ENCYCLOPÆDIA;
OR, A
DICTIONARY
OF
ARTS, SCIENCES,
AND
MISCELLANEOUS LITERATURE;
Constructed on a Plan,
BY WHICH
THE DIFFERENT SCIENCES AND ARTS.
Are digested into the Form of distinct
TREATISES OR SYSTEMS,
COMPREHENDING
THE HISTORY, THEORY, and PRACTICE, of each,
According to the Latest Discoveries and Improvements;
AND FULL EXPLANATIONS GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,
WHETHER RELATING TO
NATURAL and Artificial Objects, or to Matters Ecclesiastical,
Civil, Military, Commercial, &c.
Including ELUCIDATIONS of the most important Topics relative to RELIGION, MORALS, MANNERS,
and the Oeconomy of Life.
TOGETHER WITH
A Description of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.
throughout the World;
A General History, Ancient and Modern, of the different Empires, Kingdoms, and States;
And
An Account of the Lives of the most Eminent Persons in every Nation,
from the earliest ages down to the present times.

Compiled from the writings of the best authors in several languages; the most approved Dictionaries, as well of general science as of its particular branches; the Transactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. XI. MED—MID

INDICI DISCANT, ET AMEN MEMINISE PERITI.

PHILADELPHIA:
PRINTED BY THOMAS DOBSON, AT THE STONE-HOUSE, NO 41, SOUTH SECOND-STREET.
M. DCC. XCIII.

[Copy-Right secured according to law.]
MEDALS.

MEDAL, denotes a piece of metal in the form of coin, such as was either current money among the ancients, or struck on any particular occasion, in order to preserve to posterity the portrait of some great person, or the memory of some illustrious action. Scaliger derives the word medal from the Arabic metalla; a sort of coin with a human head upon it. But the opinion of Vossius is generally received; viz. that it comes from metalla, "metal," of which subsistance medals are commonly made.

SECT. I. Utility of Medals in History, and various other Sciences.

There are few studies of more importance to history than that of medals: the sole evidence we can have of the veracity of an historian being only such collateral documents as are evident to every body, and cannot be falsified. In modern times, these are found in public memoirs, instructions to ambassadors, and plate papers of various kinds. Such memorials, however, are subject to various accidents, and besides commonly remain in the countries where they are first published, and cannot therefore give to the world at large that perfect and entire satisfaction which ought to be derived from genuine history; so that more durable and widely diffused monuments are still to be wished for. Such are public buildings, institutions, and statutes; but these, excepting a few instances of the two last, are always confined to particular countries: so that medals alone remain as infallible documents of truth, capable of being diffused over all countries in the world, and of remaining through the latest ages.

The first who showed the importance of medals in ascertaining the dates of events, in ancient history by means of medals, was Vaillant, in his History of the Kings of Syria, printed at Paris in 1681. By medals alone, he has been enabled to fix the chronology and important events of history, in the three most ancient kingdoms of the world, viz. Egypt, Syria, and Persia. Many coins have been discovered since his time, which confirm the accounts he has given. He was followed in this method by Father Hardouin, though with less success. Hardouin's best work is his Hierothesia, or Series of Successors to Herof king of Judaea. The same plan was pursued by Noris, in his learned Treatise on the Syro-Macedonian princes, and by Bayer in his History of Othoene, as well as by Frolich, in a work entitled Anales Regum et Rerum Syria, Vien. 1754, and another named Kevenhullers Regum veterum &c., Numismata Anecdotata auctore Perrara, Vien. 1752, 4to, of which Frolich was properly the author. Corbin and Cary likewise published works of a similar nature; the former in 1744, De Minisari, a torumque Armeia Regum, Nummis, &c.; the latter 1753, Histoires des Rois de Thessalie, et du Bosphore Commelin, eclaircie par les Medailles.

The study of the Greek coins does not show the dates of events, though it illustrates the chronology Greece of reigns. This defect, however, is abundantly supplied by those of Rome, which commonly mark the dates of the prince's consulship, the year of his tribunician power; giving also upon the reverse, the representation or poetical symbol of some grand event. The year of the tribunician power is sometimes imagined by antiquaries to be synonymous with that of the emperor's reign: but this is not the case; and Mr. Pinkerton is at some pains to set them right in this respect. He finds fault with Julius Caesar, when he assumed the sovereign authority, for taking upon himself the title of Perpetual Dictator, as being synonymous with that of king or absolute governor, which the Romans abhorred. "He ought," says our author, "under the disguise of some supreme magistrate of annual election, to have lured the people with a dream, that they might terminate his power when they pleased; or that he himself would resign it, when the necessities of state which had required his temporary elevation had subsided." To this error Mr. Pinkerton ascribes the abuse of the power, and commends the policy of Augustus, who, with fair inferior abilities, continued in possession of the most absolute authority as long as he lived. The tribune ship was an office of his annual election; and if put into the hands of any others than plebeians, must have been the supreme power of the state, as it belonged to that office to put a negative upon every public measure whatever. Augustus, being of senatorial rank, could not abuse this office; but he invested himself with the tribunician power, which had the advantage of appearing to be only a temporary supremacy, though in truth it was continued during his whole lifetime. Towards the end of his reign, he frequently assumed his defined succession, Tiberius, for his colleague, though in the beginning he had enjoyed it alone. This, with his artifice of resigning his power every ten years, and

Method used by Augustus to secure his power.

Various writers on medals.

Vol. X.
re-assuming it at the desire, as was pretended, of the Senate; secured his sovereignty as long as he lived.—His example was followed by his successors; so that most of them have the inscription Tribunicia Potestate upon their medals, with the date affixed to it thus. Tr. Ps. VII. Yet though this date generally implies the year of the emperor's reign, it sometimes happens that the emperor, by special favour from a former prince, had been endowed with this title before he came to the throne, as being the successor to that prince, of which we have already given an instance in Tiberius. Besides the tribunician power, the emperors very frequently enjoyed that of the consuls; and the date of their consulship is frequently re-affumed in their coins.

The office of Pontifex Maximus was likewise assumed by the Roman emperors in order to secure themselves in their authority; which, Mr Pinkerton observes, was one of the most efficacious arts by which they could have fallen upon. In the Greek heroic times (says he), king and priest were carefully united in one person; and when sovereigns arose in Denmark and Sweden, the same plan was followed, as appears from Snorro, and other writers. Nothing could lend more security to the person of the monarch than an office of supreme sanctity, which also confirmed his power by all the terrors of superstition. Even the Roman Catholic clergy, according to Mr Addison, are chiefly impressed with the idea of their ruins being now existing; so that the uses of them to the architect are very considerable. To the connoisseur they are absolutely necessary; because in the fine arts, by them alone he is enabled to ascribe ancient buildings and statues to their proper persons, with multitudes of other points of knowledge which cannot be otherwise determined. The elucidations of obscure passages in ancient authors by means of medals, are so numerous and well known, that it is needless to insist upon them.

Mr Addison has treated the connexion between medals and poetry at considerable length; but Mr Pinkerton finds fault with him for preferring the Latin to the Greek poets. He observes also, that the knowledge of Greek medals is most necessary for a sculptor, and perhaps an architect; but an acquaintance with Latin ones is preferable for a poet, or perhaps a painter. The reason of this difference is, that the former generally have on the obverse the head of some god, god of gods, or goddess, of exquisite relief and workmanship; but the reverse seldom affords much fancy of symbol in the early Greek coins; and in the imperial Greek coins, is chiefly impressed with the temples of their deities. To a person of poetical imagination, however, the Roman coins afford the greatest entertainment, from the fine personifications and symbols to be found on their reverses; of which our author gives the following instances.

"Capitolinus (says he), in his life of Maximinus the Minor, is quite puzzled to know if Maximinus and Pulienus were two emperors, or two names for the same. Had he happened on any of those coins which bear M. CL. PULIENUS MAXIMUS AUG. he would have seen at once that Maximus was only another name for Pulienus."

Medals are useful in other sciences besides history. Use of medals in geography. In geography, we find the situation of towns determined by their vicinity to some noted river, mountain, &c. Thus, MAINITAN XIPHIA shows that Magnesia was situated near Mount Sipylos. In like manner, it is shown from a medal, that Ephesus stood on the river Cayster; and there is extant a medal, bearing an inscription, which signifies Alexandria on the Scamander; a name given to Troy by Alexander the Great. The reverse has upon it the famous Apollo Smintheus of Homer. In natural history, also, medals are useful chiefly from the coins struck on the celebration of the secular games, in which the figures of various animals are preferred; and thus it may very often be determined whether any animal be known to the ancients or not. On many of the Greek medals are several uncommon plants and animals. Thus, on most of the medals of Cyrene is the figure of the celebrated Sphinx; and on those of Tyre, the shell-fish from which the famous Tyrian purple was procured. By means of medals, also, the exact delineations of ancient noble edifices are preferred, though not even a tincture of vestige of their ruins be now existing; so that the uses of them to the architect are very considerable. To the connoisseur they are absolutely necessary; because in the fine arts they enable him to ascribe ancient buildings and statues to their proper persons, with multitudes of other points of knowledge which cannot be otherwise determined. The elucidations of obscure passages in ancient authors by means of medals, are so numerous and well known, that it is needless to insist upon them.

To a person of poetical imagination, however, the Roman coins afford the greatest entertainment, from the fine personifications and symbols to be found on their reverses; of which our author gives the following instances.

"Happiness has sometimes the caduceus, or wand of Mercury, which Cicero, 1. Offic. tells us was thought of by the Romans to procure every wish. She has in a gold coin of Severus heads of poppy, to express that our prime bles are in oblivion of misfortune."

"Hope is represented as a sprightly girl, walking quickly, and looking straight forward. With her left hand..."
M E D A L S.

SeCT. II.

Utility of them in History, &c.

Medals are useful as emblems of Patience and not of Hope. This perfonification, with some others, must have been very familiar to the ancients; for often in this and in a few more instances, no name, as Sals Aug., or the like, is inferred in the legend.

"Abundance is imagined as a fadate matron, with a cornucopia in her hands, of which she fatter the fruits, and does not hold up her cornucopia however, mean to supply, or the Annona, is finely represented as a fadate lady, with a fiifed cornucopia. In her left hand, which she holds upright, to indicate that the does not, however, mean to fatter it, as Abundance has a title to do, but to give it to Equity to deal out. This laft particular is known by her holding a little image of Equity, known by her features and bofa pura, or pointless spear, in her right hand, over a fallet filled with wheat. Behind the Annona is the prow of a ship decked with flowers, to imply that the corn was brought by tea (from Africa), and that the fhips had had a prosperous voyage. The beef poet in the world would not have given us a finer train of imagery; the beef painter would have been puzzled to express so much matter in so fmall a compaff.

"Security finds leaning upon a pillar, indicative of her being free from all designs and purfuits; and the polifhed cornucopia in her left hand, held upright, to indicate that she does not, however, mean to fatter it, as Abundance has a title to do, but to give it to Equity to deal out. This laft particular is known by her holding a little image of Equity, known by her features and bofa pura, or pointless spear, in her right hand, over a fallet filled with wheat. Behind the Annona is the prow of a ship decked with flowers, to imply that the corn was brought by tea (from Africa), and that the fhips had had a prosperous voyage. The beef poet in the world would not have given us a finer train of imagery; the beef painter would have been puzzled to express so much matter in so fmall a compaff.

"The emperor Titus, having caufe to import a great supply of corn during a fcarcity at Rome, that supply, or the Annona, is finely represented as a fadate lady, with a fiifed cornucopia. In her left hand, which she holds upright, to indicate that the does not, however, mean to fatter it, as Abundance has a title to do, but to give it to Equity to deal out. This laft particular is known by her holding a little image of Equity, known by her features and bofa pura, or pointless spear, in her right hand, over a fallet filled with wheat. Entertainment arising from the study of Medals.

Besides the purposes which the study of medals answers in the useful arts, a great variety of sources of entertainment are to be found in it. Mr Pinkerton observes, that the most barbarous nations are more pleased with the rudest efforts of art, than with the most admirable works of nature; and that in proportion as the powers of the mind are large and various, such are also the pleasures which it receives from those superlative productions of art, which can only be the offspring of vast genius. Hence works of art are agreeable both to the enlightened and to the ignorant.

The chief amusement, therefore, which attends the kind of personal acquaintance with the persons of whom played in the execution of them. It besides gives a fondness to such an object either in art or nature which is not represented upon some of them: and to the satisfaction arising from a view of these, we may likewise add that of beholding, in a lively manner, the history of manners; which, though very particular, may afford the little intercourse at that time carried on betwixt the different provinces also, greatly impeded any communication of knowledge to those who wrote histories; so that it is no wonder to find any small collections that might then have existed altogether unnoticed by them.

Almost as soon as any communication was opened between the Greeks and Romans, the latter treated the arts of the Greeks with all due respect and applause. Their coins were imitated by the Romans, and preferred in cabinets by the senators among their choicest treasures. Suetonius informs us, that on solemn occasions Augustus was accustomed to present his friends with medals of foreign states and princes, along with other valuable testimonies of his friendship. In a more advanced period of the Roman empire, however, individuals would undoubtedly form collections of coins peculiar to their own state; for Dr Stukely, in his Medallic History of Carausius, informs us, that a complete series of silver coins was lately found in Britain, containing all the emperors down to Carausius inclusively. From Banduri we also know, that certain Greek coins were specially preferred by the Romans; and it appears from their code, that ancient gold and silver coins were made use of instead of gems; to which distinction those of Sicily were particularly intituled. From the decline of the Roman empire till towards the end of the 5th centu-
History, almost all branches of literature were involved in darkness, and the medallic science among the rest. While the Christian dominion of Constantinople failed, indeed, almost all the arts and sciences may be said to have been kept within its own boundaries; though the Arabs and eastern nations had some arts and sciences of their own; but after the destruction of the imperial city by the Turks, the Greeks were once more compelled to become fathers to the European Science. Even before this time, indeed, some vestiges of a revival of the arts of Italy were observable. About the beginning of the 16th century, Hubertus Goltzius, a printer and engraver, travelled over most countries in Europe, searching for coins and medals, in order to publish books concerning them. From one of these works it appears, that there were then in the low countries 200 cabinets of medals; 175 in Germany, upwards of 300 in Italy, and 200 in France. It is probable, however, that there are now four times as many as in these countries, besides 500 in Britain; but we are not to imagine that all these were grand collections, for there are not above a dozen even in Italy; most of those just mentioned were of the class named collections of medals, containing from 100 to 1000 or 2000.

There are few countries, Italy excepted, in which a greater number of coins have been found than in Britain; though we are by no means well acquainted with the time when the study of them commenced. Mr Pinkerton supposes that Cambden was one of the first, if not the very first, British author who produced medals in his works, and who must have had a small collection. Speed's Chronicle, published in the 17th century, was illustrated with coins from Sir Robert Cotton's cabinet. Goulston's collection was purchased by Henry prince of Wales, brother to Charles I, to whom it left at his death. According to Joseph Scaliger, it consisted of 30,000 coins and medals. A collection 3500 coins was purchased by Archbishop Laud for £500, and given to the Bodleian library. Thomas earl of Arundel, earl-marshall of England, well known from the Arundelian table and other antiquities which he imported from Greece and Italy into Britain, had a rich cabinet of medals collected by Daniel Nillam. The dukes of Buckingham and Hamilton, Sir William Pagton, Sir Thomas Fantham of Wark, Sir Thomas Hammer, Ralph Sheldon, Esq; Mr Selden, &c. are enumerated by Evelyn as collectors of medals. Sir Robert Cotton, as well as his historian the earl of Clarendon, were also collectors. The king had a very fine cabinet; which, however, were dissolved and lost during the civil commotions. Oliver Cromwell had a small collection; and the cabinet of Charles II. is mentioned by Vaillant in the preface to his treatise intitled "Numism in Collect," &c. This branch of magnificence has not been much attended to by succeeding British monarchs; though his present majesty has a very good collection of ancient gold coins.

A great number of fine cabinets have been formed in Britain since the time of Evelyn. About the year 1750 Haym makes mention of those of the duke of Devonshire, the earls of Pembroke and Warwick, 

16. The first among the moderns who began to study the medallic science was Petrarch. Being directed by the Emperor Charles IV. to compose a book containing the lives of eminent men, and to place him in the list, he replied, that he would do so whenever the emperor's life and conduct deserved it. In consequence of this conversation he afterwards sent the emperor a collection of gold and silver coins bearing the representations of eminent men, with an address suitable to his former declaration. A collection of coins was made in the next age by Alphonso king of Aragon; but though this monarch collected all that could be found throughout Italy, we know that there could not have been very many, as the whole were contained in an ivory cabinet, and carried always with him. A very considerable collection was made by Anthony Cardinal St Mark, nephew to Eugene IV. who ascended the pontifical chair in 1431; and soon after the grand museum at Florence was begun by Colimo de Medici, where a collection of ancient coins and medals had a place among other curiosities. Corvinus king of Hungary about the same time formed a noble collection of coins along with ancient manuscripts and other valuable relics of antiquity.

Mr Pinkerton considers Agnolo Polizziano, more commonly known by the name of Angelus Polizzianus as the first writer who added medals as vouchers of ancient orthography and customs. He cites different coins of the Medicean collection in his Medallae written about the year 1499. By means of a cabinet of medals collected by Maximilian I. emperor of Germany, Johannes Henschenius was enabled to publish a book of the lives of the emperors, enriched with their portraits, delineated from ancient coins. It is generally supposed that this book, which appeared in 1525, was the first work of the kind; but Labbe, in his Difficile de Numismatia, mentions another named Iudiciarum Imagines, by one Andreas Fulsius, printed in 1517, in which most of the portraits seem to be from medals. About the year 1512 also, Guillaume Duode, a French author, had written his treatise De Ajf, though it was not printed till many years afterwards. M. Grollier, treasurer of the French armies in Italy, during part of the 16th century, had a great collection of coins of different kinds of metals. After his death, his brass medals were sent to Provence, and were about to be sent into Italy; when the king of France, having got information of the transaction, gave orders to stop them, and purchase the whole at a very high price for his own cabinet of antiquities. M. Grollier had an al
MEDALS

Medals are formed of gold, silver, and the various modifications of copper. The gold usually made use in coinage is about the fineness of 22 carats; and as the art of purifying this metal was very much unknown in former times, the most ancient medals are for this reason much more impure than the modern coins. Gold is never found in its native state above 22 carats fine; and the very ancient medals are much under that standard. Many of them are composed of a mixture of gold and silver, called by the ancients elec trum. The gold medals were made of much finer metal after Philip of Macedon became possessed of the gold mines of Philippi in Thrace, and the medals of his son Alexander the Great are equally fine; as well as those of some other princes of that age. Those of the Egyptian Ptolemies are of the fineness of 23 carats three grains, with only one grain of alloy. The Roman coins are very pure even from the earliest times; the art of refining gold being well known before any was coined at Rome. Some authors are of opinion, that the Roman coins begin to take place till the time of the Emperor Severus; and even then only in a very few instances. Most of the Roman gold was brought from Dalmatia and Dacia, where that metal is still to be met with. A very remarkable circumstance is observed in the eastern part of Hungary, which belonged to the ancient Dacia: It germinates in the vines of Tokay, and is found in their stems; as it is elsewhere in the straw of corn.

Metal called elec trum. Pliny informs us, and indeed it is generally known, that gold and silver are found mixed together in the earth. When the silver amounted to one-fifth part of the gold, the metal was called elec trum; but sometimes the quantity of silver was added artificially. The gold was in those days as well as at present refined by means of mercury; and the ancient artists had certainly attained to great perfection in this branch of metallurgy; as Bodin tells us, that the goldsmiths of Paris upon melting one of Vespasian's gold coins found only 777 part of alloy.

Most of the ancient silver, particularly that of Greece, is less pure than that of succeeding times; even the Roman silver is rather inferior to the present standard, and that from the very beginning; but in the time of Severus, the silver appears very bad, and continues so until the time of Diocletian. Many writers upon this subject have mistaken the denarius argenteus, "coins of brass washed with silver," for silver currency. Silver coins are extremely scarce from the time of Claudius Gothicus to that of Diocletian, or from the year 270 to 284; in which short space no fewer than eight emperors reigned. Silver at that time was found mostly in Spain and the commerce with that country was disturbed by the usurpers who arose in Gaul: and such were the troubles of the times, that not only the silver, but also the gold coins of those eight emperors, are extremely scarce. There is still, however, some silver extant of these eight emperors; and it is certain, that copper was never used as silver currency, but was entirely a distinct coinage. Occasional deprivations of silver had taken place long before; as Pliny tells us, that Mark Anthony mixed iron with his silver denarius; and Mr Pinkerton informs us, that he had seen a denarius of Anthony, which was attracted by a magnet.

