verse and prose, according to the original, from Cicero, Erasmus, Lucian, Ammianus Marcellinus, Quintus Curtius, Homer, Virgil, Martial, Ovid, Horace, and Seneca, which Russian translations were brought as examples in his Lectures upon Rhetoric; laftly, Description of the Comet which appeared in 1744. The third volume contains chiefly of Speeches and Treatises read before the Academy; Panegyric on the Emprefs Elizabeth; on Peter the Great; Treatise on the Advantages of Chemistry; on the Phenomena of the Air occasioned by the Electrical Fire, with a Latin Translation of the fame; on the Origin of Light as a new Theory of Colours; Methods to determine with precision the Course of a Vefsel; on the Origin of Metals by the means of Earthquakes; Latin Dissertation on Solidity and Fluidity; on the Transit of Venus in 1761, with a German translation. Beside these various subjects, Lomonoff made no incicdible figure in history, having published two small works relative to that of his own country. The first, styled Annals of the Russian Sovereigns, is a short chronology of the Russian monarchs; and the second is, the Ancient History of Russia, from the Origin of that Nation to the Death of the Great Duke Yaroslav I. in 1054; a performance of great merit, as it illustrates the moft difficult and obscure period in the annals of this country.

LONDON, a large city of Middlefex in England, the metropolis of Great Britain, and one of the most wealthy and populous places in the world, is situated on the river Thames, in 51° 31' north latitude, 000 miles south of Edinburgh, and 270 south-east of Dublin; 180 miles west of Amsterdam, 210 north-west of Paris, 300 north-west of Copenhagen, 400 north-west of Vienna, 700 north-west of Stockholm, 800 north-east of Madrid, 830 north-west of Rome, 930 north-east of Lisbon, 1360 north-west of Constantinople, and 1414 south-west of Moscow.

The city was by the Romans first called Londinium; as we find it in Tacitus, Polybey, Antonio, and Ammianus. That name was afterwards changed into Augufa; in honour, as some say, of Helena August, the mother of Constantine the Great; while others think it more probable that it had this name from the second legion, whose peculiar title was Augufa; and some imagine that the honourable appellation of Augufa was conferred upon this city by the Romans, as upon other principal cities of their empire, on account of its being grown up to be the capital of their British province. How long the name of Augufa prevailed, is not now certainly known; but after the establishment of the Saxons we find no more mention of Augufa. It was then called Cæsar Londoniæ; Lundoun Byrig, Lundoun Caesar, London-wyve, Lundane, Lundun-berth, or Lundenburg; since the conquest the records call it Londiniæ, Londoniæ, London, Londres; and, for several ages past, it has been called London, a manifest corruption from Tactitus's Londonium. The most probable derivation of these names appears to be, either from the British words dong "a flipp," and din "a town," i.e. a town or harbour for ships; or from Linus "a lake," i.e. Linus din, "the lake upon the land," the Sury side being supposed, upon very probable grounds, to have been anciently a great expanse of water.

Londinium, however, was not the primitive name of this famous place, which existed before the invasion founded, by the Romans; being, at the time of Caesar's arrival in the island, the capital of the Trinobantes or Trinunantes. The name of this nation, as appears from Baxter's Britifh Glossary, was derived from the three p. 230 following British words, tri, not, hant, which signify the "inhabitants of the new city." This name, it is supposed, might have been given them by their neighbours, on account of their having newly come from the continent into Britain, and having there founded a city called "tri-now, ortho" the new city; "the most ancient name of the renowned metropolis of Britain. The Tri-ners had come so lately from Belgium, that they High. vol. 1 seem scarcely to have been firmly established in Britain p. 170 at the time of the first Roman invasion: For their new city, which soon after became so famous, was then so inconsiderable, that it is not mentioned by Caesar, tho' he must have been within sight of the place where it was situated. His silence about this place, indeed, is brought as a proof that he did not cross the Thames; while Norden, the Trinunantes civitas of the Trinobantes, understoods the city in question, the Trinobantes themselves having been among the first of the Britifh states who submitted to that conqueror.

By Ptolemy, and some other ancient writers of good authority, indeed, Londinium is placed in Cantium, or Cent, on the south side of the Thames; and it is the opinion of some moderns, that the Romans probably had a station there, to secure their conquests on that side of the river, before they reduced the Trinobantes. The place fixed upon for this station is St George's fields, a large plat of ground situated between Lambeth and Southwark, where many Roman coins, bricks, and chequered pavements, have been found. Three Roman ways from Kent, Surrey, and Middlefex, intersected each other in this place; this therefore is supposed to be the original Londinium which it is thought became neglected after the Romans reduced the Trinobantes, and settled on the other
The Romans possessed themselves of London, on their second invasion in the reign of Claudius, about 105 years after their first under Caesar. They had begun with Camulodunum, the present Maldon in Essex, and taking it, planted there a colony consisting of veterans of the 14th legion. London and Verulamium were next taken possession of, about one and a half times after Camulodunum was made a colonia, or place governed entirely by Roman laws and customs; Verulamium (on the site of which St Alban's now stands), a municipium, in which the natives were honoured with the privileges of Roman citizens, and enjoyed their own laws and constitutions; and Londinium only a praefidura, the inhabitants, a mixture of Romans and Britons, being suffered to enjoy no more than the name of citizens of Rome, being governed by prefects sent annually from thence, without having either their own laws or magistrates. "It was even then of such concourse (says Mr Pennant), and such vall trade, that the white conquerors did not think fit to trust the inhabitants with the same privileges as other places of which they had less reason to be jealous." But others observe, that this is a mistake; and that the Romans, in order to secure their conquest, and to gain the affections of those Britons who had already submitted to their authority, made London equally a municipium or free city with Verulamium, as may be seen by referring to Aulus Gallius, l. 16. c. 13. and to Spanhem, orbis Roman. P. 37. 38. tom. ii.

It is difficult to say what were the particular articles of commerce exported from and imported into the port of London at this period. The imports and exports have in general we know; Strabo says, "Britain produces corn, cattle, gold, silver, iron, besides which, skins, flaves, and dogs naturally excellent hunters, are exported from that island." It is probable that the two first and three last articles were exported from London; and perhaps, too, the geese or jet-tone mentioned by Solinus as one of the productions of Britain, together with hares, were exported from thence. The imports were, at first, felt, carthn ware, and works in brass, polished bits of bones emulating ivory, horse-collars, toys of amber, glases, and other articles of the same material.

In the reign of Nero, as Tacitus informs us, London was become a city highly famous for the great concourse of merchants, her extensive commerce, and plenty of all things. No fewer than seven of the fourteen Itinera of Antoninus begin or end at London; which tends to corroborate the many proofs which might be adduced, that this city was the capital of Britain in the Roman times.

At first London had no walls or other fortifications to defend it, and was therefore exposed to the attacks of every enemy, and thus it suffered severely about the year 64, being burnt by the Britons under Boadicea, and all the inhabitants butchered. But it was soon restored by the Romans and increased so much, that in the reign of the emperor Severus it is called by Herodian a great and wealthy city. It continued, however, in a defenceless state for more than a century after this last period; when at last a wall of hewn stone and British bricks were erected round it.

London at this time extended in length from Ludgate-hill to a spot a little beyond the Tower. The breadth was not half equal to the length, and at each end grew considerably narrower. Maitland describes the building of the walls to Theodosius governor of Britain in 395. Dr. Woodward, with more probability, supposes them to have been founded under the auspices of Constantine the Great; and this seems to be confirmed by the numbers of coins of that emperor's mother Helena, which have been discovered under them, placed there by him in compliment to her. The fame emperor made it a bishop's see; for it appears that the bishops of London and York, and another English bishop, were at the council of Arles in the year 314; he also settled a mint in it, as is plain from some of his coins. The ancient course of the wall was as follows: It began with a fort near the present site of the Tower, was continued along the Minories, and the back of Houndsditch, across Bishopsgate-street, in a straight line by London-wall to Cripplegate; then returned southward by Crowder's Well Alley, (where several remnants of lofty towers were lately to be seen) to Aldergate; thence along the back of Bull and Mouth-street to Newgate, and again along the back of the houses in the Old Bailey to Ludgate; soon after which it probably finished with another fort, where the house, late the king's printing-house, in Black Friars, now stands: from hence another wall ran near the river side, along Thames-street, quite to the fort on the eastern extremity. The walls were three miles a hundred and sixty-five feet in circumference, guarded at proper distances on the land side with fifteen lofty towers; some of them were remaining within these few years, and possibly may still. Maitland mentions one twenty-six feet high, near Gravel-lane, on the west side of Houndsditch; another, about eighty paces south-east towards Aldgate; and the bales of another, supporting a modern house, at the lower end of the street called the Vineyard, south of Aldgate. The walls, when perfect, are supposed to have been twenty-two feet high, the towers forty. These, with the remnants of the wall, proved the Roman structure, by the tiles and disposition of the masonry. London-wall, near Moorfields, is now the most entire part left of that ancient precinct. The gates, which received the great military roads, were four. The Praetorian way, the Saxon Watling-street, passed under one, on the site of the late Newgate; vestiges having been discovered of the road digged above Holburn-bridge: it turned down to Dowgate, or more properly Darw-gate or Watergate, when...
London there was a trajec or ferry, to join it to the Watling-street, which was continued to Dover. The Hermin direct passed under Cripplegate; and a vicinal way went under Aldgate by Bethnal-green, towards Oldford, a pas over the river Lee to Duroleiton, the modern Leiton in Essex.

After the Romans deserted Britain, a new and fierce race succeded. The Saxons, under their leaders Hengist and Horna, landed in 449, having been invited over by the provincials as auxiliaries against the Scots and Picts; but quarrelling with their friends, they found means to establish themselves in the island, and in process of time entirely subdued them, as related under the article ENGLAND, nos 31-44. London fell into the hands of these invaders about the year 457, and became the chief city of the Saxon kingdom in Essex. It suffered much in the wars carried on between the Britons and Saxons: but it soon recovered; so that Bede calls it a principality or mart-town, under the government of a chief magistrate, whose title of portgrave, or portreue (as we find him called by both names), conveys a grand idea of the mercantile state of London in those early ages, that required a governor or guardian of the port. During the civil war of the Saxons with each other, the Londoners had always the address to keep themselves neuter; and about the year 819, when all the seven Saxon kingdoms fell under the power of Egbert, London became the metropolis of England, which it has ever since continued.

During the invasions of the Danes, London suffered greatly. In 849, these invaders entered the Thames with 250 ships, plundered and burnt the city, and massacred the inhabitants; and two years after they returned with a fleet of 350 sail, fully determined to destroy every thing that had escaped their barbarity in the former expedition. At this time, however, they were disappointed; most of their troops being cut in pieces by king Ethelwold and his son Athelbald; yet such was the destruction made by these barbarians at London, that it suffered more from these two invasions than it had done before.

In the reign of king Alfred the Great, London began to recover from its former ruinous state. He rebuilt its walls, drove out the Danish inhabitants who had settled there, restored the city to its former liberties and beauty, and committed the care of it to his son-in-law, Ethelred duke of Mercia, in hopes that this might always be a place of secure retreat within its strong walls, whatever might happen from a foreign or domestic enemy. In 893, however, he had the mortification to see his capital totally reduced to ashes by an accidental fire, which could not be extinguished, as the houses at that time were all built of wood. The walls, however, being constructed of incumbible materials, continued to afford the same protection as before; the houses were quickly rebuilt, and the city divided into wards and precincts for its better order and government. This king also instituted the office of sheriff, the nature of which office made it necessary to have it also in London; so that here we have the glimmerings of the order of magistrates afterwards settled in the city of London; in the person of the portreue, or portgrave, or governor of the city, as supreme magistrate; in the sheriff, and in the officer or subordi-

nate magistrate by what name soever then distinguished, which, being placed at the head of each ward or township, were analogous to the modern title of aldermen and common-councilmen.

Alfred having settled the affairs of England in the Brick and most prudent manner, directed his attention to the or gene namenting, as much as possible, the city of London, houses first. For this purpose, he spirited up the English to an emula
tion in building their houses of stronger and more durable materials than formerly. At that time their houses were mostly of wood; and an house built of any other materials was looked upon as a kind of wonder. But Alfred having begun to raise his palaces of stone and brick, the opulent Londoners, and the mobiility resident in and about London, followed the example, though the custom did not come into general use till some ages after.

In 1015, a foreign enemy again appeared before London. Canute king of Denmark having invaded and plundered the counties of Dorset, Somerset, and Wilts, failed up the Thames with 200 ships, and laid siege to the city. The citizens continued faithful, notwithstanding the defection of the greatest part of the kingdom; and made such a brave resistance, that Canute thought fit to withdraw his army, leaving only his fleet to blockade the city by water; that when he found a fair opportunity he might renew the siege with better success. At last, however, being defeated in several battles by Edward Ironside, he was obliged to call off his ships to cover his own army in case of necessity. In the compromise, however, which was afterwards made between Edmund and Canute, the city of London was given to the latter, and owned him for its lawful sovereign. We have a strong proof of the opulence of London even at this time, from the tax laid upon it by Canute in order to pay his army; this being no less than 10,500l. while the rest of the nation was at the same time taxed only at 72,000l.

In 1046, we have the first intimation of the Londoners sending representatives to parliament. This happened on settling the succession to the throne after Canute's death. The English in general declared for Edward, son of king Ethelred, or, in other words, for Emma, and then absented on a tour to Denmark. The city of London espoused the claim and interest of Harald Harefoot, son of Emma, and then abjured the succession in the name of Edward's party soon declined; and the Londoners agreed, for the peace of the realm, that the two brothers should divide the kingdom between them; but as Hardicanute did not return in proper time to England, a witenage-note was held at Oxford, where earl Leofric, and most of the thanes on the north of the Thames, with the pilots of London, chose Harold for their king. Here, by pilote we are to understand the directors, magistrates, or leading men of the city: and this manifestation shows, that London was then of such consequence, that important national affairs were transacted without the consent of the inhabitants; for the Saxon annals assure us, that none were admitted into this assembly of election but the nobility and the pilots of London.

On the invasion of the Normans under William I. London submitted as well as the rest of the kingdom; and received two charters from that prince, confirming &c.
ing all the privileges they had under the Saxon kings, and adding several new ones. But while the citizens were promising themselves all manner of security and tranquility under the new government, it was almost entirely reduced to ashes by an accidental fire in 1077. It had sorely recovered from this calamity, when it was visited by another of the same kind in 1086, which began at Ludgate, and destroyed the best and most opulent part of the city; consuming, among other buildings, the cathedral of St Paul's, which, however, was soon rebuilt more magnificently than before.

Under the reign of William Rufus, London suffered considerably by fires, hurricanes, and inundations, and seems to have been depressed by the tyranny of that prince; but Henry I. granted large immunities to the city, which again revived its trade, and was favorable to the progress of the arts. The king, however, still retained the privilege of appointing the portreave, or chief magistrate; but the immunities granted to the Londoners secured their affections, and tended much to secure him on the throne. At the same time, there was much money in the exchequer, and the city of London was much favored by King Henry. The Londoners, to additional power of their hands or feet cut off, were at last stopped by the execution of John Senex, who, though a very rich and reputable citizen, had engaged in these enterprises. He offered 500 lb. weight of silver, a prodigious sum in those days, for his pardon, but was refused. The king, however, still continued to drain the citizens of their money by free gifts, and at last fined every separate guild, fraternity, or company, that had professed to sell as bodies corporate without the royal letters-patent.

On the death of Henry II. the title of the first mayor of London was conferred by a charter of that time, and at the coronation of Richard I. in 1199, this monarch permitted the bailiff, named Henry Fitz Alwine, to assume the title of mayor. For, in 1192, we find certain orders of the mayor and aldermen to prevent fires; whereby it was ordained, that "all houses thereafter to be erected in London and the liberties thereof, should be built of stone, with party-walls of the same; and covered either with slates or tiles, to prevent those dreadful calamities by fire, which were frequently and chiefly occasioned by houses of wood, and thatched with straw or reeds." And for this purpose, it was also provided by the discretionary men of the city, "that 12 aldermen of the city should be chosen in full hustings, and there sworn to assist the mayor in appealing contentions that might arise between neighbours in the city upon inclosure betwixt land and land, and to regulate the dimensions of party-walls, which were to be of stone, 16 feet high and three feet thick, and to give directions about girders, windows, gutters, and wells." Such confidence also did Richard put in the wisdom and faithfulness of the city of London, that when it was resolved to fix a standard for weights and measures for the whole realm, his majesty committed the execution thereof to the sheriffs of London and Middlesex, whom he engaged in these enterprizes. He offered a standard for measures, gallons, yards, and weights for standards, to be sent to the several counties of England. This happened in 1198, at which time corn was advanced to the enormous price of 18s. 4d. per quarter.

The city of London was much favored by King John, who granted them three charters soon after his accession. The first was a recital and confirmation of the charter granted by Henry I. and II. with the farther privilege of being free from toll and every other duty or custom in his majesty's foreign dominions; for which they paid the sum of 3000 marks. The second was a confirmation of one granted by King Richard. By this the citizens of London had the jurisdiction and conservancy of the river Thames; with a clause to extend that jurisdiction, and the powers therewith granted, to the river Medway; and with another clause to enable the said city, as conservators of the rivers Thames and Medway, to inflict a penalty of 10l. upon any person that should presume to erect a weir in either of these rivers. The third charter contains a fee-farm-rent of the sheriffs of London and Middlesex at the ancient rent, of which they had been deprived by Queen Maud; granting them also the additional power of choosing their own sheriffs. This charter was given by way of conveyance from the crown to the citizens for a valuable consideration, by which the sheriffs became their freehold; and this is the first covenant or conveyance we find on record.
In the year 1212, on St. James's day, the citizens of London having carried off the victory from the people of Westminster, and other neighbouring villages, the steward of the abbot of Westminster, mediating revenge against the Londoners, proposed another wrestling-match with them, and gave a ram for the prize. The citizens reforted to the place at the time appointed, but were unexpectedly attacked by a great number of armed men, who killed and wounded many, and dispersed the rest. This raised a great commotion in the city. The populace breathed revenge; and, by the instigation of Constance Fitz-Arnulf, a great favourite of the French party during the troubles in king John's reign, they proceeded to Westminster, and pulled down the houses both of the steward and abbot. Hearing afterwards that the abbot was come into the city with his complaint to Philip Daubrey the king's counsellor, they pursuaded him, beat his servants cruelly, took away 12 of his horses, and would have murdered himself, had he not escaped by a back-door. Upon this tumult, Hubert de Bury, then chief justice, summoned the mayor and many of the principal citizens to attend him in the tower of London; and enquiring for the authors of the riot, Constance, the ringleader, boldly answered, that "he was one; and that they had done no more than they ought; and that they were resolved to avow what they had done, let the consequence be what it would." In this he was seconded by his nephew and one Geoffrey; but the judicature, having dismissed all the rest, detained these three, and ordered them to be hanged next morning, though Constance offered 15,000 marks for his pardon. Hubert then coming into the city with a strong guard, caufed the hands and feet of most of the principal rioters he could seize to be cut off; all which was executed without any legal proceedings or form of trial. After these arbitrary cruelties, he degraded the mayor and all the magistrates; placed a curfew over the city, and oblgd 30 persons of his own choosing to become securities for the good behaviour of the whole city. Several thousand marks were also exacted by the king, before he would consent to a reconciliation.

This arbitrary behaviour alarmed the whole nation. The parliament of 1224 began to be uneasy for themselves, and addressed his majesty that he would be pleased to confirm the charter of liberties which he had sworn to observe; and the commons, in imitation of the senatus consultum of the magna charta in the full parliament at Westminster in the year 1225. At this time also, the rights and privileges of the citizens were confirmed. They were exempted from procurations for barrels, i.e. a luted cloth; and were granted the right of having a common feal. The melancholy circumstances of this monarch, however, made him often exact money arbitrarily as long as he lived.

Under the succeeding reigns, as the liberty of the people in general was augmented, so the liberty, privilege, and power of the citizens of London increased till they became a kind of balance to the power of the crown itself, which in some measure they still continue to be. Riots indeed, for which they generally suffered, were by no means unfrequent; the city often suffered by fires and plagues. Nothing, however, happened which materially affected the welfare of the city, till the reign of Charles II. in 1665. This year London was ravaged by the most violent plague ever known in Britain. The whole summer had been remarkably mild and warm, so that the weather was sometimes suffocating even to people in perfect health; and by this unusual heat and sultry atmosphere, people were undoubtedly prepared for receiving the infection, which appeared in the persons of John Arundel and others in September. A violent plague had raged in Holland in the year 1663; on which account the importation of merchandize from that country was prohibited by the British legislature in 1664. Notwithstanding this prohibition, however, it seems the plague had actually been imported; for in the clofe of the year 1664, two or three persons died suddenly in Westminster, with marks of the plague on their bodies. Some of their neighbours, terrified at the thoughts of their danger, removed into the city; but their removal proved too late for themselves, and fatal to those among whom they came to reside. They soon died of the plague, and communicated the infection to so many others, that it became impossible to extinguish the seeds of it by separating those that were infected from such as were not. It was confined, however, through a hard frosty winter, till the middle of February, when it again appeared in the parish of St. Giles's to which it had been originally brought; and after another long rest till April, showed its malignant force afresh, as soon as the warmth of the spring gave it opportunity. At first, it took off one here and there, without any certain proof of their having infected each other, and houses began to be shut up, with a design to prevent its spreading, but it was too late; the infection gained ground every day, and the shutting up of houses only made the diseases spread wider. People, afraid of being shut up, and fequestered from all communications with society, concealed their illness, or found means to escape from their places of confinement; while numbers expired in the greatest torments, destitute of every assistance, and many died both of the plague and other diseases, who would in all probability have recovered, had they been allowed their liberty, with proper exercise and air.—A houfe was shut up upon account of a maid servant, who had only spots, and not the gangrenous plague-blotches, upon her, so that her master was probably a petechial fever. She recovered; but the people of the house obtained no liberty to fly, either for air or exercise, for 40 days. The bad air, the anger and vexation, attending this injurious treatment, cast the misfortunes of the family into a fever. The visitors appointed to search
fire in 1666

London.

search the houses, said it was the plague, though the physicians were of a different opinion: the family, however, were obliged to begin their quarantine anew, though it had been almost expired before; and this second confinement affected them so much, that most of the family fell sick, some of one distemper and some of another. Many examples of a similar kind happened, and this was one of the worst conflagrations of blighting up houses. A means of putting a stop to the infection were evidently ineffectual. Multitudes fled into the country; many merchants, owners of ships, &c., shut themselves up, on board their vessels, being supplied with provisions from Greenwich, Woolwich, and single farm-houses on the Kentish side. Here, however, they were safe; for the infection never reached beyond Deptford, though the people went frequently on shore to the country-towns, villages, and farm-houses to buy fresh provisions. As the violence of the plague increased, the ships which had families on board removed farther off; some went quite out to sea, and then put into such harbours and roads as they could best get at.

In the mean time, the distemper made the most rapid progress within the city. In the last week of July, the number of burials amounted to 2010; but the first week of August it rose to 3817; thence to 3880; then to 4227; the next week to 5238; and at last to 7000 and 8000 weekly. In the last week of September, however, the fury of the disease began to subside; though vast numbers were sick, yet the number of burials decreased from 7155 to 5738; the next week there was a further decrease to 4929, then to 4227, next to 2665, then to 1421, and the next week to 1037.

All this while the poor people had an immense way up into the air, and their reflection from the smoke, which in the night-time seemed also like flame, made the appearance still more terrible. The atmosphere was illuminated to a great extent, and this illumination is said to have been visible as far as Jedburgh in Scotland. Some of the light ashes also have been carried far from the city, at a distance of 16 miles. Guildhall exhibited a singular appearance. The oak with which it was built was so solid that it would not flame, but burnt like charcoal, so that the building appeared for several hours like an enchanted palace of gold or burnished brass.

At last, on Wednesday morning, when every one expected that the suburbs as well as the city were to be consumed, it began of itself to subside by reason of the wind having ceased, and some other changes no doubt taken place in the atmosphere. It was observed by the great building in Leadenhall-street, and in other streets by the blowing up several houses with gunpowder, and on Thursday the flames were quite extinguished. The following is a calculation of the damage done by this extraordinary conflagration.

Thirteen thousand two hundred houses, at 12 years purchase, supposing the rent of each 25l. Sterling, 3656000 0 0
Eighty-seven parish-churches, at 800l. each, 665000 0 0

Carried forward, 4656000 0 0

Six.
Six consecrated chapels, 2000 l. 12,000 0 0
The royal exchange 50,000 0 0
The custom-house 10,000 0 0
Fifty-two halls of companies, at 1500 l. each 78,000 0 0
Three city-gates at 3000 l. each 9000 0 0
Jail of Newgate 15,000 0 0
Four stone-bridges 6000 0 0
Schooners, &c. 7000 0 0
Guildhall, with the courts and offices belonging to it 40,000 0 0
Blackwell-hall 3000 0 0
Bridewell 5000 0 0
Poultry Compter 5000 0 0
Woodstreet Compter 3000 0 0
St Paul's church 2,000,000 0 0
Wares, household-fluff, money, and moveable-goods lost or spoiled 2,000,000 0 0
Hire of porters, carts, waggons, barges, boats, &c. for removing goods 200,000 0 0
Printed books and paper, in farms and ware-houses 150,000 0 0
Wine, Tobacco, sugar, &c. of which the town was at that time very full 1,500,000 0 0
10,689,000 0 0

It was never certainly known whether this fire was accidental or design'd. A suspicion fell upon the Papists; and this gained such general credit, that it is affirmed for a truth on the monument which is erected in memory of the conflagration. Of the truth of this aff'rmation, however, though there was not sufficient proof, it had the effect of making the Papists most violently suspected and abhorred by the Protestants, which some time after proved very prejudicial to the city itself.

From this calamity, great as it was, London soon recovered itself, and became much more magnificent than before; the streets which were formerly crooked and narrow, being now built wide and spacious; and the industri of its inhabitants repaired the losses they had sustained. In 1679, the city was again alarmed by the discovery of a design to destroy it by fire a second time. Elizabeth Oxly, servant to one Rind in Fetter-lane, having set her master's house on fire, was apprehended on suspicion, and confessed, that she had been hired to do it by one Stubbs a Papist, for a reward of 51. Stubbs being taken into custody, acknowledged that he had persuaded her to it; and that he himself had been prevailed upon by one father Gifford his confessor, who had assured him, that by burning the houses of heretics he would do a great service to the church. He also owned that he had several conferences with Gifford and two Irishmen on the affair. The maid and Stubbs also agreed in declaring, that the Papists intended to rise in London, expecting to be powerfully supported by a French army. In consequence of this discovery, the Papists were banished from the city and ten miles round, and five Jesuits were hanged for the abovementioned plot.

The Papists thought to revenge themselves, by forging what was called the meat-tub plot, in which the Presbyterians were supposed to hatch treacherous designs against the life of the king. Sir Edmonbury Godfrey also, who had been very active in his proceedings against the Papists, was murdered by some unknown persons; and this murder, together with their discovering the falsehood of the meal-tub plot, a quarrel to exasperate the Londoners, that they resolved to show their detestation of Popery, by an extraordinary exhibition on the 17th of November, Queen Elizabeth's accession to the throne, on which occasion the town had usually burnt the Pope in effigy. The procession began with a person on horseback prostrating Sir Edmondbury Godfrey, attended by a bell-man, proclaiming his execrable murder. He was followed by a person carrying a large silver cros, with priests in cope, Carmelites, and Gray-friars, followed by six Jesuits; then proceeded divers wavers, and after them some bishops with lawn-sleeves, and others with cope and mitres. Six cardinals preceded the pope, enthroned in a flately pageant, attended by divers boys with pots of incense, and the devil whispering in his ear. In this order they marched from Bishopsgate to Fleet-street; and there, amidst a great number of spectators, committed his holiness to the flames.

This procession gave great offence to the court, at which the duke of York, afterwards James II. had a great influence. This breach was farther widened by the choice of sheriffs for that year. The candidates set up by the court were rejected by a majority of almost two to one; but this did not deter their party from demanding a poll in their behalf, upon which a tumult ensued. This was represented by the Popish party in such colours to the king, that he issued out a commission that same evening for trying the rioters; which, however, was so far from intimidating the rest, that they grew more and more determined, not only to oppose the Popish party, but to exclude the duke of York from his succession to the throne.

In the mean time, the king prorogued the parliament, to prevent them from proceeding in their inquiry concerning the Popish plot, and the exclusion-bill. Upon this the lord-mayor, aldermen, and common-council, presented a petition to his majesty, in which they requested, that he would permit the parliament to sit in order to complete their salutary measures and councils. This petition was highly recommended by the king; who, instead of granting it, dissolved the parliament, and could never afterwards be reconciled to the city. From this time it was determined to feize their charter; and fresh provocations having been given about the election of sheriffs, a warrant was at last produced by the attorney-general, in order to overthrow their charter, and thereby deprive the citizens of the power to choose sheriffs, against the city. This information set forth, That the mayor and commonalty and citizens of the city of London, by the space of a month then past and more, used, and yet do claim to have and use, without any lawful warrant or regal grant, within the city of London abovefoald, and the liberties and privileges of the same city, the liberties and privileges following, viz. 1. To be of themselves a body corporate and politic, by the name of mayor and commonalty and citizens of the city of London. 2. To have sheriffs civil and criminal. 3. To have house of commons. 4. To have a form of government and laws of the city, and to name, make, and elect, and constitute
Though nothing could be more unjust than this proceeding, the mischief were determined at all events to ruin the Londoners; rightly judging, that it would be an easy matter to make all other corporations surrender their charters into the king's hands, and that they had no other body in the nation to fear. Accordingly they displaced such judges as would not approve of their proceedings, and, on the 12th of June 1683, Justice Jones pronounced the following sentence: "That a city might forfeit its charter; that the malversation of the common-council were acts of the whole city; and that the points let forth in the pleadings were just grounds for the forfeiting of a charter."

Notwithstanding the sentence, however, the attorney-general, contrary to the usual custom in such cases, was directed to move that the judgment might not be recorded; being afraid of the consequences. Yet it was judged that the king might seize the liberties of the city. A common-council was immediately summoned to deliberate on this exigency. The country party moved to have the judgment entered; but they were over-routed by the city party, who insisted upon an absolute sublimation to the king before judgment was entered; and though this was in effect a voluntary surrender of the city liberties, and depriving themselves of the means of getting the judgment reversed, the act of sublimation was carried by a great majority: and in a petition from the lord-mayor, aldermen, and common-council, they "acknowledged their own misgovernment, and his majesty'sjustice; begged his pardon, and promised constant loyalty and obedience; and humbly begged his majesty's commands and directions." To this his majesty answered, that he would not reject their suits, if they would agree upon the following particulars. 1. That no boro-, sheriff, recorder, common-serjeant, town-clerk, coroner, of the city of London, or steward of the borough of Southwark, shall be capable of, or admitted to, the exercise of their respective offices before his majesty shall have approved of them under his sign manual. 2. That if his majesty shall disapprove the choice of any person to be lord mayor, and signify the same under his sign manual to the lord-mayor, or, in default of a lord mayor, to the recorder or senior alderman, the citizens shall, within one week, proceed to a new choice, and if his majesty shall in like manner disapprove the second choice, his majesty may, if he pleases, nominate a person to be lord mayor for the year ensuing. 3. If his majesty shall, in like manner, disapprove the persons chosen to be sheriffs, or either of them, his majesty may appoint sheriffs for the year ensuing. 4. That the lord mayor and court of aldermen may, with the leave of his majesty, displace any alderman, recorder, &c. 5. Upon the election of an alderman, if the court of aldermen shall judge and declare the person preferred to be unfit, the ward shall choose again; and upon a disapproval of a second choice, the court may appoint another in his room. 6. That the justices of the peace should be by the king's commission; and the settling of those matters to be left to his majesty's attorney-general, and council learned in the law."}

To these the lord keeper added, in the king's name, "That these regulations being made, his majesty would not only pardon this proceeding, but would confirm their charter in such a manner as should be consistent with them; concluding thus: "My lord mayor, the term draws towards an end, and Midsummer-day is at hand, when some of the officers used to be chosen; whereas his majesty will reserve the approbation. Therefore, it is his majesty's pleasure, that you return to the city, and confirm the common-council, that he may speedily know your resolutions thereupon, and accordingly give his directions. That you may see the king is in earnest, and the matter is not capable of delay, I am commanded to let you know he hath given orders to his attorney-general to enter upon judgment on Saturday next; unless you prevent it by your compliance in all these particulars."

A common council was summoned, when the friends of liberty treated those bills with conditions as they deserved; and even declared, that they were ready to sacrifice all that was near or dear them, rather than submit to such arbitrary impositions; but when it was put to the vote, there appeared a majority of 18 for sublimation. Thus the king got the government of the city into his own hands, though he and his brothers entirely lost the affection of the Londoners. But, not content with their sublimation, his majesty departed from his promise; commanded the judgment upon the quo warranto to be entered; and commissioned Sir William Pritchard, the lord mayor, to hold the same office during his majesty's pleasure. In the same manner he appointed or displaced the other magistrates as he thought proper; after which the ministers, having nothing to fear, proceeded in the most arbitrary manner.

In this sucession to the will of the court, the city of London continued till the Revolution; but, in 1689, the immediate reformation of the Londoners to their privileges of the city was ordered; and in such a manner and form, as to set it out of the power of an arbitrary minister and a corrupt judge and jury to deprive them of their chartered liberties for the time to come. Accordingly a bill was brought into parliament, and passed, for reversing the judgment of the quo warranto against the city of London, and for restoring the same to its ancient rights and privileges. Since that time the city of London hath enjoyed tranquility; its commerce hath been carried to the highest pitch; and for the politeness, riches, and number of its inhabitants, as well as its extent and the magnificence of its buildings, is inferior to no city in Europe, if not superior to every one.

That part of this immense capital which is distinguished by the name of the city, stands on the north shore of the river, from the Tower to the Temple, occupying only that space formerly encompassed by the wall, which in circumference measures but three miles and 165 feet. In this wall are seen seven gates by land, viz. Ludgate, Aldgate, Cripplegate, Alderigate, Moorgate, Bishopsgate, which were all taken down in September, 1760; and Newgate, the county gaol, which was also taken down in 1776, and a massive building...
building erected a little south of it, which by the rioters in 1780 received damage to the amount of £80,000. On the side of the water there were Dowgate and Billingsgate, long since demolished, as well as the poferina-gate near the Tower. In the year 1670 there was a gate erected called Temple-Bar, which terminates the bounds of the city westward. The liberties, or those parts of this great city which are subject to its jurisdiction and lie without the walls of London, are bounded on the east, in White-chapel, the Minories, and Bishopsgate, by bars, which were formerly poles, and chains, that were frequently taken away by arbitrary power, when it was thought proper to seize the franchises of the city of London: on the north, they are bounded in the same manner in Pickaxe street, at the end of Pan-alley, and in St John's street; on the west, by bars in Holborn: at the east end of Middle Row, and at the west end of Fleet-street, by the gate called Temple-Bar, already mentioned: on the south, we may include the jurisdiction which the city holds on the river Thames, and over the borough of Southwark. The city, including the borough, is at present divided into 36 wards.

1. Aldergate ward takes its name from a city-gate which lately stood in the neighbourhood. It is bounded on the east by Cripplegate ward, on the west, by Farrington ward within and without; and on the south, by Farrington ward within. It is very large, and is divided into Aldergate-within and Aldergate-without. Each of these divisions consists of four precincts, under one alderman, eight common-council men, of whom two are the alderman's deputies, eight constables, fourteen inquest-men, eight scavengers, and a beadle; exclusive of officers belonging to the liberty of St Martin's-le-Grand, which contains 168 houses.

2. Aldgate takes its name also from a gate, which was of great antiquity, being mentioned in king Edgar's charter to the knights of the Knighton Guild about the year 967; and was probably of a much more ancient foundation, for it was the gate through which the Roman Vicinal way lay to the ferry at Oldford. In the time of the wars between king John and his barons, the latter entered the city through this gate, and committed great devastations among the houses of the religious. Aldgate was rebuilt by the leaders of the party after the Roman manner. They made use of stone which they brought from Caen, and a small brick called the Flanders tile, which Mr Pennant thinks has been often mistaken for Roman. The new gate was very strong, and had a deep well within it. In 1477 this gate was assaulted by the Baffard of Falconbridge, who got possession of it for a few hours; but the portcullis being drawn up, the troops which had entered were all cut off, and the citizens, headed by the alderman of the ward and recorder, having made a sally, defeated the remainder with great slaughter. In 1606 Aldgate was taken down and rebuilt; and many Roman coins were found in digging the foundations.—The ward of Aldgate is bounded on the east by the city-wall, which divides it from Portfoken-ward; on the north, by Bishopsgate-ward; on the west, by Lime-street and Langbourn wards; and on the south, by Tower-street ward. It is governed by an alderman, six common-council men, six constables, twenty inquest men, seven scavengers, and a beadle; besides the officers belonging to St James's, Duke's Place.—It is divided into seven precincts.

3. Bishopsgate or Bassingbolt ward is bounded on the east and south by Coleman-street ward, on the north by part of Cripplegate, and on the west by part of the wards of Cheap and Cripplegate. On the south, it begins at Blackwell-hall; and runs northward to London-wall, pulled down some time ago to make way for new buildings in Fore-street, and spreads 88 feet east, and 54 feet west against the place where that wall stood. This is a very small ward, and consists only of two precincts; the upper precinct contains no more than 66, and the lower only 76 houses. It is governed by an alderman, four common council men, of whom one is the alderman's deputy, three constables, seventeen inquest-men, three scavengers, and a beadle. It has its name from Basing-hall, the mansion-house of the family of Basing, which was the principal house in it, and flood in the place of Blackwell hall.

4. Billingsgate ward is bounded on the east by Tower-street ward, on the north, by Langbourn ward; on the west, by the ward of Bridge-within; and on the south, by the river Thames. There have been many conjectures concerning the origin of the name of Billingsgate, none of which seems to be very well authenticated. It is, for instance, supposed to have derived its name from a British king named Belinus, said to have been an affiant of Brennus, the Gauls, at the taking of Rome, and is the same with the Beli-Maur mentioned in the Welsh genealogies. The name of Ludgate is said to be derived from his son Lud.—It is divided into 12 precincts; and is governed by an alderman, ten common-council men, one of whom is the alderman's deputy, 11 constables, 14 inquest-men, six scavengers, and a beadle. The situation of Billingsgate, on the river, gives it great advantages with respect to trade and merchandize; so that it is well inhabited, and is in a constant hurry of business at the several wharves or quays.

5. Bishopsgate ward is bounded on the east by Aldgate ward, Portfoken-ward, and part of the Tower liberty, or Norton-falgate; on the west, by Broad-street ward and Moorfields; and on the south, by Langbourn ward. It is very large, and divided into Bishopsgate-within and Bishopsgate-without. The first contains all that part of the ward within the city-wall and gate, and is divided into five precincts; the second lies without the wall, and is divided into four precincts. Bishopsgate-without extends to Shoreditch, taking its name from one Sir John de Sordich, an eminent lawyer much in favour with king Edward III. both on account of his knowledge in the law, and of his personal value. In the time of Henry VII. one Barlo, a citizen and inhabitant of this place, was named duke of Shoreditch, on account of his skill in archery; and, for a number of years after, the title belonged to the captain of the London archers. This ward is governed by an alderman, two deputies, one within and the other without, 12 common-council men, seven constables, 13 inquest-men, nine scavengers, and two beadles. It took its name from the gate, which has been pulled down to make that part of the city more airy and commodious. This gate was built by Erkenwald
Erkenwald bishop of London in 675; and it is said to have been repaired by William the Conqueror soon after the Norman conquest. In the time of Henry III, the Hanfe merchants had certain privileges confirmed to them, in return for which they were to support this gate; and in consequence of this they rebuilt it elegantly in 1479. There were two statues of bishops, in memory of the founder and first repairer; other two were also put up, which are supposed to have been designed for Alfred and Elder earl of Mercia, to whose care the gate had been committed.

6. Bread-street ward is encompassed, on the north and north-west, by the ward of Pardingdon-within; on the east, by Cordwainer’s ward; on the south by Queenhithe-ward; and on the west, by Castle-Baynard ward. It is divided into 14 precincts; and is governed by an alderman, 12 common council-men, of whom one is the alderman’s deputy, 13 constables, 13 inquest-men, 13 scavengers, and a beadle; and yet contains no more than 331 houses. It takes its name from the ancient bread-market, which was kept in the place now called Bread-street; the bakers being obliged to sell their bread only in the open market and not in shops.

7. Bridge-ward within is bounded on the south by the river Thames and Southwark; on the north, by Langbourn and Bishopsgate ward; on the east, by Billingsgate; and on the west, by Candlewick and Dowgate wards. It is divided into 14 precincts, three of which are on the bridge, and is governed by an alderman, 15 common council-men, one of whom is the alderman’s deputy, 14 constables, 15 inquest-men, 14 scavengers, and a beadle. It takes its name from its connection with London-bridge.

8. Bread-street ward is bounded, on the north and east, by Bishopsgate ward; on the south, by Cornhill and Wallbrook ward; and on the west, by Coleman-street ward. It is divided into 10 precincts; and is governed by an alderman, 10 common council-men, one of whom is the alderman’s deputy, 10 constables, 13 inquest-men, 8 scavengers, and a beadle. It has its name from that part of it now distinguished by the name of Old Bread-street; and which, before the fire of 1666, was accounted one of the broadest streets in London.

9. Candlewick ward, Candlewick-street, or Candlewright street ward, as it is called in some ancient records, is bounded on the east by Bridge ward; on the south, by Dowgate and part of Bridge ward; on the west, by Dowgate and Wallbrook; and on the north, by Langbourn ward. It is but a small ward, consisting of about 216 houses; yet is divided into seven precincts. It is governed by an alderman, eight common council-men, of whom one is the alderman’s deputy, seven constables, seven inquest-men, seven scavengers, and a beadle. It has its name from a street, formerly inhabited chiefly by candle wrights or candlemakers, both in tallow and wax; a very profitable business in the times of Popery, when incredible quantities of wax-candles were consumed in the churches. That street, however, or at least its name, Candlewick, is lost since the great conflagration, for which the name Cannon-street is substituted, the candle wrights being at that time burnt out and dispersed through the city.

10. Castle-Baynard ward is bounded by Queen-street; Active and Bread-street wards on the east; on the south, by the Thames; and on the west and north, by the ward of Pardingdon-within. It is divided into 10 precincts, under the government of an alderman, 10 common council-men, one of whom is the alderman’s deputy, nine constables, 14 inquest-men, seven scavengers, and a beadle. It takes its name from a castle built on the bank of a river by one Baynard, a follower of fortune, who came in with William the Conqueror, and was by that monarch raised to great honours and authority.

11. Cheap ward is bounded on the east by Broad-street and Wallbrook wards; on the north, by Coleman-street, Bishopsgate, and Cripplegate; and on the south, by Cordwainer’s ward. It is divided into nine precincts; and is governed by an alderman, 12 common council-men, of whom one is the alderman’s deputy, 11 constables, 13 inquest-men, nine scavengers, and a beadle. It has its name from the Saxon word æche, which signifies a market, kept in this division of the city, now called Cheapside; but then known by the name of Wesleheap, to distinguish it from the market then also kept in Eastcheap, between Canon and Candlewick street and Tower-street.

12. Coleman-street ward is bounded on the east by Bishopsgate, Broad-street, and Cheap wards; on the north, by Cripplegate, Bishopsgate, and Middle Moorfields, and Bishopsgate; on the south, by Cheap ward; and on the west, by Bishopsgate ward. It is divided into six precincts; and is governed by an alderman, six common council-men, one of whom is the alderman’s deputy, six constables, six inquest-men, six scavengers, and a beadle. The origin of the name is not certainly known.

13. Cordwainers ward is bounded on the east by Wallbrook, on the south by Vintner ward, on the west by Bread-street, and on the north by Cheap ward. It is divided into eight precincts; and is governed by an alderman, eight common council-men, one of whom is the alderman’s deputy, eight constables, 14 inquest-men, eight scavengers, and a beadle. Its proper name is Cordwainers-street ward; which it has from Cordwainers street, now Bow-lane, formerly occupied chiefly by shoemakers and others that dealt or worked in leather.

14. Cornhill ward is but of small extent. It is bounded on the east by Bishopsgate, on the north by Broad-street, on the west by Cheapside, and on the south by Moorfields. It is divided into four precincts, which are governed by one alderman, six common council-men, of whom one is the alderman’s deputy, four constables, 16 inquest-men, four scavengers, and a beadle. It takes its name from the principal street in it, known from the earliest ages by the name of Cornhill, because the corn-market was kept there.

15. Cripplegate ward is bounded on the east by Moorfields, Coleman-street ward, Bishopsgate ward, and Cheap ward; on the north by the parish of St. Luke’s, Old street; on the west, by Aldermary ward; and on the south, by Cheapside. It is divided into 12 precincts, nine within and four without the wall; and is governed by an alderman, 12 common council-men, of whom two are the alderman’s deputies, 12 constables, 34 inquest-men, 16 scavengers, and three beadles.
London: takes its name from Cripplegate, which stood on the north-west part of the city-wall. It was an old plain structure, void of all ornament, with one portern; but had more the appearance of a fortification than any of the other gates. It was removed in order to widen the entrance into Wood-street, which, by the narrowness of the gateway was too much contracted and rendered dangerous for passengers and great wagons.

16. Dowgate ward is bounded on the east by Candlewick and Bridge wards, on the north by Wallbrook ward, on the west by Vintry ward, and on the south by the Thames. It is divided into eight precincts, under the government of an alderman, eight common-council men, of whom one is the alderman’s deputy, eight constables, 15 inquest-men, five scavengers, and a beadle. It has its name from the ancient water-gate, called Dowgate, which was made in the original wall that ran along the north side of the Thames, for the security of the city against all attempts to invade it by water.

17. Farringdon ward within is bounded on the east by Cheap ward and Baynard-castle ward, on the north, by Alderbury and Cripplegate wards, and the liberty of St Martin’s le Grand; on the west, by Farringdon-without; and on the south, by Baynard-castle ward, and the river Thames. It is divided into 18 precincts; and governed by one alderman, 17 common-council men, of whom one is the alderman’s deputy, 19 constables, 17 inquest-men, five scavengers, and two beadles. It takes its name from William Farringdon citizen and goldsmith of London, who, in 1279, purchased all the aldermary with the appurtenances, within the city of London and suburbs of the same, between Ludgate and Newgate, and also without those gates.

18. Farringdon ward without is bounded on the east by Farringdon within, the precinct of the late priory of St Bartholomew near Smithfield, and the ward of Alderbury; on the north, by the charter-houfe, the parish of St John’s Clerkenwell, and part of St Andrew’s parish without the Freedom; on the west, by High Holborn and St Clement’s parish in the Strand; and on the south by the river Thames. It is governed by one alderman, 16 common-council men, of whom two are the alderman’s deputies, 23 constables, 48 inquest-men, 24 scavengers; and four beadles. It takes its name from the same goldsmith who gave name to Farringdon-within.

19. Langbourn ward is bounded on the east by Aldgate ward; on the north, by part of the same, and Limestreet ward; on the south, by Tower-street, Billingsgate, Bridge, and Candlewick wards; and on the west by Wallbrook. It is divided into 12 precincts. It had its name from a rivulet or long bourn of fresh-water, which anciently flowed from a spring near Mappye alley adjoining to St Catherine Coleman’s church.

20. Limestreet ward is bounded on the east and north by Aldgate ward, on the west by Billingsgate, and on the south by Langbourn ward. It is divided into four precincts; and governed by an alderman, four common-council men, one of whom is the alderman’s deputy, four constables, 13 inquest-men, four scavengers, and a beadle. It is very small; and has its name from some lime-kilns that were formerly built in or near Lime-street.

21. Portfoken ward is bounded on the east by the parishes of Spitalfields, Stepney, and St George’s in the east; on the south, by Tower-hill; on the north, by Billingsgate ward, and on the west by Aldgate ward. It is divided into five precincts; and is governed by an alderman, five common-council men, one of whom is the alderman’s deputy, five constables, 19 inquest-men, five scavengers, and a beadle. Its name signifies the franchise of the liberty gate. This Portfoken was for some time a guild; and had its beginning in King Edgar, when 13 knights, “well beloved of the king and realm, for services by them done,” requested to have a certain portion of land on the east part of the city, left desolate and forsaken of the inhabitants by reason of too much servitude. They bought the king to have this land, with the liberty of a guild for ever. The king granted their request on the following conditions, viz. that each of them should victoriously accomplish three combats, one above the ground, one under ground, and the third in the water: and after this, at a certain day, in East Smithfield, they should run with spears against all comers. All this was gloriously performed; upon which the king named it Knighten Guild, and extended it from Aldgate to the places where the bars now are on the east, and to the Thames on the south, and as far into the water as an horfeman could ride at low water, and throw his spears.

22. Queenhithe ward is bounded on the east by Dowgate, on the north by Bread-street and Cordwainers wards, on the south by the Thames, and on the west by Castle-Baynard ward. It is divided into nine precincts; and is governed by one alderman, six common-council men, one of whom is the alderman’s deputy, and nine constables. It has its name from the hithe, or harbour for large boats, barges, and lighters; for which, and even for ships, it was the anchoring place, and the key for lading and unloading vessels almost of any burden used in ancient times. It has the name of green, because the queens of England usually poled the vessels that unloaded goods here at this hithe, which were very considerable.

23. Tower ward, or Tower-street ward, is bounded on the north by the river Thames, on the east by Tower-hill and Aldgate ward, on the north by Langbourn ward, and on the west by Billingsgate ward. It is governed by one alderman, 12 common-council men, of whom one is the alderman’s deputy, 12 constables, 13 inquest-men, 12 scavengers, and one beadle. It takes its name from Tower street, so called because it leads out of the city in a direct line to the principal entrance of the Tower of London.

24. Vintry ward is bounded on the east by Dowgate, on the south by the Thames, on the west by Queenhithe ward, and on the north by Cordwainers ward. It is a small ward, containing only 418 houses; but is divided into nine precincts, and governed by an alderman, nine common-council men, one of whom is the alderman’s deputy, nine constables, 13 inquest-men, three scavengers, and a beadle. It takes its name from the vintners or wine-merchants of Bourdeaux, who formerly dwelt in this part of the city, and were obliged to land their wines on this spot, and to sell them in 40 days, till the 28th of Edward I.
tends all over the
conveniences, can
of London.

The city and liberties of London are under an ecclesiastical, a civil, and a military government.

As to its ecclesiastical government, London is a bishop's see, the diocese of which comprehends not only Middlesex, Essex, and part of Hertfordshire, but the British plantations in America. The bishop of London takes precedence next to the archbishops of Canterbury and York; but the following parishes of this city are exempt from his jurisdiction, being peculiar under the immediate government of the archbishop of Canterbury, viz. All-hallows in Bread-street, All-hallows Lombard-street; St Dionys Back-church, S Dunfan in the East, St John Bapift, St Leonard East-cheap, St Mary Aldermar, St Mary Bothaw, St Mary le Bow, St Michael Crooked-lane, St Michael Royai, St Pancras Soper-lane, and St Vedast Foster-lane.

The civil government of London divides it into wards and precincts, under a lord-mayor, aldermen, and common-council.

The mayor, or lord-mayor, is the supreme magistrate, chosen annually by the citizens, pursuant to a charter of King John. The current manner of electing the lord-mayor is by the concurrence of the several companies assembled in Guildhall annually on Michaelmas-day, according to an act of common-council in A. D. 1476, where, and when, the liverymen choose, or rather nominate, two aldermen below the chair, who have served the office of sheriff, to be returned to the court of Aldermen, who may choose either of the two; but generally declare the tenor of the two, so returned, to the lord-mayor elected. The election being over, the lord-mayor elected, accompanied by the recorder and divers aldermen, is soon after presented to the lord-chancellor (as his majesty's representative in the city of London) for his approbation; and on the 9th of November following is sworn into the office of mayor at Guildhall; and on the day after, before the barons of the exchequer at Westminister; the procession on which occasion is exceedingly grand and magnificent.

The lord-mayor sits every morning at the munificence-house, or place where he keeps his mayorality, to determine any difference that may happen among the citizens, and to do other business incident to the office of a chief magistrate. Once in six weeks, or eight times in the year, he sits as chief judge of Oyer and Terminer, or gaol-delivery of Newgate for London, and the county of Middlesex. His jurisdiction extends all over the city and suburbs, except some places that are exempt. It extends also from Colney-ditch, above Staines-bridge in the west, to Yeoule, or Yewtree; and the mouth of the river Medway, and up that river to Uptor-castle, in the east: by which he exercises the power of punishing and correcting all persons that shall annoy the streams, banks, or fish. For which purpose his lordship holds several courts of consuancy in the counties adjacent to the said river, for its conservation, and for the punishment of offender's. See the article Mayors Court.

The title of dignity, alderman, is of Saxon original, Aldermen, and of the greatest honour, answering to that of Earl, though now it is no where to be found but in chartered societies. And from hence we may account for the reason why the aldermen and commonalty of London were called barons after the conquest. These magistrates are properly the subordinate governors of their respective wards under the lord-mayor's jurisdiction: and they originally held their aldermanries either by inheritance or purchase; at which time the aldermanries or wards changed their names as often as their governors or aldermen. The oppressions, to which the citizens were subject from such a government, put them upon the means to abolish the perpetuity of that office; and they brought it to an annual election. But that manner of election being attended with many inconveniences, and becoming a continual bone of contention amongst the citizens, the parliament, 17 Richard H. A. D. 1394, enacted, That the aldermen of London should continue in their several offices during life or good behaviour. And so it still continues: though the manner of electing has several times varied. At present it is regulated by an act of parliament, passed in the year 1724-5: and the person so elected is to be returned by the lord-mayor (or other returning officer in his stead, duly qualified to hold a court of wardmote) to the court of lord-mayor and aldermen, by whom the person so returned must be admitted and sworn into the aldermanry before he can act. If the person chosen refused to serve the office of alderman, he is fined 500l.

These high officers constitute a second part of the city legislature when assembled in a corporate capacity, and exercise an executive power in their respective wards. The aldermen who have passed the chair, or served the high office of lord-mayor, are justices of the quorum: and all the other aldermen are not only justices of the peace, but by the statute of 43 Eliz. intituled, An act for the relief of the poor, every alderman of the city of London within his ward, shall and may do and execute, in every respect as much as is appointed and allowed by the said act to be done or executed by one or two justices of peace of any county within this realm. They every one keep their wardmote, or court, for choosing ward-officers and settling the affairs of the ward, to redress grievances, and to prevent all defaults found within their respective wards.

The next branch of the legislative power in this city
city is the common-council. The many inconveniences that attended popular assemblies, which were called jolkoures, determined the commonalty of London to choose representatives to act in their name and for their interest, with the lord-mayor and aldermen, in all affairs relating to the city. At first these representatives were chosen out of the several companies; but that not being found satisfactory, nor properly the representatives of the whole body of the inhabitants, it was agreed to choose a certain number of different men out of each ward: which number has from time to time increased according to the dimensions of each ward; and at present the 25 wards, into which London is divided, being subdivided into 236 precincts, each precinct sends a representative to the common-council, who are elected after the same manner as an alderman, only with this difference, that as the lord-mayor presides in the Wardrobe, and is judge of the poll at the election of an alderman, so the alderman of each ward is judge of the poll at the election of a common-council man.

Thus the lord-mayor, aldermen, and common-council, when assembled, may be deemed the city parliament, resembling the great council of the nation. For it consists of two houses; one for the lord-mayor and aldermen, or the upper house; another for the commoners or representatives of the people, commonly called the common-council-men. And they have power in their incorporate capacity to make and repeal hystaws; and the citizens are bound to obey or submit to those laws. When they meet in their incorporate capacity, they wear deep blue silk gowns: and their aldermen are called the court of common-council, and their ordinances acts of common-council. No act can be performed in the name of the city of London without their concurrence. But they cannot assemble without a summons from the lord-mayor; who, nevertheless, is obliged to call a common-council, whenever it shall be demanded, upon extraordinary occasions, by six reputable citizens and members of that court.

This corporation is assisted by two sheriffs and a recorder. The sheriffs are chartered officers, to perform certain suits and services, in the king's name, within the city of London and county of Middlesex, chosen by the livemen of the several companies on Midsummer-day. Their office, according to Camden, in general, is to collect the public revenues within their several jurisdictions; to gather into the exchequer all fines belonging to the crown; to serve the king's writs of process; to attend the judges, and execute their orders; to impound juries; to compel headright and oblinate men by the pofta conitatus, to submit to the decisions of the law; and to take care that all condemned criminals be duly punished and executed. In particular, in London, they are to execute the orders of the common-council, when they have resolved to address his majesty, or to petition parliament.

The sheriffs, by virtue of their office, hold a court at Guildhall every Wednesday and Friday, for actions entered at Woodstreet Compter; and on Thursdays, and Saturdays for those entered at the Poultry Compter: of which the sheriffs being judges, each has his affidavit, or deputy, who are called the judges of those courts; before whom are tried actions of debt, trespass, covenant, &c., and where the testimony of any absent witnesses in writing is allowed to be good evidence. To each of these courts belong four attorneys, who, upon their being admitted by the court of aldermen, have an oath administered to them.

To each of these courts likewise belong a secondary, a clerk of the papers, a prothonotary, and four clerks-fitters. The secondary's office is to allow and return all writs brought to remove clerks out of the said courts; the clerk of the papers files and copies all declarations upon actions; the prothonotary draws and ingrosses all declarations; the clerk-fitters enter actions and attachments, and take bail and verdicts. To each of the comtours, or prisons belonging to these courts, appertain 16 serjeants at mace, with a yeoman to each, besides inferior officers, and the prison-keeper.

In the sheriffs court may be tried actions of debt, cause, trespass, account, covenant, and all personal actions, attachments, and sequestrations. When an erroneous judgment is given in either of the sheriffs courts of the city, the writ of error to reverse this judgment must be brought in the court of husting before the lord-mayor; for that is the superior court. The sheriffs of London may make arrests and serve executions on the river Thames.

We do not read of a recorder till 1504, who, by the nature of his office, seems to have been intended as an affiant to, or securer with, the lord-mayor, in the execution of his high office, in matters of justice and law. He is chosen by the lord-mayor and aldermen only; and takes place in all courts, and in the common-council, before any one that hath not been mayor. Of whom we have the following description in one of the books of the chamber. "He shall be, and is wont to be, one of the most skilful and virtuous apprentices of the law of the whole kingdom; whose office is always to sit on the right hand of the mayor, in recording pleas, and passing judgments; and by whom records and precedents, had before the lord-mayor and aldermen at Great St Martin's, ought to be recorded by word of mouth before the judges assigned there to correct errors. The mayor and aldermen have therefore used commonly to fet forth all other businesses, touching the city, before the king and his council, as also in certain of the king's courts, by Mr Recorder, as a chief man, and was with wisdom eminent for eloquence." — Mr Recorder is looked upon to be the mouth of the city, to deliver all addresses to the king, &c. from the corporation; and he is the first officer in order of precedence that is paid a salary, which originally was no more than 101. Sterling per annum, with some few perquisites; but it has from time to time been augmented to 1000l. per annum, and become the road to preferment in the law. This office has sometimes been executed by a deputy.

The next chartered officer of this corporation is the Chamber-chamberlain; an office of great reputation and trust, and fame in the choice of the livery annually. This officer, though chosen annually on Midsummer-day, is never displaced during his life, except some very great crime can be made out against him. He has the keeping of the monies, lands, and goods, of the city-orphans, or takes good security for the payment thereof when the parties come to age. And to that end he is deemed in the law a sole corporation, to him and his successors,
The other officers under the lord-mayor are, 1. The common sergeant. He is to attend the lord-mayor and court of aldermen on court days, and to be in council with them on all occasions, within or without the precincts or liberties of the city. He is to take care of orphans estates, either by taking account of them, or to sign their indentures, before their palling the lord-mayor and court of aldermen. And likewise he is to let, set, and manage the orphans estates, according to his judgment, to the best advantage. 2. The town-clerk; who keeps the original charter of the city, the books, rolls, and other records, wherein are registered the acts and proceedings of the city; so that he may not be improperly termed the city-regifter; he is to attend the lord-mayor and aldermen at their courts, and signs all public instructions. 3. The city remembrancer; who is to attend the lord-mayor on certain days, his business being to put his lordship in mind of the fœleœ days, he is to go abroad with the aldermen, &c. He is to attend daily at the parliament-house, during the session, and to report to the lord-mayor their transactions. 4. The sword-bearer: who is to attend the lord-mayor at his going abroad, and to carry the sword before him, being the emblem of justice. This is an ancient and honourable office, representing the state and princely office of the king's most excellent majesty in his representative the lord-mayor; and, according to the rule of armoury, "He must carry the sword upright, the hilts being held under his bulk, and the blade directly up the midst of his breast, and so forth between the sword-bearer's brows." 5. The common hunt; whose business is it to take care of the pack of hounds belonging to the lord mayor and citizen owners, and to prevent them in hunting in those grounds to which they are authorized by charter. 6. The common-crier. It belongs to him and the sergeant at arms, to summon all executors and administrators of freemen to appear, and to bring in inventories of the personal estates of freemen, within two months after their decease; and he is to have notice of the appraisements. He is also to attend the lord-mayor on fet days, and at the courts held weekly by the mayor and aldermen. 7. The water-bailiff; whose office is to look after the preservation of the river Thames against all encroachments; and to look after the fishermen for the preservation of the young fry, to prevent the destroying them by unlawful nets. For that end, there are juries for each county, that hath any part of it lying on the fides or shores of the said river; which juries summon, by the water-bailiff at certain times, do make inquiry of all offences relating to the river and the fish, and make their presentments accordingly. He is also bound to attend the lord-mayor on days in the week.—These seven purchase their places; except the town-clerk who is chosen by the livery.

There are also three sergeants-carvers; three sergeants of the chamber; a sergeant of the channel; four yeomen of the water-side; an under water-bailiff; two yeomen of the chamber; two meal-weighers; two yeomen of the wood wharfs; a foreign take; city marshals. There are besides these, seven gentlemen men; as, the sword-bearer's man, the common-hunt's two men, the common crier's man, and the carver's three men.

Nine of the foregoing officers have liverys of the lord-mayor, viz the sword-bearer and his man, the three carvers, and the four yeomen of the water-side. All the rest have liverys from the chamber of London.

The following officers are likewise belonging to the city; farmer of the markets, auditor, clerk of the chamber, clerk to the commissioners of the several clerks to the court of conscience, beadle of the same court, clerk of the city-works, printer to the city, justice of the Bridge-yard, clerk-comptroller of the Bridge-house, steward of the Borough, bailiff of the Borough.

There is also a coroner, called so from corona, i. e. a crown, because he deals principally with the crown, or in matters appertaining to the imperial crown of England. See the article CORONER.

Besides these officers, there are several courts in this city for the executing of justice, viz. the court of husting, lord-mayor's court, &c. In the city there are also two subordinate kinds of government. One executed by the alderman, deputy, and common-council men, and their representatives, who have a court peculiarly for themselves; and the other, by the officers of the king's household, which form are comprehended all the inhabitants free or not free of the city. Every ward is therefore like a little free state, and at the same time subject to the lord-mayor as chief magistrate of the city. The house keepers of each ward elect their representatives the common-council, who join in making bye-laws for the government of the city. The officers and servants of each ward manage the affairs belonging to it, without the assistance of the rest; and each has a court called the wardmote, as has been already described, for the management of its own affairs. The other, by the mayor, wardens, and court of aldermen, of the incorporeal companies; whose power reaches no further than over the members of their respective guilds or fraternities; except that in them is invested the power to choose representatives in parliament for the city, and all those magistrates and officers elected by a common hall; which companies are invested with distinct powers, according to the tenor of their respective charters.

The military government of the city is lodged in a military lieutenant, consisting of the lord-mayor, aldermen, and other principal citizens, who receive their authority by a commission from the king. Those have under their command the city trained bands, consisting of six regiments of foot, distinguished by the names of the white, orange, yellow blue, green, and red, each containing eight companies of 50 men, amounting in all to 7200. Besides those six regiments, there is a corps called the artillery company, from its being taught the military exercise in the artillery-ground. This company is independent of the rest, and consists of 700 or 800 volunteers. All these, with two regiments of foot of 800 men each commanded by the lieutenant of the Tower of London, make the whole militia of this city; which...
which, exclusive of Westminster and the borough of Southwark, amounts to about 10,000 men.

The trading part of the city of London is divided into 89 companies; though some of them can hardly be called so, because they have neither charters, halls, nor livery. Of these 89 companies 45 have each a hall for transacting the business of the corporation; and this consists of a master or prime warden, a court of assistants, and livery. Twelve of these companies are superior to the rest both in antiquity and wealth; and of one of those, i.e., the lord mayors have generally made themselves freemen for their election. These companies are the mercers, grocers, drapers, fishmongers, goldsmiths, skinners, merchant-tailors, haberdashers, falters, ironmongers, vinters, and clothworkers. The principal incorporated societies of the merchants of this city are the Hamburgh Company, the Hudsons Bay Company, the Russian Company, the Turkey Company, the East India company, the Royal African Company, the South Sea Company, and some Insurance Companies. The most of these companies have erected houses for transacting their business, particularly the East India and South Sea companies. See Company.

The streets and public buildings in London and its liberties being far too numerous for a particular description in this work, we shall only select the most remarkable, beginning with London-bridge as the most ancient, and proceeding in our survey through the wards into which the city is divided.

1. Remarkable buildings, &c. in the Girr.—The original bridge, which stands in Bridge-ward, was of wood, and appears to have been first built between the years 993 and 1016; but being burnt down about the year 1156, it was rebuilt of wood in 1163. The expense, however, of maintaining and repairing it became so burdensome to the inhabitants of the city, that they resolved to build a stone bridge a little westward of the wooden one. This building was begun in 1176, and finished in 1209; and was 915 feet long, 44 feet high, and 73 feet wide; but houses being built on each side, the space between was only 23 feet.

This great work was founded on enormous piles driven as closely as possible together; on their tops were laid long planks 10 inches thick, strongly bolted; and on these were placed the bands of the piles, the lowermost stones of which were bedded in pitch, to prevent the water from damaging the work; round all were the piles which were called the sterlings, designed for the preservation of the foundation piles. These contrived the space between the piers so greatly, as to occasion at the retreat of every tide a fall of five feet, or a number of temporary cataracts, which since the foundation of the bridge have occasioned the loss of many thousand lives. The number of arches was 19, of unequal dimensions, and greatly deformed by the sterlings and the houses on each side, which overhung and leaned in a most terrific manner. In most places they hid the arches, and nothing appeared but the rude piers. Within recollection, frequent arches of strong timber crossed the street from the top of the houses to keep them together, and from falling into the river (A). Nothing but the craft of the inhabitants, who soon grew deaf to the noise of the falling waters, the clamours of watermen, or the frequent shrieks of drowning wretches, in one part had been a drawbridge, useful either by way of defence or for the admission of ships into the upper part of the river. This was protected by a strong tower. It forced to repulse Fauconbridge the Ballard in his general assault on the city in 1471, with a fleet of banditti, under pretence of rescuing the unfortunate Henry, then confined in the Tower. Sixty houses were burnt on the bridge on the occasion. It also served to check, and in the end amputate, the ill-conducted insurrection of Sir Thomas Wyatt, in the reign of Queen Mary. The top of this tower, in the wild and turbulent days of this kingdom, used to be the shambles of human flesh, and covered with heads or quarters of unfortunate partizans. Even so late as the year 1598, Henszner the German-traveller, with German accuracy, counted on it above 30 heads.

The old map of the city in 1597 represents them in a most horrible cluster. An unparalleled calamity happened on this bridge within four years after it was finished. A fire began on it at the Southwark end; multitudes of people rushed out of London to extinguish it; while they were engaged in this charitable design the fire flamed on the opposite end, and hemmed in the crowd. Above 3000 persons perished in the flames, or were drowned by overloading the vessels which were hardly enough to attempt their relief.

The narrowness of the passage on this bridge having occasioned the loss of many lives from the number of carriages continually passing; and the frightfulness of the arches, with the enormous size of the sterlings, which occupied one-fourth part of the water-way, having also occasioned frequent and fatal accidents as already mentioned; the magistrates of London in 1756 obtained an act of parliament for improving and widening the passage over and through the bridge, which granted them a toll for every carriage and horse passing over it: but these tolls proving insufficient, were abolished by an act made in 1758, for explaining, amending, and rendering the former act more effectual; and for granting the city of London money towards carrying on

(A) The gallant action of Edmund Osborne, ancestor to the duke of Leeds, when he was apprentice to Sir William Hewet cloth-worker, may not improperly be mentioned in this place. About the year 1536, when his master lived in one of these tremendous houses, a servant-maid was playing with his only daughter in her arms in a window over the water, and accidentally dropped the child. Young Osborne, who was witness to the misfortune, instantly sprang into the river, and, beyond all expectation, brought her safe to the terrrace, and perished in the attempt. Several persons of rank paid their addresses to her when she was marriageable, among others the earl of Shrewsbury; but Sir William gratefully decided in favour of Osborne: Osborne, says he, saved her, and Osborne shall enjoy her. In her right he possessed a great fortune. He became sheriff of London in 1575, and lord-mayor in 1582.
Near the north side of London bridge stands the Monument, a beautiful and magnificent circular column of the Doric order, built with Portland stone, and erected in memory of the conflagration 1666. It was begun by Sir Christopher Wren in 1671, and finished by him in 1677. Its height from the pavement is 202 feet; the diameter of the shaft or body of the column, is 15 feet; the ground, plinth, or lowest part of the pedestal, is 28 feet square; and the pedestal is 40 feet high. Over the capital is an iron balcony encompassing a cone 32 feet high, which supports an alternating urn of gilt bracts. Within is a large hollow core of black marble, containing 345 steps, each 10 inches and a half broad, and six inches thick. The west side is adorned with a curious table in relief denoting the destruction and restoration of the city. The first figure represents London lying in ruins, in a languishing posture, with her head dejected, her hair dishevelled, and her hand carelessly laying her sword. Behind is Time, gradually raising her up; at her side is a woman touching her with one hand, while a winged seer in the other directs her to regard the godesses in the clouds; one with a cornucopia, denoting Plenty; the other with a palm branch, the emblem of Peace. At her feet is a herculean flout, hollow, that by industry and application the greatest misfortunes are to be overcome. Behind the figure of Time are citizens exulting at his endeavours to restore her; and beneath, in the midst of the ruins is a dragon, who as the supporter of the city arms, with his paw endeavours to preserve the same. Opposite to the city, on an elevated pavement, stands the king, in a Roman habit with a laurel on his head, and a truncheon in his hand, and approaching her, commands three of his attendants to defend her to her relief. The first represents the Sciences with a winged head, and a circle of naked boys dancing thereon; and holding Nature in her hand, with her numerous breasts, ready to give assistance to all. The second is Architecture, a plan in one hand, and square and a pair of compasses in the other; and the third is Liberty, waving a flag in the air, showing her joy at the pleasing prospect of the city's speedy recovery. Behind the king stands his brother the duke of York, with a garland in one hand to crown the ruler, and a sword in the other for her defence. The two figures behind are Justice and Fortitude; the former with a coronet, and the latter with a reined lion; and under the royal pavement lies Every, growing a heart and immediately emitting puffed-up fumes from her mouth. On the plinth the reconstruction of the city is represented by builders and labourers at work upon houses. On the north, south, and east sides, are inscriptions relating to the destruction occasioned by the conflagration, the regulations about rebuilding the city, and erecting the monument; and round it is the following one:—"This pillar was set up in perpetual remembrance of the most dreadful burning of this Protestant city, begun and carried on by the treachery and malice of the Popish faction, in the beginning of Sept. 1666, to their carrying on their horrid plot for extirpating the Protestant religion and old English liberty, and introducing Popery and slavery." Dr. Wandesborn, in his account of London, observes, that the monument, though not much above 100 years old, bears visible marks of decay already; and it will not probably be long before it must be pulled down. Some are of opinion that this is occasioned by the fault of the archdeacon, others by the continual shaking of the ground by coaches; but the Doctor inclines to the latter opinion.

Eastward from the bridge and monument stands the Tower, which gives name to another ward. It is the chief fortress of the city, and supposed to have been originally built by William the Conqueror. It appears, however, to have been raised upon the remains of a more ancient fortress, erected probably by the Romans; for in 1720, in digging on the fourth side of what is called Cesar's Chapel, there were discovered some old foundations of stone, three yards broad, and so strongly cemented that it was with the utmost difficulty they were forced up. The first work (according to Mr. Pennant) seems to have been suddenly flung up in 1606 by the Conqueror, on his taking possession of the capital; and included in it a part of the ancient wall.

The great square tower, called the White Tower, was erected in the year 1078, when it stood in the directions of Gundulph bishop of Rochester, who at that time was a great military leader. This building was originally flung up by itself. FitzStephen gives it the name of Arcus Palatina, "the Palatine Tower;" the commander who had the title of Palatine bestowed on him. Within this tower is a very ancient chapel for the use of such of the kings and queens who wished to pay their devotions here. In 1092 a violent tempest did great injury to the Tower; but it was repaired by William Rufus and his successor. The first added another castellated building on the fourth side between it and the Thames, which was afterwards called the Thomas's Tower.

The tower was first inclosed by William Longchamp, bishop of Ely and chancellor of England, in the reign of Richard I. This haughty prelate having a quarrel with John, third brother to Richard, under pretence of guarding against his designs, surrounded the whole with walls embattled, and made on the outside a vast ditch, into which, in after times, the water from the Thames was introduced. Different princes added other works. The present contents within the walls...
wells are 12 acres and 5 rods, the circuit on the outside of the ditch 1052 feet. It was again inclosed with a mud-wall by Henry III. this was placed at a distance from the ditch, and occasioned the taking down part of the city wall, which was restored by the citizens; who pulling down this precinct of mud, were punished by the king with a fine of a thousand marks.

The Lions Tower was built by Edward IV. it was originally called the Bulwark, but received the former name from its use. A menagery had very long been a piece of regal state: Henry I. had his at his manor of Woodloch, where he kept lions, leopards, lynxes, porcupines, and several other uncommon beasts. They were afterwards removed to the Tower. Edward II. commanded the sheriffs of London to pay the keepers of the king's leopards aixpence a day for the sustenance of the leopards, and three halfpence a day for the diet of the keeper out of the fee-farm of the city. The royal menagery is to this day exceedingly well supplied.

In 1758 the Tower ditch was raised all round. New barracks were some years ago erected on the Tower-wharf, which parts it from the river; and upon the wharf is a line of 16 pieces of cannon, which are fired upon state holidays. On this side of the Tower the ditch is narrow, and over it is a draw-bridge. Parallel to the wharf, within the walls, is a platform 70 yards in length, called the Ladies Line, because much frequented by the ladies in the summer; it being shaded in the inside with a row of lofty trees, and without it is a delightful prospect of the shipping with boats paying and repassing on the river Thames. You ascend this line by stone steps, and being once upon it you may walk almost round the walls of the Tower without interruption.

The principal entrance into the Tower is by a gate to the west, large enough to admit coaches and heavy carriages but there are first admitted through an outward gate, situated without the ditch upon the hill, and must pass a stout stone-bridge built over the ditch before they can approach the main entrance. There is, besides, an entrance near the very south-west corner of the tower outward wall, for persons on foot, over the draw-bridge already mentioned to the wharf. There is also a water-gate, commonly called Traitor's gate, through which it has been customary to convey traitors and other state-prisoners to or from the Tower which is seldom opened on any other occasion:

In the Tower (the curiosities of which are more particularly described in the note (a)), are a church, the

---

(a) In examining the curiosities of the Tower of London, it will be proper to begin with those on the outside of the principal gate. The first thing a stranger usually goes to visit is the wild beasts; which, from their situation first present themselves: for having entered the outer gate, and passed what is called the four-guard, the keeper's house presents itself before you, which is known by a painted lion on the wall, and another over the door which leads to their dens. By ringing a bell, and paying sixpence each person, you may easily gain admittance.

The next place worthy of observation is the Mint, which comprehends near one-third of the Tower and contains houses for all the officers belonging to the coinage. On paying the principal gate you see the White Tower, built by William the Conqueror. This is a large, square, irregular stone building, situated almost in the center, no one side answering to another nor any of its watch-towers, of which there are four at the top, built alike. One of these towers is now converted into an observatory. In the first story are two noble rooms, one of which is a small armory for the sea-service, it having various sorts of arms, very curiously laid up, for above 10,000 seamen. In the other room are many closets and presleys, all filled with warlike engines and instruments of death. Over this are two other floors, one principally filled with arms; the other with arms and other warlike instruments, as spades, shovels, pick-axes, and chevaux de frise. In the upper story are kept match, hexepkins, tanned hides, &c. and in a little room called Julius Caesar's chapel, are deposited some records, containing perhaps the ancient usages and customs of the place. In this building are also preserved the models of the new-invented engines of destruction that have from time to time been presented to the government. Near the south-west angle of the White Tower is the Spanish Armory, in which are deposited the spoils of what was vainly called the Invincible Armada; in order to perpetuate to the latest posterity the memory of that signal victory obtained by the English over the whole naval power of Spain in the reign of Philip II.