The ancient brass coins consist of two kinds: the Ancient red or Cyprian, which indeed is no other than copper; brass, and the common yellow brasses. Our author observes, that in the Roman coinage brasses was of double the value of copper, and he is of opinion, that it was the same among the Greeks; and the latter is the metal most commonly made use of in the Greek coinage. The Roman sesteri were always of brass: the middling-sized kind are partly copper and partly brass; the former being double the value of the latter, which are of the aed.

Mr Pinkerton next proceeds to give an account of the mixed metals used among the Romans. In Britain, all kinds of coins made of mixed metal are without hesitation alleged to be forgeries; although it is certain that the variety of mixed metals used in coinage was very considerable. The most valuable mixture was that of gold or silver already mentioned, named elec trum; the silver commonly amounting to one-fifth part of the gold made use of, or perhaps more. Of this mixture are many of the early coins of Lydia, and some other Asiatic states; also those of the kings of the Bosphorus Cimmerius, during the imperial ages of Rome. Next to the elec trum were the coins of Corinthian brasses; but Mr Pinkerton informs us, that these brasses, not a single coin was ever struck of this metal by the ancients; it having been constantly employed only in the fabrication of vases or toys. It was in use at any rate only for a very short time; being altogether unknown in the days of Pliny the Elder. Our author therefore ridicules those who pretend not only to find out imperial coins of this metal, but to discover three kinds of it: one, in which the gold predominates, another in which the silver prevails, and a third where the brass is most conspicuous. He gives Aeneas Vico, one of the most ancient writers on medals, as the author of this idea; but whole opinions were confuted by one Savot, a writer in the 17th century. Vico mentions a coin of this kind struck under Augustus, another of Livia, and a third of Claudius. The mistake, he is of opinion, arose from the circumstance of the first propagator not being able to account for the various

various mixtures and modifications of brass observable in ancient coins of the large size; and which in so common a metal appear very odd to the moderns.

Besides the authority of Pliny and other antiquaries of more modern date, who all declare that they never saw a single medal of Corinthian brass, or of that metal mixed with silver and gold, our author adds another evidence which he looks upon to be superior to either; viz., that those who have given into this supposition, imagine, that the large pieces called sifertius, and others called dupondiiarius, worth about twopence or a penny, are said to have been composed of this precious metal. It is unreasonable to think, that any proportion of gold or silver could have been made use of in these. The coins said to have been struck upon Corinthian brass are only done upon a modification of common brass; of which we know, that in proportion to the quantity of zinc made use of in conjunction with the copper, the metal assumes a variety of hues. On the authority of Pliny he informs us, that the coins mistaken for Corinthian brass were no other than prince's pot-metal; and after the time of Gallienus and Severus the emperor, the case was different; and the ignorance of medals is increased by some authors. The latter professes his love of medals, but quotes a curious coin with the head of Cicero; and looks upon one of the 30 pieces of silver, the reward of the treachery of Judas, and which was said to be preferred among some relics at Paris, to be worthy of reference and commemoration. Arbuthnot, if we may judge from his book, had never seen any ancient coins; and Cancer, it is well known, was quite ignorant of them. The latter, with all his labours, seems to have known nothing of the theoretic part of the real ancient money. Indeed Dr Mead's catalogue seems to have been almost the only book on medals which had undergone his perusal. On the other hand, the ignorance of medallists on this score is no less profound. To this day they look upon the drachmae of Ægina, so celebrated in antiquity, as drachmae of Ægium; and upon the early obolus as a brass coin. In the Roman clas the large brass is esteemed the æs, while it shall be proved that it is the sifertius, and worth four aedii. The denarius is reckoned at ten aedii even in the imperial times; whereas it only went at that rate for the first 50 years after the coinage of silver at Rome. The denarius æsæ is taken for silver currency; with other mistakes which evince that medallists are as ignorant of the theory as the authors are of the practice."

In his account of the ancient Greek money, Mr Money finds, that the light of science, like that of the sun, has proceeded from east to west. "It is most probable (says he), that the first invention of money arose like the other arts and sciences; and spread from thence into the western parts of the world. In its first shape it appeared as mere pieces of metal in some without any flattened form or impression; in lieu of rude state, which, it was regulated by weight. Even down to the Saxon government in England, large sums were regulated by weight; and in our own times every sidge piece is weighed in gold; though with regard to silver this nicety is not minded, nor indeed does it seem practicable. Among the ancients, whose commercial transactions were large and important and extensive to those of the moderns, silver was weighed as well as gold; and even brass, in some cases. In Greece, large sums were determined by mnae or Greek money; and the most capital sums by talents. In every one, the country the mna is supposed to have contained 100 drachmae or small silver coins, of that country, and the talent 60 mnae. The mna is supposed to be a pound weight of the country to which it belonged. The Attic pound, according to Dr Arbuthnot contained..."

Ancient Money.

Ancient opinions.

The former could adopt a coinage, and it is the Drachm.

The mina of Athens is at first 75 drachms; but by order is fixed at 100. The ancient drachm weighed the same which it does at present in medical weight, viz. the eight part of an ounce. The mina or pound of 12 ounces had consequently 96 of these drachms; but four of them were given to the round sum to supply defects in the alloy; and indeed (says our author), in consequence of a common practice in all ages and all countries, of giving some addition to a large weight. Thus the pound in weight had but 96 drachms in fact, while the pound in tale had 100; as the Roman libra in weight had but 84 denarii; in tale 100; and as our pound in tale, by an inverter progress, is not a third of our pound in common weight.

Notwithstanding the very severe criticism on Dr Arbuthnot just mentioned, however, we find our author adopting his account of the drachm. Hence it is.

Of the ancient talents.

The Syrian talent had 55 Attic mina.

Ptolemaic - 20
Antiochian - 60
Babylonian - 60
Egyptian - 80
Rhodian - 100

Notwithstanding the concession made here by Mr Pinkerton to the Doctor, he tells us, that he very much questions this lift of talents, and that many ancient writers are little to be relied upon. Writers on this subject contend, that the numbers in all ancient manuscripts are the parts most subject to error, as being almost always contracted. They ought to allow that the authors themselves must often be liable to wrong information.

Herodotus mentions, that King Darius ordered gold to be paid into his treasury by the Euboic talent, and silver by the Babylonian. The Euboic is reckoned the same with that called afterwards the Attic: and as we estimate gold by carats, so it is natural to suppose, that the most precious metal would be regulated by the most minute weight. But I confess, I take the Babylonian talent to be the same with that of Eginia. Mr Raper has proved the first coins of Macedonia to be upon the standard of Eginia. Now the early Persian coins are upon that very scale, the largest tetradrachms weighing from 430 to 440 grains. Hence it follows, that the Persian silver coins were of the Eginian standard, and the payment was certainly to be made according to the standard of the money. The larger Attic talent was of 80 letter mina; because the larger Attic mina was of 16 ounces. The Alexandrian talent, according to Ptolemy, consisted of 12,000 denarii, being the same with that used by the Egyptian kings in their coins; and is shown by Mr Raper to have been the same with the talent of Eginia. Perhaps the whole of the ancient coinage of Asia, Africa, Greece, Magna Grecia, and Sicily, are reducible to three talents or standards.

1. That of Eginia, used in most of the ancient silver coinages; as would seem in even the latest Egypt, Carthage, Cyrene, &c.

2. The Attic (being the Attic gold standard, afterwards used by Phidias king of Argos in estimating gold, and called Euboic from Euboia), was used in Athens and the greater part of the world as the standard both of gold and silver.

3. The Doric or Sicilian talent of 24 minimi, each worth an obolus and an half; whence the talent is estimated at six Attic drachms or three dirhams. These weights continued to be the standard of money after it began to be distinguished by impressions; nay, to the fall of Greece and prevalence of the Roman empire.

Coinage, according to Herodotus, was first invented by the Lydians, from whom the Greeks quickly received it. The former could not have received it from the Persians, whose empire did not begin till 570 B.C. though our author supposes that it might have proceeded from the Syrians, who carried on commerce in very ancient times. The most ancient Greek coins of gold and silver have an indented mark upon one side, and a torse upon the other; and those of greatest antiquity have no letters upon them. Those of later date have the letters marked upon them, which medallists interpret of Attilia in Achaia; being led into that supposition by the tortoise, which they look upon as the sure mark of the Peloponnesus. But though our author agrees that the tortoise was so, he thinks that they are otherwise very far wrong in their conclusions. Aegium in Achaia was a place of no consequence till the times of Aratus and the Achaean league; but there are 11 of these coins in Dr Hunter's cabinet, which show that they must have been struck in times of the most remote antiquity, and that the place where they were struck was rich and flourishing at the time. The coins which we speak of are not uncommon; but those which have the name AEGIUM at full length, and which make perhaps belong to Aegium in Achaia, are extremely scarce; infomuch that in all Dr. Hunter's vast collection there are not above one or two. They are likewise constructed upon a scale quite different from all other Greek money; being of 8, 13, 15½, 90, and about 186 grains: The Greek drachma at an average is 66 grains; Mr Pinkerton thinks it would have been of the same, if pieces had been struck of eight-tenths of an obolus, of an obolus and an half, or of a drachma and an half. Aegium being originally an obscure village, could not be the first which coined money; so that Mr Pinkerton supposes the name AEGIUM to have fixed for Aegius, the ancient name of Sicily, a wealthy and powerful city; or rather Aegium, the mint of which was much celebrated, and perhaps the most ancient in Greece.

Other arguments in favour of these coins being derived from Aegium, are drawn from their weight as well as their workmanship, which are quite different from those bearing the name of Aegium at full length. The coinage of Aegium is known to have been different from that of the rest of Greece; infomuch that its drachma was worth 10 Attic oboli, while the Attic drachma was valued only at 5. Hence the drachma...
The general denomination of the Greek money is the drachm, which is divided into oboli, hemidrachms, and tetradrachms. The obolus was worth about 1 grain of silver, and the hemidrachm was worth about 44 grains. The tetradrachm, which was the most valuable coin, was worth about 240 grains.

Many different names have been imposed on the coins belonging to the different states of Greece. The tetradrachm of Athens was called a stater, and the tetradrachm of Corinth was called a stater also. The tetradrachm of Rhodes was called a tetradrachm, and the tetradrachm of Ephesus was called a tetradrachm.

The tetradrachm was the most valuable coin, and was used for transactions of importance. The obolus was the least valuable coin, and was used for petty transactions.

Many different names have been imposed on the coins belonging to the different states of Greece, and the tetradrachm is the most valuable. The tetradrachm was worth about 240 grains, and was used for transactions of importance. The obolus was the least valuable coin, and was used for petty transactions.
magistrates inscribed upon them. Some of these bear the name of Mithridates; and few are older than the era of that prince; who, it is well known, took the city of Athens in his war with the Romans. I suppose (says Mr. Pinkerton) that no Athenian coins of silver are posterior to Sylia's infamous destruction of that city; an event the more remarkable, as Sallust tells us, that Sylia was learned in Greek. Indeed Caligula, Nero, and most of the petty states of society, have been learned men, in spite of a noted axiom of Ovid, sed ingenios dulce flecte artes. Eamque, n.e. juxta efi forma.

It is still more remarkable, that the fabric of Athenian coins is almost universally very rude: a singular circumstance, if we reflect how much the arts flourished there. It can only be accounted for from the excellence of their artists being such as to occasion all the good ones to be called into other countries, and none but the bad left at home. In like manner, the coins struck at Rome in the imperial times are excellent, as being done by the best Greek artists; while those of Greece, though famous at that time for producing miraculous artists, are during that period commonly of very mean execution. The opulence of Athens in her days of glory was very great; owing in an eminent degree to her rich commerce with the kingdoms of the Euxine sea; carried on chiefly from Delos, which belonged to Athens, and was the grand centre of that trade. Hence it has become matter of surprise to Neumann, that when there are so many coins of Mycene, an island even proverbially poor, there should be none of Delos. But Mr. Pinkerton accounts for this from Mycene's being a free state, and Delos subject to Athens. "It may be well supposed (says he), that Athens had a mint at Delos; and such Athenian coins as have symbols of Apollo, Diana, or Latona, were struck in this island."

The copper money of the Greeks is next in antiquity to the silver. Mr. Pinkerton is of opinion, that it was not used at Athens till the 226th year of the Peleponnesian war; about 404 years before Christ, and 300 after silver was first coined there. The first copper coins were those of Celo of Syracuse, about 450 years since. The chalcus of brafs, of which eight went to the silver obolus, seems to have been the first kind of Greek coin. At first it was looked upon as of no little consequence, that it became proverbial; and to say that a thing was not worth a chalcus, was equivalent to saying that it was worth nothing. As the Greeks became poor, however, even this diminitive coin was subdivided into two, four, nay eight lepta or small coins; but our author censures very severely those who have given an account of those divisions. "Pol lus and Suidas, copying from him (says he), tells us, that there were seven lepta to one chalcus; a number the most unlike that can be, from indivisibility and incapacity of proportion. "Pollux lived in the time of Commodus; so was too late to be of the smallest authority: Suidas is four or five centuries later, and out of the question." Pliny tells us, that there were ten chalices to the obolus; Diodorus and Cleopatra that there were six; Liddorus says there were four; and if such writers differ about the larger denomination, we may well imagine that the smaller equally varied in different states; an idea supported by these undeniable witnesses the coins which remain. Most of the Greek copper-coins which has reached our times consists of Chalices; the lepta being so small as to be much more liable to be lost." In Dr. Hunter's cabinet, however, there are several of the dileptos of Athens; and from being flamped with the representation of two owls, seem to be the same with the silver diobolus; "a circumstance (says Mr. Pinkerton) of itself sufficient to confute Pollux; for a dileptos can form no part of seven; a number indeed which never appeared in any coinage of the same metals, and is contradictory to common sense. It may be observed, that the whole brafs coins of Athens published by Dr. Combe are reducible to four sizes, which may be the lepton, dilepton, tetradixer or hemichelos, and lepton. The first is not above the size of one of king James I's farthing tokens; the last about that of our farthing. The lepton was also called hemichelos, as being change for the poor. The Xaikos, perhaps so called from the figure of a wolf upon it, was the coin of a particular state, and if of brafs must have weighed three chalices. The other names of the copper-coins of Greece are but little known. Lycurgus ordered iron money to be coined at Sparta; but so perishable is this metal; that none of kind of money has reached our times.

After the conquest of Greece by the Romans, most of the coins of that country diminished very much in their value, the gold coinage being totally discontinued; though some of the barbarous kings who ufed the Greek character were permitted to coin gold, but they ufed the Roman model; and the standard ufed by the few cities in Asia who spoke the Greek language in the times of the emperors is entirely unknown. Copper seems to have been the only metal coined at that time by the Greeks themselves; and that upon the Roman standard, universal through the empire, that there might be no impediment to the circulation of currency. They retained, however, some of their own terms, using them along with those of the Romans. The xarion or xarion of Rome, the name of the diminished as, being 16 to the drachma or denarius, the chalcos was so much diminished in value as to be struck in brafs not much larger than the old chalcos, and valued at between two and three xarions; which was indeed its ancient rate as to the drachma. This appears from the copper coins of Chios, which have their names marked upon them. The brafs obolus, at first equal in signe to the Roman sestertius or large brafs, lefens by degrees to about the signe of a silver drachma. From the badges of the imperial coinage in Greece also, it appears that brafs was very scarce in that country, as well as in all the cities using the Greek characters; being found mostly in the western countries of the Roman empire. The time of this declension in signe of the Greek coins is certainly marked. Mr. Pinkerton has produce these from Attic of the gulus down to Gallienus. He is of opinion however, that the copper obolus, at first above the signe of large brafs, was used in Greece about the time of its first subjection to Rome; and that the lepta ceasing, the chalce came in their room, with the chalcos and the hemichelos of brafs.
With respect to the gold coins of the Greeks, Mr Pinkerton is of opinion that none of that metal was coined before the time of Philip or Macedon, as none have reached our times prior to the reign of that monarch. From a passage in Thucydides our author concludes, that in the beginning of the Peloponnesian war the Athenians had no gold coin. Mentioning the treasure in the Aeropilis or citadel of Athens, at the commencement of that war, the historian mentions silver coin, and gold and silver in bullion: and had any of the gold been in coin, he would certainly have mentioned it. Philip began his reign about 68 years after the beginning of the Peloponnesian war; and we can scarcely suppose that any city would have preceded the elegant and wealthy Athens in the coinage of gold.

Notwithstanding, however, this deficiency of gold coin among the Greeks, it is certain that the coinage of gold had taken place in Sicily long before; as we scarcely occur of the coinage of early in coin among the Greeks, it is certain that any of the gold been in coin, he would certainly eludes, that in the beginning of the gold coins of the Greeks, was of the same weight, as is evident from ancient writings. It was anciently worth about 15s. but valuing gold now at the medium price of 41. per ounce, it is worth about 32s. The 

Gold coined early in Sicily.

The Thebans and Athenians probably coined the first gold after Philip had set them the example, and when they were attempting to refil the projects of that enterprising monarch. The Athenians probably coined their gold during the time of their greatest power about a century after Philip, and when they were combating the power of Aratus and the Achæan league. There is (says Mr Pinkerton) but one 

In Rome, as well as in Greece, the money was at first estimated by weight; and the first metal coined money. by that people was copper, silver being long unknown in Rome; nor is it certainly known that any silver has ever been found in the Italian mines. In Rome the first valuation of money was by the 

The weight made of the native gold, and now worth about 41. sterling. Some even more; but this our author supposes owing to the gold being less pure.

Of the Roman pound.

Ancient Money.

Whence the Romans derived their coinage.

Ancient Money.

Some coins are found which exceed the as librae in their own weight; and these are supposed to be prior to the ancient time of Servius Tullius. Some of them are met with in Roman coins of 34 and of 53 Roman ounces; having upon one side the figure of a bull rudely impressed, and upon the other the bones of a fish. They are most commonly found at Tuder, or Tudertum in Umbria; but they appear always broken at one end; so that Mr Pinkerton is of opinion that perhaps some might be struck of the decussi form, or weighing ten pounds. These pieces, in our author's opinion, make it evident, that the Romans derived their large brass coins from the Etruscans and the neighbouring states; they are all cast in moulds; and the greater part of them appear much more ancient than the Roman auri, even such as are of the greatest antiquity.

Mr.
Ancient Money.

Mr Pinkerton agrees with Sir Isaac Newton as to the time that Servius Tullius reigned in Rome, which he supposes to be about 460 B.C. His coinage seems to have been confined to the as, or piece of brass having the impress of Junus on one side, and the prow of a ship on the other, because Janus arrived in Italy by sea. Vatru, however, informs us, that the very first coins of Tullius had the figure of a bull, or other cattle upon them, like the Etrurian coins, of which they were imitations. Those with the figure of Janus and the prow of a ship upon them may be supposed first to have appeared about 400 years B.C. but, in a short time, various subdivisions of the as were coined. The semis or half is commonly stamped with the head of Jupiter laureated; the triens or third, having four cyphers, as being originally of four ounces weight, has the head of Minerva; the quadrans or quarter, marked with three cyphers, has the head of Hercules wrapt in the lion's skin; the sextans or sixth, having only two cyphers, is marked with the head of Mercury with a cap and wings; while the unies having only one cypher, is marked with the head of Rome. All these coins appear to have been cast in moulds, by a considerable number at a time; and in the British Museum there are four of them all united together as taken out of the mould in which perhaps dozens were cast together. In process of time, however, the smaller divisions were struck instead of being cast; but the larger still continued to be cast until the as fell to two ounces. Even after this time it was still called libra, and accounted a pound of copper; though there were now larger denominations of it coined, such as the biffas or double as; trifas and quadrifas of three and four ases; may as far as decussi or ten ases, marked X. Olivieri mentions one in his own cabinet weighing upwards of 25 ounces, and cast when the as was about three ounces weight. There is likewise in the Museum Etrurcum a decussi of 40 Roman ounces, cast when the as was at four ounces. There was likewise a curious decussi in the Jefuit's library at Rome, for which an English medalist offered 20l.; but it was seized by the Pope along with every other thing belonging to the society.

Mr Pinkerton contends the opinion of Pliny that the as continued as a pound weight till the end of the first Punic war. His opinion (he says) is confirmed by the coins which still remain; and it appears probable to him that the as decreased gradually in weight; and, from one or two of the pieces which still exist, he seems to think that the decrease was, as from a pound to eleven ounces, then to ten, nine, &c.; but neither the as nor its parts were ever correctly fixed. During the time of the second Punic war, when the Romans were fore prefied by Hannibal, the as was reduced to a single ounce. It is said to have taken place in the 215th year before our era, being about 36 years after the former change. This as libralis, with the face of Janus upon it, is the form most commonly met with previous to its being reduced to two ounces. Our author supposes that the as libralis continued for at least a century and an half after the coinage of Tullius, down to 300 B.C. about the year of Rome 452, between which and the 502d year of Rome a gradual diminution of the as to two ounces must have taken place. The following table of the dates of the Roman coinage is given by Mr Pinkerton.

The libralis, coined with Tullus with the figures of oxen, &c. about 167 years after the building of Rome, according to Sir Isaac Newton, or about the year before Christ 460, as libralis with Janus and the prow of a ship 400. For ten ounces - 300.

Eight - - - - 200.
Six - - - - 175.
Four - - - - 270.
Three - - - - 260.
Two, according to Pliny - 250.
One, according to the same author - 214.

About 175 B.C. also, we are informed by Pliny, that the as was reduced to half an ounce by the Paphian law, at which it continued till the time of Pliny himself, and long after. After the Romans began to have an intercourse with Greece, a variety of elegant figures appear upon the parts of the as, though not on the as itself till after the time of Sylla. Towards the latter end of the republican age, dupondii, or double ases, were coined, together with the sesterii as, which came in place of the quadrifas, when the demers began to be reckoned at 1600. Probably at the time the latter was reduced to half an ounce. In some instances it is to be observed, that the Romans accommodated their coins to the country where their army was stationed; whence we have many coins marked as Roman, which have been coined in Magna Grecia and Sicily, and are evidently upon the Greek scale made as Romans, and not the Roman scale. In the latter part of the republican times, also, the types began to vary; so that we have a brass coin supposed to be struck by Sextus Pompeius in Sicily, having upon it a double head of that warrior, representing a Janus. Mr Pinkerton supposes it to have been a dupondius; which indeed appears to be the case from the double head. This coin is of copper, and still weighs an ounce, notwithstanding its antiquity.

The largest imperial copper coin was the felterius, of the face a piece worth about two-pence Sterling money. Mr Pinkerton confers frequently the opinion of other medalists, all of whom say that the felterius was of silver. "In fact (says he), it would be as rational in any antiquity, a thousand years hence, to confide that the halfpenny and farthing are of silver, because they were so in the reign of Henry VIII." In confirmation of his own opinion, he quotes the following passage from Pliny: "The greatest glory of brass is now due to the Marian, called also that of Cordova. This, after the Livian, most absorbs the lapis calaminaris, and imitates the goodness of native orichalcum in our felterii and dupondii, the ase being contented with their own copper." Gronovius confesses that he does not know what to make of this passage, and that it causes him hesitate in his opinion. The Livian mine mentioned here by Pliny, is supposed to have got its name from Livius, the wife of Augustus; and it is probable that the piece marked with her portrait, intitled Justitia, Salus, Virtus, &c. were dupondii from this very mine, the metal being exceedingly fine, and of the kind named Corianian brass by the ancient medalists. "Perhaps, (says Mr Pinkerton) the mine received its name from this very cir-
No change took place in the Roman coinage from the time that the as fell to half an ounce to the days of Pliny; and Mr. Pinkerton is of opinion, that the dimeritus was added before the time of Julius Caesar; and yellow brasses began to be used, and was always looked upon to be double the value of the silver coin of Cyrenius.

There are but few coins of large brasses immediately before Julius Caesar, or even belonging to that emperor; but from the time of Augustus downward, the large coins are all found of brass, and not one of them copper. The largest of what are called the middle size are all of yellow brasses; and the next size, which is the as, and weighs half an ounce, is universally copper. What the ancients named arzibalam, or what we call brasses, was always looked upon to be of great superiority in value to the as copper. Procopius, speaking of a statue of Justinian, tells us, that the brasses inferior in colour to gold is almost equal in value to silver. The mines of native brasses were very few in number, and were owing entirely to the singular combination of copper and lapis calaminaris in the bowels of the earth, which very seldom occurs, and the ancients were far from being well acquainted with the method of combining these two bodies artificially; so that yellow brasses were always esteemed at double the value of copper; and hence, in the ancient coinages, the brasses and copper pieces were kept as distinct as those of gold and silver.

Mr. Pinkerton challenges himself to the discovery that the imperial sesterius was of brass; and is at considerable pains to bring proofs of it. Besides the testimony of Pliny, which of itself would be decisive, this is supported by the strongest collateral evidence of other authors. From a passage in Julius Africanus, who wrote the epigrams, or Treatise on Medicine, it appears that the nummus, or sesterius, weighed an ounce, and of consequence that it could not be silver but brasses; and all the large imperial Roman coins weigh an ounce. We know not the age in which Julius Africanus lived; but as he makes the denarius to contain 16 asses, he must have been before the age of Gallienus, when it had 60. Cronovius supposes him to have been the same person mentioned by Eusebius. This author speaks of a Julius Africanus who lived in the time of Heliogabulus, and whom Mr. Pinkerton supposes to have been the same person with him abovementioned.

The sesterius underwent no change till the time of Alexander Severus, when it was diminished by one third of its weight. Trajanus Decius was the first who coined double sestertii, or quintarii, of brass; but from the time of Theodosian Gallus to that of Gal
darius, when the first brasses ceased, the sesterius does not weigh above the third part of an ounce: the larger coins are accounted double sestertii; and after the time of Gallienus it totally vanishes. In the time of Valerian and Gallienus, we find a new kind of coinage, mentioned by the name of denarius, or Philip
pus, mentioned in Carcalla; the larger of this coin, of the weight of 24 as., the smaller of four sestertii, of 16 as., and the former word confined to the silver coin of the former word, of which the denarius is the double length of the latter.

The sesterius were used formerly to be struck to such a small size as not to weigh more than 36 grains; though in Caracalla’s time it weighed 56.

After the time of Gordian III. the smaller coin fell into disuse, as breeding confusion. The larger denarius of six sestertii, which had diminished at last to the size of the early denarius, still retained its value of six sestertii, or 24 as., and was called the Philippus aureus, because it came at length in place of the denarius. It was also called denarius aureus; from which we may learn not only their size, but that they were in value ten sestertii as the first denarius. In the reign of Diocletian, the place of the denarius was supplied by the follis, that emperor having restored the silver coin to its purity, and likewise given this form to the copper; but it would seem that this reformation of the coinage only took place towards the end of his reign, though we have but few of his silver coins, and still fewer of the follis, though the denarius aureus continued quite common down to the time of Constantine. The follis of Diocletian seems to have weighed above half an ounce; and Mr. Pinkerton is of opinion, that Diocletian designed this coin to supply the place of the danarius aureus; which of course was worth ten sestertii, and of them we went to the silver denarius. From this time the sestertium diminishes to the size of 30 grains; and soon after the follis appeared, the denarius aureus was entirely dropped, the former having gradually supplanted its place. Some mints appear to have retained the use of the denarius longer than others; and in some the change was preceded, and gradually brought in by washing the follis with silver or tin, as the denarius had formerly been. Pieces of this kind occur in the times of Diocletian, Maximian I. and II. and Constantine I.; that is, for about ten years after the follis made its appearance. Some countries, however, retained the denarius aureus; others the follis; and some had a medium between the two, or the follis washed in imitation of the denarius.

Towards the end of the reign of Constantine I. a new coinage was introduced throughout the whole age of the empire. The follis coined by this prince was of half the weight of the denarius aureus; 24 of them going to the milliarenum, or larger silver coin. The word follis signifies also a purse, in which sense we sometimes find it mentioned in the Byzantine history. The common follis of silver, when it occurs by itself, means a purse of 250 milliarenums, as the sesterius was 250 denarius; and by a law of Constantine I. every man paid to the state a follis, or purse according to his income. The method of counting by purses continues in Turkey to this day.

The dupondius was only half the value of the sesterius, of which the former word was used to denote an ounce weight; 24 of them going to the milliarenum, or larger silver coin. The word follis signifies also a purse, in which sense we sometimes find it mentioned in the Byzantine history. The common follis of silver, when it occurs by itself, means a purse of 250 milliarenums, as the sesterius was 250 denarius; and by a law of Constantine I. every man paid to the state a follis, or purse according to his income. The method of counting by purses continues in Turkey to this day.
Medals.

Of the smaller Roman coins.

The imperial, as, or avarium, was worth only an halfpenny. At first it weighed half an ounce, and was always of copper till the time of Gallienus, when it was made of brass, and weighed only the eight part of an ounce. From the time of Gallienus to that of Diocletian, it continued to diminish still more, the size being then twenty to an ounce. This was the same with the lepta, or smallest coins but the sestertius, which weighed only ten grains.

The parts of the as occur but seldom; which may, indeed, be well expected, considering the low value of it; though there still occur some of those called semis, triens, quadrans, sextans, and uncia, coined in the times of Nero and Domitian. There is no small brass from the time of Pertinax to that of Gallienus, excepting that of Trajanus Decius; but in the time of Gallienus it becomes extremely common; and the coins of small brass, as well as the larger, are always marked S. C. such as want it being universally accounted forgeries, and were plated with silver, though the plating be now worn off. The small pieces struck for slaves during the time of the saturnalia must also be distinguished from the parts of the as. The S. C. upon these most probably signifies Saturni Confulto, and were struck in ridicule of the true coins, as the slaves on that occasion had every privilege of irony.

The sestertius diminishes from Pertinax to Gallienus so that no parts of the as are struck, itself being for all time of Trajanus Decius; indeed, coined in pieces, which went for the semis of the time. The small brass coins under Gallienus were called avaria, sixty of which went to the silver denarius. They are about the size of the denarius, and some of them occur of the coinage of Gallus and his family, of half that size, which appear to have been struck during the latter part of his reign, when the avaria was diminished to a still smaller size. It is probable, however, that some of these very small coins had been struck in all ages of the empire, in order to scatter among the people on solemn occasions. Mr Pinkerton is of opinion that they are the mijalla, though most other medallists think that they were medallions. "But if so (says our author), they were certainly called mijalla a non mintendo; for it would be odd if fine medallions were scattered among the mob. It is a common custom just now to strike coins to scatter among the populace on such occasions, which are given to peers of the kingdom; and we may very justly reason from analogy on this occasion."

The avarium or lepton of the Constantiopolitans empire was, as we have already observed, one of the smallest coins known in antiquity, weighing no more than 20 grains; and the numia were the very smallest which have reached our times, being only one-half of the former. By reason of their extreme fineness, they are very scarce; but Mr Pinkerton informs us, that he has in his possession a fine one of Theodosius II, which has on it the emperor's head in profile. Theodosius P. F. A. V.; on the reverse a wreath, having in the centre VOT. XX. M S. XXX.

The principal coin of the lower empire was the follis, which was divided into half and quarter, named sigillaria, and scillium; the latter of which is shown by Du Cange to have been a small brass coin, as the other is supposed to have been by Mr Pinkerton. Besides these, the follis was divided into 8 obols, 16 avaria or lepta, and 32 numia, though in common computation it contained 40 of these last. This coin, notwithstanding so many divisions, was of no more value than an halfpenny.

Mr Pinkerton controverts an opinion, common among medallists, that the largest brass coin or follis of the lower empire had 40 small coins, expressed by the letter M upon it; the next had 30, expressed by the letter A; the half by the letter K; and the quarter marked I, which contained only 10. Mr Pinkerton informs us, that he has three coins of Anastasius, all marked M in large; one of them weighs more than half an ounce; the second 40 grains less; and the third 360 grains, or one-third of an ounce; but the size is so very unequal, that the last, which is very thick, does not appear above half the size of the first. There are pieces of Julianus which weigh a whole ounce; but the size of copper was increased as the silver became scarcer; and the value of the coinage cannot be deduced from the weight of the coins, as it is plain that our own coinage is not of half the value with regard to the metal. A great number of medallions were struck by Constantius II, but there is no other copper larger than the half ounce, excepting that of Anastasius, when the follis began to be struck larger. All medallions allow the others to be medallions. The metal employed in these very small coins, though at first of brass, was always a base and refuse kind; but copper is generally made use of in the parts of the as from the earliest times to the latest; and if brass be sometimes employed, it is never such as appears in the sestertii and dupondii, which is very fine and beautiful, but only the refuse. "Yellow brasses of the right fort (says Mr Pinkerton) seem to have ceased in the Roman coinage with the sestertii, under Gallienus, though a small coin of very bad metal appear under that hue as late as Julianus II."

Silver was coined in Rome only as late as the 43rd Roman year of the city, or 266 B. C. Varro indeed speaks silver, of silver having been coined by Servius Tullius, and the libella having been once in silver; but Pliny's authority must be accounted of more weight than that of his author, as he mistakes the year of Sicily for Roman coins, having been current at Rome during the time of the first Punic war. Even Pliny, according to our author, very frequently mistakes with regard to matters much antecedent to his own time; and
Among the moderns he criticizes severely Eramus and Hume. “Eramus (says he), who had been in England for some time, talks of leaden money being used here. Not even a leaden token was struck in the reign of Henry VIII.; yet his authority has been followed with due deference to so great a name; for how could Eramus, who must have seen the matter with his own eyes, assert a direct falsehood? To give a later instance in a writer of reputation, Mr Hume, in vol. vi. of his history, has these words, in treating of the reign of James I. “It appears that copper halfpence and farthings began to be coined in this reign. Trademen commonly carried on their retail business by lead tokens. The small silver penny was fo small; and at this time was nowhere to be found.” Copper halfpence and farthings were not struck till Charles II. 1672: there were small tokens for farthings struck in copper by James I. but not one for the halfpenny. The silver farthings had ceased with Edward VI. but the silver halfpence continued the sole coins till Charles II. It was by copper tokens that small bunifens was carried on. The silver penny was much used till the end of the reign of George I.; and, so far from being nowhere to be found, is superabundant of every reign since that period, not excepting even the present reign of George III. From these instances the reader may judge how strangely writers of all ages blunder, when treating of a subject of which they are entirely ignorant.

The first silver denarius coined at Rome, are supposed by our author to have been those which are impressed with the ROMA; and he inclines to account those the most ancient which have a double female head on the one side, and on the reverse Jupiter in a car, with Victory holding the reins, and the word ROMA indented in a rude and singular manner. The double female head seems to denote Rome, in imitation of the Janus then upon the as. There are 15 of these in the cabinet of Dr Hunter; one of the largest weighs 984 grains; and the rest, which seem to be of greater antiquity, are of various weights between that of the small denarius and that of the large denarius. But Mr Pinkerton is of opinion, that the large ones are of the very first Roman coinage, and struck during that interval of time between the coinage of the first silver denarius and the as of two ounces. He takes the indentation of the word ROMA to be a mark of great antiquity; such a mode being scarcely known any where else, except in Caulonia, Crotona, and other towns of Italy; all of them allowed to be struck at least 400 B.C. As these large coins are not double denarii, they must have been struck prior to the small ones; and Neumann has given an account of one of them recoiled by Trajan, in which the indentation of ROMA is carefully preserved. The first denarius was in value 10 as, when the as weighed three ounces; and allowing 90 grains at a medium for one of these large denarii, the proportion of copper to silver must have been as 1 to 160; but when as fell to one ounce, the proportion was as 1 to 80: when it fell to half an ounce, so that 16 as went to the denarius, the proportion was as 1 to 64, at which it remained. Copper with us, in coinage, is to silver as 1 to 40; but in actual value as 1 to 72.

At Rome the denarius was worth 8d.; the quinaria 4d.; and the sesterius, whether silver or brass, 2d. The denarius is the coin from which our penny is derived, and was the chief silver coin in Rome for 600 years. According to Celsus, seven denarii went to the Roman ounce, which in metals did not exceed the denarius 430 grains; but as all the denarii hitherto met with weigh at a medium only 60 grains, this would seem to make the Roman ounce only 420 grains; though perhaps this deficiency may be accounted for from the unavoidable waste of metal even in the best preferred of their coins. According to this proportion the Roman pound contained 84 denarii; but in tale there was a very considerable excess; for no fewer than 100 denarii went to the Roman pound. The Greek ounce appears to have been considerably larger than that of Rome, containing about 428 grains; yet notwithstanding this apparently great odds, the difference in the coins was so small, that the Greek money went current in Rome, and the Roman in Greece. The denarius at first was for 10 ases, and was marked X.; it was afterwards raised to 16; which Mr Pinkerton supposes to have been about 175 B.C. Some are met with bearing the number XVI. near, with every number up to CCCCLXXVI. These large numbers are supposed to have been mint-marks of some kind or other. After being raised to 16 ases, it continued at the same value till the time of Gallius: so that till that time we had to look upon its constituent parts to be 16 as or sestertii, eight dupondii, four braccia sesterii, and two silver quinarii. Under the emperor Severus, however, or his successor Caracalla, denarii were struck of two fizes, one of them a third heavier than the common; which we must of course supposes to have borne a third more value. This large piece obtained the name of argenteus, and argenteus Philippus, or the “silver Philip;” the name of Philip having become common to almost every coin. The common denarii now began to be termed minuti and argenti Philippiani minuti, &c. to express their being smaller than the sestertius. Some have imagined that the large denarii were of the same value with the small; but Mr Pinkerton observes, that among the few which have any difference of metal, the smallest are always the worth. The first mention of the minuti is in the time of Alexander Severus, who reduced the price of pork from eight minuti at Rome to two and to one. The minuti argenteus of that age was about 40 grains; and from the badness of the metal was not worth above 4d. of our money. Thus the price of meat was by this prince reduced to 8d. and then to 4d.

According to Zosimus and other writers, the present value of the Roman coin was restored by Aurelian, on the notion of the but Mr Pinkerton controverts this opinion; thinking it improbable, that he only made the attempt without success; or that his resolution might be entirely confined to gold, on which there is an evident change after the time of this emperor. His successor Tactitus is said to have allowed no braccia to be mixed with silver upon any account; yet the few coins of this emperor are very much alloyed. We are certain, however, that the emperor Dioclesian restored the silver to its ancient purity; the denarius struck in his reign being very small indeed, but of as fine silver as the most ancient coins of the empire. After Gordian...
Sect. V. M E D A L S.

Ancient Money.

Dian III. the small denarius entirely vanished, while the large one was so much diminished, that it resembled the minuta, or small one of Caracalla in size. Gallienus introduced the denarius aureus instead of the sesterius. The argenteus, though reduced more than one third in size, contained six denarii aurei, the old standard of sesterii. According to the writers of this period, and some time afterwards, the denarius or argenteus contained 60 sesterii; whereas it follows, that each denarius aurei had 10; and from this it probably had its name. The sesterii are of the size of the argenteus already mentioned, and show the copper to have retained nearly its old proportion of value to the silver, viz. 1 to 60.

A larger silver coin was introduced by Constantine I, who accommodated the new money to the pound of gold in such a manner, that 1000 of the former in tale were equal to the latter in value; so that this new piece from whence obtained the name of the milliarensis or "thousander." Its weight at a medium is 70 grains, or 70 to the pound of silver: but Mr Pinkerton is of opinion, that it might have contained 72 grains, of which two have now perished by the softness of the silver; that the pound contained 72; or that two of the number might be allowed for coinage; while the alloy alone would pay for coining gold. The code says, that 60 went to the pound; but the numbers of this are quite corrupt. The milliarensis was worth about a shilling sterling. The argenteus or denarius aureus was equal to the latter in value; so that the current milliarensis of the succeeding emperors from 20, or the time of Juliius had its name. The argenteus or denarius aureus, therefore, was the common regulation of accounts in the Eastern empire. The sesterius met with in ancient authors, according to Mr Pinkerton, was merely an improper name for the milliarensis; when, on account of the scarcity of silver, the denarius was reduced, and no milliarensis coined: so that the current milliarensis of former reigns happened to be double to the denarius or centenionales. The quinarius diminishes in size along with the other coins; those of Augustus weighing 30 grains, of Severus 25, of Constantine I, 20, of Julian 12, and of Heraclius only 5. A new silver coinage seems to have taken place after the days of this emperor; as the little we then meet with, which in the best cabinets scarcely exceeds a dozen of coins, consists entirely of large unhapely pieces of coarse metal.

2. The confular denarius had also four silver sesterii, till the as fell to half an ounce, when it was thought the denom­ proper to coin the sesterii in brafs, as it continued rius.

Deduction of the small silver coin by Con­stantine.