You are now come to the grand store-house, a noble building to the northward of the White Tower that extends 245 feet in length and 60 in breadth. It was begun by king James II. who built it to the first floor, but it was finished by king William III. who erected that magnificent room called the New or Small Armory, in which that prince, with queen Mary his consort, dined in great form, having all the warrant workmen and labourers to attend them, drested in white gloves and aprons, the usual badges of the order of montery. To this noble noble room you are led by a folding door, adjoining to the east end of the Tower chapel, which leads to a grand stair-case of 50 easy steps. On the left side of the uppermost landing-place is the work-floors in which are constantly employed about 180 workmen, in cleaning, repairing, and new-placing the arms. On entering the armory, you see what they call a wildernets of arms, so artfully disposed, that at one view you behold arms for near 80,000 men, all bright, and fit for service; a sight which it is impossible to behold without astonishment; and beside exposed to view, there were before the late war, 16 chiefs

London. -

48 Custom-house.

In the Tower ward is also the Custom house, a large, handsome, and commodious building of brick and stone. It stands upon the banks of the Thames, and is accompanied with large wharfs, keys, and ware-houses. On this spot is the busy concourse of all nations, who pay their tribute towards the support of Great-Britain. About the year 1559, the loss of the revenue, by collecting it in different parts of the city, was first discovered, and an act passed to compel people to land their goods in such places as were appointed by the commissioners of the revenue; and this was the spot fixed on: A custom-house was erected; which being destroyed by the great fire, was rebuilt by Charles II. In 1718 it underwent the same fate, and was restored in its present form. Before the custom-house was established here, the principal place for receiving the duties was at Billingsgate. In 1628 the half year's customs for foreign merchandise in the city of London came only to L. 75: 6: 10; the annual produce of the customs, ending in April 1789, amounted to L. 3,711,126.

In Water-lane, a little to the north-west of the custom-house, is the Trinity House; a society founded in 1515, at a period in which the British navy began to assume a system. The founder was Sir Thomas Spert commodore of the navy, and commander of the great ship Henry Grace de Dieu. It is a corporation, consisting of a master, four wardens, eight assistants, and eighteen elder brethren; elected from commanders in the navy and the merchants service: and now and then a compliment is paid to one or two of the first nobility. They may be considered as guardians of the ships, military and commercial. Their powers are very extensive: they examine the mathematical children of Christ's hospital, and the masters of his majesty's ships; they appoint pilots for the river Thames; settle the general rates of piloting; erect light-houses and sea-marks; grant licences to poor seamen, not free of the city, to row on the Thames; prevent foreigners from serving on board the ships without licence; punish seamen for mutiny and defection; hear and determine complaints of officers and men in the merchants service, but liable to appeal to the judge of the court of admiralty, superintend the deepening and cleansing of the river Thames, and have under their jurisdiction the bailiff office: have powers to buy lands, and receive donations for charitable uses; and, in consequence, relieve annually many thousand of poor seamen, their widows, and orphans. It is in this house the business of the incorporation is carried on: but the mother house is at Deptford, the corporation being named, the matter, wardens, and assistants of the guild or fraternity of the Dartmouth, and undivided Trinity, and of St. Clement, in the parish of Deptford Strond, in the county of Kent.

Between Aldgate and the Tower is the street called the Minority, from four poor ladies of the order of St. Clare, or minoresses. They had been invited to London by Blanch queen of Navarre, and wife to Edmund earl of Lancaster, who founded a convent for them in 1293. On the suppression of the monasteries it was converted into a dwelling-house for some of the nobility, and is now in the possession of the Dartmouth family. Till of late years, the Minorities were but a debitable street; but have now been excellently rebuilt, and are as elegant as any in the city.

On the west side of the city-walls at this place, stood the house of the Crooked or Grasped Friars, an order instituted at Bologna in 1169, and of which a branch settled in England in 1244, where they were accommodated with an house in this place by two citizens named Ralph Hotser and William Skenor, who became members of the fraternity, in form like the square White Tower, and so exquisitely wrought, that the workmanship of modern times is in no degree equal to it. It is of gold, and used only on the king's table at the coronation. 14 A noble silver font, double gilt, and elegantly wrought, in which the royal family are dipled in England in foreign wars; the achievements of England in foreign wars; the settlements of Ireland, as to law and dominion; the forms of subdivision of some Scotch kings for territories held in England; ancient grants of the kings to their subjeets; privileges and immunities granted to cities and corporations during the period above mentioned; inquisitions of charters and deeds made before the Conquest; the bounds of all the forests in England, with the several respective rights of the inhabitants to common paturage, and many other important records, all regularly disposed, and referred to in near a thousand folio indexes. This office is kept open, and attendance constantly given, from seven o'clock till one, except in the months of December, January, and February, when it is open only from eight till one, Sundays and holidays excepted. A search here is half a guinea, for which you may perceive any one subject a year.
London.

Henry VIII. granted his house to Sir Thomas Wyatt the elder, who built a handsome mansion on part of the ground where it now stands. This mansion became afterwards the residence of John Lord Lumley, a celebrated warrior in the time of Henry VIII. In process of time, it was converted into a navy-office; but this office being removed to Somerset-house, the India Company have erected in its place a most magnificent warehouse, in form of an oblong square of about 250 feet by 160, including a court of 150 by 60 feet, the entrance to which is by an arched gateway.

Billingham gate is distinguished by its market. Billingham gate was a small port for the reception of shipping, and for a considerable time the most important place for the hånding of almost every article of commerce. In the time of King William, Billingham gate began to be celebrated as a fish-market. In 1699 it was by act of parliament made a free port for fish to be sold there every day except Sunday; but Mr Pennant informs us, that the officers of this has been long since been rendered nugatory, and that fish are now no longer to be had there in perfection. The same author gives a lift of the fish which in the time of Edward III. were brought to London market; the monarch himself having comdecided to regulate the prices, that his subjects might not be imposed upon by those who sold them. Among these were the eger-cel and porpoife, neither of which is now admitted to any table. A pile at that time cost 6s. 8d.; whence our author concludes, that it was an exotic fish, and brought over at a vast expense. Some fishes are mentioned in his list with which this naturalist owns himself unacquainted, viz. the barkey, bran, bortle, carving, and ruwh. In Archbishop Neville's great feast is mentioned also a fish named thrice-poole, unknown at present. Seals were formerly accounted a precious article, and of the church of St. Paul's. There, in the year 1733, the architect George Sampson. Before that time the building was transferred to Grocers-hall. The front is a fort of veslible; the base raftic, the ornamental columns above Ionic. Within is a court leading to a second elegant building, which contains a hall and offices, where the debt of above 250 millions is punctually discharged. Of late years two wings of uncommon elegance, designed by Sir Robert Taylor, have been added to the council of a few houses, and of the church of St. Christopher's le Stocks. The palladium of Britain was in 1780 saved from the fury of an infamous banditti by the virtue of its citizens, who formed suddenly a volunteer company, and over-awed the miscreants; while the chief magistrates skulked, trembling in his manfon-houfe, and left his important charge to its fate. This important building has ever since been very properly guarded by the military; who, in palling through the city, have often given offence to many busy characters who would strive to preserve the city rights at the expense of the national destruction. A lord mayor was the last who interested himself by applying to Mr Grenville, who gave him to understand, that if the guards were not quietly permitted to discharge their duty, the bank would be removed to Somerset-houfe."

At the extremity of Three-needle street is Merchant-Taylors Hall. In this street also is the South-Sea Housè, first established in 1711 for the purpose of an exclusive trade to the South Sea, and for supplying Spanish America with negroes. Near the junction of Throgmorton street with Broad-street stood a magnificent house built by Cromwell earl of Essex; after whole, the house and gardens were bought by the Drapers company. The house was destroyed in the great fire, but rebuilt for the use of the company in a magnificent manner.

Mr Pennant informs us, that St Giles's church in the fields, and a few houses to the west of it, in the year 1600, was barely separated from Broad-street. The church was supposed to have belonged to an hospital for lepers, found about the year 1117, by Matilda queen to Henry I. In ancient times it was customary here to present to malefactors, on their way to the gallows (which, about the year 1413, was removed from Smithfield, and placed between St. Giles's high-street and Hog-lane (c), a great bowl of ale, as the last refreshment they were to receive in this life. On the

(c) This late place of execution, according to Mr Pennant, was called in the time of Edward III. when the
London. the door to the church-yard is a curious piece of sculpture, representing the last day, containing an amazing number of figures, set up about the year 1686. This church was rebuilt in 1624. By the amazing railing of the ground by fifty and various adventitious matter, the floor in the year 1730 was eight feet below the surface acquired in the intervening time. This alone made it necessary to rebuild the church in the present century. The first stone was laid in 1730; it was finished in 1734, at the expense of 10,000l. In the church-yard is a great square pit, with many rows of coffins piled upon the other, all exposed to sight and smell, the latter of which is highly offensive if not dangerous.

On the west side of Broad-street flooded the house of the Augustines, founded by Humphrey Bohun Earl of Somerset in 1253, for friars and hermits of the Augustine order. On the dissolution of the monasteries, great part of the house was granted to William Lord St John, afterwards Marquis of Winchester, and Lord Treasurer, who founded a magnificent house named Winchester-house.

The west end of the church was granted in 1550 to John Lacco for the use of the Germans and other fugitive Protestants, and afterwards to the Dutch as a place for preaching. A part of it was also converted into a glass-house for Venice glass, in which the manufacture was carried on by artists from that city, and patronized by the duke of Buckingham. The place was afterwards converted into Pinnier-ball, belonging to the company of pin makers.

To the eastward of Winchester-street flooded the house of that very eminent merchant Sir Thomas Gresham, afterwards known by the name of Gresham college (See Gresham). It has been pulled down not many years ago; and the Excise Office, a most magnificent and at the same time simple building, rose in its place.

Mr Pennant informs us, that from the 9th of January 1786 to January 5th 1787, the payments into this office amounted to no less than L. 5,321,114.6.110.

The Royal Exchange, which is the meeting place of the merchants of London, stands in the ward of Cornhill, and is the finest and strongest fabric of the kind in Europe. It was founded in the year 1566. Sir Thomas Gresham, merchant in London, made an offer to the lord mayor and citizens, to build at his own expense a commodious edifice for merchants to meet and transact business, provided the city would find him a convenient situation for the same. Mr Pennant informs us, that one Richard Clough a Welshman, originally Sir Thomas's servant, first put him on the design by a letter from Antwerp, in which he reproached the London merchants with having no place to transact their business, but walking about in the rain, more like pedlars than merchants.

Citizens, in compliance with Sir Thomas's desire, purchased, for the sum of L. 3532. 80 houses in the two alleys called New St Christopher's, and Swan-alley, leading out of Cornhill into Three-needle street. The materials of those houses were sold for L. 475, and the ground, when cleared, was conveyed to Sir Thomas Gresham, who accompanied by several aldermen, laid the first brick of the new building on the 7th of June that year. Each alderman also laid his brick, and left a piece of gold for the workmen; who set about it with such fidelity and resolution, that the whole fabric was crowned by the month of November 1567, and was soon after completed under the name of the Burse.

This building was totally destroyed by the fire in 1666; and in its place the present magnificent structure was erected at the expense of L. 80,000, which stands upon a plat of ground 203 feet in length and 171 in breadth, containing an area in the middle, of 67 square perches, surrounded with a substantial and regular stone building, wrought in rufh. It has two fronts, north and south, each of which is a piazza; and in the centre are the grand entrances into the area, under a very lofty and noble arch. The south front in Cornhill is the principal, on each side of which are Corinthian demi-columns, supporting a compas pediment; and, in the intercolumniation on each side, in the front next the street, is a niche, with the statues of King Charles I. and II. in the Roman habits, and well executed. Over the aperture, on the cornice between the two pediments, are the king's arms in relief; on each side of this entrance is a range of windows placed between demi-columns, and pilasters of the composite order, above which runs a balustrade. This building is 56 feet high; and from the centre, in this front, rises a lantern and turret 178 feet high, on the top of which is a range of gilt vases made in the shape of a glassshopper, the crest of Sir Thomas Gresham's arms. The north front in Three-needle-street is adorned with pilasters of the composite order; but has neither columns nor flates on the outside; and has triangular, instead of compas, pediments. The inside of the area is also surrounded with piazzas, forming ambulatories for merchants, &c. to shelter themselves from the weather, when met there upon business. Above the arches of this piazza is an entablature with curious ornaments; and on the cornice a range of pilasters with an entablature extending round, and a compas pediment in the middle of the cornice of each of the four sides. Under the pediment on the north side of the king's arms; on the south, the city's arms; on the east, Sir Thomas Gresham's arms; and on the west, the mercer's arms, with their respective enrichments. In these intercolumns are 24 niches, 20 of which are filled with the statues of the kings and queens of England.

The gentle Mortimer finished his days here, the Elms: but the original as well as the present name was Ty-bourne; not from tye and burn, as if it were called so from the manner of capital punishments; but from bourns, the Saxon word for a "Brook," and tye the name of that brook, which joined gave name to a manor before the conquest. Here was also a village and church denominated St John the Evangelist, which fell to decay, and was succeeded by that of Mary bourn, corrupted into Mary-in-bowme. In 1656, Queen Henrietta Maria was compelled by her priests to take a walk by way of penance to Tyburn. What her offense was we are not told; but Charles was so disguised at this interview, that he soon after sent them and all her maids and French servants out of the kingdom.
In building this expensive structure there was an eye not only to magnificence, and to accommodate the merchants, but also to reimburse the expense. For this reason a gallery was built on the four sides of the royal exchange. This was divided into 200 shops which were let out to haberdashers, milliners, &c. and which for several years were well occupied. But these shops have now for a long time been deserted, and the galleries are let out to the Royal Exchange Assurance-office, the Merchant-iemens office, the Marine Society, and to auctioneers, &c. Under the whole area there are the finest dry vaults that can be found anywhere, which are let out to the East-India company to deposit their pepper. The turret is a good clock with four dials, which is well regulated every day, so that it becomes a standard of time to all the mercantile part of the town; and it goes with chimes at three, six, nine, and twelve o'clock, playing upon twelve bells. The outside of this grand fabric suffers very much in its elegance from the shops that surround it, and are built within its walls; and which are occupied by bookfellers, toymen, cutlers, hosiers, watch-makers, &c.

South of the Royal-Exchange, and near the west extremity of Lombard-street, is the General Post Office, which is a handsome and commodious building.

In Walbrook ward is the Mansion-house, for the residence of the lord-mayor. This edifice was begun in 1739, and finished in 1753. It is built of Portland stone, with a portico of six fluted columns, of the Corinthian order, in the front. The basement story is very agreeable, and consists of rustic work; in the centre of it is the door, which leads to the kitchens, cellars, and other offices. On each side rises a flight of steps, leading up to the portico, in the middle of which is the principal entrance. The stone balustrade of the stairs is continued along the front of the portico, and the columns support a large angular pediment, adorned with a group of figures in bas relief, representing the dignity and opulence of the city of London. It is an extremely heavy building, of an oblong form, and its depth is the long side, having several magnificent apartments, which are not, however, well lighted, on account of housetops that surround it.

Behind the mansion-house is St Stephen's Church, St Stephen in Walbrook, justly reputed the master-piece of the period, celebrated Sir Christopher Wren, and is said to excel every modern structure in the world in proportion and elevation.

The mansion-house, and many adjacent buildings, stand on the place where the Stocks market once stood. This took its name from a pair of flocks erected...
In this ward is situated one of the most remarkable pieces of antiquity in London. It is a great stone, formerly standing on the north side of Canon-street, close under the south wall of St Swithin's church. It is called London-stone, and was formerly pitched edgewayson the other side of the street, opposite to where it now stands, fixed deeply in the ground, and strongly fastened with iron bars; but for the convenience of wheel-carriages it was removed to its present situation. This stone is mentioned so early as the time of Athelstan, king of the West Saxons, and has been carefully preserved from age to age. Of the original cause of its erection no memorial remains; but it is conjectured, that as London was a Roman city, this stone might be the centre, and might serve as an object from which the distance was computed to the other considerable cities or stations in the province.

In Dowgate ward is a noted academy, called Merchant-taylors School, from its having been founded by the merchant-taylors company, in the year 1561. It was destroyed by the fire of London in 1666, but was rebuilt, and is a very large structure, with commodious apartments for the masters and scholars, and a fine library. Sir Thomas White, lord mayor of this city, having founded St John's college in Oxford in 1357, appointed this school as a seminary for it, and established at Oxford 46 fellowships for scholars elected from this school.

The church of St Mary le Bow, in Cordwainers-street ward, is the most eminent parochial church in the city. It was originally built in the reign of William the Conqueror; and being the first church the free people of London were paved for, was burnt down in the fire of 1666. It was burnt down in the fire of 1666, but soon afterwards rebuilt. The steeple of this church is reckoned the most beautiful of its kind in Europe.

In Cheap ward is Guildhall, or the town-houfe of London. This was originally built in 1441, but so damaged by the great fire already mentioned, as to be rebuilt in 1690. The front has a Gothic appearance. The sign of this character is also due to the two gigantic effigies which stand within the hall. The hall is 153 feet long, 50 broad, and 55 high, adorned with the royal arms, and thole of the city and its companies, as well as with several portraits of English sovereigns and judges. In this building are many apartments for transacting the business of the city, besides one for each of the judicial courts, namely, that of the King's-Bench, the Common-Pleas, and the Exchequer.

In the year 1246 Cheapside was an open field, named Crown field, from an inn with the sign of the crown. At that time, and even for 200 years afterwards, none of the streets of London were paved excepting Thames-street, and from Ludgate-hill to Charter Cross.

Goldsmiths Hall. Goldsmiths Hall stands in Foster-lane, which opens into the west end of Cheapside. In this lane also is St Martin's le Grand, which, though surrounded by the city, was yet subject, near three centuries, to Westminster Abbey. A fine college was built here in 700 by Wycliffe king of Kent, and, about the year 1056, rebuilt and chiefly endowed by Ingelric and Edward, two noble brothers. In 1668, it was confirmed and made independent of every ecclesiastical jurisdiction, even that of the pope himself not excepted; and its privileges were confirmed by succeeding monarchs. It was governed by a dean, and a number of secular canons. In this jurisdiction a magnificent church was erected, but pulled down in 1568, when the college was surrendered, after which a tavern was erected on the spot.

A little to the westward of Mary-le-Bow church the Crosses (in the adjoining ward), stood the Crosses and Conduit and Conduit in the middle of the street. The former was built by Edward I. in 1290, in memory of his queen Eleanor, whose body was reposed on that spot in its way to be buried. Originally it had the statue of the queen at full length, resembling exactly that at Northampton. Having at length fallen to decay, it was rebuilt in 1441 by John Hetherby mayor of the city, at the expense of several citizens, being now ornamented with various images, as those of the Resurrection, the Virgin Mary, &c. As the magnificent proceedings took this road, it was new-gilt at every public entry. After the Reformation, the images gave so much offence, that it was thought proper to substitute that of Diana in place of the Virgin Mary. This, however, was refented by Queen Elizabeth, who offered a reward for the discovery of the offenders. As she imagined that a crofs, the symbol of the Christian religion, could not justly give offence to any professor of that religion, the order was given not to be placed on the summit, and gilt; but in 1643, the parliament ordered the demolition of all crosses and other marks of Romish superstition.

Splendid tournaments were held between the Crosses and Sopers-lane in the year 1331; but as Queen Philippa and a great number of other ladies, drested in rich attire, were sitting on the upper scaffolding to behold the sports, the feats gave way, and they suddenly fell down among the knights and others who stood below; many of whom were grievously hurt. The carpenters were saved from punishment by the intercession of the queen; but the king, to prevent access of the like nature, ordered a building of stone to be erected near Bow church, from whence the queen and other ladies might behold such spectacles in safety. This was used for the same purpose till the year 1410, when Henry IV. granted it to certain merchants, who converted it into shops, warehouses, and other places necessary for their trade.

A small distance eastward from the Crosses stood the Conduit, which served to fill the lefter ones with water brought by pipes from Paddington. This stood on the spot where the old conduit was situated, which was founded in 1283, constructed of stone lined with lead, and rebuilt in 1479 by Thomas Iain one of the sheriffs. On some grand occasions, these conduits have been made to run with clarer; as at the coronation of Anna Bullen.

On the north side of Cheapside stood the Hospital of St Thomas of Acon, founded by Fitz-Theobald de Hallé, and his wife Agnes, sister to the famous Thomas a Becket. The hospital was built 20 years after the murder of Thomas; and such was his reputation for
LON [255] LON

74 Old Jewry. 

for sanctity, that it was dedicated to him even before he was canonized, and that in conjunction with the Virgin Mary herself. The whole was granted by king Henry VIII. to the company of mercers. It was destroyed by the great fire in 1666; but rebuilt by the mercers company, who have their hall here. — Immediately to the east is a narrow street called the Old Jewry, which took its name from a great synagogue which stood here till the Jews were expelled the latter part of the 13th century. After them an order of friars named Fratres de fucca, or de penitentia, took possession of the synagogue, and in 1305, Robert Fitzwalter, the great banner-bearer of the city, requested that the friars might assign it to him; the reason of which probably was, that it stood near to his house, which was situated in the neighbourhood of the present Grocers-hall. The chapel was bought by the grocers from Fitzwalter in 1411 for 320 marks.

75 Blackwell Hall. 

In Billingshaw or Basing-hall ward, is Blackwell or Bakewell hall, which adjoins to Guildhall, and is the greatest mart of woollen cloth in the world. It was purchased of King Richard II. by the city; and has been used as a weekly market for broad and narrow woollen cloths, brought out of the country. Formerly proclamations were issued to compel people to bring their goods into the hall, to prevent deceit in the manufactures, which might be productive of dishonesty in foreign markets, and likewise be the means of depriving poor children of Christ's hospital of part of the revenue which arose from the sale of this great magazine. It suffered in the general devastation in 1666; but was rebuilt in 1672, and is now a spacious edifice, with a stone front adorned with columns.

76 Sion College. 

Cripplegate-ward is remarkable for a college, called Sion-college, founded in 1627, on the site of Elings-hospital (for priory, by Dr Thomas Wight, vicar of St Dunstan's in the West, for the improvement of the London clergy; and with alms-houses, under their care, for 20 poor persons, 10 men and 10 women. In the year 1631, a charter was procured for incorporating the clergy of London, by which they were constituted fellows of the college; and out of the incumbents are annually elected, on Tuesday three weeks after Easter, a president, two deans, and four suffragans, who are to meet quarterly, to hear a Latin sermon, and afterwards be entertained at dinner in the college-hall at the expense of the foundation. John Simpson rector of St Olaves, who superintended the building, added, at his own expense, for the use of the Rudens part of the London clergy, a library in feet long, and amply filled with books.

In this ward is a hall which belonged to the company of barber-surgeons, the professors of barber and surgeon being formerly exercised by the same person. It was built by the celebrated Inigo Jones, and the upper end is formed out of one of the towers or barbacins of London wall. The anatomical theatre is elliptical, and very finely contrived. This hall is now called Barbers Hall; the surgeons, who disdained to be any longer associated with their ancient brethren, having obtained a separate charter, and built themselves a new hall in the old Bailey.

Farringdon-ward Within, is distinguished by the St Paul's most magnificent Protestant church in the world, the cathedral of St Paul. The body authority we have for the origin of this church, is from its great reformer Sir Christopher Wren. His opinion that there had been a church on this spot built by the christians in the time of the Romans, was confirmed: when he searched for the foundations for his own design, he met with those of the original prefbyterium, or semicircular chancel, of the old church. They consisted only of Kenilworth-stone, artfully worked, and confoliated with exceedingly hard mortar, in the Roman manner, much excelling the superstructure. He exploits the notion of there being here a temple of Diana, and the discovery of the horns of animals used in the sacrifices to that goddess, on which the opinion had been founded, no such having been discovered in all his searches.

The first church was supputed to have been destroyed in the Doicletian persecution, and to have been rebuilt in the reign of Constantine. This was again demolished by the pagan Saxons; and restored in 603, by Sebert, a petty prince, ruling in these parts, under Ethelbert king of Kent, the first Christian monarch of the Saxon race; who, at the instance of St Augustine, appointed Melitus the first bishop of London. Erkenwald, the son of king Offa, fourth in succession from Melitus, ornamented his cathedral very highly, and improved the revenues with his own patronymy. He was moft defervedly canonized: for the very litter, in which he was carried in his last illness, contained many centuries to cure fevers by the touch; and the very chips, carried to the sick restored them to health.

When the city of London was destroyed by fire, in 1666, this church was built; the bishop Mauritius began to rebuild it, and laid the foundations, which remained till its second destruction, from the flames, in the last century. Notwithstanding Mauritius lived twenty years after he had begun this pious work, and bishop Beauvais enjoyed the see twenty more, yet such was the grandeur of the design, that it remained unfinished. The first had the ruins of the Palantine Tower bestowed on him, as materials for the building; and Henry I. bestowed on Beauvais part of the ditch belonging to the Tower, which, with purchases made by himself, enabled him to enclose the whole with a wall. The same monarch granted besides, that every ship which brought stone for the church, should be exempted from toll; he gave him also the great fish taken in his precincts, except the tongue; and, lastly, he secured to him and his successor the delicious tythes of all his venison in the county of Essex.

The style of the ancient cathedral was a most beautiful Gothic; over the east end was an elegant circular window; alterations were made in the ends of

(p) This was founded by William Elling mercer in 1299 (on the site of a decayed monastery), for the support of 100 blind men. He afterwards changed it into a priory, and became himself the first prior, who with four canons-regular were to superintend the miserable objects.
The two transepts, so that their form is not delivered down to us in the ancient plans; and from the central tower rose a lofty and most graceful spire. The dimensions, as taken in 1509, were these: The length six hundred and ninety feet; the breadth a hundred and twenty; the height of the roof of the west part, from the floor, one hundred and two; of the east part, a hundred and eighty-eight; of the tower, two hundred and fifty; of the spire, which was made of wood covered with lead, two hundred and seventy-four. The whole space the church occupied was three acres and a half, one road and a half, and six perches.

We may be astonished at the amazing building, and naturally inquire what fund could supply money to support so vast an expense. But monarchs resigned their revenues resulting from the customs due for the materials, which were brought to the adjacent wharfs; they furnished wood from the royal forests; prelates gave up much of their revenues; and, what was more than all, the pious spirit of indulgences, brought in from the good people of the realm most amazing sums. Pope Innocent III. in 1252, gave a release of sixty days penance; the archbishop of Cologne gave, a few years before, a relaxation of fifty days; and Boniface, archbishop of Canterbury, forty days.

The high altar dazzled with gems and gold, the gifts of its numerous vortaries. John King of France, when prisoner in England, first paying his respects to St Erkenwald's shrine, offered four basons of gold; and the gifts at the obsequies of princes, foreign and British, were of immense value. On the day of the conversion of the tutelar saint, the charites were prodigious, first to the founts, when an indulgence of forty days pardon was given, _vocem profanationis, contritis et confessis_; and, by order of Henry III. fifteen hundred tapers were placed in the church, and fifteen thousand poor people fed in the church-yard.

The holiness of this place did not prevent thieves and profligates of all denominations, from lurking within the precincts, and committing, under the favour of the night, murders and every sort of crimes. Edward gave the dean and canons permission to inclose the whole within a wall; and to have gates to be shut every night, to exclude all disorderly people. Within these walls, on the north-west side, was the bishop's place. Froissart tells us, that after the great tournament in Smithfield, king Edward III, and his queen lodged there, on occasion of their nuptials. In 1561, the noble spire was totally burnt by lightning, and never restored.

In consequence of the resolutions taken in 1620, by James I. to repair the cathedral, the celebrated Inigo Jones was appointed to the work. But it was not attempted till the year 1633, when Laud laid the first stone, and Inigo the fourth. That great architect began with a most notorious impropriety, giving to the west end a portico of the Corinthian order, beautiful indeed, to this ancient gothic pile; and to the ends of the two transepts, gothic fronts in an odd horrible style. The great hire made way for the reforing of this magnificent pile in its present noble form by Sir Christopher Wren, an architect worthy of a great design. It is built of fine Portland stone, in form of a cross. On the outside are two ranges of pilasters, consisting of an hundred and twenty each; the lower range of the Corinthian order, and the upper of the composite. The spaces between the arches of the windows and the architrave of the lower order, are filled with a great variety of curious enrichments, as are also those above. On the north side is a portico, the acent to which is by twelve steps of black marble, and its dome supported by six very large columns. Over the dome is a pediment, the face of which is engraved with the royal arms, regalia, and other ornaments. On the south is a portico, the acent to which is by twenty-five steps, and its dome supported by six columns, corresponding with those on the north side. The west front is graced with a most magnificent portico, supported by twelve lofty Corinthian columns: over these are eight columns of the compositive order, which support a noble pediment, crowned with its acroteria, and in this pediment is the history of St Paul's conversion, boldly carved in bas relief. The acent to this portico is

(e) Before this cathedral was the famous _Paul's Crof_, a pulpit formed of wood, mounted upon steps of stone, and covered with lead, in which the most eminent divines were appointed to preach every Sunday in the forenoon. To this place, the court, the mayor, and aldermen, and principal citizens, used to resort. The greatest part of the congregation sat in the open air; the king and his train had covered galleries; and the better sort of people were also protected from the injury of the weather; but the far greater part exposed in the open air; for which reason the preacher went in very bad weather to a place called the Shrouds; a covered space on the side of the church, to protect the congregation in inclement seasons. Considerable contributions were raised among the nobility and citizens, to support such preachers as were (as was often the case) called to town from either of the universities. In particular, the lord mayor and aldermen ordered that every preacher, who came from a distance, should be freely accommodated, during five days, with sweet and convenient lodgings, fire, candle, and all necessaries. And notice was given by the bishop of London, to the preacher appointed by him, of the place he was to repair to.

We hear of this being in use as early as the year 1259. It was used, as Mr Pennant observes, not only for the instruction of mankind by the doctrine of the preacher, but for every purpose political or ecclesiastical; for giving force to oaths, for promulgating laws, or by the royal pleasure, for the emission of papal bulls, for confinuating sinners, for benedictions, for exposing of penitents under the care of the church, for recantations, for the private ends of the ambitious, and for the depriving of those who had incurred the displeasure of crowned heads.

It was demolished in 1643 by order of parliament, executed by the willing hands of Isaac Pennington, the fanatical lord mayor of that year, who died in the tower a convicted regicide.
L O N [257]

London. is by a flight of steps of black marble, extending the whole length of the portico; and over each corner of the west front is a beautiful turret. A vast dome, or cupola, rises in the centre of the building. Twenty feet above the roof of the church is a circular range of thirty-two columns with niches, placed exactly against others within. These are terminated by their entablature, which supports a hand-fome gallery, adorned with a stone balustrade. Above the columns last mentioned is a range of pilasters, with windows between them; and from the entablature of these, the diameter of the dome gradually decreases. On the summit of the dome is an elegant balcony, from the centre of which runs a beautiful lantern, adorned with Corinthian columns. The whole is crowned with a copper ball, supporting a crofs, both finely gilt. Within, the cupola stands on eight stupendous pillars, curiously adorned: the roof of the choir is supported by six pillars, and that of the church by two ranges, consisting of twenty more. The roof of the church and choir is adorned with arches and spandrils, perpendicularly erected, admirably carved in stone. Quire round the inside of the cupola, there is a whispering iron balcony, or gallery, the top of which is richly painted by Sir James Thornhill.

The first stone of this superb edifice was laid on June 21, 1673; and the building was completed in 1722; but the whole decorations were not finished till 1732. It was a most singular circumstance, that, notwithstanding it was 35 years in building, it was begun and finished by one architect, and under one prelate Henry Compton bishop of London. The church of St Peter's was 195 years in building, in the reigns of 19 popes, and went through the hands of twelve archbishops, and was finally finished by Sir Christopher Wren.

In the east side of the cathedral is St Paul's School, founded in 1509 by Dr John Collet dean of this church who endowed it for a principal-mister, an under-mister, a chaplain, and 153 scholars.

In Warwick-lane, in the same ward, stands the Coll: of Physicians, erected in 1682 by Sir Christopher Phyfician, erected.

Adjoining to Christ-church in Newgate-street is Christ's Hospit: of Physicians, erected in 1681 by Sir Christopher Phyfician, erected.

Vol. X.
and the bishop of London. The college has an excellent library, every bishop at his consecration giving L. 20 or L. 50 towards purchasing books for it.

Near Doctors’ Commons, on St Benedict’s Hill, is the College of Heralds, who were incorporated, by King Richard III. Before the college, who is the earl-marshall of England, here are three kings at arms, viz. Garter, Clarencieux, and Norroy, with six heralds, four purveyors, and eight stents. Garter attends the infallible of knights of that order, carries the garter to foreign princes, regales the ceremonies at coronations, and the funeral of the royal family and nobility: Clarencieux directs the funeral ceremonies of those under the degree of peers south of Trent, and Norroy performs the like office for those north of Trent. This building was originally the house of the earl of Derby. It is a spacious quadrangle, built of brick and has convenient apartments. Here are kept records of the coats of arms of all the families and names in England, with an account when they were granted, and on what occasion.

In Farringdon-ward Without is a large building called Bridewell, from a spring formerly known by the name of St Bridget’s or St Bride’s-Well. It was originally a royal palace, and occupied all the ground from Fleet-ditch on the east to Water-lane on the west. That part of it now called Salisbury-court was given to the bishops of Salisbury for their town residence; and the east part, which was rebuilt by King Henry VIII. in the present Bridewell. It was granted to the city by Edward VI. as a hospital; and he endowed it for the lodging of poor travellers, and for the correction of vagabonds, runnymen, and idle persons, as well as for finding them work. In one part of the building 200 artificers have houses; and about 150 boys, distinguished by white hats and blue doublets, are put apprentices to glaziers, fletcherers, weavers, &c. and when they have served their time are intitled to the freedom of the city, with L. 10 towards carrying on their respective trades. The other part of Bridewell is a receptacle for disorderly persons, who are kept at work in hemp and other hard labour.

Near Bridewell is St Bride’s Church, a flatly fabric 117 feet long, 57 broad, and 41 high, with a beautiful spire 244 feet in altitude, and has a ring of 12 bells in its tower.

Blackfriars Bridge.

Opposite to Fleet-ditch, over this part of the river, stands Blackfriars Bridge; a most elegant structure built after the design of Mr Robert Mylne. The situation of the ground on the two shores obliged the architect to employ elliptical arches; which, however, have a very fine effect. The number of arches nine; of which the centre one is 100 feet wide. The whole length is 995 feet: the breadth of the carriage-way is 28 feet, and that of the two foot-ways 7 each. Over each pier is a recet; an apology for the beautiful Ionic pillars which support them, and which have a most beautiful effect from the river. This bridge was begun in 1760; and finished in 1768, at the expense of L. 152,840, to be discharged by a toll upon the passengers. It is situated almost at an equal distance between those of Westminster and London, commands a view of the Thames from the latter to Whitehall, and discovers the majesty of St Paul’s in a very striking manner.

West Smithfield. In this ward is an area containing three acres of ground, called in old records Smithfield-Pond or Horfepool, it having been formerly a watering-place for horses. It was in ancient times the common place of execution, and at the south-west corner there is a gallows called the Elms, from a number of elms trees that grew in the neighbourhood. It was likewise the issue of public juts and tournaments, and has been a market-place for cattle above 500.

On the south side of this area, and contiguous to St Bartholomew’s hospital, is St Bartholomew’s Hospital. It was originally founded soon after the accession of Henry 1. by Rahere the king’s jester, was an infirmary for the priory of St Bartholomew the Great, which then stood near the spot. But upon the dissolution of religious houses, Henry VIII. refounded it, and endowed it with 500 marks a year, on condition that the citizens should pay the same sum annually for the relief of 100 lame and infirm patients. The endowments of this charity have since been so much enlarged, that it now receives the diffret of all denominations. In 1702, a beautiful frontispiece was erected towards Smithfield adorned with pilasters, entablature, and a pediment of the Ionic order, with a statue of King Henry VIII. standing in a niche in full proportion, and those of two cripples on the top of the pediment over it. In 1729, a plan was formed for rebuilding the wrift of this hospital, in consequence of which a magnificent edifice has been erected.

Among many other privileges granted by Henry I. to the prior and canons of the monastery of St Bartholomew the Great, and to the poor of the infirmary, was that of keeping a fair in Smithfield on the eve, day, and morrow, of St Bartholomew. This fair, called Bartholomew-fair, has been held annually ever since; and by the indulgence of the magistrates of London, to whom the privilege of keeping it devolved upon the dissolution of the priory, it used to continue a fortnight. A great number of booths were erected in it by the actors of the theatres, for the exhibition of dramatic performances of various kinds; and it became at length a scene of much licentiousness and riot that Sir John Barnard when lord-mayor of London reduced the time of the fair to its original duration of three days. This laudable example has been followed ever since; and the magistrates have likewise prohibited all public exhibitions which had been formerly accompanied with so much disorder.

In a street in this ward, called the Old Bailey, is a court named Justice-hall, or the Sessions’ houses, where a court is held eight times a year by the king’s commission of oyer and terminer for the trial of criminals for offences committed within the city of London and county of Middlesex. The judges of this court are the lord-mayor, the aldermen that have served that office, and the recorder, who are attended by the sheriffs and by one or more of the national judges.

In this street is also the great criminal prison, lately built in a much more convenient situation, and on a more enlarged plan than the former prison, called Newgate; by which name it is still distinguished. Here the unfortunate debtor will no longer be annoyed by the dreadful rattle of chains, or by the more horrid sounds issuing from the lips of those wretched beings who yet defy all laws divine and human: and
In this ward was likewise a priory called the Fleet-prison, from a small river named the Fleet which formerly ran by it: this building is large, and reckoned the best in the city for good rooms and other conveniences. It has the benefit of a large yard which is enclosed with a very high wall. This priory is as ancient as the reign of Richard I. and belongs to the court of chancery, &c.

In Chancery-lane, in this ward, is an office consisting of a house and chapel, called the office and chapel of the Rolls, from being the great repository of the modern public rolls and records of the kingdom. This building was originally the house of an eminent Jew; but being forfeited to the Crown, King Henry III. in the year 1223 converted it into an hospital for the reception and accommodation of Jewish and other profelytes. In 1377, Edward III. granted this hospital and its chapel to William Burntall master of the rolls, to whose successors in that office it has ever since belonged. Round this office there is a small district consisting of about 200 houses, called the Liberty of the Rolls, over which the magistrates of London have no authority, it being under the government of the master of the rolls.

In this ward are several Inns of court and chancery, particularly the inner and Middle-Temple, Serjeant's Inn, Clifford's-Inn, Barnards'-Inn, and Farnival's-Inn.

The Temple received its name from being originally founded by the Knights-Templars, who settled here in 1187. It was at first called the New Temple, to distinguish it from the former house of the Knight's Templars, which stood in Holborn near Chancery-lane.

The original building was divided into three parts the Inner, the Middle, and the Outer Temple. The Inner and the Outer Temple were so called, because one was within and the other was without the Bar; and the Middle derived its name from being situated between them. Upon the dissolution of the order of Knights-Templars, the New Temple devolved to the Knights-Hospitallers of St John of Jerusalem, who granted a lease of it to the students of the common law, and converted part of it into the Inner and Middle Temple into two Inns of court for the study and practice of the common law. The Outer Temple became a house for the Earl of Ely.

The buildings of the Temple escaped the fire in 1666, but were most of them destroyed by subsequent fires, and have since been rebuilt. The two Temples are each divided into several courts, and have pleasant gardens on the banks of the Thames. They are appropriated to distinct societies and have separate halls, where the members dine in common during term-time. The Inner-Temple hall is said to have been built in the reign of Edward III. and the Middle-Temple hall which is a magnificent edifice, was rebuilt in 1572 in form of a college hall. The Middle-Temple gate, Mr Pennant informs us, was erected by Sir Amias Poulter on a singular occasion. It seems that Sir Amias, about the year 1531, thought fit to put Cardinal Wolsey, then archbishop of York, into the stocks. In 1535, being sent for to London by the cardinal on account of that ancient grudge, he was commanded not to quit town till farther orders. In consequence, he lodged five or six years in this gateway, which he rebuilt; and to pacify his eminence, adorned the front with the cardinal's cap, badges, cognizance, and other devices of this bucher's son; so low were the great men obliged to stoop to that meteor of the times! Each temple has a good library, adorned with paintings and well furnished with books. An assembly, called a parliament, in which the affairs of the society of the Inner-Temple are managed, is held there every term. Both temples have one church, first founded in 1185 by the Knights-Templars; but the present edifice is supposed to have been built in 1420. It is supported by neat slender pillars of Sufex marble, and is one of the most beautiful Gothic structures in England. In this church are many monuments, particularly of nine Knights-Templars cut in marble in full proportion, some of them seven feet and a half long: six are crofs-legged, and therefore supposed to have been engaged in the crusades. The minister of this church, who is usually called the Master of the Temple is appointed by the benchers or senior members of both societies, and preferred by a patent from the crown. Shakespeare (whether from tradition or history) makes the temple garden the place in which the badge of the white and red rose originated; the distinctive badge of the houses of York and Lancaster, under which the respective parties of each arranged themselves in the fatal quarrel which caused such torrents of English blood to flow.

Near Temple-bar is the Devil's-tavern, so called from its sign of St Dunstan rearing the evil spirit by the nose with a pair of hot tongs. Ben Jonson has immortalized it by his Leges Convivales, in which he wrote for the regulation of a club of wits held here in a room he dedicated to Apollo; over the chimney-piece of which they are preferred. The tavern was in his days kept by Simon Wadling, whom in a copy of verses over the door of the Apollo, he dignified with the title of King of Skiers.

Serjeant's Inn is a small Inn in Chancery-lane, Inn of where the judges and serjeants have chambers, but Chancery, not houses, as they had in another Inn of this name in Fleet-street, which they abandoned in 1730; but in each of them there is a hall and a chapel. Clifford's Inn is an Inn of chancery belonging to the Inner Temple. It was originally a house granted by Edward II. to the family of the Cliffords, from which it derived its name; but was afterwards let upon lease to the students of the law, and in the reign of Edward III. sold to the members of this society. Barnard's Inn is likewise an Inn of Chancery belonging to Gray's-Inn. It stands in Holborn, and was the house of John Mackworth dean of Lincoln, who gave it to the professors of the law. Staple's Inn belongs also to Gray's-Inn, and is situated in Holborn. It was once a hall for the merchants of the staple for wool, whence it derives its name; but it was purchased by the benchers of Gray's-Inn, and has been an Inn of chancery since the year 1431. Furnival's Inn is an Inn of chancery belonging to Lincoln's-Inn, and was once the house of the family of the Furnivals, by whom it was let out to the professors of the law. It is a large old building with a hall and a pleasant garden.
In Colman-street ward on the south side of a large square called Moorfields, stands Bethlem-hospital, founded in 1675 by the lord-mayor and citizens of London for the reception and cure of poor lunatics. It is a noble edifice, built with brick and stone, and adorned with pillars, entablatures, and sculpture; particularly with the figures of two lunatics over the grand gate, which are well executed. This building is 540 feet long and 40 broad, exclusive of two wings of a later erection, intended for the reception of such lunatics as are deemed incurable. This hospital contains a great number of convenient cells or apartments where the patients are maintained and receive all medical assistance without any other expense to their friends than that of bedding. The structure is divided into two stories, through each of which runs a long gallery from one end of the house to the other. On the south side are the cells, on the north the windows that give light to the galleries, which are divided in the middle by handsome iron gates, to keep the men and women separate. This hospital being united to that of Bridewell, both are managed by the same president, governors, treasurer, clerk, physician, surgeon, and apothecary; and each has a ward and inferior officers peculiar to itself.

Opposite to Bethlem-hospital stood that of St Luke, along plain building, till of late appropriated to the same purposes, but wholly independent of the former. It was founded on the humane consideration that Bethlem was incapable of receiving all the miserable objects which were offered. Of late years the patients were removed from the old hospital to a new one erected under the same name in Old-street, on the plan of the former, extending in front 393 feet. The old hospital is now pulled down, and replaced by a handsome row of houses. Uncured patients may be taken in again, by a very liberal regulation, on the payment of five shillings a week, so that their friends may if they choose, try a second time the force of medicine on their unhappy relations or acquaintances.

Besides the three markets already mentioned at Smithfield for cattle and hay, at Leadenhall for butcher's meat, wool, hides, and Colchester bairne, and at Billingsgate for fish; there are in this city the following other markets, which are all very considerable, viz. Honey-lane, Newgate, and Fleet-market, chiefly for flesh, though with separate divisions for fish, butter, eggs, poultry, herbs, and fruit; and the Three-Cranes market, for apples and other fruit. The principal corn-market is held in a neat exchange situated in Mark-lane, and that for flour at Queenhithe. In Thames-street, near Billingsgate, there is an exchange for dealers in coals and masters of vessels in that trade to transact their business.

II. The Borough of Southwark. It was called by the Saxons Suth, or the "South work," in respect to some fort or fortification bearing that aspect from London. It was also called the Borough, or Burg, probably from the same reason. It was long independent of the city of London: but in consideration of the inconveniences arising from the escape of malefactors from the great capital into this place, it was in 1327 granted by Edward III. to the city on payment of L. 10 annually. It was then called the village of Southwark; it was afterwards styled the Baldwin, of Southwark, and the mayor and commonalty of London appointed the bailiff. This power, however, not being sufficient to remedy the evil, a more intimate connection was thought necessary; and in the reign of Edward VI. on a valuable consideration paid to the crown, it was formed into a 26th ward, by the title of Bridge-Ward Without, with a reversion of certain privileges enjoyed there by the archbishop of Canterbury and some other ecclesiastics. In consequence of this, it was subjected to the lord-mayor of London, with the find and bailiff. But Southwark being divided into two parts, this is to be understood of the division called the Borough Liberty, which consists of three of the parishes belonging to the town, with the greater part of a fourth part. For the city division, the lord-mayor by his warrant holds a court of record every Monday at the feilions-house on St Margaret's Hill in this borough for all debts, damages, and trespasses, within the limits of his jurisdiction. The other division is called the Clink, or the Manor of Southwark, and is subdivided into the Great Liberty, the Guildhall, and the King's Manor: for each of which subdivisions a court-leet is held, where the constables, ale- and flesh-tasters, are chosen, and other business of this kind transacted. A court-leet, called Union-Hall, has lately been built in the new street called Union-street, which leads in a direct line from the high-street in the Borough to Great Surrey-street Blackfriars-road. The Clink liberty is under the jurisdiction of the bishop of Winchester, who, besides a court-leet, keeps here a court of record on the Bank-side near St Saviour's church by his warrant or bailiff, for pleas of debt, damages, and trespasses. Court-leets are also kept at Lambeth, Bermondsey, and Rochester, three small districts adjoining to the Borough — there is a counter for the imprisonment of offenders in the bailiwick and another for the Clink liberty — to which may be added the Surry workhouse for vagrants. Besides, there is the marshall-prison which is the county-gaol for felons, and the admiralty-gaol for pirates (a); in which is a court first erected for trials of causes between the king's domestics or ministerial servants, of which the knight marshal is president, and his warder, to whom belong four counsellors and six attorneys; and the court is held every Friday by him or his deputy, for debt, damages, and trespasses in causes for 10 miles round Whitehall, excepting London. In this quarter is also the king's-bench prison, the rules of which are above two miles in circuit, and comprise the greatest part of St George's Fields. Here was committed Henry prince of Wales, afterwards King Henry V. by the spirited and honest judge Gafcoigne, for striking or insulting him on the bench.

(a) In 1377 this prison was broke open by a mob of sailors, who murdered a gentleman confined in it for killing one of their comrades, and who had been pardoned by the court. It was again broke open by Wat Tyler and his followers in 1381. It escaped in the infamous riots of 1780; while the King's Bench, the Borough-prison, and the Clink-prison, were nearly at the same instant sacrificed to their fury.
In this prison the allowance is somewhat better than that of the common prisons; for which reason, many debtors remove themselves hither by habeas corpus. It is properly a place of confinement in all cases triable in the King’s-bench court.—The first time that Southwark is mentioned in history is on occasion of Earl Goodwin’s falling up the river to attack the royal navy of 30 ships lying before the palace of Westminster; this was in 1052, when we are told he went ad Southwark, and stayed there till the return of the tide.

Southwark consists of the parishes of St Olave, St Saviour, St George, and St Thomas; the parish of Christ-church, though contiguous to the borough, is in the county of Surrey.

The principal church in Southwark is that of St Saviour, which was formerly a priory of regular canons. Being dedicated to the Virgin Mary, and situated near the bank of the Thames, it was called St Mary Over Regis, by which appellation it is commonly known. This church is built in the manner of a cathedral, with three aisles from east to west and a crof aisles. It is reckoned the largest parish-church in England, the three aisles first mentioned measuring 269 feet, in length, and the crofs aisles 109 feet. The height within, is 47 feet and it has a tower with four spires 150 feet high.

Not far from St George’s church stood the magnificent palace of Charles Brandon duke of Suffolk, the beloved favourite of Henry VIII. After his death, in 1545, it came into the King’s hands, who established here a royal mint. At that time was called Southwark Place, and in great meaure preferred its dignity to Edward VI. once dined in it. His tither and successor presented it to Heath archbishop of York as an inn or residence for him and his successors when ever they repaired to London. As to the mint, it became a seductive for insolvent debtors; at length becoming the pest of the neighbourhood, by giving shelter to villains of every species that awakened the attention of parliament: which, by the statutes 8 and 9 Will. III. 9 George I. and 11 George I. entirely took away its abusive privileges.

In the parish of Christ-church, near the water on Bankside flood, Paris-garden, one of the ancient play houses of the metropolis. Ben Jonson is reproached by one Decker, an avocat er, with his ill success of the stage, and in particular with having performed the part of Zuliman at Paris-garden. It seems to have been much frequented on Sund.ys. This profanation (Mr Pennant observes) was at length fully published by the dire accident which befel the spectators in 1582, when the scaffolding suddenly fell, and multitudes of people were killed or miserably maimed. The occasion seems to have been accepted; for in the next century the manor of Paris-garden was erected into a parish, and a church founded under the name of Christ’s.

Beyond this place of amusement were the Bear-garden and place for baiting of bulls, the Brittan circus: “Herein (says Stow) were kept bears, bulls, and other beastes to be baited; and also maffives in several kennels nourished to bate them. These beares and other beastes are there kept in plots of ground castfould for the beholders to stand safe.” This was then an amusement for persons of the first rank: the great, if not good, Elizabeth caused the French ambasadores to be carried to this theatre, to divert them with these bloody spectacles.

Not far from these scenes of cruel pastime was the Stews, Bordello or Stew, permitted and openly licensed by government, under certain laws or regulations. They were formed out. Even a lord-mayor did not disdain to own them; but rented them to the Fnoes, that is “the bawds,” of Flanders. Among other singular regulations, no stewholder was to admit married women; nor were they to keep open their houses on Sundays; nor were they to admit any women who had on them the perilous infirmity of burning. These infamous houses were very properly suppressed in the reign of Henry VIII.

The bishop of Winchester had formerly a palace here with a park (the fame that is now called Southwark-Park), which is since converted into warehouses and tenements, held by lease from the bishops of that see.

Southwark also contains several almshouses, of which there are here St Thomas’s and Guy’s hospitals, known under the names of Southwark hospitals in England. The former was erected in 1515 by Peter de Ruphus bishop of Winchester, who endowed it with land to the amount of L. 343 a year; from which time it has been the object of the abbots of Bermondsey, one of whom in 1428 granted a right to the master of the hospital to hold all the lands it was then in possession of belonging to the said abbots and convent, the whole revenue of which did not exceed L. 266:17:6 per annum. In the year 1557, after the citizens of London had purchased of Edward VI. the manor of Southwark and its appurtenances, of which this hospital was a part, they expended L. 1100 in repairing and enlarging the edifice, and immediately received into it 260 patients; upon which the king in 1553 incorporated this hospital with those of Christ-church and Bridewell in the city of London. The building bring much decayed, three beautiful squares adorned with colonades were erected by voluntary subscription in 1693, to which in 1752 the governors added a magnificent building, consisting of several wards with proper offices. The annual disbursements of this hospital have for many years amounted to L. 8000. The house is divided into 19 wards, and is said to contain 474 beds.

Adjoining to St Thomas’s stands Guy’s hospital, perhaps the most extensive charitable foundation that ever was established by one man in private life. The founder of this hospital was Thomas Guy, a bookseller in Lombard-street, London, who lived to see the edifice roofed in; and at his death, in 1724, left L. 283,292, 1s. including the expense of the building, to mind and endow it. This hospital consists of two capacious squares, containing 12 wards and 435 beds. It was incorporated by charter from parliament, and the first governors were appointed in 1725.

In St George’s Fields, westward of the King’s-bench prison, is the Magdalen Hospital for the reception of penitent prostitutes; a little farther is situated the Asylum for orphan girls; and not far distant is the Westminster Lying-in hospital: Institutions, of which the following feeling and animated account is given by Mr Pennant.
LON [ 262 ]

The Magdalen Hospital.

The Magdalen Hospital is an institution of a most heavenly nature, calculated to save from perdition soul and body the brighter part of the creation; such as whom Providence hath betrothed angelic faces and elegant forms, designed as blessings to mankind, but too often dedicated to the vilest lusts. The hazard that these innocents contantly are liable to from a thousand temptations, from poverty, from death of parents, from the diabolical persecures, and often from the stupendous wickedness of parents themselves who have been known to sell their beautiful girls for the purpose of prostitution, induced a worthy band to found in the year 1758 the asylum or House of Refuge. Long may it flourish, and eternal be the reward of those into whose minds so amiable a conception entered!

To afford means of salvation to those unhappy beings who had the ill fortune to lose the benefits of this divine institution, the Magdalen Hospital was instituted for the reception of the penitent prostitutes. To live from vice is one great merit. To reclaim and restore to the dignity of honest rank in life, is certainly not less meritorious. The joy at the return of one daughter to repentance is experienced by the highest authority worthy of the heavenly host. That ecstasy I trust this institution has often occasioned. Since its foundation in the same year with the former, to December 25th, 1786, not fewer than 2471 have been admitted. Of these (it is not to be wondered that long and evil habits are often incurable) 300 have been discharged, uneasy under constraint; 45 proved lunatics, and afflicted with incurable fits; 60 have died; 52 never returned from Hospitals they were sent to; 328 discharged for faults and irregularities. How to be dreaded is the entrance into the bounds of vice; this palace suffers greatly; but at the same time it is not intended to increase the number; the retreat from Hospitals they have died; the retreat from Hospitals they have been induced a worthy band to found in the year 1758, the asylum or House of Refuge. Long may it flourish, and eternal be the reward of those into whose minds so amiable a conception entered!

To afford means of salvation to those unhappy beings who had the ill fortune to lose the benefits of this divine institution, the Magdalen Hospital was instituted for the reception of the penitent prostitutes. To live from vice is one great merit. To reclaim and restore to the dignity of honest rank in life, is certainly not less meritorious. The joy at the return of one daughter to repentance is experienced by the highest authority worthy of the heavenly host. That ecstasy I trust this institution has often occasioned. How to be dreaded is the entrance into the bounds of vice, this palace suffers greatly; but at the same time it is not intended to increase the number; the retreat from Hospitals they have died; the retreat from Hospitals they have been induced a worthy band to found in the year 1758, the asylum or House of Refuge. Long may it flourish, and eternal be the reward of those into whose minds so amiable a conception entered!

Lying-in Hospital.

Akin to those charities is that of the Lying in Hospital: which is not intended merely for the reception of those the honofest matron who can deposit her burden with the conciunction of lawful love; but also for the unhappy wretches whom fate villain in the unguarded moment has seduced, and then left a prey to defection of friends, to poverty, want and guilt. Left such may be driven to despair by such complicated misery, and be tempted to destroy themselves and murder their infants, here was founded in 1705 this humane preventative the Weftminifer New Lying-in Hospital, in which every assistance and accommodation requisite in such situations are provided in the most attentive and liberal manner. To obviate all objection to its being an encouragement to vice, no one is taken in a second time: but this most excellent charity is open to the worthy distressed matron as often as necessity requires. None are rejected who have friends to recommend. And of both descriptions upwards of 4000 have experienced its salutary effect.

St. George's Fields are now almost covered with the new-created buildings, from the ditch at the end of Fields. Great Savoy-street, or Burrow's buildings, to the Fifhmongers' almshouses, in one direction, and from the Marshalsea-prison to the Dog and Duck, in the other direction, with several irregular indentations in its circumference; and where the principal roads meet an obelisk has been erected, pointing out the distance it stands from different parts of London, Weftminifer and Blackfriars bridges. Among the buildings which serve to embellish and improve this entrance to London, Chatham square and and Bridge-street Blackfairs may be particularly specified.

At Lambeth, the archbishops of Canterbury have Lamberth had a palace. According to Mr. Pennant, it was in palace.

the earlier times a manor, possibly a royal one; for the great Hardiknauu died here in 1642, in the midst of the jollity of a wedding dinner; and here, without any formality, the usurper Harold is said to have received the crown and placed it on his own head. At that period it was part of the estate of God, wife to Walter Earl of Mantes, and Enstatcr Earl of Boulogne; who presented it to the church of Rochefet but referred to herself the patronage of the church. It became in 1197 the property of the see of Canterbury, by exchange transferred between Clanville Bishop of Rochefet, and the Archbishops Hubart Walter. The building was improved by Langton the seeceffor of Walter; but it was afterwards neglected and became ruinous. No pious zeal (says Mr. Pen­nant) restored the place, but the madness of prieftly pride. Boniface, a wrathful and turbulent primate, elected in 1244, took it into his head to become a vic­tor of the priory of St. Bartholomew, to which he had no right. The monks met him with reverential respect, but assured him the office did not belong to the bishop. The neek prelate rushed on the sub­prior, knocked him down, kicked, beat, and buffeted him, tore the cope of his back, and stamped on it like one policed, while his attendants paid the same complimients to all the poor monks. The people enraged at his unpriestly conduct would have torn him to pieces; when he retired to Lamberth, and, by way of expanion, rebuilt it with great magnificence. At a subsequent period it was very highly improved by the munificent Henry Chichley, who restored the vic­primacy from 1414 to 1442. I lament to find so worthy a man to have been the founder of a building so reproachful to his memory as the Lollards tower, at the exence of near L. 280. Neither Protestants or Catholics should omit visiting this tower, the cruel prilen of the unhappy followers of Wickliffe. The vast staples and rings to which they were chained before they were brought to the stake, ought to make Protestants bles the hour which freed them from so bloody a religion. During the civil wars of the last century, this palace suffered greatly; but at the restora­tion, the whole was repaired by Archbishop Juxton. The parish church of Lambeth (a), which is a small distance

(n) In describing this church, Mr. Pennant takes occasion to mention the sad example of fallen majesty in the person of Mary d'Este, the unhappy queen of James II.; who flying with her infant prince from the ruin
distance from the place, has a plain tower; and the architecture is of the Gothic of the time of Edward IV. It has very little remarkable in it, except the figure of a pedlar and his dog, painted in one of the windows; and tradition says, that the parson was obliged to this man for the bequest of a piece of land, which bears the name of the Pedlar’s Acre. In the churchyard is the tomb of old Tradescant. Both father and son were great travellers; and the former is supposed to have visited Russia and most parts of Europe, Turkey, Greece, many of the eastern countries, Egypt, and Barbary; out of which he introduced multitudes of plants and flowers, unknown before in the gardens, emblematical sculptures; and bearing the following inscription, which is both singular and historical:

Know, stranger, ere thou pass beneath this stone
Lyce Tradescant, grandfater, father, son;
The last dy’d in his spring, the other two
Lived till they had travel’d art and Nature through,
As by their choice collections may appear,
Of what is rare, in land, in sea, in air;
Wittliy they (as Homer’s Iliad in a nut)
A world of wonders in one cleft shut.
Thefe famous Antiquarians, that had been
Both gardener to the Rose and Lily Queen,
Transplanted now themselves, sleep here; and when
Angels shall with their trumpets wake men,
And fire shall purge the world, these hence shall rise,
And change this garden for a paradise.

Know, stranger, ere thou pass beneath this stone
Lyce Tradescant, grandfater, father, son;
The last dy’d in his spring, the other two
Lived till they had travel’d art and Nature through,
As by their choice collections may appear,
Of what is rare, in land, in sea, in air;
Wittliy they (as Homer’s Iliad in a nut)
A world of wonders in one cleft shut.
Thefe famous Antiquarians, that had been
Both gardener to the Rose and Lily Queen,
Transplanted now themselves, sleep here; and when
Angels shall with their trumpets wake men,
And fire shall purge the world, these hence shall rise,
And change this garden for a paradise.

From Lambeth, eastward along the river side, was
once a long tract of dreary marsh, and till in some parts called
Lambeth-marsh; about the year 1560, there was
not a house on it from Lambeth palace as far as
Southwark. In a street called Narrow-wall (from
one of the ancient embankments), is Mrs Conde’s noted
manufactory of artificial stone (1); And at a small
distance, Melf. Beaunoy’s great work for making
wines (x), and that for making vinegar (y).

This ground, so profitable to the proprietors, and Great ma-
fo productive of revenue to the state, was within me-
ory the scene of low dilipation. Here stood Cuper’s
garden, noted for its fire-works, and the great retort
of the prodigal of both sexes. This place was orna-
mented with several of the mutilated statues belonging
to Thomas Earl of Arundel, which had been for that
purpose begg’d from his lordship by one Boyder Cuper,
a gardener in the family. The great timber-
yards beneath which these antiquities were found, are
very well worthy of a visit. One would fear that the
forests of Norway and the Baltic would be exhausted,
to supply the want of the overgrown capital, were
we not assured that the resources will successively be
increasing equal to the demand for succeeding ages.—
In this parish are also the vail distilleries, till of late
the property of Sir Joseph Mawbey; where are seldom
less than 2000 hogs constantly granting, and
kept entirely on the grains.

III. City and Liberties of WESTMINSTER. The city City and
of Westminster derives its name from a minster or ab-
beys, and west, on account of its situation with respect
St Paul’s cathedral, which was formerly called East-
minster. In ancient times this district formed upwards
of a mile from the city of London, and contained only
two parishes, which were those of St Margaret and
st John, with two chapels of ease, but at present it
has seven other parochial churches, viz. St Clement’s-
Danes, St Paul’s Covent-garden, St Mary’s le-Strand,
St Martin’s in the Fields, St Anne’s, St James’s, and
St George’s Hanover-square.

Westminster

rain impending over their house after crossing the Thames from the abdicated Whitehall, took shelter beneath
the ancient walls of this church a whole hour, from the rain of the inclement night of December 6th, 1688.
Here she waited with aggravated misery, till a common coach procured from the next inn, arrived, and con-
voyed her to Gravesend, from whence she failed, and bid an eternal adieu to these kingdoms.

(1) "Where (says Mr Pennant) the foreign wines are most admirably mimicked. Such is the prodi-
gality and luxury of the age, that the demand for many sorts exceeds in a great degree the produce of the
native vineyards. We have skillful fabricators who kindly supply our wants. It has been estimated, that
half of the port, and five sixths of the white wines consumed in our capital, have been the produce of our
home wine presses. The product of the duty to the state from a single house was in one year, from July
4th 1785, to July 5th 1786, not less than L 7,365; 9: 8:�. The generall banks of the Thames opposite to
our capital, yield almost every species of white wine; and by a wondrous magic, Melf. Beaunoy pourr fort
the materials for the rich Frontiniacs, to the more elegant tables; the Madeira, the Calavalla, and the Lig
bon, into every part of the kingdom."

(2) "There is a magnificence of buildings (our author remarks) in this ocean of sweets and fous, that
cannot fail exciting the greatest admiration: whether we confider the number of vessels or their fize. The
boatful at Heydelberg does not surpass them. On first entering the yard, two rice before you, covered
at the top with a thatched dome; between them is a circular turret, including a winding staircase, which
brings you to their fumitories, which are above 4 feet in diameter. One of these conservatories is full of fweet
wine, and contains 53,799 gallons, or 1,185 barrels of Winchefer measure. Its fuperficial is full of
vinegar, to the amount of 56,799 gallons, or 1,774 barrels of the fame standard as the former. The fa-
famous German veffel yields even to the laft by the quantity of 40 barrels.—Besides thefe, is an avenue of
fifer veffels, which hold from 12,500 to 16,974 gallons each. After quitting this Brobdingnagian feene,
we prf to the acres covered with common barrel-yards, cannot diminish our ideas. fuddenly, but at firft we
imagined we could quaff them off as easily as Gulliver did the little hogheads of the kingdom of Lilliput."
London

Westminster was anciently called Thorny-island, from its having been covered with thorn-brushes, and encompassed by a branch of the Thames, which is said to have run through the ground now called St James's park, from west to east, and to have rejoined the river at Whitehall.

Till the general dissolution of religious houses, Westminster was subject to the ordinary rules of its abbot and monks; but in 1541, upon the surrender of William Benfon the last abbot, Henry VIII. not only turned it into an honour, but created the fee of a bishop, and appointed for a diocese the whole county of Middlesex, except Fulham, which belonged to the bishop of London. This bishopric, however, soon after its institution, was dissolved by Edward VI.

The city of Westminster is governed by an high steward, an officer of great dignity, who is usually one of the first peers in the realm; and is chosen for life by the dean and chapter of the collegiate church of St Peter. There is also a deputy steward and a high bailiff, who also hold their offices for life; being nominated by the dean and chapter, and confirmed by the high steward.

The dean and chapter are invested with an ecclesiastical and civil jurisdiction within the liberties of Westminster, St Martin's-le-Grand, near Cheapside, in the city of London, and some towns in Essex, which are exempted from the jurisdiction of the bishop of London and the archbishop of Canterbury.

St Margaret's church was founded by Edward the Confessor, since which time it has been frequently rebuilt. In the east end of this church is a window curiously painted, with the history of the crucifixion, and with the figures of several apostles and saints finely executed. It formerly belonged to a private chapel at Coth-hall, near Epping in Essex, and was purchased by the officers of this parish some years ago for 400 guineas. In this church the house of commons attends divine service on state holidays.

The church of St John the Evangelist was erected in 1275, and having sunk considerably whilst it was building, occasioned an alteration of the plan. On the north and south sides are magnificent porticoes, supported by vast stone pillars, as is also the roof of the church; at each of the four corners is a beautiful stone tower and pinnacle, which were added with the view of making the whole structure sink equally. The parts of this building are held together by iron bars, which run across even the aisles.

The most remarkable structure in Westminster is the abbey-church of St Peter. On its site stood once a temple of Apollo, which according to tradition was thrown down by an earthquake in the time of Antoninus Pius; and from the ruins of which, Sebert king of the west Saxons raised a Christian church, which was ruined by the Danes. It was repaired by Edward the Confessor, and given to a few monks; and this spot he chose for his burial-place. Henry III. 150 years after, took down this fabric of Edward's, and erected a new church, which was 50 years in building. It suffered much by fire in 1274, but was repaired by Edward I. Edward II. and the abbots. In 1700 this church being much decayed, the parliament granted money for repairing it, and has frequently repeated the bounty since that time. The form of the abbey is that of a long cross; its greatest length is 489 feet, and the breadth of the west front 66 feet; the length of the cross aisle is 189 feet, and the height of the roof 92 feet. At the west end are two towers: the nave and cross aisle are supported by 30 slender pillars of Suffolke marble, exclusive of pilasters. In the upper and lower ranges there are 94 windows, all which, with the arches, roofs, and doors, are in the Gothic taste. The inside of this church is much better executed than the outside; and the perspective is good, particularly that of the grand aisle. The choir, from which there is an ascent by several steps to a fine altar-piece, is paved with black and white marble; having 28 stalls on the north, the same number on the south, and eight at the west end. The altar is made of a beautiful piece of marble, the gift of Queen Anne, inclosed by a curious balustrade, and upon a pavement of porphyry, jasper, Lydian, and serpine stones laid in the Mosaic style, at the expense of abbot Ware, A.D. 1572; and is said to be one of the most beautiful of its kind in the world. On each side of this altar a door opens into St Edward's chapel; round which are 10 other chapels, ranging from the north to the south cross aisles, and are dedicated, 1. To St Andrew. 2. To St Michael. 3. To St John Evangelist. 4. Hip's chapel. 5. To St John Baptist. 6. To St Paul. 7. Henry V.'s chapel. 8. To St Nicholas. 9. To St Edmund. 10. To St Benedict.

In St Edward's chapel are still to be seen the remains of his shrine, which, though now in obscurity, and robbed of all its riches and luster, was once esteemed the glory of England, so far as it aids and riches could make it. Here are the tombs of King Edward I. and several other kings and queens of England; and here also is shown the famous chair in which the kings of Scotland used to be crowned at Scoon. Henry V.'s chapel is divided from St Edward's by an iron screen, on each side of which are statues as big as life.—St Andrew's chapel, which is next to the north cross, and the others which surround the choir are crowded with the monuments of noble personages, worthy the attention of the curious—At the corner of St Benedict's chapel, an iron gate opens into the south cross aisle; which from the number of monuments erected therein to celebrate English poets, has obtained the name of the poet's corner: there we find a most magnificent monument erected at the south end in memory of the late John duke of Argyle and Greenwich; another to William Camden the antiquarian; and others to the celebrated divine Dr Isaac Barrow, to Thomas Parr who died at the age of 152 years; &c.—The south aisle is adorned with 19 curious monuments of the pious, the brave, and the learned; and turning northward from the west door, we view a great number more.

On the east of the abbey, and which, though sepulchre of Henry's rate from the other chapels in the choir, seems to be one and the same building with the abbey, stands the chapel of King Henry VII. which was built according to the year 1524, and was at that time called the Wonder of the world; and is now one of the most expensive remains of the ancient English taste and magnificence. There is no looking upon it without admiration:
On the north-east side of the abbey is an old Gothic building called Westminster Hall, first built by William Rufus as an addition to a royal palace, and afterwards rebuilt by Richard II. in the year 1397. It is reckoned one of the largest rooms in Europe, being 200 feet long, 70 broad, and 90 high, supported only by buttresses. The roof is of timber, and was formerly thatched; the old covering of lead being reckoned too heavy. It is paved with stone.

In this spacious room the kings of England have generally held their coronation and other solemn feasts; and it is used for the trial of peers. Since the reign of Henry III. the three great courts of Chancery, King's Bench, and Common Pleas, have been held in separate apartments of this hall; and the court of Exchequer above stairs.

Adjoining to the south-east of Westminster Hall is a building formerly called St Stephen's Chapel, from its having been dedicated to that saint. It was founded by King Stephen; and in 1347 was rebuilt by King Edward III. who converted it into a college church; but it was separated from the abbey church by King Edward VI. It has been used for the assembly of the representatives of the commons of England, and is now generally called the House of Commons. The benches, which are behind another as in a theatre, are covered with green cloth; the floor is matted; and round the room are wainscot galleries, supported by canopies adorned with carved work, in which strangers are often permitted to sit and hear the debates.

On the south side of the hall is the House of Lords, formerly called from being the place where the peers of Great Britain assemble in parliament. It is an oblong room, not quite so large as the house of commons; and is hung with fine old tapestry, representing the defeat of the Spanish Armada in 1588. The design was drawn by Cornelius Vroom, and the tapestry executed by Francis Spiering. It was not put up till the year 1650, two years after the extinction of monarchy, when the house of lords was used as a committee-room for the house of commons. The heads of the naval heroes who commanded on the glorious day form a matchless border round the work, animating peltory to emulate their illustrious example. Here is a throne for the king, with seats on the right and left for such peers of the realm as are of the blood royal. Before the throne are three broad seats; and on the first of these, next the throne, sits the Lord Chancellor, or keeper of the great seal, who is speaker of the house of peers; and on the other two sit the judges, the master of the rolls, and the masters of chancery, who attend occasionally to give their opinions on points of law. The two archbishops sit at some distance from the throne on the right hand, and the other bishops in a row under them. All the benches are covered with red cloth studded with wool. Here likewise, by a late order of the house, a gallery for strangers has been erected.

Adjoining to the house of lords is the Prince's Prince's Chamber, where the king is robed when he comes to chamber, the parliament. On the other side is the Privy Council Chamber, which is said to have been Edward the Conserver's bed-chamber, and the room in which the parliaments were anciently opened. Here conferences are

Vol. X
are often held between the two houses, or their committees. Contiguous to these is an apartment called the Court of Requests, where such as have business in either house may attend.

Near these buildings is a bridge over the Thames, called Westminster Bridge, accounted one of the most complete and elegant structures of the kind in the known world. It is built entirely of stone, and extends over the river at a place where it is 1233 feet broad; which is about 350 feet broader than at London Bridge. On each side is a fine balustrade of stone, with places of shelter from the rain. The width of the bridge is 44 feet, having on each side a fine footway for passengers. It consists of 14 piers, and 13 large and two small arches, all semicircular, that in the centre being 76 feet wide, and the rest decreasing four feet each from the other, so that the two largest arches of the 13 great ones are each 52 feet. It is computed that the value of 40,000l. in stone and other materials is always under water. This magnificent structure was begun in 1739, and finished in 1750, at the expense of 389,000l. defrayed by the court. It was built after the design of Mr. Labelye, an ingenious architect, a native of France.

On the bank of the Thames, at the east confines of St. Margaret's parish, was a palace called Whitehall, originally built by Hubert de Burgh earl of Kent, before the middle of the 13th century. It afterwards devolved to the archbishop of York, whence it received the name of York Place, and continued to be the city residence of the archbishops till it was purchased by Henry VIII. of cardinal Wolsey in 1530. At this period it became the residence of the court; but in 1597 was destroyed by accidental fire, all except the banqueting-house, which had been added to the palace of Whitehall by James I. according to a design of Inigo Jones. This is an elegant and magnificent structure of hewn stone, adorned with an upper and lower range of pillars, of the Ionic and Composite orders; the capitals are enriched with fruit and foliage, and between the columns of the windows. The roof is covered with lead, and surmounted with a balustrade. The building chiefly consists of one room of an oblong form, 40 feet high, and a proportionable length and breadth. The ceiling is painted by the celebrated Sir Peter Paul Rubens. It is now used only as a chapel royal, and the other part of the house is occupied with state-offices.

Opposite to the banqueting-house stands the Horseguards, so called from being the stables where that part of his majesty's troops usually do duty. It is a strong building, of hewn stone, consisting of a centre and two wings. In the former is an arched passage into St. James's Park; and over it, in the middle, rises a cupola. In a part of the building is the War-office. Near the Horse-guards is the Treasury; a large building, which fronts the Parade in St. James's Park; and where the board of treasury is kept.

Eastward of the Horse-guards is the Admiralty-office, a large pile, built with brick and stone. The front towards Whitehall has two deep wings, and a loftily portico supported by four large stone pillars. A piazza, consisting of beautiful columns, runs almost from one end to the other. The wall before the court has been lately built in an elegant manner, and each side of the gate is ornamented with naval emblems. Besides a hall, and other public apartments, here are spacious houses for seven commissiories of the admiralty.

At a little distance from the admiralty, where three Charing-crofs, from one of the croffes which King Edward I. caused to be erected in memory of his queen Eleanor, and Charing the name of a village in which it was built. The crofs remained till the civil wars in the reign of Charles I. when it was destroyed by the fanatics, as a monument of popish superstition; but after the Restoration, an equesrian statue of Charles I. was set up in its stead. This, which is of brass, and finely executed, continues to be an ornament to the place. It was made in 1633, at the expense of the Howard-Arundel family. The parliament fold it to a brazier in Holborn, with strict orders to break it to pieces; but he concealed it under ground till the Restoration, when it was set up in 1678.

At the west end of the Mall, in St. James's Park, Queen's house, a which begins near Charing-crofs, stands the Queen's Palace. It was originally known by the name of Arlington-house; but being purchased by the late duke of Buckingham's father, who rebuilt it from the ground in 1703, it was called Buckingham-house, till the year 1762, when it was purchased by his majesty for a royal residence. It is built of brick and stone, having in the front two ranges of pilasters of the Corinthian and Tuscan orders. It has a spacious court-yard, inclosed with iron rails, fronting St. James's Park, with offices on each side, with two pavilions, separated from the mansion-house by colonades of the Tuscan, Doric, and Ionic orders. Its majesty has here built a fine library, in an octagonal form, besides several other additions.

Eastward of the queen's palace stands St. James's, St. James's, an old building, which, till the former was purchased by the crown, had been the town-residence of the royal family since the burning of Whitehall in 1697. This palace was built by Henry VIII. and obtained its name from an hospital which formerly stood on the spot. It is an irregular building, of mean appearance without, but contains several magnificent apartments. Here the court and levees are still kept, and most of the persons belonging to the household have their residence. The chapel of the hospital was converted to the use of the royal family, as it now remains, and is a royal peculiary, exempted from all episcopal Jurisdiction. When this palace was built, it abutted in the Mall ground, which the king inclosed and converted into a park, called from the palace St. James's Park. He also laid it out into walks, and collected the water into one body. It was afterwards much enlarged and improved by king Charles II. who planted it with lime-trees, and formed a beautiful villa, near half a mile in length, called the Mall, from its being adapted to a play at bowls distinguished by that name. He also formed the water into a canal 100 feet broad and 280 feet long; and furnished the park with a decoy, and other pond for water-fowls; but these have lately been
In a line with St. James's palace, on the east side, is Marlborough House; which belongs to the duke of Marlborough, and is a large brick edifice, ornamented with fountains.