66 Account of the small Roman coins.

The smaller silver coins of Rome were, 1. The quinarius, at first called victorius, from the image of Victory on its reverse; and which it continued to bear from first to last. Its original value was five alae, but it was afterwards raised to eight, when the value of the denarius increased to 16. According to Pliny, it was first coined in consequence of the fire of Clodius, about the 525th year of Rome. Some are of opinion, that it was called victorius under the Constantinopolitan empire, because it was worth a theure of gold, 14 of which went to the ounce; but this is denied by Mr Pinkerton, because at the time that the word seiss was under the Constantinopolitan empire, because it was worth a theure of gold, 14 of which went to the ounce; but this is denied by Mr Pinkerton, because at the time that the word sesterius appears in history, the denarius did not weigh above 30 grains; and of consequence, as 25 must have gone to the gold solidus, of which there were six in the ounce, 150 denarii must have gone to the ounce of gold. He is therefore of opinion, that the word sesterius was only another name for the denarius when much reduced in size; probably owing to the great scarcity of silver in Constantinople, though in the fame city there was plenty of gold; and of consequence, the gold solidus was never diminished. "For Montef­ quieu (says our author) has well observed, that gold musl be common where silver was rare. Hence gold was the common regulation of accounts in the Eastern empire." The victorius is of the same kind, but double, marked xxxx; and its triple, marked xxxx; the 4 being the old numeral character for 50." Mr Pinkerton, the discoverer of this, treats other medals with great aperity. Savot and Hardouin are mentioned by name; the latter (he says) is "ignorant of common sense!" and neither he nor Savot could explain it but by reading
the rich city of Palmyra, and thus became master of the treasures of the east, obtained such a profusion of gold, that he looked upon it to be produced by nature in greater plenty than silver. It is remarkable, that during this emperor's reign there was a rebellion among the money-coiners, which could not be quelled but by the destruction of several thousands; which Mr Pinkerton ascribes to his having ordered the gold to be refurled to its former size, but to go for no more silver than it formerly did. "So very little silver (says he) occurs of this period, that it is plain no alteration in the silver produced the war with the moneys: and in the brass he made no change; or if he had, it were strange that such commotions should arise about so trifling a metal. But if, as appears from the coins, he ordered the aureus, which had fallen to 80 denariis, to be raised to about 100, it is no wonder that the contractors should be in an uproar; for a whole quarter of their coinage, amounting as would seem to all their profits, was lost. Aurelian judged, that when he found gold so common in the east, it was equally so in the west; and that the moneys must have made a most exorbitant profit; but his ideas on this subject were partial and unjust: and after his short reign, which did not exceed five months after the alteration, the gold returned to its former course; though a few pieces occur of Aurelian's standard, struck, as would seem, in the commencement of the reign of Probus his successor.

From this time to that of Constatine I. the aureus weighed between 70 and 80 grains; but in his reign it was changed for the foliis, of which fix went to the ounce of gold, which went for 14 milliareus, and 25 denariis as before; the value of silver being now to gold as 14 to 1. This new coin continued of the same value to the final downfall of the Constantinopolitan empire; gold being always very plentiful in that city, though silver became more and more scarce. The foliis was worth 12s. 4d. flerling. Here again our author must severely criticise Mr Clarke and Mr Raper: the former (he says) with respect to the value of gold in the time of Constatine I. "has left all his senses behind him. In page 267, he ably asserts, that 20 denariis went to the foliis in the time of Theodosius I. and proceeds with this deplorable error to the end of his work. He then tells us, that only 14 denariis went to the foliis under Constatine I. &c."

To Mr Raper, however, he is a little more merciful, as he owns, that "though he (Mr Raper) has strangely confounded the milliareus with the denariis, he has yet kept common sense for his guide." Mr Pinkerton argues, indeed with great probability, "that had any change in the coinage taken place between the time of Constatine and Theodosius I. that is, in less than 50 years, the laws of that period, which are all in the Theodosian code, must have noticed it." To this and other arguments upon the subject, Mr Pinkerton adds the following observation upon the value of gold and silver: "As a late advances to its height, gold increases in value; and as a late declines, it decreases, providing the metals are kept on a par as to purity. Hence we may argue, that gold decreased in its relation to silver perhaps four or five centuries, furnished most European kingdoms with gold in coin, which otherwise would, from their want of arts, and
of intercourse with the sae, then the grand seminary of that metal, have almost been ignorant of what gold was. These gold coins were called Besants in Europe, because sent from Byzantium or Constantinople; and were solidi of the old scale, fix to the ounce. In Byzantine writers, the solidus is also called nomisma, or "the coin" ergynus, because of gold; hyperperos, from its being refined with fire, or from its being of bright gold flaming like fire. The solidi also, as the aurei formerly, received names from the princes whose portraits they bore; as Michaelis, Manuelis. Solidus is a term used also for the aureus by Apuleius, who lived in the time of Antoninus the Philosopher; nay, as early as in the Procerian edicts of the time of Trajan, it was then a distinction from the semissi or half.

In the time of Valerian, when aurei of different weights were found of Valerian and his son Gallienus, and weigh about 30 grains. Thos. of Salonina the wife of Gallienus, and weigh about 30 grains. Thos. of Salonina the wife of Gallienus, and weigh about 33 grains. Under the Constantinopolitans, the semissi again make their appearance; and from the time of Valentinian downwards, the third is the most common coin of gold, being worth about 4 s. sterl. The semissi is likewise mentioned, but none occur earlier than the time of Balsificus. The gold semissi was the pattern of the French and Spanish gold coins. The silver semissi, in its diminished state, was of the Gothic and Saxon penny.

We shall close this account of the Roman money with some remarks concerning the mint, and method of coinage. This at first seems to have been under the direction of the quaestor. About the time that silver was first coined in Rome, vis. about 256 B.C. the triumviri monetales were created. They were at first of senatorial rank, but were Augustal like Chosen from among the equestrians; and the title of triumviri was continued till after the time of Caracalla; but under Aurelian there was probably but one master of the mint called Rationalis; and Mr Pinkerton is of opinion that the change took place under Gallienus. He seems to have permitted the provincial cities to coin gold and silver, as well as to have altered the form of the mints in the capital, and to have ordered them all to strike money with Latin legends, and of the same forms; as in his time we first meet with coins with mint-marks of cities and offices. The violent insurrection which took place in his reign has already been mentioned, as well as its probable cause; and Mr Gibbon has shown, that the concealed enemies of Aurelian took such advantage of this insurrection, that it cost 7000 of his reb troops before it could be quelled. About this time the procurator monete seems to have succeeded the rationalis as director of the mint. In the colonies, the direction of the mint seems to have been given to the decurio, whose names frequently occur on colonial coins; "which (says Mr Pinkerton), though generally of rude invention, and ruder execution, are yet often interesting and important."

The engraving of the ancient dyes used in coinage was a work of much genius and labour; and at Rome Greek artists were generally employed in it; but it has been thought a matter of great surprize, that scarce any two ancient coins are to be found exactly the same. Hence some antiquaries have imagined, that only a single coin was thrown off from each dye. M. Beaulieu informs us, that the only two Roman imperial coins of the first times which he had seen perfectly alike were those of the emperor Galba. It is, however, the opinion of the best judges, that a perfect similarity between two medals is a very great reason for supposing one of them to be forged. "It cannot be observed (says Mr Pinkerton), that the differences in coins, apparently from the same dye, are often so minute as to escape an eye not used to macroscopic observations of this sort. But it would be surprising if any two ancient coins were now found struck with the same dye; for out of each million coined, not above one has reached us. Dyes soon give way by the violence of the work; and the ancients had no punchers nor matrices, but were forced to engrave many dyes for the same coin. Even in our mint, upon sending for a shilling's worth of new halfpence, it will appear that three or four dyes have been used. Sometimes the obverse of the dye gives way, sometimes the reverse; but among us it is renewed by punchers, though with variations in the lettering or other minute strokes, while the ancients were forced to recur to another dye differently engraved. The engravers of the dye were called castraiores; other officers employed in the mint were the spectatores spectatores, or numismatists. The melters were styled futilarii, futilarii, and flacteriai; those who adjusted the weight were called equatores monetarum; those who put the pieces into the dye futilitores, and those who struck them molentores. At the head of each office was an officer named privi­ rius, and the foreman was named opitio et exictus."

In order to affit the high relief on the coins, the metal, after being melted and refined, was cast into bullets, as appears from the ancient coins not being cut or filed on the edges, but often cracked, and always rough and unequal. These bullets were then put into the dye, and received the impression by repeated strokes of the hammer, though sometimes a machine appears to have been used for this purpose; for Boerius informs us, that there was a picture of the Roman mintage in a grotto near Baise, where a machine was represented holding up a large stone as if to let it fall suddenly, and strike the coin at once. None of the ancient money was cast in moulds, excepting...
MEDALS.

Sect. VI.

Of the Preservation of Medals.

We now come to consider what is that distinguishes one medal from another, and why some are so highly prized more than others. This, in general, besides its genuineness, consists in the high degree of preservation in which it is. This, by Mr. Pinkerton, is called preservation of medals, and is by him regarded as good and as perfect. In this, he says that a true judge is so nice, that he will reject even the rarest coins if they appear defaced either in the figures or legend. Some, however, are obliged to content themselves with those which are a little rubbed, while those of superior taste and abilities have in their cabinets only such as are in the very state in which they came from the mint; and such he says, are the cabinets of Sir Robert Anlins, and Mr. Walpole of Roman silver at Strawberryhill. It is absolutely necessary, however, that a coin be in what is called good preservation; which in the Greek or Roman emperors, and the colonial coins, is supposed to be when the legends can be read with some difficulty; but when the preservation is perfect, and the coin just as it came from the mint, even the most common coins are valuable.

The fine ruft, like varnish, which covers the surface of brass and copper coins, is found to be the best preserver of them; and is brought on by laying in a foil impregnated with iron; but silver is susceptible of various kinds of rust, principally green and red; both of which yield to vinegar. In gold and silver coins the rust must be removed, as being prejudicial; but in brass and copper it is preservative and ornamental; a circumstance taken notice of by the ancients. "This fine rust (says Mr. Pinkerton), which is indeed a natural varnish not imitable by the art of man, is sometimes a delicate blue, like that of a turquoise; sometimes of a bronze brown, equal to that observable in ancient statues of bronze, and so highly prized; and sometimes of an exquisite green, a little on the azure hue, which last is the most beautiful of all. It is also found of a fine purple, of olive, and of a cream colour or pale yellow; which last is exquisitely, and shows the impression to as much advantage as paper of cream colour, used in all great foreign presses, does copperplates and printing. The Neapolitan patina (the rust in question) is of a light green; and when free from excrescence or blemish is very beautiful. Sometimes the purple patina gleams through an upper coat of another colour, with as fine effect as a variegated silk or gem. In a few instances a rust of a deeper green is found: and it is sometimes spotted with the red or bronze shade, which gives it quite the appearance of the East Indian stone called the blood-stone. These rufts are all, when the real product of time, as hard as the metal itself, and preserve it much better than any artificial varnish could have done; concealing at the same time not the most minute particle of the impression of the coin."

The value of medals is lowered when any of the letters of the legend are misplaced; as a suspicion of forgery is thus induced. Such is the case with many of those of Claudius Gothicus. The same, or even greater, diminution in value takes place in such coins as have not been well fixed in the dye, which has occasioned their slipping under the strokes of the hammer, and thus made a double or triple image. Many coins of this kind are found in which the one side is perfectly well-formed, but the other blundered in the manner just mentioned. Another blemish, but of smaller moment, and which to some may be rather a recommendation, is when the workmen through inattention have put another coin into the dye without taking out the former. Thus the coin is convex on one side, and concave on the other, having the same figure upon both its sides.

The medals said by the judges in this science to be countermarked are very rare, and highly valued. They marked a small stamp impressed upon them, in some an medal, head, in others a few letters, such as AUG.; N. PROBUS, &c., which marks are supposed to imply an alteration in the value of the coin; as was the case with the countermarked coins of Henry VIII. and Queen Mary of Scotland. Some have a small hole through them; sometimes with a little ring fastened in it, having been used as ornaments; but this makes no alteration in their value. Neither is it any diminution in the value of a coin that it is split at the edges; for coins of undoubted antiquity have often been found in this state, the cause of which has already been explained. On the contrary, this cracking is generally considered as a great merit; but Mr. Pinkerton supposes that one of these cracked coins has given rise to an error with respect to the wife of Carausius who reigned for some time in Britain. The inscription is read ORIUMA AUG.; and there is a crack in the medal just before the O of oriuma. Without this crack Mr. Pinkerton supposes that it would have been read FORTUNA AUG.

Some particular foils have the property of giving silver and silver a yellow colour as if it had been gilt. It naturally acquires a black colour through time, which any tarnished sulphureous vapour will bring on in a few minutes. From its being so susceptible of injuries, it was always mixed by the ancients with much alloy, in order to harden it. Hence the impressions of the ancient silver coins remain perfect to this day, while those of modern coins are obliterated in a few years. On this ac-
account Mr Pinkerton expresses a wish, that modern states would allow a much greater proportion of alloy in their silver coin than they usually do. As gold admits of no rust except that from iron abovementioned, the coins of this metal are generally in perfect conservation, and fresh as from the mint.

To clean old gold coins from this rust, it is best to steep them in aquafortis, which, though a very powerful solvent of other metals, has no effect upon gold, silver may be cleaned, by steeping for a day or two in vinegar, but more effectually by boiling in water with three parts of tartar and one of sea-fust; on both these metals, however, the rust is always in spots, and never forms an entire incrustation as on brass or copper. The coins of these two metals must never be cleaned, as they would thus be rendered full of small holes eaten by the rust. Sometimes, however, they are found so totally obscured with rust, that nothing can be discovered upon them; in which case it is best to clear them with a graver; but it may also be done by boiling them for 24 hours in water with three parts of tartar and one of alum; not sea-salt as in silver coins.

The high state of preservation in which ancient coins are usually found, is thus accounted for by Mr Hancarville. He observes, that the chief reason is the custom of the ancients always to bury one or more coins with their dead, in order to pay for their funeral over the river Styx. "From Phidias of Argos (says he) to Constantine I. are 36 generations: and from Magna Graecia to the Ephrups, from Cyrene to the Euxine Sea, Graecian arts prevailed, and the inhabitants amounted to about 30,000,000. There died therefore, in that time and region, not less than ten thousand millions of people, all of whom had coins of one sort or other buried with them. The tombs were sacred and untouched; and afterwards neglected, till modern curiosity or chance began to disclose them. The urn of Flavia Valentina, in Mr Trowley's capital collection, contained seven brass coins of Antoninus Pius and Elegabalis. Such are generally black, from being burnt with the dead. The best and finest coins were used on these occasions from respect to the dead; and hence their fine conservation. At Syracusa a skeleton was found in a tomb, with a beautiful gold coin in its mouth; and innumerable other instances might be given, for hardly is a funeral urn found without coins. Other incidents also conspire to furnish us with numbers of ancient coins, though the above-quoted circumstance is the chief cause of perfect conservation. In Sicily, the silver coins with the head of Proserpine were found in such numbers as to weigh 600 French livres or pounds. In the 16th century, 60,000 Roman coins were found at Modena, thought to be a military chest hid after the battle of Bedriacum, when Otho was defeated by Vitellius. Near Brefl, in the year 1760, between 20 and 30,000 Roman coins were found. A treasure of gold coins of Lyfimachus was found at Deva on the Marus; and Scarbo, lib. vii. and Paulus in Attic. tell that Pherennius was defeated by the Gete; at which time this treasure seems to have fallen into their hands.

Thus Mr Pinkerton, from the authority of Mr Hancarvilles and others; but considering these vast numbers of coins found in various places, it seems surprising how so few should now remain in the cabinets of the curious, as the same author informs us that the whole of the different ancient coins known to us amount only to about 80,000, though he owns that the whole cannot be esteemed accurate.

The most difficult and the most important thing in the whole science of medals is the method of distinguishing the true from the counterfeit. The value put upon ancient coins made the forgery of them almost coeval with the science itself; and as no laws inflict a punishment upon such forgers, men of great genius and abilities have undertaken the trade; but whether to the real detriment of the science or not, is a matter of some doubt; for if only exact copies of genuine medals are sold for the originals, the imposition may be deemed trifling; but the cafe must be accounted very different, if people take it upon them to forge medals which never existed. At first the forgeries were extremely gross; and medals were forged of Priam, of Ariloto, Artemisia, Hannibal, and most of the other illusrious personages of antiquity. Most of these were done in such a manner, that the fraud could easily be discovered; but others have imposed even upon very learned men. Mr Pinkerton mentions a remarkable medal of the emperor Heraclius, representing him in a chariot on the reverse, with Greek and Latin inscriptions, which Joseph Scaliger and Lipsius imagine to have been struck in his own time, but which was certainly issued in Italy in the 15th century. "Other learned men (says our author) have been strangely misled when speaking of coins; for to be learned in one subject excludes not gross ignorance in others. Budaes, de Asse, quotes a denarius of Cicero, m. tert. Eraclius, in one of his Epistles, tells us with great gravity, that the gold coin of Brutus' struck in Thrace, Rosam, bears the patriarch Noah coming out of the ark with his two sons, and takes the Roman eagle for the dove with the olive branch. Winkelmann, in his letters, informs us, that the small brass piece with Virgil's head, Reverse spo, is undoubtedly ancient Roman; and adds, that no knowledge of coins can be had out of Rome: but Winkelmann, so convenient in staters, knew nothing of coins. It is from other artists and other productions that any danger of deceit arises. And there is no wonder that even the skilful are misled by such artists as have used this trade; for among them appear the names of Victor Cambello, Giovanni del Cavino, called the Paduan, and his son Alessandro Baffiano engaged by excellent artists.
were Dervict of Florence who confined himself to medallions, and Cogornier who gave coins of the 50 tyrants in small brases. The chief part of the forgeries of Greek medals which have come to my knowledge are of the first mentioned, and a very great kind, representing persons who could never appear upon coin, such as P trium, Æneas, Plato, Alcibiades, Artemis, and others. The real Greek coins were very little known or valued till the works of Goltzius appeared, which were happily posterior to the era of the grand forgers. Why later forgers have seldom thought of counterfeitting them cannot easily be accounted for, if it is not owing to the masterly workmanship of the originals, which sets all imitation at defiance. Forgeries however, of most ancient coins may be met with, and of the Greek among the rest.

"The forgeries are more conspicuous among the Roman medals than any other kind of coins: but we are not to look upon all these as the work of modern artists. On the contrary, we are assured that many of them were fabricated in the times of the Romans themselves, some of them being even held in more estimation than the genuine coins themselves on account of their being plated, and otherwise executed in a manner to which modern forgers could never attain. Even the ancients held some of these counterfeits in such estimation, that Pliny informs us there were frequently many true denarii given for one false one." Caracalla is said to have coined money of copper and lead plated with silver; and plated coins, the work of ancient forgers often occur of many Greek cities and princes; nay, there are even forgeries of barbaric coins. Some Roman coins (says Mr Pinkerton) are found of iron or lead plated with brases, perhaps trials of the skill of the forger. Iron is the most common; but one decurio of Nero is known of lead plated with copper. Neumann judiciously observes, that no historic faith can be put in plated coins, and that the counterfeits are always exactly circular, which is not the case with ancient medals, especially after the time of Trajan.

The Paduan forgeries may be distinguished from those of inferior artists by the following marks: 1. The former are seldom thinner than the ancient. 2. They are very seldom appear as worn or damaged, but the others very frequently, especially in the reverse, and legend of the reverse, which sometimes, as in forged Othos, appear as half consumed by time. 3. The letters in moulds taken from the antique coins have the rudenes of antiquity. 4. False varnish is commonly light green or black, and shines too much or too little. 5. The sides of forged coins are frequently quite smooth, and undistinguishable from the ancient, though to accomplish this requires but little art. 6. Counterfeit medals are frequently as irregular in their form as the genuine; but the Paduan are generally circular, though false coins have often little pieces cut off, in perfect imitation of the genuine. 7. In cast coins the letters do not go sharp down into the metal, and have no fixed outline; their minute angles, as well as those of the draperies, are commonly filled up, and have not the sharpness of the genuine kind. Where the letters or figures are faint, the coin is greatly to be suspected.

The letters form the great criterion of medals: the letters of the ancient being very rude, but the modern otherwise; principal the reason of which, according to Cenini, is, that the ancients engraved all their matrices with the graver on the reverse side of the coin, while the modern forgers strike theirs with a punch. According to Vico, the false patina is green, black, Vico's ac-ruffet, brown, grey, and iron-colour. The green is count of made from verdigris, the black is the smoke of sulphur, the grey is made of chalk steeped in urine, the coin being left for some days in the mixture. The ruffet is next to the natural, by reason of its being a kind of froth which the fire forces from ancient coins; but when false it shines too much. To make it they frequently took the large brases coins of the Poelmies, which were often corroded, and made them red hot in the fire; put the coins upon them, and a fine patina adhered. Our author does not say in what manner the iron-covered patina was made. "Sometimes (adds he) they take an old defaced coin, covered with real patina, and damp it anew; but the patina is then too bright in the cavities, and too dull in the protuberances. The trial of brases coins with the true medals is as hard as the metal itself. Instead of the greasy black varnish above mentioned, indeed, they have sometimes a light green one, fp:ted with a kind of iron marks, and is composed of sulphur, verdigris, and vinegar. It may frequently be distinguished by the hairstrokes of the pencil with which it was laid on being visible upon it. 5. The sides are either filed or too much smoothed by art, or bear the marks of a small hammer. 6. The counterfeits are always exactly circular, which is not the case with ancient medals, especially after the time of Trajan.

Mr Pinkerton informs us, that all medallions from Julius Caesar to Adrian are much to be suspected of forgery; the true medals of the first 14 emperors being

Medals cast from the Paduan forgeries.

Sect. VII.

How to distinguish true from counterfeit medals.

I. The second class of counterfeit medals contains those cast from moulds taken from the Paduan forgeries, and others done by eminent masters. There are sometimes more difficult to be discovered than the former, because calling them they can give any degree of thickness they please; and, filling the small hollows with matter, they retouch the letters with a graver, and cover over the whole with varnish. The instructions already given for the former class, however, are also useful for those of the second, with this addition, that medals of this class are generally lighter than the genuine, because fire rareifies the metal in some degree, while that which is struck is rather condensed by the blows. In gold and silver medals there cannot be any deception of this kind; because these metals admit not of patching, and consequently the varnish betrays the imposition. The marks on the file on the margin of those of the second class are a certain sign of forgery; though these do not always indicate the forgery to be of modern date, because the Romans often filed the edges of coins to accommodate them to the length of their pockets, as quarter guineas are sometimes put into the bottom of punch ladders. It is common to imitate the holes of medals made by time by means of aqua-fortis; but this destroys the sides of a coin more effectually than if it had been eaten into naturally. The fraud, however, is not easily distinguished.

III. Medals cast in moulds from an antique.—In this mode some forgers, as Beauvais informs us, have been so very careful, that they would melt a common medal of the emperor whom they meant to counterfeit, left the quality of the metal should betray them. This (says Mr Pinkerton) has been done in the silver Septimius Severus, with the reverse of a triumphal arch, for which a common coin of the same prince has been melted; and in other instances. Putting metals in the fire or upon hot iron to cleanse them, gives them an appearance of being cast; for some part of the metal being softer than the other will run, which makes this one of the worst methods of cleaning medals.

The directions given for discovering the two former deceptions hold good also in this.

IV. Ancient medals retouched and altered.—This is a class of counterfeits more difficult to be discovered than any other. The art (says Mr Pinkerton) is exercised in this class is astonishing; and a connoisseur is the least apt to suspect it, because the coins themselves are in fact ancient. The acute minds of the Italian artificers exercised themselves in this way, when the other forgeries became common and known. With graving tools they alter the portraits, the reverses, and the inscriptions themselves, in a surprising manner. Of a Claudius struck at Antioch they make an Otho; of a Faustina, a Titania; of a Julia Severa, a Didia Clarice; of a Maximiainus, a Pefcinus, &c. Give them a Marcus Aurelius, he starts up a Pertinax, by thickening the beard a little, and enlarging the nose. In short, wherever there is the least resemblance in portraits, reverses, or legends, an artist may from a trivial medal generate a most scarce and valuable one. This fraud is indistinguishable by the false varnish which sometimes marks it; but, above all, by the letters of the legend, which are always altered. Though this be sometimes done with an artifice almost miraculous, yet most commonly the characters struggle, are dismantled, and not in a line.

In counterfeits of this kind sometimes the obverse is not touched, but the reverse made hollow, and filled with matter coloured like the coin, and engraven with such devices and legends as was most likely to bring a great price; others are only retouched in some minute parts, by which, however, the value of the coin is much diminished. Against all these arts (says Mr Pinkerton), severe scrutiny must be made by the purchaser upon the medal itself; and the investigation and opinion of eminent antiquaries had upon its being altered, or genuine as it is issued from the mint.

V. Medals impressed with new devices, or folded.—Medals in the first article of this class the reverses have been totally filed off, and new ones impressed with a dye and hammer. This is done by putting the face or obverse, which ever is not touched, upon different folds of pasteboard, afterwards applying the dye and striking it with a hammer. The forgery in this class is very easily discovered, as the devices and inscriptions on the coins but are known not to exist on true medals: as the Pons Aelius on the reverse of Adrian; the Expeditio Judaica of the same emperor, &c. The difference of fabrication in the face or reverse will be discovered at the first glance by any person of skill.

The folded medals consist of two halves belonging to different medals, sawed through the middle and then joined with folder. This mode of counterfeiting is common in silver and brass coins. They will take an Antoninus, for example, and saw off the reverse, then folder to the obverse which they have treated in the same manner. This makes a medal, which from an unknowing purchaser, will bring an hundred times the price of the two coins which compose it. When the deceit is used in brass coins, they take care that the metals be of one hue; though indeed some pretenders in this way sometimes folder copper and brass together, which at once reveals the deceit. Medals which have a portrait on each side, and which are generally valuable, are the most liable to a spurious of this fraud. To a very nice eye the minute ring of folder is always visible; and upon inferring a graver, the fabrication falls into halves.

In the same manner reverses are sometimes foldered to faces not originally belonging to them, as one mentioned by Petre Jobert of Domitian with an amphitheatre, a reverse of Titus joined to it. Another art is sometimes made use of in this kind of counterfeits, of which there is an instance of the temple of Janus upon Nero's medals; where the middle brass is taken off, and infused in a cavity made in the middle of a large coin of that prince. In the coins of the lower empire, however, the reverses of medals are sometimes so connected with their obverses, that a suspicion of forgery sometimes occurs without any foundation. They are met with most commonly after the time of Gallienus, when such a number of usurpers arose, that it was difficult to obtain an exact portrait of their features; the coiners had not time, therefore, to strike a medal for thee as they could have done for other emperors who reigned longer. Hence, on the reverse
MEDALS.

VI. Plated medals, or those which have clefts. — It has been already remarked, that many true medals are cracked in the edges; owing to the repeated strokes of the hammer, and the little degree of ductility which the metal possesses. This the forgers attempt to imitate by a file; but it is easy to distinguish between the natural and artificial cleft by means of a small needle. The natural cleft is wide at the extremity, and appears to have a kind of almost imperceptible filmaments; the edges of the crack corresponding with each other in a manner which no art can imitate.

The plated medals which have been forged in ancient times were long supposed to be capable of refiling every effort of modern imitation; but of late years, some ingenious rogue (says Mr. Pinkerton) thought of piercing the medals of silver with a red hot needle, which gave a blackness to the inside of the coin, and made it appear plated to an injudicious eye. This fraud is easily distinguished by scraping the inside of the metal. It is, however, very difficult to distinguish the forgeries of rude money when not cast; and our author gives no other direction than to consult a skilful medallist. Indeed, notwithstanding all the directions already given, this seems to be a resource which cannot by any means with safety be neglected. A real and practical knowledge of medals "is only to be acquired (says he) by seeing a great number, and comparing the forged with the genuine. It cannot therefore be too much recommended to the young collector, who wishes to acquire some knowledge in this way, to visit all the sales and cabinets he can, and to look upon all ancient medals with a very microscopic eye. By these means only is to be acquired that ready knowledge which enables at first glance to pronounce upon a forgery, however ingenious. Nor let the science of medals be from this concluded to be uncertain; for no knowledge is more certain and immediate, when it is properly studied by examination of the real objects. A man who buys coins, trusting merely to his theoretical knowledge of medallic books, will find himself woefully mistaken. He ought to study coins first, where only they can be studied, in themselves. Nor can it be matter of wonder or implication of caprice, that a medal of skill should at one preception pronounce upon the veracity or falsehood of a medal; for the powers of the human eye, employed in certain lines of science, are amazing. Hence a student can distinguish a book among a thousand similar, and quite alike to every other eye; hence a shepherd can discern, &c.: hence the medallist can say in an infant, "this is a true coin, and this is a false;" though to other people no distinction be perceptible."

Forgeries of modern coins and medals, Mr. Pinkerton observes, are almost as numerous as of the ancient. The satyric coin of Louis XII. PerdiP Babylons nomem, is a remarkable instance; the false coin is larger than the true, and bears date 1512. The rude coins of the middle ages are very early forged, and forgeries have accordingly become common. Forged coins of Alfred and other early princes of England have appeared, some of which have been done with great art. "The two noted English pennies of Rich. I. says our author, are of this stamp; and yet have imposed upon Meffrs. Folkes and Snelling, who have published them as genuine in the two books upon English coins. But they were fabricated by the late Mr. White of Newgate-street, a noted collector, who contaminated an otherwise fair character by such practices. Such forgeries, though easy, require a skill in the history and coining of the time which luckily can hardly fall to the lot of a common Jew or mechanic forger. But the practice is detectable, were no gain propounded: and they who floup to it must suppose, that to embarras the path of any science with forgery and futility, implies no infancy. In forgeries of ancient coin, the fiction is perhaps sufficiently stoned for by the want skill required; and the artifié may plausibly allege, that his attention was not to deceive, but to excite his utmoft powers, by an attempt to rival the ancient masters. But no possible apology can be made for forging the rude money of more modern times. The crime is certainly greater than that which leads the common coiner to the galloways; inasmuch as it is committed with more ease, and the profit is incomparably larger."

Sect. VIII. Of the Value of Medals.

All ancient coins and medals, though equally genuine, are not equally valuable. In medals, as well as in every thing else, the scarcity of a coin flamps a value upon it which cannot be otherwise derived from its intrinsic worth. There are four or five degrees of rarity reckoned up; the highest of which is called unique. The cause is generally ascribed to the fewness of number thrown off originally, or to their having been called in, and recasted in another form. To the former cause Mr. Pinkerton ascribes the scarcity of the copper of Otho and the gold of Pescennius Niger; to the latter that of the coinage of Caligula; "though this last (says he) is not of singular rarity; which flows that even the power of the Roman senate could not annihilate an established money; and that the first cause of rarity, arising from the small quantity originally struck, ought to be regarded as the principal."

In the ancient cities Mr. Pinkerton ascribes the scarcity of coin to the poverty or smallness of the state; the scarcity but the scarcity of ancient regal and imperial coins of medals in ancient cities, Causes of

93 Forgeries of modern coins.

94 Sometimes the rarest coins lose their value, and become common. This our author ascribes to the high price given for them, which tempts the poseffors to bring them to market; but chiefly to the discovering of hoards of them. The former cause took place with Queen Anne's farthings, some of which formerly sold at five guineas; nay, if we could believe the newspaper,

pens, one of them was some years ago sold for 560 l., the latter with the coins of Cunna, the Danish king of England: which were very rare till a had of them was discovered in the Orfordays. As discoveries of this kind, however, produce a temporary plenty, so when they are dispersed the former scarcity returns; while on the other hand some of the common coins become rare through the mere circumstance of neglect.

As double the number of copper-coins of Greek cities are to be met with that there are of silver, the latter are of consequence much more esteemed; but the reverse is the case with those of the Greek princes. All the Greek coin of silver are very rare except those of Athens, Corinth, Melfina, Dyrrachium, Maecilla, Syracuse, and some others. Of the Greek monarchical coins the most rare are the tetradrachms of the kings of Syria, the Ptolemaics, the sovereigns of Macedon and Ethiopia, excepting those of Alexander the Great and Lydiamachus. Those of the kings of Cappadocia are of a smaller size, and scarce to be met with. Of those of Numidia and Mauritania, the coins of Juba the father are common: but those of the son and nephew Ptolemy scarce. Coins of the kings of Sicily, Parthia, and Judea, are rare; the last very much so. We meet with no coins of the kings of Arabia and Comagene except in bronzes; those of the kings of Bohorus are in electrum, and a few in bronzes, but all of them rare; as are likewise those of Philetanis king of Pergamus and of the kings of Pontus. In the year 1775, a coin of Mithridates sold for 12s. 6d. Didrachms of all kings and cities are scarce excepting those of Corinth and her colonies; but the gold coins of Philip of Macedon, Alexander the Great and Lydiamachus, as has already been observed, are common. The silver tetradrachms of all kings bear a very high price. The didrachm of Alexander the Great is one of the rarest of the smaller Greek silver coins; some of the other princes are not uncommon.

In most cases that money of the Greek monarchs is scarce; but that of Hiero I. of Syracuse is uncommonly plenty, as well as that of several of the Ptolemaics.

The most rare of the confular Roman coins are those reformed by Trajan: of the others the gold confular coins are the most rare, and the silver the most common; excepting the coin of Brutus with the cap of Liberty already mentioned, with some others. Some of the Roman imperial coins are very scarce, particularly those of Otho in bronzes: nor indeed does he occur at all on any coin struck at Rome: but the reason of this may with great probability be supposed to have been the shortness of his reign. His portrait upon the bronzes coins of Egypt and Antioch is very bad; as well as almost all the other imperial coins of Greek cities. The best likeness is on his gold and silver coins; the latter of which are very common. The Greek and Egyptian coins are all of small or middling size, and have reverses of various kinds; those of Antioch have Latin legends, as well as most of the other imperial coins of Antioch. They have no other reverse but the SC in a wreath, excepting in one instance or two of the large and middle bronzes, where the inscriptions are in Greek. Latin coins of Otho in bronzes, with figures on the reverse, are certainly fake; though in the cabinet of D’Ennery at Paris there was an Otho in middle bronzes restored by Titus, which was esteemed genuine by connoisseurs.

The lead coins of Rome are very scarce: Most leaden Roman coins are pieces struck or cast on occasion of the Saturnalia: other are tickets for festivals and exhibitions, both private and public. The common tickets for theatres were made of lead, as were the contornacci; perpetual tickets, like the English silver tickets for the opera. Leaden medallions are also found below the foundations of pillars and other public buildings, in order to perpetuate the memory of the founders. From the time of Augustus also we find that leaden seals were used. The work of Ticorini upon this subject, intitled Pisoni Antiochis, is much recommended by Mr Pinkerton.

The Roman coins, which have been blundered in the manner formerly mentioned, are very rare, and undervalued by the connoisseurs. The blunders in the legends of the coins, which in all probability are the mere effects of accident, have been so far imitated by some medallists, that they have given rise to imaginary emperors who never existed. A coin of Faustina, which on the reverse boueci., e puzzled all the German antiquaries, till at last Klotz gave it the following facetious interpretation: =ine omni utilitate Jeflamini tantas ineptias.

The heptarchic coins of England are generally rare except those call flycre, which are very common, as well as those of Burgred king of Mercia. The coins of Alfred which bear his bull are scarce, and his money much more so. Those of Haraldknut are so rare, that it was even denied that they had an existence; but Mr Pinkerton informs us, that there are three in the British museum, upon all of which the name harthcanut is quite legible. No English coins of King John are to be met with, tho’ there are some Irish ones; and only French coins of Richard L “Leake (says Mr Pinkerton) made a strange blunder in ascribing coins of different kings with two faces, and otherwise spoiled in the flamping, to this prince; and which, as usual, he has been followed by a milled number.”

Coins of Alexander II. of Scotland are rather scarce, but of Alexander III. are more plentiful. Those of John Balliol are rare, and none of Edward Balliol to be found.

Sect. IX Of the Purchase of Medals.

Medals are to be had at the shops of goldsmiths and silversmiths, with those who deal in curiosities, &c. but in great cities there are professed dealers in them. The best method of purchasing medals, however, is that of buying whole cabinets, which are every year exposed to auction at London. In these the rare medals are fold by themselves, but the common ones are put up in large lots, so that the dealers commonly purchase them. Mr Pinkerton thinks it would be better that medals were sold one by one; because a lot is often valued and purchased for the sake of a single coin; while the others separately would sell for perhaps four times the price of the whole lot. “If any man of common sense and honesty (says Mr Pinkerton)
M E D A L S.

Sect. IX.

Pur- The name of weights given to the ancient Roman aces is, according to our author exceedingly improper; as that people had weights of lead and brass, without the least appearance of a portrait upon them. These denote the weight by a certain number of knobs; and have likewise small fleur-ettes engraved upon them. According to Mr Pinkerton, whenever we meet with a piece of metal flamped on both sides with bulls and figures, we may lay it down as a certain rule that it is a coin; but when slightly ornamented and marked upon one side only, we may with equal certainty conclude it to be a weight.

The ancient Roman aces are worth from 2s. to 2l. Price of the according to the singularity of their devices. Conflar- lar gold coins are worth from 1l. to 5l. Pompey, with his sons 2l. and the two Brutis 2s. The silver coins are universally worth from a shilling to half a crown, excepting that of the cap of Liberty and a few others, which if genuine will bring from 10s. to 5l. The confular copper bears an equal price with the silver, but is more rare; the confular silver coins reftored by Trajan are worth 20s. each.

With regard to the Roman imperial coins, it is to be observed, that some of those which belong to princes whose coins are numerous, may yet be rendered extremely valuable by uncommon reverses. Mr Pinkerton particularly points out that of Augustus, with the legend C. MAURUS TAOVS, which is worth three guinea's, though the silver coins of that prince in general are not worth above a shilling. In like manner, the common gold coins of Trajan are not worth above twenty shilling's, while those with BAVILICA UFA, Forum Trajan, Divi nero et Trajanus, Pater, Divi Neron et Plinna Ang. Profelito Aug. Regina Aflignata, Rex Partibus, and some others, bear from three to 10 bound. The ticket medals belong to the Roman Senate, and are worth from three to ten shilling's. The forged coins and medallions of the Pudian fell from one to three shilling's each.

Of the coins of other nations, those of Hilderic the Barbaric king of the Vandals are in silver, and worth 10s. each. The small brass of Atharanic, 5s.; the gold of Theodoric 2l.; the second brass of Theodahat 5s.; the second brass of Badueta rare, and worth 10s.; the third brass, 3s. The British coins are very rare, and worth from ten shilling's to two guinea's each, sometimes much more. Medals with unknown characters are always scarce and dear. Saxon pennies of the heptarchy are rare, and worth from ten shilling's to ten pounds, according to their scarcity and preservation. The coins of the English kings are common; those of Edward the Confessor, in particular; others are rare and worth from ten shilling's to two guinea's, while two of Hardynkute are worth no less than ten guinea's. The gold medals of Henry, in 1545, and the coronation of Edward, are worth 20l. each; the Mary of Trezzo, 3l.; Simon's head of Thurloe in gold is worth 12l.; his oval medal in gold upon Blake's naval victory at sea is worth 30l.; and his trial piece, if brought to a sale, would, in Mr Pinkerton's opinion, bring a still higher price. The medals of Queen Anne, which are intrinsically worth above two guinea's and a half, fell for about 3l. each; the silver, of the size of a crown piece, fell for 10s. and the copper from five to ten shilling's. Daffier's copper pieces fell from two to five shilling's, and a few bear a higher price.

The Scottish gold coins fell higher than the Eng-
Medals.

Arrangement, &c.

Medals are divided into two classes: those which are made to commemorate events, and those which are made to commemorate persons. The first class includes such medals as are given to celebrate the accession of a new sovereign, or the conclusion of a treaty, or the peace of a war. The second class includes such medals as are given to commemorate the death of a ruler, or the captivity of a prince.

The arrangements of these medals are generally based on the principles of symmetry and harmony. The design is usually divided into two or more parts, each part representing a different aspect of the event or person being commemorated. The use of a radiating or Portland-crown medallion is typical of this style.

The use of medals as a form of visual representation of historical events or persons is a very common practice. The use of such medals is not limited to the time of Alexander the Great, but rather it continues to the present day.

The laurel wreath is a common symbol on medals, representing victory and honor. It is often found on medals that commemorate military victories.

The use of symbols and inscriptions on medals is also common. These can include the name of the ruler, the date of the event, or the name of the city or province where the event occurred.

In conclusion, the use of medals as a form of visual representation of historical events or persons is a very common practice. The use of such medals is not limited to the time of Alexander the Great, but rather it continues to the present day. The use of symbols and inscriptions on medals is also common.
guftpup, the augurs having a particular kind of gown
called lana, with which they covered their heads when
observing an omen. In latter times this implies only
consecration, and is common in coins of emperors.
It is first met with on the coins of Claudius Gothicus
as the mark of consecration of an emperor. The
nimbus, or glory, now appropriated to saints, has been
already mentioned. It is as ancient as Augustus, but
is not to be met with on many of the imperial medals,
even after it began to be appropriated by them. There
is a curious coin, which has upon the reverse of
the common piece with the head of Rome Urbs Roma,
in large brafs, Contantine I. sitting amidst victories
and genii, with a triple crown upon his head for Eu-
rope, Asia, and Africa, with the legend Securitas
Roma.

In general only the bust is given upon medals,
though sometimes half the body or more; in which
latter case the hands often appear with emblems of ma-
jesty in them; such as the globe said to have been
introduced by Augustus as a symbol of universal domi-
nion; the sceptre sometimes confounded with the con-
sular staff, a roll of parchment, the symbol of legis-
lative power, and an handkerchief expressive of the power
over the public games, where the emperor gave the
signal. Some princes hold a thunderbolt, showing that
their power on earth was equal to that of Jupiter in
Heaven; while others hold an image of Victory.