The Strand, from Charing-cross, runs that fine street the Strand, which terminates at Temple-bar. In the year 1533 the whole of it was an open highway, with gardens to the water-side. In that year it was so ruinous, that Edward III. by an ordinance directed a tax to be raised upon wool, leather, wine, and goods carried to the staple at Westminster, from Temple-bar to Westminster abbey, for the repair of the road; and that all owners of houses adjacent to the highway should repair as much as lay before their doors. Before the above period, it entirely cut off Westminster from London; nothing intervened except the scattered houses, and a village which afterwards gave it the name of St. Giles. As the court withdrew part of the site of Snow-hill, Convent-garden, and upon the Thames where this street stands, is that noble palace called Whitehall, which took its name from a place built originally by the illustrious Thomas de Catfield, elected bishop of Durham in 1245; designed by him for the town residence of him and his successors. At this place, in 1540, was held a most magnificent feast, given by the challengers of England, who had caused to be proclaimed, in France, Flanders, Scotland, and Spain, a great and triumphant Jubilee to be held at Westminster, for all comers that would undertake them. But both the challengers and defendants were English. After the gallant sports of each day, the challengers rode unto this Durham-house, where they kept open household, and tainted the king and queen (Anne of Cleves) with her ladies, and all the court. In the reign of Edward VI. the mint was established in this house, under the management of Sir William Sharrington, and the influence of the aspiring Thomas Seymour, lord admiral. Durham-house was reckoned one of the royal palaces belonging to queen Elizabeth, who gave the use of it to the great Sir Walter Raleigh.

Durham-yard is now filled with a most magnificent and comprehensive building, called the Adelphi, in honour of the two brothers, the ingenious Adams, its architects. Besides its fine lodgings, it is celebrated for its enchanting prospect, the utility of its wharfs, and its subterranean apartments answering a variety of purposes of general benefit.

Farther on, the ruins of the Savoy. Henry III. had granted to Peter of Savoy, uncle to his queen Eleanor, daughter of Berenguer of Provence, all the gardens upon the Thames where this building now stands, to hold to him and his heirs, yielding yearly at the Exchequer three barbed arrows for all services. This prince founded the Savoy, and bestowed it on the foreign hospital of Montjoy. Queen Eleanor purchased it, and bestowed it on her son Edmund earl of Lancaster. It was rebuilt in a most magnificent manner by his son Henry. It was made the place of confinement of John king of France in 1356, after he was taken prisoner at the battle of Poitiers. In 1381 it was entirely destroyed by Wat Tyler, out of spleen to the greater owner John of Gaunt. Henry VII. began to rebuild it, with a design of forming it into an hospital for a hundred distressed people, and Henry VIII. completed the design. The revenues, at the suppression by Edward VI. amounted to above 500 l. a year. Queen Mary restored it; and her maids of honour, with exemplary piety, furnished it with all necessaries. It was again suppressed by Queen Elizabeth; and at present part serves as lodgings for private people, for barracks, and a scandalous infectious prison for the foldery and for transport-convicts.

A little to the eastward flooded Somerset-house, a palatial pile built by Somerset the Protector in the time of house. Edward VI.; and to make way for which he demolished a great number of buildings without making any recompense to the owners. Part of the church of St. John of Jerusalem and the Tower were blown up for the

The Strand, when first formed.

Northumberland House,
London. The site of the materials, and the cloisters on the north side of St Paul's, with the charnel-house and chapel, were not the same; the tombs being destroyed, and the bones thrown into Finsbury-fields. This happened in 1549; but it is probable that he did not live to inhabit the palace he built, as he was executed in the year 1552. After his death the palace fell to the crown; and it became an occasional place of residence first to Queen Elizabeth, and afterwards to Catherine queen to king Charles II. It was built in a style of architecture compounded of the Grecian and Gothic; and the back, front, and water-gate, were done from a design of Inigo Jones, about the year 1623. A chapel was begun the same year by that architect, and finished some time after. The whole of this structure was demolished in 1775, in consequence of an act of parliament; and a most magnificent edifice, from a design by Sir William Chambers, has been erected for the accommodation of all the public offices,—those of the Treasury, the Secretary of State, the Admiralty, the War, and the Excise, excepted. The Royal Society, and the Society of Antiquaries, hold their meetings here, in apartments which have been allotted to them by royal munificence; and here also are annually exhibited the works of the British painters and sculptors. The terrace on the fourth side is a walk bordered by the Thames, and unparalleled for grandeur and beauty of view.

The church of St Martin is distinguished by the name of St Martin's in the Fields, from its situation, which was formerly a field, with only a few scattered houses. The church being decayed, was rebuilt by Henry VIII. and again by James I. but not being large enough to accommodate the inhabitants of the parish it was augmented in 1667, at the charge of Prince Henry, eldest son of James I. and several of the nobility. After many expensive repairs, however, it was entirely taken down in 1720, and a new church began, which was finished in 1726. This is an elegant edifice, built of stone. On the front is a noble portico of Corinthian columns, supported a pediment, in which are represented the royal arms in bas-relief. The ascent to the portico is by a flight of very long steps. The length of this church is about 140 feet, the breadth 60, and height 45. It has a fine arched roof supported by stone columns of the Corinthian order. The steeple has a beautiful spire, and one of the best rings of bells in London.

St James's Church was built in the reign of Charles II., at the expense of Henry earl of St Alban's, and other neighbouring inhabitants. The building is of brick and stone, about 24 feet long, 60 broad, and 45 feet high, with a handsome steeple 150 feet in height.

St George's Church, near Hanover-square, is a beautiful structure. This was one of the fifty new churches erected within the bills of mortality, by act of parliament, in the reign of Queen Anne. The ground for the edifice was given by the late lieutenant-general Stewart, who also left 4000l. to the parish, towards erecting and endowing a charity school; which, by additional benefactions and subscriptions, is become very considerable.

The greater part of the parish of St Paul's Covent-garden, was anciently a garden, belonging to the abbot and convent of Welfminder, and was then called Covent-Garden, a name corrupted into Covent, and more generally Common-garden. In 1552, Edward VI. gave it to the earl of Bedford, with an adjoining field, formerly called the Seven Acres, but now, being turned into a long street, called Long-aca. The church of St Paul's, Covent-garden, was built by Inigo Jones, and is esteemed one of the most simple and perfect pieces of architecture in England. In the front is a plain portico of the Tuscan order, with masonry columns. Before the church is a square area, containing about three acres of ground, called Covent-garden market, and is the beef in England for herbs, fruit, and flowers. On the north, and part of the east side, is a magnificent piazza, designed by Inigo Jones.

Next to the parish of St Paul, Covent-garden, is St Mary-le-Strand. This is also one of the fifty new churches built in the reign of Queen Anne, and is a handsome piece of architecture, though not very extensive. At the entrance, on the west side, is an ascent by a flight of steps, in a circular form, which leads to a similarly shaped portico of Ionic columns, covered with a dome, that is crowned with a vase. The columns are continued along the body of the church, with pilasters of the same order at the corners; and in the intercolumniations are niches handsomely ornamented. Over the dome is a pediment supported by Corinthian columns, which are also continued round the body of the structure, over those of the Ionic order. A handsome balustrade is carried round the top of the church, and adorned with vases.

A little eastward from the preceding church is that of St Clement's Danes, situated like wise in the Strand. A church is said to have stood in this place since about the year 700; but the present structure was begun in 1680, designed by Sir Christopher Wren. It is built of stone, with two rows of windows, the lower plain, but the upper ornamented; and the termination is by an aisle, the pilasters of which are covered with vases. On the fourth side is a portico, covered with a dome, supported by Ionic columns; and opposite to this is another. The steeple is beautiful, and of a great height.

The church of St George, Bloomsbury, is also one of the fifty new churches erected by act of parliament. It is distinguished from all the rest by standing south and north, and by the statue of King George I. at the top of its pyramidal steeple.

In Lamb's Conduit-fields, on the north side of the town, is a large and commodious structure, called the Foundling-hospital, for the reception of exposed and deserted children. This laudable charity was projected by several eminent merchants in the reign of Queen Anne; but was not carried into execution till many years afterwards, when a charter for its establishment was obtained, through the indefatigable assiduity of Mr Thomas Coram, the commander of a merchant vessel, who spent the remainder of his life in promoting this design. From the time of its institution, the parliament has occasionally granted considerable sums for its support; and in some years upwards of 6000 infants have been received.

Not far from hence is an Hospital for the Small-pox; and
and in different parts of the town there are others, either for the sick of all kinds, or those in particular circumstances. Of the latter are several Lying-in hospitals, and the Lock-hospital for female patients in the venereal disease. Of the former are St George's and the Middlesex hospitals, besides several infirmaries. Gray's Inn is one of the four principal inns of court; which, though situated within the limits of the parish of St Andrew, Holborn, is yet without the liberties of the city of London. It took its name from an ancient family of the name of Gray, which formerly resided here, and in the reign of Edward III. demised it to some students in the law; but it is said to have been afterwards conveyed to the monks of Shene, near Richmond in Surrey, who leased it to the society of the Inn. It was held by this tenure till the dissolution of the monasteries, when Henry VIII. granted it to the society in fee-farm. This inn consists chiefly of two quadrangles, and has an old hall well built of timber, with a chapel in the Gothic style. Here is also a good library, and The Inn is accommodated with a spacious garden.

Lincoln's Inn, another of the four principal inns of court, was originally the palace of Ralph Neville, bishop of Chichester, and chancellor of England about the year 1260. It afterwards devolved to the earl of Lincoln, who converted it into a court for the students of law about the year 1310. From him it received the name of Lincoln's inn, and consisted only of what is now called the old square, which is entered from Chancery-lane. At present this square contains, besides buildings for the lawyers, a large hall where the lord chancellor hears causes in the fittings after term. To this inn belongs likewise a fine garden, which has lately been diminished by the building of some large and commodious offices, for the use of the six clerks in the court of Chancery, &c.

In the parish of St James, Clerkenwell, is an hospital called the Charter-house, which is a corruption of the word chartres, a name formerly used for a convent or priory of the Carthusians, which place formerly was. After the dissolution of monasteries it fell to the earl of Suffolk, who disposed of it to Thomas Sutton, Esq.; a citizen of London in the time of king James I. for L. 15,000. The purchaser intending it for an hospital, applied to the king for a patent, with letters patent in council, and the grant was confirmed by parliament in 1623. Mr Sutton having expended L. 7000 in fitting up the buildings, gave it the name of king James's hospital, and endowed it with lands to the amount of near L. 4500 a-year, for the maintenance of 80 gentlemen, merchants, or soldiers, who should be reduced to indigent circumstances; and 40 boys to be instructed in classical learning. The men are provided with handsome apartments, and all the necessaries of life except clothes; instead of which each of them is allowed a gown, and L. 7 a-year. Of the boys, 29 are at a proper time sent to the universities, where each has an allowance of L. 25 a-year for eight years. Others who are judged more fit for trade, are put apprentices, and the sum of L. 40 is given with each of them. As a further encouragement to the scholars, there are nine ecclesiastical prefections in the gift of the governors. It is also by the recommendation of the latter that all penioners and youth are received into the hospital. They consist of 16, of which number the king is always one, and the others are generally noblemen of the first rank.

To this hospital belong a master, a preacher, two schoolmasters, a physician, a regent, a receiver, a treasurer, a steward, an auditor, and other officers; and the annual revenues of it being now increased to upwards of L. 6000, five men and four boys have been added to the original number.

In the parish of St Luke stands the haberdashers' almshouse, or Ask's hospital, so called from having been erected by the company of haberdashers, parliamen
tary to the will of Robert Ask, Esq; one of their members, who left 30,000 for the building and the relief of 20 poor members of the company; besides the maintenance and education of 20 boys, sons of decayed freemen of the name company. This is a large edifice of brick and stone, 400 feet long, with a pediment in front 340 feet in length, consisting of four columns of the Tuscan order. In the middle of the building is a chapel adorned with columns, entablatures, and pediment of the Ionic order; and under the pediment is a niche, with a statue of the founder.

In the same parish is the Ironmongers hospital, likewise a large building.

In the parish of St Mary, Whitechapel, stands the London hospital, for the reception of the sick. It is a large building, and was erected a few years since by voluntary contribution. Here are also some considerable almshouses.

Within the precincts of Westminster are several Houses of flaxen houes belonging to the nobility, some of which have been already mentioned. Of the others, the most remarkable are presente, turlington-houe, Devonshire-houe, Egremont-houe, and Bedford-houe, Carleton-houe, the magnificent abode of the prince of Wales, and the superb residence erected by the duke of York between the treasury and the horse-guards. To these may be added Montague-houe (now the British Museum), which was built on a French plan by the first duke of Montagu, who had been ambas
dador in France. The staircases and ceilings were painted by Bouffleau and La Fosse; the apothecaries of Iris, and the assembly of the gods, are by the last. It was purchased of the duke's executors by parliament, forming together the Royal Cottonian, Harlscian, Scotlandian, and other collections of books, MSS., coins, antiques, subjects in natural history, &c., &c., for the public use, for which it is excellently adapted. The list of these libraries contains the books and MSS. of the princes from Henry VII. to Charles II.; the second MSS. collected by Sir Robert Cotton, his son, and grandson Sir John, which left gave it to the public, by act 12 and 13 William III. c. 7. The Harlscian collection of MSS. was formed by Edward earl of Oxford, and purchased by government in 1732, at the same time with the library, MSS., and natural curiosi)
ties of Sir Hans Sloane. This last cost Sir Hans L. 50,000; and he left it, by will, to the public, on condition that the parliament would pay L. 20,000 to his executors. It comprehends an amazing number of curiosities; among which are, the library, including books of drawings, MSS. and prints, amounting,
London, amounting to about 50,000 volumes; medals and coins, ancient and modern, 20,000; cameos and intaglios, about 700; seals, 268; vellums, &c. of agate, Jasper, &c. 542; antiquities, 1125; precious stones, agates, Jasper, &c. 2256; metals, minerals, ores, &c. 2725; crystal, flars, &c. 1864; fossils, flints, flumes, 1275; earths, lands, soils, 1035; bituminous sulphurs, amber, &c. 399; tales, misc., &c. 328; corals, sanples, &c. 1421; teats, or shells, &c. 5843; echini, echiniae, &c. 6591; alterations, trochi, &c. 241; crofica, crabs, lobsters, &c. 363; shells, marine, star-fishes, &c. 1733; fish, and their parts, &c. 1555; birds, and their parts, eggs, and nuts, of different species, 1172 quadrupeds, &c. 1886; vipers, serpents, &c. 524; insects, &c. 5439; vegetables, 12,506; herbs, fucceus, or volumes of dried plants, 534; human, as calculi, anatomical preparations, 756; miscellaneous things, natural, 2068; mathematical instruments, 55. A catalogue of all the above is written in a number of large volumes. It is a large and magnificent building, and has behind it a garden, consisting nearly of nine acres.

Buses a great number of spacious streets, which are daily increasing, this part of the metropolis is ornamented with several magnificent squares, viz. Grosvenor-square, Berkeley-square, Portman-square, Cavendish-square, Hanover-square, St. James's-square, Soho-square, Bloomsbury-square, Queen's-square, Lincoln's-inn-fields, Leicestersquare, Red-Lion-square, some of which have been particularly described; not to mention others that are at present building. In general, the new buildings in the liberty of Westminster have increased to a prodigious degree; in such as they reach as far as Marybone to the north, Piccadilly to the south, and Hyde-park wall to the west.

Before the conflagration in 1666, London (which, like most other great cities, had arisen from small beginnings) was totally inelegant, inconvenient, and unhealthy, of which latter misfortune, many melancholy proofs are authenticated in history, and which without doubt, proceeded from the narrowness of the streets, and the unaccountable projections of the buildings, that confined the putrid air, and joined with other circumstances, such as the want of water, rendered the city seldom free from pestilential devastation. The fire which consumed the greatest part of the city, dreadful as it was to the inhabitants at that time, was productive of confquences which made ample amends for the losses sustained by individuals: a new city arose on the ruins of the old; but, though more regular, open convenient, and healthful than the former, yet, it by no means answered to the characters of magnificence or elegance, in many particulars, and is never to be lamented (such was the infatuation of those times), that the magnificent, elegant, and useful plan of the Great Sir Christopher Wren, was totally disregarded, and sacrificed to the mean and the selfish views of private property which did irreparable injury to the citizens themselves and to the nation in general: for had that great architect's plan been followed, what has often been asserted must have been the result: the metropolis of that kingdom would incontestably have been the most magnificent and elegant city in the universe, and of consequence must, from the predilections of foreign of distinction and taste who would have visited it, have become an inexhaustible fund of riches to that nation. But as the deplorable blindness of that age has deprived them of so valuable an acquisition, it is become absolutely necessary that some efforts should be made to render the present plan in a greater degree answerable to the character of the richest and most powerful people in the world.

The plan of London, in its present state, will in its plan still have many instances appear to very moderate judges to be as injudicious a disposition as can easily be conceived for a city of trade and commerce, on the borders of so noble a river as the Thames. The wharfs and quays on its banks are extremely mean and inconvenient; and the want of regularity and uniformity in the streets of the city of London, and the mean avenues to many parts of it, are also circumstances that greatly lessen the grandeur of its appearance. Many of the churches and other public buildings are likewise thruf up in corners, in such a manner as might tempt foreigners to believe that they were designed to be concealed. The improvements of the city of London for some years past have, however, been very great; and the new streets, which are numerous, are in general more spacious, and built with greater regularity and elegance.

The very elegant and necessary method of paving and enlightening the streets is also felt in the most sensible manner by all ranks and degrees of people. The roads are continued for several miles around upon the same model; and, exclusive of lamps regularly placed on each side, at distant distances, are rendered more secure by watchmen stationed within call of each other. Nothing can appear more brilliant than those lights when viewed at a distance, especially where the roads run across; and even the principal streets, such as Pall-Mall, New Bond-street, Oxford-street, &c. convey an idea of elegance and grandeur.

London, then, in its large sense, including Westminster, Southwark, and part of Middlesex, forms one great metropolis of vast extent and prodigious wealth. When considered with all its advantages, it is now what ancient Rome once was; the seat of liberty, the encourager of arts, and the admiration of the world. It is the centre of trade; has an intimate connection with all the counties in the kingdom; and is the grand mart of the nation, to which all parts send their commodities, from whence they are again sent back into every town in the nation and to every part of the world. From hence innumerable carriages by land and water are constantly employed; and from hence arise that circulation in the national body which renders every part healthful, vigorous, and in a prosperous condition; a circulation that is equally beneficial to the head and the most distant members. Merchants here are as rich as noblemen; winneth their incredible loans to government; and there is no place in the world where the shops of tradesmen make such a noble and elegant appearance, or are better stocked.

The Thames on the banks of which London is situated, is a river which, though not the largest, is the richest and most commodious for commerce in
London. It is continually filled with fleets, failing to or from the most distant climates and its banks from London Bridge to Blackwall, form almost one continued great magazine of naval stores: containing three large wet docks, 32 dry docks, and 33 yards for the building of ships for the use of the merchants besides the places allotted for the building of boats and lighters, and the king's yards lower down the river for the building of men of war. As the city is about 60 miles distant from the sea, it enjoys by means of this beautiful river all the benefits of navigation, without the danger of being surprized by foreign fleets, or of being annoyed by the moist vapours of the sea. It rises regularly from the water-side, and to reach the extent of its length from east to west, it is generally allowed for one million of people for one week 14,383. 6. 8

It inalt and fretfulness, at 1 d. a-day, for half a million of people for one week 14,383 6. 8

In bread of all sorts, white and brown at 1 d. a-day, for one million of people for a week 29,166 13. 4

300 Tons of wine, of all sorts, at 50 l., one ton for another, for one million of people for a week 15,000 0. 0 Weekly consumption of provisions.

In fruit of all sorts, at one farthing a-day, for a million of people for a week 29,166 13. 4

In eggs of hens, ducks, geese, &c. at half a farthing a-day, for a million of people for a week 7,291 13. 4

In beef and mutton, at 2 d. a-day, for a million of people for a week 36,45 16. 8

In bread of all sorts, white and brown at 1 d. a-day, for one million of people for a week 29,166 13. 4

In bread of all sorts, white and brown at 1 d. a-day, for one million of people for a week 29,166 13. 4

In wheat-flour, for pies and puddings, oatmeal and rice, &c. at half a farthing a-day, for a million of people for a week 14,383 6. 8

In salt, oil, vinegar, capers, olives, and other sauces, at half a farthing a-day, for a million of people for a week 36,45 16. 8

In vegetables, at 2 d. a-day, for a million of people for a week 14,383 6. 8

In roasts and herbs of all sorts, both for food and physic, at half a farthing a-day, for a million of people for a week 36,45 16. 8

In fruits and vegetables, at 2 d. a-day, for a million of people for a week 14,383 6. 8

In flowers, at 2 d. a-day, for a million of people for a week 14,383 6. 8

In sea-coal, charcoal, candles, and firewood, of all sorts, at 1 d. a-day, for a million of people for a week 29,166 13. 4

In paper of all sorts (a great quantity being used in printing) quills, pens, ink, and wax, at a farthing a-day, for a million of people for a week 7291 13 4

In tobacco, pipes, and snuff, at half a farthing a-day, for a million of people for a week 3645 16 8

In clothing, as linen and woollen, for men, women, and children; shoes, stockings, &c. at 3s. 6d. per week, for a million of people for a week 175,000 0 0

Expenses for horse-meat, in hay, oats, beans, 1000 load of hay a-week, at 45s. a load, comes to 2001. in oats and beans the like value, 2001.

which is in all, for one week 4000 0 0

Cider, rum, brandy, strong waters, coffee, chocolate, tea, &c. at 1 d. a day, for a million of people for one week 29,166 13 4

The common firiing is pit-coal, commonly called Fire-coal, for which there is consumed upwards of 766,880 chaldrons every year. The annual consumption of oil in London and Westminster for lamps, amounts to 400,0001. In 1737, the quantity of port Lawrence brewed in London for home-consumption and foreign exportation, amounted to 1,176,856 barrels.

This great and populous city is happily supplied with abundance of fresh water from the Thames and the New River; which is not only of inconceivable service to every family, but by means of fire plugs every where dispersed, the keys of which are deposited with the parish officers, the city is in a great measure secured from the spreading of fire; for these plugs are no sooner opened, than there are vast quantities of water to supply the engines. The plenty of water has been attended with another advantage, it has given rise to several companies, who infure houses and goods from fire: another advantage that was not to be met with in any other nation on earth: the premium is small, and the recovery in case of loss is easy and certain. Every one of these offices keep a fist of men in pay, who are ready at all hours to give their assistance in case of fire; and who on all occasions extremely bold, dexterous, and diligent; but though all their labours should prove unsuccessful, the person who suffers by this devouring element has the comfort that must arise from a certainty of being paid the value (upon oath) of what he has injured.

The places for diversion are, Vauxhall, Ranelagh-gardens, the two play-houses, one of them rebuilding, the Pantheon lately burnt down; and the little theatre in the Hay-market, with Saddlers wells, Hughe's Circus, and Astley's Royal-Grove, &c. The fine repositories of rarities and natural history, are Sir Hans Sloane's, in the British museum, already depredated; and another collected by the late Sir Athon Lever, now the private property of Mr Pankinford, and deposited in proper apartments for public inspection, near the south end of Blackfriars bridge.

LONDONDERRY, or COLERAINE, a county of Ireland, in the province of Ulster. It is bounded on the south and south-west by the county of Tyrone; by Antrim on the east, from which it is parted by the river Bann; by Donegal on the west; and that county and the Dacaledonian ocean on the north. Its greatest length is about 36 miles, its breadth 30, containing about 251,510 acres. The bogs and heaths of this county are manured with sea-shells, as those of Donegal. Like that, too, it is pretty champaign and unfruitful. It is particularly noted for a very clear river called the Bann, abounding with salmon, a fish held to delight in limpid streams. This river to distinguish it from a letter of the same name, is called the Greater or Lower Bann. In order to cultivate, settle and civilize this county, King James I. granted it, by letters patent, to a society, by the name of the Governor and Assistants at London, of the new plantation of Ulster in the province of Ireland. It contains fix baronies; and, besides the two knights of the shire, sends to parliament two members for the city of Londonderry, and two each for Coleraine and Newton-Limavady or Lammavady.

LONDONDERRY, or Derry, the capital of the county, and the see of a bishop, stands at the bottom of Lough Foyle. This city has a very good port, to which the greater burden have access, and a considerable trade. It will be ever famous for the gallantry and perseverance of which it defended itself in three memorable sieges, in defiance of the greatest hardships and discouragements, namely, 1st, in 1641, when the rebels could not reduce it either by fraud or force.

2dly, In 1649, when it was besieged by the Lord Ardes, and reduced almost to extremity by famine, till at last relieved by troops sent from England. 3dly, When it held out against the French and Irish from the 7th of December 1688 to the last day of July 1689, though it was neither well fortified nor provided with a garrison or stores of provision and ammunition, and hardly any attempt made to relieve it during so long a time. Though the city is 20 miles up the river, yet very large ships can come up to the quay, where there are four or five fathoms of water. It is now well fortified with a strong wall, besides outworks, and along the banks of the river are several castles and a fort. This city is of no great antiquity having been built and planted in the reign of James I. by a colony sent by the society abovementioned. The Trade of the town is very considerable, having not only a large share in the herring fishery, but sending ships also to the West-Indies, New-England, and Newfoundland, for which they are so advantageously situated, that a vessel bound from thence to America often arrives there before a London ship can get clear of the foundings, or arrive in the latitude of Londonderry. Tho' there are a great many shallows in Lough-Foyle, which serve it instead of a road; yet they are easily avoided, as there are deep channels between them. These points called Emilsheen, Rucherhall, or Golby-head which lie a little to the west of the mouth of the harbour are counted the most northerly of Ireland, lying in lat. 55. 20. The inhabitants of this city are almost all Protestants. It gave title of earl and baron to a branch of the family of Pitt, which became extinct in 1784; but part of the title was revived in Robert Stewart, who was created Baron Londonderry in 1789. A late traveller says, "Derry is per-
happily, the cleanest, best built, and most beautiful situated town in Ireland; and, excepting Cork, as convenient as any for commerce, foreign and rural. The lake of four round is it, and the whole ground plot below it and its liberties belongs to the 12 great companies of London. Great quantities of salmon, salted and barrelled, are exported from hence to America.

LONG, an epithet given to whatever exceeds the usual standard of length. *Long boat*, the largest and strongest boat belonging to any ship. It is principally employed to carry great burdens, as anchors, cables, ballasts, &c. See: Boat.

LONG (Roger), D.D. master of Pembroke-hall in Cambridge. Lowdias’s protreitor of astronomy in that university, rector of Cherryhinton in Huntingdonshire and of Bromwell *sola nox* in Wroxham, was author of a well known and much approved treatise of astronomy and the inventor of a remarkably curious astronomical machine, thus described by himself, ‘I have, in a room lately built in Pembroke-hall, erected a sphere of 18 feet diameter, wherein above 30 persons may fit conveniently; the entrance into it is over the south pole by fix steps; the frame of the sphere consists of a number of iron meridians, not complete meridies, the northern ends of which are screwed to a large round plate of brass, with a hole in the centre of it; thro’ this hole, from a beam in the ceiling, comes the north pole, a round iron rod, about three inches long, and fastens the upper parts of the sphere to its proper elevation for the latitude of Cambridge; the lower part of the sphere, so much of it as is invisible in England, is cut off; and the lower or southern ends of the meridies, or truncated meridies, terminate on, and are screwed down to, a strong circle of oak, of about 13 feet diameter; which, when the sphere is put into motion, runs upon large rollers of lignum vitae in the manner that the tops of some windmills are made to turn round. Upon the iron meridians is fixed a zodiac of tin painted blue, whereon the ecliptic and heliocentric orbits of the planets are drawn, and the constellations and stars traced; the Great and Little Bear and Draco are already painted in their places round the north pole; the rest of the constellations are proposed to follow; the whole is turned round with a small wheel, with as little labour as it takes to wind up a jack, though the weight of the iron, tin, and wooden circle, is about 1000 pounds. When it is made use of, a planetarium will be placed in the middle thereof. The whole, with the floor, is well supported by a frame of large timber.’ Thus far Dr Long, before this curious piece of mechanism was perfected. Since the above was written, the sphere has been completely finished; all the constellations and stars of the northern hemisphere, visible at Cambridge, are painted in their proper places upon plates of iron joined together, which form one concave surface. Dr Long published a commencement *eremon* 1748; and an answer to Dr Galley’s pamphlet on Greek Accents; and died December 16th 1770, at the age of 91.

As the materials for this article are scanty, we shall forbear. For 1783, from the Gentleman’s Magazine, a few traits of him, as delineated in 1769 by Mr Jones. ‘He is now in the 88th year of his age, and for his years vigorous and active. He was lately (in October) put in nomination for the office of vice-chancellor. He executed the work once before. I think in the year 1777; a very ingenious person, and sometimes very facetious. At the public commencement in the year 1713, Dr Greene (master of Bennet-college, and afterwards bishop of Ely) being then vice-chancellor, Mr Long was pitched upon for the tripos-performance; it was witty and humorous, and has passed through divers editions. Some that remembered the delivery of it, told me, that in addressing the vice-chancellor (whom the university wags usually styled Miss Greene), the tripos orator, being a native of Norfolk, and assuming the Norfolk dialect, instead of saying *Domina Vice-Chancellor*, did very archly pronounce the words thus, *Domina Vice-Chancellor*, which occasioned a general jeer in that great auditory. His friend the late Mr Bonfoy of Rypen told me this little in jest, ‘That he and Dr Long walking together in Cambridge in a dicky evening, and coming to a short poll fixed in the pavement, which Mr B. in the midst of chat and inattention, took to be a boy standing in his way, he said in a hurry, ‘Get out of my way, boy.’ ‘That boy, Sir,’ said the Doctor very calmly and flilly, is a poftboy, who turns out of his way for nobody.—I could recollect several other ingenious repartees if there were occasion. One thing is remarkable, he never was a sly and hearty man, always of a tender and delicate constitution; yet took great care of it. His common drink water; he always dines with the fellows in the hall. Of late years he has left off eating flesh-meats; in the room thereof, puddings, vegetables, &c. sometimes a glass or two of wine.’

LONGEY, length of life.

From the different longevitys of men in the beginning of the world, after the flood, and in these ages, Mr Derham draws an argument for the interpolation of a divine Providence.

Immediately after the creation, when the world was to be peopled by one man and one woman, the ordinary age was 900 and upwards.—Immediately after the flood, when there were three persons to stock the whole world, their age was 350 years shorter, and none of those patriarchs but Shem, arrived at 500. In the third century we find none that reached 240: in the third, none but Terah that came to 200 years; the world, at least a part of it, by that time being so well peopled, that they had built cities, and were cantoned out into distant nations. —By degrees, as the number of peopled increased, their longevity dwindled, till it came down at length to 70 or 80 years: and there it flood, and has continued to stand ever since the time of Moses.—This is found a good medium, and by means hereof the world is neither overstocked, nor kept too thin; but life and death keep a pretty equal pace.

That the common duration of man’s life has been the same in all ages since the above period, is plain both from sacred and profane history. To pass by others, Plato lived to 81, and was acquainted an old man; and the instances of longevity produced by Pliny L. vii. c. 48. as very extraordinary, may most of them be matched in modern histories. In the following Tables are collected into one point of view the most memorable instances of long-lived persons of whole age...
Longevity. we have any authentic records. The 1st and 2nd are extracted from Mr. Whitewort's Inquiry into the Origin and State of Earth, with some additions by Dr. Fowler, who inserted them, accompanied by a 3d, toge-
ther with a number of useful observations, in the fullest volume of the Memoirs of the Manchester Literary Society,

| William Walker, aged 112, not mentioned above, who was a soldier at the battle of Edge-hill. |

If we look back to an early period of the Christian era, we shall find that Italy has been, at least about that time, peculiarly propitious to longevity. Lord Bacon observes that the year of our Lord 75, in the reign of Vespasian, was memorable; for in that year was a taxing which afforded the most authentic method of knowing the ages of men. From it, there were found in that part of Italy lying between the Appennine mountains and the river Po 124 persons who either equalled or exceeded 100 years of age, namely:

Longevity. Mr Carew, in his survey of Cornwall, affirms us, that it is not unusual, with the inhabitants of that county to reach 90 years of age and upwards, and even to retain their strength of body and perfect use of their senses. Besides Brown, the Cornish beggar, who lived to 120, and one Polezow to 130 years of age, he remembered the decease of persons living to even that it is still comparatively convenient. He took a journey to Versailles, to be hold and return thanks to the National of the Prince de Beaufremont. His memory continued good to the end of his life. He was made for a chair, and his body was taken in the middle of the dog-days, although longevity evident.

(a) This man, in 1780, at the age of 120, quitted his native hills, and from the summit of Mount Jura undertook a journey to Versailles, to be hold and return thanks to the National Assembly for the vote which had freed him and his poor countrymen from the feudal yoke. In the early part of his life, he was a servant in the family of the Prince de Beaufract. His memory continued good to the last day of his life; and the principal inconveniences which he felt from his great age were, that his sight was weakened, and the natural heat of his body was so diminished, that he shivered with cold in the middle of the dog-days if he was not sitting by a good fire. This old man was received in the body of the house by the National Assembly, indulged with the public prints, Jan. 1790, with great funeral pomp, in the parish-church of St Eulalie at Paris.

(b) He served as a private at the taking of Gibraltar in 1704. (r) Memoirs of the Life and gallant Exploits of the Old Highlander Sergeant Donald Macleod, &c. published Jan. 1791, in the 102d year of his age.–This old gentleman, for it appears that he really is a gentleman both by birth and by behaviour, was born in the year of the Revolution, in the parish of Bracadill, in the isle of Sky and county of Inverness, North Britain. He is a cadet of the family of Ulinithe in Sky; and descended, through his mother, from Macdonald of Slate, the ancestor of the present Lord Macdonald. The earlier part of his life coincided with the family of seven years in Scotland; which was so great as to suggest, even to the patriotic Mr Fletcher, the idea of the people telling themselves as slaves for immediate subsistence. He was bred in the midst of want and hardships, cold, hunger, and for the years of his apprenticeship with a mason and stonemason in Inverness, in incessant fatigue. He enlisted, when a boy, in the Scottish service, in the town of Perth, in the last part of the reign of King William. The regiment into which he enlisted was
Longevity.

The Antrimians are purposely omitted, as bearing too little reference to the present race of mortals, to afford any satisfactory conclusions; and as they have been already taken notice of in a separate article; (see Antrimians). As the improbable stories of some persons who have almost rivalled them in modern times, border too much upon the marvellous to find a place in these tables, the present examples are abundantly sufficient to prove, that longevity does not depend, to much, as has been supposed, on any particular climate, situation, or occupation in life: for we see, that it often prevails in places where all these are extremely dissimilar; and it would, moreover, be very difficult, in the histories of the several persons abovementioned, to find any circumstance common to them all, except, perhaps, that of being born of healthy parents, and of being inured to daily labour, temperance, and simplicity of diet. Among the inferior ranks of mankind, therefore, rather than among the sons of ease and luxury, shall we find the most numerous instances of longevity; even frequently, when other external circumstances seem extremely unfavorable—as in the case of the poor sexton at Peterborough, who, notwithstanding his unprospering occupation, among dead bodies, lived long enough to bury two crowned heads, and to survive his complete generations. The livelihood of Henry Jenkins and old Parke, is said to have consisted chiefly of the coarsest fare, as they depended on plentiful alms. To which may be added the remarkable instance of Agnes Melbourne, who, after bringing forth a numerous offspring, and being obliged, through extreme in ligence, to pass the latter part of her life in St Luke's workhouse, yet reached her 108th year in that forlorn and unfriendly situation. The plain diet and invigorating employments of country life are acknowledged on all hands to be highly conducive to health and longevity, while the luxury and refinements of large cities are allowed to be equally destructive to the human species; and this consideration alone, perhaps, more than counterbalances all the boasted privileges of superior longevity, elegance and civilization resulting from a city life.

From country villages, and not from crowded cities, have the preceding instances of longevity been chiefly supplied. Accordingly it appears, from the London bills of mortality, during a period of 30 years, viz. from the year 1728 to 1758, the sum of the deaths amounted to 750,322, and that, in all this prodigious number, only 242 persons survived the 100th year of their age! This overgrown metropolis is computed by Dr Price to contain a ninth part of the inhabitants of England, and to consume annually 7000 persons, who remove into it from the country every year, without increasing it. He moreover observes, that the number of inhabitants in England and Wales has diminished about one fourth part since the Revolution; and so rapidly of late, that in 11 years, near 200,000 of the common people have been lost. If the calculation be just, however alarming it may appear in a national view, there is this consolation, when considered in a philosophical light, that without partial evil, there can be no general good; and that what a nation loses in the state, or occupation in life: for policy is computed sufficient to bury two thus probably, the average number of inhabitants on the surface of the globe continues at all times nearly the same. By this medium, the world is neither overstocked with inhabitants nor kept too thin, but life and death keep a tolerably equal pace. The inhabitants of Britain comparatively speaking, are but as the dust of the balance; yet instead of being diminished, we are assured by other writers, that within these 30 years they are greatly increased.

The desire of self-preservation, and of protracting the short span of life, is so intimately interwoven with our constitution, that it is justly esteemed one of the first principles of our nature, and, in spite even of pain and misery, seldom quits us to the last moments of our existence. It seems, therefore, to be no less our duty than our interest, to examine minutely into the various

was the Scots Royals, commanded by the earl of Orkney. That old military corps, at that time, used bows and arrows as well as swords, and wore full caps. He served in Germany and Flanders under the duke of Marlborough, under the duke of Argyll in the rebellion 1715, in the Highland Watch, or companies raised for enforcing the laws in the Highlands; in the same companies when, under the name of the 42d regiment, they were sent abroad to Flanders, to join the army under the duke of Cumberland; in the same regiment in Ireland, and on the breaking out of the French war, 1757, in America. From the 42d he was draughted to act as a drill sergeant in the 78th regiment, in which he served at the reduction of Louisburg and Quebec: After this he became an out-pensioner of Chelsea Hospital. But such was the spirit of this brave and hardy veteran, that he served in 1761 as a volunteer in Germany under the marquis of Granby; and offered his services in the American war to Sir Henry Clinton; who, though he declined to employ the old man in the fatigues and dangers of war, treated him with great kindness, allowed him a liberal weekly pension out of his own pocket, and sent him home in a ship charged with dispatches to government.—The sergeant, as his memory, according to the observation of his biographer, is impaired, does not pretend to make an exact enumeration of all his offspring: but he knows of 16 sons now living, 14 of whom are in the army and navy, besides daughters: the eldest of whom by his present wife is a mantuemaker in Newcastle. His eldest son is now 83 years old, and the youngest only nine. Nor, in all probability, would this lad clothe the rear of his immediate progeny, if his present wife, the boy's mother, had not attained to the 40th year of her age. In his prime, he did not exceed five feet and seven inches. He is now inclined through age to five feet five inches. He has an interesting phlogiston expressive of sincerity, sensibility, and manly courage. His biographer very properly submits is to the consideration of the Polygraphical Society, whether they might not do a thing worthy of themselves and their ingenious art, if they should multiply likenesses of this living antiquity, and circulate them at an easy rate throughout Britain and Europe. They would thus gratify a very general curiosity; a curiosity not confined to the present age.
Longevity. Various means that have been considered as conducive to health and long life; and, if possible to distinguish such circumstances as are essential to that great end from those which are merely accidental. But here it is much to be regretted, that an accurate history of the lives of all the remarkable personages in the above table, so far as relates to the diet, regimen, and the use of the non-naturals, has not been faithfully handed down to us; without which it is impossible to draw the necessary inferences. Is it not then matter of astonishment, that historians and philosophers have hitherto paid so little attention to longevity? If the present imperfect list should excite others of more leisure and better abilities, to undertake a full investigation of fo interesting a subject, the inquiry might prove not only curious but highly useful to mankind. In order to furnish materials for a future history of longevity, the bills of mortality throughout the British dominions and foreign parts have already given a specimen highly worthy of imitation. The plan, however, might be further improved with very little trouble, by adding a particular account of the diet and regimen of every nation, who dies at 80 years of age or upwards; and mentioning whether his parents were healthy, long-lived people, &c. An accurate register, thus established throughout the British dominions would be productive of many important advantages to society, not only in a medical and philosophical, but also in a political and moral view.

All the circumstances that are most essentially necessary to life, may be comprised under the six following heads: 1. Air and climate; 2. Meat and drink; 3. Motion and rest; 4. The secretions and excretions; 5. Sleep and watching; 6. Affections of the mind.

These, though all perfectly natural to the constitution, have by writers been stigmatized the non-naturals, by a strange perversion of language; and have been all copiously handled under that improper term. However, it may not be amiss to offer a few short observations on each, as they are so immediately connected with the present subject.

1. Air, &c. It has long been known that fresh air is more immediately necessary to life than food for a man may live two or three days without the latter, but not many minutes without the former. The vivifying principle contained in the atmosphere, so essential to the support of flame, as well as animal life, concerning which authors have proposed so many conjectures, appears now to be nothing else but that pure dephlogisticated fluid lately discovered by that ingenious philosopher Dr Priestley. The common atmosphere may well be appoised to be more or less healthy in proportion as it abounds with this animating principle. As this exhales in copious streams from the green leaves of all kinds of vegetables, even from those of the most poisonous kind, may we not, in some measure, account why instances of longevity are so much more frequent in the country than in large cities where the air, instead of partaking to a large extent of this salutary impregnation, is daily contaminated with noxious animal effluvia, and phlogiston?

With respect to climate, various observations, confpire to prove, those regions which lie within the temperate zones are best calculated to promote long life. Hence, perhaps, may be explained, why Italy has produced so many long lives; and why islands in general are more salutary than continents; of which Bermudas and some others afford examples. And it is a pleasing circumstance for Great Britain that the appearing from the above table (notwithstanding the fudden vicissitudes to which it is liable) to contain far more instances of longevity than could well be imagined. The ingenious Mr Whitehurst affures us from certain facts, that Englishmen are in general longer lived than North Americans; and that a British constitution will last longer, even in that climate, than a native one. But it must be allowed in general, that the human constitution is adapted to the peculiar state and temperature of each respective climate, so that no part of the habitable globe can be pronounced too hot or too cold for its inhabitants. Yet in order to promote a friendly intercourse between the most remote regions, the Author of nature has wisely enabled the inhabitants to endure great and surprising changes of temperature with impunity.

2. Food and drink. Though foods and drink of the most simple kind are allowed to be the best calculated for supporting the body in health, yet it can hardly be doubted but variety may be safely indulged occasionally, provided men would restrain their appetites within the bounds of temperance; for bountiful Nature cannot be supposed to have poured forth such a rich profusion of provisions, merely to tantalize the human species, without attributing to her the part of a cruel step-dame, instead of that of the kind and indulgent parent. Besides, we find that by the wonderful powers of the digestive organs, a variety of animal and vegetable substances, of very discordant principles, are happily assimilated into one bland homogenous chyle; therefore it seems natural to distrust those cynical writers, who would rigidly confine mankind to one simple dish, and their drink to the mere water of the brook. Nature, it is true, has pointed out that mild insipid fluid as the universal diluent, and therefore most admirably adapted for our daily beverage. But experience has equally proved, that vinous and spirituous liquors, on certain occasions, are no less salutary and beneficial, whether it be to support strength against sickness or bodily fatigue, or to exhilarate the mind under the preliure of heavy misfortunes. But, alas! what Nature meant for innocent and useful cordials, to be used only occasionally, and according to the direction of reason, custom and caprice have, by degrees, rendered habitual to the human frame, and liable to the most enormous and destructive abuses. Hence it may be justly doubted, whether gluttony and intemperance have not depopulated the world more than even the sword, pestilence and famine. True, therefore, is the old maxim, "Ab nos utendi ex veneno facit medicamentum, ex medicamento venenum.

3. and 4. Motion and rest; sleep and watching. It is allowed at all hands, that alternate motion and rest, and sleep and watching, are necessary conditions to health and longevity; and that they ought to be adapted to age, temperament, constitution, temperature of the climate, &c. but the errors which mankind daily commit in these respects become a fruitful source of diseases. While some are bloated and relaxed in cafe
Longevity, cafe and indulgence, others are engrafted, and become rigid through hard labour, watching and fatigue.

5. Secretions and Excretions. Where the animal functions are duly performed, the secretions go on regularly; and the different evacuations so exactly correspond to the quantity of aliment taken in, in a given time, that the body is found to return daily to nearly the same weight. If any particular evacuation happen to be preternaturally diminished, some other evacuation is proportionally augmented, and the equilibrium is commonly preferred: but continued irregularities, in these important functions, cannot but terminate in disease.

6. Affections of the mind. The due regulation of the passions, perhaps, contributes more to health and longevity than that of any other of the non-naturals. The animating passions, such as joy, hope, love, &c. when kept within proper bounds, gently excite the nervous influence, promote an equable circulation, and are highly conducive to health: while the depressing affections, such as fear, grief, and despair, produce the contrary effect, and lay the foundation of most formidable diseases.

From the light which history affords us, as well as from some instances in the above table, there is great reason to believe, that longevity is in a great measure hereditary; and that healthy long-lived parents would commonly transmit the fame to their children, were it not for the frequent errors in the non-naturals, which so evidently tend to the abbreviation of human life.

Whereas it, but from these causes, and the unnatural modes of living, that of all the children which are born in the capital cities of Europe, nearly one half die in early infancy! To what else can we attribute this extraordinary mortality! Such an amazing proportion of premature deaths is a circumstance unheard of among savage nations, or among the young of other animals! In the earliest ages, we are informed, that human life was protracted to a very extraordinary length; yet how few persons, in these later times, arrive at that period which nature seems to have designed! Man is by nature a field animal, and feeoms destined to rise with the sun, and to spend a large portion of his time in the open air, to inure his body to robust exercises and the inclemency of the seasons, and to make a plain honestly repast only when hunger dictates. But art has Fludently defeated the kind intentions of nature; and by endowing him to all the blemishments of life, has left him, alas! an easy victim to folly and caprice. To enumerate the various abuses which take place from the earliest infancy, and which are continued through the succeeding stages of modifh life, would carry us far beyond our present intention. Suffice it to observe, that they prevail more particularly among people who are the most highly polished and refined. To compare their artificial mode of life with that of nature, or even with the long-livers in the wilds, would probably afford a very striking contrast; and at the same time supply an additional reason why, in the very large cities, instances of longevity are so very rare.

LONGFORD, a county of Ireland, in the province of Leinster, bounded by the county of Leitrim on the north, Meath on the east and south, and Roscommon on the west. It contains 134,700 Irish plantation acres, 24 parishes, 6 baronies, and 4 boroughs; and returns 10 members to parliament. It is small and much encumbered with bog, intermixed with a tolerable good soil; and is about 25 miles long and 15 broad.

LONGFORD, a town of Ireland, situated on the river Cromlin, in the county of Longford and province of Leinster, 64 miles from Dublin; which river falls a few miles below this place into the Shannon. It is a borough, port, market, and fair town; and returns two members to parliament; patron Long Fingal. It gave title of earl to the family of Anngier; of esq., to the family of Meelehwaite; and now gives that of baron to the family of Packenham. Within a mile and a half of the town is a charter-school for above 40 children. This place has a barracks for a troop of horse. It is large and well built; and in a very early age an abbey was founded here, of which St Idus, one of St Patrick's disciples, was abbot. In the year 1400, a fine monastery was founded to the honour of the Virgin Mary, for Dominican friars, by O'Ferral prince of Acailly. This monastery being destroyed by fire, Pope Martin V. by a bull in the year 1429, granted an indulgence to all who should contribute to the rebuilding of it. In 1433, Pope Eugene IV. granted a bull to the same purpose; and in 1438 he granted another to the like effect. The church of this friary, now the parish-church, is in the diocese of Ardagh. The fairs are four in the year.

LONG ISLAND, is an island of North America belonging to the state of New-York, which is separated from the continent by a narrow channel. It extends from the city of New-York 140 miles, terminating with Montauk point; and is not more than 10 miles in breadth on a medium. It is divided into three counties, King's, Queen's, and Suffolk. The north side of the island is flat land, of a light sandy soil, bordered on the sea-coast with large tracts of fall-meadow, extending from the west point of the island to Southampton. This soil, however, is well calculated for raising grain, especially Indian corn. The north side of the island is hilly, and of a strong soil, adapted to the culture of grain, hay and fruit. A ridge of hills extends from Jamaica to Southold. Large herds of cattle feed upon Hampton plain and on the salt marshes upon the south side of the island. Hampton plain in Queen's county is a curiosity. It is 16 miles in length, east and west, and 7 or 8 miles wide. The soil is black, and to appearance rich, and yet it was never known to have any natural growth, but a kind of wild grass and a few shrubs. It is frequented by vast numbers of plovers. Rye grows tolerably well on some parts of the plain. The most of it lies common for cattle, horses and sheep. As there is nothing to impede the prospect in the whole length of this plain, it has a curious but tiresome effect upon the eye, not unlike that of the ocean. The island contains 30,863 inhabitants.

LON GIMETRY, the art of measuring lengths, both accessible and inaccessible. See GEOMETRY and TRIGONOMETRY.

LONGING, is a preternatural appetite in pregnant women; and in some fickle persons when about to recover. It is called pica, from the bird of that name, which is said to be subject to the same disorder. The disorder con-
LON[279]LONGITUDES.

Longinus contends both of a desire of unusual things to eat and drink, and in being soon tired of one another. It is called malacis, from ma-gas, "weakness." In pregnant women it is somewhat relieved by bleeding, and in about the fourth month of their pregnancy it leaves them. Choleric girls, and men who labour under suppurated haemorrhoids, are very subject to this complaint, and are relieved by promoting the rectification of evacuations. In general, whether this disorder is observed in pregnant women, in persons recovering from an acute fever, or in those who labour under obstructions of the natural evacuations, this craving of the appetite should be indulged.

LONGINUS, a town of Turkey in Europe, in the Morea, anciently called Olympia, famous for being the place where the Olympic games were celebrated, and for the temple of Jupiter Olympus, about a mile distant. It is now but a small place, situated on the river Aphaeus, 10 miles from its mouth, and 50 south of Lepanto, E. Long. 29° 20'. N. Lat. 37° 30'.

LONGINUS (Dioctylus), a celebrated Greek critic of the third century, was probably an Athenian. His father's name is unknown, but by his mother he was allied to the celebrated Plutarch. His youth was spent in travelling with his parents, which gave him an opportunity to increase his knowledge, and improve his mind. After his travels, he fixed his residence at Athens, and with the greatest assiduity applied to study. Here he published his "Treatise on the Sublime," which raised his reputation to such a height, and gave the Athenians such an opinion of his judgment and taste, that they made him sovereign judge of all authors, and every thing was received and rejected by the public according to his decisions. He seems to have died at Athens a long time; here he taught the academic philosophy, and among others had the famous Porphyry for his pupil. But it was at length his fortune to be drawn from Athens, and to mix in more active scenes; to train up young princes to virtue and glory; to guide the bashful lions of the great to noble objects; to struggle, and at last die, in the cause of liberty. Zenobia, queen of the East, prevailed on him to undertake the education of her sons; and he soon gained an uncommon share in her confidence: he spent the vacant hours of his life in his conversation, and modelled her sentiments and conduct by his instructions. That prince was at war with Aurelian; and being defeated by him near Antioch, was compelled to hurl herself up in Palmyra, her capital city. The emperor wrote her a letter, in which he ordered her to surrender; to which she returned an answer, drawn up by Longinus, which filled him with resentment. The emperor laid siege to the city; and the Palmyrians were at length obliged to open their gates and receive the conqueror. The Queen and Longinus endeavoured to fly into Persia; but were unhappily overtaken and made prisoners when they were on the point of crossing the Euphrates. The Queen, intimidated, weakly laid the blame of vindicating the liberty of her country on its true author; and the brave Longinus, to the disgrace of the conqueror, was carried away to immediate execution. The writings of Longinus were numerous, some on philosophical, but the greater part on critical subjects. Dr. Pearce has collected the titles of 25 treatises, none of which, excepting that on the Sublime, have escaped the depredations of time and barbarians. On this imperfect piece the great fame of Longinus is raised, who, as Pope expresses it, "is himself the great sublime he draws." The best edition of his works is that of Tullius, printed at Utrecht in 1694, "cum suis variis." It has been translated into English by Mr. Smith.

LONGISSIMUS DORSI. See Anatomy, Table of the Muscles.

LONITUDE, in geography and navigation, is the distance of any place from another eastward or westward, counted in degrees, upon the equator; but when the distance is reckoned by leagues or miles and not in degrees, or in degrees on the meridian, and not of the parallel of latitude, in which case it includes both latitude and longitude, it is called departure.

To find the longitude at sea, is a problem to which the attention of navigators and mathematicians has been drawn ever since navigation began to be improved. The importance of this problem soon became so well known, that, in 1598, Philip III. of Spain offered a reward of 1000 crowns for the solution; and his example was soon followed by the States General, who offered 10,000 florins. In 1714 an act was passed in the British parliament, empowering certain commissioners to make out a bill for a sum not exceeding 2000l. for defraying the necessary expenses of experiments for ascertaining this point; and likewise granting a reward to the person who made any progress in the solution, proportionable to the degree of accuracy with which the solution was performed: 10,000l. was granted if the longitude should be determined to one degree of a great circle, or 60 geographical miles; 15,000 if two thirds of that distance; and 20,000l. to the half the distance.

In consequence of these offered rewards, innumerable attempts were made to discover this important secret. The first was that of John Morin professor of mathematics at Paris, who proposed it to Cardinal Richelieu; and though it was judged insufficient on account of the imperfection of the lunar tables, a subscription of 2000 livres per annum was procured for him in 1645 by Cardinal Mazarine. Gemma Frisius had, indeed, in 1530, projected a method of finding the longitude by means of watches, which at that time were newly invented; but the structure of these machines was then by far too imperfect to admit of any attempt; nor even in 1631, when Metius made an attempt to this purpose, were they advanced in any considerable degree. About the year 1664, Dr. Hooke and Mr. Huygens made a very great improvement in watchmaking, by the application of the pendulum spring. Dr. Hooke having quarrelled with the ministry, no experiment was made with any of his machines; but many were made with those of Mr. Huygens. One experiment, particularly, made by Major Holmes, in a voyage from the coast of Guinea in 1665, answered so well, that Mr. Huygens was encouraged to improve the structure of his watches; but it was found that the variations of heat and cold produced such alterations in the rate of going of the watch, that unless this could be remedied, the watches could be of little use in determining the longitude.

In 1714 Henry Sully, an Englishman, printed a small tract at Vienna upon the subject of watchmaking.
Longitude-making. Having afterwards removed to Paris, he applied himself to the improvement of time-keepers for the discovery of the longitude. He taught the famous Julian de Roy; and this gentleman, with his son, and M. Berthoud, are the only persons who, since the days of Sully, have turned their thoughts this way. But though experiments have been made at two with some of their watches, it does not appear that they have been able to accomplish anything of importance with regard to the main point. The first who succeeded in any considerable degree was Mr. John Harrison; who, in 1726, produced a watch which went so exactly, that for ten years together it did not err above one second in a month. In 1736 it was tried in a voyage to Lisbon and back again, on board a ship of his Britannic Majesty; during which it corrected an error of a degree and a half in the computation of the ship’s reckoning. In consequence of this he received public encouragement to go on; and by the year 1761 had finished three time-keepers, each of them more accurate than the former. The last turned out so much to his satisfaction, that he now applied to the commissioners for leave to make an experiment with his watch in a voyage to the West-Indies. Permission being granted, his son Mr. William Harrison set out in a British ship the Deptford for Jamaica in the month of November 1761. This trial was attended with all imaginable success. The longitude of the island, as determined by the time-keeper, differed from that found by astronomical observations only one minute and a quarter of the equator; the longitude of places seen by the way being also determined with great exactness. On the ship’s return to England, it was found to have erred no more during the whole voyage than 1° 54½', in time, which is little more than 28 miles in distance; which being within the limits preferred by the British act, the inventor claimed the whole L.20,000 offered by government. Objections to this, however, were soon started. Doubts were pretended about the real longitude of Jamaica, as well as the manner in which the time had been found both there and at Portsmouth. It was alleged also, that though the time-keeper happened to be right at Jamaica, and after its return to England, this was by no means a proof that it had always been so in the intermediate times; in consequence of which allegations, another trial was appointed in a voyage to Barbadoes. Observations were now taken to obviate as many of these objections as possible. The commissioners felt out proper persons to make astronomical observations at that island; which, when compared with others in England, would afford more than a doubt its true situation. In 1764 then, Mr. Harrison junior set sail for Barbadoes; and the result of the experiment was, that the difference of longitude betwixt Portsmouth and Barbadoes was shown by the time-keeper to be 3½ 55½'; and by astronomical observations to be 3½ 54° 20'; the error being now only 43½' of time, or 10½' of longitude. In consequence of this and the former trials, Mr. Harrison received one half of the reward promised, upon making a discovery of the principles upon which his timekeepers were constructed. He was likewise promised the other half of the reward as soon as time-keepers should be constructed by other artists which should answer the purpose as well as those of Mr. Harrison himself. Longitude. At this time he delivered up all his time-keepers, the last of which was sent to Greenwich to be tried by Mr. Nevil Maskelyne the astronomer-royal. On trial, however, it was found to go with much less regularity than had been expected; but Mr. Harrison attributed this to his having made some experiments with it which he had not time to finish when he was ordered to deliver up the watch. Soon after this, an agreement was made by the commissioners with Mr. Kendall to construct a watch upon Mr. Harrison’s principles; and this upon trial was found to answer the purpose even better than any that Harrison himself had constructed. This watch was sent out with Captain Cook in 1773; and during all the time of his voyage round the world in 1772, 1773, 1774, and 1775, never erred quite 1½ seconds per day: in consequence of which, the house of commons, in 1774, ordered the other L.10,000 to be paid to Mr. Harrison. Still greater accuracy, however, has been attained. A watch was lately constructed by Mr. Arnold, which, during a trial of 13 months, from February 1779 to February 1780, varied not more than 6½' during any single day, and the greatest difference between its rates of going on any day and the next to it was 4½'. The greatest error it would have committed therefore in the longitude during any single day would have been very little more than one minute of longitude; and thus the longitude be determined with as great exactness as the latitude generally can. This watch, however, has not yet been tried at sea.

Thus the method of constructing time-keepers for discovering the longitude seems to be brought to as great a degree of perfection as can well be expected. Still, however, as these watches are subject to accidents, and may thus alter the rate of their going with out any possibility of a discovery, it is necessary that some other method should be fallen upon, in order to correct from time to time these errors which may arise either from the natural going of the watch, or from any accident which may happen to it. Methods of this kind are all founded upon celestial observations of some kind or other; and for these methods, or even for an improvement in time-keepers, rewards are still held out by Great Britain. After the discoveries made by Mr. Harrison, the act concerning the longitude was repealed, excepting so much of it as related to the constructing, printing, publishing, &c. of nautical almanacks and other useful tables. It was enacted also that any person who shall discover a method for finding the longitude by means of a time-keeper, the principles of which have not hitherto been made public, shall be intitled to a reward of L.5000, if, after certain trials made by the commissioners, the said method shall enable a ship to keep her longitude during a voyage of six months within 60 geographical miles or a degree of a great circle. If the ship keeps longitude within 40 geographical miles for that time the inventor is intitled to a reward of L.7500, and to L10,000 if the longitude is kept within half a degree. If the method is by improved astronomical observations, the author is intitled to L5000 when they show the distance of the moon from the sun and tides, within 15 seconds of a degree, answering to about 7 minutes of longitude, after allowing half a degree for cites.
longitude.

Errors of observation, and under certain restrictions, and after comparison with astronomical observations for a period of 18 years, during which the lunar irregularities are supposed to be completed. The same rewards are offered to the person who shall with the like accuracy discover any other method of finding the longitude.

These methods require celestial observations; and any of the phenomena, such as the different apparent places of stars with regard to the moon, the beginning and ending of eclipses, &c. will answer the purpose: only it is absolutely necessary that some variation should be perceptible in the phenomenon in the space of two minutes; for even this short space of time will produce an error of 30 miles in longitude. The most proper phenomena therefore for determining the longitude in this manner are the eclipses of Jupiter's satellites. Tables of their motions have been constructed, and carefully corrected from time to time, as the mutual attractions of these bodies are found greatly to disturb the regularity of their motions. The difficulty here, however, is to observe these eclipses at sea; and this difficulty has been found so great, that no person seems able to accomplish it. The difficulty arises from the violent agitation of a ship in the ocean, for which no adequate remedy has ever yet been found, nor probably will ever be found. Mr. Christopher Irwin indeed invented a machine which he called a marine chair, with a view to prevent the effects of this agitation; but on trying it in a voyage to Barbadoes, it was found to be totally useless.

A whimsical method of finding the longitude was proposed by Melliss Whilton and Ditton from the report and flash of great guns. The motion of sound is known to be nearly equal, from whatever body it proceeds or whatever be the medium. Supposing therefore a mortar to be fired at any place the longitude of which is known, the difference between the moment that the flash is seen and the report heard will give the distance between the two places; whence, if we know the latitudes of these places, their longitudes must also be known. If the exact time of the explosion be known at the place where it happens, the difference of time at the place where it is heard will likewise give the difference of longitude. Let us next suppose the mortar to be loaded with an iron shell filled with combustible matter, and fired perpendicularly upwards into the air, the shell will be carried to the height of a mile, and will be seen at the distance of nearly 100; whence, supposing neither the flash of the mortar should be seen nor the report heard, still the longitude might be determined by the altitude of the shell above the horizon.

According to this plan, mortars were to be fired at certain times and at proper stations along all frequented coasts for the direction of mariners. This indeed might be of use, and in stormy weather might be a kind of improvement in light-houses, or a proper addition to them; but with regard to the determination of longitude, is evidently ridiculous.

We shall now proceed to give some practical directions for finding the longitude at sea by proper celestial observations; exclusive of those from Jupiter's Satellites, which, for reasons just mentioned, cannot be practised at sea. In the first place, however, it will be

necessary to point out some of those difficulties which stand in the way, and which render even this method of finding the longitude precarious and uncertain. These lie principally in the reduction of the observations of the heavenly bodies made on the surface of the earth to similar observations supposed to be made at the centre; which is the only place where the celestial bodies appear in their proper situation. It is also very difficult to make proper allowances for the refraction of the atmosphere, by which all objects appear higher than they really are; and another difficulty arises from their parallaxes, which makes them, particularly the moon, appear lower than they would otherwise do, excepting when they are in the very zenith. It is also well known, that the nearer the horizon any celestial body is, the greater its parallax will be; and as the parallax and refraction act in opposite ways to one another, the former depressing and the latter raising the object, it is plain, that great difficulties must arise from this circumstance. The sun, for instance, whose parallax is less than the refraction, must always appear higher than he really is; but the moon, whose parallax is greater than her refraction, must always appear lower.

To render observations of the celestial bodies more easy, the inconsiderable parallaxes have caused an Ephemeris or Nautical Almanack to be published annually, containing every requisite for solving this important problem which can be put into the form of tables. But whatever may be done in this way, it will be necessary to make the necessary preparation concerning the dip of the horizon, the refraction, sidereal distances, &c. in order to reduce the apparent to the true altitudes and distances; for which we shall here subjoin two general rules.

The principal observation for finding the longitude at sea is that of the moon from the sun, or from some remarkable star near the zodiac. To do this, the operator must be furnished with a watch which can be depended upon for keeping time within a minute for six hours; and with a good Hadley's quadrant, or, which is preferable, a sextant; and this last instrument will still be more fit for the purpose if it be furnished with a screw for moving the index gradually, likewise an additional dark glass, but not so dark as the common kind, for taking off the glare of the moon's light in observing her distance from a star. A small telescope, which may magnify three or four times, is also necessary to render the contact of a star with the moon's limb more discernible. A magnifying glass of 1; or 2 inches focus will likewise assist the operator in reading of his observations with the greater facility.

1. To make the observation. Having examined and adjusted his instrument as well as possible, the observer is next to proceed in the following manner: If the distance of the moon from the sun is to be observed, turn down one of the screens; look at the moon directly through the transparent part the horizon-glass; and keeping her in view, gently move the index till the sun's image be brought into the filtered part of that glass. Bring the nearest limbs of both objects into contact, and let the quadrant limb lie on the lunar ray; by which means the sun will appear to rise and fall by the side of the moon; in which motion the nearest limbs must be made to touch one another exactly by

Vol. X.

longitude.

Longitude.
Longitude moving the index. The observation is then made; and the division coinciding with that on the Vernier scale, will show the distance of the nearest limbs of the object.

When the distance of the moon from a star is to be observed when the moon is very bright, turn down the lighted screen, or use a dark glass lighter than the screen, and designed for this particular purpose; look at the star directly through the transparent part of the horizon-glass; and keeping it there, move the index till the moon’s image is brought into the silvered part of the same glass. Make the quadrant librate gently on the star’s ray, and the moon will appear to rise and fall by the star; move the index between the librations, until the moon’s enlightened limb is exactly touched by the star, and then the observation is made. In these operations, the places of the quadrant must always pass through the two objects, the distance of which is to be observed; and for this purpose it must be placed in various positions according to the situation of the objects, which will soon be rendered easy by practice.

The observation being made, somebody at the very instant that the operator calls must observe by the watch the exact hour, minute, and quarter minute, if there be no second hand, in order to find the apparent time; and at the same instant, or as quick as possible, two assistants must take the altitudes of those objects the distance of which is observed; after which, the observations necessary for finding the longitude are completed.

The ephemeris shows the moon’s distance from the sun, and likewise from proper stars, to every three hours of apparent time for the meridian of Greenwich; and that the greater number of opportunities of observing this luminary may be given, her distance is generally set down from at least one object on each side of her. Her distance from the sun is set down while it is between 40 and 120 degrees, so that, by means of a sextant, it may be observed for two or three days after her first and before her last quarter. When the moon is between 40 and 90 degrees from the sun, her distance is set down both from the sun and from a star on the contrary side; and, lastly, when the distance is above 120 degrees, the distance is set down from two stars, one on each side of her. The distance of the moon from objects on the east side of her is found in the ephemeris in the 8th and 9th pages of the month; and her distance from objects on the west is found in the 10th and 11th pages of the month.

When the ephemeris is used, the distance of the moon must only be observed from those stars the distance of which is set down there; and these afford a ready means of knowing the star from which her distance ought to be observed. The observer has then nothing more to do than to set his index to the distance roughly computed at the apparent time, estimated nearly for the meridian at Greenwich; after which he is to look to the east or west of the moon, according as the distance of the star is found in the 8th or 9th, or in the 10th or 11th, pages of the month; and having found the moon upon the horizon-glass, the star will easily be found by sweeping with the quadrant to the right or left, provided the air be clear, and the star be in the line of the moon’s shortest axis produced. The time at Greenwich is estimated by turning into time the supposed longitude from that place, and adding it to the apparent time at Longitude, the ship, or subtracting it from it as occasion requires.

The distance of the moon from the sun, or a star, is roughly found at this time, by saying, as 180 minutes (the number contained in three hours) is to the difference in minutes between this nearly estimated time and the next preceding time set down in the ephemeris; so is the difference in minutes between the distances in the ephemeris for the next preceding and next following times, to a number of minutes; which being added to the next preceding distance, or subtracted from it, according as it is increasing or decreasing, will give the distance nearly at the time the observation is to be made, and to which the index must be set.

An easier method of finding the angular distance is by bringing the objects nearly into contact in the common way, and then fixing the index tight to a certain degree and minute; waiting until the objects are nearly in contact, giving notice to the assistants to get ready with the altitudes, and when the objects are exactly in contact to call for the altitudes and the exact time by the watch. The observer may then prepare for taking another distance, by setting his index three or four minutes backwards or forwards, as the objects happen to be receding from or approaching to each other; thus proceeding to take the distance, altitudes, and time by the watch, as before. Thus the observer may take as many distances as he thinks proper; but four at the distance of three minutes, or three at the distance of four minutes, will at all times be sufficient. Thus not only the eye of the observer will be less fatigued, but he will likewise be enabled to manage his instrument with much greater facility in every direction, a vertical one only excepted. If in taking the distances the middle one can be taken at any even division on the arch, such as a degree, or a degree and 20 or 40 minutes, that distance will be independent of the Nomius division, and consequently free of those errors which frequently arise from the inequality of that division in several parts of the graduated arch. The observation ought always to be made about two hours before or after noon; and the true time may be found by the altitude of the sun taken at the precise time of the distance. If three distances are taken, then find the time by the altitude corresponding with the middle distance; and thus the observation will be free from any error arising from the irregularity of the going of the watch. As the time, however, found by the altitude of a star cannot be depended upon, because of the uncertainty of the horizon in the night, the best way of determining the time for a night observation will be by two altitudes of the sun; one taken on the preceding afternoon, before he is within six degrees of the horizon; and the other on the next morning, when he is more than six degrees high. It must be observed, however, that in order to follow these directions, it is necessary that the atmosphere should be pretty free from clouds; otherwise the observer must take the observation at such times as he can best obtain them.

2. To reduce the observed Distance of the Sun or a Star from the moon to the true Distance. 1. Turn the longitude into time, add it to the time at the ship if the longitude be east, or subtract it if it be west, which
Longitude, which will give the supposed time at Greenwich; and this we may call reduced time. 2. Find the nearest noon or midnight both before and after the reduced time in the seventh page of the month in the ephemeris. 3. Take out the moon's semidiameter and horizontal parallaxes corresponding to these noons and midnights, and find their differences. Then say, As 12 hours is to the moon's semidiameter in 12 hours, so is the reduced time to a number of seconds; which, either added to or subtracted from the moon's semidiameter at the noon or midnight just mentioned, according as it is increasing or decreasing, will give her apparent semidiameter; to which add the correction from Table VIII. of the ephemeris, and the sum will be her true semidiameter at the reduced time. And as 12 hours is to the difference of the moon's horizontal parallax in 12 hours, so is the reduced time to a fourth number; which, being added to or subtracted from the moon's horizontal parallax at the noon or midnight before the reduced time, according as it is increasing or decreasing, the sum or difference will be the moon's horizontal parallax at the reduced time. 4. If the reduced time be nearly any even part of 12 hours, viz. 17th, 14th, &c. these parts of the difference may be taken, and either added or subtracted according to the directions already given, without being at the trouble of working by the rule of proportion. 5. To the observed altitude of the sun's lower limb add the difference between his semidiameter and dip; and that sum will be his apparent altitude. 6. From the sun's refraction take his parallax in altitude, and the remainder will be the correction of the sun's altitude. 7. From the star's observed altitude take the dip of the horizon, and the remainder will be the apparent altitude. 8. The refraction of a star will be the correction of its altitude. 9. Take the difference between the moon's semidiameter and dip, and add it to the observed altitude if her lower limb was taken, or subtract it if her upper limb was taken; and the sum or difference will be the apparent altitude of her centre. 10. From the proportional logarithm of the moon's horizontal parallax, taken out of the nautical almanac (increasing its index by 10), take the logarithmic cosine of the moon's apparent altitude, the remainder will be the proportional logarithm of her parallax in altitude; from which take her refraction, and the remainder will be the correction of the moon's altitude. 11. To the observed distance of the moon from a star add her semidiameter if the nearest limb be taken, but subtract it if the farthest limb was taken, and the sum or difference will be the apparent distance. 12. To the observed distance of the sun and moon add both their semidiameters, and the sum will be the apparent distance of their centres.

3. To find the true Distance of the Objects, having their apparent Altitudes and Distances. 1. To the proportional logarithm of the correction of the sun or star's altitude, add the logarithmic cosine of the sun or star's apparent altitude; the logarithmic sine of the apparent distance of the moon from the sun or star; and the logarithmic co-tangent of the moon's apparent altitude. The sum of these, rejecting 20 in the index, will be the proportional logarithm of the first angle. 2. To the proportional logarithm of the correction of the sun or star's altitude, add the logarithmic co-tangent of the sun or star's apparent altitude, and the logarithmic tangent of the apparent distance of the moon from the sun or star. The sum of these, rejecting 30 in the index, will be the proportional logarithm of the second angle. 3. Take the differences between the first and second angles, adding it to the apparent distance if it be less than 90, and the first angle be greater than the second; but subtracting it if the second be greater than the first. If the distance be greater than 90, the sum of the angles must be added to the apparent distance, which will give the distance corrected for the refraction of the sun or star. 4. To the proportional logarithm of the correction of the moon's altitude add the logarithmic cosine of her apparent altitude; the logarithmic sine of the distance corrected for the sun or star's refraction, and the logarithmic co-tangent of the sun or star's apparent altitude. The sum, rejecting 30 in the index, will be the proportional logarithm of the third angle. 5. To the proportional logarithm of the correction of the moon's apparent altitude, add the logarithmic co-tangent of her apparent altitude, and the tangent of the distance corrected for the sun or star's refraction; their sum, rejecting 30 in the index, will be the proportional logarithm of the fourth angle. 6. Take the difference between the third and fourth angles, and subtract it from the distance corrected for the sun or star's refraction if less than 90, and the third angle be greater than the fourth; or add it to the distance if the fourth angle be greater than the third: but if the distance be more than 90, the sum of the angles must be subtracted from it, to give the distance corrected for the sun or star's refraction, and the principal effects of the moon's parallax. 7. In Table XX. of the ephemeris, look for the distance corrected for the sun and star's refraction, and the moon's parallax in the top column, and the correction of her altitude in the left-hand side column; take out the number of seconds that stand under the former, and opposite to the latter. Look again in the same table for the corrected distance in the top column, and the correction of the moon's altitude in the left-hand side column; take out the number of seconds that stand under the former, and opposite to the latter. Look again in the same table for the corrected distance in the top column, and the correction of the moon's altitude in the the left-hand side column; take out the number of seconds that stand under the former, and opposite to the latter. Look again in the same table for the corrected distance in the top column, and the principal effects of the moon's parallax in the left-hand side column, and take out the number of seconds. The difference between these two numbers must be added to the corrected distance if less than 90, but subtracted from it if greater; and the sum or difference will be the true distance.
Longitude, the computed distance; then take the proportional logarithms of the first and second differences, and the difference between these two logarithms will be the proportional logarithm of a number of hours, minutes, and seconds; which being added to the time standing over the first distance, will give the true time at Greenwich. Or it may be found by saying, As the first difference is to three hours, so is the second difference to a proportional part of time; which being added as above directed, will give the time at Greenwich. The difference between Greenwich time and that at the ship, turned into longitude, will be that at the time the observations were made; and will eke if the time at the ship is greatest, but would if it is least.

Having given these general directions, we shall next proceed to show some particular examples of finding the longitude at sea by all the different methods in which it is usually tried.

1. To find the Longitude by Computation from the Ship’s Course.—Were it possible to keep an accurate account of the distance the ship has run, and to measure it exactly by the log or any other means, then both latitude and longitude would easily be found by settling the ship’s account to that time. For the course and distance being known, the difference of latitude and departure is readily found by the Traversee Table; and the difference of longitude being known, the true latitude and longitude will also be known. A variety of causes, however, concur to render this computation inaccurate; particularly the ship’s continual deflection from the course set by her playing to the right and left round her centre of gravity; the unequal care of those at the helm, and the distance supposed to be sailed being erroneous, on account of stormy seas, unsteady winds, currents, &c. for which it seems impossible to make any allowance. The place of the ship, however, is judged of by finding the latitude every day, if possible, by observation; and if the latitude found by observation agrees with that by the reckoning, it is presumed that the ship’s place is properly determined; but if they disagree, it is concluded that the account of the longitude stands in need of correction, as the latitude by observation is always to be depended upon.

Currents very often occasion errors in the computation of a ship’s place. The cause of these in the great depths of the ocean are not well known, though many of the motions near the shore can be accounted for. It is supposed that some of these in the great oceans are owing to the tide following the moon, and a certain libration of the waters arising from thence; likewise that the unsettled nature of these currents may be owing to the changes in the moon’s declination. In the torrid zone, however, a considerable current is occasioned by the trade-winds, the motion being constantly to the west, at the rate of eight or ten miles per day. At the extremities of the trade winds or near the 20th degree of north or south latitude, the currents are probably compound of this motion to the westward, and of one towards the equator; whence all ships falling within these limits ought to allow a course each day for the current.