Medals likewise afford a good number of portraits
of illustrious men; but they cannot easily be arranged
in chronological order, so that a series of them is not
to be expected. It is likewise vain to attempt the
formation of a series of gods and goddesses to be found
on ancient coins. Mr Pinkerton thinks it much bet-
ter to arrange them under the several cities or kings
whose names they bear. A collection of the portraits
of illustrious men may likewise be formed from medals
of modern date.

The reverse of ancient Greek and Roman coins
afford an infinite variety of instruction and amusement.
They contain figures of deities at full length, with
their attributes and symbols, public symbols and diver-
fions, plants, animals, &c. &c. and in short almost
every object of nature or art. Some have the portrait
of the queen, son, or daughter of the prince
whose image appears on the face or obverse; and these
are esteemed highly by antiquaries, not only because
every coin stamped with portraits on both sides is ac-
counted valuable, but because they render it certain
that the person represented on the reverse was the
wife, son, or daughter of him who appears on the
obverse; by which means they assist greatly in the ad-
justing of a series. Some, however, with two portraits
are common, as Augustus, the reverse of Caligula;
and Marcus Aurelius, reverse of Antoninus Pius.

We find more art and design in the reverse of the
Roman medals than of the Greek: but, on the other
hand, the latter have more exquisite relief and work-
manship. The very ancient coins have no reverses,
excepting a rude mark struck into the metal remi-
bling that of an instrument with four blunt points on
which the coin was struck, and was owing to its ha-
vings been fixed by such an instrument on that side
to receive the impression upon the other. To this
succeeds the image of a dolphin, or some small animal,
in one of the departments of the rude mark, or in an
hollow square; and this again is succeeded by a more
perfect image, without any mark of the hollow square.

Some of the Greek coins are hollow in the reverse, as
those of Caelonia, Crotona, Metapontum, and some
other ancient cities of Magna Grecia. About 500
B.C. perfect reverses appear on the Greek coins, of
exquisite relief and workmanship. The very muf-
cles of men and animals (says Mr Pinkerton) are seen,
and will bear inspection with the largest magnifier as
ancient gems. The ancients certainly had not eyes
different from ours; and it is clear that they must have
magnified objects. A drop of water forms a micro-
scope; and it is probable this was the only one of the
ancients. To Greek artists we are indebted for the
beauty of the Roman imperial coins; and these are
so highly finished, that on some reverses, as that of
Nero's decurion, the adventus and progression of vari-
ous emperors, the fundator paxis of Severus, the fea-
tures of the emperor, riding or walking, are as exact
as on the obverse. But though the best Greek artis-
tes were called to Rome, yet the Greek coins under
the Roman emperors are sometimes well executed,
and always full of variety and curiosity. No Roman
or Etruscan coins have been found of the globular
form, or indented on the reverse like the early Greek.
The first Greek are small pieces of silver, while the
Roman are larger masts of copper. The former are
fruck; the latter cast in moulds. The reverses of the
Roman coins are very uniform, the prow of a ship, a
car, or the like, till about the year 100 B.C. when
various reverses appear on their consular coins in all
metals. The variety and beauty of the Roman im-
perial reverses are well known. The medallist much va-
lues those which have a number of figures; as the
Pudica Faustina, of Faustina, a gold coin no larger
than a fiscence, which has 12 figures: that of Trajan,
regna aeternata, has four; the congiarium of Nerva
five; the allocation of Trajan seven; of Hadrian 10; of
Probus 12. Some Roman medals have small figures
on both sides, as the Apollo Danilo of Julian II.
Such have not received any peculiar name among the
medalists. Others have only a reverse, as the noted
Spitiatri,
which have numerals I. II. &c. on the
obverse.

The names of the deities represented on the rever-
se of the de-

The principal symbols of the divine attributes to
be met with on the Greek medals are as follow:
1. Jupiter is known on the coins of Alexander the
Great by his eagle and thunderbolts; but when the
figure occurs only on the obverse of coins, he is dis-
tinguished by a laurel crown, and plaid bearded coun-
tenance. Jupiter Ammon is known by the ram's-
horn twisting round his ear; a symbol of power and
strength, assumed by some of the successors of Alex-
ander the Great, particularly by Lycurgus.
2. Neptune is known by his trident, dolphin, or being drawn by sea-horses; but he is seldom met with on the Grecian coins.

3. Apollo is distinguished by an harp, branch of laurel, or tripod; and sometimes by a bow and arrows. In the character of the Sun, his head is surrounded with rays; but when the bust only occurs, he has a fair round face, and is crowned with laurel. He is frequent on the coins of the Syrion princes.

4. Mars is distinguished by his armour, and sometimes by a trophy on his shoulders. His head is armed with a helmet, and has a ferocious countenance.

5. Mercury is represented as a youth, with a small cap on his head, wings behind his ears and on his feet. He is known by the cap, which resembles a small hat, and the wings. He appears also with the caduceus, or wand crowned with pomegranates, or purples, which he holds in his hand.

6. Eléphantus is known by his bulk; beard, and his leaning on a club with a serpent twisted round it. He sometimes occurs with his wife Hygeia or Health, with their son Telêphorus or Convalescence between them.

7. Bacchus is known by his crown of ivy or vine, his diadem and horn, with a tyger and satyrs around him.

8. The figure of Hercules is common on the coins of Alexander the Great; and has frequently been mistaken for that of the prince himself. He appears sometimes as a youth and sometimes with a beard. He is known by the club, lion's skin, and remarkable apparent strength; sometimes he has a cup in his hand, and a poplar tree, as a symbol of vigour, is sometimes added to the portrait.

9. The Egyptian Serapis is known by his bulky beard, and a measure upon his head.

10. Apis is delineated in the form of a bull, with a flower of the lotos, the water lily of the Nile, supposing by Macrobius to be a symbol of creation and Jamblichs tells us, that Odris was thought to have his throne in his head.

11. Harpocrates, the god of Silence, appears with his finger on his mouth; sometimes with the sistrum in his left hand; a symbol common to most of the Egyptian deities.

12. Canopus, another Egyptian deity, appears in the shape of a human head placed on a kind of pitcher. “This deified pitcher (says Mr Pinkerton) seems to refer to an anecdote of ancient superstition, which, I believe, is recorded by Plutarch. It seems some Persian and Egyptian priests had a contract of which their deities had the superintendency. The Egyptian said, that a single vase, sacred to Serapis, would extinguish the whole power of the Persian deity of fire. The experiment was tried; and the wily Egyptian, boring holes in the vase and flooding them with wax, afterwards filled the vase with water; which, gushing through the holes as the wax melted, extinguished the Persian deity. Hence the vase was deified.”

13. The Holy Senate and Holy People, appear frequently on Greek imperial coins, sometimes represented as old men with beards, at others as youths.

The deities represented on medals are:

1. Juno, represented by a beautiful young woman, sometimes with a diadem, sometimes without any badge, which is reckoned a sufficient distinction, as the other goddesses all wear badges. Sometimes she appears as the goddess of marriage; and is then veiled to the middle and sometimes to the toes. She is known by the peacock, a bird sacred to her from the fable of Argus.

2. Minerva is very common on the coins of Alexander the Great; and her bust has been mistaken by the celebrated painter Le Brun for the hero himself. She is very easily distinguished by the helmet. Her symbols are, her armour; the spear in her right hand, and the aegis, with a Medusa's head, in her left; an owl commonly standing by her.

3. Diana of Ephesus is commonly represented on the Greek imperial coins; and appears with a great number of breasts, supposing to denote universal nature. She is supported by two deer, and carries a panier of fruit upon her head. The bust of this goddess is known by the crescent on her brow, and sometimes by the bow and quiver at her side.

4. Venus is known by an apple, the prize of beauty, in her hand. Sometimes she is distinguished only by her total want of drefs; but is always to be known by her extraordinary beauty, and is sometimes adorned with pearls about her neck.

5. Cupid is sometimes met with on the Syrian coins, and is known by his infancy and wings.

6. Cybele is known by a turreted crown and lion; or is seen in a chariot drawn by lions.

7. Ceres is known by her garland of wheat, and is common on the Sicilian coins; that land being remarkable for its fertility. Sometimes she has two serpents by her, and is sometimes drawn in a chariot by them. She carries in her hands the torches with which she is said to have gone in search of her daughter Proserpine.

8. Proserpine herself is sometimes met with on coins with the name of Atis or the girl.

9. The Egyptian Isis has a bud or flower on her head; a symbol of the perpetual bloom of the inhabitants of heaven. She carries also a sistrum in her hand.

10. The Sidonian Astarte appears on a globe supported on a chariot with two wheels, and drawn by two horses.

There are the deities most commonly represented on the Greek coins. The more uncommon are, Saturn with his fcythe, or with a hook on the Heraclean coins; Vulcan with his tongs, on the reverse of a coin of Thyatira, repreented at work in the presence of Minerva. Adr anus, a Sicilian god, is sometimes represented on coins with a dog. Anubis, an Egyptian deity, has a dog's head. Aatis is known by his Phrygian bonnet; Caltor and Pollux by a star on the head of each; Dis, by his old face, dishevelled hair and beard, and a hook; Flora by her crown of flowers; Nemesis by her wheel, and Pan by his horns and ears belonging to some kind of beast.

There are likewise to be found on medals many Table of different symbols by themselves; of the most remarkable, Symbols, able of which we shall give the following table, with their significations:

- 41. Mituus, or twisted wand.
- 42. Apex, or cap with flyings.
- 43. Thetis, or chariot employed to carry images.
- 44. Peacock.
- 45. Eagle.

The legends put upon medals are designed as ex-Legends of plannations of them; but as the compass of even the Medals, largest coins do not admit of any great length of inscription, it has always been found necessary to use abbreviations; and in readily deciphering these lies a considerable part of the difficulty of the science. This, however, is greater in the Roman than in the Greek medals; for the Greeks commonly insert as much of the word as is sufficient to enable us easily to understand its meaning; but it is common for those who attempt to explain letters that do not often occur, to fall into very ridiculous errors. Of this Mr Pinkerton gives a most remarkable instance in Fortunius Lictor, a learned man, who finding upon a coin of Augustus, the letters \textit{Lictor} signifying the 14th year of that emperor's reign, imagined that they signified \textit{Lucernae inventi Delta}; \textit{\textquotedblright}Delta invented lanthorns;\textquotedblright; and others supposed to be a river. Accolony drawn from one legion. Apis, strength or securitie. Peace and concord. Abundance. Priestshood. Baton of command.

- 32. Cornucopia.
- 33. Pontificial hat.
- 34. Parazonium.

### Sect. XI.

Besides the ordinary coins of the ancients, which passed in common circulation through the country, there were others of a larger size, which are now termed medallions. These were struck on the commencement of the reign of a new emperor and other solemn occasions: frequently also, by the Greeks in particular, as monuments of gratitude or of flattery. Sometimes they were mere trial or pattern pieces; and those abound after the time of Maximian with the words \textit{Tres Moneta} on the reverse. The common opinion

The world preserved, &c.
is, that all the Roman pieces of gold exceeding the
denarius aureus, all in silver exceeding the
denarius, and all in brasses exceeding the
electrum, went under the
denomination of medalliones: but Mr Pinkerton
thinks that many of these large pieces went in
circulation, though not very commonly, as the five and
two guinea pieces, silver crowns, &c. do in Britain.
The finest medalliones were presented by the mint-masters
to the emperor, and by the emperor to his friends,
as specimens of fine workmanship. The belt we have
at present are of brass, and many of them composed
of two sorts of metal; the centre being copper, with
a ring of brass around it, or the contrary: and the
inscription is sometimes confined to one of the metals,
sometimes not. There is a remarkable difference be-
tween the Greek and Roman medalliones in point of
thickness; the latter being frequently three or four
lines thick, while the other seldom exceed one. Very
few medalliones, however, were struck by the Greeks
before the time of the Roman emperors; but the Greek
medalliones of the emperors are more numerous than
those of the Romans themselves. All these pieces,
however, are of such high price that few private
persons are able to purchase them. In the last century
Christina queen of Sweden procured about 3000.
In the king of France's collection there are 1200; a num-
ber formerly supposed not to exist; and Dr Hun-
ter's collection contains about 400, exclusive of the
Egyptian.

Besides these large pieces, there are smaller ones of
a size somewhat larger than half-crowns; and by
Italian medalliones are called medalliones civil, or small
medalliones. They are still scarcer than the large
kind.

There is still a third kind, which have almost elpa-
ced the notice of medalliones, viz. the small coins or
spintriati, scattered among the people on solemn occa-
sions; such as those struck for the slaves on account of
the Saturnalia; counters for gaming; tickets for
baths and feasts; tokens in copper and in lead; &c.
These are distinguished by Mr Pinkerton by the name
of medalliones. Many, or perhaps almost all, of those
struck for the Saturnalia, were satirical; as the slaves
had then a licence to ridicule not only their masters
but any person whatever. Mr Pinkerton mentions
one of the most common pieces of this kind, which
has on the obverse the head of an old woman veiled,
with a laurel crown; the reverse only s. c. within a
wreath. Baudelot is of opinion that it is the head of
Acca Laurentia, the nurse of Romulus, to whom a
sacrifice was ordained. "Perhaps (says Mr Pinkerton),
it was struck in ridicule of Julius Cæsar; for the man-
er of the laurel crown, and its high appearance over
the head, perfectly resemble that of Julius on his coins."
Some have a slip upon one side; on the reverse T, or
a crook, which was the image of Priapus; and oc-
casioned many false invectives against the first Chi-
ristians, who paid such respect to the crooks. Some pieces
have the heads of the emperors upon one side; on
the reverse only numerals III. IV. V. &c. and the
noted spintriati of Tacitus. Both these kinds appear to be
tickets for the baths, as the number seems to denote the
particular bath. Some have the head of a girl, with
a veil used at the baths in her hand. The spintriati
are so inmodest, that few will bear mention. But
some are merely ludicrous; as one which has an as
with a bell about his neck, and a soldier riding him;
another with two figures hoisting a woman in a basket
into the air. Of those that will just bear mention, is
a man with titles around him, as chief of the games;
and a woman in ridicule of the modest bath-girl above-
mentioned. There is also one marked xix, on which
appears an emperor triumphant in a car; this car is
placed on the back of a camel; and behind the em-
peror is a monkey mimicking him.

A fourth class of medals are called contorniati from of the con-
the Italian contorniati, "encircled," because of the
hollow circle which commonly runs around them.
They are distinguished from medalliones by their thin-
ers, faint relief, reverses sometimes in relief, some-
times hollow; and in general by the inferiority in
their workmanship. The opinions of medalliones con-
cerning these pieces are very various; some suppose
that they have been struck by Gallienus to the memory
of illustrious men and celebrated athletes, at the time
that he caused all the consecrated coins of his pre-
deceivers to be restored; others attribute their inven-
tion to Greece, &c. but Mr Pinkerton is of opinion that
they were only tickets for places at public games.

Many of them, notwithstanding their inferior work-
manship, are very valuable on account of their pre-
serving the portraits of some illustrious authors of an-
tiquity, no where else to be found. Much depend-
ance, however, cannot be put on the portraits of
Greek authors and eminent men found upon some
of them; for though we know that the busts of Sallust,
Horus, &c. must have been struck when their per-
sions were fresh in the memory of the artists, yet it
was otherwise with Homer, Solor, Pythagoras, &c.
which are to be found in some of them. Even these,
however, are valuable, as being ancient and perhaps
traditional portraits of these great men. The last
whole portraits are supposed to have been delineated
in this way, are Apollonius Tyaneus who flourished
in the time of Domitian, and Apuleius in that of
Marcus Antoninus. Mr Pinkerton thinks it a con-
firma tion of his opinion concerning these medals, that
the reverses always contain some device alluding to
public games, as that of a charioteer driving a char-
riot, &c.

Sect. XII. Directions for Making Cabinets

We must now proceed to the last part of our sub-
ject, viz. that of giving directions for the formation
of cabinets. As we have already seen that the forma-
tion of any one must be attended with very consider-
able expense, it is necessary for every one who at-
tempts this to proportion the cabinet to his own cir-
cumstances. There are, properly speaking, three kinds
of cabinets. I. Those meant to contain a coin of
every fort that has been issued from the mint in every
age and country; but this, which may be called the
large and complete cabinet, is not to be purchased by
private persons. That of Dr Hunter already men-
tioned is perhaps one of the best private cabinets ever
known; and cost 23,000l. but as many duplicates
were sold as cost 2000l. by which means the expense
was reduced to 21,000. The vast collection made by
the king of France cost upwards of 100,000. The-

MEDALS.

Sect. XII.

Directions for making smaller cabinet may be supposed to consist only of middle and small Roman brass, English pennies, groats, &c. with a few medals of the more valuable kind, and may be supposed to incur an expense of from 200 to 1000. The smallest kind is called a casket of medals and does not consist of above a thousand at most of various kinds; and consequently the expense must depend on the pleasure of the proprietor.

In the formation of the grand cabinet, it must be observed that the Greek medals of every denomination do not admit of any arrangement by the metals like the Roman; not any regular series of this kind being met with even in the most opulent cabinets. Hence in all collections the civic coins are ranged according to an alphabetical order; and the monarchic in a chronological one. The same rule is to be observed in the Roman consulary medals; they are ranged, like the coins of the Greek cities, in the alphabetical series of the families. The Roman imperial coins are only those capable of being arranged according to sizes and metals. Even from this must be excepted the minimi, or very smallest coins; which are so scarce, that the only regular series of them in the world is that belonging to the king of Spain, which was formed by a most skilful French medallist, and consists of all the metals. The arrangement of a grand cabinet, according to Mr Pinkerton, is as follows.

I. The coins of cities and of free states in alphabetical order; whether using Greek, Roman, Punic, Etruscan, or Spanish characters.

II. Kings in chronological series, both as to foundation and seniority of reign.

III. Heroes, heroines, founders of empires, and cities.

IV. Other illustrious persons.

V. Roman ales.

VI. Coins of families, commonly called consulary.

VII. Imperial medallions.

VIII. Imperial gold.

IX. Imperial minimi of all metals.

X. Imperial silver.

XI. Imperial first brass.

XII. Second brasses.

XIII. Third brasses.

XIV. Colonial coins, which are all of brass.

XV. Greek cities under the emperors, of all metals and sizes. In a smaller cabinet they may be put with the Roman, according to their metal and size. Those without the emperor's head go to classes I. though struck in Roman times.

XVI. Egyptian coins struck under the Roman emperors, of all metals and sizes. They are mostly of a base metal called by the French pain; it is a kind of pot metal or brittle brass.

XVII. Cornorniati, or ticket medals.

XVIII. Coins of Gothic princes, &c. inscribed with Roman characters.

XIX. Coins of southern nations using uncommon alphabets; as the Perian, Punic, Etruscan, and Spanish.

XX. Coins of northern nations using uncommon characters, as the Punic and German.

In the modern part no series can be formed of copper that will go back above two centuries; but seq-

quences (chronological series) of gold and silver may be arranged of all the different empires, kingdoms, and states, as far as their several coinages will allow. Those of England and France will be the most perfect. Modern silver is commonly arranged in three series; the dollar, the groat, and the penny sizes. The medals of each modern country ought of course to be separated; though it is best to arrange each set in chronological order, let their size of metal be what they will. It may be remarked here, that modern medals, of the size of a tea-saucer, are only so many monuments of barbarism. The ancient medallions are almost universally but little larger than our crown-piece, though three or four of them may extend to about two inches diameter, but very many modern medals to four inches and more. A large medal always declares an ignorant prince or an ignorant artist. Into the size of a crown-piece the ancients threw more miracles in this way than will ever appear in these monstrous productions.

These directions will likewise apply to the formation of a cabinet of the second kind; but if the collector means to form a series of large Roman brasses, he will find the coins of four or five emperors so scarce as not to be attainable in that series, even at any price. He must therefore supply their places with middle brasses, as is allowed with regard to Otho; even in the best cabinets, there not being above three coins of that emperor in large brass known in the world; whereas the middle brasses, two or three hundred may exist. For this reason Mr Pinkerton concludes, that in cabinets of the second class, the collector may mingle the large and second brasses together as he thinks proper, in order to save expense; though it would not do so well to unite such disproportionate sizes as the large and small. In the small series, however (says he), there can be no harm in his mixing gold, silver, and brasses, as chance or curiosity may lead him to purchase any of these metals. And though your starched bigotted medallist may sneer because such a sequence would controvert his formal and narrow way of thinking, common sense will authorize us to laugh at the pedant in our turn, and to pronounce such a series more various, rich, and interesting, than if the collector had arranged only one metal, and rejected a curious article because he did not collect gold or silver. In like manner, if, in the modern part of the smaller cabinet, any coin of a series is of high price, or of bad impression, there can be no impropriety in putting another of the same reign, which is cheaper, or better executed, though of a different denomination or of a little larger size. In short, the collector has no rules but in the Greek cities and Roman families, to observe alphabetical order and chronology in every thing else.

TABLES OF ANCIENT COINS.

The most ancient coins, according to Froelich, are distinguished by the following marks, which he accounts infallible. 1. Their oval circumference, and globulous swelling shape. 2. Antiquity of alphabet. 3. The characters being retrograde, or the first division of the legend in the common style, while the next is retrograde. 4. The indented square already described. 5. The simple structure of the mintage. 6. Some

</thead>
<tbody>
<tr>
<td>1. Thoric without impression.</td>
</tr>
<tr>
<td>2. With one or more hollow indented marks on one side, and an impression in relief on the other.—Of Chalcis on the Hellepont, Lesbos, Abdera, in Thrace, Acarnis in Macedon, those said to belong to Eginum in Achaea. This class continues from about 900 to 700 B.C.</td>
</tr>
<tr>
<td>3. With an indented square divided into segments, having a small figure in one of them; the rest blank, with a figure in relief on the obverse.—Of Syracuse and other places adjacent.—Continue from 700 to 600 B.C.</td>
</tr>
<tr>
<td>4. Coins hollow on the reverse, with figures in relief on the obverse.—Of Caulon, Crotoma, Metapontum, &amp;c. Supposed by some to be a local coinage of Magna Grecia; but probably of equal antiquity with the former.</td>
</tr>
<tr>
<td>5. Coins in which a square dye is used on one or both sides.—Of Athens, Cyrene, Argos, &amp;c.—Of Alexander I. and Archelaus I. of Macedon. Difused in the reign of the latter about 430 B.C.</td>
</tr>
<tr>
<td>6. Complete coins, both in obverse and reverse, occur first in Sicily in the time of Gelo, about 491 B.C.</td>
</tr>
<tr>
<td>7. Coins of Alexander the Great and his successors. About the time of this hero the Greek coins began to attain to perfection, and were struck of uncommon beauty. It is remarkable, that on the coins of this monarch his own image seldom occurs. The only one yet found of Alexander with his portrait upon it, and struck during his reign, is a silver hemidrachm in Dr. Hunter's cabinet, which is represented Plate CCXCI. No. 3. After his death many coins bear his portrait. Trebellius Pollio informs us, that some coins, particularly those of Alexander, used to be worn as amulets; and many medals are met with in cabinets bore evidently for that intention.</td>
</tr>
<tr>
<td>8. Coins of the successors of Alexander.—Those of the Syrian monarchs almost equal the coins of Alexander himself in beauty. Those of Antiochus VI. are supposed to be the most perfect patterns of malebeauty to be met with anywhere. The Egyptian Ptolemies are somewhat inferior.</td>
</tr>
<tr>
<td>9. The coins of the Aralidae of Parthia done by Greek workmen.</td>
</tr>
<tr>
<td>10. The Greek imperial coins, being such as have the head of an emperor or empress; such as have not these impressions being chiselled with the civic coins, though struck under the Roman power. None of the imperial coins occur in gold. Of silver there are those of Antioch, Tyre, Sidon, Tarshis, Berythus, Caphare. Egyptian silver coins of base metal. Syrian silver coins, which sometimes bear on the reverse the club of Hercules, or the Tyrian shell-fish. Thae of Sidon bear the image of the goddess Astarte, or her chariot. Those of Caphare in Cappadoxia of better work than the Syrian. Lycian coins of good workmanship; on the reverse two harps and an owl sitting upon them. Silver coins of Gelo in Sarmatia resembling the Syrian. The situation of this town is very much unknown. It seems to have been situated on the north of the Euxine sea where some Sarmatic or Slavonic tribes were mingled with the Scythians or Goths. The Greek imperial brass coins are very numerous. A series of almost all the emperors may be had from those of Antioch, with a Latin legend on the obverse, and Greek on the reverse. Those of Bithynia and Phrygia remarkable for good workmanship. Those of Tauris remarkable for their curious views of objects, almost in perspective. The Egyptian coins, from the time of Augustus to Nero are worked out than afterwards. From Nero to Commodus they decline, and are lost after the reign of Constantius I. The Egyptian brass coins of the Roman period are like wise in excellent workmanship, especially in the time of Antoninus Pius.</td>
</tr>

<table>
<thead>
<tr>
<th>Table II. Roman Coins.</th>
</tr>
</thead>
<tbody>
<tr>
<td>I. The consular coins, called also the coins of families, and arranged alphabetically in cabinets, according to the names of the families which appear on them. They are, 1. Dracon coins.—These consist chiefly of large pieces of rude workmanship, without any interesting imagery. In cabinets they are generally kept in boxes apart by themselves. The as bears the head of Janus; the semis of Jupiter with S; the triens of Minerva with four paws. In all these pieces the prow of a ship is constantly the figure on the reverse, with very few exceptions. Sometimes, indeed, they have a shell, two heads of barley, a frog, an anchor, or a dog, on the reverse. About the time of Julius Cesar both the obverses and the reverses of the coins began to be altered. 2. Silver. Of this the denarius was the first and principal coin. It was stamped originally with X, denoting that the value was ten aces. On the reverse was Caesar and Pollarus, or a chariot of victory. Afterwards the busts of various deities make their appearance; and in the seventh century of Rome the portraits of illustrious personages deceased are met with: but till the time of Julius Cesar no figure of any living person is to be met with; Julius himself being the first who assumed that honour. The workmanship on the best and worst silver is much the same. The reverses are very curious, and point out many remarkable events in Roman history; but none of these occur till about a century before the Christian era. The large denarius, with ROMA, are the most ancient; and some of these bear the Pelopig A, not the Roman. The silver sesterii have a head of Mercury, with a caduceus on the reverse. The quinarii have always a head of Jupiter, with a victory on the reverse. 3. Gold. Most of these are of great value. The number of these exceeds not 100; those of brass 200; and of silver 2000. The aureus is the general gold coin; but two or three gold emblems of families likewise occur.</td>

| E II. |
Ancient coins.

1. Brafs.—This is of three sizes, large, middle, and small. The first forms a most beautiful series, but very expensive. The various colours of the plating have the finest effect. It is the most important of all the Roman coins, and exceeds even the gold in value.

The middle brafs is next in value to the former; and in it are many rare and curious coins, particularly interesting to Britons, as elucidating the history of the island. Of these are the triumphal arch of Claudius; the reverse Britannicus of Adrian; the coins of Antoninus Pius, Commodus, Severus, with a Victory, Victoria Britann.; but especially those personifying the country Britannia. The number of Roman coins relating to Britain (says Mr Pinkerton) is remarkable, more than 20 having been struck at various times; while those personifying himself had of gold, Gaul, Spain, and other regions of the empire, exceed not four or fix at most for each country. Only one country vies with Britain, and that is Dacia on the extreme north-east of the empire, as Britain on the extreme north-west. No doubt this circumstance of remoteness in these two countries recommended them to this particular attention, as more expressive of the Roman power.

The small brafs series abounds also with curious coins. They are scarce till the time of Valerian and Galienus, but very common afterwards. Mr Pinkerton recommends, therefore, to form a series in silver as well as brafs; both being the cheapest of all the Roman coins. In this series (says he), it is a common fault to arrange many coins which have been plated with gold or silver, the forgeries are numerous, but which time has worn off either wholly or in part. All real brafs coins have the s. c. till the time of Galienus; as the senator alone had the power of striking brafs, while the emperor himself had that of gold and silver. When the s. c. therefore, is wanting, the coin was certainly once plated; but in general, the different type and fabric, being those of gold and silver, sufficiently show themselves. With Pertinax, A.D. 192, there is a temporary cessation of small brafs; nor after him do any pieces occur in that series till Valerian, A.D. 254, excepting Trajanus Decius, A.D. 250 only. After Valerian the series is continuous and common. The brafs coinage gradually declined in size from the time of Severus; so that parts of the as could not be struck, or at least it was held unnecessary to strike them. Trajanus Decius attempted in vain to restore the coinage; and Valerian and Galienus were forced to issue denarii ære and small auras. The size of large and of middle brafs are of two fixed and known sizes; the former about that of the crown, the latter of the half crown; though after Severus they gradually lessened. But the small brafs takes in all parts of the æs; and every brafs coin not larger than a shilling belongs to this series. The minima, indeed, or very small, it is proper to keep apart. The coins of Julius Cæsar in this size are of peculiar fine workmanship. They bear his portrait reversed of Augustus or the reverse has a crocodile Egypto Cæsura. There are several with Mark Anthony, and one with Cleopatra; but the more common pieces are those with only numerals on the obverse, which go the length of XIII; perhaps tickets for the baths. A great many occur in the time of Nero; of which Mr Pinkerton particularly one which has "on the reverse a tablet ornamented with griffins and other devices. Upon it is placed a wreath of laurel; and a beautiful vase, of which the embossed human figures are 10 minute, and finished so surpassingly, as to have these coins the most exquisite productions of the ancient mint." From the time of Nero to that of Vespasian no small brafs occurs; but there are many of this emperor and of his son Titus; while Domitian has as many as Nero, and Domitia his wife has almost as many. Succeeding emperors to the time of Pertinax have also many brafs coins; but from his time to that of Valerian there are no real small brafs, excepting those of Trajanus Decius. After Gallienus there are a great many coins of this kind; and Mr Pinkerton mentions one in Dr Hunter's cabinet, of an unknown person named Nigrianus. The coin seems to have been struck at Carthage; and our author concludes that he was an African Usurper, father to Nigerius.

2. Silver.—This series is very complete, and the cheapest of any; especially as the small brafs becomes a fine supplement to it; the latter being had in plenty when the silver becomes scarce, and the silver being plentiful when the brafs was scarce.

3. Gold.—The Roman imperial gold coins form a series of great beauty and perfection; but on account of their great price they are beyond the purchase of private persons.

4. The colonial coins occur only in brafs, none, excepting that of Nemausus, having a right to coin silver. They begin in Spain with Julius Cæsar and Anthony, and cease with Calpugna, who took away the privilege of coinage from the Spanish colonies. The most beautiful are those of Corinth. The other remarkable colonial coins are those of Emeita, Illice, Terraco, Caffandria, Babbia, Berytus, Cæsarea, Patra, Emilia, Heliopolis, or Dalbec, Prolemata, Sidon, Tyre, Deulon, Dios, Tros, Rehaim, Neapolis of Samaria, which bears a representation of Mount Gerizim with the temple on it, Hippo in Africa, &c. On many of these coins we meet with fine representations of temples, triumphal arches, gods, goddesses, and illustrious persons. But coins with these representations are by no means common; the colonial coins till the time of Trajan bearing only a plough, or some other simple badge of a colony. Camelodunum is the only colony in Britain of which we have any coins.

5. The minima.—This includes the smallest coins of all denominations most of which do not exceed the size of a silver penny. They are the most curious of all; but no series of them was ever formed by any person except the abbe Rothelin, whose collection formed of all metals passed to the queen of Spain. The reason of the scarcity of these small coins is probably their diminutive size; by reason of which they are mostly lost. It is surprising that numbers of Roman coins are found through all countries once subjected to that powerful people. Some have been met with in the Orkneys.
Ancient Coins.

The Lydians appear to have invented coinage; though, perhaps, this honour may be disputed with them by the Greeks.

1. The Lydians invented gold coins, of which the ancient Lydian coin has a gnomonic figure, with indented marks on one face, and on the other a human figure, with a shield on the contrary side. These coins are of considerable value, having been coined by the famous Lydian kings, and are still esteemed in Asia Minor.

2. The Phoenicians, Medes, Babyloniens, Phenicians, and Egyptians, had no coins. In the mouths of the mummies are only thin, unburnt, and round pieces of gold to pay Charon's fare.

3. No Indian or Chinese coins are to be met with till a very late period; and even then they were scarce. Voltaire mentions a collection of ancient Chinese and Indian coins made by the emperor of China in 1715; but Mr. Pinkerton supposes it to have consisted only of the Greek and Roman money which had been introduced into those countries.

4. The Lydian coins have no legends; so that mere conjecture only determines the ancient coins of electrum and silver found in Asia, and different from the Persian, to belong to Lydia. Creatus coined gold into a form which he called "flaters"; and Mr. Pinkerton mentions a very ancient gold coin in Dr. Hunter's cabinet, which he supposes to have been one of these. It has a globous figure, with indented marks on one side, and on the other a man kneeling, with a shield held out in the left hand, and a sword depending in the right. It weighs four drams; which Josephus tells us was the weight of the Lydian gold coins. In the same collection are other gold coins little inferior in antiquity; the most ancient of which, our author supposes, may have been coined by the cities of Asia Minor, as coinage passed through them to Greece. They are of admirable workmanship, and as much superior to the best Sicilian coins, as the latter are to all the rest in the world. These gold coins are all extremely pale; owing to the want of knowledge in refining gold.

5. Persian coins. These were first struck by Darius Hyphates, whence they had the name of "Darics." They are of gold, and generally have the figure of an archer: they weigh about four drachms; and some occur with the indented mark on one side, while others have figures upon both. The silver coins have generally a king in a chariot of two horses, with a charioteer, and sometimes another figure on foot behind on the obverse; while the reverse presents a ship, sometimes a ram, bull, or other animal. The gold coins, which only had the title of "Darics," are extremely scarce, having been melted down, as is supposed, and recoin'd by Alexander the Great on his conquest of Asia.

There is a second series of Persian coins beginning with Artaxares, or Artaxerxes, who overthrew the Parthian monarchy about the year 210. These are large and thin, with the king's bust on one side and the altar of Mithras on the other; generally with a human figure on each side. These coins continue till the year 636, when Persia was conquered by the Saracens. These have only Persian letters upon them, which have never been explained by any antiquaries. Mr. Pinkerton says that they seem to partake of the ancient Greek, Gothic, and Alanic.

6. The Hebrew shekels, originally didrachms, but after the time of the Maccabees tetradrachms, are almost all forgery from modern Jews, as well as the brass coins with Samaritan characters upon them. They have all a spring upon one side and a valve on the other. Mr. Pinkerton says, that the admission of one of them into a cabinet would almost be a disgrace to it.

7. Phoenician and Punic coins are very interesting on account of the great power and wealth of these nations. The alphabets have been cleared by their relation to the Hebrew and Syrian languages.

8. The coins of Palmyra come under the same denomination with the former, Palmyra being a Syrian city.

9. The Etruscan coins have the characters of that nation, which have been explained by their affinity to the Pelasgic, or oldest Greek and Latin.

10. The Spanish coins are inscribed with two or three alphabets allied to the old Greek and Punic; but the inscriptions have not been sufficiently explained.

11. Gaulish coins. These are numerous; but the most ancient have no legends; and even after the Greek letters were introduced into Gaul by a colony at Marseille, the legends are very difficult to be explained.

12. British coins. From a passage in Caesar's commentaries, it has been inferred that the Britons used some kind of coins even in his time. Mr. Pinkerton informs us, that some rude coins of copper very much mingled with tin are frequently found in England; which, he supposes, may be some of the ancient British money. They are of the size of a didracma, the common form of the nummus aureus among the ancients. After the time of Caesar, coinage increased among the Britons; and there are many found of Carthaginian mentioned in the Roman history. Most of these have on one side "CUNO," with an ear of wheat, a horse, a kind of head of Janus, or other symbol; and have frequently also the letters "CANT," supposed to mean Camelodunum. Sometimes the word "TASCA" occurs; the meaning of which has not yet been explained.

13. Gothic coins of France, Italy, and Spain, to the time of Charles the Great. These have the Roman characters upon them. The Italian coins are mostly of the size of small brass; and in this way we meet with coins of Athalaric, Theodosius, Vitigez and other Gothic princes. Many others occur, the inscriptions of which, though meant for Roman, are so perverted as to be illegible.

Table IV. Modern Coins.

1. Of Japan. These are thin plates of gold and silver, of an oval figure, with small marks or figures impressed on them.

2. China. These are only copper, about the size of a farthing, with a square hole in the middle to put them on strings. The inscriptions on them do not express the name of the sovereign, but the year of his reign; as the happy year, the illustrious year, &c.

3. The Tartarian coins are rude, having only inscriptions upon them; and they are all posterior to the time of Jenghis Khan.

4. Coins of Thibet, Persia, and Siam, are much the same.
MEDALS.

first coin of the family of Vitconti occurs in 1330 under Azo. The set finishes with Louis XII.

Naples. Coinage begins in 840 and 880, with Duke Sergius and Bishop Athanasius. The next coins are of Roger of Sicily, and Roger II. in 1130, William I. II. and Tancred. Naples and Sicily were subdued in 1194 by the emperor of Germany; in 1255 Manfred appears; in 1266 Charles of Provence; and others till Joan in 1414: after which follow the house of Arragon, and later kings.

Venice begins in the 10th century. The first coins are silver pennies marked VENECI. Then follow the coins of Henrico Dandulo in 1192, of Ziani in 1202, &c. Gold was first coined at Venice in 1280, and copper in 1471; but the silver groats are as old as 1192.

Florence. Silver was coined here in the 12th century, or before; but in 1252 the first gold coins struck in Europe after the 8th century made their appearance, and were named forins from the flower of the lily upon them. They were imitated by the popes, by France, and England. They have on one side St John the Baptist standing, on the other a large fleur de lis, and it is not doubted that the French fleur de lis took their origin from these coins. They weigh about 75 c., and are no less than 24 carats fine according to Italian writers, and are worth about 12 florins Sterling.

Geneva first began to coin money in 1129, under the government of Conrad. Those of the dukes of Savoy began in the same century.

Aguilas. Coins were issued from this city by the patriarchs from 1204 to 1440.

Ferrara. Coins of the marquises from 1340.

11. French coins. During the race of Clovis, from 490 till 751, the coins are chiefly gold trinets, with some solidi and sesterti. The former are of good workmanship, with the heads of kings. The reverse has a crofs, with the name of the town where they were struck.

The coins of the second race begin with Pepin in 751, and continue till Hugh Capet in 987. The coins of the first race are elegant, but those of the second entirely the reverse, being almost all silver pennies, and seldom bearing the portrait of the king. Those of Charlemagne have only Carolus in the field; while the reverse bears s. p. or some such inscription; though one piece struck at Rome has a rude bust of him. The coins of Louis le Debonnaire are better done.

The third race begins with Hugh Capet in 987, and extends to this time. The coinage did not begin to improve till 1226 under St Louis, when the groat appears. Its name in Italian is griffa, in French gréf, in English groat, or great coin; so called from its size in comparison with the penny; and it passed from Italy to France, to Germany, and to England. After the conquest of France by the English, base coins of many kinds were introduced; and in the year 1574, in the time of Henry III. copper was first introduced into the French coinage. Besides these, the other remarkable coins of France are, the blancs or billet gros, first issued in 1348; the ecus a la couronne, or crowns of gold, so called from the crown on one side.

MILAN. Coinage began with Charlemagne. The

5. India. Some old coins have been found in the neighbourhood of Calcutta, of gold, silver, copper, and tin, all mixed together. They are thus, presenting only inscriptions without any figures. They are of late date.

6. Perlia. The Peric coins since its conquest by the Arabs continue on the Arabic model.

7. Arabia. Some coins of the petty princes of Arabia are met with as old as the imperial ages of Rome; but till the time of Haroun Alrachid, no regular coinage appears in the vast empire of the Saracens. Even then the reverse has only an inscription, and the obverse is copied from any Greek or Syrian coin which happened to fall in the money's way. The later Arabian coins are mostly silver, with the name and titles of the prince on one side, and some inscription from the Koran on the other. The more modern coins of this country are in the shape of a fish-hook, with Arabic inscriptions.

8. Turkey. No regular coinage was formed by the Turks till they became masters of Constantinople. They resemble those of Perlia and Arabia, having merely inscriptions on both sides.

9. The coins of the African states, at least such as profess the Mohammedan religion, have merely inscriptions without any figures; those of the internal parts are unknown; and no coinage was used among the Mexicans and Peruvians, the only civilized nations in America; but La Hontan mentions an American bivage who had a square medal of copper depending from his neck. Mr Pinkerton supposes it to have come from Japan.

10. Modern Italian coins. Besides the Gothic princes mentioned in the former table, the exarchs of Ravenna coined money with the inscription Felix Ravenna, &c. The Lombards issued no coins, but there are some still extant of Charlemagne. The following list shows the origin of the coinage in various Italian states.

Rome. Papal coinage originates with Hadrian I. Size of silver pennies, with the Pope's name on one side, and Scoz Peter on the other. No coins appear from 925 to 1099, excepting of Leo IX. In 1303 appear pennies of the senates and people of Rome, with Peter on the one side and Paul on the other. There are groats of Clement V. with his portrait three quarters length; but the side-head begins with Sixtus V. in 1470. Gold was first coined by John XXII. in 1316. The coins of Alexander VI. Julius II. and Leo X. are remarkable for beauty and elegance.