When the error is supposed to have been occasioned by a current, it ought if possible to be tried whether the case is to or not; or we must make a reasonable estimate of its drift and course. Then with the setting and drift, as a course and distance, find the difference of latitude and departure; with which the dead reckoning is to be increased or diminished: and if the latitude thus corrected agrees with that by observation, the departure thus corrected may be safely taken as true, and thus the ship’s place with regard to the longitude determined.

Example. Suppose a ship in 24 hours finds, by her dead reckoning, that she has made 96 miles of difference of latitude north and 38 miles of departure west; but by observation finds her difference of latitude 112, and on trial that there is a current which in 24 hours makes a difference of 16 miles latitude north and 10 miles of departure east: Require the ship’s departure.

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Here the dead reckoning corrected by the current gives the difference of latitude 112 miles, which is the same as that found by observations; whence the departure 28 is taken as the true one.

When the error is supposed to arise from the courses and distances, we must observe, that if the difference of latitude is much more than the departure, or the direct course has been within three points of the meridian, the error is most probably in the distance. But if the departure be much greater than the difference of latitude, or the direct course be within three points of the parallel, or more than five points from the meridian, the error is probably to be ascribed to the course. But if the courses in general are near the middle of the quadrant, the error may be either in the course, or in the distance, or both. This method admits of three cases.

1. When, by the dead reckoning, the difference of latitude is more than once and a half the departure; or when the course is less than three points: Find the course to the difference of latitude and departure. With this course and the meridional difference of latitude by observation, find the difference of longitude.

2. When the dead reckoning is more than once and an half the difference of latitude; or when the course is more than five points: Find the course and distance with the difference of latitude by observation, and departure by account; then with the course middle of latitude by observation, and departure by account, find the difference of longitude.

3. When the difference of latitude and departure by account is nearly equal, or the direct course is between three and five points of the meridian: Find the course with the difference of latitude and departure by account since the last observation. With this course and the difference of latitude by observation find another departure. Take half the sum of these departures for the true one. With the true departure and difference of latitude by observation find the true course; then with the true course and meridional difference of latitude find the difference of longitude.

2. To find the Longitude at Sea by a Variation-chart.
Dr. Halley having collected a great number of observations on the variations of the needle in many parts of the world, by that means enabled to draw certain lines on Mercator's chart, showing the variation in all the places over which they fell in the year 1700, at which time he first published the chart; whence the longitude of those places might be found by the chart provided its latitude and variation was given. The rule is, Draw a parallel of latitude on the chart through the latitude found by observation; and the point where it cuts the curved line marked with the variation that was observed will be the ship's place.

Exam. A ship finds by observation the latitude to be 18° 20' north; and the variation of the compass to be 48° west. Required the ship's place. — Lay a ruler over 18° 20' north parallel to the equator; and the point where its edge cuts the curve of 48° west variation gives the ship's place, which will be found in about 27° 10' west from London.

This method of finding the longitude, however, is attended with two inconveniences. 1. That when the variation lines run east or west, or nearly so, it cannot be applied; though as this happens only in certain parts of the world, a variation chart may be of great use for the rest. Even in those places indeed where the variation curves do run east or west, they may be of considerable use in correcting the latitude when meridian observations cannot be had; which frequently happens on the northern coasts of America, the Western Ocean, and about Newfound land; for if the variation can be found exactly, the east and west curve answering to it will show the latitude. But, 2. The variation itself is subject to continual change; whence a chart, though ever so perfect at first, must in time become totally useless; and hence the charts constructed by Dr. Halley, though of great utility at their first publication, became at length almost entirely useless. A new one was published in 1746 by Meffrs. Moutaine and Dollon, which so well received, that in 1756 they again drew variation lines for that year, and published a third chart the year following. They also presented to the Royal Society a curious paper concerning the variation of the magnetic needle, with a set of tables annexed, containing the result of more than 50,000 observations in six periodical reviews from the year 1700 to 1756 inclusive, adapted to every five degrees of latitude and longitude in the more frequented oceans; all of which were published in the Philosophical Transactions for 1757.

3. To Find the Longitude by the Sun's Declination. —Having made such observations on the sun as may enable us to find his declination at the place, take the difference between this computed declination and that shown at London by the ephemeris; from which take also the daily difference of declination at that time; then say, as the daily difference of declination is to the longitude of London, so is 360 degrees to the difference of longitude. In this method, however, a small error in the declination will make a great one in longitude.

4. To Find the Longitude by the Moon's culminating. —Seek in the ephemeris for the time of her coming to the meridian on the given day and on the day following, and take their difference; also take the difference between the times of culminating on the same day as found in the ephemeris, and as observed; then

5. By Eclipses of the Moon. —This is done much in the same manner as by the eclipses of Jupiter's satellites: For if, in two or more distant places where an eclipse of the moon is visible, we carefully observe the times of beginning and ending, the number of digits eclipsed, or the time when the shadow touches some remarkable spot, or when it leaves any particular spot on the moon, the difference of the times when the observations were made will give the difference of longitude. Phenomena of this kind, however, occur too seldom to be of much use.

In 1783, Mr. Pigot informs us, that he thought of finding the difference of meridians by observing the meridian right ascensions of the moon's limbs. This he thought had been quite original: but he found it afterwards in the Nautical Almanack for 1769, and in 1784 read a pamphlet on the subject by the Abbé Delafield; but still found that the great exactness of this method was not suspected; though he is convinced that it must soon be universally adopted in preference to that from the first satellite of Jupiter.

After giving a number of observations on the satellites of Jupiter, he concludes, that the exactness expected from observations, even on the first satellite, is much over-rated. "Among the various objections (says he), there is one I have often experienced, and which proceeds solely from the disposition of the eye, that of seeing more distinctly at one time than another. It may not be improper also to mention, that the observation I should have relied on as the best, that of Aug. 30. 1783, marked excellent, is one of those most different from the truth."
Proceeds from the observation of the moon's limb, which may be considerably increased, if certain little round spots near each limb were also observed in settled observatories; in which case the libration of the moon will perhaps be a consideration. 7. When the difference of meridians, or of the latitudes of places, is very considerable, the change of the moon's diameter becomes an equation.

"Though such are the requisites to use this method with advantage, only one or two of them have been employed in the observations that I have reduced. Two-thirds of these observations had not even the same stars observed at Greenwich and York; and yet none of the results, except a doubtful one, differed 15" from the mean; therefore I think we may expect a still greater exactness, perhaps within 10" if the above particulars be attended to.

"When the same stars are not observed, it is necessary for the observers at both places to compute their right ascension from tables; in order to get the apparent right ascension of the moon's limb. Though this is not so satisfactory as by actual observation, still the difference will be trifling, provided the star's right ascensions are accurately settled. I am also of opinion, that the same method can be put in practice by travellers with little trouble, and a transit instrument, constructed as to fix up with facility in any place.

It is not necessary, perhaps, that the instrument should be perfectly in the meridian for a few seconds of time, provided stars, nearly in the same parallel of declination with the moon, are observed; may, I am inclined to think, that if the instrument deviates even a quarter or half a degree, or more, sufficient exactness can be attained; as a table might be computed, showing the moon's parallax and motion for such deviation; which last may easily be found by the well known method of observing stars whose difference of declination is considerable.

"As travellers very seldom meet with situations to observe stars near the pole, or find a proper object for determining the error of the line of collimation, I shall recommend the following method as original—

Having computed the apparent right ascension of four, six, or more stars, which have nearly the same parallel of declination, observe half of them with the instrument inverted, and the other half when in its right position. If the difference of right ascensions between each set by observation agrees with the computation, there is no error; but if they disagree, half that disagreement is the error of the line of collimation.

The same observations may also serve to determine, whether the distance of the corresponding wires are equal. In case of necessity, each limb of the sun might be observed in the same manner, though probably with less precision. By a single trial I made above two years ago, the result was much more exact than I expected. Mayor's catalogue of stars will prove of great use to those that adopt the above method.—I am rather surprised that the impenetrable thicknesses of known stars of the sixth and seventh magnitudes, behind the dark limb of the moon, are not constantly observed in fixed observatories, as they would frequently be of great use."
Longitude. The annexed rule for finding the ship's place, with the miscellaneous observations on different methods, we have been favoured with Mr. John M'Lean of the Observatory, Edinburgh. The rule was examined and approved of by Sir Joseph Banks president of the Royal Society.

1. With regard to determining the ship's place by the help of the course and distance sailed, the following rule may be applied. It will be found as expeditious as any of the common methods by the middle latitude or meridian parts, and is in some respects preferable, as the common tables of lines and tangents only are requisite in applying it. Let $a$ and $b$ be the distances of two places from the same pole in degrees, or their complete latitudes; $C$ the angle which a meridian makes with the rhumb line passing through the places; and $L$ the angle formed by their meridians, or the difference of longitude in minutes; then $A$ and $B$ being the logarithmic tangents of $a$ and $b$, $S$ the sine of $C$, and the sine of $(C + L')$, we shall have the following equation:

$$S = S - S$$

The property of the rhumb line, we have the following equation:

$$S + E = R + D$$

where $S$ is the logarithmic cofine of $C$, $E$ the logarithm of the length of the rhumb line, or distance, $D$ the logarithm of the minute's difference of latitude, and $R$ the logarithm of the radius.

By the help of these two equations, we shall have an easy solution of the several cases to which the middle latitude, or meridianal parts, are commonly applied.

Example. A ship from a port, in latitude 56° N., sails SW. by W. till she arrives at the latitude of 40° N.: Required the difference of longitude.

Here $a = 34°$, $b = 50°$, $C = 6° 15'$, $A = 9.493544$, $B = 9.569707$, $S' = 9.0192308$, $S = 9.0198464$; therefore, $L = A - B = 973200 = 897$ the minutes difference of longitude. Also, $S = 9.74474$, $D = 2.98227$; therefore $E = R + D = 3.23752$, to which the natural number is 1738, the miles in the rhumb line sailed over.

2. The common method of finding the difference of longitude made good upon several courses and distances, by means of the difference of latitude and departure made good upon the several courses, is not accurately true.

For example: If a ship should sail due south 600 miles, from a port in 60° north latitude, and then due west 600 miles, the difference of longitude found by the common method of solution would be 1053; whereas the true difference of longitude is only 933, less than the former by 120 miles, which is more than 1/4 of the whole. Indeed every considerable alteration in the course will produce a very liable error in the difference of longitude. Though, when the several rhumb lines sailed over are nearly in the same direction, the error in longitude will be but small.

Therefore of this will easily appear from the annexed figure, in which the ship is supposed to sail from $Z$ to $A$, along the rhumb lines $ZB$, $BA$; for if the meridians $PZ$, $P_{10}eBL$ be drawn, and very near the latter other two meridians $PhD$, $Pmn$; and likewise the parallels of latitude $Bn$, $De$, $mo$, $hk$; then it is plain that $De$ is greater than $hk$ (for $De$ is to $hk$ as the line of DP to the sine of $hP$): and since this is the case every where, the departure corresponding to the distance $BZ$ and course $BZC$, will be greater than the departure to the distance $oz$ and course $ozC$. And in the same manner, we prove that $hB$ is greater than $mo$; and consequently, the departure corresponding to the distance $AB$, and course $ABL$, is greater than the departure to the distance $Ao$, and course $AoL$: Wherefore, the sum of the two departures corresponding to the courses $ABL$ and $BZC$, and to the distances $AB$ and $BZ$, is greater than the departure corresponding to the distance $AZ$ and course $AZC$; therefore the course answering to this sum as a departure, and $CZ$ as a difference of latitude, (AD being the parallel of latitudes passing through $A$), will be greater than the true course $AZC$ made good upon the whole. And hence the difference of longitude found by the common rule will be greater than the true difference of longitudes; and the error will be greater or less according as $BA$ deviates more or less from the direction of $BZ$.

2. Of determining the ship's longitude by lunar observations.

Several rules for this purpose have been lately published, the principal object of which seems to have been to abbreviate the computations requisite for determining the true distance of the sun or a star from the moon's centre. This, however, should have certainly been attended to than the investigation of a solution, in which considerable errors in the data may produce a small error in the required distance. When either of the luminaries has a small elevation, its altitude will be affected by the variables of the atmosphere; likewise the altitude, as given by the quadrant, will be affected by the inaccuracy of the instrument, and the uncertainty necessarily attending all observations made.

(1) $A \omega B$ signifies the difference between $A$ and $B$. 
Long. [283] Lon.

Longitude. made at sea. The sum of these errors, when they all tend the same way, may be supposed to amount to at least one minute in altitude; which, in many cases, according to the common rules for computing the true distance, will produce an error of about 30 minutes in the longitude. Thus, in the example given by Mont. Callet, in the Tables Rectoriana, if we suppose an error of one minute in the sun's altitude, or call it 6° 26' 24", instead of 6° 27' 34"; we shall find the alteration in distance according to his rule to be 54", producing an error of about 27 minutes in the longitude.

Perhaps the only method of determining the distance, so as not to be affected by the errors of altitude, is that by first finding the angles at the sun and moon, and by the help of them the corrections of distance for parallax and refraction. The rule is as follows:

Add together the complement of the sun's apparent altitude, the complement of the sun's apparent altitude, and the apparent distance of centres; from half the sum of these subtract the complement of the sun's altitude, and add together the logarithmic cofecant of the complement of the sun's altitude, the logarithmic co-secant of the apparent distances of centres, the logarithmic cofine of the sun's altitude, and the logarithmic co-secant of the remainder; and half the sum of these four logarithms, after rejecting 20 from the index, is the logarithmic cofine of half the angle at the moon.

As radius is to the cofine of the angle at the moon, so is the difference between the moon's parallax and refraction in altitude to a correction of distance; which is to be added to the apparent distance of centres Longitude, when the angle at the moon is obtuse; but to be subtracted when that angle be acute, in order to have the distance once corrected.

In the above formula, if the word sun be changed for moon, and vice versa, wherever these terms occur, we shall find a second correction of distance to be applied to the distance, once corrected by subtraction when the angle at the sun be obtuse, but by addition when that angle is acute, and the remainder or sum is the true distance nearly.

In applying this rule, it will be sufficient to use the complement, altitudes, and apparent distances of centres, true to the nearest minute only, as a smaller error in the angles at the sun and moon will very little affect the corrections of distances.

If D be the computed distance in seconds, d the difference between the moon's parallax and refraction in altitude, S the sine of the angle at the moon, and R the radius; then \(d S\) will be a third correction of Distance, to be added to the distance twice corrected: But it is plain, from the nature of this correction, that it may be always rejected, except when the difference D is very small, and the angle at the moon nearly equal to 90°.

This solution is likewise of use in finding the true distance of a star from the moon, by changing the word sun into star, and using the refraction of the star, instead of the difference between the refraction and parallax in altitude of the sun, in finding the second correction of distance.

Ex. Given the observed distance of a star from the centre of the moon, 50° 8' 41'": the moon's altitude, 55° 58' 5": the star's altitude, 192° 18' 5": and the moon's horizontal parallax, 1° 0' 5": Required the true distance.

Here the first correction of distance is additive, since the angle at the moon is obtuse; and the second correction is also additive, since the angle at the stars is acute: therefore the sum 923°+418°=1361°=:17° 41', being added to 50° 8' 41', the apparent distance of the star from the moon's centre, gives 50° 25' 21" for the true distance of centres nearly; and 2xL (445)—L (2 L R+L 2+L D) =L 8", which, being added to the distance twice corrected, gives 50° 26' 29", for the true distance. By comparing
LONGITUDINAL, in general, denotes something placed lengthwise; thus some of the fibres in the vessels of the human body are placed longitudinally, others transversely or across.

LONGOBARDI. See Langobardi.

LONGOMONTANUS (Christian), a learned astronomer, born in a village of Denmark in 1562. He was the son of a ploughman; and was obliged to suffer during his studies all the hardships to which he could be exposed, dividing his time, like the philosopher Cle- anthes, between the cultivation of the earth and the lessons he received from the minister of the place. At last, when he was 15, he stole away from his family, and went to Wiburg, where there was a college, in which he spent 11 years: and though he was obliged to earn a livelihood, he applied himself to study with such ardour, that among other sciences he learned the mathematics in great perfection. He afterwards went to Copenhagen; where the professors of that university in a short time conceived to high an opinion of him, that they recommended him to the celebrated Tycho Brahe. Longomontanus lived eight years with that famous astronomer, and was of great service to him in red

LONGOMONTANUS, in the month of July.

LONGWY, a town of France, on the frontiers of the duchy of Luxembourg, with a castle, divided into the old and new towns. This last was built and fortified by Louis XIV. It is feated on an eminence, E. Lon. 51. N. Lat. 40. 32.

LONGUS, a Greek sophist, author of a book intitled 

Avranches, speaks very advantageously of this works but he extolles the oblicen touches with which it is

LONICERA, honeysuckle, in botany: A genus of the monogynia order, belonging to the pentandra class of plants. The corolla is monopetalous and irregular; the berry polysepmorous, bilocular, and inferior.

Species. 1. The alpigena, or upright red-berried honeysuckle, rises with a thorny, short, thick upright stem branching long and erectly four or five feet high; large, heart-shaped leaves, in pairs opposite; and from the sides of the branches many red-flowers two's on long four-flacks, each succeeded by two red berries joined together at their base; it flowers in August, and the berries ripen in autumn. 2. The carées, or blue-berried upright honeysuckle, rises with a thorny upright stem, branching moderately three or four feet high, with many white flowers proceeding from the sides of the branches; appearing in May, and succeeded by blue berries joined together at their base.

Species. 9. The alpigena, or upright red-berried honeysuckle, rises with a thorny, short, thick upright stem branching long and erectly four or five feet high; large, heart-shaped leaves, in pairs opposite; and from the sides of the branches many red-flowers two's on long four-flacks, each succeeded by two red berries joined together at their base; it flowers in August, and the berries ripen in autumn. 2. The carées, or blue-berried upright honeysuckle, rises with a thorny upright stem, branching moderately three or four feet high, with many white flowers proceeding from the sides of the branches; appearing in May, and succeeded by blue berries joined together at their base.

LOOM, at sea. If a ship appears big, when at a distance, they say the looms, or appears a great sail; the term is also used to denote the indistinct appearance of any other distant objects.

LOOM-sail, at sea, a gentle easy gale of wind, in which a ship can carry her top-sails a-trip.

LOOP, in the iron works, is a part of a few or block of cast iron broken or melted off from the rest, and prepared for the forge or hammer. The usual method is, to break off the loop of about three quarters of a hundred weight. This loop they take up with their flinging-tongs; and beat it with iron pledges upon an iron plate near the fire, that so it may not fall to pieces, but be in a condition to be carried under the hammer. It is then placed under the hammer, and a little water being drawn to make the hammer move but softly, it is beat very gently, and by this means the drofs and foulness are forced off, and after this they draw more and more water by degrees, and beat it more and more till they bring it to a four square mafs, of about two feet long, which they call a bloom.

LOOPING, in metallurgy, a word used by the miners of some counties of England, to express the running together of the matter of an ore into a mafs, in the roasting or first burning, intended only to calcine it to be used as powdering. This accident, which gives the miners some trouble, is generally owing to the continuing the fire too long in this process.

LOOSE-stripe. See LYSIMACHIA.

LOOSA, in botany: a genus of the monogynia order, belonging to the polyandria class of plants. The calyx is pentaphyllous, superior; there are five ovate, cucullated, and large petals; the nectarium consists of five leaves, gathered into a conical figure, each terminated by two filaments; the capsule is turbinate, unilocular, and trivalved at top; the seeds are very numerous; and there are three linear and longitudinal hairs.

LOPE, or INDIAN, Root, in the materia medica. The plant to which this article belongs is unknown. Neither the woody nor cortical part of the root has any remarkable sensible quality. A slight bitterness is perceptible; and it is recommended, like samaruba, in diarrhoeas even of the colliquative kind, in half-dram doses four times a day. Little of this root has been brought to Europe: but some of those who have had an opportunity of employing it, speak in very high terms of the effects obtained from it.

LOPHIUS, FISHING-Frog, Tead-fish or Sea-devil; a genus of the branchiostegous order of fishes, whose head is equal in size to all the rest of the body. There are three species; the most remarkable of which is the picaforius or common fishing-frog, an inhabitant of the British seas. This singular fish was known to the ancients by the name of Barus, and rand; and to us by that of the fishing-frog, for it is of a figure resembling that animal in a tadpole state. Pliny takes notice of the artifice used by it to take its prey: Eminencia fab occultis cornulis tauto lino extenuatae, affilatina, pliosus attrahens, donum tam prope ascendit, ut affila.

It puts forth the hinder horns it has beneath its eyes, enticing by that means the little fish to play round, till they come within reach, when it springs on...

house of Lords, one of the three estates of the parliament of Britain, and composed of the Lords Spiritual and Temporal.

1. The Spiritual Lords consist of 2 archbishops and 24 bishops; and, at the dissolution of monasteries by Henry VIII., consisted likewise of 26 mitred abbots and two priors; a very considerable body, and in those times equal in number to the temporal nobility. All these hold, or are supposed to hold, certain ancient baronies under the king: for William the Conqueror thought proper to change the spiritual tenure of frank-

the feudal or Norman tenure by barony; which subjected their estates to all civil charges and afligments, from which they were before exempt, and in right of succession to those baronies, which were unalienable from their respective dignities, the bishops and abbots were allowed their seats in the house of lords. But though these lords spiritual are in the eye of the law a distinct estate from the lords temporal, and are so distinguished in most of the acts of the British parliament; yet in practice they are usually blended together under the name of the lords; they intermix in their votes, and the majority of such intermixture joins both estates. And from this want of a separate assembly, and separate negative of the prelates, some writers have argued very cogently, that the lords spiritual and temporal are now in reality only one estate; which is unquestionably true in every effectual sense, though the ancient distinction between them still nominally continues. For if a bill should pass their house, there is no doubt of its validity, though every lord spiritual should vote against it; of which Selden and Sir Edward Coke give many instances: as, on the other hand, doubts it would be equally good, if the lords temporal present were inferior to the bishops in number, and every one of those temporal lords gave his vote to reject the bill; though this Sir Edward Coke seems to doubt of.

2. The Temporal Lords consist of all the peers of the realm, (the bishops not being in their places held to be such, but merely lords of parliament,) by whatever title of nobility distinguished; dukes, marquises, earls, viscounts, or barons.

Some of these sit by descent; they as do all ancient peers; some by creation, as do all new-made ones; others, since the union with Scotland, by election, which is the case of the 16 peers, who represent the body of the Scots nobility. Their number is indefinite, and may be increased at will by the power of the crown; and once, in the reign of Queen Anne, there was an instance of creating no less than 12 together; in contemplation of which, in the reign of King George I., a bill passed the house of lords, and...
was countenanced by the then ministry, for limiting the number of the peerage. This was thought by forebears to promise a great acquisition to the crown, by retaining the prerogative from gaining the ascendancy in that august assembly, by pouring in at pleasure an unlimited number of new-created lords. But the bill was ill relished, and misconstrued in the house of commons, whose leading members were then defirous to keep the avenues to the other house as open and easy as possible.

"The distinction of ranks and honours is necessary in every well-governed state: in order to reward such as are eminent for their services to the public, in a manner the most desirable to individuals, and yet without burthen to the community; exciting thereby an ambitious yet laudable ardour and generous emulation in others. And emulation, or virtuous ambition, is a spring of action which, however dangerous or invidious in a mere republic or under a despotic sway, will certainly be attended with good effects under a free monarchy; where, without destroying its existence, its excesses may be continually restrained by that superior power from which all honour is derived. Such a spirit, when nationally diffused, gives life and vigour to the community; it sets all the wheels of government in motion, which, under a wise regulator, may be directed to any beneficial purpose; and thereby every individual may be made fulfilling to the public good, while he principally seeks to promote his own particular views. A body of nobility is also more particularly necessary in a mixed and compounded constitution, in order to support the rights of both the crown and the people, by forming a barrier to withstand the encroachments of both. It creates and preserves that gradual scale of dignity which proceeds from the peafant to the prince; rising like a pyramid from a broad foundation, and diminishing to a point as it rises. It is this ascending and contracting proportion that adds stability to any government; for when the departure is sudden from one extreme to another, we may pronounce that state to be precarious. The nobility therefore are the pillars, which are reared from among the people, more immediately to support the throne; and, if that fails, they must also be buried under its ruins. Accordingly, when in the last century the commons had determined to extirpate monarchy, they also voted the house of lords to be useless and dangerous. And since titles of nobility are thus expedient in the state, it is also expedient that their owners should form an independent and separate branch of the legislature. If they were confounded with the mass of the people, and like them had only a vote in electing representatives, their privileges would soon be borne down and overwhelmed by the popular torrent, which would effectually level all distinctions. It is therefore highly necessary that the body of nobles should have a distinct assembly, distinct deliberations, and distinct powers from the commons." See also King, Nobility, Parliament, Commons, and Commonalty.

As to the peculiar laws and customs relating to the house of lords: One very ancient privilege is that declared by the charter of the forest, confirmed in parliament 9 Hen. III.: viz. that every lord spiritual or temporal summoned to parliament, and pulling through the king's forests, may, both in going and returning, kill one or two of the king's deer without warrant; in view of the forest if he be present, or on blowing a horn if he be absent; that he may not seem to take the king's venison by stealth.

In the next place, they have a right to be attended, and constantly are, by the judges of the court of king's-bench and common-pleas, and such of the barons of the exchequer as are of the degree of the cot, or have been made serjeants at law; as likewise by the king's learned counsel, being serjeants, and by the masters of the court of chancery; for their advice in point of law, and for the greater dignity of their proceedings. The secretaries of state, with the attorney and solicitor general, were also used to attend the house of peers, and have to this day (together with the judges, &c.) their regular writs of summons intituled at the beginning of every parliament, ad tradandum et consiliium impendendum, though not ad confertendum: but, whenever of late years they have been members of the house of commons, their attendance here hath fallen into disuse.

Another privilege is, that every peer, by licence obtained from the king, may make another lord of parliament his proxy, to vote for him in his absence: A privilege, which a member of the other house can by no means have, as he himself but a proxy for a multitude of other people.

Each peer has also a right, by leave of the house, when a vote paves contrary to his sentiments, to enter his dissent on the journals of the house, with the reasons for such dissent; which is usually styled his protest.

All bills likewise, that may in their consequences any way affect the rights of the peerage, are by the custom of parliament, to have their first rise and beginnings in the house of peers and to suffer no changes or amendments in the house of commons.

There is also one statute peculiarly relative to the house of lords, 6 Ann. c. 23. which regulates the election of the 16 representatives peers of North Britain, in consequence of the 22d and 23d articles of the union; and for that purpose prescribes the oaths, &c. to be taken by the electors; directs the mode of balloting; prohibits the peers electing from being attended in an usual manner; and expressly provides that no other matter shall be treated of in that assembly save only the election, on pain of incurring a prænunia. See also the Articles Nobility and Peers.

LORDOSIS, (of ἄμφος, bent inward), in the medical writings, a name given to a diseased state of the spine, in which it is bent inward, or towards the anterior parts. It is used in opposition to gibbus or hump-backed. See Surgery.

LORETTO, a town of Italy, in the Marche or Marche of Ancona, with a bishop's see. It is small, but fortified; and contains the famous festa santo, or holy chapel, so much visited by pilgrims. This chapel, according to the legend, was originally a small house in Nazareth, inhabited by the virgin Mary, in which she was saluted by the angel, and where she bore our Saviour. After their deaths, it was held in great veneration by all believers in Jesus, and at length consecrated into a chapel, and dedicated to the virgin; upon which occasion St Luke made that identical image
The sacred chapel stands due east and west, at the farther end of a large church of the most durable stone of Iferia, which has been built around it. This may be considered as the external covering or as a kind of great cost to the casa santa, which has a smaller coat of more precious materials and workmanship nearer its body. This internal covering or casa is of the choicest marble, after a plan of San Savino’s, and ornamented with baso relieves, the workmanship of the best sculptors which Italy could furnish in the reign of Leo X. The subject of these baso relieves are, the history of the blest virgin, and other parts of the Bible. The whole casa is about 50 feet long, 30 in breadth, and the main in height; but the real house itself is no more than 32 feet in length, 14 in breadth, and at the sides about 18 feet in height; the centre of the roof is four or five feet higher. The walls of this little holy chapel are composed of pieces of a reddish substance, of an oblong square shape, laid one upon another, in the manner of brick. At first sight, on a superficial view, these red-coloured oblong substances appear to be nothing else than common Italian bricks; and which is still more extraordinary, on the second and third view, with all possible attention, they still have the same appearance. Travellers, however, are assured, with great earnestness, that there is not a single particle of brick in their whole composition, being entirely of a stone, which, though it cannot now be found in Palestine, was formerly very common, particularly in the neighbourhood of Nazareth.

The holy house is divided within into two unequal portions, by a kind of grate-work of silver. The division towards the well is about three-fourths of the whole; that to the east is called the Sacrauriy. In the larger division, which may be considered as the main body of the house, the walls are left bare, to show the true original fabric of Nazareth stone; for they must not be supposed to be bricks. At the lower or western wall there is a window, the frame through which the angel Gabriel entered at the Annunciation. The architraves of this window are covered with silver. There are a great number of golden and silver lamps in this chapel; one of the former, a present from the republic of Venice, is said to weigh 37 pounds, and some of the silver lamps weigh from 120 to 130 pounds. At the upper end of the largest room is an altar, but so low, that from it you may see the famous image which stands over the chimney in the small room or sanctuary. Golden and silver angels, of considerable size, kneel around her, borne in shining hearts of gold, enriched with diamonds, and one an infant of pure gold. The wall of the sanctuary is plated with silver; and adorned with crucifixes, precious stones, and votive gifts of various kinds. The figure of the Virgin herself by no means corresponds with the fine furniture of her house: She is a little woman, about four feet in height, with the features and complexion of a negro. Of all the sculptors that ever existed, assuredly St Luke, by whom this figure is said to have been made, is the least of a flatterer; and nothing can be a stronger proof of the blest Virgin’s contempt for external beauty, than her being satisfied with her reprentation of herself. The figure of the infant Jesus, by St Luke, is of a piece with that of the Virgin: he holds a large golden globe in one hand, and the other is extended in the act of blessing. Both figures have crowns on their heads, enriched with diamonds: these were presents from Ann of Austria queen of France. Both arms of the Virgin are incorporeal with her robes. and no part but her face is to be seen; her dress is so magnificent, but in a wretched ruff; this is not surprising, for the two female attendants. She has particular cloaks for the different feasts held in honour of her, and, which is not quite so decent, is always dressed and undressed by the priests belonging to the chapel: her robes are ornamented with all kinds of precious stones down to the hem of her garment.

There is a small place behind the sanctuary, in which are shown the chimney, and some other furniture which they pretend belonged to the Virgin when she lived at Nazareth; particularly a little earthen potter’s wheel, out of which the infant used to eat. The pilgrims bring rotaries, little crucifixes, and Agnus Dei’s, which the obliging priest makes for half a minute in this dish; after which it is believed they acquire the virtue of curing various diseases, and prove an excellent preventative of all temptations of Satan. The gown which the image had on when the chapel arrived from Nazareth is of red camble, and carefully kept in a glass shrine.

Above 100 masas are daily paid in this chapel, and in the church in which it stands. The jewels and riches

Loretto
Loretto; riches to be seen at any one time in the holy chapel are in small value in comparison of those of the treasury, which is a large room adjoining to the vestibule of the great church. In the predator of this room are kept those presents which royal, noble, and rich bishops of all ranks, have, by oppressing them subjects and injuring their families, sent to this place. To enumerate every particular would fill volumes. They consist of various utensils and other things in silver and gold; as lamps, candlesticks, goblets, crowns, and crucifixes; lambs, eagles, fames, apostles, angels, virgins, and infants: then there are cameos, pearls, gems, and precious stones, of all kinds and in great numbers. What is valued above all the other jewels is, the miraculous pearl wherein they assert that Nature has given a faithful delineation of the virgin sitting on a cloud with the infant Jesus in her arms.

There was not room in the predator of the treasury to hold all the silver pieces which have been presented to the Virgin. Several other predicators in the vestry are completely full. It is said that those pieces are occasionally melted down by his holiness for the use of the state, and also that the most precious of the jewels are picked out and sold for the same purpose, false stones being substituted in their room.

Pilgrimages to Loretto are not so frequent with foreigners, or with Italians of fortune and distiction, as formerly; nineteen out of twenty of those who make this journey now are poor people, who depend for their maintenance on the charity they receive on the road. To those who are of such a rank in life as make this journey by themselves or on mules; others of considerable merit which ornament the altars are apt to make on any occasion, and fathers and husbands, in moderate or confined circumstances, are frequently brought to disagreeable dilemmas, by the ruinous of going to Loretto, which their wives or daughters are apt to make on any supposed deliverance from danger. To refuse, is considered by the whole neighbourhood as cruel, and even impious; and to grant, is often highly disquieting, particularly to such husbands as from affection or any other motive, do not choose that their wives should be long out of their sight. But the poor, who are maintained during their whole journey, and have nothing more than a bare maintenance to expect from their labour at home, to them a journey to Loretto is a party of pleasure as well as devotion, and by much the most agreeable road they can take to heaven. The greatest concourse of pilgrims is at the feasons of Easter and Whitintide. Thither travel in their carriages; a greater number come on horseback or on mules; or, what is still more common, on asses. Great numbers of females come in this manner, with a male friend walking by them as their guide and protector; but the greatest number of both sexes are on foot. The pilgrims on foot, as soon as they enter the suburbs, begin a hymn in honour of the Virgin which they continue till they reach the church. The poorer sort are received into an hospital, where they have bed and board for three days.

The only trade of Loretto consists of rosaries, crucifixes, images, Agnus Dei's, and medals, which are manufactured here, and sold by the pilgrims. There are great numbers of shops full of these commodities, some of them of a high price; but infinitely the greater part are adapted to the purities of the buyers, and sold for a mere trifle. The evident poverty of those manufacturers and traders, and of the inhabitants of this town in general, is a sufficient proof that the reputation of our Lady of Loretto is greatly on the decline.

In the great church which contains the holy chapel are confessionals, where the penitents from every country of Europe may be confided in their own language, priests being always in waiting for that purpose: each of them has a long white rod in his hand, with which he touches the heads of those to whom he thinks it proper to give absolution. They place themselves on their knees in groups around the confessional chair; and when the holy father has touched their heads with the expiatory rod, they retire, freed from the burden of their sins, and with renewed courage to begin a fresh account.

In the spacious area before this church there is an elegant marble fountain, supplied with water from an adjoining hill by an aqueduct. Few even of the most inconsiderable towns of Italy are without the useful ornament of a public fountain. The embellishments of sculpture and architecture are employed with great propriety on such works, which are continually in the people's view; the air is refreshed and the eye delighted by the streams of water they pour forth; a sight peculiarly agreeable in a warm climate. In this area there is also a statue of Sextus V. in bronze. Over the portal of the church itself is a statue of the Virgin; and above the middle gate is a Latin inscription, importing, that within is the house of the mother of God, in which the Word was made flesh. The gates of the church are likewise of bronze, embellished with bas-reliefs of admirable workmanship; the subjects taken partly from the Old and partly from the New Testament, and divided into different compartments. As the gates of this church are shut at noon, the pilgrims who arrive after that time can get no nearer the Santa Casa than these gates, which are by this means sometimes exposed to the first violence of that holy ardour which was designed for the chapel itself. All the sculpture upon the gates which is within reach of the mouths of those zealots, is in some degree effaced by their kisses.

There are also several paintings to be seen here, some of which are highly esteemed, particularly two in the treasury. The subject of one of these is the Virgin's Nativity, by Annibal Carracci; and of the other, a Holy Family, by Raphael. There are some others of considerable merit which ornament the altars of the great church. These altars, or little chapels, of which this fabric contains a great number, are lined with marble and embellished by sculpture; but nothing within this church interests a traveller of sensibility so much as the iron grates before those chapels which were made of the fetters and chains of the Christian slaves, who were freed from bondage by the glorious victory of Lepanto.

The place where the governor resides stands near the church, and the ecclesiastics who were employed in it lodge in the same palace, where they receive the pilgrims of high distinction. The environs of this town are very agreeable, and in fine weather the high mountains
LORICA, was a cuirass, brigantine, or coat of mail, in use among the Roman soldiers. It was generally made of leather, and is supposed to be derived from *lorum*—The loricae were fet with plates of metal in various forms; sometimes in hooks or rings like a chain, sometimes like feathers, and sometimes like the scales of serpents or fishes, to which plates of gold were often added. There were other lighter cuirasses consisting only of many folds of linen cloth; or of flax made strong enough to withstand weapons. Such soldiers as were rated under 1000 drachms, instead of the lorica now described, wore a *pelio* (lorica).—The Roman lorica was made like a shirt, and defended the wearer both before and behind, but was so contrived that the back part could be occasionally separated from the front. Some of the loricae were made of cords of hemp or flax, close fet together; whence they are called *tortices*, *billices*, *trilices*, &c. from the number of the cords fixed one upon another; but these were used rather in hunting than in the field of battle.

LORICATION, in chemistry, is the covering a glass or earthen vessel with a coat or crust of a matter able to withstand the fire, to prevent its breaking in the performing an operation that requires great violence of fire. See CHEMISTRY.

LORIS, in zoology. See LEMUR.

LORIMERS, one of the companies of London, that make bits for bridles, spurs, and such like small iron ware. They are mentioned in statute 1 Rich. II. c. 12.—The word is derived from the Latin word *lorum*, a thong.

LORNE, a division of Argyllshire in Scotland, which gives the title of marquis to the duke of Argyll. It extends above 30 miles in length from north to south, and about nine at its utmost breadth; bounded on the east by Bracklauch; on the west, by the islands; on the north, by Lochaber; and is divided from Knapdale on the south by Loch Etive, on the banks of which stands the castle of Bergomarn, wherein the courts of justice were anciently held. This district, abounding with lakes, is the most pleasant and fertile part of Argyllshire, producing plenty of oats and barley. It once belonged to the ancient family of Macdougal, till residing on the spot; but devolved to the lords of Argyll in consequence of a marriage with the heiresses, at that time a branch of the Stuart family. The chief place of note in this district is the castle of Dunstaffnage, a seat of the Scottish kings previous to the conquest of the Picts in 843 by Kenneth II. In this place was long preferred the famous *fion*, the palladium of North Britain; brought, says legend, out of Spain, where it was first used as a seat of justice by Cathlucus, coeval with Moses. It continued here as the coronation-chair till the reign of Kenneth II, who removed it to Scone, in order to secure his reign; for, according to the inscription,

\[ \text{Ni fallat fatum. Scoti quosque locatum} \\
\text{Inuentum tepident, regnare tibi intus idheem.} \]

Some of the ancient regalia were preserved till the present century, when the keeper's servants, during his infirm years, embezzled them for the silver ornaments; and left only a battle-axe, nine feet long, of beautiful workmanship, and ornamented with silver.

The castle is square; the inside only 87 feet; partly ruinous, partly habitable. At three of the corners are round towers; one of them projects very little. The entrance is towards the sea at present by a stair-case, in old times probably by a draw-bridge, which fell from a little gate-way. The masonry appears very ancient; the tops battlemented. This pile is seated on a rock near the mouth of Loch Ewe, whose waters expand within to a beautiful bay, where ships may safely ride in all weather. Of this building, the founder of which is unknown, nothing remains except the outer walls, which, though roofless, are still in good order; and within which some buildings have been erected, which serve as the residence of the laird. The duke of Argyll is hereditary keeper under the Crown.—At a small distance from the castle is a ruined chapel, once an elegant building; and at one end an inclosure, a family-cemetery. Opposite to these is a high precipice, ending abrupt and turning suddenly towards the south-east. A person concealed in the recess of the rock, a little beyond the angle, surprizes friends stationed at some distance beneath the precipice with a very remarkable echo of any word, or even a sentence, he pronounces; which reaches the last distinct and unbroken. The repetition is single, but remarkably clear.

In 1307, this castle was possessed by Alexander Macdougal lord of Argyll, a friend to the English; but was that year reduced by Robert Bruce, when Macdougal sued for peace with that prince, and was received into favour.

We find, about the year 1455, this to have been a residence of the lords of the illes; for here James I of Douglas, after his defeat in Annandale, fled to Donald, the regent of the time, and prevailed on him to take arms and carry on a plundering war against his monarch James II.

The situation of this regal seat was calculated for pleasure as well as strength. The views of mountains, valleys, waters, and islands, are delightful. On the north side of Loch Etive flows the town of Beregromaticum, supposed to have been the capital of the West Highlands. It forms, from certain mounds, excavations, and other appearances, to be a strong fortres, to prevent invasion, or to secure a retreat, as occasions might require. On the bank of the same loch is the site of Ardochattan, a priory, or monks of Valliaecum in Burgundy, founded in 1320 by Donald MacCool, ancestor of the Macdougals of Lorn. Here Robert Bruce, who remained master of this country before he got entire possession of Scotland, held a parliament or council.—The country abounds in Druidical, Danilith, and other monuments.

LORRAINE, a foreign state of Europe, bounded on the north by Luxemburg and the archbishopric of Troyes, on the east by Allace and the duchy of Deux Ponts,
PONTS, on the south by Franche comté, and on the west by Champagne and the duchy of Bar. It is about 100 miles in length, and 75 in breadth; and abounds in all sorts of corn, wine, hemp, flax, rape-seed, game, and fish, with which it carries on trade, and in general all the necessaries of life. There are fine meadows and large forests, with mines of iron, flint, and copper, as also salt-pits. There are a great number of rivers; of which the principal are the Meuse or Meuto, the Moselle, the Seille, the Meure, and the Sarre. It is divided into three parts; the duchy of Lorraine, properly so called, which was herefore a sovereign state; the duchy of Barr, which formerly belonged to the dukes of Lorraine, but afterwards came under the government of France; and the third comprehends the three bishoprics of Metz, Toul, and Verdun, which have belonged to France ever since the year 1355. In 1733, the emperor of Germany being at war with France, this last got possession of the duchy of Lorraine; and when there was a peace made in 1735, it was agreed, that Stanislaus king of Poland, father-in-law to the king of France, should possess these dominions, and that after his death they should be united for ever to the crown of France. It was also then agreed, that Francis Stephen, duke of Lorraine, and the emperor's son-in-law, should have the grand duchy of Tuscany an equivalent for Lorraine. After the death of the great duke of Tuscany, in 1737, King Stanislaus and the duke of Lorraine took possession of their respective dominions, and the cession was confirmed and guaranteed by a treaty in 1738. The inhabitants are laborious and valiant, and their religion is the Roman Catholic. They have but little trade with strangers, because they have no navigable rivers, and because they have all necessaries within themselves; but little trade they have consist of corn and linen cloth. Nancy is the capital town.

LORRAIN (Robert), an eminent sculptor, born at Paris in 1666. From his infancy, he made so rapid a progress in the art of designing, that at the age of 18 the celebrated Girardon intrusted him with the care of teaching his children and correcting his disciples. He committed to him also, in composition, the tomb of Noullemon, the execution of the famous tomb of Cardinal Richelieu in the Sorbonne, and his own tomb at St. Landres in Paris. On his return from Rome, he finished several pieces at Marcielles, which had been left imperfect by the death of Mr. Puget. He was received into the academy of Sculpture in 1701. His chief d'œuvre is Galatea, a work universally admired. Lorrain afterwards made a Bacchus for the gardens at Versailles, a Faun for those of Marly; and several bronzes, among which is an Andromeda; all in an excellent taste. This artist succeeded chiefly in heads; and more particularly in that of young girls, which he performed with incomparable delicacy and truth.

LOTHIAN (Robert), See Claude.

LOTEN (John), a good landscape painter of the English school; though a native of Switzerland. His taste led him to solemn and dreary scenes, as landscapes accompanied with flowers of rain, &c. and he seldom omitted to introduce oak-trees in his prospects: his landscapes are generally large; and he painted with nature, truth, and force. But the effect of his composition had been much greater if he had been less cold in his colouring: for the judicious eye is not pleased with the darkish tint that predominates in it. He died in London about 1681.

LOT, a name given to three counties of Scotland, viz. Haddington-shire, Edinburgh-shire, and Linlithgow-shire; otherwise called East, Mid, and West Lothians.

1. East Lothian, or Haddington-shire, is bounded on the north-west by the Frith of Forth; and on the east by the German Sea; on the south-east by Berwickshire; and on the west by the county of Edinburgh. It extends about 25 miles from east to west, and where broadest, nearly 15 from north to south. The coast, advancing northward into the Frith, forms an irregular curve.—This is one of the most fruitful counties in Scotland, producing great quantities, of wheat and all sorts of grain, well-watered, and plentifully supplied with fish, fuel, and all the necessaries of life. It abounds with towns, villages, and farms, intersected with a great number of agreeable houses belonging to persons of rank and fortune. For cultivation, populousness, and fertility, this shire may vie with any tract of land in the island of Great Britain. Over and above the farming, which turns out to great account, the people towards the sea-coast employ themselves in the filhery, salt-making, and in foreign trade; and some of the more inland inhabitants engage in the linen and woollen manufactures. Lime-fl ())1 and coal are found in most parts of the country, and great numbers of sheep are fed on the hills of Lammermuir.

2. Edinburgh-shire, or Mid-Lothian, is about 35 miles long, but varies in its breadth in different places from five to 16 miles. It is bounded on the east by Haddington-shire; on the west by the shire of Linlithgow; on the south, by Tweeddale or Peebles-shire; and on the north, by part of West-Lothian and the Frith of Forth. The aspect of the county is in general level andpleasant, intersected with a few hills, that help to exhibit agreeable prospects. It is well watered with rivers, and laden with woods. It produces plenty of coal, lime-stone, a soft black marble, and some copper-ore. The soil, of itself fertile, is finely cultivated, and yields as plentiful harvests of excellent wheat as are found in any part of Great Britain. The whole shire is intersected with noble houses and plantations, belonging to noblemen and gentlemen of fortune. The farmers are masters of the sciences of agriculture; and wealthy in consequence of their skill, some of them paying 500 l. of yearly rent. The country is well inhabited, and prefers us with a good number of towns and populous villages. Along the sea-coast the common people subsist by fishing, and traffic in coals and salt, and some few carry on a smuggling commerce. Those in the inland are employed in farming, and some branches of the weaving manufacture. The fertility of this shire is in the gift of the crown; and Edinburgh is a county in itself.

3. The shire of Linlithgow, or West Lothian, is bounded on the north by the Frith of Forth. The small river Almond divides it from Edinburghshire on the east. On the south-west it joins the county of Lanark; and on the west it is parted from Stirlingshire by Avon, a small river. Its form, though irregular,
LOT [297]

L O T

regular, approaches to a parallelogram. It measures from north-east to south-west, nearly 20 miles. Its breadth, except on the shore of the Frith, does not exceed 12. — The country is pleasant and fertile, abounding with corn and pasturage. Here is found plenty of coal, limestone and lead ore; nay, in the reign of James VI. it produced a rich mine of silver.

LOTION, is, strictly speaking, such washing as concerns beautifying the skin, by cleansing it of those deformities which a disfigured blood throws upon it. Medicines of this kind, however, are for the most part insigificant, and sometimes very dangerous; the only proper method of treating these disorders is, by administering such medicines as tend to correct the morbid state of the constitution from whence they arise.

Lotion, in pharmacy, denotes a preparation of medicines, by washing them in some liquid, either made very light, so as to take away only the dregs; or harsh, so as to penetrate them, in order to clear them of some fat, or corrotive spirit as is done to antimony, precipitates, magisterics, &c. or intended to take away some foulness or ill quality, or to communicate some good one.

LOTAPHAGI (anc. geog.), a people of the Regio Syrica (loc'd from their living on the lotus); inhabiting between the two Syretes, from the Cinnyphus to Triton. The lotus was said to be a food gain'd by the prince of Trinacria, and a dish served by* Antoninus. 

LOTTERY, a kind of public game at hazard, frequent in Britain, France, and Holland, in order to raise money for the service of the state; being appointed in Britain by the authority of parliament, and managed by commissioners appointed by the lords of the treasury for that purpose. It consists of several numbers of blanks and prizes, which are drawn out of wheels, one of which contains the numbers, and the other the corresponding blanks or prizes.

The Romans invented lotteries to enrich their Saturnalia. This festival began by the distribution of tickets which gained some prize. Augustus made lotteries which consisted of things of little value; but Nero established some for the people, in which 1000 tickets were distributed daily, and several of those who were favoured by Fortune got rich by them. Heliodorus invented some very singular: the prizes were either of great value or of none at all; one gained a prize of six flaves, and another of six flies; some got valuable vases, and others vases of common earth. A lottery of this kind exhibited an excellent picture of the inequality with which Fortune distributes her favours.

The first English lottery we find mentioned in history was drawn A. D. 1569. It consisted of 40,000 lots, at 10s. each lot: the prizes were plate; and the profits were to go towards repairing the havens of the kingdom. It was drawn at the west door of St Paul's cathedral. The drawing began on the 11th of January 1562, and continued incessantly drawing, day and night, till the 6th of May following; as Maitland from Stowe, informs us in his History, Vol. I. p. 237. There were then only three lottery-offices in London. The proposals for this lottery were published in the years 1567 and 1568. It was at first intended to have been drawn at the house of Mr Derick, her majesty's servant (i.e. her jeweler), but was afterwards drawn as abovementioned.

Dr Rawlinson showed the Antiquary Society, 1748, "A Proposal for a very rich lottery, general without any blanks, containing a great number of good prizes as well as of redy money as of plate and certain forts of merchandizes, having been valued and priced by the commandment of the queen's most excellent majesties order, to the extent that such commodities as may chance to arise thereof after the charges borne may be converted towards the reparations of the havens and the strength of the realme, and towards such other public good works. The number of lots shall be four hundred thousand, and no more; and every lot shall be the sum of tenne shillings sterling, and no more. To be filled by the feast of St Bartholomew. The four of prizes are to be seen in Cheapside at the sign of the Queen's Armes, the house of Mr Derick, goldsmith, servant to the queen. Some other orders about it in 1567-8. Printed by Hen. Byromsman." In the year 1612, king James, in special favour for the present plantation of English colonies in Virginia, granted a lottery, to be held at the west end of St Paul's; whereof one Thomas Sharpless, a taylor of London, had the chief prize, which was 4000 crowns in fair place." Baker's Chronicle.

In the reign of queen Anne, it was thought necessary to suppress lotteries, as nuisances to the public. Since that time, however, they have been licenced by an act of parliament, under various regulations. The act passed in 1776 restrains any person from keeping an office for the sale of tickets, shares, or chances, or for buying, selling, infuring, or registering, without a licence; for which licence each office-keeper must pay 51. to continue in force for one year, and the produce to be applied towards defraying the expenses of the lottery. And no person is allowed to sell any share or chance less than a sixteenth, on the penalty of 51. All tickets divided into shares or chances are to be deposited in an office, to be established in London by the commissioners of the treasury, who are to appoint a person to conduct the business thereof; and all shares are to be stamped with the name of the office, who is to give a receipt for every ticket deposited with him. The number of all tickets so deposited are to be entered in a book, with the names of the owners, and the number of shares into which they are divided; and two pence for each share is to be paid to the officer on depositing such tickets, who is therewith to pay all expences incident to the office. All tickets deposited in the office are to remain there three days after the drawing. And any person keeping an office, or selling shares, or who shall publish any scheme for receiving monies in consideration of any interest, to be granted in any ticket in the said lottery, &c., without being in possessi on of such ticket, shall forfeit 500l. and suffer three months imprisonment. And no business is to be transacted at any of the offices after eight in the evening, except on the evening of the Saturday preceding the drawing. No person is to keep any office for the sale of tickets, &c. in Oxford or Cambridge, on penalty of 20l. Before this regulating statute took place, there were upwards of 400 lottery offices in and about London only; but the whole number afterwards, for all Britain, as appeared by the list published by authority, amounted to no more than 51.
LOTUS, or bird's-foot trefoil, in botany: A

lotus

LOTUS, or bird's-foot trefoil, in botany: A
genus of the decandria order, belonging to the diadel-
phia class of plants; and in the natural method rank-
ing under the 32d order, Papilionaceae. The legumen
is cylindrical, and very erect; the ale closing upwards
longitudinally; the calyx is tubulated. There are
many species, but only five or six are usually cul-
tivated in our gardens. 1. The trigonolobus, or wing-
ed pea, hath trailing, slender, branchy stalks, about
a foot long, garnished with trifoliate oval leaves; and,
from the axils of the branches, large, papilionaceous
red flowers, one on each footstalk; succeeded by tri-
gonous solitary pods, having a membranous wing or
lobe, running longitudinally at each corner. It flowers
in June and July, and the seeds ripen in autumn.

2. The cretica, or Creten silvery lotus, hath a flender
under shrubby stalk, rising by support three or four
feet high, ornamented with trifoliate bright, silvery
leaves; and branches terminated by several yellow
flowers succeeded by subternate pods. 3. The Jaco-
baeus, or lotus of St James's island, hath upright her-
bacous stalks branching two or three feet high, and,
from the upper part of the branches, long slender
footstalks, terminated each by three to five yellowish
purple flowers, appearing most part of the summer and
autumn, and succeeded by subternate pods filled with
plenty of seeds. 4. The hirsutus, or hairy Italian lo-
tus, hath upright hairy stalks branching a yard high;
and terminated by heads of whitish hoary-cupped flowers
appearing in June, which are succeeded by oval pods
full of seed, which ripen in autumn. 5. The dory-
cnium, white Austrian lotus, or shrub-trefoil of Mont-
pelier, has under shrubby smooth stalks, branching three
or four feet high, and the branches terminated by
aphylous heads of small white flowers appearing in
June, succeeded by short pods. 6. The edulis, sends
forth several trailing stalks about a foot long, furnished
at their joints with trifoliate, roundish, smooth leaves,
having oval stipules. The flowers come singly from
the sides of the stalks, on long peduncles, with three
oval floral leaves, the length of the flower: the latter
is small, yellow; and is succeeded by a thick arched
pod, having a deep furrow on its outside.

Culture, &c. The first species is a hardy annual,
and is easily raised from seed joiny any time from the
mouth of February to May; the plants requiring no
other culture than to be kept free from weeds. It was
formerly cultivated as an excellent: for its young green
seed-pods may be dried and eat like peas, or in the
manner of kidney-beans. The other species may be
propagated either by seeds or cuttings, but require to
be kept in pots in the green-house during the winter-
seas. — The sixth species is an annual, and a native
of several parts of Italy, where the inhabitants eat the
young pods as we do kidney beans. The green pods of
the first species were formerly gathered in Scotland
and dried in the manner of kidney beans, and are used
so still in some of the northern counties of England;
but they are coarse, and not very agreeable to such as
have been accustomed to feed upon better fare.

LOTUS of Homer. See Diospyros.

Egyptian Lotus. See Nymphaea.

Libyan Lotus. See Rhamnus.

LOVAGE, in botany. See Ligusticum.

LOVE, in a large sense of the word denotes all
those affections of the pleasing kind which objects and
incidents raise in us; thus we are said to love not on-
ly intelligent agents of morally good dispositions, but
also sensual pleasures, riches, and honours.

Love, in its usual and more appropriate signification,
may be defined, "that affection which, being com-
ounded of animal desire, esteem, and benevolence,
becomes the bond of attachment and union between in-
dividuals of the different sexes; and makes them feel
in the society of each other a species of happiness
which they experience no where else." We call it an af-
fession rather than a passion, because it involves a desire
of the happiness of object: And that its constituent
parts are these which have been just enumerated, we
shall first endeavour to prove, and then proceed to
trace its rise and progress from a selfish appetite to a
generous sentiment.

Animal desire is the actual energy of the sensual
appetite: and that it is an essential part of the complex
affection, which is properly called love, is apparent
from this consideration, that though a man may have
sentiments of esteem and benevolence towards women
who are both old and ugly, he never supposes himself
to be in love of any woman, to whom he feels not the
sensual appetite to have a stronger tendency than to
other individuals of her sex. On the other hand,
that animal desire alone cannot be called the affection of
love is evident; because he who gratifies such a desire
without esteeming its object, and wishing to communi-
cate at the same time that he receives enjoyment, loves not
the woman, but himself. Mere animal desire has nothing
in view but the species and the sex of its object; and
before it make a feclusion, it must be combined with
sentiments very different from itself. The first sen-
timent with which it is combined, and by which a man
is induced to prefer one woman to another, seems to
be that by which we are delighted with graces, such as
person, regularity of features, and beauty of comple-
xion. It is not indeed to be denied that there is
something irresistible in female beauty. The most fe-
vere will not pretend, that they do not feel an im-
mediate prepossession, in favour of a handsome woman;
but this prepossession even when combined with an-
imal desire, does not constitute the whole of that af-
fection which is called love. Savages feel the influ-
ence of the sensual appetite, and it is extremely prob-
able that they have some ideas of beauty; but among
savages the affection of love is seldom felt. Even among
the lower orders in civil society it seems to be a very
great passion, and to have in it more of the selfishness of
appetite than of the generosity of esteem. To these ob-
servations many exceptions will no doubt be found (A);
but we speak of savages in general, and of the great
body of the labouring poor, who in the choice of their
mates do not study—who indeed are incapable of stu-
(1) Such as the negroes whose story is so pathetically told by Addison in No. 215 of the Spectator; the
two lovers who were killed by lightning at Stanton Harcourt, August 9th, 1718, (see Pope's Letters); and
many others which will occur to every reader.
Love

Love is the sentiment without which neither man nor woman can live. In the savage state, and even in the first stages of refinement, the bond of union between the sexes seems to consist of nothing more than mere animal desire and instinctive tenderness for their infant progeny. The former impels them to unite for the propagation of the species; and the latter preserves the union till the children, who are the fruit of it, be able to provide for their own subsistence. That in such unions, whether casual or permanent, there is no mutual esteem and benevolence, is apparent from the state of subjection in which women are held in rude and uncultivated nations, as well as from the manner in which marriages are in such nations contracted.

Sweetness of temper, a capital article in the female character, displays itself externally in mild looks and gentle manners, and is the first and perhaps the most powerful inducement to love in a cultivated mind. "But such graces (says an ingenious writer*) are scarce discernible in a female savage; and even in the most polished woman would not be perceived by a male savage. Among savages, strength and boldness are the only valuable qualities. In these, females are miserably deficient; for which reason they are contemned by the males as beings of an inferior order. Memoirs threatened to rob him of his favourite female in the marriage, which prevailed universally among nations emerging from the savage state, or in the rudest stage of society: and wherever it prevailed, men could not possibly have for the fair sex any of that tender regard and esteem which constitute so essential a part of the complex affection of love.

Accordingly we find the magnanimous Achilles an absolute stranger to that generous affection, though his heart was susceptible of the warmest and purest friendship. His attachment to Patroclus was so heroically disinterested, that he willingly sacrificed his own life to revenge the death of his friend; but when Agamemnon threatened to rob him of his favourite female captive, though he felt the insult offered to his pride, he never spoke of the woman as a woman, but as a slave whom he was coerced to prefer to in point of honour, and as a testimony of his glory. Hence it is that we never hear him mention her but as his spoil, the reward of war, or the gift which the Grecians gave him.

"And dar'st thou threaten to snatch my prize away,
Due to the deeds of many a dreadful day?
A prize as small, O tyrant! match'd with thine,
As thy own actions if compar'd with mine.
Thine in each conquest is the wealthy prey,
Thee mine the sweat and danger of the day.
Some trivial present to my lips I bear,
Or barren praises pay the wounds of war."

And again, after upbraiding the general with his tyranny and want of regard for merit, he adds, with the greatest indifference to the charms of the woman,

"Seize on Briseis, whom the Grecians deem'd
My prize of war, yet tamely see retain'd.
And seize secure; no more Achilles draws
His conquering sword in any woman's cause,
The gods command me to forgive thepast;
But let this first insult be the last.
For know, thy blood, when now dar'st invite,
Shall stream in vengeance on my reeking blade."

Pope made the language of this rough warrior less inflammatory and purely natural to an injured lover than it is in the original (a); but from p. 2.

(a) The original passages are:

And, Alle, de τω ξώια, τον τε φιλεῖ θάλασσαν αὐτός.

καὶ ἔδω τις γράφεις αὐτῷ συνεκεπέθησεν αὐτῷ,

τινί ἐπείδ' ἐμερόνεσκεν, ὥσπερ ἐν τοῖς ἀρχαῖοι.

οὐ μὴ κατ' οὓς ὑπάρχει, ὡς εἴρηκα τοῖς Ἀρχαῖοι.

τῶν εὔπορων παραδίδοντος τοῦ θυγατέρου.

Ἀλλ' ἐπὶ τὸν κόσμον πολίτες τελείωσεν.

χρείας ἐκεί πέπεθεν ἀνὴρ ὅτι δὲν ἐπιρρέας ἐκείνῳ.

καί τὸ γράφειν έκτὸς μενούς, θῶς ὑπ' ὑπήρχε τὸ σόλος τι.

ἀπράξια ἡ τοις ἐκείνοις προσκεκλήθη ἁπατάτη.

It is, Lib. 1.

And, Alle de τε φιλέω, τον τε φιλεῖ θάλασσαν αὐτός.

καὶ ἔδω τις γράφεις αὐτῷ συνεκεπέθησεν αὐτῷ,

τινί ἐπείδ' ἐμερόνεσκεν, ὥσπερ ἐν τοῖς ἀρχαῖοι.

οὐ μὴ κατ' οὓς ὑπάρχει, ὡς εἴρηκα τοῖς Ἀρχαῖοι.

τῶν εὔπορων παραδίδοντος τοῦ θυγατέρου.

Ἀλλ' ἐπὶ τὸν κόσμον πολίτες τελείωσεν.

χρείας ἐκεί πέπεθεν ἀνὴρ ὅτι δὲν ἐπιρρέας ἐκείνῳ.

καί τὸ γράφειν έκτὸς μενούς, θῶς ὑπ' ὑπήρχε τὸ σόλος τι.

ἀπράξια ἡ τοις ἐκείνοις προσκεκλήθη ἁπατάτη.

In this latter passage the hero says expressly, "I will not fight with you or with any other man for the sake of a girl; but you shall not rob me of any other part of my property." which it fairly the language of a man to whom heart love must have been an utter stranger.
the last quoted passage, even as translated by him, it is apparent that Achilles would have been equally hurt had Agamemnon threatened to deprive him of any other part of his plunder. Accordingly he yields up Briseis, not in grief for a mistress whom he loves, but in fulfèmets for an injury that is done him. Nor let it be imagined, that this coldness proceeded from the pride of the hero, which would not permit him to acknowledge his love of a captive. With the generous affection of love captives and princesses were equally incapable of inspiring him. He repeatedly affirmed indeed that he delighted in his fair Lyrian slave, but it was only as an instrument of sensual gratification; for as to every thing else in a woman, he was so totally indifferent, that he declared he would not, when he should be disposed to marry, give himself the trouble to make a choice, but leave the whole matter to his father.

"If heaven refuse me to my realms with life,"

"The rev'rend Pelus shall elect my wife." But this was said merely to enhance the value of the prize, which for the public good he was about to resign; for that he was dear to him only as ministering to his pleasure, is past dispute from the language which he had previously held with her father, as well as from his requiring grateful Greece to pay a just equivalent, and to repair his private loss. A man who really loved would have thought nothing an equivalent for the object of his love; much less would he have intimated to her father a possibility of his dismissing from his embrace a woman whom he esteemed, when time should have robbed her of every youthful grace.

Since, then, it is so apparent, that in the heroic age of Greece even princes and kings were strangers to the generous affection of love, it needs not occasion much surprise that the same affection has very little influence upon mankind in the lowest ranks of the most polished societies of modern Europe. That this is actually the case, that among the generality of uneducated men and women there is no other bond of attachment than the sensual appetite, every year furnishes multiplied proofs. We daily see youths, rejected by their mistresses, paying their addresses without delay to girls who, in looks, temper, and disposition, are diametrically opposite to those whom so lately they pretended to love: We daily see maidens, flighted by their lovers, receiving the addresses of men, who, in nothing but their sex, resemble those to whom a week before they wished to be married: and we believe it is not very uncommon to find a girl entertaining several lovers together, that if one or more of them should prove false, she may still have a chance not to be totally deferred. Did esteem and benevolence, placed on manners and character, constitute any part of vulgar love, these people would act very differently; for they would find it impossible to change their lovers and their mistresses with the same ease that they change their cloaths.

To this account of love, as it appears in savage nations, some one may perhaps oppose the paintings of the softer passions in the poems of Ossian. That bard describes the female character as commanding respect and esteem, and the Caledonian heroes as cherishing for their mistresses a flame so pure and elevated as never was surpassed, and has seldom been equalled, in those ages which we commonly call most enlightened. This is indeed true: and it is one of the many reasons which have induced Johnson and others to pronounce the whole a modern fiction. Into that debate we do not enter. We may admit the authenticity of the poems, without acknowledging that they furnish any exception to our general theory. They furnish indeed in the manners in which they describe a wonderful anomaly in the general history of man. All other nations of which we read were in the hunter-state savage and cruel. The Caledonians, as exhibited by Ossian, are gentle and magnanimous. The heroes of Homer fought for plunder, and felt no clemency for a vanquished foe. The heroes of Ossian fought for fame; and when their enemies were subdued, they took them to their bosoms. The first of Greeks committed a mean infult on the dead body of the first of Trojans. Among the Caledonians infults offered to the dead, as well as cruelty to the living, were condemned as infamous. The heroes of Ossian appear in no instance as savages. How they came to be polished and refined before they were acquainted with agriculture and the most useful arts of life, it is not our business to enquire; but suffice it to say, they unquestionably were so, in the treatment of the female sex, instead of oppressing, confirms our theory; for we never conceived rich cloaths, superb houses, highly-dressed food, or even the knowledge of foreign tongues, to be necessary to the acquisition of a generous sentiment. Luxury indeed appears to be as imical to love as barbarism: and we believe, that in modern nations the tender and exalted affection which devolves that name is as little known amongst the highest orders of life as among the lowest. Perhaps the Caledonian ladies of Ossian resembled in their manners the German ladies of Tactius, who accompanied their husbands to the chase, who fought by their side, who gave them all for their beauty, and partook with them of every danger. If so, they could not fail to be respected by a race of heroes among whom courage took place of all other virtues: and this single circumstance, from whatever cause it might proceed, will sufficiently account for the estima­tion of the female character among the ancient Germans and Caledonians, so different from that in which it has been held in almost every other barbarous nation.

But if among savages and the vulgar, love be unknown, it cannot possibly be an instinctive affection: and therefore it may be asked, How it gets possession of the human heart; and by what means we can judge whether in any particular instance it be real or imaginary? These questions are of importance, and deserve to be fully answered, though many circumstances conspire to render it no easy task to give to them such answers as shall be perfectly satisfactory. Love can distinguish only between individuals of the different sexes. A man can hardly love two women at the same time;
and we believe that a woman is still less capable of loving at once more than one man. Love, therefore, has a natural tendency to make men and women pair, or, in other words, it is the source of marriage: but in polished Society, where alone this affection has any place, so many things besides mutual attachment are necessary to make the married life comfortable, that we rarely see young persons uniting from the impulse of love, and have therefore but few opportunities of tracing the rise, progress, and consequences of the affection. We shall, however, throw together such reflections as have occurred to us on the subject, not without indulging a hope, that they may be useful to the younger part of our readers when forming the most important connection in life.

We have said, that the perception of beauty, combined with animal desire, is the first inducement which a man can have to prefer one woman to another. It may be added, that elegance of figure, a placid masculine countenance, with a person which indicates strength and agility are the qualities which first tend to attach any woman to a particular man. Beauty has been defined †, "That particular form, which is the most common of all particular forms to be met with in the same species of beings." Let us apply this definition to our own species, and try, by means of it, to ascertain what constitutes the beauty of the human face. It is evident, that of countenances we find a number almost infinite of different forms, of which forms one only constitutes the beauty, whilst the rest, however numerous, constitute what is not beauty, but deformity, or ugliness. To an attentive observer, however, it is evident, that of the numerous particular forms of ugliness, there is not one which includes so many faces as are formed after that particular cast which constitutes beauty. Every particular species of the animal as well as of the vegetable creation, may be said to have a fixed or determinate form, to which, as to a centre, nature is continually inclining. It may be compared to pendulums vibrating in different directions over one central point; and as they all cross the centre, though only ones pass through any other point; so it will be found that perfect beauty is oftener produced by nature than deformity; we do not mean that deformity is greater than any one kind and degree of deformity. To instance in a particular part of a human feature: the line which forms the ridge of the nose is deemed beautiful when it is straight; but this is likewise the central form, which is oftener found than any one particular degree of convex, convex, or any other irregular form that shall be proposed. As we are then more accustomed to beauty than deformity, we may conclude that to be the reason why we approve and admire it, just as we approve and admire fashions of dres of for no other reason than that we are used to them. The same thing may be said of colour as of form: it is custom alone which determines our preference of the colour of the European to that of the Ethiopian, and which makes them prefer their own colour to ours: so that though habit and custom cannot be the cause of beauty (see Beauty), they are certainly the cause of our liking it.

That we do like it cannot be denied. Every one is conscious of a pleasing emotion when contemplating beauty either in man or woman; and when that pleasure is combined with the gratification of the sensual appetite, it is obvious that the sum of enjoyment must be greatly increased. The perception of beauty, therefore, necessarily directs the energy of the sensual appetities to a particular object, but still this combination is a mere selfish feeling, which regards its object only as the best of many similar instruments of pleasure. Before it can deserve the name of love, it must be combined with esteem, which is never bestowed but upon moral character and internal worth; for let a woman be ever so beautiful, and of course ever so desirable as an instrument of sensual gratification, if she be not possessed of the virtues and dispositions which are peculiar to her sex, she will inspire no man with a generous affection. With regard to the outlines, ind ed, whether of internal disposition or of external form, men and women are the same; but nature, intending them for mates, has given them dispositions, which, though concordant, are, however, different, so as to produce together delicious harmony. "The man more robust, is fitted for severe labour, and for field exercises; the woman, more delicate, is fitted for sedentary occupations, and particularly for nursing children. The man bold and vigorous, is qualified for being a protector ‡; the woman, delicate and timid, requires protection. Hence it is, that a man never admires a woman for possessing bodily strength or personal courage; and women always despise men who are totally destitute of these qualities. The man, as protector, is directed by nature to govern; the woman, conscious of inferiority, is disposed to obey. Their intellectual powers correspond to the definition of nature: Men have penetration and solid judgment to fit them for governing; women have sufficient understanding to make a decent figure under good government: a greater proportion would excite dangerous rivalry between the sexes, which nature has avoided by giving them different talents. Women have more imagination and sensibility than men, which make all their enjoyment more exquisite; at the same time that they are better qualified to communicate enjoyment. Add another capital difference of disposition: the gentle and ingenuous manners of the female sex tend to soften the roughness of the other sex; and wherever women are indulged with any freedom, they are more gentle than men. "These are not the only particulars that differ in the sexes. With respect to the ultimate end of love, it is the privilege of the male, as superior and protector, to make a choice: the female, preferred, has no privilege but barely to content or to refuse. Whether this distinction be the immediate result of the originally different dispositions of the sexes, or only the effect of associations inevitably formed, may be questioned; but among all nations it is the practice for men to court, and for women to be courted; and were the most beautiful woman on earth to invert this practice, she would forfeit the esteem, however by her external grace she might excite the desire, of the man whom she addressed. The great moral virtues which may be comprehended under the general term integrity, are all absolutely necessary to make either men or women estimable; but to procure esteem to the female character, the modestly peculiar to their sex is a very essential circumstance. Nature hath provided them with it as a defence against the artful solicitations of the other.
A woman, therefore, whose dispositions are gentle, delicate, and rather timid than bold, who is possessed of a large share of sensibility and modesty, and whose manners are soft and inimitable, must, upon moral principles (See Moral Philosophy), command the esteem and benevolence of every individual of the other sex who is possessed of sound understanding; but if her perfections be deformed, or not such as to excite some degree of animal desire, she will attract no man's love. In like manner, a man whose moral character is good, whose understanding is acute, and whose conversation is instructive, must command the esteem of every sensible and virtuous woman; but if his figure be disagreeable, his manners unpolished, his habits slovenly, and above all, if he be deficient in personal courage, he will hardly excite desire in the female breast. It is only when the qualities which command esteem are, in the same person, united with those which excite desire, that the individual so accomplished can be an object of love to one of the other sex; but when these qualities are thus united, each of them increases the other in the imagination of the lover. The beauty of his mistress gives her, in his apprehension, a greater promise of happiness, than perhaps she really desires; whilst his perfections of her internal worth makes him, on the other hand, apprehend her beauty to be absolutely unrivalled.

To this theory an objection readily offers itself, which it is incumbent upon us to obviate. Men and women sometimes fall in love at a first sight, and very often before they have opportunities of forming a just estimate of each other's moral character: how is this circumstance to be reconciled with the progressive generation of love? We answer, By an association of ideas which is formed upon principles of physiognomy. Every passion and habitual disposition of mind gives a particular cast to the countenance, and is apt to discover itself in some feature of the face. This we learn by experience; and in time, without any effort of our own, the idea of each particular cast of countenance comes to be so closely associated in our minds with the internal disposition which it indicates, that the one can never afterwards be presented to our view without instantly suggesting the other to the imagination. (See Metaphysics and Physiognomy). Hence it is that every man, who has been accustomed to make observations, naturally forms to himself, from the features and lineaments of a stranger's face, some opinion of his character and fortune. We are no sooner presented to a person for the first time, than we are immediately impressed with the idea of a proud, a revered, an affable, or a good-natured man; and upon our going into a company of absolute strangers, our benevolence or aversion, our awe or contempt, rises instantly towards particular persons, before we have heard them speak a word, or know so much as their names or denigrations. The same thing happens when we are presented to the fair sex. If a woman, for the first time, have that particular cast of countenance, and that expression of features, to which we have associated notions gentle, modest, and other female virtues, the instantly commands our esteem; and if she have likewise to much beauty as to make her an object of particular desire, esteem and desire become suddenly combined; and that combination constitutes the affection of love. Such, too, is the nature of all mental associations, that each part of which they are composed adds strength and vividness to the other parts; so that, in the present instance, desire makes us imagine virtues in the woman which her countenance perhaps does not indicate; and the virtues which are there actually visible, make us apprehend her beauty as more perfect than it is.

The affection thus generated is more or less pure, and will be more or less permanent, according as the one or the other part of which it is compounded predominates. Where desire of possession prevails over our esteem of the person and merits of the desirable object, love loses its benevolent character: the appetite for gratification becomes ungovernable, and tends violently to its end, regardless of the misery that must follow. In that state love is no longer a sweet agreeable affection; it becomes a selfish, painful passion, which, like hunger and thirst, produces no happiness but in the instant of fruition; and when fruition is over, disgust and aversion generally succeed to desire. On the other hand, where esteem, founded on a virtuous character and gentle manners, prevails over animal desire, the lover would not for the world gratify his appetite at the expense of his mistress's honour or peace of mind. He wishes, indeed, for enjoyment; and to him enjoyment is more exquisite than to the mere sensual lover, because it unites sentiment with the gratification of sense; at the same time that, by far from being succeeded by disgust or aversion, it increases his benevolence to the woman, whose character and manners he esteems, and who has contributed so much to his pleasure. Benevolence to an individual, having a general end, admits of acts without number and is seldom fully accomplished. Hence mutual love, which is composed chiefly of esteem and benevolence, can hardly be of a shorter duration than its objects. Frequent enjoyment endears such lovers to each other, and makes constancy a pleasure; and when the days of sensual enjoyment are over, esteem and benevolence will remain in the mind, making sweet, even in the old age, the society of that pair, in whom are collected the affections of husband, wife, lover, friend, the tenderest affections of human nature.

From the whole of this investigation, we think it appears, that the affection between the sexes which deferves the name of love, is inseparably connected with virtue and delicacy; that a man of loose morals cannot be a faithful or a generous lover; that in the breast of him who has ranged from woman to woman for the mere gratification of his sensual appetite desire must have effected all esteem for the female character; and that, therefore, the maxim too generally received, "that a reformed rake makes the best husband," has very seldom a chance to be true. We think it may likewise be inferred; that thousands fancy themselves in love who know not what love is, or how their affections are generated in the human breast: and therefore we beg leave to advise such of our readers as may imagine themselves to be in that state, to examine their own minds, with a view to discover, whether, if the objects of their love were old or ugly, they would still esteem them.
them for the virtues of their character, and the propriety of their manners. This is a question which
ought to be well weighed by the young and the amorous, who, in forming the matrimonial connection are
often blind to the pleasures of gratifying that desire is gone and if not refined by esteem and benevolence, goit must
with a swift pace), that a new bond of attachment may be formed upon more dignified and more lasting prin-
ciples; but this is a dangerous experiment. Even sup-
posing good fortune, good temper, and internal worth
of every fort, yet a new attachment upon such quali-
fications is rarely formed; because it commonly, or ra-
ther always, happens, that such qualifications, the only
solid foundation of an indissoluble connection, if they
did not originally make esteem preponderate over an-
imal desire, are afterwards rendered altogether invi-
bable by fatiey of enjoyment creating disgust."

Love, in medicine. The symptoms produced by
this passion as a disease, according to medical writers,
are as follows: The eye-lids often twinkle; the eyes
are hollow, and yet appear as full with pleasure;
the pulse is not peculiar to the passion, but the same
with that which attends solicitude and care. When
the object of this affection is thought of, particularly
in the idea is sudden, the spirits are confused, the pulse
changes, and its force and time are very variable; in
some instances, the person is sad and watchful; in oth-
ers, the person, not being conscious of his state,
pines away, is loath, and regardless of food, though
the wiser, when they find themselves in love, seek
pleasent company and active entertainments. As the
force of love prevails, sighs grow deeper; a tremor af-
fects the heart and pulse; the countenance is alter-
nately pale and red; the voice is suppressed in the
fauces, the eye grow dim; cold sweats break out; deep
abductions itself, at least until the morning; the secre-
tions become disturbed; and a loss of appetite, a hec-
tic fever, melancholy, or perhaps madness, if not
dead, constitutes the fatal catalepsy. On this sub-
ject the curious may consult Egineta, lib. iii. cap. 17.
Oribat. Synop. lib. viii. cap. 9. or a treatise proficul-
ously written on love, as a diatemper, by James Fer-
rard, Oxford, printed 1640.

The manner of the Greeks and Romans were simi-
lar to each other in the affairs of love. They gen-
erally made a discovery of their passion, by writing
upon trees, walls, doors, &c. the name of their be-
loved. They usually decked the door of their dulci-
nea with flowers and garlands, made libations of wine
before their houses, sprinkling the pofts with the same
liqueur, as if the object of their affection was a real
goddes. For a man’s garland to be untied, and for a
woman to compose a garland, were held to be in-
dubitable indications of their love.

When their love was without success, they used se-
veral arts to excite affection in the object of their de-
 sire. They had recourse to enchantresses, of whom
the Thessalian were in the highest estimation. The
means made use of were most commonly philtres or
love potions, the operation of which was violent and
dangerous, and frequently deprived such as drank them
of their reason. Some of the most remarkable ingre-
dients of which they were composed were these: the
hippopomans, the jynx, insects bred from purpae-
tation, the fig remora, the lizard, brains of a calf, the
hairs on the tip of a wolf’s tail, his secret parts, the
bones of the left side of a toad eaten with ants, the blood
of doves, bones of fisakes, feathers of ferich-ows,
twisted cords of wool in which a person had hanged
himself, rags, torches, reliquies, of swallows bu-
ried and famished in the earth, bones snatched from
hungry bitches, the marrow of a boy famished in the
midst of plenty, dried human liver; to these may be
added several herbs growing out of putrid substances.
Such were the ingredients that entered into the com-
poition of that infernal draught a love potion.

But, besides the philtres, various other arts were
used to excite love, in which the application of certain
substances was to have a magical influence on the per-
son against whom they levelled their skill. A hyaena’s
uder worn under the flat arm, they fancied would
draw the affections of whatever woman they fixed
their eyes upon. That species of olives called πινυτις,
and barley-straw made up into a paste, and thrown into
the fire, they thought would excite the flame of love.
Flower was used with the same intention. Burning
laural, and melting wax, were supposed to have the
like effect. When one heart was to be hardened, and
another mollified, clay and wax, were exposed to the
same fire together. Images of wax were frequently
used, representing the persons on whom they wished
to make an impression; and whatever was done to the
substitute of wax, they imagined was felt by the per-
son represented. Enchanted medicaments were often
sprinkled on some part of the house where the per-
son resided. Love-pledges were supposed to be of singu-
lar use and efficacy; these they placed under their
threshold, to preserve the affections of the owner from
warding. Love-knots were of singular power, and the
number three was particularly observed in all they
did. But no good effect was expected, if the use of
these things was not attended with charms or magical
verses and forms of words. See Magic.

Having mentioned their arts of exciting love, it
may not be amiss to take notice, that, the ancients ima-
gined, that love excited by magic might be allayed by
more powerful spells and medicaments, or by applying
to demons more powerful than those who had been
concerned in raising that passion. But love inspired
without magic had no cure; Apollo himself could find
no remedy, but cried out

He miki quad nilis amor cf medicabilis herbis.
The antidotes against love were generally anus caflus,
which has the power of weakening the generative fa-
culty; sprinkling the dust in which a mule had rolled
himself; tying threads in the hide of a beast newly slain;
applying annules of minerals or herbs, which were sup-
ppanied of great efficacy in other cases, and invoking
the assistance of the infernal deities. Another cure
for love was bathing in the waters of the river Selem-
nus; to which we may add the lover’s leap, or jump-
down from the Lacedian promontory.

Love-Apple. See SOLANUM.

LOVENTINUM, or LuENtinum, (anc. geog.)
a town of the Demetian Britain, near the mouth of
the Tauribus or Tivis. Supposed to have been after-
wards.
wards swallowed up by an earthquake, and to have
flood where is now the lake called Lin Swatan in
Brecknockshire.

LOUGHBOROUGH, a town of Leicestershire in
England, 110 miles from London. It is the sec-
tend town in the county, and was in the Saxons time
a royal village. Its market is on Thursday; and its
fairs are on April 25th, May 28th, August 1st, and
November 2d. It has a large church, and a free
school; besides a charity school for 80 boys and
another for 20 girls. It has been very much reduced
by fires; but is still a very agreeable town, with rich mea-
dow-ground, on the Fosse, which runs here almost
parallel with the river Soar. The New canal has made
the coal-trade here very extensive.

LOUGHBOROUGH, a fair and post town of
Ireland, situated in the county of Down, and province
of Ulster, 58 miles from Dublin. The name signi-
fies the lake of the speckled trouts; and it was so called
from a lake near it, which abounds with these fish. It
consists of one broad street, at the end of which is the
parish-church, said to have been built by Dr Taylor
when bishop of Dromore, soon after the Resur-
lation. The linen manufacture is carried on here very
extensively; and the town is a great thoroughfare,
the turnpike road from Dublin to Belfast passing
through a red bog near it. The fairs are five in the
year.

LOCH-DERGH, anciently Derg-abhan, i.e., "the
rivulet of the woody moras," from a river which issues
out of this lake. This loch is situated in the county
of Donegal and province of Ulster in Ireland, and is
famous for having in it the island that contains St
Patrick's purgatory, which is a narrow little cell,
hewn out of the solid rock, in which a man could
fearce stand upright.—There is also a lake of this
name situated between the counties of Galway and
Tipperary.

LOUCH-NEACH, a loch or lake of Ireland, sit-
tuated in the counties of Armagh, Down, Derry;
and Antrim, and province of Ulster. It is the largest
in Europe, the size of Ladoga and Onega in Russia, and
that of Geneva in Switzerland, excepted; being 20
miles long and 15 broad. The area of this lake is
computed to be 100,000 acres. It is remarkable
for a healing virtue; and likewise for petrifying wood,
which is not only found in the water, but in the ad-
Jacent soil at a considerable depth. On its shore
several beautiful gems have been discovered. Its
ancient name was Loch-sucha or Loch-Neach from loch,
"a lake," and Neach, "wonderful, divine, or emi-
inent." Its petrifying powers are not insconstant
as several of the ancients have supposed, but require a
long series of ages to bring them to perfection, and
appear to be occasioned by a fine mud or sand, which
infuscates itself into the pores of the wood, and which
in process of time becomes hard like bone. On the
borders of this lake is Slane's castle, the elegant seat
of the right honourable John O'Neil. Dr Smyth
seems to doubt whether the healing quality in this
lake is not to be confined to one side of it, called the
fishing bank; and he informs us, that this virtue was
discovered in the reign of Charles II, in the instance
of the son of one Mr Cunningham, who had an evil
which ran on him in eight or ten places; and notwith-
standing all applications seemed incurable, at length
he was perfectly healed, after bathing in this lough
about eight days. Hence that writer gives us another
imputation of the name Loch-Neach, which seems to hint at the quality Neagh or Near, in Irish,
signifying a fore or ulcer," which might not impro-
bly be corrupted into Neagh. Hence he apprehends
this lake was remarked at a much earlier period for
its healing property. As to its petrifying power, it
is mentioned by Nenius, a writer at the ninth century,
who says, "Eli clad flagnum quod facit ligna du-
resce in lapides. Homines autem findunt Iyria, et
post quam formaverunt, projequant in flagnum, et ma-
orient in eo uque ad caput anni, et in capite anni lapis
inventurus, et vocatur flagnum Loch-Euch." Lough-
Neach gives title of baron to the family of Struf-
ton.

LOUGH-STRANGFORD, a lake of Ireland,
situated in the county of Down and province of
Ulster. It takes its present name from a small port-
town called Strangford, seated on the west side of
the narrow entrance into the sea. It was formerly
known by the name Lough-Cone or Lough-Coyne. It is a
deep bay or inlet of the sea, about 17 miles long and
four or five broad; it goes as far as Downpatrick,
and north as far as Comber and Newtown, and by
computation covers 25,775 acres, Irish plantation
measure. It abounds with excellent fish, particularly
finches; and off the bar there is a peopled hering
fishery in or about August. The bar or entrance
into this lough is about three miles below Stra-
ngford. There is a long rock at the entrance in the
middle of the passage, dangerous to strangers on ac-
count of the current; yet there is a broad passage
on either side, and deep water. The current here is
very strong and rapid, running at the rate of six or seven
miles an hour. There are but few vessels that go
higher up than Strangford. A good many vessels
bound up the channel put in here, if the wind is un-
 favourable to their passage. The islands of this lake
are numerous; Doctor Boat enumerates them at 250.
But from an actual survey, made at the time Dr Smith
wrote his history of that country, it appears, there
are 54 islands small and large, known by different
names, and many others nameless; the contents of
these 54 islands added together amount to 954 acres
and an half. The great and profitable manufacture
carried on in these islands, and the flat sandy coasts
surrounding the lake, is the burning of sea-weed into
kelp, which employs a number of hands, and has been
computed to produce to the several proprietors a net
profit of 1000l. per annum and upwards. Four of
the islands here are called Swan Islands, from the num-
ber of swans that frequent them.

LOUIS, or Knights of St Louis, the name of a
military order in France, instituted by Louis XIV. in
1693. Their colors are of flame colour, and pales
from left to right: the king is their grand master.
There are in it eight great crosses, and 24 com-
manders; the number of knights is not limited. At
the time of their institution, the king charged his revenue
with a fund of 300,000 livres for the pensions of the
commanders and knights.

LOUIS, Lewis, Louis d'or, or Lewidore, a French
coin, first struck in 1640, under the reign of Louis
XIII. and which has now a considerable currency.
See Money-Table.

LOUISIANA,
LOUISIANA, a country in North-America, bounded on the south by the gulf of Mexico, on the east by the river Mississippi, on the west by New Mexico, and on the north by an unknown country. It extends from the 29th to the 40th degree of north latitude, and from about the 80th to the 96th or 97th degree west longitude from London. The climate of Louisiana varies according to the latitudes. The southern parts are not so hot as those parts of Africa which lie under the same parallel, and the northern parts are colder than the countries of Europe at the same distance from the pole; the causses of which are supposed to be the thick forests which over-run the country, and the great number of rivers; the former preventing the sun from heating the earth, and the latter supplying it with moist vapours: besides the cold winds which come from the north over vast tracks of land. They have bad weather but it never lasts long, for the rain generally falls in storms and sudden showers; the air is wholesome, the inhabitants healthy, and they who are temperate live to a great old age. The country is extremely well watered; and almost all the rivers that run through it fall into the Mississippi, which discharges itself into the Gulf of Florida.

LOUSE, in zoology. See Pediculus and Lice. LOUSY DISEASE. See Medicine-Index.

LOUTH, a town of Lincolnshire in England, 156 miles from London. It is a town corporate; and one of the handsomest and gayest in the county, there being in it not only frequent assemblies, concerts, &c. but even masquerades. Here are several handsome houses. From hence there is a canal to the sea at Tilney, about eight miles. Besides a charity school for 40 children, it has a free school founded by Edward VI. with a large church, and a fine steeple, which some think is as high as Grantham spire which is 288 feet high. Its markets are on Wednesday and Saturday, and its fairs on May 24th, and August 16th.

LOUTH, a county in the eastern part of Ireland, which extends in the form of a bow or half-moon, on the side of the ocean, being much longer than it is broad; it is bounded on the south and west by the county of East-Meath, on the north-west by Monaghan, on the north by Armagh, and on the north-east by the bay of Carlingford, which parts it from the county of Down; it is washed by several small rivers which fall into the sea; and its four frontiers are watered by the river Boyne. Its chief towns are Dundalk and Carlingford; unless we include Drogheda, a part whereof is in this county. It is the smallest county in the kingdom but very fertile and pleasant and abounding with many remains of antiquities, of which Mr Wright, in his Louthian, has given a very ample description. It contains 111,180 Irish plantation acres, 50 parishes, 5 baronies, and 5 boroughs, and returns to members to parliament; it is about 22 miles long and 14 broad.

LOUTH, a town in the above county, having a yearly fair.

LOUVAIN, a city in the Austrian Netherlands, in the province of Brabant, pleasantly seated on the river Dyle, in a plentiful and agreeable country. The walls are about eight or nine miles in circumference; but they include several fields and vineyards. The castle stands on a high hill, surrounded with fine gardens, and has a charming prospect all over the country. This town contains nine market places, 14 water-mills, 126 streets, 16 stone bridges, and several handsome palaces. The town-house is a venerable old building, adorned with statues on the outside; and the churches are very handsome, particularly the collegiate church of St Peter, but the principal ornament is the university, founded only in 1426 by John IV. duke of Brabant, with the concurrence of Pope Martin V. It contains about 40 colleges, four of which are called Pedegren. There is in the number also an English college of friars, preachers, which owes its establishment to the liberality of Cardinal Philip Howard, brother to the duke of Norfolk, who, before he was raised to the purple, had been private chaplain to Queen Catherine, con­ fort to Charles II. The Irish have likewise a seminary, erected in part under the care of Engenius Mathes, titular archbishop of Dublin, anno 1622, which receives its appointments from the propaganda at Rome. Besides the above, there are two colleges for the Irish, one of Recollects and the other of Dominicans, where divinity and the Mathesia are taught. In the last century the number of scholars exceeded 3000, but in the year 1743 the inhabitants amounted to 12,000, including 2000 students only. At the beginning of the 14th century, under John III, it flourished considerably in the manufacture of woollen cloth: 400 houses were then occupied by substantial clothiers, who gave employment to an incredible number of weavers, but great loss is said, that it was ruinous by the injuries which the children in the streets might receive from the crowd and hurry of their returning from work. In 1382, these weavers, however, took up arms, and rebelled against their sovereign Prince Wenceslaus, throwing from the windows of the Town-hall of the aldermen and councillors; and afterwards proceeded to lay waste great part of Brabant: but being besieged and reduced to great extremities, they submissively implored his clemency; which was granted after the execution of some of the principal ringleaders. The weavers, the chief instigators to this revolt, were banished, the greater part of whom took refuge in England; where they first introduced, or at least augmented very much, the woollen manufacture. The town, by this circumstance, being almost depopulated, the university was established to supply in some measure the loss of the rebellious clothiers. Since that time the manufacture gradually declined, no cloth of any account being made there at present. This impolitic step of the Duke Wenceslaus sent treasures to England, through the hands of those exiled people; an impolitic step to governors, that they should deal with great precaution respecting such useful members of the community. Upon the ruin of those looms was formed the cloth manufacture of Limbourg, which is carried on with good advantage to this day. There is yet flourishing at Louvain part of the old drapers-hall, now converted into four public schools, where lectures in divinity, philosophy, law, and physic, are given and the public acts are made. Adjoining to the schools is the university library, which altogether compose a large pile of buildings. Over the door of the chief entrance we read these words, Sapientia edificans ibi domum. The principal church is collegiate, dedicated to St
LOW [ 306 ]

LOW, or Louis (John), an engraver of considerable eminence, who flourished about the middle of the 17th century. According to Bannet, he was a native of Flanders. He learned the art of engraving from Peter Soumman, at the time that Eyderheof died under the fame master; and his usual style of engraving bears some resemblance to that of his master's. One of his best prayers is, Diana, with her nymphs, reposing after the chase; a muddling-sized plate, lengthwise from Rubens.

LOW-BELL, in birding, a name given to a bell, by means of which they take birds in the night, in open plains, and among rough, in October. The method is to go out about nine o'clock at night in a still evening, when the air is mild and the wind does not blow. The low-bell should be of a deep, hollow sound, and of such a size that a man may conveniently carry it in one hand. The person who carries it is to make it toll all the way he goes, as nearly as may be, in such manner in which the bell on the neck of a sheep tows as it goes on and feeds. There must also be a box made like a large lantern, about a foot square, and lined with tin, but with one side open. Two or three great lights are to be set in this; and the box is to be fixed on the person's breast, with the open side forwards, so that the light may be cast forward to a great distance. It will spread as it goes out of the box, and will naturally close on the person who carries the bell, no matter where it is. The birds are to be then caught in the slip or poach, and whichever bird any bird is seen at, to be taken, the person who is nearest is to lay his net over it, and take it with as little noise as possible. When the net is over the bird, the person who laid it is not to be in a hurry to take the bird, but must stay till he who carries the light is got beyond it, that the motions may not be discovered. The blaze of the light and the noise of the bell terrify and amaze the birds in such a manner that they remain still to be taken; but the people who are about the work must keep the greatest quiet and stillness that may be.

Some people are fond of going on this scheme alone. The person then fixes the light box to his breast and carries the bell in one hand and the net in the other; the net in this case may be somewhat smaller, and the handle shorter. When more than one are out at a time, it is always proper to carry a gun; as it is no uncommon thing to flay a hare when on this expedition.

LOW (East), a town of Cornwall in England, 231 miles from London, in the post-road from Plymouth. It is an ancient borough by prescription, made a corporation by charter of queen Elizabeth, consisting of nine burgesses (one of whom is yearly chosen the mayor), a recorder, aldermen, &c.; and the mayor, magistrates, and freemen, who are about 68, choose the members of parliament. This being a manor of the duchy of Cornwall, was settled by king William on lord Somers, and is now held by the corporation at the free-rent of 20s. a-year. It is feated pretty commodiously on a creek of the sea, over which there is a large stone bridge, supported by 15 arches, which leads to Well Low, standing between two hills. The chief benefit which the inhabitants have is in their fishery. Here is a battery of four guns, and a small chapel. Its market is on Saturday, and has two fairs in the year.

Low (Well), called also Port-Pigham, a town of Cornwall, divided from East Low by a stone bridge of 15 arches over the river Low, from whence both towns receive their name, as the river does from the lowness of its current between its high banks. The corporation, by charter of queen Elizabeth, consists of 12 burgesses, one of whom is annually chosen mayor, and, with the other burgesses, has power to choose a steward. Its members, whom it has sent to parliament ever since the 6th of Edward VI. are elected by the corporation and freemen, who are about 60. There was a chapel of ease here in the reign of Henry VIII. which was afterwards converted into a town-hall; and the town lying in the parish of Tolland, the people go thither to church. The market is on Saturday, and fair on April 25. There is a pretty little harbour here; near the mouth of which is a small island called St George's, which abounds with fish and pies. The river here is navigable for vessels of 1000 tons.

LOWELL Richard), an eminent English physician in the 17th century, was born in Cornwall, and educated at Westminster-School and Oxford. He entered on the physic line; and practiced under Dr Thomas Willis, whom he instructed in some parts of anatomy, especially when the latter was writing his Cerebri anatome. He, with Dr Willis, in 1674, discovered the medicinal waters at Athopin Northamptonshire, which, upon their recommendations, became very much frequented. In 1666 he followed Dr Willis to London; practiced physic under him; and became fellow of the royal society, and of the college of physicians. In 1609 he published his Tractatus de verde; and, after the death of Dr Willis in 1675, he was esteemed the most eminent physician in London. Upon the breaking out of the Popish plot in 1678, says Mr. Wood in his Athenae Oxonienses, he closed with the Whigs, supposing that party would carry all before them; but, being mistaken, he lost his credit and practice. He died in 1691.
LOW

LOWTH (William), D.D. a learned divine, born at London in 1661, was the son of an apothecary, and took his degrees at Oxford. His eminent worth and learning recommended him to Dr Mew bishop of the diocese of Durham, while he was in his chaplain, gave him two livings in his own province, and conferred on him a prebend in the cathedral of Winchester. He acquired an unusual share of critical learning. Thus situated in life, the labours of Mr Lowth appear to have been strictly confined within the limits of his own province, and applied solely to the peculiar duties of his own function: yet, in order that he might acquit himself the better in theology, he had purified his studies with a more general and extensive view. Few were more deeply verfied in critical learning; there being fearcely any ancient author, Greek or Latin, profane or ecclesiastical, especially the latter, but what he had read with accuracy, confantly accompanied his reading with critical and philological remarks. Of his collections in this way he was upon all occasions very communicative. Hence his notes on Clemens Alexandrinus, which are to be met with in Potter's edition of that author. Hence his remarks on Josephus, communicated to HUDSON for his edition, and acknowledged in the preface; as also those larger and more numerous annotations on the Ecclesiastical Historians, inserted in Reading's edition of them at Cambridge. The author of Bibliotheca Biblica was indebted to him for the same kind of assistance. Chandler, late bishop of Durham, while engaged in his 'Defence of Christianity, from the Prophecies of the Old Testament,' against the Difficulties of the Grounds and Reasons of the Christian religion,' and in his 'Vindication of the Defence, in answer to the Scheme of Literal Prophecy considered,' held a constant correspondence with him, and confulted him upon many difficulties that occurred in the course of that work. The most valuable part of his character was that which least appeared in the eyes of the world, the private and retired part, that of the good Christian and the useful parish-priest. His piety, his diligence, his hospitality and beneficence, rendered his life highly exemplary, and greatly enforced his public exhortations.

He married Margaret, daughter of Robert Pitt, Esq., of Blandford, by whom he had two sons and three daughters. (See the next article.) He died in 1732, and was buried by his own orders in the churchyard at Birtton. He published, 1. A vindication of the divine authority and inspiration of the Old and New Testaments; 2. Directions for the profitable reading of the Holy Scripture; 3. Commentaries on the prophets and other works.

LOWTH (Robert), D.D. second son of the preceding Dr William Lowth, and bishop successively of St. David's, Oxford, and London was born on the 29th of November 1710, probably at Burton in the county of Hants. He received the rudiments of his education in Winchester college, where his school exercises were distinguished by uncommon elegance; and having resided the requisite number of years in that seminary, in 1730 he succeeded on the foundation at New College, Oxford. He took the degree of M. A. June 8, 1737. Though his abilities must have been known to those with whom he was connected, he was not forward to appear before the world as a writer. At Oxford he continued many years improving his talents, with little notice from the great, and with preferment so small as to have at present escaped the distinct recollection of some of his contemporaries.

He was not, however, suffered to languish for ever in obscurity. His genius and his learning forced themselves upon the notice of the illustrious society of which he was a member; and he was placed in a station where he was eminently qualified to shine. In 1741 he was elected by the university to the professorship of poetry, re-elected in 1743, and whilst he held that office he read his admirable lectures De faera post Hebraorum. In 1744 Bishop Hoadley collated him to the rectory of Ovington in the county of Hants; added to it, nine years afterwards, the rectory of East Wealdhay in the same county; and in the interim raised him to the dignity of archdeacon of Winchester. These repeated favours he some years afterwards acknowledged in the following manly and respectful terms of gratitude: "This address, My Lord, is not more necessary on account of the subject, than it is in respect of the author. Your Lordship unfomented and unasked, called him from one of those colleges to a station of the first dignity in your diocese, and took the earliest opportunity of accumulating your favour upon him, and adding to that dignity a suitable support. These obligations he is now the more ready thus publicly to acknowledge, as he is removed out of the reach of further favours of the like kind. And though he hath relinquished the advantages so generously conferred on him, yet he shall always esteem himself highly honoured in having once enjoyed the patronage of the great advocate of civil and religious liberty.""}

On the 8th of July 1754 the university of Oxford conferred upon him the degree of D. D. by diploma; an honour which, as it is never granted but to distinguished merit, was probably conferred on Mr Lowth in consequence of his prelections on the Hebrew poetry, which had then been lately published. Having in 1749 travelled with Lord George and Lord Frederick Cavendish, he had a claim upon the patronage of the
Devonshire family; and in 1755, the late Duke being then Lord Lieutenant of Ireland, Dr Lowth went to that kingdom as his grace's first chaplain. Soon after this appointment he was offered the Bishopric of Limerick; but preferring a less dignified station in his own country, he exchanged it with Dr Leslie, prebendary of Durham and rector of Segedfield, for these preferments. In November 1765 he was chosen F.R.S. In June 1766 he was, on the death of Dr Squire, preferred to the bishopric of St David's; which, in the October following, he resigned for that of Oxford, vacant by the translation of Bishop Hume to Salisbury. In April 1777, he was translated to the see of London, vacant by the death of Bishop Terrick; and in 1783 he declined the offer of the primacy of all England.

Having been long afflicted with the stone, and having long borne the severest sufferings of pain and sickness with the most exemplary fortitude and resignation, this great and good man died at Fulham Nov. 3, 1787; and on the 12th his remains were privately interred in a vault at Fulham church, near those of his predecessor. He had married in 1752, Mary, the daughter of Laurence Jackon of Christchurch, Hants, Esq; by whom he had two sons and five daughters. His lady and two children only survived him.

His literary character may be estimated from the value and the importance of his works, in the account of which we may begin with his Prelections on the Hebrew Poetry. The choice of so interesting a subject naturally attracted general attention, and the work has been read with equal applause abroad and at home. In these prelections the author has acquitted himself in the most masterly manner, as a poet, a critic, and a divine; and such is the classic purity of his Latin style, that though we have read the work with the closest attention, and with no other view than to discover, if possible, an Anglicism in the composition, we never found a single phrase to which, we believe, a critic of the Augustan age could possibly have objected. This is an excellence to which neither Milton nor Johnson has attained; to which indeed no other English writer of Latin with whom we are acquainted has attained, unless perhaps Atterbury must be excepted. To the prelections was subjoined a short compendium of bishop Hare's system of Hebrew metre: which occasioned a Latin letter from Dr Edwards of Clare-hall, Cambridge, to Dr Lowth, in vindication of the Harian metre. To this the author of the prelections replied in a larger compendium, in which bishop Hare's system is completely overthrown, and the fallacy upon which it was built accurately investigated. After much attentive consideration, bishop Lowth has pronounced the metre of the Hebrew to be perfectly irrecoverable.

In 1758 he published The Life of William of Wykeham, Bishop of Winchester, with a dedication to Bishop Hoadley, which involved him in a dispute concerning a decision which that bishop had lately made respecting the wardship of Winchester-college. This controversy was on both sides carried on with such abilities, that, though relating to a private concern, it was yet to be read, if not with pleasure at least with improvement. The life of Wykeham is drawn from the most authentic sources; and affords much information concerning the manners, and some of the public transactions of the period in which Wykeham lived, whilst it displays some private intelligence respecting the two literary societies of which he was the founder. In these two societies Dr Lowth was educated, and he gratefully expresses his obligations to them.

In 1762 was first published his Short Introduction to English Grammar, which has since gone through many editions. It was originally designed only for private and domestic use, but its judicious remarks being too valuable to be confined to a few, the book was given to the world; and the excellence of its method, which teaches what is right by showing what is wrong, has inferred public approbation and very general use. In 1765 Dr Lowth was engaged with bishop Warburton in a controversy, which made much noise at the time, which attracted the notice even of royalty, and of which the memory is still recent. If we do not wish to dwell on the particulars of this controversy, it is because violent literary contention is an evil, which though like other war it may sometimes be unavoidable, is yet always to be regretted; and because the characters of learned, ingenious, and amiable men, never appear to lefs advantage than under the form in which that state of hostility obliges them to assume. The two combattants indeed engaged with such unius- and ingenuity such as is seldom brought into conflict; but it appears that, in the opinion of Dr Johnfon, Warburton had the most scholastic learning, and that Lowth was the most correct scholar: that, in their contest with each other, neither of them had much argument, and that both were extremely abusive. We have heard, and we hope it is true, that they were afterwards reconciled, and expressed mutual regret for the violence of their past conduct.

In 1778 Bishop Lowth published his last great work, A Translation of Isaiah. To his literary and theological abilities, the translator joined the most critical knowledge of the character and spirit of the eastern poetry; and, accordingly, the prophecies of Isaiah (which, though almost always sublime or elegant, are yet sometimes obscure) were translated in a manner adequate to the highest expectations of the public. Several occasional discourses, which the Bishop, by his station, was at different times called upon to deliver, were of course published, and are all worthy of their excellent author; but there is one on the kingdom of God, on the exaltation and progressive improvement of Christ's religion and on the means of promoting these by the advancement of religious knowledge, by freedom of inquiry, by toleration, and mutual charity, which may be distinguished above the rest, as exhibiting a most comprehensive view of the successive states of the Christian church, and containing the truer principles of Christianity.

Of the Bishop's poetical pieces, none display greater merit than Verses on the Genealogy of Christ, and the Choice of Hercules, both written very early in his life. He wrote a spirited imitation of an ode of Horace, applied to the alarming situation of this country in 1745; and likewise some verses on the death of Frederick prince of Wales, with a few smaller poems. The following inscription on the tomb of his daughter, beautifully displays his paternal affection and classical taste. As it is short, and, in our opinion, has all the merit
Learning and taste, however, did not constitute Bishop Lowth's highest excellence. Eulogium itself can scarcely afford to extravagant when speaking of him either as a private man or as a pastor of the church of Christ. His amiable manners rendered him an ornament to his high station, whilst they endeared him to all with whom he conversed; and his zeal for the interests of true religion made him eager to promote to places of truth and dignity such clergymen as he knew were best qualified to fill them. Of his modesty, gentleness, and pleasing conversation, we have the testimony of one whose decision will hardly be disputed.—"It would answer no end (says Bishop Warburton) to tell you what I thought of the author of Hebrew poetry, before I saw him. But this I may say, I was never more surprized, when I did fee him, than to find him of such amiable and gentle manners, so modest, temperate, and disengaged a deportment." He united, indeed, in an eminent degree, the qualities of the gentleman with those of the scholar: he conversed with elegance, as he wrote with accuracy. As a husband, a father, or the master of a family, he was as nearly faultles as the imperfections of humanity will easily permit. His temper, when roused by what he thought improper conduct, was indeed susceptible of considerable warmth; but if he could be highly offended, upon a light conceit he could likewise forgive. His heart was tender and sympathetic. He polished a mind which felt its own strength, and decided on whatever came before it with promptitude and firmness. In those trials where affection was to be suffered or subdued, he behaved as a man and a Christian. His piety had no tincture of moroseness; his charity no leaven of affectation. To his whole diocese he was endeared by his laudable discretion and his useful zeal. To the world he was a benefit by his exemplary life and his splendid abilities. And whilst virtue and learning are revered among men, the memory of Lowth will be respected and admired.

Loxia, in zoology, the name of a genus of birds of the order of passerines, the distinguishing characters of which are these: The bill is strong convex above and below, and very thick at the base: the nostrils are small and round: the tongue is as if cut off at the end: the toes are four, placed three before and one behind, excepting in one species, which has only two toes before and one behind.

The curvirostra, or common crow-bill, which is about the size of a lark, is known by the irregularity of its bill, both mandibles of which curve opposite ways and crofs each other: The general colour of the plumage in the male is of a red-lead inclining to rose-colour, and more or less mixed with brown: the wings and tail are brown; the legs black. The female is of a green colour; more or less mixed with brown in these parts where the male is red. This species is a constant inhabitant of Sweden, Germany, Poland, Switzerland, Russia, and Siberia, where it breeds; but migrates sometimes in vast flocks into other countries, as is now and then the case in respect to England; for though in some years it is met with, yet in others it has been known to visit there by thousands, fixing on such spots as are planted with pines, for the sake of the seeds, which are its natural food: it is observed to hold the cone in one claw like the parrot, and to have all the actions of that bird when kept in a cage. It is also found in North America and Greenland; and is said to make the nest in the highest parts of the fir-trees, fastening it to the branch with the resinsious matter which exudes from the trees.

2. The coccothraustes, or hawk-thrush, is in length seven inches; breadth, 13: the bill is funnel-shaped, strong, thick, and of a dull pale pink colour; the breast and whole under side are of a dirty flesh colour; and neck ash coloured; the back and coverts of the wings of a deep brown, those of the tail of a yellowish bay: the greater quill-feathers are black, marked with white on their inner webs; the tail is short, spotted with white on the inner sides; and the legs are of a flesh-colour. This species is ranked among the British birds; but only visits these kingdoms occasionally, and for the most part in winter, and never known to breed there. It is more plentiful in France, coming into Burgundy in small flocks, about the beginning of April; and soon after making the nest, which is placed between the bifurcation of the branches of trees, about twelve feet from the ground; it is composed of small dry fibres, intermixed with liverwort, and lined with finer materials. The eggs are of a roundish shape, of a bluish green, spotted with olive brown, with a few irregular black markings interposed. It is also common in Italy, Germany, Sweden, and the west and southern parts of Russia, where the wild fruits grow. It feeds on berries, kernels, &c., and from the great strength of the bill, it cracks the bones of the fruit of the haws, cherries, &c., with the greatest ease.

3. The emeulet, or pine-grosbeak, is nine inches in length, and weighs two ounces. The bill is strong, dusky, and forked at the end; the head, back, neck, and breast are of a rich crimson; the bottoms of the feathers ash-colour: the quill-feathers and tail dusky, their exterior edges of a dirty white: the legs are black. This species frequents the most northern parts of England, being only met with in Scotland, and especially the Highlands, where it breeds, and inhabits the pine-forests, feeding on the seeds, like the croft-bill. It is also found in all the pine forests of Siberia, Lapland, and the northern parts of Russia; it is common about St Peterburgh in autumn, and is caught in great plenty at that time for the use of the table; returning north in spring. They are likewise common to the northern parts of America; appearing at Hudson's Bay in May, to which place they are said to come from the south, and are observed to feed on the buds of willow. The southern settlements are inhabited by them throughout the year, but the northern only in the summer season. Our last voyagers met with this bird in Norton Sound; it was also found at Aoonalafkia.

4. The pyrrhula, or bullfinch, is so generally known, as,
L O X  

as almost to superfede description: The head, wings, and tail, are black; the breast and belly red; the upper tail coverts and vent white; and the breast ash-colour. The female differs in having the under parts of a reddish brown. This species is common in most parts of the continent of Europe, and throughout Russia and Siberia, at which latitudes it is caught for the table. It is pretty common in England; and builds in the bushes, five or six feet from the ground. The nest is composed chiefly of moss; and the eggs, which are five or six in number, are dirty bluish white, marked at the large end with dark spots. The time of breeding is about the end of May or beginning of June. In the summer it mostly frequents woods and the more retired places. In winter it approaches gardens and orchards, and has been generallyigmatized for making havoc among the buds of trees. From some late observations, however, it would appear, that the object of these birds is not the bud, but the worm in the bud; and that this species, in conjunction with various other species of small birds, are the frequent means of defending the embryo-fruits, and hence promoting their growth to maturity: for the warmth that swells the buds, not only hatches nidos (eggs) of unnumbered tribes of insects, whose parent flies, by an unerring instinct, laid them there,—but brings forward a numerous race already in a caterpillar state, that now issue from their concealments, and make their excursion along the budding branches, and would probably destroy every hope of fruitage, but for these useful instruments for its preservation. Those young are principally fed by eating caterpillars.——The bullfinch, in its wild state, has only a plain note; but when tamed it becomes remarkably docile and may be taught any tune after a pipe, or to whistle any notes in the jutest manner: it seldom forgets what it has learned; and will become so tame as to come at call, perch on its master's shoulders, and (at command) go through a difficult musical lesson. They may be also taught to speak, and some thus instructed are annually brought to London from Germany.

5. The coccineus, or blue grosbeak, is the size of the bullfinch: The bill is stout, brown, and the base of it surrounded with black feathers which reach on each side as far as the eye; the whole plumage besides is of a deep blue, except the quills and tail, which are brown, with a mixture of green, and across the wing coverts a band of red: the legs are dusky. It is an inhabitant of South America; but is sometimes found in Carolina, where it is a very solitary bird, and seen only in pairs, but disappears in winter. It has only a single note.

6. The violaceus, or purple grosbeak, is about the size of a sparrow: The bill is black: the plumage, violet black; except the irises, a streak over the eye, the chin, and the vent, which are red: the legs are dusky grey. This species inhabits the Bahama Islands, Jamaica, and the warmer parts of America.

7. The cardinalis, or cardinal grosbeak, is near eight inches in length. The bill is stout, and of a pale red colour: the irises are hazel: the head is greatly crested, the feathers rising up to a point when erect: round the bill, and on the throat, the colour is black; the rest of the bird of a fine red; the quills and tail duller than the rest, and brownish within: the legs are the colour of the bill. The female differs from the male, being mostly of a reddish brown. This species is met with in several parts of North America; and has attained the name of nightingale from the fineness of its song, the note of which resembles that of the nightingale. In spring, and most part of the summer, it sits on the tops of the highest trees, singing early in the morning, and piercing the ear with its loud pipe. These birds are frequently kept in cages, in which they sing throughout the year, with only short intervals of muteness. They are fond of maize and buckwheat; and will get together great hoards of these, often as much as a bushel, which they artfully cover with leaves and small twigs, leaving only a small hole for entrance into the magazine. They are also fond of bees. They come the beginning of April into New York and the Jerseys, and frequent the Magnolia swamps during the summer: in autumn they depart towards Carolina. They are very tame, frequently hopping along the road before the traveller, but are not gregarious, scarce ever more than three or four being met with together. From their being familiar birds, attempts have been made to breed them in cages, but without success.

8. The orix, or grenadier grosbeak, is about the size of a house-sparrow. The forehead, sides of the head, and chin, are black: the breast and belly the same: the wings are brown, with pale edges; and the rest of the body of a beautiful red colour: the legs are pale. These birds are inhabitants of Saint Helena; they are also in plenty at the Cape of Good Hope, where they frequent watery places that abound with reeds, among which they are supposed to make their nest. If (as is supposed) this be the fame with Kolben's Finch, he says that the nest is of a peculiar contrivance, made with small twigs, interwoven very closely and tightly with cotton, and divided into two apartments with but one entrance (the upper for the male, the lower for the female), and is so tight as not to be penetrated by any weather. He adds, that the bird is scarlet only in summer, being in the winter wholly ash-coloured. These birds, seen among the green reeds, are said to have a wonderful effect; for, from the brightness of their colours, they appear like so many scarlet lilies.

9. The Philippina, or Philippine grosbeak, is about the size of a sparrow: the top of the head, the hind part of the neck and back, and the scapulars, are yellow, the middle of the feathers brown: the lower part of the back is brown, with whitish margins: the fore part of the neck and breast are yellow; and from thence to the vent yellowish white: the wing-coverts brown, edged with white: the quills are brown, with pale rufous or whitish edges: and the tail the same: the legs are yellowish. These birds inhabit the Philippine Islands; and are noted for making a most curious nest, in form of a long cylinder, swelling out into a globose form in the middle. This is composed of the fine fibres of leaves, &c. and fastened by the upper part to the extreme branch of a tree. The entrance is from beneath; and, after ascending the cylinder as far as the globular cavity, the true nest is placed on one side of it; where this little architect lays
Lox

Lox lays her eggs and hatches her brood in perfect security.

A variety of this species, the Baglafechat (Buff. iii. 460), an inhabitant of Abyssinia, makes a very curious nest like the former, but a little different in shape; and is said to have somewhat of a spiral form, not unlike that of a nautilus. It suspends it, like the other, on the extreme twig of some tree, chiefly one that hangs over some still water; and always turns the opening towards that quarter from whence least rain may be expected.

10. The Abyssinica, or Abyssinian grosbeak, is about the size of the heathfinch: the bill is black: the irides are red: the top and sides of the head, throat, and breast are black: the upper parts of the body, belly, and thighs, pale yellow, inclining to brown where the two colours divide: the capulars are blackish: the wing-coverts brown, bordered with grey; the quills and tail brown edged with yellow: the legs are of a reddish grey. This bird is found in Abyssinia; and makes a curious nest of a pyramidal shape, which is suspended from the ends of branches like the others. The opening is on one side, facing the east: the cavity is separated in the middle by a partition; upon which the bird rides perpendicularly about half-way, when describing the nest is within the cavity on one side. By this means the brood is defended from snakes, squirrels, monkeys, and other mischievous animals, besides being secure from rain, which in that country sometimes lasts for six months together.

11. The penfils, or penistle grosbeak, (the Teddy-bird of Fryer), is about the size of the house-sparrow: the bill is black: the irides are yellow: the head, throat, and fore-part of the neck, the same: from the nostrils springs a dull green stripe, which passes through the eye and beyond it, where it is broader: the hind part of the head and neck, the back, rump, and wing-coverts are of the same colour: the quills are black, edged with green: the belly is deep grey, and the vent of a rufous red: the tail and legs are black. This species is found at Madagascar; and fabricates the nest of a curious construction, composed of straw and reeds interwoven in shape of a bag, the opening beneath. It is fastened above to a twig of some tree; mostly to those growing on the borders of streams. On one side of this, within, is the true nest. The bird does not form a new nest every year, but selects a new one to the end of the last; and often as far as five in number, one hanging from another. These build in society, like rooks; often five or six hundred being seen on one tree. They have three young at each hatch.

Kämpfer mentions a bird similar to this, if not the same, which makes the nest near Siam, on a tree with narrow leaves and spreading branches, the size of an apple-tree: the nest in the shape of a purse, with a long neck, made of dry grass and other materials, and suspended at the ends of the branches; the opening always to the north-west. He counted fifty on one tree only; and describes the bird itself as being like a Canary-bird, of a dark yellow, and chirps like a sparrow.

Fryer also talks of the ingenuity of the Teddy-bird, making a nest "like a satchel, with winding meanders," and tying it by a slender thread to the bough of a tree. Hundreds of these pendulous nests may be seen on these trees.

12. The chloris or greenfinch, is a well-known bird: the general colour is a yellowish green, palest on the rump and breast, and inclining to white on the belly; the quills are edged with yellow, and the four outer tail-feathers are yellow from the middle to the base; the bill is pale-brown, and stout; and the legs of a flesh-colour.—This species is pretty common in Britain, and flies in troops during the winter. It makes the nest in some low bush or hedge, composed of dry grass, and lined with hair, wool, &c. laying five or six greenish eggs, marked at the larger end with red brown; and the male takes his turn in sitting. This bird soon becomes tame; even old ones being familiar almost as soon as caught: it lives five or six years. Like the chiffinch, it is apt to grow blind if exposed to the sun. This species is also pretty common every where on the continent of Europe; but not very frequent in Russia; and is not at all found in Siberia, though it has been found in Kamtschatka. It is sufficiently common both in Cumberland and Scotland: yet in the first, it is scarce ever observed in the winter season; but the last week in March becomes plentiful, and breeds as in other parts of England.

13. The Bengalensis, or Bengal grosbeak, is a little bigger than a house-sparrow: the bill is of flesh-colour; the irides are whitish; the top of the head is of a golden-yellow; the upper parts of the body are brown, with paler edges; the sides of the head and under parts rufous white; across the breast is a brown band, uniting to, and of the same colour with, the upper parts of the body; the legs are of a pale yellow; the claws grey. This species (thus described by Mr Latham) seems to be the same with the Indian grosbeak described as follows in the Asiatic Researches. "This little bird, called baya in Hindi, bâr bâ in Sanscrit, bârânî in the dialect of Bengal, nilâ in Persian, and tonaw威尔 in Arabic, from his remarkably pendant nest, is rather larger than a sparrow, with yellow brown plumage, a yellowish head and feet, a light-coloured breast, and a conic beak very thick in proportion to his body. This bird is exceedingly common in Hindoostan: he is holomisingly tuneful, faithful, and docile, never voluntarily defirring the place where his young were hatched, but not averse, like most other birds, to the society of mankind, and easily taught to perch on the hand of his master. In a state of nature he generally builds his nest on the highest tree that he can find, especially on the palmyra, or on the Indian fig-tree, and prefers that which happens to overhang a wall or a rivulet: he makes it of grass, which he weaves like cloth and shapes like a large bottle, suspending it firmly on the branches, but so as to rock with the wind, and placing it with its entrance downwards to secure it from birds of prey. His nest usually consists of two or three chambers; and it is the popular belief that he fights them with fire-flies, which he catches alive at night, and confines with moist clay or with cow-dung: That such flies are often found in his nest, where pieces of cow-dung are also flung, is indubitable; but as their light could be of little use to him, it seems probable that he only feeds on them. He may be taught with ease to fetch a piece of paper, or any

Loxia. small thing that his master points out to him: it is an attedled [lo], that if a ring be dropped into a deep well, and a signal given to him, he will fly down with amazing celerity, catch the ring before it touches the water, and bring it up to his master with apparent exultation; and it is confidently asserted, that if a house, or any other place be thrown to him once or twice, he will carry a note thither immediately on a proper signal being made. One instance of his docility I can myself mention with confidence, having often been an eye-witness of it. The young Hindoo women at Benares, and in other places, wear very thin plates of gold, called [lores], slightly fixed by way of ornament between their eyebrows; and when they pass through the crowds, it is not uncommon for the youthful libertines, who amuse themselves with training baya's, to give them a signal, which they understand, and send them to pluck the pieces of gold from the foreheads of their mistresses, which they bring in triumph to the lovers. The baya feeds naturally on grashoppers and other insects; but will, if bribed, when tame, on puce macerated in water: his flesh is warm and drying, of easy digestion, and recommended in medical books as a solvent of stone in the bladder or kidneys; but of that virtue there is no sufficient proof. The female lays many beautiful eggs resembling large pearls; the white of them, when they are boiled, is transparent, and the flavour of them is exquisitely delicate. When many baya's are assembled on a high tree, they make a lively din; but it is rather chirping than singing: Their want of musical talents is however amply supplied by their wonderful sagacity, in which they are not excelled by any feathered inhabitant of the forest.

14. The nigra, or black grosbeak, is about the size of a Canary bird: the bill is black, stout, and deeply notched in the middle of the upper mandible; the plumage is black, except a little white on the forepart of the wing and base of the two first quills: the legs are black. It inhabits Mexico.

15. The minuta, or minute grosbeak, is about the size of a wren: the bill is stout, thick, short, and brown: the upper parts of the plumage are grey brown, the under parts and rump ferruginous cheiman; the four, fifth, and sixth quills are white at the base: the legs are brown. It inhabits Surinam and Cayenne. —It is said to keep paired to its mate the whole year; and is a lively and not very tame bird. It mostly frequents lands which have lain for some time uncultivated, and lives both on fruits and seeds. It makes a roundish nest, the hollow of which is two inches in diameter, composed of a reddish herb, and placed on the trees which it frequents. The female lays three or four eggs.

16. The focial, or focial grosbeak, is about the size of a bullfinch: the general colour of the body above is a russet brown, the under parts yellowish; the beak and eyelid are black; the legs brown; and the tail is short. It inhabits the interior country at the Cape of Good Hope; where it was discovered by Mr Carter. —These birds, according to one author, live together in large societies, and their mode of widendition is entirely uncommon. They build in a species of Mimosa, which grows to an uncommon size; and which they seem to have selected for that purpose, as well on account of its ample head, and the great strength of its branches, calculated to admit and to support the extensive buildings which they have to erect, as for the taints and smoothness of its trunk, which their great enemies, the serpent-tribe, are unable to climb. The method in which the nests themselves are fabricated, is highly curious. In the one described by Mr Parson there could be no less a number (he says) than from 300 to 1,000 residing under the same roof. He [see the Plate referred to at Mimosa.] calls it a roof, because it perfectly resembles that of a thatched house, and the ridge forms an angle so acute and so smooth, projecting over the entrance of the nest below, that it is impossible for any reptile to approach them. The industry of these birds seems almost equal (says our author) to that of the bee; throughout the day they appear to be busily employed in carrying a fine species of grasa, which is the principal material they employ for the purpose of erecting this extraordinary work, as well as for additions and repairs. Though my short stay in the country was not sufficient to satisfy me by ocular proof, that they added to their nest as they annually increased in numbers, still from the many trees which I have seen borne down with the weight, and others which I have observed with their boughs completely covered over, it would appear that this is really the case; when the tree which is the support of this aerial city is obliged to give way to the increase of weight, it is obvious that they are no longer protected, and are under the necessity of rebuilding in other trees. One of these deserted nests I had the curiosity to break down, so as to inform myself of the internal structure of it, and found it equally ingenious with that of the external. There are many entrances, each of which forms a regular door, with neatness on both sides, at about two inches distance from each other. The grasa with which they build is called the Bolsman's grasa; and I believe the feed of it to be their principal food; though, on examining their nests, I found the wings and legs of different insects. From every appearance, the nest which I dissected had been inhabited for many years; and some parts of it were much more complete than others: this therefore I conceive nearly to amount to a proof, that the animals added it at different times, as they found necessary, from the increase of the family, or rather of the nation or community.

17. The tridactyla, or three-toed grosbeak (the gfronis balio of Buffon), has only three toes, two before and one behind. The bill is toothed on the edges: the head, throat, and fore-part of the neck are of a beautiful red, which is prolonged in a narrow band quite to the vent; the upper part of the neck, back, and tail are black; the wing coverts brown; edged with white; quills brown, with greenish edges; and legs a dull red: the wings reach half way on the tail. This species inhabits Abyssinia; where it frequents woods, and is a solitary species. It feeds on kernels of seeds, which it breaks with ease with its bill. The name in its native place is gufronis bulla dimus-won ferk. Buffon's figure is from Mr Bruce's drawings. There are 78 other species of this genus; the whole number, besides varieties enumerated in the Soc. Nat. (Gmelin), and in Mr Latham's Journeys into the Country of the Hindoos, is p. 133, &c.
On Plate CCLXXIV. are given specimens of six, viz., A, the Cenolea; B, the Longicuda; C, the Sociæ; D, the Cardinalis; E, the Nigra; F, the Violacea. Loyola (Ignatius). See Ignatius.

Lozenge, in heraldry, a four-cornered figure, resembling a pane of glass in old casemates. See Heraldry, p. 455. col. 1. Though all heralds agree, that single ladies are to place their arms on lozenges, yet they differ with respect to the causes that give rise to it. Plutarch says, in the life of Thefeus, that in Megas, an ancient town of Greece, the tomb-stones, under which the bodies of the giants and rofe diamonds, in brilliants, they are set factory with ballions, moats, walls, and ramparts; in the latter, by the deleting of the facets in the horizontal ribs of the crown. See Facets.

Lozenge is also a form of medicine, made into small pieces, to be held or chewed in the mouth till they are melted there; the same with what are otherwise called trochis, troches.

Lubec, a city and port-town of Germany, in the circle of Lower Saxony and duchy of Holstein, in E. Long. 10. 35. N. Lat. 54. 20. it stands at the confluent of several rivers, the largest of which is the Trave, 12 miles from the Baltic, where it has a fine harbour, and 40 north-east of Hamburg. By the Stekenitz, another of those rivers, it has a communication with the Elbe, and consequently with the German ocean. The city lies on the side of a hill, with the Trave, increased by the Stekenitz on one side, and the Weckenitz on the other; and is strongly fortified with bastions, moats, walls, and ramparts; the hack of which are planted with trees, and form an agreeable walk. Lubec being formerly the chief of the Hanfe towns, was very powerful in consequence of the vast trade it carried on; but a great part of that trade is now transferred to Hamburg; however, it is still said to employ 500 of its own ships, and has a great share of the Baltic trade. It is about two miles in length, and more than one in breadth. The houses are all of stone, but old-fashioned. Several of the streets have on each side rows of lime-trees, with canals in the middle, like those of Holland. The public structures consist of the ancient cathedral of the bishopric of Lubec, and several other Lutheran churches; a nunnery for 22 ladies, with an abbess and prioress; a poor-house, an alms-house, and house of correction; an orphan-house; an hospital dedicated to the Holy-Ghost; a house in which poor travellers are entertained three days, and then sent forward with a pass; but such as happen to be sick, are provided with all necessaries till they recover or die; the city-armoury, a grammar-school of seven classes, the Calvinist church, and the Poppish chapel. The deputies of the Hanfe-towns used to meet here formerly in the town-house.

An alliance still subsists between Lubec, Hamburg, and Bremen; and these cities, under the name of Hanfe-townes, negotiate treaties with foreign powers. Here are divers manufactures, and the city’s territory is about 60 miles in compass. In the diet of the empire Lubec is polled of the third part of the Rhein imperial cities; and among those of the circle, has the first. In the morals, its affinities are to the Rhin, and to the chamber of Wetzlar it pays 557 rixdollars and 83 krunters. The city is a republic within itself, and both makes and executes laws in regard to civil and criminal matters, &c. A father and son or two brothers, cannot be in the regency at the same time. The famous league of the Hanfe-townes was begun here in 1164. This city had its charter of privileges from the emperor Frederic II. Formerly it carried on wars, both offensive and defensive, for several years, not only against the dukes of Mecklenburg, but against the kings of Sweden and Denmark; particularly in 1428, when it fitted out 350 ships of force against Eric X. king of Denmark. There are about 20 churches in Lubec, with lofty steeples or spires. The Trave brings ships of burden into the very heart of the city; but the largest unload at Travemunde, i.e. the mouth of the Trave, eight or ten miles distant. Formerly it is said to have employed no less than 600 ships. In the famous cellar here, it is said there is wine 200 years old. The church of St Mary’s, a noble lofty pile, is supported by tall pillars, all of one stone each, and has a high spire, covered with gilt lead. The town’s garrison consists of about 700 or 800 men. The revenue of its Lutheran bishop, though he is a prince of the empire, is said not to exceed 3000 pounds.

Lubienietski (Stanislaus), a Polish gentleman, descended from a noble family, and born at Cracow in 1623, was educated by his father with great attention. He became a celebrated Socinian minister; and took great pains to obtain a toleration from the German princes for his Socinian brethren. His labours, however, were intellectual; being himself persecuted by the Lutheran ministers, and banished from place to place; until at length he was banished out of the world, with his two daughters, by poison, his wife narrowly escaping, in 1675. We have of his writing A history of the reformation in Poland; A treatise on comets; with other works in Latin.

Lubin (Eilhard), was professor of poetry in the university of Rostock in 1595; and ten years after, was promoted to the professorship of divinity. He wrote notes on Anacreon, Juvenal, Persius, &c. and several other works; but that which made the most noise is a Treatise on the nature and origin of evil, intitled, l’homme du dieu père et nature mal, printed at Rostock in 1596; in which we have a hypothesis to account for the origin of moral evil. He supposed two co-eternal principles; not matter and ca-
LUCANUS (Marcus Annaeus), a Latin poet, born at Corduba in Spain, about A. C. 39. He was the son of Annaeus Mela, the youngest brother of Seneca; and was conveyed to Rome from the place of his nativity at the age of eight months: a circumstance, as his more indigent critics observe, which sufficiently retires the colour of those who consider his language as provincial. At Rome he was educated under the Stoic Cornutus, to warmly celebrated by his disciple Perinnus the fatirists, who was the intimate friend of our poet. In the close of his education, Lucan is said to have passed some time at Athens. On his return to Rome he rose to the office of quaestor, before he had attained the legal age. He was afterward imbibed among the anesurs; and married a lady of noble birth, and of an amiable character. Lucan had for some time been admitted to familiarity with Nero, when the emperor chose to confound for poetical honours by the public recital of a poem he had composed on Niobe; and some verses of this imperial production were supposed to be preferred in the first satire of Perfins. Lucan had the hardihood to repeat a poem on Orphus, in competition with that of Nero; and, what is more remarkable, the judges of the contest were just and bold enough to decide against the emperor. From hence Nero became the perceptor of his successful rival, and forbade him to produce any poetry in public. The well-known conspiracy of Piso against the tyrant soon followed; and Tacitus, with his usual sarcastic severity, concludes that Lucan engaged in the enterprise from the poetical injuries he had received: "a remark (says Mr. Hayley), who has endeavoured to refute the imputation) which does little credit to the character of the historian; but might have found a much nobler, and, I will add, a more probable motive for his conduct, in the generous ardor of his character, and his passionate adoration of freedom. In the sequel of his narration, Tacitus accuses a charge against our poet, which, if it were true, must lead us to detect him as the most abject of mankind. The historian affirms, that Lucan, when accused of the conspiracy, for some time denied the charge; but corrupted at last by a promise of impunity, and desirous to stone for the tarduefulness of his confession, accused his mother Atilla as his accomplice. This circumstance is so improbable in itself, and so little consonant to the general character of Lucan, that some writers have treated it with contempt, as a calumny invented by Nero, to vilify the object of his envious abhorrence. But the name of Tacitus has given such an air of authority to the story that it may seem to deserve a more serious discussion, particularly as there are two subsequent events related by the same historian, which have a tendency to invalidate the accusation fo injurious to our poet. The events I mean are, the fate of Annaeus, and the escape of Atilla, the two parents of Lucan. The former died in consequence of the accusation brought against him, after the death of his son; and his witnesses, who had complained of his innocence to Nero, were afterward executed. The latter, who was an intimate friend of Annaeus, and to whom Lucan had confided many secrets, is said to have been murdered by Atilla, the mother of Lucan; and the name of Tacitus is said to have been given to the tradition of his being so murdered. Lucan. verses of the Pharsalia which the author quoted in so memorable a manner. The two passages he is supposed to have repeated are the following; of which Lipius contends for the latter.

Sanguis erat lacryma : quaeque foramina nova
Humor, ab his largus mutat crudor; ora redundat,
Et pauper oculis: lacus ruber; omnia plevis
Membras fluent venis: totum eft pro vulnere corpus.

Lib. i. 814.

Now the warm blood at once, from every part,
Ran purple o'er all, and drain'd the fainting heart.
Blood falls for tears; and a teeming mourful face
The Hudiy drop their tainted passage trace.
Where'er the liquid juices find a way.
There streams of blood, thence crimson rivers flow.
His mouth and gulping nostrils pour a flood,
And e'en the pores issue out the trickling blood;
In the red deluge all the parts lie drowned,
And the whole body feems one bleeding wound.

Scinditur avulius; nec facta vulnere languit
Emicuit, quasi prosoftique venis,
Diffecursumque animas, diversa in membra mentis,
Interceptus aquis.

Lib. iii. v. 632.

No single wound the gaping rupture feems,
Where trickling crimson wells in f tender streams;
But, from an opening horrible and wide,
A thousand vellae pour the bursting tide:
At once the winding channel's course was broke,
Where wandering life her mazes journey took;
At once the currents all forgot their way,
And left their purple in the azure sea.

Rowe.

Such was the death of Lucan before he had completed his 27th year.—His wife, Polla Argentaria, is said to have transcribed and corrected the three Ariftotle books of the Pharsalia after his death. It is much to be regretted (Mr Hayley observes) that we have not the poem which he wrote on the merits of this amiable and accomplished woman; but her name is immortalized by two surviving poets of that age. The veneration which the public paid to the memory of her husband is recorded by Martial; and more poetically described in that pleasing and elegant little production of Statius, Genethliacum Lucani, a poem said to have been written at the request of Argentaria. The author, after invoking the poetical deities to attend the ceremony, touches with great delicacy and spirit on the compositions of Lucan's childhood, which are lost, and the Pharsalia, the production of his early youth: he then pays a short compliment to the humanity and talents of Argentaria; laments the cruel fate which deprived her of such immaturity of domestic happiness; and concludes with an address to the shade of Lucan, which, with Mr Hayley's translation, we shall join in a Note, as it seems to furnish a strong presumption of Lucan's innocence in regard to one of the accusations mentioned above (A). "Had he been really guilty of basely endangering the life of his mother (says Mr Hayley), it is not probable that his wife would have honoured his memory with such enthusiastic veneration; or that Statius, in verses designed to do him honour, would have alluded to the mother of Nero. If his character as a man has been injured by the historian (continues Mr Hayley), his poetical reputation has been treated not less injuriously by the critics. Quintilian, by a frivolous distinction, disputes his title to be classed among the poets; and Scaliger says, with a brutality of language disgraceful only to himself, that he seems rather to bark than to finge. But these insults may appear amply compensated, when we remember, that in the most polished nations of modern Europe the most elevated and poetical spirits have been his warmest admirers; that in France he was idolized by Corneille, and in England translated by Rowe.—The severest cenures on Lucan have proceeded from those who

And mock the confines of the tomb;
Or whether in Elysium blest
You grace the groves of facred cell,
Where the Pharsalian heroes dwell;
And, as you strike your epic shell,
The Pompeys and the Catos throng
To catch the animating song;
Of Tartarus the dread contoul
Links not your high and hallow'd foul;
Diftant you hear that wailing cease,And flee the guilty Nero's ghoul
Grow pale with anguish and affright.
His mother flanching on his light.
Be present to your Polla's vows,
While to your honour'd name the bow's!
One day let your interest gain
From those who rule the shadowy train!
Their gates have op'd to blest a wife,
And given a husband back to life.
In you the tender fair invites
No fancied god with frantic rite:You are the object of her prayers,
You in her inmost heart the bears:
And, flant on mimic gold, your head
Adonis the faithfl mourner's bed,
And fothes her eyes before they close,
The guardian of her chaste repose.
Away with all funeral bace!
From hence his nobler life we date:
The mourners change the pang severe
To fond devotion's greatful tear;
And fateful grief, its anguish o'er,
What it lamented, now adores!
have fairly compared his language to that of Virgil: but how unjust and absurd is such a comparison! It is comparing an uneven block of prophecy, taken rough from the quarry, to the most beautiful superficies of polished marble. How differently should we think of Virgil as a poet, if we pitied only the verses which he wrote at that period of life, when Lucan composed his Pharsalia! In the disposition of his subject, in the propriety and elegance of dictation, he is undoubtedly far inferior to Virgil: but if we attend to the bold originality of his design, and to the vigour of his sentiments, if we consider the Pharsalia as the rapid and uncorrected sketch of a young poet, executed in an age when the spirit of his countrymen was broken, and their taste in literature corrupted; it may justly be esteemed as one of the noblest and most wonderful productions of the human mind."—Lucan wrote several poems; but we have none remaining beside his Pharsalia, of which an excellent English version has been given by Mr Nicholas Rowe.

LUCANUS, the Stag-bettle, in zoology; a genus of insects of the order coleoptera. The antennæ end in a club or knob, which is compressed or flattened on one side, and divided into short laminae, resembling the teeth of a comb; the jaws are produced or advanced before the head, and are dentated. There are 20 species. The largest, as well as the most singular, is the cervus; which is easily to be known by two large moveable maxillae, resembling in form the horns of a stag, which project from its head, and have in a special manner acquired it theappellation of Stag-bettle. Those maxillae, broad and flat, equal to one third of the insect's length, have in the middle, towards their inner part, a small branch, and at their extremity are forked. Besides this, they have several small teeth throughout their whole length. The head that bears these maxillae is very irregular, very broad and short. The thorax is something narrower than the head and body and margined round. The elytra are very plain, without either streaks or lines. The whole animal is of a deep brown colour. It is commonly found upon the oak, but is scarce in the neighbourhood of London, and though the largest of coleopterous insects to be met with in Europe, it is much smaller than those of the same species that are found in woody countries. This creature is strong and vigorous, and its horns, with which it pincers severely, are carefully to be avoided.—The jaws are sometimes as red as coral, which gives this insect a very beautiful appearance; the female is distinguished by the shortness of the jaws, which are not half so long as those of the male.

These insects feed on the liquor that oozes from oak, which they suck with their trunk or tongue. The females deposit their eggs in the trunks of decayed trees, such as the oak and the ash. The larvae or grubs lodge under the bark and in the hollow of old trees, which they eat into and reduce into fine powder, and there transform themselves into chrysalids. They are common in Kent and Suffex, and are sometimes met with in other parts of England. The poreded jaws are particularly useful to these animals, in stripping off the bark from trees, and affixing themselves thereto by the tree, while they suck with their trunk the juice that oozes from it.

LUCAR de Barameda (St), a handsome and considerable town of Spain, with a very good harbour, well defended, in Andalulus. It was once the greatest port in Spain, before the galleons unloaded their treasure at Cadiz. It is seated at the mouth of the river Quadsiver. W. Long. 6, 5. N. Lat. 36, 40.

LUCAR de Guadiana (St), a strong town of Spain, in Andalusia, on the confines of Algarve; seated on the river Guadiana, with a little harbour. W. Long. 5, 59. N. Lat. 57, 32.

LUCAR la maior (St), a small town of Spain, in Andalusia, with the title of a duchy. It is seated on the river Guadiana, in W. Long. 5, 32. N. Lat. 27, 21.

LUCARIA, a feast celebrated at Rome on the 18th of July, in memory of the flight of the Romans into a great wood, where they found an asylu, and saved themselves from destruction. This wood, in which they found protection, was situated between Tyber and the Pin Salaria. The enemies from whom the Romans fled were the Gauls.—On this festival, Plutarch tells us, it was customary to pay the actors, and such as contributed to the public amusement, with the money arising from the felling of wood. This money was called lucar. It is obvious, from what has been observed, that lucar and lucaria are derived from lucus, a grove.

LUCAS (Jacob), an eminent artist, more generally known by the name of Lucas van Leyden, or Huygens, was born at Leyden in 1494. He received his first instructions in the art of painting from his father Hugues Jacobs; but completed his studies in the school of Cornelius Engelbrecht. He gained much money by his profession; and being of a generous turn of mind, he spent it freely, dressed well, and lived in a superior style. It is said, that a few years before his death, he made a tour into Belgium and Brabant; and during his journey, a painter of Flanders, envious of his great abilities, gave him poison at an entertainment; which, though very slow, was too fatal in its effect, and put an end to his life, after six years languishing under its cruel influence. Others, denying the story of the poison, attribute his death to his incessant industry. The superiority of this artist's genius manifested itself in his infancy: for his works, even from the age of nine, were so excellent, as to excite the admiration of all contemporary artists; and when he was about 15, he painted a St Hubert, which gained him great applause. His taste in colouring (Mr Pilkington observes) is good, his attitudes (making a reasonable allowance for the stiff German taste) are well chosen, his figures have a considerable expression in their faces, and his pictures are very highly finished. He endeavoured to proportion the strength of his colouring to the different degrees of distance in which his objects were placed; for in that early time, the true principles of perspective were but little known, and the practice of it was much less observed. In the town-hall at Leyden, the most capital picture of Lucas, the subject of which is the Last Judgement, is preserved with great care; the magistrates have refused very large sums which have been offered for it.

This artist painted not only in oil, but also in temper and upon glass. Nor was he less eminent for his engraving than for his painting. He carried on a familiar and friendly correspondence with Albert Durer,
Luca. Durer, who was his coetemporary; and, it is said, that as regularly as Albert Durer published one print, Lucas published another, without the least jealousy on either side, or with to depreciate each other's merit. And when Albert came to Holland upon his travels, he was received by Lucas in a most cordial and affectionate manner. His style of engraving, however, according to Mr. Strutt, differed considerably from that of Albert Durer, and seems evidently to have been founded upon the works of Israel van Mecklen. His prints are very neat and clear, but without any powerful effect. The strokes are as fine and delicate upon the objects in the front, as upon those in the distances; and this want of variety, joined with the feebleness of the malleus of shadow, give his engravings with all their neatness, an unfinish'd appearance, much unlike the firm substantial effect which we find in the works of Albert Durer. He was attentive to the minute of his art. Every thing is carefully made out in his prints, and no part of them is neglected. He gave great character and expression to the heads of his figures; but, on examination of his works, we find the same heads too often repeated. The hands and feet are rather mannered than correct; and when he attempted to draw the naked figure, he succeeded but very indifferently.

He affected to make the folds of his draperies long and flowing; but his female figures are frequently excessively loaded with girdles, bandages, and other ornamental trappings, that much of the elegance of the design is lost. He engraved on wood, as well as on copper; but his works on the former are by no means numerous. They are, however, very spirited; though not equal upon the whole, to those of his friend Albert. The prints of this master are pretty numerous, but very seldom met with complete; especially fine impressions of them. For though they are, generally speaking, executed with the graver only, yet, from the delicacy of the execution, they soon suffered in the printing. Of his engravings the few following may be mentioned as among the principal. 1. Madonnat sleeping, with a priest murdered by his side, and another figure holding his sword, a middle-sized upright plate, dated 1508, said to be one of his most early productions. 2. An ece ecora, a large plate, lengthwise, dated 1510. 3. The Crucifixion on Mount Calvary, the same. 4. The Wife Mens Offering, the same, dated 1513. 5. Return of the Prodigal Son, a middle-sized upright plate, lengthwise, dated 1518. 6. A large plate breadthwise called the Dance of Magdalen, dated 1570. His own Portrait, a small upright plate, dated 1525.

8. David playing before Saul, a middle-sized upright plate, dated 1530. This is a very fine print; the expression of Saul's countenance, in particular, is admirable. 9. A print known by the name of Ulaufige, which is the scariest of all the works of this master. It is in the collection of the king of France; and said by Marolles, and other matters, to be Unique. But Bafan informs us, that M. Mariette had also an impression of this plate; and it has been since found in one or two other collections. It represents a travelling bag-piper with his family; himself playing as he goes along, and carrying two children in a basket at his back; his wife trailing by his side, supporting with one hand an infant on her shoulder, and with the other leading an ass loaded with two baskets, having two children in each; and another child going before, with a little dog, completes the singular group. This rare print is dated 1520, and is known to have been sold for 16 louis-d'ors.—It is nearly 71 inches high by 41 broad; and has been twice copied. One of the copies is the reverse way; but the other is the same way with the original, and though not well executed, might without a comparison be mistaken for it.

Lucas (Richard), D. D. a learned English divine, was born in 1649, and studied at Oxford; after which he entered into holy orders, and was for some time master of the free school at Abingdon. Being esteemed an excellent preacher, he became vicar of St Stephen's, Coleman Street, in London, and lecturer of St. Olave's in Southwark. He was doctor of divinity; and in 1696 was instituted prebendary of Westminster. His life began to fail him in his youth; and he totally loft it in his middle age. He was greatly esteemed for his piety and learning; and published several works, particularly, 1. Practical Christianity. 2. An Inquiry after happiness. 3. Several sermons. 4. A Latin translation of the whole duty of man. He died in 1715.

Lucas, a small republic of Italy on the coast of the Mediterranean, between the territory of Genoa on the west, Modena on the north, and Tuscany on the east. According to Keyler, it is only about 30 miles in circumference, but is exceeding fertile and populous. It contains, besides the city of Lucca, 500 villages. The number of inhabitants are computed at 120,000. The government is lodged in a gofoner, whose power is much the same with that of the doges of Venice and Genoa. He is assisted by nine councillors; but the power of all the ten continues only for two months; during which time they live in the state-palace, and at the public expense. They are chosen out of the great council, which consists of 240 nobles; but even this council is changed by a new election every two years. The revenues of the republic are about 400,000 fudi or crowns; out of which they maintain 300 men by way of regular force, and 70 Swifts as a guard to their acting magnates. The city of Lucca is situated in a plain, terminating in most delightful eminencies, adorned with villas, summer-houses, corn-fields, and plantations of every kind; so that nothing either for use or pleasure is here wanting. The city, which is about 3 Italian miles in circumference, has regular well-lined fortifications; and its streets, though irregular, are wide, well-paved, and full of handsome houses. The number of its inhabitants is computed to be above 40,000; and they carry on large manufactures, especially of silk-fluffs, Lucca has a bishop, who enjoys several extraordinary privileges; and its cathedral is Gothic. The city stands in E. Long. 11°. 27'. N. Lat. 43° 52'.

Lucenti, Lucentia, or Lucensum, a town of the Hither Spain, now Alcañiz, a sea-port of Valencia. W. Long. 32°, N. Lat. 38° 57'.

Luceres, in Roman antiquity, the third in order of the three tribes into which Romulus divided the people, including all foreigners; so called from the lucem or grove, where Romulus opened a asylum.

Luceria (anc. geog.), a town of Apulia in Italy; which in Strabo's time still exhibited marks of Dioscorides.
LUCERNE

Diomed's sovereignty in those parts. Ptolemy has Nuceria; whether from midlake, or the column of his time uncertain. Now Nocera de Pagani, in the kingdom of Naples. E. Long. 15. 0. N. Lat. 40. 40.

LUCERUS, in mythology, a name given to Jupiter, as Luceria was given to Juno, as the deities which gave light to the world.

LUCERNE, one of the 13 cantons of Switzerland. It holds the third place among the 13; and is the head of the Catholic cantons. Though less than Zuric, and consequently much less than Berne; it is however, far more extensive than any of the rest, being 15 or 16 leagues long, and eight broad. The population is estimated at 100,000. Even the mountains part is not barren, but abundant in wood and pasture, furnishing cattle, hides, cheese, and butter, for exportation. All the north part is fertile in grain, fruit, and hay; supplying sufficient for the consumption of the inhabitants: but as the mountainous part of the little cantons come to their market for corn, the people of Lucerne purchase this commodity from other parts of Switzerland, but especially from Alsace and Swabia. Their manufactures are very inconsiderable; confiling only in a little silk and cotton thread. — The government is oligarchical. The councils are chosen from among 500 citizens only. The great council of 64 members is the nominal sovereign; choosing the two Avoysers, or Axer; council of 36, having for their chiefs the two Avoysers. — The whole canton professes the Roman Catholic religion. The pope's nuncio, at Lucerne. — They threw off the Austrian yoke in 1532, and by entering into a perpetual alliance with the three ancient cantons, they gave such weight to the confederacy, as to enable it in 1536 to resist all the efforts of the enemy at the bloody battle of Sempach.

The town of Lucerne is situated at the extremity of a most beautiful lake of the same name, where the river Reuss issues from it. The buildings are ancient, and the streets narrow; nor is Lucerne populous in proportion to its extent, the inhabitants being only between 3 and 4000. Since this is the great passage to Italy by Mount St. Gothard, and the merchandise which passes the Alps on mules, and is to be transported by the rivers Reuss, Aar, and Rhine, is all deposited here, it might have a flourishing trade if arts and manufactures were attended to. The Reuss separates the town into two unequal parts, which are connected by three bridges; one wide for carriages; and two narrow covered ones for foot passengers: besides these, there is a fourth over an arm of the lake, to pass to the cathedral. Three of these bridges have old bad paintings of the Dance of Death, and the History of the Bible, and of Switzerland. They make a commodious dry walk for the inhabitants. — Of religious edifices, the principal are the cathedral, or collegiate church of St. Leger; the convent of Cordeliers; the college of Jesus; the convent of Conches; and the two convents of nuns. Of the secular buildings, the hotel de Ville is the principal. The arsenal is also large, and well furnished. The water tower is remarkable only for its position and antiquity: it is said to have been a pharos or lighthouse. — What greatly attracts most the notice of strangers is, a plan in relief of part of the cantons of Lucerne, Zug, and Berne, and the whole of Schweitz, Uri, and Underwald, executed by General Piiffer on a large scale. He has completed about 60 square leagues; the plan is 12 feet long, and nine and an half broad: every mountain is accurately measured; and every object distinctly placed.

The lake of Lucerne exhibits greater variety and more picturesque scenery than any other of the Swiss lakes. It is seven leagues long in a right line, and three wide about Kufinaeht; but the shape is very irregular. The whole south side is bordered by high mountains; but the north exhibits hills of no great height. The narrow gulf that extends towards the west, is bordered on the west and north-west by Mount Pilat, which is a single mountain rising boldly more than 6000 feet above the lake; and on the south by Mount Burgenberg, Stanz-Stadt, belonging to the canton of Unterwald, is on this side; and hereabouts the lake is deepest. Kufinaeht is on the point of the other gulf, which extends towards the east, and is wider than the former. All the country to the west of these gulfs, and part of it to the north of the latter, belongs to the canton of Lucerne; but that which is to the south and north-east is dependent on the canton of Zir. All the mountains on the left shore of the lake belong to the canton of Unterwald; those on the right, partly to the canton of Uri, partly to that of Schweitz, partly to the little republic of Gersau, but principally to the canton of Lucerne.

Lucerne, in botany. See Medicago.—For the culture of this plant, see Agriculture, n° 183.

LUCIA (St.), one of the Caribbee Islands in the West-Indies, about 22 miles long, and 11 broad, the middle of it lying in N. Lat. 19° 14'. W. Long. 72° 0. It was first settled by the French in 1650; but was reduced by the English in 1664; who evacuated it in 1666. The French immediately re-settled the island, but were again driven away by the Caribbes. As soon as the savages were gone, the former inhabitants returned, but only for a short time; for being afraid of falling a prey to the first privateer that should visit their coasts, they removed either to other French settlements that were stronger, or where they might expect to be better defended. There was then no regular culture or colony at St. Lucia; it was only frequented by the inhabitants of Martinico, who came thither to cut wood, and to build canoes, and who had considerable docks on the island. In 1718 it was again settled by the French; but four years after, it was given by the court of London to the duke of Montague, who was sent to take possession of it. This occasioned some disturbance between the two courts; which was settled, however, by an agreement made in 1731, that, till the respective claims should be finally adjusted, the island should be evacuated by both nations, but that both should wood and water there. This precarious agreement furnished an opportunity for private interest to exert itself. The English no longer molested the French in their habitations; but employed them as their subjects in carrying on with richer colonies a more struggle trade, which the subjects of both governments thought equally advantageous to them. This trade has been more or less considerable till the treaty of 1763, when the pro-
Lucian, a celebrated Greek author in the first century, was born at Samosata, of obscure parents, in the reign of the emperor Trajan. He studied law, and practiced some time as an advocate; but growing weary of the wrangling oratory of the bar, he commenced rhetorician. He lived to the time of Marcus Aurelius, who made him regifter of Alexander in Egypt; and, according to Suidas, he was at last worried by dogs. Lucian was one of the finest wits in all antiquity. His dialogues, and other works, are written in Greek. In these he has joined the useful to the agreeable, instruction to fatire, and erudition to elegance; and we every where meet with that fine and delicate raillery which characterizes the Attic style. Thosc who censure him as an impious scoffer at religion, have reason on their side, if religion confuted in the theology of the Pagan poets, or in the extravagant opinions of philosophers; for he perpetually throws such ridicule on the gods and philosophers, with their vices, as inspires hatred and contempt for them; but it cannot be said that he writes any where against an over-ruling providence.

Lucianists, or Lucanists, a religious sect, so called from Lucianus, or Lucanus, a heretic of the second century, being a disciple of Marcion, whose errors he followed, adding some new ones to them. Epiphanius says he abandoned Marcion, teaching that people ought not to marry, for fear of enriching the Creator; and yet other authors mention that he held this error in common with Marcion and other Gnostics. He denied the immortality of the soul: asserted it to be material.

There was another sect of Lucanists, who appeared some time after the Arians. They taught, that the Father had been a Father always, and that he had the name even before he begot the Son; so as having in him the power of the faculty of generation; and in this manner they accounted for the eternity of the Son.

Lucid Intervals, the fits of Lunatics or maniacs, wherein the phrenzy leaves them in possession of their reason.

Lucifer, according to the poets, was the son of Jupiter and Aurora: in astronomy, Lucifer is the bright planet Venus, which either goes before the sun in the morning, and is our morning star; or in the evening follows the sun, and is called Hesperus or the evening star.

Luciferia, in mythology, a surname given to Diana, under which title she was invoked by the Greeks in childhood. She was represented as covered with a large veil, interspersed with stars, bearing a crescent on her head, and holding in her hand a lighted flambeau.

Luciferians, a religious sect, who adhered to the schism of Lucifer, bishop of Cagliari, in the fourth century, who was banished by the emperor Constance for having defended the Nicene doctrine concerning the three persons in the Godhead. Didascylus seems to intimate, that they believed the soul, which they considered as of a carnal nature, to be transmitted to the children from their fathers. Theodosius says, that Lucifer was the author of a new error. The Luciferians increased mightily in Gaul, Spain, Egypt, &c. The occasion of the schism was, that Lucifer would not allow any acts he had done to be abolished. There were but two Lucerian bishops, but a great number of priests and deacons. The Luciferians bore a peculiar aversion to the Arians.

Lucilius (Caius), a Roman knight, and a Latin poet, was born at Sicilia in Italy, about 140 B. C. He served under Scipio Africanus in the war with the Numantines; and was in great favour with that celebrated general, and with Lælius. He wrote 50 books of fables, in which he lashed several persons of quality very harshly. Some learned men ascribe the invention of satire to him; but M. Dacier has maintained, with great probability, that Lucilius only gave a better turn to that kind of poetry, and wrote it with more wit and humour than his predecessors Ennius and Pausias had done. His fragments have been carefully collected.
LUCAS [320] LUCAS

Lucian collected by Francis Douce at Leyden in 1559, with notes. But they require still to be better illustrated by some learned critics.

LUCINA, a goddess among the Romans, who presided over women in labour. Some take her to be Diana, others Juno. She is called Lucina, because she brought children to the light; from the Latin word lux, "light."

LUCIUS, in ichthyology. See Esox.

LUCONIA. See MAP.".

LUCOPHEREA, in ichthyology. See PERCA.

LUCRETIA, the famous Roman matron, wife of Collatinus, and the cause of the revolution in Rome from a monarchy to a republic; this lady being ravished by Sextus, the eldest son of Tarquin king of Rome, stabbed herself, 509 B. C. See the article CHASTITY. The bloody poignard, with her dead body exposed to the Senate, was the signal of Roman liberty; the expulsion of the Tarquins, and abolition of the regal dignity, was instantly resolved on, and carried into execution. See ROMEx.

LUCRETius, or TITUS LUCRETIUS CAIUS, one of the most celebrated of the Roman poets, was born of an ancient and noble Latin family, and studied at Athens, where he became one of Epicurus's disciples. He acquired great reputation by his learning and eloquence; but in the flower of his age fell into a frenzy, occasioned by a philtrum given him by his wife, who was distracted with fond of him. Lucretius, during the intervals of his madness, put Epicurus's doctrines into verse, and composed his six books De rerum natura, which are still extant. It is said, that he killed himself in a fit of madness, in the 54th year before the Christian æra, when 57 years old. The most correct edition of Lucretius is that of Simon de Coline. The cardinal de Polignac has refuted Lucretius's arguments in his excellent Latin poem intitled ANTI-LUCRETIUS. His poem De rerum natura has been translated into English by Mr Creech.

LUCRINUS LUCUS (anc. geog.), a lake of Campania, between Baie and Puteoli, famous for its outers (Horace, Martial, Juvenal); Lucrinienses (Cicero), the people dwelling on it. Now a perfect bay since the earthquakes in 1538.

LUCULLUS (Lucius Lucinius), a Roman general, celebrated for his eloquence, his victories, and his riches. In his youth he made a figure at the bar; and being afterwards made praetor in Asia, and praetor in Africa, governed those provinces with great moderation and justice. Scarse was he known as a military man, when he twice beat the fleet of Amilcar, and gained two great victories over him. His happy genius was greatly improved by study; for he employed his leisure in reading the best authors on military affairs. Being made consul with Aurelius Cotta, during the third war with Mithridates king of Pontus, he was sent against this prince; and this expedition was attended with a series of victories, which did him more honour than an act of generosity towards his colleague, who, willing to take advantage of his absence to signe him, if some great exploit, happened to fight Mithridates; but was defeated and shut up in Calcedon, where he must have perished, if Lucullus, sacrificing his refreshment to the pleasure of saving a Roman citizen, had not flown to his assistance, and

disengaged him. All Pontus then submitted to Lucullus; who being continued in his government of Asia, entered the territories of Tigranes, the most powerful king in Asia. That prince marched with a formidable army against Lucullus: who defeated him with a handful of men, and killed great numbers of his forces; took Tigranocertes, the capital of his kingdom; and was ready to put an end to the war, when the intrigues of a truce got him deposed, and Pompey nominated in his room. Lucullus having brought home prodigious riches, now gave himself up to excessive luxury; and his table was served with a profusion till that time unknown. He brought from the East a great number of books, which he formed into a library, and gave admittance to all men of learning, who frequented it in great numbers. Towards the end of his life, he fell into a kind of madness; and Lucullus, his brother, was appointed his guardian. He is said to have been the first who brought cherries into Europe, having brought the grafts from the kingdom of Pontus.

LUCUS, in general, denotes a wood or grove sacred to a deity; so called à lucene, because a great number of lights were usually burning in honour of the god (Lucus); a proper common with idolaters, as we learn from Scripture: hence Homer's ἀλέες αἰχμαλώτης.

LUD, a British king mentioned in our old chronicles, and said to have reigned about the year of the world 3878. He is reported to have enlarged and walled about Troy, or New Troy, where he kept his court, and made it his capital. The name of London is hence derived from Lud's town, and Ludgate, from his being buried near it: but this is only one among many other derivations of the name of London, which are at least equally probable. See LONDON.

LUDI, a term used for shows and public representations made by the Romans, for the entertainment of the people. See GAMES.

For an account of the particular games of Greece and Rome, as the Isthmian, Nemean, Olympic, &c. See ISTMHIAN, &c.

LUDIUS, a celebrated painter, lived in the reign of Augustus Caesar, and excelled in grand compositions. He was the first who painted the fronts of houses in the streets of Rome; which he beautified with great variety of landscapes, and many other different subjects.

LUDLOW (Edmund), son of Sir Henry Ludlow, was born at Maidenhead, and educated in Trinity college, Oxford. His father opposing the king's interest, Mr Ludlow joined with the same party, and was present at the battle of Edgehill as a volunteer under the earl of Essex. Upon the death of his father, he was chosen knight of the shire for Wilts, and obtained the command of a regiment of horse for the defence of that county. He was one of King Cha. 1.'s judges: after whole death he was sent by the parliament into Ireland, in quality of lieutenant-general of the horse; which employment he discharged with diligence and success till the death of the lord-deputy Ireton, when he acted for some time as general, though without that title; Cromwell, who knew him to be sincerely in the interest of the commonwealth, always finding out some pretext to hinder the conferring of that character upon him. The last stroke had been given
Ludlow, given by Ludlow to the Irish rebellion, if the surpuration of Cromwell had not prevented it. Under his power he never acted; and though Cromwell used his utmost efforts, he remained inexcusable. After Cromwell's death, he endeavoured to restore the commonwealth; but Charles II. being recalled, he thought proper to conceal himself, and escaped into Switzerland, where he settled. After the revolution, he came over into England, in order to be employed in Ireland against King James: but appearing publicly in London, it gave great offence; and an address was presented by Sir Edward Seymour to King William III. for a proclamation in order to apprehend Colonel Ludlow, attained for the murder of King Charles I. Upon this he returned to Switzerland, where he died. During his retirement in Switzerland he wrote his Memoirs.

Ludlow, a town of Shropshire in England, situated at the confluence of the Teme and Corve, 18 miles from Shrewsbury, and 138 from London. The president of the council of the marches, established by Henry VIII. generally kept his courts in it, by which the town was much benefited, these courts not having been abolished till the 1st of William and Mary. Its neighbourhood to Wales makes it a great thoroughfare, and engages many of the Welsh to send their children of both sexes to it for education. It was incorpored by Edward IV. and among other privileges has that of trying and executing criminals within itself. It is one of the nearest towns in England, with walls and seven gates. It is divided into four wards; and is governed by a bailiff, 12 aldermen, 25 common-councillors, a recorder, a town clerk, steward, chamberlain, coroner, &c. From the castle on the top of the hill on which the town stands is a most delightful prospect. In an apartment of the outer gatehouse Samuel Butler is said to have written the first part of Hudibras. Of this castle, which was besieged and taken by King Stephen some of the offices are fallen down, and great part of it turned into a bowling-green; but part of the royal apartments and the tower of state are still left. The walls were at first a mile in compass, and there was a lawn before it for near two miles, of which much is now inclosed. The battles are very high and thick, and adorned with towers. It has a neat chapel, where are the coats of arms of abundance of Welch gentry, and over the flable doors are the arms of Queen Elizabeth, the earls of Pembroke, &c. This castle was a palace of the prince of Wales, in right of his prinopality. The river Teme has a good bridge over it, several weirs and crofts on it, and turns a great many mills. Here is a large parochial church, which was formerly collegiate; in the choir whereof is an inscription relating to Prince Arthur, elder brother to King Henry VIII. who died here, and whose bowels were here deposited, though it is said his heart was taken up some time ago in a leaden box. In this choir is a cloister, commonly called God's House, where the priests used to keep their consecrated utensils; and in the market-place is a conduit, with a long stone crost on it, and a niche wherein is the image of St. Lawrence, to whom the church was dedicated. On the north side of the town there was a rich priory, whereof there are few ruins to be seen except those of its church. Here are an alms-house for 30 poor people, and two charity-schools where 50 boys and 30 girls are both taught and clothed. It has a market on Monday, and three fairs on Wednesday, Friday, and Saturday. Its fairs are on the Tuesday Easter, Whit-Wednesday, August 27, Sept. 28, and Dec. 8. Provisions are very cheap here; and at the annual horse-races there is the best of company. The country round is exceedingly pleasant, fruitful, and populous, especially that part called the Corve-dale, being the vale on the banks of the river Corve. Ludlow sends two members to parliament.

Ludolph (Job), a very learned writer of the 17th century, was born at Erfurt in Thuringia. He travelled much, and was master of 25 languages; visited libraries, searched after natural curiosities and antiquities every where, and conversed with learned men of all nations. He published A History of Ethiopia, and other curious books.

Ludolph (Henry William), nephew of Job above-mentioned, was born at Erfurt in 1655. He came over to England as secretary to M. Lenthe, envoy from the court of Copenhagen to that of London; and being recommended to Prince George of Denmark, was received as his secretary. He enjoyed this office for some years, until he was incapacitated by a violent disorder; when he was discharged with a handsome pension; after he recovered, he travelled into Muscovy, where he was well received by the czar, and where his knowledge made the Muscovite priests suppose him to be a conjurer. On his return to London in 1694, he was cut for the stone; and as soon as his health would permit, in acknowledgment of the civilities he had received in Muscovy, he wrote a grammar of their language, that the natives might learn their own tongue in a regular method. He then travelled into the East, to inform himself of the state of the Christian church in the Levant; the deplorable condition of which induced him, after his return, with the aid of the bishop of Worcester, to print an edition of the New Testament in the vulgar Greek, to present to the Greek church. In 1705, when such numbers of Palatines came over to England, Mr. Ludolph was appointed by Queen Anne one of the commissioners to manage the charities raised for them; and he died early, the following year. His collected works were published in 1712.

Ludwidgeia, in botany: A genus of the monogynia order, belonging to the tetrandra class of plants; and in the natural method ranking under the 17th order, Calycanthemata. The corolla is terrapetalous; the calyx quadripartite, superior; the capsule tetragonal, quadrilocular, inferior, and polypersomous.

Lux, among physicians, is in general used for a disease of any kind; but in a more particular sense is restrained to contagious and pestilential diseases: thus the lux Gallica, or venerea, signifies the venereal disease. See Medicine. Index.

Luff, the order from the pilot to the steerman to put the helm towards the lee-side of the ship, in order to make the ship fall nearer the direction of the wind. Hence, luff round, or luff a-lee, is the excess of this movement, by which it is intended to throw the ship's head up in the wind, in order to tack her course. A ship is accordingly said to bring her lee when she yields to the effort of the helm, by falling nearer
LUCK [322]

LUCK

Lull nearer to the line of the wind than she had done before. See also HALLING the Wind.

Tackle, a name given by sailors to any large tackle that is not defined for a particular place, but may be variously employed as occasion requires. It is generally somewhat larger than the jigger tackle, although smaller than those which serve to hoist the heavier materials into and out of the vessel, which latter are the main and fore-tackles, the stay and quarter-tackles, &c.

LUG-SAIL, a square-sail, hoisted occasionally on the mast of a boat or smaller vessel upon a yard which hangs nearly at right angles with the mast. There are more particularly used in the barca longas, navigated by the Spaniards in the Mediterranean.

LUGDUNUM (anc. geog.), the capital of the Seguiani in Gallia-Celtica, situated at the confluence of the Arar and Rhodanus; on an eminence, as the Celtic term dune signifies; built by Maximianus Plancus under Augustus, while commanding in that part of Gaul; and whither he led a colony. Now Lyons, capital of and Lyoinois.

LUGGER SHALL, a town of the Baravi in Gallia Belgica. Now Leyden in Holland.

LUGGER SHALLEN (anc. geog.), a town of Gaul in Aquitania, at the foot of the Pyrenees. Now S. Bertrand, in Garcomy.

LUGUEUS TACUS (anc. geog.), a lake of Japydia, the western district of Illyricum, to the south of the Save, and near the head of the Arda. Now commonly called the Zirichnitz Lake, from a small adjoining town. It is locked on every side with mountains; from which scanty currents run down; the lefs in quantity their waters, because drank up by the earth; till at length they are swallowed up in rocky furrows, so formed as to resemble artificial. In thefe the water being brought as to refuse receiving any more, they regurgitate, and return the water with extraordinary celerity; which thus spreading itself, forms a lake, in most places 13 cubits high. These waters afterwards retire with no lefs celerity than they came on, not only through the furrows, but pass through the whole of the bottom, as through a sieve; which when perceived by the inhabitants, they directly stop up the larger apertures, and thus take large quantities of fish; when the lake is dry, they cut down their harvest on the spot where they flowed, and soon again before the inundation comes on: and graft shoots to quick it, that it may be cut down in three weeks time (Lazius, Lernherus).

LUGGERSHALL, a borough of Wiltshire, 22 miles north of Salisbury, and 75 north by west of London. It is an ancient borough by prescription, though but a small hamlet, near the forest of Chute, in a delightful country; and was the residence of several kings. It had formerly a castle. It is governed by a bailiff chosen yearly at the lord of the manor's court.

On the neighbouring downs there used to be horse-races. It has a fair on the 25th of July, and sends two members to parliament.

LUKE (St), the evangelist, and the disciple of the apostles, was originally of Antioch in Syria, and by profession a physician. He particularly attached himself to St Paul, and was his faithful companion in his travels and labours. He went with him to Troas in Macedonia about the year 51. He wrote his Gospel in Achaia about the year 53; and, ten years after, the Acts of the Apostles, which contains a history of 30 years. Of all the inspired writers of the New Testament, his works are written in the most elegant Greek. It is believed that St Luke died at Rome, or in Achaia.

Gospel of St Luke, a canonical book of the New Testament. Some think that it was properly St Paul's Gospel; and that, when the apostle speaks of his Gospel, he means what is called St Luke's. Jerome says, that St Luke digested into writing what St Paul preached to the Gentiles; and Gregory Nazianzen tells us, that St Luke wrote with the assistance of St Paul.

St Luke the Evangelist's Day, a festival in the Christian church, observed on the 18th of October.

LULA, a town of Swedish Lapland; seated at the mouth of the river Lula, on the west side of the gulph of Bothnia, 42 miles south-west of Torne. E. Long. 21.0. N. Lat. 64. 30.

LULIA LAPMARK, a province of Swedish Lapland; bounded by that of Torne on the north, by the Bothnic Gulph on the east, by Pithia Lapmark on the south, and Norway on the west.

LULLI (John Baptist), the most celebrated and most excellent musician that has appeared in France since the revival of learning, was born at Florence. He was taken to France when very young by a person of quality; and he carried the art of playing on the violin to the highest perfection. Louis XIV. made him superintendent of music. Some time after Perinna having introduced operas into France, and quarrelling with his company, he resigned his privilege to Lulli. Operas were then carried on to the utmost perfection by this celebrated musician, and were attended with continual applause. Lulli every year, after this time, gave a piece of his own composition, till his death, which happened in 1687.

LULLY (Raymond), a famous writer, farnamed the Enlightened Doctor, was born in the island of Majorca in 1625. He applied himself with indefatigable industry to the study of the Arabian philosophy, to chemistry, physic, and divinity; and acquired great reputation by his works. He at length went to preach the gospel in Africa; and was stoned to death in Mauritania, at the age of 80. He is honoured as a martyr at Majorca, whither his body was carried. He wrote many treatises on all the sciences, in which he shows much study and industry, but little judgment or solidity. A complete edition of his works has been printed at Mentz. He ought not to be confounded with Raymond Lully of Terraca, farnamed Neophyto, who from being a Jew turned Dominican friar. This last Lully maintained several opinions that were condemned by Pope Gregory XI.

LUMBAGO, a fixed pain in the small of the back. See Medicine—Index.

LUMBARIS, a name given to the arteries and veins which spread over the loins.

LUMBRICAL, a name given to four muscles of the fingers and to as many of the toes.

LUMBRICUS, the Worm, in zoology; a genus of insects belonging to the order of Hemiptera. The body is cylindrical, annulated, with an elevated belt near the middle, and a vent-hole on its side. There are two species of this animal.

1. Lumu-
LUM

1. **Lumbricus terrestris**, the earth or dew worm, Mr. Barlow observes, differs extremely in colour and external appearance in the different periods of its growth, which hasoccasioned people little acquainted with the variations of this kind of animals to make four or five different species of them. The general colour is a dusky red. — They live underground, never quitting the earth but after heavy rains or at the approach of storms, and in the season of their amours. The method to force them out is, either to water the ground with infusions of bitter plants, or to trample on it. The bare motion on the surface of the soil drives them up, in fear of being surprized by their formidable enemy the mole. The winding progress of the worm is facilitated by the inequalities of its body, armed with small, stiff, sharp pointed bristles: when it means to in-line it fall into the earth, these ooze from its body a clamorous liquor, by means of which it slides down. It never damages the roots of vegetables. Its food is a small portion of earth, which it has the faculty of digesting: The superfluity is ejected by way of excrement, under a vermicular appearance. Earth-worms are hermaphroditic, and have the parts of generation placed near the neck: their coagulation is performed on the ground; nothing being more usual than to see it full of holes, which holes are thought to be made by those kind of worms coming to the surface in quest of females. During their custom they would sooner suffer themselves to be crushed than parted.

2. The *marinus*, marine worm, or lug, is of a pale red colour, and the body is composed of a number of annular joints; the skin is feeble and all the rings or joints are covered with little prominences, which render it extremely tough to the touch. It is an inhabitant of the mud about the sea-fllores, and serves for food to many kinds of fish: surprising large ones are to be met with about the Bognor rocks in Sussex, England. The fishermen bait their hooks and nets with it.

For the effects of these animals in the human body, and the method of expelling them, see Medicine-Index.

**Plate cclxxiv.**

**Lunell**o, a village in Italy, which gives name to the Lunellin, a small district in the duchy of Milan, lying along the river Po, and of which Mortarina and Valencia are the principal places. It was ceded to the duke of Savoy in 1707, and confirmed by the treaty of Utrecht in 1713. E. Long. 8. 42. N. Lat. 45. 5.

**Lumino**us, an epithet applied to any thing that shines or emits light.

**Luminous Emanations,** have been observed from human bodies, as also from those of brutes. The light arising from currying a horse, or from rubbing a cat's back, are known to mist. Instances of a like kind have been known on combing a woman's head. Bartholin gives us an account, which he titles *mulier resplendens*, of a lady in Italy whose whole body would shine whenever slightly touched with a piece of linen. These effluvia of animal bodies have many properties in common with those produced from glafs; such as their being lucid, their snapping, and their not being excited without some degree of friction; and are undoubtedly electrical, as a cat's back has been found strongly electrical when stroked. See Electricity, and Light.
LUNAT\(\text{ic}\), in law. Under the general term of non composit\(\text{a}\) mentis (which Sir Edward Coke says is the most legal name) are comprised not only lunatics, but persons under frenzies, or who lose their intellects by disease; those that grow deaf, dumb, and blind, not being born so; or fucht, in short, as are judged by the court of chancery incapable of conducting their own affairs. To these also, as well as idiots, the king is guardian, but to a very different purpose. For the law always imagines, that these accidental misfortunes may be removed, and therefore only constitutes the crown a trustee for the unfortunate persons, to protect their property, and to account to them for all profits received, if they recover, or after their decease to their representatives. And therefore it is declared by the statute 17 Edw. II. c. 10, that the king shall provide for the custody and satisfaction of lunatics, and preserve their lands, and the profits of them, for theirnie when they come to their right mind; and the king shall take nothing to his own use: and if the parties die in such estate, the residue shall be distributed for their souls by the advice of the ordinary, and of course (by the subsequent amendments of the law of administrations) shall now go to their executors or administrators.

On the first attack of lunacy or other occaional in\(\text{s}\)t\(\text{f}\)inity, when there may be hopes of a speedy restitution of reason, it is usual to confine the unhappy objects in private custody under the direction of their nearest friends and relations: and the legislature, to prevent all abuses incident to such private custody, hath thought proper to interpose its authority, by 14 Geo. III. c. 49, for regulating private madhouses. But when the disorder is grown permanent, and the circumstance of the party will bear such additional expence, it is thought proper to apply to the royal authority to warrant a lodging confinement.

The method of proving a person non composit is very similar to that of proving him an idiot. The lord chancellor, to whom, by special authority from the king, the custody of idiots and lunatics is intrusted, upon petition or information, grants a commission in nature of the writ de id\(\text{i}\)st\(\text{is}\) inquirenda, to inquire into the party's state of mind; and if he be found non composit, he usually commits the care of his person, with a suitable allowance for his maintenance to some friend, who is then called his committee. However, to prevent fin\(\text{i}\)ller practices, the next heir is seldom permitted to be of this committee of the person; because it is his interest that the party should die. But, it hath been said, there lies not the same objection against his next of kin, provided, he be not his heir; for it is his interest to preserve the lunatic's life, in order to increase the personal estate by savings, which he or his family may hereafter be entitled to enjoy. The heir is generally made the manager or committee of the estate, if he be in his interest, by good management to keep it in condition: accountably, however, to the court of chancery, and to the non composit himself, if he recovers; or otherwise, to his administrators. See\textit{ Id\(\text{io}\)cy}.

LUNATION, the period or space of time between one new moon and another; also called\textit{ synodical month}. See\textit{ Cycle and Earth}.

LUNDEN, or\textit{ Lunden}, a considerable town of Sweden in Gothland; and capital of the territory of Schon, with an archbishop's see and an university. It was ceded to the Swedes by the Danes in 1658. L. Long. 13° 25'. N. Lat. 55° 40'.

LUNDY-\textit{Island}, situated 50 miles in the sea, off the N.W. coast of Devonshire, is 5 miles long and 2 broad, but so encompassed with inaccessible rocks, that it has but one entrance to it, so narrow that two men can scarce go abreast. It is reckoned in the hundred of Branton. It had once both a fort and a chapel. The south part of it is indifferent good soil, but the north part of it is barren, and has a high pyramidal rock called the Constable. Here are hares, kine, hogs, and goats, with great store of sheep and rabbits; but the chief commodi\(\text{ty}\) is fowl, with which it abounds much, their eggs being very thick on the ground at their season of breeding. No venomous creature will live in this island. In the reign of King Henry VIII. one William Morisco, who had conspired to murder him at Woodstock, fled to this island, which he fortified, turned pirate, and did much damage to this coast, but was taken by surprize at length, with 16 of his accomplices, and put to death.

LUNE,\textit{ Lunula}, in\textit{ Geometry}, a plane in form of a crescent or half-moon, terminated by the circumference of two circles, that intersect each other within.

LUNENBURG, or\textit{ Luneburg Zell}, a principality of Germany, bounded to the north by that of Calenberg, the diocese of Hildesheim, and the duchy of Brunswick; to the north by the duchy of Lauenburg and the Elbe, by the laft of which it is separated from the territory of the imperial city of Hamburg; to the east, by the duchy of Brunswick, the Alte Mark, and the duchy of Mecklenburg; and to the west, by the duchies of Bremen and Verden, the country of Hoya, and the principality of Calenberg. The soil, except along the Elbe, Aller, and jetz, is either sand, heath, or moors. In the more fruitful parts of it are produced wheat, rye, barley, oats, peas, buck wheat, flax, hemp, hops, pulfe, oak, beech, fir, pines, birch, and alder, together with black cattle and horses. The heaths abound with bees and honey, and a small kind of sheep whose wool is long and coarse. Lauenburg is well furnished with salt springs and limestone, and the forest of Gorde with venison. The rivers Elbe, Ilmenau, and Aller, are navigable; and, consequently very advantageous to the country, independent of the fish which they yield. The general diets of this principality are convened by the sovereign twice a year, and held at Zell. They consist of the deputies of the nobility and the towns of Lauenburg, Uelzen, and Zell, who have the nomination of the members of the high colleges, and other officers, jointly with the sovereign.
L U N E N B U R G | 325 |

Lunenburg reign. There are near 200 Lutheran churches in the county, under two general and 15 subordinate superintendents, several grammar-schools, two Calvinistic churches at Zell, and an academy of exercises at Lunenburg. The manufactures are chiefly linen cloth, cottons, ribbons, stockings, hats,itch, bleached wax, refined sugar, gold and silver wires, all kinds of wooden wares, barges, boats, and ships. The exports of these to Hamburg, Lubeck, and Altena, are considerable. The neighbourhood of these cities, with the facility of conveying goods and merchandise to them and other places; either by land or water, is very advantageous to this country, and contributes greatly to its subsistence. On account of this principality, the king of Great Britain has a seat and voice both in the college of the princes of the empire and of the circle of Lower Saxony. Its quota in the Matricula is 20 horses and 120 foot, or 720 florins in lieu of them. The revenue of the principality arises chiefly from the demesnes, tolls on the Elbe, contributions, duties on cattle, beer, wine, brandy, and other commodities, which altogether must be very considerable; some bawliwaks alone yielding upwards of 20,000 rixdollars.

L U N E N B U R G, the capital of the principality of the same name, is a pretty large town of Germany, on the river Elmen, or the Ilmenau, which is navigable from the town to the Elbe, at the distance of 13 miles. It is 27 miles from Hamburg, 47 from Zell, 6 from Brunswick, 70 from Bremen, 68 from Hannover; and stands in E. Long. 10. 40. N. Lat. 53. 28. Its inhabitants are reckoned at between 8000 and 9000. Formerly this town was one of the Hanze, and an imperial city. Some derive its name from Lina, the ancient name of the Ilmenau; others from Luna the moon, an image of which is said to have been worshipped by the inhabitants in the times of Paganism. Here were anciently several convents, viz. one of minims, another of Premonstratensians, another of Benedictines, and a fourth of Minorites. Out of the revenues of the Benedictine monastery was founded an academy for the martial exercises, where young gentlemen of the princely family of Lunenburg are maintained gratis, and taught French, fencing, riding, and dancing; but foreigners are educated at a certain fixed price. A Latin school was also founded, consisting of four classes, and well endowed out of these revenues. The superintendency and management of these, and the estates appropriated to their maintenance, belongs to the landsdorff, or the auffreiter, who are both chosen from among the Lunenburg nobility. The first came in place of the Popplin abbot, and as such is head of the files of the principality, and president of the provincial college. He has the title of excellency; and in public instruments styles himself by the grace of God landschafi director, and lord of the mansion of St Michael in Lunenburg. The chief public edifices are three parish-churches, the ducal palace, three hospitals, the town-house, the salt-magazine, the anatomical theatre, the academy; the conventual church of St Michael, in which lie interred the ancient dukes; and in which is the famous table eight feet long, and four wide, plated over with chased gold, with a rim embellished with precious stones, of an immense value, which was taken from the Saracens by the emperor Otho, and presented to this church; but in 1698, a gang of thieves stripped it of 200 rubies and emeralds, together with a large diamond, and most of the gold, so that at present but a small part of it remains. Here are some very rich fai springs. Formerly, when there was a greater demand for the salt, upwards of 120,000 tons have been annually boiled here, and sold off; but since the commencement of the present century, the salt trade hath declined greatly. A fifth of the salt made here belongs to the king, but is farmed out. It is said to excel all the other salt made in Germany. This town is well fortified; and has a garrison, which is lodged in barracks. In the neighbourhood is a good lime-stone quarry, and along the Ilmenau ware-houses in which are lodged goods brought from all parts of Germany, to be forwarded by the Ilmenau to Hamburg, or by the Ache to Lubeck, from whence other goods are brought back the same way. The town itself drives a considerable traffic in wax, honey, flax, linen, salt, lime, and beer.

L U N E N S E M A R M O R, in the natural history of the ancients, the name of that species of white marble now known among us by the name of the Carrara marble, and distinguished from the statuary kind by its greater hardness and less splendour. I was ever greatly esteemed in building and ornamental works, and is so still. It is of a very close and fine texture, of a very pure white, and more transparent than any other of the white marbles. It has always been found in great quantities in Italy, and is so to this day. See LUNA.

L U N E T T E, in fortification, an enclosed court-yard, or elevation of earth, made beyond the second ditch, opposite to the places of arms; differing from terracellins only in their situation. Lunettes are usually made in ditches full of water, and serve to the same purpose as fan de brays, to dispute the passage of the ditch. See Fortification.

L U N E T T E, in the manage, is a half-shoefshoe, or such a shoe as wants the spur, i. e. that part of the branch which runs towards the quarters of the foot. Lunette is also the name of two small pieces of felt, made round and hollow, to clap upon the eyes of a vicious horse that is up to bite, and strike with his fore feet, or that will not suffer his rider to mount him.

L U N G S, in anatomy, a part of the human body, serving for respiration. See Anatomy, no. 117.

In the Journal de Medicine for June 1789 is a description of a

Inventor of Inflating the Luxes, invented by M. Gorey physician to the military hospital at Neufbruck, which appears, to be extremely well adapted to the purpose, whilst it may be used with the greatest ease and facility.

This instrument, which the inventor styles apotropos, that is, 'refiner of respiration consists of a double pair of bellows, BCLM, fig. 1, the two different parts of which have no communication with each other. In the lower side B M is an aperture A for a valve constructed on the principles of those of Mr Nairne's air-pump. It consists of a rim of copper, closed at one end by a plate of the same metal, in which plate are seven small holes placed at equal distances. This plate is
is covered with a piece of silk coated with elastic gum, in which are six transverse incisions of two or three lines in length. Each incision is so made as to be situated between two of the holes, and at an equal distance from each: see D, fig. 2. The silk must be made very secure, by a thread passing several times round the rim. It is obvious, that a stream of air applied to that side of the plate which is opposite to the silk, will pass through the holes, and lifting up the silk, escape through the incisions. On the contrary, a stream of air applied to the other side will press the silk upon the plane, and thus close the holes, so that it will be impossible for it to pass through them. This valve opens internally, so as to admit the air from without. At B is another valve, on the same construction, but opening in a contrary direction, thus permitting the air to escape out of the lower part into the tube E, but preventing its entrance. At C is another valve, opening internally to admit the air from the tube E; and at D there is a fourth, opening externally, to discharge the air from the upper part.

The flexible tube E, screwed on at the end C B, being introduced into one of the nostrils, whilst the mouth and the other nostril are closed by an asphyxiant, if we separate the two handles L M, which were close together at the introduction of the tube, it is evident, that the air in the lungs will roll into the upper part through the valve C, whilst the external air will fill the lower part through the valve A: the two handles being again brought into contact, the atmospheric air will be forced into the lungs through the valve B, and at the same time the air in the upper part will be discharged at the valve D. Thus by the alternate play of the double bellows, the lungs will be alternately filled and emptied as in respiration. In using the instrument care should be taken not to be too violent; as the more perfectly the natural motion of respiration is imitated the better.

To prevent any irritations from without injuring the valves A D, fig. 1, the rim is made with a screw, B, fig. 3, in order to receive a cap A A, fig. 3, full of small holes. This screw has also another use. If dephephlogisticated air be preferred, a bladder filled with it, fig. 4, may, by means of the screw A, be fastened to the valve A, fig. 1; and to prevent waists, as this air may serve several times, a flexible tube may be fastened on the valve D, fig. 1, communicating with the bladder by means of the opening d, fig. 4: thus it may be employed as often as the operator thinks proper.

There is a handle K to the partition in the middle, in order that, if it be at any time necessary to use either of the divisions alone, the other may be confined from acting. e, fig. 5, represent the two valves to be applied at the end of the instrument C B, fig. 1: and fig. 6, is a section of the end C B, showing the valves in their proper places.

It is proper to add, that the capacity of the instrument should be proportioned to the quantity of air received into the lungs in inspiration, which Dr Goodwyn has ascertained to be twelve cubical inches or somewhat more. Each division of the instrument, therefore, should be capable of containing that quantity.

**Long-Wort**, in botany. See **Pulmonaria**.

**LUNISOLAR year**, in chronology, the space of 532 common years; found by multiplying the cycle of the sun by that of the moon.

**LUNULA.** See **LUNAE**.

**LUPERCALIA**, feasts instituted in ancient Rome, in honour of the god Pan—The word comes from **Lupercal**, the name of a place under the Palatine mountain, where the sacrifices were performed.

The Lupercalia were celebrated on the 15th of the kalends of March, that is, on the 15th of February, or as Ovid observes, on the third day after the ides. They are supposed to have been established by Evander.

On the morning of this feast, the Luperci, or priests of Pan, ran naked through the streets of Rome, striking the married women they met on the hands and belly with a thong or strap of goat's leather, which was held an omen promising them fecundity and happy deliveries. See **LUPUS**.

This feast was abolished in the time of Augustus but afterwards restored, and continued to the time of the emperor Anastasius.—Baronius says it was abolished by the pope in 496.

**LUPERSI**, a name given to the priests of the god Pan. See **LUPERCALIA**.

The **luperci** were the most ancient order of priests in Rome: they were divided into two colleges or companies, the one called **Fabii** and the other **Quintili**.

To these Caesar added a third, which he called **Julii**.

**LUPINUS, Lupine**, in botany: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, Papilionaceae. The calyx is bilabiate; there are five oblong and five roundish anthers; the legumes are coriaceous. There are seven species, six of them hardy herbaceous flowere, annuals, and one perennial, rising with upright stalks from one to three or four feet high, ornamented with digitate or fingered leaves, and terminated by long whorled spikes of papilionaceous flowers, white, blue, yellow, and rose-coloured. They are all easily raised from seed; and succeed in any open borders, where they make a fine variety.

The seeds of the white lupine, which have a leguminous tail accompanied with a disagreeable bitter one, are said to be anethelmine, both internally taken, and applied externally. Caspar Hoffman cautions against their internal use, and tells us (one of the Arabian writers) that they have sometimes occasioned death. Simon Paulus also says that he saw a boy of eight or ten years of age, after taking a dram of these seeds in powder, feized with exquisite pains in the abdomen, a difficulty of respiration, and almost total loss of voice; and that he was relieved from these complaints by a glass of milk and sugar, which brought away a vast quantity of worms. But Mr Geoffroy observes, very justly, that either these symptoms were owing to the worms, and not to the medicine; or that these seeds, if they have any noxious quality, lose it with their bitterness in boiling; since they were commonly used among the Greeks as food, and recommended by Galen as very wholesome.

**LUPULUS, in botany.** See **Humulus**.

**LUPUS**, in zoology. See **Canis**.

**Lupus-Marinus.** See **Anarrhichas**.

Lurcer, a kind of hunting dog much like a mongrel gundog, with pricked ears, a flagged coat, and generally of a yellowish white colour: they are very swift runners, so that if they get between the barrows and the coisons they seldom miss; and this is their common practice in hunting: yet they use other faculties, as the tumbler does, some of them bringing their game and those are the best. It is also observable, that a lurcher will run down a hare at stretch.

Lure, in falconry, a device of leather, in the shape of two wings, fixed with feathers, and basted with a piece of flesh, to call back a hawk when at considerable distance.

Lurgan, a port and fair town in the county of Armagh and province of Ulter in Ireland, 67 miles from Dublin. It is a flourishing town, agreeably situated in the midst of a much improved country; and the inhabitants are extensively engaged in the linen manufacture. It stands on a gentle eminence, about two miles from Lough Neagh, of which it commands the middle of the lake.

Lurgan-green, a port and fair town of Ireland, in the county of Louth and province of Leinster, 37 miles from Dublin; a mile beyond which is a handsome seat of the earl of Charlemont. It has three fairs in the year.

Luridæ, the name of the 28th order in Linnaeus's fragments of a natural method. See Botany, p. 462.

Lusatia, a marquisate of Germany in upper Saxony, bounded to the east by Silesia, to the west by Mefnia, to the south by Bohemia, and to the north by the marquisate of Brandenburg. Till towards the middle of the 15th century, the Upper Lusatia was called the Mark, i.e. the marquisate or the land of Budiftn and Gorlitz; and the Lower only Lusatia, which it is said, in the Schononic signifies "a woody or marshy country." The air of the Upper Lusatia, which is hilly or mountainous, is better than that of the Lower, a great part of which is moorish and boggy. Both abound in wood, especially the Lower, and turf for fuel. The heath and mountainous tracts are generally barren; but the lower championship and marsh lands are tolerably fertile, producing barley, wheat, rye, oats, barley, buck wheat, peas, lentils, beans, and millet; together with flax, hops, tobacco, some white and red wine, and what is called manna. Of several of these articles, however, considerable quantities are imported. In this country are found also quarries of stone, medicinal springs, bastard diamonds, agates, and Jasper, earths and clays for tobacco-pipes and all sorts of earthen ware, alum, good iron, stone, vitriolic and copper water; uranium is deficient of cattle, fish, and venison. The rivers Spee, the Schwarze or Black Elter, and the Pulznitz, have their sources in the Lusatias, which are also watered by the Neisse and Queis. The ancient inhabitants of this country were the Saxons, who were succeeded by the Vandals, and thence by the Sobers-Wends, a Slavonian people. The present inhabitants, the descendents of the Wends, have an odd dress; and the language is so inarticulate and guttural, that it hath been so curs'd, it might be pronounced without lips, teeth or tongue: but the towns are almost wholly peopled by Germans.

In the Upper Lusatia are six towns which appear at the land-diets, 16 smaller country towns, and four market towns. In the Lower are four diet-towns, 13 country-towns, and two market ones. Both marquisates were formerly subject either to the kings of Bohemia, or electors of Brandenburg: but, in 1620, both were absolutely ceded to the elector of Saxony, in lieu of the 72 tons of gold which he expended in assisting the emperor Ferdinand II. against the Bohemians.

Christianity was first planted in Lusatia in the seventh century, but it was several centuries after that before Popery was fully established. In the 11th century many cloisters were erected in the country; but at the reformation such numbers embraced Lutheranism, that it became the predominant religion and still continues, though there are still several Roman Catholic foundations, churches, market-towns, and villages. The feel of Hessian politics has great influence and esteem here. There are considerable manufactures of woollen and linen stuffs in the Lusatias, especially the Upper. At Budiftn, and in the adjacent country, prodigious quantities of flockings, spatterdashes, caps, and gloves are made. The linen manufactures also flourish here, chiefly in the Upper Lusatia, where all sorts of linen are made, printed, and dyed. Exclusive of these, there are considerable manufactures of hats, leather, paper, gunpowder, iron, glafs, bleached wax, &c.

Though the demand and exportation of these commodities, particularly linens and woollens, is not so great as formerly, yet it is still considerable, and more than overbalances their importations in wool, yarn, silk, wines, spices, corn, fresh and baked fruits, garden stuff, and hops. Difficulties of many years standing have subsisted between the country-artificers and linen-manufacturers on the one side, and the diet towns on the other. The natives of this country are said to have quick natural parts, but to be forbidly pensive. We are told they observe the Saxon laws much better than they did the Bohemian. Learning hath been much esteemed and encouraged in both marquisates since the reformation, but the schools in the six diet-towns of Upper Lusatia, particularly at Gorlitz, Budiftn, and Zittau, great distinction themselves, having handsome stipends. In Lower Lusatia also are some good schools, with stipends for the maintenance of students. Printing is said to be much followed, and brought to great perfection in this country.

In Upper Lusatia, the fates confit, 1st, of those called fiete-foils; 2dly, of the prelates; 3dly, of the gentry and commonalty, under which are comprehended the counts, barons, nobles, and burgesses, poftfors of fces and fief-efates; and, 4thly, of the representatives of the six principal towns. Without the consent of these fates no taxes can be imposed, nor any thing of importance, that regards the public interest. The diets are ordinary or extraordinary. The ordinaries meet once in three years, and the extraordinary when summoned by the sovereign upon particular emergencies. As to ecclesiastical matters, the dean of the
Lus 

Lustria, an epithet given by the ancients to the water used in their ceremonies to sprinkle and purify the people. From them the Romanists have borrowed the holy water used in their churches.

Lustral Day, (Dies Lustricus), that wherein the lustrations were performed for a child, and its name given; which was usually the ninth day from the birth of a boy, and the eighth from that of a girl. Others performed the ceremony on the last day of that week wherein the child was born, and others on the fifth day from its birth.

Over this feast-day the goddess Nundina was supposed to preside; the midwives, nurses, and domestics, handed the child backwards, and forwards, around a fire burning on the altar of the gods, after which they sprinkled it with water; hence this feast had the name of amphibromia. The old women mixed salvia and ditt with the water. The whole ended with a sumptuous entertainment. The parents received gifts from their friends on this occasion. If the child was a male, their door was decked with an olive garland; if a female, with wool, denoting the work about which women were to be employed.

Lustration, in antiquity, sacrifice of sacred lustration, by which the ancients purified their cities, fields, armies, or people, destitute of any crime or impurity. Some of these lustrations were public, others private. There were two species or manners of performing lustration, viz. by fire and sulphur, by water, and by air; which last was done by fanning and agitating the air round the thing to be purified. Some of these lustrations were necessary, i. e., could not be dispensed with; as lustrations of houses in times of a plague, or upon the death of any person; others again were done out of choice, and at pleasure. The public lustrations at Rome were celebrated every fifth year; in which they led a victim thrice round the place to be purified, and in the mean time burnt a great quantity of perfumes. Their country lustrations, which they called ambarvalia, were celebrated before they began to reap their corn; in those of the armies, which they called armilustra, some chosen soldiers, crowned with laurel, led the victims, which were a cow, a sheep, and a bull; thrice round the army ranged in battle-array in the field of Mars, to which deity the victims were afterwards sacrificed, after pouring out many imprecations upon the enemies of the Romans. The lustrations of their flocks were performed in this manner: the shepherd sprinkled them with pure water, and thrice surrounded his sheepfold with a composition of fava, laurel, and brimstone set on fire; and afterwards sacrificed to the goddesses Palas an offering of milk boiled, wine, a cake, and millet. As for private houses, they were sprinkled with water, a fumination of laurel, juniper, olive tree, fava, and such like; and the victim commonly was a pig. Lustrations made for particular persons were commonly called expiations; and the victims pisula. There was also a kind of lustration used for infants, by which they were purified girls the third, and boys the ninth, day after their birth, which ceremony was performed with pure water and spittle. See the article AMBARVALIA. In their lustratory sacrifices, the Athenians sacrificed two men, one for the men of their city, and the other for the women. Divers of these expiations were after: some fasted; others abstained from all sensual pleasures; and some, as the priests of Cybele, castrated themselves. The purifiers of the penitents were different according to the different sacrifices. The priests changed their habits according to the ceremony to be performed; white, purple, and black, were the most usual colours. They cast into the river, or at least out of the city, the animals or other things that had served for a lustration or sacrifice of atonement; and thought themselves threatened with some great misfortune when by chance they trod upon them. Part of these ceremonies were abolished by the emperor Constantine, and his successors: the rest sublifted till the Gothic kings were masters of Rome; under whom they expired, excepting what the popes thought proper to adopt and bring into the church.

For the lustration, or rather expiation, of the ancient Jews, see EXPIATION.

Lustre, the glows or brightness appearing on any thing, particularly on manufactures of silk, wool, or fluff. It is likewise used to denote the composition or manner of giving that glow. The lustre of silks is given them by washing in soap,
then clear water, and dipping them in alum water cold. To give fluid a beautiful lute: For every eight pounds of stuff allow a quarter of a pound of linseed; boil it half an hour, and then strain it through a cloth, and let it stand till it is turned almost to a jelly; afterwards put an ounce and a half of gum to dissolve 24 hours; then mix the liquor, and put the cloth into this mixture, rake it out, dry it in the shade, and press it. If once doing is not sufficient, repeat the operation. Curriers gives a lute to black leather first with juice of barberries, then with gum-arabic, ale, vinegar, and Flanders-glue, boiled together. For coloured leather, they use the white of an egg beaten in water. Moroccas have their lute from juice of barberries, and lemon or orange. For hats, the lutes is frequently given with common water; sometimes a little black dye is added: the same lute serves for furs, except that for very black furs they sometimes prepare a lute of galls, copperas, Roman alum, ox's marrow, and other ingredients.

LUSTRE, an appellation given to a branched candle-stick, when made of glas. See BRANCH and JESSE.

LUSTRINGS. A company was incorporated for making, dressing, and intrating alamos and lustrings in England, who were to have the sole benefit thereof, by Stat. 4. and 5. William and Mary. And no foreign filks known by the name of lustrings or alamos are to be imported but at the port of London, &c. Stat. 9. and 10. W. III. c. 43. See SILK.

LUSTRUM, in Roman antiquity, a general mutter and review of all the citizens and their goods, which was performed by the censors every fifth year, who afterwards made a solemn lustration. See the article LUSTRATION.

This custom was first instituted by Servius Tullius, about 180 years after the foundation of Rome. In course of time the lustra were not celebrated so often; for we find the fifth lustrum celebrated at Rome only in the 574th year of that city.

LUTE, or LUTING, among chemists, a mixed, tenacious, rude substance, which grows solid by drying, and, being applied to the juncture of velvets, flops them up so as to prevent the air from getting either in or out. See CHEMISTRY-INDEX.

Lute, is also a musical instrument with strings.—The lute consists of four parts, viz. the table, the body or belly, which has nine or ten sides; the neck, which has nine or ten flops or divisions, marked with strings; and the head or croo, where the fereu for raling and lowering the flings to a proper pitch of tone are fixed. In the middle of the table there is a nole or passage for the sound; there is also a bridge that the strings are fasten to, and a piece of ivory between the head and the neck to which the other extremities of the strings are fitted. In playing, the strings are struck with the right hand, and with the left the fops are prefixed. The lutes of Bologna are esteemed the best on account of the wood, which is said to have an uncommon disposition for producing a sweet sound.

LUTETIA PARISIARUM, (anc. geogr.), a town of the Parisii, in Gallia Celta, situated in an island in the Scenna or Seine. It received its name, as some suppose from the quantity of clay, lutum, which is in its neighbourhood. J. Caesar fortified and embellished it, from which circumstance some authors call it Juli Ci.

Vol. X.
gustativos to check by this authority the rashness of an arrogant monk, which brought disgrace upon their order, and gave offence and disturbance to the whole church.

From these letters, and the appointment of his open enemy Priérias to be his judge, Luther easily saw what sentence he might expect at Rome; and therefore discovered the utmost solicitude to have his cause tried in Germany, and before a less suspected tribunal. He wrote a submissive letter to the pope, in which he promised an unrestrained obedience to his will, for as yet he entertained no doubt of the divine original of the pope’s authority; and by the intercession of the other professors, Cajetan the pope’s legate in Germany was appointed to hear and determine the cause. Luther appeared before him without hesitation; but Cajetan thought it below his dignity to dispute the point with a person so much his inferior in rank: and therefore required him, by virtue of the apostolic powers with which he was clothed, to retract the errors which he had uttered with regard to indulgences and the nature of faith, and to abstain for the future from the publication of new and dangerous opinions; and at the last forbade him to appear in his presence, unless he proposed to comply with what had been required of him.

This haughty and violent manner of proceeding, together with some other circumstances, gave Luther’s friends such strong reasons to suspect that even the imperial safe-conduct would not be able to protect him from the legate’s power and refentment, that they prevailed upon him secretly to withdraw from Augsburg, where he had attended the legate, and to return to his own country. But before his departure, according to a form of which there had been some examples, he prepared a solemn appeal from the pope, ill-informed at that time concerning his cause, to the pope, when he should receive more full intimation with respect to it.—Cajetan, enraged at Luther’s abrupt retreat, and at the publication of his appeal, wrote to the elector of Saxony, complaining of both, and requiring him as he regarded the peace of the church, or the authority of its head, either to seduce that demented monk a prisoner to Rome, or to banish him out of his territories. Frederic had hitherto, from political motives, protected Luther, as thinking he might be of use in checking the enormous power of the see of Rome; and though all Germany rejoiced with his fame, the elector had never yet admitted him into his presence. But upon this demand made by the cardinal, it became necessary to throw off somewhat of his former reserve. He had been at great expense and bestowed much attention on founding a new university, an object of considerable importance to every German prince; and foreseeing how fatal a blow the removal of Luther would be to its reputation, he not only declined complying with either of the pope’s requests, but openly discovered great concern for Luther’s safety.

The situation of our reformer, in the mean time, became daily more and more alarming. He knew very well what were the motives which induced the elector to afford him protection, and that he could by no means depend on a continuance of his friendship. If he should be obliged to quit Saxony, he had no other asylum, and must stand exposed to whatever punishment the rage or bigotry of his enemies could inflict; and so ready were his adversaries to condemn him, that he had been declared a heretic at Rome before the expiration of the 60 days allowed him in the citation for making his appearance. Notwithstanding all this, however, he discovered no symptoms of timidity or remissness; but continued to vindicate his own conduct and opinions, and to inveigh against those of his adversaries with more vehemence than ever. Being convinced, therefore, that the pope would soon proceed to the most violent measures against him, he appealed to a general council, which he affirmed to be the representative of the Catholic church, and superior in power to the pope, who being a fallible man, might err, as St Peter, the most perfect of his predecessors, had done. The court of Rome were equally affiduous in the mean time to crush the author of these new doctrines which gave them so much uneasiness. A bull was issued by the pope, of a date prior to Luther’s appeal, in which he magnified the virtues of indulgences, and subjected to the heaviest ecclesiastical censures all who presumed to teach a contrary doctrine. Such a clear decision of the sovereign pontiff against him might have been very fatal to Luther’s cause, had not the death of the emperor Maximilian, which happened on January 17, 1519, contributed to give matters a different turn. Both the principles and interest of Maximilian had prompted him to support the authority of the see of Rome; but, in consequence of his death, the vicarate of that part of Germany which is governed by the Saxon laws devolved to the elector of Saxony; and, under the shelter of his friendly administration, Luther himself enjoyed tranquillity, and his opinions took such root in different places, that they could never afterwards be eradicated. At the same time, as the election of an emperor was a point more interesting to the pope (Leo X.) than a theological controversy which he did not understand, and of which he could not foresee the consequences, he was so extremely solicitous not to irritate a prince of such considerable influence in the electoral college as Frederic, that he discovered a great unwillingness to pronounce the sentence of excommunication against Luther, which his adversaries continually demanded with the most clamorous importunity.

From the reason just now given, and Leo’s natural aversion to severe measures, a suspension of proceeding against Luther took place for 18 months, though perpetual negotiations were carried on during this interval in order to bring the matter to an amicable issue. The manner in which these were conducted having given our reformer many opportunities of observing the corruption of the court of Rome, its obstinacy in adhering to established errors, and its indifference about truth, however clearly proposed or strongly proved, he began, in 1520, to utter some doubts with regard to the divine original of the papal authority, which he publicly disputed with Erasmus, one of his most learned and formidable antagonists. The dispute was indecisive, both parties claiming the victory; but it must have been very mortifying to the partizans of the Romish church to hear such an essential point of their doctrine publicly attacked.
The Papal authority being once suspected, Luther proceeded to push his inquiries and attacks on one doctrine to another, till at last he began to shake the firmest foundations on which the wealth and power of the church were established. Luther then began to perceive that there were no grounds of reclaiming such an incorrigible heretic; and therefore prepared to denounce the sentence of excommunication against him. The college of cardinals was often assembled, in order to prepare the sentence with due deliberation; and the able canonsiffs were consulted how it might be expressed with unexceptional formality. At last it was decided on the 15th of June 1520. Forty-one propositions, extracted out of Luther's works, were therein condemned as heretical, scandalous, and offensive to pious ears; all persons were forbidden to read his writings, upon pain of excommunication; such as had any of the propositions gathered from the canon law were pronounced an obstinate heretic, excommunicated, and delivered to Satan for the destruction of the flesh; and all secular princes were required, under pain of incurring the same censure, to seize his person, that he might be punished as his crimes deserved.

Luther was not in the least disconcerted by this sentence, which he had for some time expected. He renewed his appeal to his general council; declared the pope to be that antichrist, or man of sin, whose appearance is foretold in the New Testament; declaimed against his tyranny with greater vehemence than ever; and at last, by way of retaliating, having assembled all the professors and students in the university of Wittemberg, with great pomp, and in the presence of a vast multitude of spectators, he called the volumes of the canon law, together with the bull of excommunication, into the flames; he himself, if he did not within sixty days, publicly recant his errors, and burn his books, was pronounced an obstinate heretic, excommunicated, and delivered to Satan for the destruction of the flesh; and all secular princes were required, under pain of incurring the same censure, to seize his person, that he might be punished as his crimes deserved.

Luther was not in the least disconcerted by this sentence, which he had for some time expected. He renewed his appeal to his general council; declared the pope to be that antichrist, or man of sin, whose appearance is foretold in the New Testament; declaimed against his tyranny with greater vehemence than ever; and at last, by way of retaliating, having assembled all the professors and students in the university of Wittemberg, with great pomp, and in the presence of a vast multitude of spectators, he called the volumes of the canon law, together with the bull of excommunication, into the flames; he himself, if he did not within sixty days, publicly recant his errors, and burn his books, was pronounced an obstinate heretic, excommunicated, and delivered to Satan for the destruction of the flesh; and all secular princes were required, under pain of incurring the same censure, to seize his person, that he might be punished as his crimes deserved.

On the accession of Charles V. to the empire, Luther found himself in a very dangerous situation. Charles, in order to secure the pope's friendship, had determined to treat him with great severity. His eagerness to gain this point, rendered him not averse to gratify the papal legates in Germany, who insisted, that, without any delay or formal deliberation, the diet then sitting at Worms ought to condemn a man whom the pope had already excommunicated as an incorrigible heretic. Such an abrupt manner of proceeding, however, being deemed unprecedented and unjust by the members of the diet, they made a point of Luther's appearing in person, and declaring whether he adhered or not to those opinions which had drawn upon him the censures of the church. Not only the emperor, but all the princes through whose territories he had to pass, granted him a safe conduct; and Charles wrote to him at the same time, requiring his immediate attendance on the diet, and renewing his promises of protection from any injury or violence. Luther did not hesitate one moment about yielding obedience; and set out for Worms, attended by the herald who had brought the emperor's letter and safe-conduct. While on his journey, many of his friends, whom the court of Hapsburg, under familiar circumstances, and notwithstanding the same security of an imperial safe-conduct, filled with solicitude, advised and interceded him not to rush wantonly into the midst of danger. But Luther, superior to such fears, silenced them with this reply, "I am lawfully called (said he) to appear in that city; and thither will I go in the name of the Lord, though as many devils as there are tiles on the housetops were there combined against me."

The reception which he met with at Worms, was such as might have been reckoned a full reward of all his labours, if vanity and the love of applause had been the principles by which he was influenced. Greater crowds assembled to behold him than had appeared at the emperor's public entry; his apartments were daily filled with princes and personages of the highest rank; and he was treated with an homage more extraordinary, as well as more flattering, than which any preeminence in birth or condition can command. At his appearance before the diet, he behaved with great decency, and with equal firmness. He readily acknowledged an excess of acrimony and vehemence in his controversial writings; but refused to retract his opinions unless he were convinced of their falsehood, or to consent to their being tried by any other rule than the word of God. When neither threats nor injunctions could prevail on him to depart from this resolution, some of the ecclesiastics proposed to imitate the example of the council of Constance, and, by publishing the author of this pestilent heresy, who was now in their power, to deliver the church at once from such an evil. But the members of the diet refusing to expel the German integrity to freth reproach by a confession of violation of public faith, and Charles being now unwilling to bring a blame upon the beginning of his administration by such an ignominious action, Luther was permitted to depart in safety. A few days after he left the city, a severe edict was published in the emperor's name and by authority of the diet, depriving him, as an obstinate and excommunicated criminal, of all the privileges which he enjoyed as a subject of the empire, forbidding any prince to harbour or protect him, and requiring all to seize his person as soon as the term specified in his protection should be expired.

But this rigorous decree had no considerable effect; the execution of it being prevented partly by the multiplicity of occupations which the commons in Spain, together with the wars in Italy and the Low Countries, created to the emperor; and partly by a prudent precaution employed by the elector of Saxony, Luther's faithful patron. As Luther, on his return from Worms, was palling near Altenbrunn in Thuringia, a number of horsemen in masks rushed suddenly out of a wood, where the elector had appointed them to lie in wait for him, and, surrounding his company, carried him, after dismissing all his attendants, to Worms, a strong castle not far distant. There the elector ordered him to be supplied with everything necessary or agreeable; but the place of his retreat was carefully concealed, until the fury of the present storm against
against him began to abate, upon a change in the political system of Europe. In this solitude, where he remained nine months, and which he frequently called his Parnas, after the name of that island to which the apostle John was banished, he exerted his usual vigour and industry in defence of his doctrines, or in controversy of his adversaries, publishing several treatises, which revived the spirit of his followers, affihliated to a great degree and disheartened, had given little or no check to Luther's edict. But immediately wrote him a letter, distressing and disheartening his retirement, appeared publicly again at Wittemberg, upon the 6th of March 1522. He appeared indeed without the elector's leave; but immediately wrote him a letter, to prevent his taking it ill. The edict of Charles V. as severe as it was, had given little or no check to Luther's doctrine, for the emperor was no sooner gone into Flanders, than his edict was neglected and despised, and the doctrine seemed to spread even faster than before. Caroloftadius, in Luther's absence, had pushed things on faster than his leader; and had attempted to abolish the use of masses, to remove images out of the churches, to fet aside auricular confession, invocation of saints, the abstaining from meats; had allowed the monks to leave their monasteries, to neglect their vows, and to marry; in short, had quite changed the doctrine and discipline of the church at Wittemberg; all which, though not against Luther's sentiments, yet was blamed by him, as being rashly and unseasonably done. Lutheranism was still confined to Germany; it was not got to France; and Henry VIII. of England made the most vigorous acts to hinder it from invading his realm. Nay, he did something more: to show his zeal for religion and the holy see, and perhaps his skill in theological learning, he wrote a treatise, Of the seven sacraments, against Luther's book, Of the Captivity of Babylon, which he presented to Leo X. in October 1521.

The pope received it very favourably, and was so well pleased with the king of England, that he complimented him with the title of Defender of the faith. Luther, however, paid no regard to his kingship; but answered him with great sharpness, treating both his person and performance in the most contemptuous manner. Henry complained of Luther's rude usage of him to the princes of Saxony: and Fiiher, bishop of Rocheftcr, replied to his answer, in behalf of Henry's treatise: but neither the King's complaint, nor the bishop's reply, was attended with any visible effects.

Luther, though he had put a stop to the violent proceedings of Caroloftadius, now made open war with the pope and bishops: and, that he might make the people despise their authority as much as possible, he wrote one book against the pope's bull, and another against the order falsely called the order of bishops. The same year, 1522, he wrote a letter, dated June the 29th, to the assembly of the states of Bohemia; in which he assured them that he was labouring to establish his doctrine in Germany, and exhorted them not to return to the communion of the church of Rome; and he published also, this year, a translation of the New Testament in the German tongue, which was afterwards corrected by himself and Melancthon. This translation having been printed several times, and being in every body's hands, Ferdinand archduke of Austria, the emperor's brother, made a very severe edict to hinder the farther publication of it; and forbade all the subjects of his imperial majesty to have any copies of it, or of Luther's other books. Some other princes followed his example; and Luther was so angry at it, that he wrote a treatise, Of the secular power, in which he accuses them of tyranny and impiety. The diet of the empire was held at Nuremburg, at the end of the year; to which Hadrian VI. sent his brief, dated November the 25th: for Leo X. died upon the 2d of December 1521, and Hadrian had been elected pope upon the 9th of January following. In his brief, among other things, he observes, how he had heard with grief, that Martin Luther, after the sentence of Leo X. which was ordered to be executed by the edict of Worms, continued to teach the same errors, and daily to publish books full of heresies: that it appeared strange to him, that so large and so religious a nation could be seduced by a wretched apolite friar: that nothing, however, could be more pernicious to Christendom; and that therefore he exhorts them to use their utmost endeavours to make Luther, and the authors of these tumults, return to their duty; or, if they refuse and continue obstinate, to proceed against them according to the laws of the empire, and the severity of the last edict.

The resolution of this diet was published in the form of an edict, upon the 6th of March 1522; but it had no effect in checking the Lutherans, who still went on in the same triumphant manner. This year Luther wrote a great many pieces: among the rest, one upon the dignity and office of the supreme magistrate; which Frederic elector of Saxony is said to have been highly pleased with. He sent, about the same time, a writing in the German language to the Waldenses, or Pickards, in Bohemia and Moravia, who had applied to him "about worshipping the body of Christ in the eucharist." He wrote also another book, which he dedicated to the senate and people of Prague, "about the institution of ministers of the church." He drew up a form of laying masses. He wrote a piece, entitled, An example of popish doctrine and divinity: which Dupins calls a satire against men and things who profess a monastic life. He wrote also against the vows of virginity, in his preface to his commentary on 1 Cor. viii. And his exhortations here were, it seems, followed with effects; for soon after, nine nuns, among whom was Catherine de Bore, eloped from the nunneries at Nymphenhen, and were brought by the assistance of Leonard Oppen, a burgess of Torgau, to Wittenberg. Whatevcr offence this proceeding might give to the Papists, it was highly extolled by Luther; who, in a book written in the German language, compares the deliverance of these nuns from the slavery of a monastic life, to that of the Jews which Jesus Christ has delivered by his death. This year Luther had occasion to canonize two of his followers, who, as Melchior Adam relates, were burnt at Bruffels in the beginning of July, and were the first who suffered martyrdom for his doctrine. He wrote also a confolatory epistle to three noble ladies at Mifdia, who were banished from the duke of Saxony's court at Friburg, for reading his books.

In the beginning of the year 1524, Clement VII. sent
sent a legate into Germany to the diet, which was to be held at Nuremberg. Hadrian VI. died in October 1523, and was succeeded by Clement upon the 19th of November. A little before his death he canonized Benno, who was bishop of Meissen in the time of Gregory VII. and one of the most zealous defenders of the holy see. Luther, imagining that this was done directly to oppose him, drew up a piece with this title, *Against the New Idol and Old Deev.* in which he treats the memory of Gregory with great freedom, and does not spare even Hadrian. Clement VII.'s legate represented to the diet of Nuremberg the necessity of enforcing the execution of the edict of Worms, which had been strangely neglected by the princes of the empire; but, notwithstanding the legate's solicitations, which were very prevailing, the decrees of that diet were thought to be inefficacious, that they were condemned at Rome, and rejected by the emperor. It was in this year that the dispute between Luther and Erasmus, about free-will, began. Erasmus had been much moved by the Papists to write against Luther; but he was all along of opinion, that writing to take his difsenting from him in opinion would not be found an effectual way to end the differences and establish the peace of the church. However, tired out at length with the importunities of the pope and the Catholic princes, and dea. ...
Luther. Protestant, when the Protestant religion was first established on a firm basis. See PROTESTANTS AND REFORMATION.

As he had little else to do than to sit down and contemplate the mighty works he had finished: for that a single monk should be able to give the church a rude shock, that there needed but such another entirely to overthrow it, may very well seem a mighty work. He did indeed little else: for the remainder of his life was spent in exhorting princes, states, and universities, to confirm the reformation which had been brought about through him; and publishing from time to time such writings as might encourage, direct, and aid, them in doing it. The emperor threatened temporal punishment with armies, and the pope eternal with bulls and anathemas; but Luther cared for none of their threats. His friend and confederate Melancthon was not so indifferent; for Melancthon had a great deal of softheartedness, moderation, and diffidence in his make, which made him very uneasy, and even sorrowful, in the present disorders. Hence we find many of Luther’s letters written on purpose to support and comfort him under these several difficulties and anxieties.

In the year 1533, Luther wrote a consolatory epistle to the citizens of Osnitz, who had suffered some hardships for adhering to the Augsburg confession of faith; in which, among other things, he says: "The devil is the host, and the world is his inn; so that wherever you come, you shall be found and this ugly host." He had also about this time a terrible controversy with George duke of Saxony, who had such an aversion to Luther’s doctrine, that he obliged his subjects to take an oath that they would never emancipate any kind within, or do anything against it. But Luther, having been accused of sedition, by proving, that he had not only abased his person, but also taught rebellion among his subjects. The elector ordered Luther to be acquainted with this; and so he was told at the same time, that if he did not clear himself of the charge, he could not possibly escape punishment. But Luther easily refuted the accusation, by proving, that he had been so far from stirring up his subjects against him, on the score of religion, that on the contrary he had exhorted them rather to undergo the greatest hardships, and even suffer themselves to be banished.

In the year 1534, the Bible translated by him into German was first printed, as the old privilege, dated at Bibliopolis, under the elector’s hand, flows; and it was published the year after. He also published this year a book against mafles and the consecration of priests, in which he relates a conference he had with the devil upon those points; for it is remarkable in Luther’s whole history, that he never had any conflicts of any kind within, but the devil was always his antagonist. In February 1537, an assembly was held at Smallkald about matters of religion, to which Luther and Melancthon were called. At this meeting Luther was wearied with so grievous an illness, that there were no hopes of his recovery. He was afflicted with the flore, and had a filthpage of urine for 11 days. In this terrible condition he would needs undertake to travel, notwithstanding all that his friends could say or do to prevent him: his resolution, however, was attended with a good effect; for the night after his departure he began to be better. As he was carried along, he made his will, in which he declared his detestation of Popery to his friends and brethren; agreeably to what he often used to say: *Ibis crum view, moriones ero mortuus, papa;* that is, "I was the plague of Popery in my life, and shall continue to be so in my death."

This year the Pope and the court of Rome, finding it impossible to deal with the Protestants by force, began to have recourse to stratagem. They affected therefore to think, that though Luther had indeed carried things on with a high hand and to a violent extreme, yet what he had pleaded in defence of these measures was not entirely without foundation. They talked with a seeming show of moderation; and Pius III. who succeeded Clement VII. proposed a reformation first among themselves, and even went so far as to fix a place for a council to meet at for that purpose. But Luther treated this farce as it deserved to be treated; unmasked and detected it immediately; and, to ridicule it the more strongly, casued a picture to be drawn, in which was represented the pope seated on high upon a throne, some cardinals about him with foxes tails on, and seeming to evacuate upwards and downwards (*sursum deorandum repurgare,* as Melchor Adam expressis it). This was fixed over-against the title-page, to let the readers see at once the scope and design of the book; which was, to expone that cunning and artifice with which those subtle politicians affected to cleanse and purify themselves from their errors and fiderflections. Luther published about the same time A Confutation of the pretended Grant of Constantine to Sylvester Bishop of Rome; and also some letters of John Hus, written from his prison at Constance to the Bohemians.

In this manner was Luther employed till his death, which happened in the year 1546. That year, accompanied by Melancthon, he paid a visit to his own country, which he had not seen for many years, and returned again in safety. But soon after he was called thither again by the earls of Mansfeld, to compose some differences which had arisen about their boundaries. Luther had not been used to such matters; but because he was born at Eisleben, a town in the territory of Mansfeld, he was willing to do his country what service he could, even in this way. Preaching his last sermon therefore at Wittemberg, upon the 17th of January, he left off on the 23d; and at Hall in Saxony lodged with Julius Jonas, with whom he stayed three days, because the waters were out. Upon the 29th, he pulled over the river with his three sons and Dr. Jonas; and being in some danger, he said to the Doctor, "Do not you think it would rejoice the devil exceedingly, if I and you, and my three sons, should be drowned?" When he entered the territories of the earls of Mansfeld, he was received by 100 horsemen or more, and conducted in a very honourable manner; but was at the same time so very ill, that it was feared he would die. He said, that the fits of sickness were often upon him when he had any great business to undertake: of this, however, he did not recover; but died upon the 18th of February, in the
in relation to justification: he also set aside the Apoca-
lypse: both which are now received as canonical in the
Lutheran church.

Luther reduced the number of sacraments to two
viz. baptism, and the eucharist; but he believed the
implication, or consubstantiation, that is, that the
matter of the bread and wine remain with the body
and blood of Christ; and it is in this article that the
main difference between the Lutheran and English
churches consists.

Luther maintained the mass to be no sacrifice; ex-
ploded the adoration of the host, auricular confession,
meritorious works, indulgences, purgatory, the wor-
ship of images, &c. which had been introduced in the
corrupt times of the Romish church. He also op-
posed the doctrine of free-will, maintained predesti-
nation, and asserted our justification to be solely by
the imputation of the merits and satisfaction of Christ.
He also opposed the satiety in the Romish church,
monastic vows, the celibate of the clergy, &c.

LUTHERANS, the Christians who follow the op-
inions of Martin Luther, one of the principal reformers
of the church in the 16th century. See LUTHER.

The Lutherans, of all protestants, are those who
differ least from the Romish church; as they affirm
that the body and blood of Christ are materially pre-
sent in the sacrement of the Lord’s supper, though in
an incomprehensible manner; and likewise represent
some religious rites and institutions, as the use of
images in churches, the distinguishing vesture of the
clergy, the private confession of sins, the use of wafer
in the administration of the Lord’s supper, the form of
exorcism in the celebration of baptism, and other ce-
remonies of the like nature, as tolerable, and some of
them as useful. The Lutherans maintain, with regard
to the divine decrees, that they respect the salvation
or misery of men, in consequence of a previous know-
ledge of their sentiments and characters, and not as
free and unconditional, and as founded on the mere
will of God. Towards the close of the last century,
the Lutherans began to entertain a greater liberality
of sentiment than they had before adopted; though in
many places they persevered longer in severe and
defruiting principles than other Protestant churches.
Their public teachers now enjoy an unbounded liberty
different from the decisions of those symbols or
creeds which were once deemed almost infallible rules
of faith and practice, and of declaring their different
in the manner they judge the most expedient. Motheim
attributes this change in their sentiments to the maxim
which they generally adopt, that Christians were ac-
countable to God alone for their religious opinions;
and that no individual could be justly punished by the
magistrate for his erroneous opinions, while he con-
ducted himself like a virtuous and obedient subject,
and made no attempts to disturb the peace and order
of civil society.

LUTHER, in architecture, a kind of window
over the corinie, in the roof of a building: standing
perpendicularly over the naked part of a wall, and
failing to illuminate the upper story.

Luthers are of various forms: as square semi-
circular, round, called bull’s eye, flat arch, &c.

LUTRA, in zoology. See Mustela.

LUTTI (Benedetto), an eminent painter, born at
Flo-
LUXURY; voluptuousness, or an extravagant indulgence in diet, dress, and equipage.

Luxury, among the Romans, prevailed to such a degree, that several laws were made to suppress, or at least limit it. The extravagance of the table began about the time of the battle of Actium, and continued in great excess till the reign of Galba. Peacocks, cranes of Malta, nightingales, venison, wild and tame fowl, were considered as delicacies. A prohibition of provisions was the reigning topic. Whole wild boars were often served up, and sometimes they were filled up with various small animals, and birds of different kinds: this dish they called the Trojan horse, in allusion to the wooden horse filled with soldiers.
Luxury. Fowls and game of all sorts were served up in whole pyramids, piled up in dishes as broad as moderate tables. Lucullus had a particular name for each apartment; and in whatever room he ordered his servants to prepare the entertainments, they knew by the direction the expense to which they were to go. When he dined in the Apollo, the expense was fixed at 50,000 drachmas, that is L. 1,250. M. Antony provided eight boars for 12 guests. Vitellius had a large silver platter, fated to have cost a million of sesterces, called Mumeron's buckler. In this he blended together the livers of gilt-heads, the brains of pheasants and peacocks, the tongues of phalacrocorax, and the milts of lampreys. Caligula served up to his guests pearls of great value dissolved in vinegar; the same was done also by, Clodius the son of Apollon, the tragedian. Apicius laid aside, 100,000,000 of sesterces, besides a mighty revenue, for no other purpose but to be sacrificed to luxury: finding himself involved in debt, he looked over his accounts, and thought he had the sum of 10,000,000 of sesterces still left, he poisoned himself for fear of being starved to death.

The Roman law to restrain luxury were Lex Orbis, Fami, Didia, Livia, Cornelia, and many others. But all these were too little; for as riches increased acquainted. Again, our purveyors in time past employed the use of pewter only upon dishes and pots, and a few other trifes for service; whereas now they are grown into such exquisite cunning, that they can in a manner imitate by infusion any form or fashion, of cup, dish, salt, bowl, or goblet, which is made by the goldsmiths' craft, though they be so curious and very artificially forged. In some places beyond the sea, a garnish of good flat English pewter (I say flat, because dishes and platters in my time began to be made deep, and like basons, and are indeed more convenient both for sauce and keeping the meat warm) is esteemed so precious as the like number of vessels that are made of fine silver.

What were the ideas of luxury entertained in England about two centuries ago, may be gathered from the following passage of Holinshed; who, in a discourse prefixed to his History, speaking of the increase of luxury, says, "Neither do I speak this in reproach of any man, God is my judge; but to show, that I do rejoice rather to see how God has blessed us with his good gifts, and to behold how that in a time wherein all things are grown to the most exquisite prices, we yet do find means to obtain and achieve such furniture as heretofore was impossible. There are old men yet dwelling in the village where I remain, which have noted three things to be marvelously altered in England within their sound remembrance. One is the multitude of chimneys lately erected; whereas in their young days there were not above two or three, if so many, in most uplandish towns of the realm (the religious houses, and manor places of their lords, always excepted, and peradventure some great pernages), but each made his fire against a reedows [scream] in the hall where he dined his meat and dined. — The second is the great amendment of lodging; for, said they, our fathers and we ourselves have lain full oft on straw pillets covered only with a sheet, under coverlets made of a dogstine or horsehairs (to use their own term), and a good log under their head instead of a bolster. — If it were so that the father or good man of the house had a marrasf, or flock bed and sheets, a fack of chaff to rest his head upon, he thought himself to be as well lodged as the lord of the town. So well were they customed, that pillows (faid they) were thought meet only for women in childbed; as for servants, if they had any sheet above them, it was well; for seldom had they any under their bodies to keep them from prickings straw, that ran oft through their coverlets and their hardened hides. — The third thing they tell of, is the exchange of treene [wooden] platters into pewter, and wooden spoons into silver or tin; for Vol. X.
LUX [338]

Luxury. attained a great height long before Holinshed's time: For in the reign of Edward III. we find no fewer than sevenumptious laws passed in one session of parliament to restrain it. It was enacted, that men or servants of lords, as also of tradesmen and artisans, shall be content with one meal of fish daily, and the other meals, daily, shall be of milk, cheese, butter, and the like. Neither shall they use any ornaments of gold, silk embroidery, nor their wives and daughters any veils above the price of twelvepence. Artificers and yeomen shall not wear cloth above 40s. the whole piece (the finest then being about L. 6 per piece), nor the ornaments before named. Nor the women any veils of silk, but only those of thread made in England. Gentlemen under the degree of knights, not having L. 100 yearly in land, shall not wear any cloth above 45s. marks the whole piece. Neither shall they or their females use cloth of gold, silver, or embroidery, &c. But exceptures having L. 200 per annum or upwards of rent, may wear cloths of five marks the whole piece or cloth; and they and their females may also wear stuff of silk, silver, ribbons, girdles, or furs. Merchants, citizens, burgheurs, and artificers of tradesmen, as well of London as elsewhere, where who have goods and chattels of the clear value of L. 500, and their females, may wear as is allowed to gentlemen and esquires of L. 100 per annum. And merchants, citizens, and burgheurs, worth above L. 1000 in goods and chattels, may (and their females) wear the same as gentlemen of L. 200 per annum. Knights of 200 marks yearly may wear cloth of fine marks the cloth, but no higher; but no cloth of gold, nor furred with ermine; but all knights and ladies having above 400 marks yearly, up to L. 1000 per annum, may wear as they please, ermine excepted; and they may wear ornaments of pearl and precious stones for their heads only. Clerks having degrees in cathedrals, colleges, &c. may wear as knights and esquires of the same income. Plowmen, carter, shepherds, and such like, not having 40s. value in goods or chattels, shall wear no sort of cloth but blanket and reft of lawn of 2d. and shall wear girdles and belts; and they shall only eat and drink sufficient for their stations. And whatsoever other apparel than is prescribed by the above laws shall forfeit the same.

Concerning the general utility of luxury to a state, there is much controversy among the political writers. Baron Montesquieu lays it down, that luxury is necessary in monarchies, as in France; but ruinous to democracies, as in Holland. With regard therefore to Britain, whole government is compounded of both species, it is held to be a dubious question, how far private luxury is a public evil; and, as such, cognizable by public laws. And indeed their legislators have several times changed their sentiments as to this point; for formerly there were a number of penal laws existing to restrain excess in apparel, chiefly made in the reigns of Edward III. IV. and Henry VIII. a specimen of which we have inferred above. But all of them appeared expedient to repeal at an after period. In fact, although luxury will of necessity increase according to the influx of wealth, it may not be the general benefit of commerce to impose, as in the above cited laws, an absolute prohibition of every degree of it: yet, for the good of the public, it may be necessary that such as go beyond proper bounds in eating, drinking, and wearing what by no means is suitable to their station, should be taxed accordingly, could it be done without including those who have a better title to such indulgence. This is certainly, however, a point from which they may be weighed before executed; and, in mercantile countries at least, such restrictions may be found prejudicial, most likely impracticable, especially where true liberty is established. Sir William Temple observes, speaking of the trade and riches, and at the same time of the frugality of the Hollanders, "That some of our maxims are not to certain as current in politics as that encouragement of excess and luxury, if employed in the contemplation of native commodities, is of advantage to trade. It may be fo to that which impoverishes, but not to that which enriches a country. It is indeed less prejudicial, if it lies in native than in foreign wares, but the humour of luxury and expense cannot stop at certain bounds; what begins in native will proceed in foreign commodities; and though the example arise among idle persons, yet the imitation will run into all degrees, even of those men by whose industry the nation subsists. And besides, the more of our own we spend, the less we shall have to fend abroad; and fo it will come to pass, that while we drive a vast trade, yet, by buying much more than we sell, we shall come to be poor at last."

LYBIA, or LIBYA, a name anciently given to all that part of Africa lying between the borders of Egypt and the river Trion, and comprehending Cyrenaica, Marmarica, and the Regio Syrtha. See these articles.

LYCEUM, Λυκείον, in antiquity the name of a celebrated school or academy at Athens, where Aristotle explained his philosophy. The place was composed of poriicaces, and trees planted in the quincunx form, where the philosophers disputed walking. Hence phi~ophy of the Lyceum is used to signify the philosophy of Aristotle, or the Peripatetic philosophy. Suidas observes, that the Lyceum took its name from its habitation, which had been originally a temple of Apollo Lyceus; or rather a portico or gallery built by Lyceus son of Apollo; but others mention it to have been built by Pith utanus or Pericles.

LYCEUS (anc. geog.), a mountain of Arcadia, sacred to Jupiter; whence Jupiter Lyceum (Pliny). Sacred also to Pan (Virgil); and hence Lyceus, the rites performed to Pan on this mountain; which Evander carrying with him to Latium, were called Lyceana (Virgil).

LYCAON (lab. hik.), the first king of Arcadia, son of Pelasgus and Meliboea. He built a town called Lycofora, on the top of mount Lycaon, in honour of Jupiter. He had many wives, by whom he had a daughter called Calitoph, and 50 sons. He was succeeded on the throne by Nyctimus, the eldest of his sons. He lived about 1820 years before the Christian era.—Another king of Arcadia celebrated for his cruelties. He was changed into a wolf by Jupiter, because he offered human victims on the altar of the god Pan. Some attribute this metamorphosis to another cause. The sins of mankind, as they relate, were become so enormous, that Jupiter visited the earth to punish wickedness and impiety. He came to Arcadia, where he was
LYCIA, a country of Asia Minor, bounded by the Mediterranean on the south, Caria on the west, Pamphylia on the east, and Phrygia on the north. It was anciently called Mileos and Tremites, from the Mileae, or Solymi, a people of Crete, who came to settle there. The country received the name of Ly西亚 from Lycus, the son of Pandion, who established himself there. The inhabitants have been greatly commended by all the ancients for their sobriety and justice. They were conquered by Croesus king of Lydia, and afterwards by Cyrus. Though they were subject to the power of Pericles, yet they were governed by their own kings, and only paid a yearly tribute to the Persian monarch. They became part of the Macedonian empire when Alexander came into the east, and afterwards were ceded to the house of the Seleucidae. The country was reduced into a Roman province by the emperor Claudius.

LYCUM, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 23rd order, Caryophyllae. The calyx is monophyllous, oblong, and smooth; there are five unguiculated petals; with the segments of the limb almost bifid; the capsule quinquiseptic.

Species, &c. 1. The Chaledonica, or Chaleconia scarlet lychnis, hath a frayed perennial root; upright, straight, hairy, annual stalks, rising three or four feet high; garnished with long, spear-pointed, close-fitting leaves, by pairs opposite; and the stalk crowned by a large, compact, flat bunch of beautiful scarlet or flame-coloured flowers, appearing in June and July. Of this there are varieties, with single scarlet flowers, with large double scarlet flowers of exceeding beauty and elegance, with pale-red flowers, and with white flowers. Of these varieties, the double scarlet lychnis is superior to all for size and elegance; the flowers being large, very double, and collected into a very large bunch, exhibit a charming appearance; the single scarlet kind is also very pretty; and the others effect an agreeable variety with the scarlet kinds. 2. The discia, or dicous lychnis, commonly called bachelor's button, hath frayed perennial roots; upright stalks, branching very diffuse and irregular, two or three feet high; having oval, acute-pointed, rough leaves, by pairs opposite; and all the branches terminated by clusters of discios flowers of different colours and properties in the varieties; flowering in April and May. The varieties are the common single red-flowered bachelor's button, double red, double white, and single white-flowered. The double varieties are exceedingly ornamental in their bloom: the flowers large, very double, and continue long in blow; the single red sort grows wild by ditch sides and other moist places in many parts of England; from which the doubles were accidentally obtained by culture in gardens. The flowers are often dioecious, i. e. male and female on distinct plants.

3. The vicaria, or vicous German lychnis, commonly called catchfly, hath fibrous perennial roots; crowned by a tuft of long grancy leaves close to the ground; many erect, straight, single stalks, rising a foot and an half or two feet high, exuding from their upper part a viscid or clammy matter; garnished with long narrow leaves, by pairs opposite; and terminated by many redish purple flowers, in clusters one above another, forming a fort of long hoarse spike; all the flowers with entire petals, flowering in May. Of this also there are varieties with single red flowers, with double red flowers, and with white flowers. The double variety is considerably the most eligible for general culture, and is propagated in plenty by parting the roots. All the varieties of this species emitting a glutinous liquid matter from their stalks, flies happening to light thereon sometimes stick and entangle themselves, whence the plant obtains the name Catch-fly. 4. The flos-cuculi, cock-flower lychnis, commonly called ragged-robin, hath fibrous perennial roots; upright, branchless, channelled stalks, rising near two feet high; garnished with long, narrow, spear-shaped leaves, in pairs opposite; and terminated by branchy foot-stalks, sustaining many purple deeply quadrifid flowers, appearing in May. The flowers having each petal deepiy quadrifid in a torn or ragged like manner, the plant obtained the cant name of Ragged-robin. There are varieties with single flowers and double flowers. The double sort is a large, very multiple, fair flower: it is an improved variety of the single, which grows wild in most moist meadows, and is rarely cultivated; but the double, being very ornamental, merits culture in every garden. All the four species and respective varieties are very hardy; all fibrous rooted, the roots perennial; but are annual in stalks, which rise in spring, flower in summer, succeeded in the fall by plenty of seed in autumn, by which all the single varieties may be raised in abundance, but the doubles only by dividing the roots, and some by cuttings of the flower-stalks.
LYCOMEDES, a king of Scyros. He was son of Apollo and Parnathoe. He was secretly entrusted with the care of young Achilles, whom his mother Thetis had disguised in woman's clothes, to remove him from the Trojan war, where he knew he must unavoidably perish. Lycomedes has rendered himself famous for his treachery to the Phrens, who had implored his protection when driven from his throne of Athens by the usurper Mnelheus. Lycomedes, as it is reported, either envious of the fame of his illustrious guests, or bribed by the envoys of Mnelheus, led Thessus to an elevated place, on pretense to shew him the extent of his dominions, and perfidiously threw him down a precipice, where he was killed.

LYCOPERDON, in botany: A genus of the natural order of fungi, belonging to the cryptogamia class of plants. The fungus is roundish, and full of farinaceous seeds. There are 10 species, of which the following are the most remarkable.

1. The tuber, truffles, or subterraneous puff-balls, is a native of woods both in Scotland and England. It is a subterraneous fungus, growing generally in clusters three or four inches under ground, without any visible root. The figure of it is nearly spherical, the size of a potato; the exterior coat at first white, afterwards black, and fluted with pyramidal or polyhedrous tubercles; the internal substance solid and callous, of a dirty white or pale-brown colour, grained like a nutshell, or when ripe, and throws off a light yellow powder, which blown into the mouth, is said to intoxicate bees. See Cent. Mag. July 1766. The Italians fry the great variety, and indeed any of the others when young, and cut them with salt and oil, according to the relation of Marigli.

LYCOPERSON. See SOLANUM.

LYCOPODIUM, or CLUB-MOSS; a genus of the natural order of muffel, belonging to the cryptogamia class of plants. The antherae are bivalved and fiddle; there are no calyptra. There are 24 species; of which the following are the most remarkable.

1. The clubium, or common club-mosses, is common in dry and mountainous places, and in fir forests. The flalk is profusely branched, and creeping, from a foot to two or three yards long; the radicles woody. The leaves are numerous, narrow, lanceolated, acute, often incurved at the extremity, terminating with a long white hair, and every where surrounding the flalk. The peduncles are erect, firm, and naked (except being thinly felt with lanceolate scales), and arise from the end of the branches. They are generally two or three inches long and terminated with two cylindrical yellowish spikes, imbricated with oval-acute scales, finely lacerated on the edges, and ending with a hair. In the ace or base of the scale is a kidney-shaped capsule, which bursts with elasticity when ripe, and throws out a light yellow powder, which blown into the flame of a candle, flashes with a small explosion. The Swedes make matts of this moss to rub their shoes upon. In Russia, and some other countries, the powder of the capsules is used in medicine to heal galls in children, chops in the skin, and other sores. It is also used to powder over official pills, and to make artificial lightning at theatres. The Poles make a decoction of the plant, and, dipping a linen cloth into it, apply it to the heads of persons afflicted with the diffuse called the place palatina, which is said to be cured by this kind of fomentation.

LYCOPOLIS, or LYCON, (anc. geog.) so called from the worship of wolves. **Lycopolis**, the people; **Lycopites**, the district. There were two towns of this name, one in the Delta, or lower Egypt, near Sky, in Bosphorus, and some other places, the inhabitants make use of this plant instead of alum, to fix the colours in dying. The Highlanders also sometimes take an infusion of it as an emetic and cathartic: but it operates violently; and, unless taken in a small dose, brings on giddiness and convulsions. Linnaeus informs us, that the Swedes use a decoction of it to destroy lice on swine and other animals.

LYCOPHORON, a famous Greek poet and grammarian, born at Colchi in Euxina, flourished about 304 B.C. and, according to Ovid, was killed by an arrow. He wrote 20 tragedies; but all his works are lost, except a poem intitled *Claisanda*, which contains a long train of predictions, which he supposes to have been made by Callandra, Priam's daughter. This poem is extremely obscure. The best edition of it is that of Dr Potter, printed at Oxford in 1697, folio.

LYCOPSIS, in botany: A genus of the monogy- 

nia order, belonging to the penstemon class of plants; and in the natural method ranking under the 41st order, **Asteriflie**. The corolla has an incarvated tube.

Lydia (anc. geog.), a celebrated kingdom of Asia Minor.—All the ancient writers tell us, that Lydia was first called Mæonia or Mæonia, from Mæon, king of Phrygia and Lydia; and that it was known under no other denomination till the reign of Arts, when it began to be called Lydia from his son Lydus. Bochart finding in his learned collection of Phcenian words the verb lus, signifying “to wind,” and observing that the country we are speaking of is watered by the Maeander so famous for its windings, concludes that it was thence named Lydia, or Lydus. As to the ancient name of Mæonia, he takes it to be a Greek translation of the Phcenian word lud; wherein he agrees in some measure with Stephanus, who derives the name of Mæonia from Mæon the ancient name of the Mæander. Some take the word mæonia to be a translation of a Hebrew word signifying “metal,” because that country, say they, was in former times enriched above any other with mines. Though Lydia and Mæonia are by most authors indifferently used for one and the same country, yet they are sometimes distinguished; that part where mount Tmolos stood, watered by the Pæolus, being properly called Mæonia; and the other, lying on the coast, Lydia. This distinction is used by Homer, Callimachus, Dionysius, and other ancient writers. In after ages, when the Ionians, who had planted a colony on the coast of the Egean Sea, began to make some figure, that part was called Ionia, and the name of Lydia given to the ancient Mæonia.—Lydia, according to Pliney, Ptolemy, and other ancient geographers, was bounded by the Mytis Major on the north, by Caria on the south, by Phrygia Major on the east, and Ionia on the west, lying between the 37th and 39th degrees of north latitude. What the ancients style the kingdom of Lydia was not confined within these narrow boundaries, but extended from Halys to the Egean sea. Pliney’s description includes Eolia, lying between the Hermus and the Calus.

As to the origin of the Lydians, Josephus, and after him all the ecclesiastical writers, derive them from Lud shem’s fourth son; but this opinion has no other foundation than the multitude of names. Some of the ancients will have the Lydians to be a race of the Mæonians, of Phrygians, Mæonians, or Lydians. Others finding some conformity in religion and religious ceremonies between the Egyptians and Tufans, who were a Lydian colony, conclude them, without any farther evidence, to be originally Egyptians. All we know for certain is, that the Lydian nation, as it is manifest from their very tables, for Artes, Tantalus, Pelops, Niobe, and Arachne, are all said to have been the children of Lydus. And Zanthis in his Lydiana, quoted by Stephanus, informs us, that the ancient city of Afcalon, one of the five fairs of the Philistines, mentioned in the books of Joshua and the Judges, was built by one Afcalus a Lydian, whom Achiamus king of Lydia had appointed to command a body of troops which he sent, we know not on what occasion, into Syria. The Heracleae, or kings of Lydia, descended from Heracles, began to reign before the Trojan war; and had been preceded by a long series of sovereigns sprung from Artes, and hence styled Atyads: a strong proof of the antiquity of that kingdom.

The Lydians began very early to be ruled by kings whose government seems to have been truly despotick and the crown hereditary. We read of three distinct races of kings reigning over Lydia, viz. the Atyads, the Heracleae, and the Mermnadæ.

The Atyads were so called from Artes the son of Cotys and grandson of Mænes the first Lydian king. But the history of this family is obscure and fabulous. The Atyads were succeeded by the Heracleæ, or the descendants of Heracles. For Heracles being, by the direction of the oracle, told as a flame to Omphale a queen of Lydia to expiate the murder of Iphitus, had, during his captivity, by one of her flaves, a son named Cleitus, who was the first of the Heracleæ that ascended the throne of Lydia. This race is said to have reigned 503 years, the father succeeding the son for 22 generations. They began to reign about the time of the Trojan war. The last of the family was the unhappy Candales, who loft both his life and his kingdom by his imprudence. An event of which we have the following account. By Herodotus, Candales had a wife whom he passionately loved, and believed the most beautiful of her sex. He extolled her charms to Gyges his favourite, whom he used to intrust with his most important affairs; and the more to convince him of her beauty, resolved to show her to him quite naked: he accordingly placed her in the porch of her chamber where the queen used to undress when she went to bed, ordering him to retire after he should have seen her, and take all possible care not to be observed. But notwithstanding all the caution he could use, the plainly discovered him going out; and though she did not doubt but it was her husband’s connivance, yet the passion that night in a seeming tranquillity, supposing her resentment till next morning, when the scene for Gyges, and resolutely told him that he must either by his death stow for the criminal action he had been guilty of, or put to death Candales the contriver of it, and receive both her and the kingdom of Lydia for his reward. Gyges at first earneaily begged of her that she would not drive him to the necessity of such a choice. But finding that he could not prevail with her, and that he must either kill his master or lose himself, he chose the latter part of the alternative. Being led by the queen to the same place where her husband had posted him the night before, he stabbed...
Gyges having thus possessed himself of the kingdom of Lydia, sent many rich and valuable presents to the oracle of Delphi, among others, six cups of gold weighing 30 talents, and greatly esteemed for its weight in gold; a circumstance which shows how early the art of painting began to be in request, for Candaules was contemptuous with Romulus.

prove dangerous to himself, and therefore resolved to put a stop, if possible, to his progress. In taking this resolution, which might probably be attended with the most important consequences, he was desirous to learn the will of heaven concerning the issue of the war. The principal oracles which he consulted were those of Branchis in Ionia, of Hammon in Libya, and of Delphi in Greece. Amongst these respected shrines, the oracle of Delphi maintained its ascendant as the most faithful interpreter of fate. Croesus was fully persuaded of its veracity; and desirous generously to compensate for the trouble which he had already given, and still meant to give, the priests of Apollo, he sacrificed 3000 oxen to the god, and adorned his shrine with dedications equally valuable for the workmanship and for the materials; precious vessels of silver, ewers of iron beautifully inlaid and enamelled; various ornaments of pure gold, particularly a golden lion weighing ten talents, and a female figure three cubits or near five feet high. In return for these magnificent presents, the oracle, in ambiguous language, flattered Croesus with obtaining an easy victory over his enemies, and with enjoying a long life and a prosperous reign. The god at the same time enjoined him to contract an alliance with the most powerful of the Grecian states.

Elevated with these favourable predictions of Apollo, Croesus prepared to yield a ready obedience to the only condition required on his part for the accomplishment of his aspiring purpose. Not deeming himself sufficiently acquainted with the affairs of Greece, to know what particular republic was meant by the oracle, he made particular inquiry of those well informed concerning the state of Europe; and discovered, that among all the members of the Grecian confederacy, the Athenians and Lacedemonians were justly intitled to the pre-eminence. In order to learn which of these communities deserved the epithet of most powerful of the Grecian states.

The Lydians dispatched with this important commission, soon discovered that the Athenians, after having been long harassed by internal dissensions, were actually governed by the tyrant Pisistratus. The Spartans, on the other hand, though anciently the worst regulated of all the Grecian communities, had enjoyed domestic peace and foreign prosperity ever since they had adopted the wise institutions of Lycurgus. After that memorable period, they had repeatedly conquered the warlike Argives, triumphed over the hardy Arcadians, and notwithstanding the heroic exploits of Aristomenes subdued and enslaved their unfortunate rivals of Megara. To the Lydian ambassadors, therefore, the Spartan republic appeared to be pointed out by the oracle as the community whose alliance they were enjoined to solicit. Having repaired accordingly to Sparta, they were introduced not only to the king and female, but as the importance of the negotiation required, to the general assembly of the Lacedemonians, to whom they, in few words, declared the object of their mission: "We are sent, O Lacedemonians! by Croesus, king of the Lydians and of many other nations, who being commanded by the oracle of Apollo to seek the friendship of the most powerful people of Greece, now summons you, who justly merit that epithet, to become his faithful allies, in obedience to the will of the god whose authority you acknowledge."

The Lacedemonians, pleased with the alliance of a warlike king, and still more with the fame of their valor, readily accepted the proposal. To the strict connection of an offensive and defensive league, they joined the more respected ties of sacred hospitality. A few years before this transaction, they had sent to purchase gold at Sardis for making a flame of Apollo. Croesus had on that occasion gratuitously supplied their want. Remembering this generosity, they gave the Lydian ambassadors at their departure, as a present for their matter, a vessel of brags containing 300 amphoras (above 12 hogheads), and beautifully carved on the outside with various forms of animals.

Croesus, having thus happily accomplished the design recommended by the oracle, was eager to set out upon his intended expedition. He had formerly entered into alliance with Amasis king of Egypt, and Lysanetus king of Babylon. He had now obtained the friendship of the most warlike nation of Europe. The newly-raised power of Cyrus and the Persians seemed incapable of withstanding such a formidable confederacy. Elevated with these flattering ideas of his own invincible greatness, Croesus waited not to attack the Persian dominions until he had collected the strength of his allies. The faning impetuousity of his temper unexperienced in adversity, unfortunately precipitated him into measures no less ruinous than daring. Attended only by the arms of Lydia, and a numerous band of mercenaries, whom his immense wealth enabled him at any time to call into his service, he marched towards the river Halys; and having crossed with much difficulty that deep and broad stream, entered the province of Cappadocia, which formed the western frontier of the Median dominions. That unfortunate country soon experienced all the calamities of invasion. The Pherian plain, the most beautiful and the most fertile district of Cappadocia, was laid waste; the ports of the Euxine, as well as several inland cities, were plundered; and the inoffensive inhabitants were either put to the sword or dragged into captivity.

Encouraged by the unsatisfying softness of the natives of those parts, Croesus was eager to push forwards; and if Cyrus did not previously meet him in the field, he had determined to proceed in triumph to the mountains of Persia. Against this dangerous resolution he was in vain exhorted by a Lydian named Sandanis; who, when asked his opinion of the war, declared it with that freedom which the princes of the East have in every age permitted, amidst all the pride and caprices of despotic power, to men distinguished by the gifts of nature or education. "You are preparing, O king, to march against a people who lead a laborious and a miserable life; whose daily subsistence is often denied them, and is always scanty and precarious; who drink only water, and who are clothed with the skins of wild beasts. What can the Lydians gain by the conquest of Peria? they who enjoy all the advantages of which the Persians are destitute? For my part I deem it a blessing of the gods, that they have not excited the warlike poverty of these miserable barbarians to invade and plunder the luxurious wealth of Lydia." The moderation of this advice was rejected by the fatal presumption of Croesus; who confounding the
LYD

the dictates of experienced wisdom with the mean suggestions of pusillanimity, diffused the counsellor with contempt.

Meanwhile, the approach of Cyrus, who was not of a temper to permit his dominions to be ravaged with impunity, afforded the Lydian king an opportunity of bringing the war to more speedy issue than by his intended expedition into Persia. The army of Cyrus gradually augmented on his march, the tributary princes cheerfully contributing with their united strength towards the assistance of a master whose valour and generosity they admired, and who now took arms to protect the safety of his subjects, as well as to support the grandeur of his throne. Such was the rapidity of his movement, especially after being informed of the destructive ravages of the enemy in Cappadoea, that he arrived from the shores of the Caspian to those of the Euxine Sea before the army of Croesus had provided the necessaries for their journey. That prince, when apprised of the neighbourhood of the Persians, encamped on the Persian plain; Cyrus likewise encamped at no great distance; frequent skirmishes happened between the light troops; and at length a general engagement was fought with equal fury and perseverance, and only terminated by the darkness of night. The loss on both sides hindered a renewal of the battle. The numbers, as well as the courage of the Persians, much exceeded the expectation of Cyrus. As they discovered not any intention to harass his retreat, he determined to move back towards Sardis, to spend the winter in the amusements of his palace; and after amusing his numerous allies to his standard, to take the field early in the spring with such increase of force as seemed sufficient to overpower the Persians.

But this design was defeated by the careful vigilance of Cyrus. That experienced leader allowed the enemy to retire without molestation; carefully informing himself of every step which they took, and of every measure which they seemed determined to pursue. Patiently watching the opportunity of a just revenge, he waited until Croesus had re-entered his capital, and had disbanded the foreign mercenaries, who composed the most numerous division of his army. It then seemed the proper time for Cyrus to put his Persians in motion; and such was his celerity, that he brought the first news of his own arrival in the plain of Sardis. Croesus, whose firmness might well have been shaken by the imminence of this unforeseen danger, was not wanting on the present occasion to the duties which he owed to his fame and the lustre of the Lydian throne. Though his mercenaries were disbanded, his own subjects, who served him from attachment, who had been long accustomed to victory, and who were animated with a high sense of national honour, burned with a desire of enjoying an opportunity to check the daring insolence of the invaders. Croesus indulged and encouraged this generous ardour. The Lydians in that age fought on horseback, armed with long spears; the strength of the Persians consisted in infantry. They were so little accustomed to the use of horses, that camels were almost the only animals which they employed as beasts of burden. This circumstance suggested to a Mede, by name Harpagus, a stratagem, which being communicated to Cyrus, was immediately adopted with approbation by that prince. Harpagus, having observed that horses had a strong aversion to the shape and smell of camels, advised the Persian army to be drawn up in the following order: All the camels which had been employed to carry baggage and provisions were collected into one body, arranged in a long line, and placed at a due distance. The Median horse (for a few squadrons of these followed the standard of Cyrus) formed the rear of the army. As the troops on both sides approached to join battle, the Lydian cavalry, terrified at the unusual appearance of the camels, mounted with men in arms, were thrown into disorder, and turning their heads, endeavoured to escape from the field. Croesus, who perceived the confusion, was ready to depair of his fortune; but the Lydians abandoning their horses, prepared with uncommon bravery to attack the enemy on foot. Their courage seemed better fated; but unaccustomed as they were to this mode of fighting, they were received and repelled by the experienced valour of the Persian infantry, and obliged to take refuge within the fortified strength of Sardis, where they imagined themselves secure. The walls of that city bid defiance to the rude art of attack, as then practised by the most warlike nations. If the Persian army should invest it, the Lydians were provided with provisions for several years; and there was reason to expect, that in a few months, if not weeks, they would receive such assistance from Egypt, Babylonia, and Greece (to which countries they had already sent embassadors), as would oblige the Persians to raise the siege.

The Lydian ministers dispatched into Greece met with great sympathy from the Spartans. That people were particularly observant of the fate of treaties; and while they punished their enemies with unexampled severity, they behaved with generous compa.ssion towards those whom they had once accepted as allies. They immediately resolved therefore to send him a speedy and effectual relief; and for this purpose assembled their troops, made ready their vessels, and prepared every thing necessary for the expedition.

The valour of the Spartans might perhaps have upheld the sinking empire of Lydia; but before their armament could set sail, Croesus was no longer a sovereign. Norwithstanding the strength of Sardis, that city had been taken by storm on the 20th day of the siege; the walls having been scaled in a quarter which, appearing altogether inaccessible, was too carelessly guarded. This was effected by the enterprize of Hyrereades a Mede, who accidentally observed a sentinel defend part of the rock in order to recover his helmet. Hyrereades was a native of the mountainous province of Mardia, and being accustomed to clamber over the dangerous precipices of his native country, resolved to try his activity in passing the rock upon which he had discovered the Lydian. The design was more easily accomplished than he had reason to expect: emulation and success encouraged the bravest of the Persians to follow his example: these were supported by greater numbers of their countrymen; the garrison of Sardis was surprized; the citadel formed;

LYN

LYING-IN-WOMEN. See MIDWIFERY.

LYING-To, or LYING-By, the situation of a ship, when she is retarded in her course, by arranging the sails in such a manner as to counteract each other with nearly an equal effort, and render the ship almost immovable, with respect to her progressive motion, or head-way. A ship is usually brought to by the main and fore-top sails, one of which is laid aback, whilst the other is full; so that the latter pushes the ship forward, whilst the former resists this impulse by forcing her after. This is particularly practised in a general engagement, when the hostile fleets are drawn up in two lines of battle opposite each other. It is also used to wait for some other ship, either approaching or expected; or to avoid piloting a dangerous course, especially in dark or foggy weather, &c.

LYME-KING a sea-port town of Dorsetshire in England, 148 miles from London. It lies near the sea, on the very borders of Devonshire, in a cavity between two rocky hills, which makes it difficult of access. It is about five furlongs long, and contains about 200 houses. As it lies on the declivity of a hill, the houses make a good show, one above another; and some of them are built of freestone, and covered with blue flate. The corporation consists of a mayor (who is justice of peace during his mayoralty and the year after, and in the third year both justice and coroner), a recorder, 15 capital burgesses, and a town-clerk. This place had formerly a very flourishing trade to Spain, the Straits, Newfoundland, and the West Indies; during which the customs amounted some years to 16,000. But it stands on such a high steep rock, that the merchants are obliged to load and unload their goods at a place a quarter of a mile off, called the Cobb, originally built in the reign of Edward III. which costs a great sum to maintain, but forms such a harbour as perhaps is not to be equalled in the world, the ships being sheltered by a high thick stone wall, raised in the main sea a good way from the shore, broad enough for carriages and warehouses, and the custom-house officers have one upon it. The cellars of the low part of the town near the sea, are however often overflowed by the spring-tides 10 or 12 feet. There are guns planted for defence both of the Cobb and the town, the shore here being very proper for batteries. The custom-house stands on pillars, with the corn-market under it. There is an alms-house in church-street, also Presbyterian and Anabaptist meeting-houses. The town-hall is near Broad-street. The church stands at the east end of the town on a rising ground. The market here is Friday, and there are two fairs in the year. We read, that, in 774, the Saxon King Kinwulf gave land hereabouts to the church of Sherborne, for the boiling of salt there to supply its necessities. At this place the duke of Monmouth landed in 1685. A few years ago above £2000 worth of gold and silver coin of Char. I. and II. were discovered by some labourers.

LYMINGTON, a borough town of Hampshire in England, 97 miles south-west of London. It stands about a mile from the channel, running between the main land and the Isle of Wight; and has a harbour for...
LYNCHURUS. Days, and two tiers:

Pha, of Legeus, married Hypermnestra, one of the
nymphs of Danaus. See Hypermnestra.

LYMPHA'TI, was a name given by the Romans
to such as were seized with madness. It is supposed
to be used for Nympia'tis, because the ancients imagined
that every person who had the misfortune to see a
nymph was instantly struck with phrenzy. Lympia'tis
may indeed signify "madmen," as derived from lyn-
pha, "water" over which element the nymphs were
thought to preside. But it appears most likely, that
distracted people were called Lympia'tis, from the cir-
cumstance of madmen's being affected with the hydra-
phobia, or dread of water after the bite of a mad dog;
for this peculiarity, in cases of canine madness, was
not unknown to the Romans.

LYNEUS, in fabulous history, one of the 50 sons
of Egeus, married Hypermnestra, one of the 50 daugh-
ters of Danaus. See Hypermnestra.

LYNEUS, in fabulous history, one of the Argo-
nae, who went with Jason in the expedition to ob-
tain the golden fleece. He was of great use to the
Argonauts, by enabling them to avoid the sand-banks
and rocks they found in their way. The poets say, that
Lynceus had so piercing a sight, that it could not only
penetrate to the bottom of the sea, but even to hell.
Some mythologists suppose, that this fable is taken from
Lynceus's skill in observing the stars, and discovering
the mines of gold and silver concealed in the earth.

LYNCURIIUM, a stone thought to be the same
with the toarumini. The name is derived from Λύς
"lynx," and υών urine.

LYNCURIUS LAPIIS, a stone capable of produ-
cing mushrooms.

In the Ephemerides of the Curious we find men-
tion made of a stone, so called by Dr John George
Wolckamcrer, who was one in Italy, which never cea-
sest to produce in a few days mushrooms of an
excellent flavour by the most simple and easy pro-
cess imaginable. "It is (say he) of the bigness of an
ox's head, rough and uneven on its surface, and
on which also are perceived some clefts and crevices.
It is black in some parts, and in others of a lighter
and greyish colour. Internally it is porous, and nearly
of the nature of the punice-flone, but much hea-
der: and it contains a small piece of flint, which is
so incorporated with it as to appear to have been for-
cast at the same time the stone itself received its for-
mat. This gives room to judge, that those stones have been
produced by a fat and vicid juice, which has the pro-
perity of indurating whatever matter it infiltrates into.
The stone here spoken of, when it has been lightly
covered with earth, and sprinkled with warm water,
produces mushrooms of an exquisite flavour which are
usually round, sometimes oval, and whose borders, by
their inflexions and different curvities represent some
measure human ears. The principal colour of these
mushrooms is sometimes yellowish, and sometimes of a
bright purple; but they are always disseminated with
different spots, of a deep orange colour, or red brown;
and when these spots are recent, and still in full bloom, Lyncuriius,
they produce a very agreeable effect to the sight. But Lyn
curiius
what appears admirable is, that the part of the stalk
which remains adhering to the stone, when the mush-
room has been separated from it, grows gradually and
petrifies in time, so that it seems that this fungi
to relores to the stone the nutritive juice it received from
it, and that it thus contributes to its increase." John
Bapift Porta pretends, that this stone is found in fe-
veral parts of Italy; and that it is not only to be met
with at Naples, taken out of mount Vesuvius, but al-
so on mount Pantherico, in the principality of Arca-
lino; on mount Garganus, in Apulia; and on the sum-
mit of some other very high mountains. He adds, that
the mushrooms which grow on those sorts of stones, and
are usually called fungi lynceus, have the property of
dissolving and breaking the stone of the kidneys and
bladder; and that, for this purpose, nothing more is
required than to dry them in the shade, and being re-
duced to powder, to make the patient, fasting, take
a sufficient quantity of this power in a glass of white-
wine, which will so cleanse the excretory ducts of the
urine, that no stones will ever after be collected in
them.

As to the form of those mushrooms, their root
is fomy, uneven, divided according to its longitudinal
direction, and composed of fibres as fine as hairs, in-
terwoven one with another. Their form, on first shoo-
ing out, resembles a small bladder, scarce then larger
than the bud of a vine; and if in this state they are
squeezed between the fingers, an aqueous subacid li-
quor issues out. When they are at their full growth,
their pedicle is of a finger's length, larger at top than
at bottom, and becomes infinitely slenderer in propor-
tion as it is nearer the earth. Thefe mushrooms are
also formed in an umbrella, and variegated with an in-
finitiy of little specks situated very near one another.
They are smooth and even on the upper part, but un-
derneath leafy like the common mushrooms. Their
ant is likewise very agreeable, and the ficks are not
debarr'd eating of them when they have been drenched
in a proper manner. Curiosity having prompted some
naturalists and physicians to submit these stones to a
chemical analysis, in order to be more competent judges
of the ufe they might be put to in medicine, there
first came forth, by distillation, an infipid water, and
afterwards a spiritious liquor. The retort having been
heated to a certain point, there arose an oil, which had
nearly the smell and flavour which will so cleanse the excretory
the urine, that no stones will ever after be collected in
them. As to the form of those mushrooms, their root
is fomy, uneven, divided according to its longitudinal
direction, and composed of fibres as fine as hairs, in-
terwoven one with another. Their form, on first shoo-
ing out, resembles a small bladder, scarce then larger
than the bud of a vine; and if in this state they are
squeezed between the fingers, an aqueous subacid li-
quor issues out. When they are at their full growth,
their pedicle is of a finger's length, larger at top than
at bottom, and becomes infinitely slenderer in propor-
tion as it is nearer the earth. Thefe mushrooms are

LYN

Lynn-regis It has had 15 royal charters; and is governed by a mayor, high-steward, under-steward, recorder, 12 aldermen, and 18 common-council men. It has two churches, besides St Nicholas, a chapel of ease to St Margaret's, a presbyterian and a quakers meeting-house, with a bradewell or workhouse, and several almshouses, and a free-school. In September 1741 the spires of its two churches were both blown down by a storm of wind; and that of St Margaret's, which was 193 feet in height, having beat in the body of the church, it has been since rebuilt, towards which king George II. gave L. 1000, and the late earl of Orford, then Sir Robert Walpole, L. 500. This church was formerly an abbey, and afterwards one of the largest parish-churches in England. The town-house, called Trinity-hall, is a noble old fabric; and to the Exchange, which is of free-flone, with two orders of columns. St Nicholas's chapel is very ancient, and reckoned one of the fairest and largest of the kind in England. It has a bell-tower which is perpendicular. In the great market-place a statue of the first Monday in the month, the mayor, aldermen, preachers, &c. meet to hear and determine all controversies amicably, for preventing law-suits. This was first established in 1588, and is called The Feast of Reconciliation. The markets are on Tuesdays and Saturdays; and it has two fairs: one of which, beginning Feb. 14, lasts for a fortnight, and is called Lynn-mart; the other is a cheese-fair on Oct. 6. The adherence of this town to king John and to Henry VIII. as abovementioned, are not the only instances of its loyalty to its sovereigns; for, in the late civil wars, it held out for king Charles I. and sustained a formal siege of above 18,000 men of the parliament-army, for above three weeks; but, for want of relief, was obliged to surrender, and submit to the terms of paying 10s. a-head for every inhabitant, and a month's pay to the soldiers, to save the town from plunder. There are more gentry, and consequently more gaiety in this town than in Yarmouth or even Norwich; there being fuch plenty of eatables and drinkables, that Spelman says Ceres and Bacchus seem to have established their magazines at this place; the east side abounding with corn, sheep, rabbits, hares, &c. the west side with cheese, butter, black-cattle, swans, and the wild-fowl common to marshes, besides the abundance of sea and river fish; so that he thinks there is no place in Great Britain, if in Europe, has such a variety in so small a compas of ground. At a small distance from the town stands a mount called the Lady's or Red Mount, where was once a chapel dedicated to the Virgin Mary, which was a resting-place for pilgrims on their way towards her convent at Walthingham. The king's fish-pond, or quay, where the greatest part of the imported wines is landed and put into large vaults, is a handsome square, with brick buildings, in the centre whereof is a statue of king James I. People pass hence into the fen-country, and over the famous washes into Lincolnshire in boats, which are often lost, by venturing out at an improper season and without guides.

LYNX, in zoology. See Felis.

LYON King of Arms. See King; and Law, &c. civiii. 16.

This office is of great antiquity and respect in Scotland; and although the precise time of its institution is unknown, yet it must have been as early as the introduction of armorial figures as hereditary marks of gentility and distinction into that country, which was in the 14th century. His regalia are, a crown of gold, with a crimson velvet-cap, a gold tassel, and an ermine lining; a velvet-rope reaching to his feet, with the arms of the kingdom embroidered thereon before and behind in the proper uncultures; a triple row of gold chain round his neck, with an oval gold medal pendant thereon, on one side of which is the royal bearing, and on the other St Andrew with his croft enamelled in proper colours, and a baton of gold enamelled green powde-
Lyonet's rank is superior to that of any other king of arms, as he holds his office immediately from the sovereign by commission under the great seal; whereas the kings of arms in England are deputies to the Earl Marshal, and act under his authority. Formerly Scotland was divided into two provinces, the one on the north and the other on the south side of Forth; and these provinces were under the management of two deputies appointed by the Lord Lyon to superintend the execution of all the business of his office. Before the revolution, the Lord Lyon, at his admission into office, was most solemnly crowned by the sovereign or his commissioner, in presence of the nobility, the officers of state, and other great men, after a suitable sermon preached in the royal chapel; and his crown was of the same form with the imperial crown of the kingdom. On solemn occasions he wears the regalia above described; at all other times, he wears the oval gold medal or badge on his breast, suspended by a broad green ribbon. He has the absolute disposal of all the offices in his own court, and of the heralds and pursuivants places. The messengers at arms throughout Scotland are also created by him, and are amendable to his jurisdiction. And the powers vested in him by his commission are the same with those of the sovereign in all matters relative to the marks of gentility.

Lyonet (Peter), an ingenious naturalist, and member of several learned societies, was born at Maastricht, and was descended from a very ancient and respectable family of Lorraine. He had (nearly attained his seventh year before he displayed an uncommon strength and agility in all bodily exercises; but he was not less diligent in the improvement of his mind. Being placed at the Latin school, he learned chronology, and exercised himself in Latin, Greek, and French poetry, as also in Hebrew, logic, and the Cartesian physics. He was particularly fond of the study of languages, whereof he understood no less than nine, living and dead. Having entered the university of Leyden, he studied the Newtonian philosophy, geometry, algebra, &c.; but his father (who was a clergyman), desiring he should attach himself to divinity, he reluctantly abandoned the former studies, as his passion for them was not easily to be overcome. He at the same time applied himself to anatomy, and also to music and drawing. He began afterwards to practise sculpture: and performed several pieces in wood, some of which are preserved, and have been greatly admired by the artists. After this, he betook himself to drawing portraits of his friends from life; whereon, after three or four months practice, he became a great proficient. Having attained the degree of candidate in divinity, he resolved to study law, to which he applied himself with so much zeal, that he was promoted at the end of the first year. Arrived at the Hague, he undertook the study of deciphering; and became secretary of the ciphers, translator of the Latin and French languages, and patent-master, to their High Mightinesses. Meanwhile, having taken a strong liking to the study of insects, he undertook an historical description of such as are found about the Hague, and to that end collected materials for several volumes; and having invented a method of drawing adapted thereto, he enriched this work with a great number of plates, universally admired by all the connaisseurs who had seen them. In the year 1742 was printed at the Hague a French translation of a German work, the 'Theology of Insects,' by Mr Leffer. Love of truth engaged Mr Lyonet to defer the publication of his above-mentioned description, and to make some observations on that work, to which he has added two most beautiful plates, engraved from his designs. This performance caused his merit to be universally known and admired. The celebrated M. de Beaunour had the above translation reprinted at Paris, not so much on account of the work itself as of Mr Lyonet's observations; and believed on it, as did also many other authors, the highest encomiums. He afterwards executed drawings of the fresh water polygus for Mr Trembley's beautiful work, 1744. The ingenious Wandelaar had engraved the first five plates; when Mr Lyonet, who had not witnessed this operation, concerned at the difficulties he experienced in getting the remaining eight finished in the proper style, he required, resolved to perform the task himself. He accordingly took a lection of one hour of Mr Wandelaar, engraved three or four small plates, and immediately began upon the work itself, which he performed in such a manner as drew on him the highest degree of praise, both from Mr Trembley and from many other artists, particularly the celebrated Van Goü, who declared that the performance astonished not only the amateurs, but also the most experienced artists. In 1748 he was chosen member of the Royal Society of London. In 1749 he began (by mere chance) his amazing collection of horns and shells, which, according to the universal testimony of all travellers and amateurs who have visited it, is at present the most beautiful, and certainly one of the most valuable, in Europe. In 1753 he became member of the newly-established Dutch Society of Sciences at Haarlem; and in 1757, after the celebrated M. le Cat, professor in anatomy and surgery, and member of almost all the principal societies in Europe, had seen Mr Lyonet's incomparable Traité Anatomique de la Cheville qui rouge le Bois de Santé, with the drawings belonging to it (which work was afterwards published), he was elected member of the Royal Academy of Sciences of Rome, whereof M. le Cat was perpetual secretary. After the publication of this treatise, he became, in 1760, member of the Royal Academy of Sciences of Berlin; in 1761, of the Imperial Academy of Naturalists; and, in 1762, of the Imperial Academy of Sciences at St Peterburg. In order to enable such as might be desirous of following him in his intricate and most astonishing discoveries respecting the structure of this animal, Mr Lyonet published, in the 'Tranactions of the Dutch Society of Sciences at Haarlem,' a description and a plate (as he also afterwards did in French at the beginning of his Traité Anatomique) of the instrument and tools he had invented for the purpose of dissection, and likewise of the method he used to ascertain the degree of strength of his magnifying glasses. Notwithstanding all this labour, which was considerably increased by the extensive correspondence which he for many years carried on with several learned and respectable personages, he still found means to,
Concerning the number of strings with which this instrument was furnished, there is great controversy. Some assert it to be only three; and that the sounds of the two remote were acute, and that of the intermediate one a mean between these two extremes: that Mercury, the inventor, resembled those three chords to as many seasons of the year, which were all that the Greeks reckoned, namely, Summer, Winter, and Spring: aligning the acute to the first, the grave to the second, and the mean to the third.

Others assert that the lyre had four strings; that the interval between the first and the fourth was an octave; that the second was a fourth from the first, and the fourth the same distance from the third, and that from the second to the third was a tone.

Another class of writers contend that the lyre of Mercury had seven strings. Nichomacus, a follower of Pythagoras, and the chief of them, gives the following account of the matter: "The lyre made of the shell was invented by Mercury; and the knowledge of it, as it was conveyed by him of seven strings, was transmitted to Orpheus. Orpheus taught the use of it to Thamyris and Linus; the latter of whom taught it to Hercules, who communicated it to Amphion the Theban, who built the seven gates of Thebes to the seven strings of the lyre." The same author proceeds to relate, "That Orpheus was afterwards killed by the Thracian women; and that they are reported to have cast his lyre into the sea, which was afterwards thrown up at Antium, a city of Lepcis: that certain fishermen finding it, they brought it to Terpander, who carried it to Egypt, exquisitely improved, and, flowing it to the Egyptian priests, afforded himself the honour of its invention."

This difference among authors seems to have arisen from their confusing together the Egyptian and the Grecian Mercury. — The invention of the primitive lyre with three strings was due to the first Egyptian Hermes, as mentioned under that article. — The lyre attributed to the Grecian Mercury is described by almost all the poets to be an instrument of seven strings.
LYR [ 351 ]

Boethius gives a different history of the scale, and tells us, that the system did not long remain in such narrow limits as a tetrachord. Chasboas, the son of Athias, or Atys, king of Lydia, added a fifth string; Hygrois, a sixth; Terpander, a seventh; Lycammon of Samos, an eighth. But all these accounts are irreconcilable with Homer's hymn to Mercury, where the chelys, or tefiudo, the invention of which he ascribes to that god, is said to have had seven strings. There are many claimants among the musicians of ancient Greece to the stringed instruments that were afterwards added to these, by which the scale, in the time of Aristoxenus, was extended to two octaves. Athenæus, more than once, speaks of the nine-stringed instrument; and Ion of Chios, a tragic and lyric poet and philosopher, who first recited his pieces in the 82d olympiad, 452 B. C. mentions, in some verses quoted by Euclid, the ten-stringed lyre; a proof that the third conjoint tetrachord was added to the scale in his time, which was about 50 years after Pythagoras is supposed to have constructed the octachord.

The different claimants among the Greeks to the fame musical discoveries, only prove, that music was cultivated in different countries; and that the inhabitants of each country invented and improved their own instruments, some of which happening to resemble those of other parts of Greece, rendered it difficult for historians to avoid attributing the fame invention to different persons. Thus the single flute was given to Minerva and to Marys; the syrinx or aulula, to Pan; and to Cybele; and the lyre or cithara, to Mercury, Apollo, Amphion, Linus, and Orpheus. Indeed, the mere addition of a string or two to an instrument without a neck, was so obvious and easy, that it is scarcely possible not to conceive many people to have done it at the same time.

With respect to the form of the ancient lyre, as little agreement is to be found among authors as about the number of strings. The best evidence concerning it are the representations of that instrument in the hands of ancient statues, bas-reliefs, &c. See Plate CCLXXV, where Fig. 1. is a representation of the tefiudo, or lyre of Amphion, in front, as it appears on the base of the celebrated Toro of Arfane at Rome. This admirable work, confisting of four figures bigger than the life, besides the toro, or bull, was found in Caracalla's baths, where the Arfane Hercules was likewise discovered; and, except

(a) It has been already related, that the lyre invented by the Egyptian Mercury had but three strings; and by putting these two circumstances together, Dr Burney observes, that we may perhaps acquire some knowledge of the progress of music, or at least, of the extension of its scale, in the highest antiquity.

Mefo, in the Greek music, is the fourth found of the second tetrachord of the great system, and first tetrachord invented by the ancients, answering to our A, on the fifth line in the base. If this sound then was added to the former three, it proves two important points: first, that the most ancient tetrachord was that from E in the base to A; and that the three original strings in the Mercurian and Apollonian lyre were tuned E, F, G, which the Greeks called Hypate Mefo, Parhypate Mefon, Mefon Diaton. The addition therefore of Mefo to these, completed the first and most ancient tetrachord, E, F, G, A.

The string Ichanos, then, being added to these, and answering to our D on the third line in the base, extended the compass downwards, and gave the ancient lyre a regular series of five sounds in the Dorian mode, the most ancient of all the Greek modes; and the two strings called Hypate and Parhypate, corresponding with our B and C in the base, completed the tetrachord, or seven sounds, B, C, D, E, F, G, A, a compass that received no addition till after the time of Pindar, who calls the instrument then in use the secto-tongued lyre.
The Lyre held by Terpophilus, in the picture of that muse dug out of Herculaneum.

3. The Abydlian lyre, or lyre in use at present in the province of Tigre, from a drawing of Mr Bruce, communicated to Dr Burdett. "This instrument (says he) has sometimes five, sometimes six, but most frequently seven strings, made of the thongs of raw sheep or goat skins, cut extremely fine, and twisted; they soon, are very subject to break in dry weather, and have scarce any found in wet. From the idea, however, of this instrument being to accompany and sustain a voice, one would think that it was better mounted formerly. "The Abydlians have a tradition, that the lyre in Ethiopia, by tambourine, and tambourine, were brought from Egypt into Ethiopia, by Thoth, in the very first ages of the world. The flute, kettle-drum, and trumpet, they say, were brought from Palestine, with Menelek, the son of their queen of Saba by Solomon, who was their first Jewish king.

"The Lyre in Ambaric is called bog, the sheep; in Ethiopia, it is called melasko; the verb melasko signifies to strike strings with the fingers; no plectrim is ever used in Abydliam; so that melasko, being literally interpreted, will signify the 'fretted instrument played upon with the fingers.'

"The sides which constitute the frame of the lyre were anciently composed of the horns of an animal of the goat kind called agazan, about the size of a small cow, and common in the province of Tigre. I have seen several of these instruments very elegantly made of such horns, which nature seems to have shaped on purpose. Some of the horns of an African species of this animal may be seen in M. Buffon's History of the king of France's cabinet. They are bent, and left regular than the Abydlians; but after fire-arms became common in the province of Tigre, and the woods were cut down, this animal being more scarce, the lyre has been made of a light red wood; however, it is always cut into a spiral-twisted form, in imitation of the ancient materials of which the lyre was composed. The making I find was one of these instruments made of wood. "The kingdom of Tigre, which is the largest and most populous province of Abydliam, and was during many ages the seat of the court, was the first which received letters and civil and religious government; it extended once to the Red Sea; various reasons and revolutions have obliged the inhabitants to resign their seacoast to different barbarous nations, pagan and Mahometan; while they were in possession of it, they say that the Red Sea furnished them with tortoise shells, of which they made the bodies of their lyres, as the Egyptians did formerly, according to Apollodorus and Lucian; but having now lost that resource, they have adopted, in its place, a particular species of gourd, or pumpkin, very hard and thin in the bark, still imitating with the knife the squares, compartments, and figure of the shell of the tortoise.

"The lyre is generally from three feet to three feet six inches high; that is, from a line drawn through the point of the horns, to the lower part of the base of the sounding-board. It is exceedingly light, and easy of carriage, as an instrument should naturally be in a rugged and mountainous a country.

"When we consider the parts which compose this lyre, we cannot deny it the earlist antiquity. Man in his first state was a hunter and a fisher, and the oldest instrument was that which partakes most of that state. The lyre composed of two principal pieces, owes the one to the horns of an animal, the other to the shell of a fish.

"It is probable, that the lyre continued with the Ethiopians in this rude state as long as they confined themselves to their rainy, steep, and rugged mountains; and afterwards, when many of them descended along the Nile in Egypt, its portability would recommend it in the extreme heats and want of theirs way. Upon their arrival in Egypt, they took up their habitation in caves, in the sides of mountains, which are inhabited to this day. Even in these circumstances, an instrument larger than the lyre must have been inconvenient and liable to accidents in those caverns; but when these people increased in numbers and courage, they ventured down into the plain, and built Thebes. Being now at their ease, and in a fine climate, all nature flourishing around them, music and other arts were cultivated and refined, and the imperfect lyre was extended into an instrument of double its compass and volume. The size of the harp could be now no longer an objection; the Nile carried the inhabitants everywhere easily and without effort; and we may naturally suppose in the fine evenings of that country, that the Nile was the favourite scene upon which this instrument was practised; at least the sphinx and Anubis upon its head, seem to hint that it was someway connected with the overflows of that river." See Harp.

4. An Etruscan lyre, with seven strings, in the collection of Etruscan, Greek, and Roman antiquities, published from the cabinet of the Hon. Sir William Hamilton, Vol. i. Naples 1766. Pl. cix. With respect to this instrument, it is worthy of observation, that though the vase upon which it is represented is of such indubitable and remote antiquity, the tail-piece, bridge, belly, and found holes have a very modern appearance, and manifest a knowledge in the construction of musical instruments among the Etruscans superior to that of the Greeks and Romans in much later times. The lower part of the instrument has much the appearance of an old bass viol, and it is not difficult to discover in it more than the embryo of the whole viol family. The strings lie round, as if intended to be played on with a bow; and even the crois lines on the tail-piece are such as we frequently see on the tail-pieces of old viols.

5. The Tripodian lyre of Pythagoras the Zacynthian, from a bass-relief in the Maecen palace at Rome representing the whole choir of the muses. Athenæus gives the following account of this extraordinary instrument, lib. xiv. cap. 15. p. 679. "Many ancient instruments are recorded (says Artemon), of which we have so little knowledge, that we can hardly be certain of their existence; such as the tripod of Pythagoras the Zacynthian, which, on account of its difficulty, continued in use but a short time. It resembled in form the Delphic tripod, whence it had its name. The legs were equidistant, and fixed upon
Bellows for inflating the lungs in order to restore suspended respiration.

Fig. 6
**LYS**

Lyric upon a moveable base that was turned by the foot of the player; the strings were placed between the legs of the foot; the vane at the top served for the purpose of a found board, and the strings of the three sides of the instrument were tuned to three different modes, the Doric, Lydian, and Phrygian. The performer sat on a chair made on purpose; strking the strings with the fingers of the left hand, and using the plectrum with the right, at the same time turning the instrument with his foot to which ever of the three modes he pleased; so that by great practice he was enabled to change the modes with such velocity, that those who did not see him would imagine they heard three different performers playing in three different modes. After the death of this admirable musician, no other instrument of the same kind was ever constructed.

6. A lyre in the famous ancient picture dug out of Herculaneum, upon which Chiron is teaching the young Achilles to play. See CHIRON.

LYRIC-POETRY, was such as the ancients sung to the lyre or harp.—It was originally employed in celebrating the praises of gods and heroes, and its characteristic was sweetness. Who was the author of it is not known. It was much cultivated by the Greeks; and Horace was the first who attempted it in the Latin language. Anacreon, Alcaeus, Stesichorus, Sappho, and Horace, were the most celebrated lyric poets of antiquity.

LYRID, among the ancients, a kind of musicians who played on the lyre and sung at the same time. This appellation was also given to such as made it their employment to sing lyric poems composed by others.

LYS, or LIS. See LIS.

LYS, the name of a measure used by the Chinese in estimating distances. Two hundred lys make 60 geographical miles, which are equal to one degree.

LYSANDER, a famous Spartan general. See SPARTA.

LYSANDRIA, a Samian festival, celebrated with games and sacrifices in honour of the Lacedemonian general Lyander. It was anciently called herse; but this name the Samians abolished by a public decree.

LYSIARCH, an ancient magistrate, who superintended the sacred games, and presided in matters of religion in the province of Lydia. He was created in a council consisting of deputies from all the provincial cities, in number 23. The lysiarchs were both heads of the council and pontiffs of the province.

LYSIAS, an ancient Grecian orator, was born at Syracuse in the 60th Olympiad. At 15, he went to Thurion, a colony of the Athenians; and when grown up, allotted in the administration of the government there many years. When about 47 years of age, he returned to Athens; whence, being afterwards banished by the 50 tyrants, he went to Megara. Upon his return, Thrasybulus would have had him employed again in state matters; but this not taking place, he spent the remainder of his life as a private man. He was very familiar with Socrates, and other illustrious philosophers. He proceeded to teach the art of speaking, not that he pleaded at the bar himself, but he supplied others with speeches. "Fuit Lyssmachia Lylias in causis forensibus non verius" (says Cicero), fed egregie suis scriptis et agitatis legibus," &c. Quinti.-LYSIPPUS, a celebrated Greek statuary, was born at Sicyon, and at first followed the butylæum of a locksmith which he quitted in order to practise painting; but he afterwards applied himself entirely to sculpture; in which he acquired an immortal reputation, and made a great number of statues that were the admiration of the people of Athens and Rome. His grand statue of the fun represented in a car drawn by four horses, was worshiped at Rhodes; he made several statues of Alexander and his favourites, which were brought to Rome by Metelius after he had reduced the Macedonian empire; and the statue of a man wiping and anointing himself after bathing, being particularly excellent, was placed by Agrippa before his baths in that city. He lived in the time of Alexander the Great, about 354 B.C.; and left three sons, who were all famous sculptors.

LYTHRUM, PURPLE LOOSESTRIFE, in botany. A genus of the monogyne order belonging to the pentandria class of plants; and in the natural method ranking under the 20th order, Rotaece. The corolla is rotaceous; the capsule globular, beaked, and ten-valved. There are ten species, but only four are commonly cultivated in gardens. These are hardy, herbaceous perennials and biennials, rising with erect stalks from 18 inches to two or three feet high; garnished with narrow entire leaves; and terminated by spikes and clusters of monopetalous, rotated, five-parted spreading flowers of white and yellow colours. They are easily propagated by seeds, and will thrive in any soil or situation.

LYSIMACHIA, a loosestrife, in botany: A genus of the monogyne order belonging to the pentandria class of plants; and in the natural method ranking under the 20th order, Rotaece. The corolla is rotaceous; the capsule globular, beaked, and ten-valved. There are ten species, but only four are commonly cultivated in gardens. These are hardy, herbaceous perennials and biennials, rising with erect stalks from 18 inches to two or three feet high; garnished with narrow entire leaves; and terminated by spikes and clusters of monopetalous, rotated, five-parted spreading flowers of white and yellow colours. They are easily propagated by seeds, and will thrive in any soil or situation.
LYTTELTON (Edward), lord Lyttelton, keeper of the great seal in the reign of Charles I., was eminent for his probity and his moderation at the commencement of that monarch's disputes with his subjects. Without forfeiting his fidelity to the king, he preserved the esteem of parliament till 1644, when he was made colonel of a regiment in the king's army at York. He died in 1645. Besides several of his speeches which have been printed, he wrote reports in the common pleas and exchequer printed at London in 1663, in folio; several arguments and discourses, &c.

LYTTELTON (George lord) eldest son of Sir Thomas Lyttelton, bart., descended from the great judge Lyttelton, was born in 1600, at seven months; and the midwife fopping him to be dead, threw him carelessly into the cradle; where, had not some signs of life been taken notice of by one of the attendants, he might have never recovered. He received the elements of his education at Eaton-school, where he showed an early inclination to poetry. His pastoral and some other light pieces were originally written in that Seminary of Learning; from whence he was removed to the University of Oxford, where he pursued his classical studies with uncommon avidity, and sketched the plan of his Persian Letters, a work which afterwards procured him great reputation, not only from the elegance of the language in which they were composed, but from the excellent observations they contained on the manners of mankind.

In the year 1728, he set out on the tour of Europe; and, on his arrival at Paris, accidentally became acquainted with the honourable Mr. Poyntz, then the British minister at the court of Versailles; who was so struck with the extraordinary capacity of this young traveller, that he invited him to his home, and employed him in many political negotiations, which he executed with great judgment and fidelity.

Mr. Lyttelton's conduct, while on his travels, was a lesson of instruction to the rest of his countrymen. Instead of lounging away his hours at the coffee-houses frequented by the English, and adopting the fashionable fables and vices of France and Italy, his time was passed alternately in his library and in the society of men of rank and literature. In this early part of his life, he wrote a poetical epistle to Dr. Ayloough, and another to Mr. Pope, which show singular taste and correctness.

After continuing a considerable time at Paris with Mr. Poyntz, who, to use his own words, behaved like a second father to him, he proceeded to Lyons and Geneva; and from thence to Turin, where he was honoured with great marks of friendship by his Sardinian majesty. He then visited Milan, Venice, Genoa, and Rome, where he applied himself closely to the study of the fine arts; and was, even in that celebrated metropolis, allowed a perfect judge of painting, sculpture, and architecture.

During his continuance abroad, he constantly corresponded with Sir Thomas, his father. Several of his letters are yet remaining, and place his filial affection in a very distinguished light. He soon after returned to his native country, and was elected representative for the borough of Ockhampton in Devonshire; and behaved so much to the satisfaction of his constituents, that they several times re-elected him for the same place without putting him to the least expense.

About this period, he received great marks of friendship from Frederic prince of Wales, father of his present majesty: and was, in the year 1757, appointed principal secretary to his royal highness, and continued in the strictest intimacy with him till the time of his death. His attention to public business did not, however, prevent him from exercising his poetical talent. A most amiable young lady, Miss Fortescue, inspired him with a passion, which produced a number of little pieces, remarkable for their tenderness and elegance; and he had a happy facility of striking out an extempore compliment, which obtained him no small share of reputation. One evening being in company with lord Cobham and several of the nobility at Stowe, his lordship mentioned his design of putting up a bust of lady Sisfolk in his beautiful gardens; and, turning to Mr. Lyttelton, said, "George, you must furnish me with a motto for it." "I will, my lord," answered Mr. Lyttelton; and directly produced the following couplet:

Her wit and beauty for a court were made,
But truth and goodness fill her for a Shade.

When Mr. Pitt, the late earl of Chatham, lost his commission in the guards, in consequence of his spirited behaviour in parliament, Mr. Lyttelton was in waiting at Leicester house, and, on hearing the circumstance, immediately wrote these lines:

Long had thy virtue mark'd thee out for fame,
Far far superior to a corret's name;
This generous Walpole saw, and grieved to find
So mean a post disgrace that noble mind;
The fervile standard from thy free-born hand
He took, and bade thee lead the patriot-band.

In the year 1742, he married Lucy, the daughter of Hugh Fortesque, Esq.; of Fillleigh in the county of Devon, the lady above-mentioned, whose exemplary conduct, and uniform practice of religion and virtue, established his conjugal happiness upon the most solid basis.

In 1744, he was appointed one of the lords commissioners of the treasury; and, during his continuance in that station, constantly exerted his influence in rewarding merit and ability. He was the friend and patron of the late Henry Fielding, James Thomson, author of the Seasons, Mr. Mallet, Dr. Young, Mr. Hammond, Mr. Welf, Mr. Pope, and Voltaire. On the death of Thomson, who left his affairs in a very embarrased condition, Mr. Lyttelton took that poet's sister under his protection. He revived the tragedy of Coriolanus, which that writer had not put the last hand
L Y T  [ 355 ]

hand to; and brought it out at the theatre-royal, Covent-garden, with a prologue of his own writing, in which he so affectionately lamented the loss of that delightful bard, that not only Mr Quin, who spoke the lines, but almost the whole audience, spontaneously burst into tears.

In the beginning of the year 1746, his felicity was interrupted by the loss of his wife, who died in the 29th year of her age; leaving him one son, Thomas, the late lord Lyttelton; and a daughter, Lucy, who some time since married lord viscount Valentia. The remains of his amiable lady were deposited at Over-Arley in Worcestershire; and an elegant monument was erected to her memory in the church of Hagley, which contains the following inscription written by her husband:

Made to engage all hearts, and charm all eyes: Tho' meek, magnanimous; tho' witty, wise; Polite, as all her life in courts had been; Yet good, as all her temper from the miracles of Christ, and her eloquence was sweeter than her song, Her mind was virtue by the graces dress'd. Her form was beauty in a living state, Her mind was virtue by the graces dress'd.

Besides these beautiful lines, Mr Lyttelton wrote a monody on the death of his lady, which will be remembered while conjugal affection and a taste for poetry exist in this country.

His judicious observations on the conversion and apostleship of St Paul, were written at the desire of Gilbert Weft, in consequence of Mr Lyttelton's affecting, that beside all the proofs of the Christian religion, which might be drawn from the prophecies of the Old Testament, from the necessary connection it has with the whole system of the Jewish religion, from the miracles of Christ, and from the evidence given of his resurrection by all the other apostles, he thought the conversion of St Paul alone, duly considered, was of itself a demonstration sufficient to prove Christianity to be a divine revelation. Mr Weft was struck with the thought; and assured his friend, that so compendious a proof would be of great use to convince those unbelievers that will not attend to a longer series of arguments; and time has shown he was not out in his conjecture, as the tract is esteemed one of the best defences of Christianity which has hitherto been published.

In 1754, he resigned his office of lord of the treasury, and was made cofferer to his majesty's household, and sworn of the privy-council: Previous to which, he married, a second time, Elizabeth daughter of field-marshal Sir Robert Rich, whose indifferet conduct gave him great uneasiness, and from whom he was separated by mutual consent, a few years after his marriage.

After being appointed chancellor and under-treasurer of the court of exchequer, he was, by letters-patent dated the 19th of November 1757, 31 Geo. II. created a peer of Great Britain, by the title and style of lord Lyttelton, baron of Frankies, in the county of Worcestershire. His speeches on the Scotch and mutiny bills in the year 1747, on the Jew bill in 1753, and on the privilege of parliament in 1762, showed found judgment, powerful eloquence, and inflexible integrity. During the last ten years he lived chiefly in retirement, in the continual exercise of all the virtues which can ennoble private life. His last work was Dialogues of the Dead, in which the morality of Cambray and the spirit of Fontenelle are happily united.

He was suddenly seized with an inflammation of the bowels, in the middle of July 1773, at his seat at Hagley; which termi rated in his death, on the 22d of that month. His last moments were attended with unimpaired understanding, unaffected greatness of mind, calm resignation, and humble but confident hopes in the mercy of God. As he had lived universally esteemed, he died lamented by all parties. A complete collection of his works has been published since his decease, by his nephew George Aycough, Esq.

M.

M a liquid consonant, and the twelfth letter in the alphabet.

It has one unvaried sound, and is pronounced by striking the upper lip against the lower; in which the pronunciation of this letter agrees with that of b; the only difference between the two consisting in a little motion made in the nose in pronouncing m, and not in b: whence it happens that those who have taken cold, for m ordinarily pronounce b; the nose in that case being disabled from making the necessary motion.

All consonants are formed with the aid of vowels; in em the vowel precedes, in be it follows; and m is never mute.

Quintilian observes, that the m sometimes ends Latin words, but never Greek ones; the Greeks always changing it in that case into n, for the sake of the better sound.

M is also a numeral letter, and among the ancients was used for a thousand; according to the verse,

M capit ell numeri, quem quinque milli ten. vi.

When a dash is added to the top of it, as m, it signifies a thousand times a thousand.

Y y 2
MAC

M. as an abbreviation, stands for Manlius, Marcus, Martinus, and Mricius: M. A. signifies magister artium, or master of arts; MS. manuscript, and MSS. manuscripts.

M., in astronomical tables, and other things of that kind, is used for meridional or southern; and sometimes for meridian or midday.

M. in medicinal prescription, is frequently used to signify a maniple or handfull: and it is sometimes also put at the end of a recipe, for mixture "a mingle;" or for mixture "a mixture." Thus, m. s. julipium, signifies a mixture and make a julep.

M. in law, the brand or figma of a person convicted of manslaughter, and admitted to the benefit of his clergy. It is to be burnt on the brawn of his left thumb.

MAAT (John). See Blankop.

MARA, in botany: A genius of the triandria order, belonging to the dioscia class of plants. The perianthium of the male is trifid; that of the female is as in the male; the fruit is a plum two-celled superior.

MABILLON (John), a very learned writer of France in the 17th century, was born at Perre-monte, on the frontiers of Champagne, in 1632. He was educated in the university of Rheims, and afterwards entered into the abbey of the Benedictines of St. Remy. In the year 1663, he was appointed keeper of the treasuries and monuments of France at St. Dennis; but having unfortunately broke a looking-glass there, which was pretended to have belonged to Virgil, he defied leave of his superiors to quit an employment which frequently obliged him to tell things he did not believe. Next year he went to Paris: and was very serviceable to Father d'Achery, who was devious of having some young monk who could assist him in compiling his Spicilegium. This made him known. Soon after the congregation of St. Maur having formed a design of publishing new editions of the fathers, revised from the MSS. in the libraries of the Benedictines, Mabillon was charged with the edition of St. Bernard, which he prepared with extraordinary diligence. After that, he published many other works, which are evidences of his vast capacity and industry. In 1682, he was employed by Mr. Colbert in examining some ancient titles relating to the royal family. The year following he went into Germany, to search the archives and libraries of the ancient abbeys for what was most curious and proper to illustrate the history of the church in general, and that of France in particular. He has published an account of this journey. In 1689, he undertook another journey into Italy, by order of the king of France; and returned the year following with a very noble collection. He placed in the king's library above 3000 volumes of rare books, printed and in MSS. and composed two volumes of the pieces which he had discovered in the country. He was highly esteemed for his virtues as well as his learning.

MACCO, or MACAU. See Lemur.

MACAO, a town of China, in the province of Canton, seated in an island at the mouth of the river Tae. The Portuguese have been in possession of the harbour for 150 years. Formerly they had a great trade here; but now they have only a fort with a small garrison. The houses are built after the European manner; and there is a Chinese mandarin, as well as a Portuguese governor, to take care of the town and the neighbouring country. E. Long. 112° 13'. N. Lat. 22° 12'.

MACAO, in ornithology. See PSEITACUS.

MACARIANS, in ecclesiastical history, the followers of Macarius, an Egyptian monk, who was distinguished towards the close of the fourth century for his sanctity and virtue. In his writings there are some superstitious tenets, and also certain opinions that are tainted with Origenism. The name has been also applied to those who adopted the sentiments of Macarius a native of Ireland, who, about the close of the ninth century, propagated in France the error afterwards maintained by Averrhoes that one individual intelligence or soul performed the spiritual and rational functions in all the human race.

MACARONI. See FoLENGIO, and the next article.

MACARONIC, or MACARONIAN, a kind of burlesque poetry, consisting of a jumble of words of different languages, with words of the vulgar tongue Latinized, and Latin words modernized. Macaroni among the Italians; as has been observed by Callius Rhodiginus, signifies a coarse clownish man; and because this kind of poetry is patched out of several languages, and full of extravagant words, &c. the Italians, among whom it had its rise, gave it the name of macaronian, or macaronic poetry. Others choose to derive it from macaronibus, from macaroni, a kind of confection made of meal not boiled, sweet almonds, sugar, and the white of eggs, accounted a great dainty among the country-people in Italy; which, from their being composed of various ingredients, occasioned this kind of poetry, which consists of Latin, Italian, Spanish, French, English, &c. to be called by their name.

Example.—A bold fellow in the macaronic style, says,

\[\text{Enflavi omnes oradoneis \& regimandois, \&c.}\]

Another example:

\[\text{Archelos psilofiers saramique manum,}\]
\[\text{Et grandem esimenta que inopinum fallaruelle est;}\]
\[\text{Porsumque alio trubiliante corda elpohre, \&c.}\]

Theol. Folengio, a Benedictine monk of Nantua, was the first who invented, or at least cultivated, this kind of verse. See FoLENGIO.

The best pieces of this kind are the Béllius, of PoLengio, and Maccaronis Forza by Stefonio a Jesuit, among the Italians; and the Beatus veritabilis super terribilis eisuenta pazianarium de Caelius, among the French. The famous Rabelais first transferred the macaronic style out of the Italian verfe into French prose; and on the model thereof formed some of the best things in his Pantagruel. We have little in English in the macaronian way; nothing scarce, but some little loose pieces collected in Camden's remains. But the Germans and Netherlanders have had their macaronic poets; witness the Cererum Catholicum von Calviniss, of one Martinius Hancius Frizius, which contains about 1200 verses, all the words whereof begin with the letter C.

MACARSKA,
MACCABEUS (Judas). See JUDAS.

MACCABEES, two apocryphal books of scripture, containing the history of Judas and his brothers, and Maccabees, their wars against the Syrian kings in defence of their religion and liberties, so called from Judas Maccathias, furnamed Maccabees, as some say from the word מָכַבֵּה מַכָּבִיא, formed of the initials of מַכָּבֵה מַכָּבִיא, q. d. Whoe is like unto thee, O Lord, among the gods? which was the motto of his standard; whence those who fought under his standard were called Maccabees, and the name was generally applied to all who suffered in the cause of the true religion, under the Egyptian or Syrian kings. The first book of the Maccabees is an excellent history, and comes nearest to the style and manner of the sacred historians of any extant. It was written originally in the Chaldee language. Of the Jerusalem dialect, and was extant in this language in the time of Jerom. From the Chaldee it was translated into Greek, from the Greek into Latin. It is supposed to have been written by John Hyrcanus the son of Simon, who was prince and high priest of the Jews near 30 years, and began his government at the time where this history ends. It contains the history of 40 years, from the reign of Antiochus Epiphanes to the death of Simon the high priest; that is from the year of the world 3829 to the year 3869; 111 years before Christ. The second book of the Maccabees begins with two epistles sent from the Jews of Jerusalem to the Jews of Egypt and Alexandria; to exhort them to observe the feast of the dedication of the new altar erected by Judas on his purifying the temple. The first was written in the 169th year of the era of the S leucide, i.e. before Christ 144; and the second in the 188th year of the same era, or 153 before Christ; and both appear to be furious. After these epistles follows the preface of the author to his history, which is an abridgment of a larger work, composed by one Jason, a Jew of Cyrene, who wrote in Greek the history of Judas Maccabees and his brethren, and the wars against Antiochus Epiphanes, and Eupator his son. This second book does not by any means equal the accuracy and excellency of the first. It contains a history of about 15 years, from the execution of Heliodorus's commissio, who was sent by Seleucus to fetch away the treasures of the temple, to the victory obtained by Judas Maccabees over Nicanor; that is, from the year of the world 3829, to the year 353, 147 years before Christ.

There are in the Polyglot bibles, both of Paris and London, Syriac versions of both these books; but they, as well as the English versions which we have among the apocryphal writers in our Bibles, are derived from the Greek. There is also a third book of the Maccabees, containing the history of the persecution of Ptolemy Philopator against the Jews in Egypt, and their sufferings under it, and seems to have been written by some Alexandrian Jew in the Greek language, not long after the time of Strabo. It is in most of the ancient manuscript copies of the Greek Septuagint, particularly in the Alexandrian and Vatican, but was never inserted into the vulgar Latin version of the Bible, nor consequently into any of the English copies. Moreover, Josephus's history of the martyrs that suffered under Antiochus Epiphanes, is found in some manuscript Greek Bibles, under the name of the fourth book of the Maccabees.
MACBETH, a Scots nobleman in the 11th century, nearly allied to Duncan king of Scotland.—Not contented with carving the king's authority, he carried his petulant ambition so far as to put him to death; and, chasing Malcolm Kenmure his son and heir into England, usurped the crown. Siward earl of Northumberland, whose daughter Duncan had married, undertook, by the order of Edward the Confessor, the protection of the fugitive prince. He marched with an army into Scotland; defeated and killed Macbeth; and restored Malcolm to the throne of his ancestors. Shakespeare has made this transfiguration the subject of one of his best tragedies.

MACBRIDE (Dr David) an eminent physician and philosopher, was descended from an ancient family in the county of Galloway in Scotland. His grandfather, a clergyman, had settled in Ireland about the end of the last century, as minister to a Presbyterian congregation at Belfast; and his father, who followed the same line, was settled at Ballymony in the county of Antrim, where he married, and where our author was born in April 1726. After a proper school-education, and having passed some time under the tuition of an eminent surgeon in his native place, he was sent to the university of Glasgow. Having there completed the usual course of scientific studies, he came to Edinburgh for the further prosecution of medical science. After a short stay here, a war then prevailing between France and Britain, he was induced to go on board the navy in the station of a surgeon's mate. In the service of his country he continued for several years; and after discharging for some time the duties of an assistant, he was raised to the rank of surgeon. In this situation, he first turned his thoughts towards the discovery of a remedy for the seafury. It was not, however, at this period, that either chance or reasoning suggested to him the employment of an article which has since been attended with the most beneficial consequences. Here he had an opportunity only of observing the symptoms, of studying the nature, and of lamenting the consequences, of the disease.

The termination of the war by the peace of Aix-la-Chapelle put a period to Dr Macbride's employment as a naval surgeon. He had now probably obtained much medical knowledge in the school of experience; but he was enabled that he had still much to acquire in that of science. An ardent keenness to mingle in active life had led him from the schools of medicine at an earlier period than could have been wished; and an earnest desire to find his future practice in the best established principles led him back to them, when a judgment, matured by years, and informed from the observation of facts, rendered him capable of hearing teachers with greater advantage. He returned therefore to Edinburgh, and again entered on the career of academical pursuits, under the tuition of Dr Monro, and these other teachers, whose abilities raised the fame of the medical school at this place. But not satisfied with the instructions to be had from any one set of professors, the celebrity of the medical teachers in London led him also to visit that capital. There he particularly became the pupil of those distinguished lecturers, Dr Hunter and Dr Smellie. And while from the former he laboured to acquire an accurate surgical knowledge, from the latter he endeavoured to obtain the true principles of midwifery considered as a science. At the same time, he was no less industrious in improving himself in the useful practice of both arts by attention at hospitals.

Thus prepared for the exercise of his profession about the end of the year 1745, he fixed his residence in Dublin in the character of surgeon and accoucheur. If amiable manners, and extensive knowledge of his profession, could alone have been sufficient introductions to practice, he might in a short time have looked for a competent share of business in that capital; but while he had to combat that objection which very generally arises from youth, his progress was also not a little retarded by an uncommon degree of modesty. Hence for several years he remained almost in a state of obscurity, and was employed by but few people either of rank or fortune. But, if it is to be regretted that for many years his time was not so fully employed in the lucrative part of his profession as was due to his merit it ought still to be remembered, that this essentially promoted the cause of science; for by this means his genius and industry were directed to medical researches; and were productive of discoveries which will with honour transmute his name to latest posterity. These, though some of them might have been successfully turned to his own emolument, were freely communicated to the world in different publications; and he did not show greater ingenuity in making discoveries, than liberality of sentiment in publishing them for the advantage of others.—His first publication intitled, "Experimental Essays on Medical and Philosophical Subjects," made its appearance in the year 1754.—These Essays are five in number: 1. On the fermentation of alimentary mixture and the digestion of the food. 2. On the nature and properties of fixed air. 3. On the different kinds of antiseptics. 4. Of the dissolvent power of quicklime. 5. Of the fea-scurvy. The merit of all these is sufficiently known and acknowledged; but the last of them is unquestionably the most important; the method therein proposed of both the prevention and cure of that dreadful disease the scurvy, having been confirmed by repeated and undeniable observation.

Having thus equally distinguished himself as an ingenious philosopher and able practitioner, the world were no now flow in bellowing upon him the tribute of applause to which he was intitled. His name was enrolled with honour in the lists of many learned societies, and the university where his studies had first been commenced, were proud to confer upon him the degree of Dr of Medicine.

The reputation, however, of being a distinguished author, was to him a but secondary object: and his talents were not confined to the advancement of medicine alone. Having successfully discovered a considerable improvement in the art of tanning, with that spirit of generosity which is ever the concomitant of real worth, he speedily and freely communicated it to the public, by publishing, first, "An Account of a New Method of Tanning," and afterwards, "Instructions for carrying on the New Method of Tanning." As a mark of approbation for this liberal conduct, as well as a testimony of respect for his ingenuity, prizes were conferred upon him by the Societies of Arts both in London and Dublin. But his last and most
MACE, an ancient weapon, formerly much used by the cavalry of all nations. It was commonly made of iron; its figure much resembles a chocolate mill; and is carminative, an ailriment, is made of copper or silver gilt, ornamented with a crown, globe, and croft, and is now the chief insignia of authority throughout Great Britain. Similar to the ancient maces, were those staves at the end of which iron or leaden balls armed with spikes were suspended by chains: they were till lately carried by the pioneers of the trained-bands or city militia.

MACE, in the materia medica, the second coat of covering of the kernel of the nutmeg, is a thin and membranaceous substance, of an oleaginous nature, and a yellowish colour: being with fragments of an inch in length, which are divided into a multitude of ramifications. It is of an extremely fragrant, aromatic, and agreeable flavour; and of a pleasant, but acid, oleaginous taste.

Mace is carminative, stomachic, and astringent; and polishes all the virtues of nutmeg, but has less astrignency.—The oils of mace and nutmeg, whether prepared by distillation or expression, are so much of the same nature, that they may be indifferently used for one another on all occasions. They give ease in colics, and often in nephritic cases, taken internally from one drop to five or six of the distilled oil, on an equal quantity of the expressed; and externally, they are of use in rub paralytic limbs: they also assist digestion; and will often stop vomitings and hiccoughs, only by being rubbed on the region of the stomach. The nurfes have a custom of applying oil of mace by expression to childrens navels to ese their gripes, and that often with success: and we are assured, by authors of credit, that when rubbed on the temples, it promotes sleep.

MACEDON, or MACEDONIA, a most celebrated kingdom of antiquity, was bounded on the east by the Ægæan sea; on the south by the Ætolian sea or Adriatic; on the north, first by the river Strymon and the Scardian mountains, but afterwards by the river Néssus or Neus. In a direct line the whole country extended only 150 miles in length; but the windings of the coast lengthened it out to three times that extent; in which almost every convenient situation was occupied by a Grecian sea-port. The country was naturally divided by the Thermaic and Strymonic gulfps, into the provinces of Pheros, Calcs, and Pangræs. The middle region, which took its name from a city of Euboea from whence it was originally peopled, was very fertile and pleasant; the inland country, being diversified by lakes, rivers, and arms of the sea, was extremely convenient for inland navigation, while the towns of Amphipolis, Potidea, Acmades, and many others, afforded marls for the commerce of the republics of Greece, as well as of Thrace and Macedon. On one side of this district were the mountains of Pangræs, and on the other the plains of Pheros. The Pangræs
MACEDON [360]

Macedon. mountains, which extended 90 miles towards the east and the river Nestus, though proper neither for corn nor pasture, produced plenty of timber for ship-building; while the southern branches of the mountain contained rich veins of gold and silver; but these, though wrought successively by the Thessians and the Athenians, were only brought to perfection by Philip of Macedon, who extracted from them gold and silver to the value of 200,000. Sterling annually. Pieria extended 50 miles along the Thermaic gulf, to the confines of Thessaly and mount Pindus. The inland part of the country was beautifully diversified with hilly hills and fountains; and so admirably calculated for solitary walks and retreat, that the ancients looked upon it to be the favourite haunt of the muses, and accordingly contained rich veins of gold and silver; while wrought by the Macedonians and their barbarous neighbours begun to suffer an interruption; and in 691 B.C. the kingdom was invaded by the Illyrians. At first they did considerable damage by their Illyravages; but the Macedonian monarch, Argaeus, having decoyed them into an ambush, cut off great numbers, and obliged the remainder to leave the kingdom. In the reign of his successors, however, they returned, and occasionally proved very troublesome enemies till the reigns of Philip and Alexander. The mean time the kingdom of Macedon began to be affected by those great events which took place of invasion by

In the mean time the kingdom of Macedon began to be affected by those great events which took place in other parts of the world. Cyrus having overthrown the Babylonian empire, and conquered all the western part of Asia, established a mighty monarchy, which threatened all the eastern parts of Europe with subjection. The Greeks, however, having now emerged from their barbarism, and acquired great knowledge in the art of war, were able to resist effectually this very formidable power; but the kingdom of Macedon, obscure and unconnected, was obliged to yield, and though not formally made a province of the Persian empire, was nevertheless accounted in some sort as under the vailage and protection of the Persians. Alcetas, who ascended the Macedonian throne about the time that the Persian monarch was established, had the dexterity to preserve his dominions from the encroachments of the Greeks on the one hand, and of the Persians on the other; but in the reign of his successor Amyntas a formal demand was made of submission to the great King Darius, by sending him a present of earth and water. Seven ambassadors were sent on this errand by Megabizus, one of the officers of Darius. They were impudently entertained by Amyntas; but having attempted to take some indecent liberties with the Macedonian women, Alexander the king's son caufed them all to be murdered. This rash action had had almost proved the ruin of the kingdom; but Alexander found means to pacify the Persians, and Georgia the general sent against him by Megabizus, by showing him his sister Hygea, a very beautiful woman, with whom the Persian fell in love at first sight, and afterwards married her.

From this time the Macedonians were accounted the faithful allies of the Persians; and, through the interest of his son-in-law, Amyntas obtained the country. In the neighbourhood of mount Haemos and Olympus, at the same time that the city of Albaund in Phrygia was given to Amyntas the nephew of Alexander. The Macedonians distinguished themselves in the time of

The little colony of Argives led into Emathia by Caranus would soon have been overwhelmed by the barbarous nations who surrounded it, had not this prince and his subjects taken care to ingratiate themselves with their neighbours, rather than to attempt to subdue them by force of arms. They introduced to them the Greek religion and government, and in the knowledge of many useful arts; adopting themselves, in some degree, the language and manners of the barbarians; importing to them in return some part of the Grecian civilization and polite behaviour. Thus they gradually associated with the fierce and warlike tribes in their neighbourhood; and this prudent conduct, being followed by succeeding generations, may be looked upon as one of the causes of the Macedonian greatness.

Caranus, dying after a reign of three years, left the kingdom to his son Caranus; who having considerably enlarged his dominions, was succeeded by Thurnyss, and he by Perdiccas I. This last prince is by Thu- ccipides and Herodotus accounted the founder of the Macedonian monarchy; though his history is obs¬ furred by fable, that nothing certain can now be known concerning it. In process of time, however, the good understanding which had subsisted between the Macedonians and their barbarous neighbors began to suffer an interruption; and in 691 B.C. the kingdom was invaded by the Illyrians. At first they did considerable damage by their Illyravages; but the Macedonian monarch, Argaeus, having decoyed them into an ambush, cut off great numbers, and obliged the remainder to leave the kingdom. In the reign of his successors, however, they returned, and occasionally proved very troublesome enemies till the reigns of Philip and Alexander.

The mean time the kingdom of Macedon began to be affected by those great events which took place in other parts of the world. Cyrus having overthrown the Babylonian empire, and conquered all the western part of Asia, established a mighty monarchy, which threatened all the eastern parts of Europe with subjection. The Greeks, however, having now emerged from their barbarism, and acquired great knowledge in the art of war, were able to resist effectually this very formidable power; but the kingdom of Macedon, obscure and unconnected, was obliged to yield, and though not formally made a province of the Persian empire, was nevertheless accounted in some sort as under the vailage and protection of the Persians. Alcetas, who ascended the Macedonian throne about the time that the Persian monarch was established, had the dexterity to preserve his dominions from the encroachments of the Greeks on the one hand, and of the Persians on the other; but in the reign of his successor Amyntas a formal demand was made of submission to the great King Darius, by sending him a present of earth and water. Seven ambassadors were sent on this errand by Megabizus, one of the officers of Darius. They were impudently entertained by Amyntas; but having attempted to take some indecent liberties with the Macedonian women, Alexander the king's son caufed them all to be murdered. This rash action had had almost proved the ruin of the kingdom; but Alexander found means to pacify the Persians, and Georgia the general sent against him by Megabizus, by showing him his sister Hygea, a very beautiful woman, with whom the Persian fell in love at first sight, and afterwards married her.

From this time the Macedonians were accounted the faithful allies of the Persians; and, through the interest of his son-in-law, Amyntas obtained the country. of the Persian invasion of Greece, by furnishing their allies with 200,000 recruits; though some, particularly Potidae, Olynthus, and Pelleae, adhered to the Grecian interest. The two last were taken and railed, and the inhabitants massacred by the Persians; but Potidae escaped by reason of the sea breaking into the Persian camp, where it did great damage. Alexander, however, afterwards thought proper to court the favour of the Greeks by giving them intelligence of the time when Mardonius designed to attack them. The remaining transactions of this reign are entirely unknown, farther than that he enlarged his dominions to the river Nestis on the east and the Axios on the west.

Alexander I. was succeeded by his son Perdiccas II, who according to Dr Gillies, "inherited his father's abilities, though not his integrity." But from his duplicity abovementioned both to Greeks and Persians, it does not appear that he had much to boast of as to the latter quality. In the Peloponnesian war he espoused the cause of the Spartans against the Athenians, from whom he was in danger by reason of their numerous settlements on the Macedonian coast, and their great power by sea. For some time, however, he ammied the Athenians with a show of friendship; but at last, under pretence of enabling Olynthus and some other cities to recover their liberties, he affixed in destroying the influence of the Athenians in those places, in hopes of establishing that of the Macedonians in its stead. But this design failed of success; the Olynthian confederacy was broken, and the members of it became subjects to Sparta, until at last, by the misfortunes of that republic, they became sufficiently powerful not only to re Bill the encroachments of the Macedonians, but to make considerable conquests in their country.

Perdiccas II. was succeeded about 416 B.C. by Archelaus I. He enlarged his dominions by the conquest of Pydna, and other places in Pieria, though his ambition seems rather to have been to extend his dominions than greatly to extend them. He facilitated the communication between the principal towns of Macedonia, by cutting straight roads through most part of the country; he built walls and fortresses in such places as afforded a favourable situation; encouraged agriculture and the arts, particularly those subservient to war; formed magazines of arms; raised and disciplined a considerable body of cavalry; and in a word, says Dr Gillies, added more to the solid grandeur of Macedonia than had been done by all his predecessors put together. Nor was he regardant of the arts of peace. His palace was adorned by the works of Grecian painters. Euripides was long entertained at his court; Socrates was earnestly solicited to live there, after the example of this philosophic poet, formed by his precepts and cherished by his friendship: men of merit and genius in the various walks of literature and science we invited to reside in Macedonia, and treated with distinguished regard by a monarch duly attentive to promote his own glory and the happiness of his subjects."

This great monarch died after a reign of six years, a space by far too short to accomplish the magnificent projects he had formed. After his death the kingdom fell under the power of usurpers or weak

wicked monarchs. A number of competitors for the throne; and these by turns called in to their assistance the Thracians, Illyrians, Thessalians; the Olynthian confederacy, Athens, Sparta, and Thebes. Bardylis, an active and daring chief, who, from being head of a gang of robbers, had become sovereign of the Illyrians, entered Macedon at the head of a numerous army, depoited Amyntas II., the father of Philip, and set up in his place one Argeus, who confined to become tributary to the Illyrians. Another candidate for the throne, named Pausanias, was supported by the Thracians, but, by the assistance of the Thessalians and Olynthians, Amyntas was enabled to resume the government. After his restoration, however, the Olynthians refused to deliver up several places of importance belonging to Macedonia which Amyntas had either entrusted to their care, or which they had taken from his antagonist. Amyntas complained to Sparta; and that republic, which had already formed schemes of the Olynthian war with it, was readily complied with the thians.
ordered the remainder of the archers and cavalry to pursue; while he himself advanced at the head of the heavy armed foot with such celerity that they began to fall into disorder. The Olynthians allowed them to proceed, and the Lacedaemonians very imprudently advanced just under the towers and battlements of the city. The townsmen then mounted the walls, and discharged upon them a shower of darts, arrows, and other missile weapons, while the flower of the Olynthian troops, who had been purposely posted behind the gates, felled forth and attacked them with great violence. Teleutias attempting to rally his men, was slain in the first onset; the Spartans who attended him were defeated, and the whole army left dispersed with great slaughter, and obliged to shelter themselves in the towns of Acanthus, Apollonia, Spartolus, and Potidaea.

The Spartans, undisputed by this terrible disaster, next sent their King Ageipolis with a powerful reinforcement to Macedon. His presence greatly roused the spirits of the Lacedaemonian allies, and his rapid success seemed to promise a speedy termination to the war, when he himself died of a febrilitie. He was succeeded in the throne by his brother Cleombrotus, and the city of Pella was now completely blocked up by land, while a squadron of Lacedaemonian galleys blocked up the neighbouring port of Mycebera. The Olynthians, however, held out for nine or ten months, but at last were obliged to submit on very humiliating conditions. They formally renounced all claim to the dominion of Chalcis; they ceded the Macedonian cities to their ancient governor; and in consequence of this Amyntas left the city of Aegae or Edessa, where till now he had held his royal residence, and fixed it at Pella, a city of great strength and beauty, situated on an eminence, which together with a plain of considerable extent was defended by impregnable morsels, and by the rivers Axius and Lydias. It was distant about 15 miles from the Aegan sea, with which it communicated by means of the above-named rivers. It was originally founded by the Greeks, who had lately conquered and peopled it; but in consequence of the misfortunes of Olynthus, it now became the capital of Macedon, and continued ever after to be so.

Amyntas, thus fully established in his dominion, continued to enjoy tranquillity during the remaining part of his life. The reign of his son Alexander was short, and disturbed by invasions of the Illyrians; from whom he was obliged to purchase a peace. He left behind him two brothers, Perdiccas and Philip, both very young; so that Pausanias again found means to usurp the throne, being supported not only by the Thracians, but a considerable number of Greek mercenaries, as well as a powerful party in Macedon itself. In this critical juncture, however, Iphicrates the Athenian happening to be on an expedition to Amphipolis, was addressed by Eurydice the widow of Amyntas, so warmly in behalf of her two sons, whom she preferred to him, that he interested himself in their behalf, and got Perdiccas the elder established on the throne. He was induced also to this piece of generosity by the kindnss which Eurydice and her husband had formerly shown to himself, and he likewife saw the advantages which must ensue to his country from a connexion with Macedon. During the minority of the young prince, however, his brother Ptolemy, who was his guardian, openly aspired to the throne; but he was deposed by the Theban general Pelopidas, who reinfeated Perdiccas in his dominions; and in order to secure, in the most effectual manner, the dependence of Macedon upon Thebes, carried along with him thirty Macedonian youths as hostages; and among them Philip, the younger brother of the king. Perdiccas now, elated by the protection of such powerful allies, forgot Iphicrates and the Athenians, and even disputed with them the right to the city of Amphipolis, which had been deereed to them by the general council of Greece, but which his opposition rendered impossible for them to recover. In consequence of the truth he put in these new allies, also, it is probable that he refused to Bardyllis the Illyrian the tribute which the Macedonians had been obliged to pay him; which occasioned a war with that nation.

In this contest the Macedonians were defeated with the loss of 4000 men, Perdiccas himself being taken prisoner, and dying soon after of his wounds.

The kingdom was now left in the most deplorable state. Amyntas, the proper heir to the throne, was an infant; the Thebans, in whom Perdiccas had placed so much confidence, were deprived of the sovereignty of Greece; the Athenians, justly provoked at the ungrateful behaviour of the late monarch, showed an hostile disposition; the Illyrians ravaged the west, and the Paeonians the north quarter of the kingdom; the Thracians still supported the cause of Pausanias, and proposed to send him into Macedon at the head of a numerous army; while Argaeus, the formal rival of Amyntas, renewed his pretensions to the throne, and by flattering the Athenians with the hopes of recovering Amphipolis, easily induced them to support his claims; and in consequence of this they fitted out a fleet, having on board 3000 heavy armed soldiers, which they sent to the coast of Macedon.

Philip, the late king's brother, no sooner heard of Philip's defeat and death, than he set out privately from his residence in Thessalus, and on his arrival in Macedon found matters in the situation we have just now described. Fired with an infaatible ambition, it is very probable that from the very first moment he had resolved to seize the kingdom for himself; yet it was not till after he had pretended that he assumed the throne only to preferve it for his nephew. Philip, as has already been mentioned, was carried off as a hostage by Pelopidas, but for a long time past had remained in such obscurity, that historians disagree as to his place of residence; some placing him in Thebes, and others in Macedon. It is certain, however, that from the age of 15 he had been very much in the family of Epaminondas, from whose lessons he could not but derive the greatest emulation. It is probable also that he attended this celebrated general in many of his expeditions; and it is certain, that, with an attendance fuitable to his rank, he visited most of the principal republics, and showed an attention to their institutions, both civil and military, far superior to his years. Having easy access to whomever he pleased, he cultivated the friendship of the first people in Greece. Even in Athens,
Retrieves the affairs of the kingdom.

The new king being thus left at liberty to regulate his domestic concerns, began to circumscribe the power of his chief subjects; who, especially in the more remote provinces, paid very little regard to the authority of the kings of Macedon; sometimes, even in times of public calamity, throwing off their allegiance altogether, and assuming an independent government over considerable tracts of country. To counteract the ambition of these chiefs, Philip chose a body of Wannmen for companions.

The appearance of the Athenian fleet before Methone, with that of Argeus at the head of a numerous army in Peria, filled the whole country with consternation; and Philip, who was by no means deficient in talents necessary to recommend himself to the good graces of the people, took the opportunity of obtaining Amyntas' seat aside, and himself declared king, for which indeed the danger of the times afforded a very plausible pretext. Argeus, in the mean time, advanced with his Athenian allies towards Edessa, or Eage, the ancient capital of the Macedonian empire, where he hoped to have been amicably received, but finding the gates shut against him, he turned back to Methone. Philip harried him in his retreat, cutting off great numbers of his men, and afterwards defeated him in a general engagement, in which Argeus himself, with the flower of his army, were cut in pieces, and all the rest taken prisoners.

This first instance of success contributed greatly to raise the spirits of Philip's party; and he himself took care to improve it in the best manner possible. Having taken a great number of prisoners, both Macedonians and Athenians, he determined, by his treatment of them, to ingratiate himself with both parties. The former were called into his presence, and, after a gentle reprimand, admitted to swear allegiance to him; after which they were distributed through the army; the Athenians were entertained at his table, distinguished without ransom, and their baggage restored. The prisoners were let alone, allowed time to return to their native city and to spread abroad the news of Philip's generosity, when they were followed by ambassadors from Macedonia with proposals for peace. As he knew that the loss of Amphipolis had greatly irritated them, he now thought proper to renounce his jurisdiction over that city; and it was accordingly declared free and independent, and subject only to the government of its own free and equal laws. This artful conduct, together with his kind treatment of the prisoners, so wrought upon the minds of the Athenians, that they conferred to the renewal of a treaty which had formerly subsisted between them and his father Amyntas. Thus he found means to remove all jealousy of his ambition or the schemes he might afterwards undertake to their prejudice; and only this to induce them to engage in a ruinous war with their allies, which occupied their attention until Philip had an opportunity of getting his matters so well established that it was impossible to overthrow them.

The appearance of the Athenian fleet before Methone, with that of Argeus at the head of a numerous army in Peria, filled the whole country with consternation; and Philip, who was by no means deficient in talents necessary to recommend himself to the good graces of the people, took the opportunity of obtaining Amyntas' seat aside, and himself declared king, for which indeed the danger of the times afforded a very plausible pretext. Argeus, in the mean time, advanced with his Athenian allies towards Edessa, or Eage, the ancient capital of the Macedonian empire, where he hoped to have been amicably received, but finding the gates shut against him, he turned back to Methone. Philip harried him in his retreat, cutting off great numbers of his men, and afterwards defeated him in a general engagement, in which Argeus himself, with the flower of his army, were cut in pieces, and all the rest taken prisoners.

This first instance of success contributed greatly to raise the spirits of Philip's party; and he himself took care to improve it in the best manner possible. Having taken a great number of prisoners, both Macedonians and Athenians, he determined, by his treatment of them, to ingratiate himself with both parties. The former were called into his presence, and, after a gentle reprimand, admitted to swear allegiance to him; after which they were distributed through the army; the Athenians were entertained at his table, distinguished without ransom, and their baggage restored. The prisoners were let alone, allowed time to return to their native city and to spread abroad the news of Philip's generosity, when they were followed by ambassadors from Macedonia with proposals for peace. As he knew that the loss of Amphipolis had greatly irritated them, he now thought proper to renounce his jurisdiction over that city; and it was accordingly declared free and independent, and subject only to the government of its own free and equal laws. This artful conduct, together with his kind treatment of the prisoners, so wrought upon the minds of the Athenians, that they conferred to the renewal of a treaty which had formerly subsisted between them and his father Amyntas. Thus he found means to remove all jealousy of his ambition or the schemes he might afterwards undertake to their prejudice; and only this to induce them to engage in a ruinous war with their allies, which occupied their attention until Philip had an opportunity of getting his matters so well established that it was impossible to overthrow them.

The new king being thus left at liberty to regulate his domestic concerns, began to circumscribe the power of his chief subjects; who, especially in the more remote provinces, paid very little regard to the authority of the kings of Macedon; sometimes, even in times of public calamity, throwing off their allegiance altogether, and assuming an independent government over considerable tracts of country. To counteract the ambition of these chiefs, Philip chose a body of Illustrations of young men for companions.

The appearance of the Athenian fleet before Methone, with that of Argeus at the head of a numerous army in Peria, filled the whole country with consternation; and Philip, who was by no means deficient in talents necessary to recommend himself to the good graces of the people, took the opportunity of obtaining Amyntas' seat aside, and himself declared king, for which indeed the danger of the times afforded a very plausible pretext. The former were called into his presence, and, after a gentle reprimand, admitted to swear allegiance to him; after which they were distributed through the army; the Athenians were entertained at his table, distinguished without ransom, and their baggage restored. The prisoners were let alone, allowed time to return to their native city and to spread abroad the news of Philip's generosity, when they were followed by ambassadors from Macedonia with proposals for peace. As he knew that the loss of Amphipolis had greatly irritated them, he now thought proper to renounce his jurisdiction over that city; and it was accordingly declared free and independent, and subject only to the government of its own free and equal laws. This artful conduct, together with his kind treatment of the prisoners, so wrought upon the minds of the Athenians, that they conferred to the renewal of a treaty which had formerly subsisted between them and his father Amyntas. Thus he found means to remove all jealousy of his ambition or the schemes he might afterwards undertake to their prejudice; and only this to induce them to engage in a ruinous war with their allies, which occupied their attention until Philip had an opportunity of getting his matters so well established that it was impossible to overthrow them.

The new king being thus left at liberty to regulate his domestic concerns, began to circumscribe the power of his chief subjects; who, especially in the more remote provinces, paid very little regard to the authority of the kings of Macedon; sometimes, even in times of public calamity, throwing off their allegiance altogether, and assuming an independent government over considerable tracts of country. To counteract the ambition of these chiefs, Philip chose a body of Illustrations of young men for companions.
Macedon, who swelled it to 16,000, only rendered that order of battle more unwieldy and inconvenient. Instead of this, Philip, according to our author, employed himself in procuring arms, horses, and other necessary materials for war; and in introducing a more severe and exact military discipline than had formerly been known in Macedon.

While the king took these last methods to render himself secure at home and formidable abroad, the Paeonians again began to make incursions into the kingdom. The death of Agis their king, however, who was a man of great military skill, deprived them almost of every power of resistance when they were attacked. Philip, of consequence, over-ran their country with little opposition, and reduced them to the state of tributaries to Macedon. No sooner was this accomplished, then he undertook a winter's campaign against the Illyrians, who had long been the natural enemies of Macedon. They had now extended their territory to the east; by which means the Macedonians were excluded from the harbours on the coast of the Adriatic. This was a grievance to Philip, who seems early to have meditated the raising of a naval power; neither could he hope in safety should the kingdom be left open to the incursions of a barbarous enemy; for which reason he determined at once to humble those enemies in such a manner that they should no longer be in a situation to give him any disturbance. After an ineffectual negotiation, he was met by Bardyllis at the head of a considerable body of infantry, but with only 400 horse. They made a gallant resistance for some time; but being unable to cope with such a skilful general as Philip, they were defeated with the loss of 7000 men, among whom was their leader Bardyllis, who fell at the age of 50.

By this disaster the Illyrians were so much disheartened, that they sent ambassadors to Philip, humbly begging for peace on any terms. The conqueror granted them the same conditions which had been imposed upon the Paeonians, viz. the becoming tributary, and yielding up to him a considerable part of their country. That part of which lay to the eastward of a lake named Lycaenidaus he annexed to Macedon: and probably built a town and settled a colony there: the country being fertile, and the lake abounding with many kinds of fish highly esteemed by the ancients. This town and lake were about 50 miles distant from the Ionian sea; and such was the ascendency which the arms and policy of Philip acquired over his neighbours, that the inhabitants of all the intermediate districts adopted the language and manners of their conquerors; and their territory, hitherto unconnected with any foreign power, sunk into such absolute dependence upon Macedon, that many ancient geographers supposed it to be a province of that country.

Philip had no sooner reduced the Illyrians, than he began to put in execution greater designs than any he had yet attempted. The rich coasts to the southward of Macedon, inhabited chiefly by Greeks, presented a strong temptation to his ambition and avarice. The confederacy of Olynthus, after having thrown off the yoke of Sparta, was become more powerful than ever, and could send into field an army of 10,000 heavy armed troops, besides a number of cavalry in proportion. Most of the towns in Chalcidice were become tributary. It was its allies or subjects; so that this populous and wealthy province, together with Pangaenus on the right, and Pieria on the left, of both which the cities were either independent or subject to the Athenians, formed a barrier not only sufficient to guard against any incursions of the Macedonians, but which was even formidable to them. But though Philip was sensible enough of the importance of those places, he considered the conquest of Amphipolis as more necessary at the present time. By the possession of this place Macedon would be connected with the sea, and would be secured in many commercial advantages, which could not but contribute greatly to the prosperity of the kingdom at large; a road was likewise opened to the woods and mines of Pangaenus, the former of which were so necessary to the raising of a naval power; and the latter for the establishment of a proper military force. This city had indeed been declared independent by Philip himself in the beginning of this reign; but this was only to prevent a rupture with the Athenians, who still affected their right to it as an ancient colony; though, by reason of the perfidy of Charidemus, a native of Eubea, they had hitherto failed in their attempts to recover it. The Amphipolitans, however, having once enjoyed the sweets of liberty, prepared to maintain themselves in their independence. In the mean time the hostile designs of Philip, which all his precaution had not been able to conceal, alarmed the inhabitants to such a degree, that they thought proper to put themselves under the protection of the Athenians. By them they were readily received into the confederacy; and, trusting to the strength of their new allies, behaved in such an intemperate manner to Philip, that he was not long of finding a specious pretext for hostility; at which the Olynthians, greatly alarmed, sent ambassadors to Athens requesting their assistance against such a powerful enemy. Philip, however, justly alarmed at such a formidable conspiracy, sent agents to Athens, with such expedition that they arrived there before any thing could be concluded with the Olynthian deputies. Having gained over the popular leaders of that place, he deceived and flattered the magistrates and senate in such an artful manner, that a negotiation was instantly set on foot, by which Philip engaged to conquer Amphipolis for the Athenians, upon condition that they surrendered to him the strong forts of Pydna, a place which he represented as of much left importance to them; promising also to confer upon them many other advantages, which, however, he did not specify at that time. Thus the Athenians, deceived by the perfidy of their own magistrates, elated with the hopes of recovering Amphipolis, and outwitted by the superior policy of Philip, rejected with disdain the proffers of the Olynthians.

The ambassadors of Olynthus returned home highly disgraced with the reception they had met with; but had scarce time to communicate the news to their countrymen, when the ambassadors of Philip arrived at Olynthus. He pretended to condole with them on the alteration they had received at Athens; but testified his surprise that they should court the assistance of that fiant and haughty republic, when they could avail themselves of the powerful kingdom of Macedon, which

Philip no sooner reduced the Illyrians, than he began to put in execution greater designs than any he had yet attempted. The rich coasts to the southward of Macedon, inhabited chiefly by Greeks, presented a strong temptation to his ambition and avarice. The confederacy of Olynthus, after having thrown off the yoke of Sparta, was become more powerful than ever, and could send into field an army of 10,000 heavy armed troops, besides a number of cavalry in proportion. Most of the towns in Chalcidice were become Macedonian
Philip now lost no time in executing his purposes on Amphipolis; and pressed the city to close, that the people were glad to apply to the Athenians for relief. Accordingly they dispatched two of their most eminent citizens, Herax and Stratoes, to reprent the danger of an alliance between Philip and the Olymolphians, and to protested their sorrow for having so deeply offended the parent state. This representation had such an effect, that though the Athenians were then deeply engaged in the civil war, they would probably have paid some attention to the Amphipolitans, had not Philip taken care to send them a letter with fresh assurances of friendship, acknowledging their right to Amphipolis, and which he hoped shortly to put into their hands in terms of his recent agreement. By these specious pretences the Athenians were persuaded to pay as little regard to the deputies of the Amphipolians as they had already done to those of the Olymolphians; so that the city, unable to defend itself alone against so powerful an army, surrendered at last at discretion of the year 357 B.C.

Philip still proceeded in the same cautious and politic manner in which he had begun. Though the obstinate defence of the Amphipolitans might have furnished a pretext for severity, he contented himself with banishing a few of the popular leaders from whom he had most cause to dread opposition, treating the rest of the inhabitants with all manner of clemency; but took care to add Amphipolis to his own dominions, from which he was determined that it never should be separated, not withholding the promises he had made to the Athenians. Finding that it was not his interest at this time to fall out with the Olymolphians, he cultivated the friendship of that republic with great affiduity; took the cities of Pydna and Potidea, which he readily yielded to the Olymolphians, though they had given him but little assistance in the reduction of these places. Potidea had been garrisoned by the Athenians; and them the artful king bent back without remonstrance, lamenting the necessity of his actions which obliged him, contrary to his inclination, to oppose their republic. Though this was rather too gross, the Athenians at present were so much engaged with the foreign war, that they had not leisure to attend to the affairs of other nations. Philip made the best use of his time, and next projected the conquest of the gold mines of Thrace. That rich and fertile country was now held by one Cotys, a prince of such weak intellectual faculties, that the superflition of the Greeks, into which he was newly initiated, had almost entirely subverted his reason; and he wandered about in quest of the goddess Minerva, with whom he fancied himself in love. The invasion of the Macedonians, however, awaked him from reverie; and Cotys, finding himself destitute of other means of opposition, attempted to fly the progress of the enemy by a letter. To this Philip paid no regard: the Thracians were instantly expelled from their possessions at Crenide, where there were very valuable gold mines. These had formerly been worked by colonies from Thebes and Athens; but the colonists had long since been expelled by the barbarous Thracians, who knew not how to make use of the treasure they were in possession of. Philip took the trouble to defend into the mines himself, in order to inspect the works; and having caused them to be repaired, planted a Macedonian colony at Crenide, bestowed upon it the name of Philippi, and drew annually from the gold mines to the value of near 1000 talents, or 200,000 l. sterling; an immense sum in those days. The coins struck here were likewise called Philippi.

Philip having obtained this valuable acquisition, settled the next took upon him to settle the affairs of Thrace, where every thing was in confusion. This country had been formerly oppressed by Alexander tyrant of Philip: after whose death three others appeared, viz. Tituphorus, Phileolus, and Lycopbron, the brothers-in-law of Alexander, who had likewise murdered him. By the united efforts of the Thessalians and Macedonians, however, these usurpers were easily overthrown, and effectually prevented from making any disturbances for the future; and the Thessalians, out of a mistaken gratitude, surrendered to Philip all the revenues arising from their fairs and tourns of commerce, as well as all the conveniences of their harbours and shipping; a concession which Philip took care to secure in the most effectual manner.

Having now not only established his sovereignty in the most effectual manner, but rendered himself very powerful and formidable to his neighbours, Philip determined to enjoy some repose from his fatigue. Having formed an alliance with Arybbas king of Epirus, Olympia, he, in the year 357 B.C. married Olympia, the sister of that prince; a match thought the more eligible, as the kings of Epirus were supposed to be defended from the encroachments of the Athenians by the friendship of Philip, with great pomp, and several months were spent in shows and diversions during which Philip showed such an extreme propensity to vice of every kind, as disgraced him in the eyes of his neighbours, and most probably laid the foundation of his future domestic unhappiness. So much was this behaviour of the Macedonian monarch taken notice of by the neighbouring states, that the Paeonians and Illyrians threw off the yoke, engaging in their schemes the king of Thrace, and notwithstanding the immense state of that prince, their expeditions were now carried on with more judgment, and was unequal with barbarians. Philip, however, not. gaining success, withdrew his disciplined, got warning of his danger in sufficient time to prevent the bad consequences which might have ensued had the confederates got time to bring their matters to a proper bearing. Early in the spring 356 he took the field with the flower of the Macedonian troops. Having marched in person against the Paeonians and Thracians, he dispatched Parmenio his best general into Illyria. Both entered; but Philip returned victorious from Thrace, he received an account of the victory.
victory gained by Parmenio; a second messenger informed him of a victory gained by his chariot at the Olympic games; and a third, that Olympias had been delivered of a son at Pella. This was the celebrated Alexander, to whom the diviners prophesied the highest prosperity and glory, as being born in such auspicious circumstances.

A short time after the birth of Alexander, Philip wrote a letter to the philosopher Aristo, with whom he chose for preceptor to his young son. The letter was written with great brevity, containing only the following words: "Know that a son is born to us. We thank the gods not for so much for their gift, as for bestowing it at a time when Aristotle lives. We assure ourselves that you will form him a prince worthy of his father, and worthy of Macedon." He next set about the farther enlargement of his territories, which were already very considerable. Paeonia was now one of his provinces; on the east his dominions extended to the sea of Thasos, and on the west to the lake Lymneus. The Thessalians were in effect subject to his jurisdiction, and the possession of Amphipolis had secured him many commercial advantages; he had a numerous and well-disciplined army, with plentiful resources for supporting such an armament, and carrying through the other schemes suggested by his ambition; though his deep and impenetrable policy rendered him more truly formidable than all these put together. His first scheme was the reduction of Olynthus, the most populous and fertile country on the borders of Macedon; after which his ambition prompted him to acquire the sovereignty of all Greece. By this decree all Greece was again involved in the war. It was from gaining any farther advantage than they had already done; saying, as he drew off his men, that they did not retreat through fear, but like rams, in the following extraordinary manner, if we may give the siege of Methone. Philip, having taken part with the Phocians, Lycephon, one of the Thessalian tyrants, whom Philip had formerly deprived of his authority, had again found means to re-establish his authority; and his countrymen having taken Thebes, Philip called in Onomarchus the Phocien general to protect him against the power of Philip, by whom he was sensible that he would soon be attacked. The king accordingly marched into Thessaly with a considerable army, defeated Phyllus the brother of Onomarchus, whom the latter had sent into the country with a detachment of 7000 men. After this he besieged and took the city of Pegase, driving the enemy towards who retreated with the whole army; and Philip, though inferior in numbers, did not decline the engagement. The Phocians at first gave ground, on which the Macedonians pursued, but in good order; but coming near a precipice, on the top of which Onomarchus had posted a detachment of soldiers, the latter rolled down stones and fragments of the rock in such a manner as did dreadful execution, and threw them into the utmost disorder. Philip, however, rallied his troops with great presence of mind, and prevented the Phocians from gaining any farther advantage than they had already done; saying, as he drew off his men, that they did not retreat through fear, but like rams, in order to strike with the greater vigour. Nor was he long before he made good his assertion; for having recruited his army with the greatest expedition, he returned into Thessaly at the head of 20,000 foot and 600 horse, where he was met by Onomarchus. The Macedonians at this time were superior in number to all the rest of the enemies; and Philip moreover took care to re-educate and kindle them; that their quarrel was that of heaven, and that their enemies had been guilty of sacrilege, by profaning the temple of Delphi. That they might be still more encouraged in the cause, he put crowns of laurel on their heads. Thus fired by enthusiasm, and having besides the advantage of numbers, the Phocians were altogether unable to withstand them. They threw away their
MAC [367]

he was still enabled to make a very formidable appearance; and the Phocians took the field with great prospect of success.

Philip now thought it time to throw off the mask Philip entirely, for which the proceeding of the Athenians, gages in particular their league with Olynthus, furnished him the quarter with a plausible pretext; and the revenging fuch horrid sacrilege as had been committed at Delphi seemed to give him a title to march at the head of an army into Greece. The superstitious of the Greeks, however, had not yet blinded them to such a degree, but they could easily perceive that Philip’s piety was a mere pretence, and that his real design was to invade and conquer the whole country. The Athenians no sooner heard of the march of the Macedonian army than they dispatched, with all expedition, a strong guard to secure the pass of Thermopylae; so that Philip was obliged to return greatly chagrined and disappointed. Their next step was to call an assembly to deliberate upon the measures proper to be taken in order to restrain the ambition of the Macedonian monarch; and this assembly is rendered memorable by the first appearance of Demosthenes as an orator against Philip. Athens for some time had been in a very alarming situation. They were deeply involved in the sacred war; their northern possessions were continually insulted and plundered by Philip; while a number of his mercenary partisans drew off the public attention to such a degree, that, instead of taking measures to counteract that ambitious prince, they amused themselves with speculations about the designs of the Perian monarch, who was preparing for war against the Cyprians, Egyptians, and Phocians. I-locrates the celebration orator, and Phocion the statesman, joined the multitude in their present opinion, though not from any mercenary motives, but purely from a sense of the unready conduct of the Athenians; who, they said, could not contend with a prince of the vigour and activity of Philip; and they were exhorsted them by all means to cultivate the friendship of Philip, whom they could not oppose with any probability of success. I-locrates, indeed, greatly wished for an expedition into Asia, and looked upon Philip to be the only general capable of conducting it, though at present the Greeks had no pretence for making war upon the Persians, but that of revenging former injuries; and on this subject he addressed Philip himself, and it is even said, to I-locrates, by the power of his rhetoric, prevailed upon Philip and the Athenians to lay aside their animosities for a short time, and content to undertake this expedition in conjuncture.

If this coalition, however, did really take place, it was of very short duration. The views of Phocion and I-locrates were violently opposed by Demosthenes, who, says the historian, “had been at great pains to cultivate, and in which he is said to have excelled all men that ever existed.”

In his first address to the people, this celebrated orator exhorted them to awake from their indolence, and to assume the direction of their own affairs. They had been too long governed, he said, by the incapacity...
O Macdon. city of a few ambitious men, to the great disadvantage as well as disgrace of the community. In the first place, an orator who had placed himself at the head of a faction of no more than 300 or 400, availed himself and his followers of the carelessness and negligence of the people to rule them at pleasure. From a confederation of their pretense weaknesses and corruption, as well as of the designs and commotions of the neighboring powers, he advised them to abandon all romantic and distant schemes of ambition; and instead of carrying their arms into remote countries, to prepare for repelling the attacks which might be made upon their own dominions. He insisted also upon a better regulation of their finances, a more equal distribution of the public burdens, in proportion to the abilities of those upon whom they were laid, and upon the retrenching many superfluous expenses. Having pointed out in a strong light the vigorous conduct of Philip; and shewn by what means he had attained to such a respectable footing in the world, he next laid down a proper plan for their military operations. He told them, that they were not yet prepared to meet Philip in the field; they must begin with protecting Olynthus and the Chersonesus, for which it would be necessary to raise a body of 2000 light armed troops, with a due proportion of cavalry, which ought to be transported under a proper convoy to the islands of Lemnos, Thasos, and Scatthos, in the neighborhood of Macedonia. In these they would enjoy all kinds of necessaries in abundance, and might avail themselves of every favourable incident, to appear at the first summons of their allies; and either to repel the incursions of the Macedonians, or harass their territories. While this was going on, more vigorous preparations might be made for war at home; and it was proposed, that only the fourth part of the Athenian citizens should enlist, and no more supplies were wanted at present but 90 talents. But notwithstanding the moderation of these proposals, and the urgent necessities of the state, it was impossible to prevail upon the indefatigable and careless Athenians to provide for their own safety. They appear, indeed, at this time, to have been desperately funk in effeminacy and dissipation; which disposition Philip took care to encourage to the utmost of his power. There was an assembly in the city called the Sixty, from their confiding originally of that number, who met expressly for the purposes of extinguishing all care about public affairs, and to intoxicate themselves with every kind of pleasure they had in their power. With this assembly Philip was so well pleased, that he sent them money to support their extravagances; and so effectually did they answer his purposes, that all the eloquence of orators could not counteract the speeches of orators much his inferiors when backed by Macedonian gold.

Philip himself, as we have already hinted, was excessively debauched in his private character, and the most infamous stories are related of him by the ancient writers, particularly by Demosthenes. Theopompus too, an author who flourished in the time of Alexander, and was rewarded and honoured by that monarch, also speaks of him in such terms as we cannot with decency relate; but these accounts coming from the avowed enemies of the king, are scarcely to be credited; and perhaps policy, as well as inclination, might contribute somewhat to this scandalous behaviour, that Macedon, he might thereby recommend himself to the liberties of Athens, and prevent even many of the more thinking part of the people from suspecting his designs. But in whatever excesses he might at times indulge himself, he never lost sight of his main object, the subjugation of the Greek states. On pretense of being in want of money to defray the expense of his buildings, he borrowed money at a very high price throughout the whole country; and this he found an easy matter to do, as the dissipation of the Delphic treasurers had rendered cash very plentiful in Greece. Thus he attached his creditors firmly to his own interest; and on pretense of paying debts, was enabled without molestation to bellow a number of pensions and gratuities upon the Athenian orators, who by their treacherous harangues contributed greatly to the ruin of their country; at least as far as it could be ruined by subjection to a prince who would have obliged them to remain at peace, and apply themselves to useful arts. These he himself encouraged in a very eminent degree. The greatest part of his time was employed at Pella, which city he adorned in the most magnificent manner with temples, theatres, and porticoes. He invited, by liberal rewards, the most ingenious artists in Greece; and as many of these met with very little encouragement in their own country, great numbers flocked to him from all quarters. In the government of his people, also, Philip behaved with the utmost impartiality; listening with condescension to the complaints of the meanest of his subjects; and keeping up a constant correspondence with those whom he thought worthy of his acquaintance; from which, it is not easy to imagine how he could be so guilty of the vices we have already mentioned from some ancient historians.

The fate of Olynthus was now soon determined. This city, which held the balance of power between Athens and Macedon, was taken and plundered, and the inhabitants sold for slaves; but the chief hope of Philip was in putting an end to the Phocian war. For this purpose he attempted neutrality, that he might thereby become the arbiter of Greece. His hopes were well founded; for the Thebans, who were at the head of the league against the Phocians, solicited him on the one side, and the states confederate with the Phocians did the like on the other. He answered neither, yet held both in dependence. In his heart he favoured the Thebans, or rather placed his hopes of favouring his own cause in that state; for he well knew, that the Athenians, Spartans, and other states allied with Phocis, would never allow him to pass his inconstancy, and lead an army into their territories. So much respect, however, did he show to the ambassadors from these states, particularly Ctesiphon and Phrynion, who came from Athens, that they believed him to be in their interest, and reported as much to their masters. The Athenians, who were now dissolved in ease and luxury, received this news with great satisfaction; and named immediately ten plenipotentiaries to go and treat of a full and lasting peace with Philip. Among these plenipotentiaries were Demosthenes and Megacles, the most celebrated orators in Athens. Philip gave directions that these ambassadors should be treated with the utmost civility; naming at the same time, three of his...

Macedon. 

his ministers to confer with them, viz. Antipater, Parmenio, and Eurypylus. Demosthenes being obliged to return to Athens, recommended it to his colleagues not to carry on their negotiations with Philip's deputies; but to proceed with all diligence to court, there to confer with the king himself. The ambassadors, however, were far from following his instructions, that they suffered themselves to be put off for three months by the arts of Philip and his ministers.

In the mean time, the king took from the Athenians such places in Thrace as might best cover his frontiers; giving their plenipotentiaries, in their stead, abundance of fair promises, and the strongest assurances that his good will should be as beneficial to them as ever their colonies had been. At last a peace was concluded; but then the ratification of it was deferred till Philip had poissessed himself of Pherae in Thessaly, and fixed himself at the head of a numerous army: then he ratified the treaty; and dismissed the plenipotentiaries with assurances, that he would be ready at all times to give the Athenians proofs of his friendship on their return to Athens, which this matter came to be debated before the people. Demosthenes plainly told them, that, in his opinion, the promises of Philip ought not to be relied on, because they appeared to be of little significance in themselves; and came from a prince of so much art, and so little fidelity, that they could derive no authority from their maker. Achilles, on the other hand, gave it as his sentiment, that the king of Macedon's assurances ought to give them full satisfaction. He said, that for his part, he was not politician enough to see anything of difficulty or diminution in the king's conduct, that there was great danger in dejecting princes; and that the fairest method of putting men upon deceit was to show that we suspected them of it. The rest of the plenipotentiaries concurred with Achilles; and the people, desirous of quiet and added to pleasure, easily gave credit to all that was said, and decreed that the peace should be kept. All this was the easier brought about, because Phocion, the wrothiest man in the republic, did not oppose Philip; which was owing to his having a just sense of the fate his country was in. He conceived, that the Athenians of those times were nothing like their ancestors; and therefore as he expressed himself on another occasion, he was desirous, since they would not be at the head of Greece themselves, that they would at least be upon good terms with that power which would be so.

Philip, who knew how to use as well as to procure opportunity, while the Athenians were in this good humour, passed Thermopylae, without their knowing whether he would fall on Phocis or Thebes; but he quickly undeceived them, by commanding his soldiers to put on crowns of laurel, declaring them thereby the trophies of Apollo, and himself the lieutenant general of that god. He then entered Phocis with an air of triumph; which so terrifyed the Phocians, whom he had caus'd to be proclaimed sacrilegious persons, that they immediately dismissed all thoughts of defence, and without more ado submitted to his mercy. Then, on the Phocian war, which had so long employed all Greece, was ended without a stroke; and the judgment on the Phocians remitted to the Amphictyons, or grand council of Greece. By their decree the walls of three Phocian cities were demolished, the people were forbidden to inhabit in any but villages, to pay a yearly tribute of 60 talents, and never to make use either of houses or arms till they had repaid to the temple of Apollo the money they had sacrilegiously carried from there. Their arms were taken from them, broken to pieces, and burnt; their double voice in the council was taken from them, and given to the Macedonians. Other orders were made for settling the affairs both of religion and state throughout Greece: all of which were executed by Philip with great exactness and moderation, he paying the most profound respect to the council; and, when he had performed its commands, retiring peaceably with his army back to Macedon, which gained him great reputation.

At Athens alone, the justice and piety of Philip was not understood. The people began to see, though a little too late, that they had been abused and deceived by those who had negociated the late peace. They saw, again, that, through their acceptance of it, the Phocians opposed by were destroyed; that Philip was become master of the Thermopylae, and might enter Greece when he pleased; that, in abandoning their allies, they had abandoned themselves; and that, in all probability, they might soon feel the weight of his power, whom they had so foolishly trusted: they therefore began to take new and hasty measures; they ordered that the women should retire out of the villages into the city, their walls be repaired, and their forts newly strengthened. They seemed inclined to question Philip's election into the council of the Amphictyons, because it had been done without their consent, and even proceeded to an open war. In all likelihood they had carried things to extravagancy, if Demosthenes had not intercepted. He told them, that though he was not for making the peace, he was however for keeping it, and that if he saw no manner of occasion for their entering into so unequal a contest as would needs ensue, if they took up arms, not only against Philip, but against all the states concerning with him in the late transactions. This seems to have cooled the rage of the Athenians: and to have brought them to think of ruining Philip by degrees, as by degrees they had raised him.

The fame of his achievements without the bounds of Macedon having dispossessed the subjects of Philip to hope every thing from his conduct, and the several states of Greece to desire above all things his friendship; that prudent monarch laid hold of this favourable situation to fix his dominion on such a stable foundation, as that a reverse of fortune should not immediately destroy it. To this end, while he carried on his negotiations through Greece, he like-wise kept his army in exercise, by taking several places in Thrace, which terribly incommoded the Athenians. Diocrates, who had the government of the Athenian colonies in these parts, perceiving well what end Philip had in view, did not stay for instructions from home; but having raised with much expedition a considerable body of troops, taking advantage of the king's being absent with his army, entered the adjacent territories of Philip, and wasted them with fire and sword.

The king, who, on account of the operations of the camp...
campaign in the Chersonese, was not at leisure to repel Diopithes by force, nor indeed could divide his army without imminent hazard, chafe, like an able general, rather to abandon his enemies to insults, which might be afterwards revenged, than, by following the dictates of an ill-tempered passion, to hazard the loss of his veteran army, whereon lay all his hopes. He contented himself, therefore, with complaining to the Athenians of Diopithes's conduct, who, in a time of peace, had entered his dominions, and committed such devastations as could scarce have been justified in a time of war. His partisans supported this application with all their eloquence. They told the Athenians, that unless they recalled Diopithes, and brought him with all their force to the aid of Athens, they must either for the friendship of Philip or of any other prince or state; neither could they justly complain, if, prompted by such a precedent, others should break faith with them, and fall without the least notice upon their dominions. Demosthenes defended Diopithes; and undertook to shew that he deserved the praise and not the censure of the Athenians. Those of the other party began then to charge him with crimes of a different nature; they alleged, that he oppressed the subjects and maltreated the allies of Athens. Demosthenes replied, that of these things there were as yet no proofs; that when such should appear, a single gully might be sent to bring over Diopithes to abide their judgment, but that Philip would not come if they sent a fleet; whence he inferred, that they ought to be cautious, and to weigh well the merits of this cause before they took any resolution.

He said, that it was true Philip had not as yet attacked Attica, or pretended to make a descent on their territories in Greece, or to force his way into their ports; when it came to that, he was of opinion they would hardly be able to defend themselves; wherefore he thought such men were to be esteemed as thwarted with crimes of a different nature; they alleged, that he oppressed the subjects and maltreated the allies of Athens. Demosthenes replied, that of these things there were as yet no proofs; that when such should appear, a single gully might be sent to bring over Diopithes to abide their judgment, but that Philip would not come if they sent a fleet; whence he inferred, that they ought to be cautious, and to weigh well the merits of this cause before they took any resolution.

Macedon. of Philip, the continual clamour of the Athenians against him, and his dethroning at pleasure the petty princes of Thrace, made him now regarded in another light. When therefore he led his troops against Perinthus, or Great King, as he was called by the Greeks, sent his letters mandatorily to the governors of the maritime provinces, directing them to supply the place with all things in their power; in consequence of which they filled it with troops, granted subsidies in ready money, and sent besides great convoys of provisions and ammunition. The Byzantines also, supporting their own turn would be next, exerted their utmost endeavours for the preservation of Perinthus: sending their flowers of their youth, with all other necessities for an obstinate defence. The consequence of all this was, that Philip found himself obliged to raise the siege with great loss.

That the reputation of the Macedonian arms might not sink by this disgrace, Philip made war on the Sicilians and Triballians, both of whom he defeated; and then formed a design of invading Attica, though he had no fleet to transport his troops, and knew very well that the Thessalians were not to be depended on if he attempted to march through the Pisa, and that the Thebans would even then be ready to oppose his march. To obviate all these difficulties, he had recourse to Athens itself; where, by means of his partisans, he procured his old friend Aeschines to be sent their deputy to the Amphictyons. This seemed a small matter, and yet was the hinge on which his whole project turned. By that time Aeschines had taken his seat, a question was raised in the council, whether the Locrians of Amphipolis had not been guilty of sacrilege in ploughing the fields of Cyrrhus in the neighbourhood of the temple of Delphi. The assembly being divided in their opinions, Aeschines proposed to take a view; which was accordingly decreed. But when the Amphictyons came in order to see how things stood, the Locrians, either jealous of their property, or spurred thereto by the suggestions of some who saw farther than themselves, fell upon those venerable persons so rudely, that they were compelled to secure themselves by flight. The Amphictyons decreed, that an army should be raised, under the command of one of their own number, to chastise the delinquents; but as this army was to be composed of troops sent from all parts of Greece, the appearance at the rendezvous was so incon siderable, that the Amphictyons sent to command them durst undertake nothing. The whole matter being reported to the council, Aeschines in a long and eloquent harangue, showed how much the welfare and even the safety of Greece depended on the deference paid to their decrees; and after inveighing against the want of public spirit in such as had not been the patrons at the time appointed by the council, he moved that they should elect Philip for their general, and pray him to execute their decree. The deputies from the other states, conceiving that by this expedient their respective confidants would be free from any farther trouble or expense, came into it at once; whereupon a decree was immediately drawn up, purporting that ambassadors should be sent to Philip of Macedon, in the name of Apollo and the Amphictyons, once more to require his assistance, and to notify to him, that the states of Greece had unanimously chosen him their general, with full power to act as he thought fit against such as had opposed the authority of the Amphictyons. Thus of a sudden Philip acquired all that he sought; and having an army readvance of this event, he immediately proceeded to execute the commands of the Amphictyons in appearance, but in reality to accomplish his own designs. For having passed into Greece with his army, instead of attacking the Locrians, he seized immediately upon Euria, a great city of Phoci on the river Cephissus.

The Athenians in the mean time were in the utmost confusion on the news of Philip's march. However by the advice of Demosthenes, they invited the Thebans to join them against the common enemy of Greece. Philip endeavoured as much as possible to prevent this confederacy from taking place; but all his efforts proved ineffectual. The Athenians raised an army, which marched immediately to Eleusis, where they were joined by the Thebans. The confederates made the best appearance that had ever been seen in Greece, and the troops were exceedingly good; but unfortunately the generals were men of no conduct or skill in the military art. An engagement ensued at Cheronea; where Alexander commanded one wing of the Macedonian army, and his father Philip the other. The confederate army was divided according to the different nations of which it consisted; the Athenians having the right and the Boeotians the left. In the beginning of the battle the confederates had the better; whereupon Stratocles an Athenian commander cried out, "Come on brother soldiers, let us drive them back to Macedon," which being overheard by the king, he said very coolly to one of his officers, "These Athenians do not know how to conquer." Upon this he directed the files of the phalanx to be straitened; and drawing his men up very close, retired to a near by hill where, when the Athenians were eager in their pursuit, he rushed down with impetuousity, broke, and routed them with prodigious slaughter. The orator Demosthenes behaved very unbecomingly in this engagement; for he deserted his post, and was one of the first that fled: nay, we are told, that a flake catching hold of his robe, he, not doubting but it was an enemy, cried out, "Alas! spare my life."

This victory determined the fate of Greece; and as it appeared from this time we must reckon Philip supreme lord of all the Grecian states. The first use he made of this power was to convene a general assembly, wherein he was recognised generally, and with full power appointed their leader against the Persians. Having, by virtue of his authority, settled a general peace among them, and appointed the quota that each of the states should furnish for the war, he dismissed them; and returning to Macedon, began to make great preparations for this new expedition. His pretence for making war on the Persians at this time was the assistance given by the Persians to the city of Perinthus, as already mentioned. In the mean time, however, the king, by reason of the dissensions which reigned in his family, was made quite miserable. He quarrelled with his wife Olympias to such a degree, that he divorced her, and married another woman named Cleopatra. This produced a quarrel between him and his son Alexander,
Alexander, Macedon.; which also came to such a height, that Alexander retired into Epirus with his mother. Some time afterwards, however, he was recalled, and a reconciliation took place in appearance; but in the mean time a conspiracy was formed against the king's life, the circumstances and causes of which are very much unknown. Certain it is, however, that it took effect, as the king was exhibiting certain shows in honour of his daughter's marriage, with the king of Epirus. Philip, having given a public audience to the ambassadors of Greece, went next day in state to the theatre. All the seats were early taken up; and the shows began with a splendid procession, wherein the images of the 12 superior deities of Greece were carried, as also the image of Philip, habited in like manner, as if he now made the 13th, at which the people shouted aloud. Then came the king alone, in a white robe, crowned, with his guards at a considerable distance, that the Greeks might see he placed his safety only in his confidence of the loyalty of his subjects. Pausanias, the assassin, however, had fixed himself close by the door of the theatre; and observing that all things fell out as he had foreseen, they took his opportunity when the king drew near him, and plunging his sword in his left side, laid him dead at his feet. He then fled as fast as he was able towards the place where his horses were; and would have escaped, had not the tug of a vine caught his shoe and thrown him down. This gave time to those who pursued him to come up with him; but instead of securing him, in order to extort a discovery of his accomplices, they put an end to his life.

With regard to the character of this monarch, it appears certain, that he was one of the most eminent persons that ever sat on a throne. Had he lived for some time longer, he would in all probability have subdued the Persians, which was in truth less difficult than what he had already done. 'Had that event taken place (says Dr. Gillies), the undertakings of his long and successful reign would have been enabled and illuminated by the splendor of extensive foreign conquest. Philip would have reached the height of such renown as is obtained by the habits of activity, vigilance, and fortune, in the pursuit of unbounded greatness; and in the opinion of posterity, would perhaps have surpassed the glory of all kings and conquerors who either preceded or followed him. Yet, even on this supposition, there is not any man of sense and probity, who, if he allows himself time for serious reflection, would purchase the imagined grandeur and prosperity of the king of Macedon at the price of his artifices and his crimes; and to a philosopher, who considered either the means by which he had obtained his triumphs, or the probable consequences of his dominion over Greece and Asia, the boly ambition of this mighty conqueror would appear but a deceitful scene of splendid misery.

No sooner did the news of Philip's death reach Athens, than, as if all danger had been past, the inhabitants showed the most extravagant signs of joy. Demosthenes and his party put on chaplets of flowers, and behaved as if they had gained a great victory. Phocion reproached them, for this reason; he remembered that "the army which had beaten them at Chaeronea was left behind by one." This reproach, however, had very little effect. The people heard with pleasure all the harsh things which the orators could say of the young Alexander king of Macedon, whom they represented as a giddy wrong-headed boy, ready to grasp all things in his imagination, and able to perform nothing. The affairs of Macedon indeed were in a very distracted state on the accession of Alexander: for all the neighbouring nations had the same notion of the young king with the Athenians; and being irritated by the usurpation of Philip, were well revoluted; and the states of Greece entered into a confederacy against him. The Persians had been contriving to transfer the war into Macedon; but as soon as the news of Philip's death reached them, they behaved as if all danger had been over. At the same time Attalus, one of the Macedonian commanders aspiring to the crown, and fought to draw off the soldiers from their allegiance.

In the counsels held on this occasion, Alexander's best friends advised him rather to make use of diffamation than force, and to cajole those whom they thought he could not subdue. These advices, however, were ill-suited to the temper of his monarch. He thought that vigorous measures only were proper, and therefore immediately led his army into Thessaly. Here he harangued the princes to effectually, that he had thoroughly gained them over to his interests, and was declared by them general of Greece; upon which he returned to Macedon, where he caused Attalus to be felonized and put to death.

In the spring of the next year (325 B.C.) Alexander resolved to subdue the Triballians and Illyrians, who inhabited the countries now called Bulgaria and Selonvania, and had been very formidable enemies to the Macedonian power. In this expedition he discovered, though then but 20 years of age, a surprising degree of military knowledge. Having advanced to the passage of Mount Hames, he found that the barbarians had posted themselves in the most advantageous manner. On the tops of the cliffs, and at the head of every passage, they had placed their carriages and wagons in such a manner as to form a kind of parapet with their shafts inwards, so that when the Macedonians should have half ascended the rock, they might be able to pull these heavy carriages down upon them. They reckoned the more upon this contrivance, because of the close order of the phalanx, which, they imagined, would be terribly expelled by the soldiers wanting room to stir, and thereby avoid the falling waggons. But Alexander, having directed his heavy-armed troops to march, gave orders, that, where the way would permit, they should open to the right and left, and suffer the carriages to go through; but that, in the narrow passes, they should throw themselves on their faces with their shields behind them, that the carts might roll over them. This had the desired effect, and the Macedonians reached the enemy's works without the loss of a man. The dispute was then quickly decided; the barbarians were driven from their posts with great slaughter, and left behind them a considerable booty to the conquerors.

The next exploits of Alexander were against the Goths, the Thracians, and the other nations inhabiting the country on the other side of the Danube. Them he also overcame; showing in all his actions the

the most perfect skill in military affairs, joined with the greatest valour. In the mean time, however, all Greece was in confusion by a report which had been confidently spread abroad, that the king was dead in Illyria. The Thebans, on this news, seized Amyntas and Timolaus, two eminent officers in the Macedonian Gar- rison which held their citadel, and dragged them to the market-place, where they were put to death without either form or proces, or any crime alleged against them. Alexander, however, did not suffer them to remain long in their mistake. He marched with such expedition, that in seven days he reached Pella in Thessaly; and in six days more he entered Boeotia, before the Thebans had any intelligence of his passing the Isthmopyle. Even then they would not believe that the king was alive; but inferred that the Macedonian army was commanded by Antipater, or by one Alexander the son of Aesopus. The rest of the Greeks, however, were not so hard of belief; and therefore sent no assistance to the Thcbans, who were thus obliged to bear the consequences of their own folly and obstinacy. The city was taken by storm, and the inhabitants were for some hours massacred without distinction of age or sex; after which the houses were demolished, all except that of Pindar the fa- mous poet, which was spared out of respect to the mer- it of its owner, and because he had celebrated Alexan- der 1 king of Macedon. The lands, excepting those dedicated to religious use, were flung among the sol- diers, and all the prisoners sold for slaves; by which 440 talents were brought into the king's treasury.

By this severity the rest of the Grecian states were so thoroughly humbled, that they thought no more of making any resistance, and Alexander had nothing further to hinder him from his favourite project of invading Asia. Very little preparation was necessary for the Macedonian monarch, who went out as to an as- ferred conquest, and reckoned upon being supplied only by the spoil of his enemies. Historians are not agreed as to the number of his army: Arrian says, that there were 30,000 foot and 5000 horse, Diodorus Sicu- lus tells us, that there were 23,000 Macedonian foot, 7000 of the confederate states, and 5000 mercenaries. These were under the command of Parmenio. Of the Odri- ans, Triballians, and Illyrians, there were 5000; and of the Agrians, who were armed only with darts, 1000. As for the horae, he tells us there were 18,000 com- mand ed by Philotas, and as many Thebassans under the command of Callas: out of the confederate states of Greece, were 600 commanded by Eurybius; and 900 Thracians and Phocianis, who led the van under Caffander. Plutarch tells us, that, according to a low computation, he had 90,000 foot and 5000 horse; and, according to the largest reckoning, he had 34,000 foot and 4000 horse. As to his fund for the pay- ment of the army, Aristoibius says it was but 70 ta- lent; and Oeniceritius, who was also in this expedition, not only takes away 70 talents, but affirms that the king was 200 in debt. As for provisions, there was just sufficient for a month and no more; and to prevent disturbances, Antipater was left in Macedon with 12,000 foot and 1500 horse.

77 Consequence of his victory.

The army having assembled at Amphiopolis, he marched from thence to the mouth of the river Stry- mon; then crossing mount Pangeus, he took the road to Abdera. Crossing the river Euraus, he proceeded Macedo- through the country of Peris, and in 20 days reached Sehos; thence he came to Eleus, where he sacrificed on the tomb of Poseidnus, because he was the first among the Greeks who at the siege of Troy set foot on the Asiatic shore. He did this, that his landing might be more propitious than that of the hero to whom he sacrificed, who was slain soon after. The greatest part of the army, under the command of Par- menio, embarked at Sehos, on board a fleet of 165 galleys of three benches of oars, besides small craft. Alexander himself sailed from Eleus; and when he was in the middle of the Hellespont, offered a ball to Neptune and the Nereids, pouring forth at the same time a libation from a golden cup. When he drew near the shore, he landed a javelin, which struck in the earth; then in complete armour, he leaped upon the strand; and having erected altars to Jupiter, Minerva, and Hercules, he proceeded to Ilium. Here again he sacrificed to Minerva; and taking down some arms which had hung in the temple of that goddess since the time of the Trojan war, consecrated his own in their stead. He sacrificed also to the ghost of Priam, to avert his wrath on account of the deceit which he himself claimed from Achilles. In the mean time the Persians had assembled a great army in Phrygia; amongst whom was one Memnon, a Median, the chief officer in the service of Darius. Alex- ander, as soon as he had performed all the ceremonies which he judged necessary, marched directly towards the enemy. Memnon gave it as his opinion, that they should burn and destroy all the country round, that they might deprive the Greeks of the means of subsisting, and then transport a part of their army into Macedon. But the Persians, depending on their cavalry, rejected this helitorious advice: and posted themselves along the river Gr cabbage, in order to wait the arrival of Alexander. In the engagement which happened on the banks of that river, the Persians were defeated, and Alexander became master of all the neighboiring country; which he immediately began to take care of, as if it were his country, and as his dominions. The city of Sardis was immediately de- Consequence of his victory. Consequence of his victory. Consequence of his victory. Consequence of his victory. Consequence of his victory. Consequence of his victory. Consequence of his victory.

Almost all the cities between Miletus and Halicarnasus submitted as soon as they heard that the former was taken; but Halicarnasus, where Memnon com- manded with a very numerous garrison, made an obsti- nate defence. Nothing, however, was able to resist
the Macedonian army; Memnon was at last obliged to abandon the place; upon which Alexander took and razed the city of Tralles in Phrygia; received the submission of several princes tributary to the Persians, and having destroyed the Marmarians, a people of Lydia, who had fallen upon the rear of his army, put an end to the campaign; after which he went home all the new married-men, in obedience, it would seem, to a precept of the Mosaic law, and which endeared him more to his soldiers than any other action of his life.

As soon as the season would permit, Alexander quitted the province of Phælius; and having sent part of his army through the mountainous country of Perga, by a short but difficult road, took his route by a certain promontory, where the way is altogether impassable, except when the north winds blow. At the time of the king's march the south wind had held for a long time; but of a sudden it changed, and blew from the north so violently, that, as he and his followers declared, they obtained a safe and easy passage through the mountainous country. By his march was held to be miraculous, and compared to that of the children of Israel through the Red Sea; while, on the other hand, it is the opinion of others, that there was nothing at all extraordinary in it. He continued his march towards Gordium, a city of Phrygia; the enemy having abandoned the strong posts of Telmissus, through which it was necessary for him to march. When he arrived at Gordium, and found himself under a necessity of staying some time there till the several corps of his army could be united, he expressed a strong desire of seeing Gordius's chariot, and the famous knot in the harness, of which such strange stories had been published to the world. The cord in which this knot was tied, was made of the inner rind of the cornel-tree; and no eye could perceive where it had begun or ended. Alexander, when he could find no possible way of untying it, and yet was unwilling to leave it tied up, as it should cause some fears in the breasts of his soldiers, is said by some authors to have cut the cords with his sword, saying, "It matters not how it is undone." But Arifobulus affures us, that the king wrenched a wooden pin out of the beam of the waggon, which, being driven in across the beam, held it up; and so took the yoke from under it. Be this as it will, however, Arrian informs us, that a great tempest of thunder, lightening, and rain, happening the succeeding night, it was held declarative of the true solution of this knot, and that Alexander should become lord of Asia.

The king having left Gordium, marched towards Cilicia; where he was attended with his usual good fortune, the Persians abandoning all the strong posts as he advanced. As soon as he entered the province, he received advice that Arfakes, whom Darius had made governor of Tarfus, was about to abandon it, and that the inhabitants were very apprehensive that he intended to plunder them before he withdrew. To prevent this, the king marched incognito, and arrived just in time to save the city. But his leaving it had the effect of driving the inhabitants from the city, and the excessive fatigue of marching, as some say, or, according to others, by his plunging when very hot into the river Cydnus, which, as it runs through thick shades, has its waters excessively cold, he fell into such a different temper as threatened his immediate dissolution. His army lost their spirits immediately; the generals knew not what to do; and his physicians were so much affrighted, that the terror of his death hindered them from using the necessary methods for preserving his life. Philip the Macedonian alone preferred temper enough to examine the nature of the king's disease; the word symptom of which was a continual whining, and which he took off by means of a potion, and in a short time the king recovered his usual health.

Soon after Alexander's recovery, he received the agreeable news that Ptolemy and Alexander had defeated the Perian generals, and made great conquests on the Hellespont; little after that, he met the Perian army at Issus, commanded by Darius himself. A bloody engagement ensued, in which the Persians were defeated with great slaughter, as related under the article Issus. The consequences of this victory were very advantageous to the Macedonians. Many governors of provinces and pety princes submitted themselves to the conqueror; and the Macedonians were received by a newly-conquered people, as his old hereditary subjects; being neither bothered with soldiers nor oppressed with tribute. Among the number of those places which, within a short space after the battle of Issus, sent deputies to submit to the conqueror, was the city of Tyre. The king, whose name was Azemimus, was absent in the Persian fleet; but his son was among the deputies, and was very favourably received by Alexander. The king probably intended to confer particular honours on the city of Tyre; for he acquainted the inhabitants that he would come and sacrifice to the Tyrian Hercules, the patron of their city, to whom they had erected a most magnificent temple. But these people, like most other trading nations, were too suspicious to think of admitting such an enterprising prince with his troops within their walls. They sent therefore the deputies again to him, to inform him, that they were ready to do whatever he should command them; but, as to his coming and sacrificing in their city, they could not consent to that, but were positively determined not to admit a single Macedonian within their gates. Alexander immediately dismissed their deputies in great displeasure. He then assembled a council of war, wherein he inflicted strongly on the disobedient state of Greece, (for most of the Grecian states had sent ambassadors to Darius, to enter into league with him against the Macedonians), the power of the Persians by sea, and the folly of carrying on the war in distant provinces, while Tyre was left unreduced behind them; he also remarked, that if once the city was subdued, the sovereignty of the sea would be transferred to them, because it would fix their possession of the coast; and as the Persian fleet was composed chiefly of tributary squadrons, those tributaries would fight the battles, not of their late but of their present masters. For these reasons the siege of Tyre was resolved on. The town was not taken, however, without great difficulty; which provoked Alexander to such a degree of revenge, that he treated the inhabitants with the greatest cruelty.

Macedon. an expedition into Syria; and in his way thither proposed to chastise the Jews, who had highly offended him during the siege of Tyre: for when he sent to them to demand provisions for his soldiers, they answered, That they were the subjects of Darius, and bound by an oath not to supply his enemies. The king, however, was pacified by their submissian; and not only pardoned them, but conferred many privileges upon them, as related under the article Jews.

Egypt submits. From Jerusalem, Alexander marched directly to Gaza, the only place in that part of the country which still held out for Darius. This was a very large and strong city, situated on an high hill, about five miles from the sea shore. One Battis, or Betis, an encun, had the government of the place; and had made every preparation necessary for sustaining a long and obstinate siege. The governor defended the place with great valor, and several times repulsed his enemies: but at last it was taken by storm, and all the garrison slain to a man: and this secured to Alexander an entrance into Egypt, which having before been very impatient of the Persian yoke, admitted the Macedonians peaceably.

Alexander visits the temple of Jupiter Ammon. Here the king laid the foundations of the city of Alexandria, which in many years after continued to be the capital of the country. While he remained here, he also formed the extraordinary design of visiting the temple of Jupiter Ammon. As to the motives by which he was induced to take this extraordinary journey, authors are not agreed; but certain it is, that he hazardad himself and his troops in the highest degree, there being two dangers in this march, which, with the example of Cambyses, who loft the greatest part of his army in it, might have terrified any body but Alexander. The first was the want of water, which, in the sandy deserts surrounding the temple, is no where to be found; the other, the uncertainty of the road from the fluctuation of the sands; which changing their situation every moment, leave the traveller neither a road to walk in nor mark to march by. These difficulties, however, Alexander got over, though not without a miraculous interposition, as is pretended by all his historians.

Alexander having consulted the oracle, and received a favourable answer, returned to pursue his conquests. Having settled the government of Egypt, he appointed the general rendezvous of his forces at Tyre. Here he met with ambassadors from Athens, requesting him to pardon such of their countrymen as he found serving the enemy. The king, being devious to oblige such a famous state, granted their request; and sent also a fleet to the coast of Greece, to prevent the effects of some commotions which had lately happened in Pelo-

ponnesus. He then directed his march to Thapsacus; and having passed the Euphrates and Tigris met with Darius near Arbela, where the Persians were again overthrown with prodigious slaughter, and Alexander in effect became master of the Persian empire.

After this important victory, Alexander marched directly to Babylon, which was immediately delivered up; the inhabitants being greatly disaffected to the Persian interest. After 30 days stay in this country, the king marched to Susa, which had already surrendered to Philoxenus; and here he received the treasures of the Persian monarch, amounting, according to the most generally received account, to 50,000 talents. Having received also at this time a supply of 6000 foot and 500 horse from Macedon, he set about reducing the nations of Media, among whom Darius was retired. He first reduced the Oaxians: and having forced a passage to Persepolis the capital of the empire, he like a barbarian destroyed the fateful palace there, a pile of building not to be equalled in any part of the world; after having given up the city to be plundered by his followers. In the palace he found 120,000 talents, which he appropriated to his own use, and caused to be carried away upon mules and camels; for he had such an extreme aversion to the inhabitants of Persepolis, that he determined to leave nothing valuable in the city.