Milan. Coinage began with Charlemagne. The
12. Spanish coins. The most early series of these consist almost entirely of tritennials, finely done. On one side they have the head of the king with his name, and on the other a cross, with the name of the town, commonly in Bética, or the south part of Spain, where there were a great many Roman colonies, and which was fertile to a proverb. The Moorish coins of Spain, like those of the Mohammedan states, present us only with insipid inscriptions on both sides. Indeed the Mohammedan religion, by its absolute refusal to allow the representation of any living creature, has prevented the progress of coinage in any degree throughout those regions which it has overthrown. The inscriptions on the ancient Spanish coins are in the Cufic or old Arabic characters.

13. Portugal. No description of the coins of this kingdom has yet appeared.

14. Germany. No account of the German coins has been published; though it is well known that not only the emperors, but many of the cities, particularly those called Hansvorderen, issued money; and many of the coins issued by the cities were superior in elegance even to those issued by the emperors.

15. Denmark. Here the coinage begins with Canute the Great in 1014. The pieces are at first extremely rude, ornamented only with rings and runic characters. These are succeeded by copper pieces, some of which have a cross, others a pastoral staff on one side, with the letter A on the other. Later coins have strokes 1111, &c. all round them; but those of Harold, Hardicanute, and Magnus Bonus, in 1041, are of neat workmanship, and have the portraits of the princes at half length. The coins of Nicolas or Nel, as he is called by the Danes, are rude, as well as those of Waldemar I. and the celebrated Margaret. In 1376 Olaf caused money to be struck with a grinning full face, with a crowned O upon the other side. "The Swedes (says Mr Pinkerton) took these coins extremely ill, as they thought they grinned at them." Silver was first coined in Denmark by Philippa queen of Eric, and daughter to Henry IV. of England.

16. Sweden. The coinage of this kingdom began in 1018 under Birorno, on the plan of Charlemagne. The coins are marked with a cross. Next follow those of Olaf in 1019; which Mr Pinkerton supposes to have been the first true Swedish coins; and that the art of coinage first passed from England into Denmark in the time of Canute the Great, and from Denmark into Sweden. These coins were struck on the English model. During the time that Sweden was subject to Denmark, or miserably harassed by the Danes, the coins of both kingdoms were the same but after the time of Gustavus Adolphus many elegant pieces appear. In 1644, dollars were coined with the modern portrait of Gustavus Adolphus, who was killed two years before. On the reverse they have the arms of Sweden, with the chemical marks of mercury and sulphur. In 1716, 1717, and 1718, Charles XII. being in extreme want of money, issued small copper coins with Satan, Jupiter, Mars, &c. upon them, to go for dollars; and on account of this scheme, Baron Goertz, the forger of it, was brought to the block.

17. Norway. The coins of this country begin with Olaf 1066; after which there are various coins of other princes; but copper was not coined till the year 1343.

Besides the coins already mentioned, there are ecclesiastical coins of France, Germany, Denmark, Sweden, Norway, &c. Thoese of Denmark and Sweden are numerous, but the Norwegian coins of this denomination are rare. Mr Pinkerton describes a silver one in his possession as having arms and a mitre, with the inscription on one side SANCTUS OLAWS REX NORVEGIE; on the reverse OLAVS DEI GRAARCEP.; NIDEN, meaning NIDROSIENIS, or archbishop of Nidaros, now Drontheim.

18. Bohemia. The coinage of this kingdom appears at a very early date, viz. in the year 929, under Duke Boleslaus I. These coins are followed by others of Boleslaus II. and Emma his wife in 970; of Boleslaus III. in 1002; Jaromir in 1020; Udalrich in 1030, and other princes. The bratilsko money of Otocar I. was coined in 1197.

19. Poland. The coinage of this country is nearly as ancient as that of Bohemia. The coins are on the German model, but no particular account of them has been published.

20. Russia. None of the Russian money appears to be more ancient than the 13th century. The first are the kopists or silver pennies, which have upon them rude figures of animals upon one side, and a man fumbling with a bow or spear upon the other. There are likewise coins of Moscow struck by Architeles the architect in 1487. The roubles or dollars and their halfs. There are some of the impoliter Demetrius in 1653, which are very scarce.

21. Prussia. The first Prussian coins were struck at Culm by the Teutonic knights in 1230. They were silver pennies, and upon the German plan. In the next century were struck shillings, groats, and shutes; the last were the largest, and are extremely rare. They have the Prussian shield, an eagle surmounting a cross, with a rose-shaped border, money doinorum Prussiae; on the reverse is a cross fleury, within a border of a similar kind, having the inscription HONOR MAGISTRI, JUSTITIAM REGIT. Gold coins were struck in the same century. In the time of Copericus the money was in debased, that 12 or 13 marks were worth but one of pure silver.

22. England. The English coins are of various kinds.

18. Hiberniae. These are only of two sorts, viz. the cent or penny of silver, and the fola or penny of copper. Few of the pennies appear till after the year 700; though some are met with which bear the name of Ethelbert I. king of Kent, as old as 560. At first they had only rude figures of serpents but in latter times
M E D A L S.

From the year 1601 to the present time the coins of England remain the same.

Gold was coined in England by Henry III. in 1257; the piece was called a "groat" or "penny," and was larger than the silver one; and the execution is by no means bad for the time. The series of gold coinage, however, commences properly from Edward III. In 1344 this monarch first struck florins, in imitation of those in Italy; and it is remarkable, that though these coins at the time they were first issued bore only six shillings value, they are now intrinsically worth 12s.; so much has the value of gold increased since that time. The half and quarter florin were struck at the same time, but only the half has been found. The florin, however, being found inconvenient, gave place to the noble of 6s. 8d. value, and exactly half a mark. The latter had its name from being a limited sum in accounts; and was eight ounces in weight, two-thirds of the money pound. It is sometimes also called "feather," as being one half of the commercial pound of 16 ounces. The noble had its name from the nobility of the metal; the gold of which it was coined being of the finest fort. Sometimes it is called "Rye Noble," from both sides being impaled in an undulating circle. It continued with the half and quarter noble to be the only gold piece till the reign of Edward IV. appeared in 1465. These had their name from being stampped with the image of Michael and the dragon. The angelines of 5s. 4d. value were substituted in their place.

In 1527 Henry VIII. added to the gold coins the crown and half-crown at their present value; and the same year he gave sovereigns of 22s. 6d. and ryal of 11s. 3d. angels at 7s. 6d. and nobles at their old value of 6s. 8d. In 1546 he caused sovereigns to be coined of the value of 20s. and half sovereigns in proportion. His gold coin is about the size of the shilling, and the half-crown of sixpence, but thin. All his coins, however gold as well as silver, are much debased; and it was not without much labour and trouble that Edward VI. brought it back to its former standard. On the union of the two crowns, James gave the sovereign the name of "unite"; the value continuing of 20s. before. He coined also rye-rays of 30s. value four-rays of 15s. angels of 10s. and angelets of 5s. Under the commonwealth, the sovereign got the name of the "twenty-shilling piece," and continued current till the coinage of guineas. These were so called from their being stampped of Guinea gold, and were at first only to go for 20s. though by an universal but tacit consent they always passed for 21s. Half-guineas, double guineas, and five guinea pieces, were also coined during the same reign; which still continue, though the two latter are not in common circulation. Quarter guineas were coined by George I. and likewise by his present majesty; but they were found so troublesome on account of their small size, that they were stopped within a year or two when received at the bank of England; and thus are not to be met with at present. A few pieces of 75s. value have likewise been coined, and are known by the lion above the helmet; but none have been issued. In 1688 the guinea rose to 21s. 6d. and continued to increase in value till 1696, when it was as high as 30s.; but after the recoinage in 1697 and 1698 it fell by degrees, and in 1717 was at its old standard of 21s. and at that time silver...

was fixed at its present standard value, viz. as 1 to 15½
in weight.

Though the first money coined in Britain, as we
have already observed, was copper, yet, excepting
the Northumbrian tyes, no copper coin was found in
England from the time of the Saxon conquest till the
year 1672. An aversion to a copper coinage it seems
was prevalent throughout the nation; and Queen Eliz-
beth, who without hesitation used base money for
Ireland, yet scrupled at coining copper for England.
This want of small coin occasioned such an increase of
private tokens for halfpennies and farthings, that it be-
came a serious object to government; and in 1594 a cop-
ner coinage was seriously thought of. This year a small
copper coin was struck about the size of a silver two-
pence, with the queen's monogram on one side, and a
rose on the other; the running legend on both sides
being THE PLEDGE OF A HALFPENNY. Of this there are
patterns both in copper and silver, but both of them
soon fell into disuse. On the 20th of May 1613, King
James by royal proclamation issued farthing to-
kens. They are generally of the same size with the
two pence, with two scepters in fidalier-surmounted
with a crown, and the harp upon the other; with an
intention, as it would seem, that if they were refused
in England they might pass in Ireland. In inten-
tion, as it would seem, that if they were re-

and was accordingly marked XL.; in 1597 the mark

the Scottish money being then only one-tenth of the
English; the mark was IX in 1601, the value being then
reduced to one-twelfth, at which it has ever since
continued. In the time of Charles I. half

marks, 40 and 20 penny-pieces, were coined. In
1675 the Scottish dollars first appeared, in value 56 s.
Scots, with halves and quarters of proportional value.
In 1686, James VII. coined 60, 40, 20, 10, and 5 s.
pieces; but only those of 40 and 10 s. are known,
with these numbers under the bull. At the Union of
the kingdoms, all the Scottish coins were called in,
and recoined at Edinburgh, with the mark £ under
the bull to distinguish it; since which there has been
no coinage in Scotland. The Scottish silver coins are
in general equal, if not superior, in the workmanship
to the English.

GOLD was first issued by Robert II. about 30 years
after Edward III. of England had coined the same
metal in that country. The pieces were at first called
St. Andrew's from the figure of that tutelar Saint
upon
Modern Coins.

The copper coinage of Scotland is of more early date than that of England. It was preceded by money of bilIon, or copper washed with silver, called black money. James III. first coined black halfpence in 1465; and this is recorded by historians as one of his greatest faults. This kind of coinage, however, continued as late as the reign of James VI. In his time the true copper coinage began; but as the value of Scotch money was now declined almost to the utmost, the pieces suddenly assumed a form almost resembling that of the French coins. The bodis, so called from bothwell the mintmaster, being equal in size to the franc, and worth two pennies Scottish, was struck. The bilIon, formerly called bas-pieces, and worth six pennies Scots, was now coined in copper, and termed the bas-bee. Thus it corresponded with the French half sol and English halfpenny, the Scots penny being now equivalent to the French denier. Some pieces named Atkinson were coined by James VI. in 1582, when the Scotch money was to the English as 1 to 8; but on its being still farther reduced they went for 8 pennies, a third more than the value of the bas-bee. Besides these there were the hardie and plack, the former being worth three and the latter four pennies Scots. This coinage continued through the reigns of Charles I. and II. but Scotch coins of the former are, perhaps, the scarcest of any.

24. Ireland. The first coins introduced into this kingdom seem to have been those of the Danes, and which have only a number of strokes around them instead of letters. In the tenth century, however, this coinage had been considerably improved; and in 920 and 924 there are pennies struck in Dublin, with the inscription DVFIL or DVFIL, Duffin or Duffin, being the Danish name of that city. There are likewise coins of the Irish princes themselves, and of the English monarchs, struck in Ireland as early as the ninth century; and it is ascertained by some that Ireland even in those days was conquered by England; of which, indeed, these coins seem to be a proof. None of the Irish coins of Henry II. are to be met with, but we have some of the coins of John; and from his time to that of Henry V. the Irish coins are known by a triangle inclosing the king's head, which appears also upon the coins of other nations at this period. The harp does not appear upon the Irish coins till the time of Henry VIII. Till the time of this monarch, the English and Irish coins are the same; but the name denoting the basement of the coin which at that time took place in England extended also to Ireland; but in 1601 copper halfpence and farthings were coined also for this kingdom. They were in circulation in Ireland when James VI. assumed his farthing-tokens of copper, the latter being of two sizes, that if they failed in England they might be sent to Ireland as pennies and halfpence. In 1635 a mint was established in Dublin by Charles I. but it was stopped by the Irish massacre, and the many disturbances which followed; since which time the scheme has not been resumed. After the massacre, St. Patrick's halfpence and farthings were coined by the Parliaments, bearing the legends Florinat Rex; on the reverses Eccles REX; on the farthing Quietat Pleris. Copper-tokens were struck by towns and tradesmen, as in England and Scotland. In 1680, halfpence and farthings were issued by authority, with the harp and date. In 1689, James II. having invaded Ireland, instituted a mint, and coined shillings and half-crowns of all the refuse metal he could find, particularly some brassy guns were employed, whence the coinage is commonly called gun-money. Even this metal, however, soon became so scarce, that a diminution in its size is quite apparent from June 1689 to July 1690; and as the month of their mintage is marked upon them, this decrease is easily perceived. In March 1690, pennies of lead mixed with tin were issued; and on the 15th of June the same year, crowns of white metal were coined; but these are now very scarce. In 1732, the patent for coinage halfpence and farthings was given to William Wood, which excited such discontent in Ireland. From the small size allowed by the patent to these pieces, it was supposed that the patentee would have gained 60,000l. but as he caused them to be struck of a size still smaller, his gains were estimated at 100,000l. The coins, however, are of admirable workmanship, and very fine copper, bearing the bust portrait of king George I. to be found any where. Sir Isaac Newton, at that time at the head of the mint, declared that they were superior to the English coins in every thing except the size. In 1757 the Irish halfpence and farthings, with the harp on the reverse, were coined, and continue to the present time. In 1760, there was such a scarcity of copper coin, that some private persons applied for leave to coin halfpence, which appeared with a very bad portrait of George II. and the words VOTs Po-Puli around it. No gold or silver has been coined in Ireland since the massacre of 1641.

Table V. Modern Medals, properly so called.

1. Scotch medals. These take the lead in the present article, the first modern medals of gold being those of David II. struck between the years 1330 and 1370. Only two of them now exist; one in the collection of Mr. Barker of Birmingham, and the other in that of Dr. Hunter. In 1478, there is a medal of James III. sent to the shrines of St. Ambrose in France. It is described as of two inches and a third in diameter: the weight near two ounces; having on the obverse a bearded king, with long hair, sitting on a throne, holding in one hand a naked sword; in the other a shield, with the Scottish arms. On the borders of the canopy above the throne is an inscription in Gothic letters, in mi Deffen, being corrupt French.
French for *In my defense*; a common motto in the Scottish arms. Above the canopy is *Villa Berwick*: the reverse bears St. Andrew and his cross, *Salvum fac populum tuum Dominie*. There is also a medal of James IV. in the collar of St. Michael, having on the reverse a Doric pillar surmounted by a young James, standing on a hill, beyond which is the sea, and land on either side. This, however, is by some suspected to be a forgery.

The most remarkable Scottish medals are those of the unfortunate Mary. The first is properly French, having been inflicted at her coronation as queen of France, along with her husband, King Francis II. On the obverse of this piece, there are portraits of Francis and Mary, face to face, with three legends around them, the outermost containing their titles; the middle one the following sentence: *Hora nona Domini juxta hortus claramus*; the innermost the name of the city (Paris). On the reverse are the arms of France and Scotland. Fine telfoons were also coined upon the same plan, and are now so rare that Dr. Hunter gave ten guineas for one he has in his collection. The same portraits appear on the fine crown of Mary and Henry, in 1555, which is so rare as to be esteemed a medal of the highest value; and Mr. Pinkerton imagines, that if brought to market, it would bring 40 or 50 guineas.

Another remarkable medal of Mary represents her full face, and weeping, with the inscription, *O God grant patience to that I suffer wrong*. The reverse has in the centre, QWNO CAN COMPARE WITH ME IN GRIEVE, I DRE AND DARE NOT SELL MY LIST; with this legend around, HOURS NOT THE (figure of a heart) QUAIN JOY Thou ART. There are also many counters of this unfortunate princess, being thin silver-pieces of the size of a thilling. "They all appear (says Mr. Pinkerton) to have been done in France by Mary's direction, who was fond of devices. Her cruel captivity could not debar her from intercourse with her friends in France, who must with pleasure have executed her orders, as affording her a little consolation."

The coronation medal of Charles I. struck at Edinburgh for his inauguration, June 18, 1603, is remarkable as being the only one ever coined of Scottish gold, and the first in Britain struck with a legend on the edge. With respect to the workmanship, it is inferior to Simon's. Of these medals only three are known to exist, of which one is in the Museum. It is not uncommon in silver; in which case it sometimes wants the legend on the edge.

2. Italian medals. These appear in the 15th century, and from that time successively in most European countries. Vittore Pisano, a painter of Verona, is celebrated as the refoter of the art, but it remains to be accounted for how the medals of King David already mentioned came to exist so long before. Mr. Pinkerton considers this artist rather as an inventor than a refoter, his medals having no resemblance to the ancient coins, as being large, and all cast. They were first modelled in wax, then a mould taken from the model in fine sand, and other ingredients. After a good cast was procured, it was touched up, and made a model for the pel. These medals of Pisano are almost always inscribed *Oraz Pifani Pistorius*. The portraits of a great number of illustrious men were done by him in this manner; and in the British Museum is a large brass medal of Sancho by himself. Other artists were Della, Morellotto, Matthias de Padua, Sperande, Maidalone, &c. Towards the end of the century, however, the medals began to assume a more elegant appearance; and the papal ones are not only the most elegant but the most ancient series of all the modern medals. The improvement began in the reign of Alexander VI. so famous for his own crimes, and those of his nephew Cæsar Borgia. His successors, Julius II. Leo X. Hadrian VI. and Clement VII. had many of their medals designed by Raphael, Julio Romano, and other eminent painters, and the engraving executed by artists of equal merit. Among these were the celebrated Cellini, and the noted Paduan forgers of Roman coins, Cavino and Baffiano. In 1644 Gormanni, a medallistic artist, was imprisoned on account of a piece which represented the Pope upon one side, and Olympia Maidalchines, the relation of his holiness, on the other. The unfortunate Gormanni poisoned himself. About this time the family of the Hapsburgs, originally from Germany, began to engrave the papal medals; which they did with surpassing merit for several generations. Each of the daughters did a fine medal, as we are informed by Venuti.

Besides the papal medals, there are many issued by the various states of Italy. There are medals of Frederic II. of Sicily in 1501, of several Venetian generals in 1509, of Alfonso duke of Ferrara in 1511, and of the celebrated Andrew Doria in 1528.

3. French medals. Till the reign of Louis XIV. the medals of this country are neither fine nor numerous; but this monarch exceeds all modern princes in this way. Many of his pieces are well designed and executed, though objectionable on account of their falsehood.

5. Swedish medals. These begin with Gustavus Vasa; and several of Christiana are likewise to be met with. There are also some curious ones of Charles XII.

6. Dutch medals. These begin in 1566; and many of them are remarkable for maps and plans, which must be very interesting to potters. "Had the Greeks and Romans (says Mr. Pinkerton) given us maps and plans, what a fine sytem of ancient geography and topography a cabinet of medals must have been!"

7. Medals of Spain, Portugal, and Germany. The Spanish medals began with Gonzalo in 1503, many of which are curious and interesting. Under Charles V. there are many curious Spanish medals; but those of Germany begin with Frederic in 1453. They are extremely numerous; as we may easily supposse from the greatness of the empire, and the various states which compose it. There is a famous medal of Sebastian king of Portugal, famous for his unfortunate expedition into Africa in 1578; with his bust, full face, and three quarters in length. On the reverse is a shell-shaped in the sea, with the moon and seven stars, bearing the inscription *Serena Caæsa Fævent*. There is also a curious lozenge-shaped coin of the same with the arms of Portugal, and the king's name and title; On the
MEDALS.

To this account of modern coins and medals we must add that of another set called siege pieces, and which were issued during the time of a siege in cafes of urgent neediness. They were formed of any kind of metal; sometimes of no metal; and Patin mentions a remarkable one struck at Leyden in 1574, when the place was beleaguered by the Spaniards. It was of thick paper or pasteboard, having a lion rampant, with this inscription, PVNIO PRO PATRIA, 1574; and on the reverse, SVVGDVM SYAVATVR.

There are various siege pieces of Charles I. both in gold and silver, some of the latter being of the value of 20 shillings.

The nummi bracteati are a species of modern coins somewhat between counters and money; and have their name from the word bractea, a spangle or thin bit of metal. They are commonly little thin plates of silver, stamped as would seem with wooden dies upon one side only, with the rude impression of various figures and inscriptions. Most of them are ecclesiastic, and were struck in Germany, Switzerland, Denmark, Sweden, Norway, and a few in Poland. They continued to be in use in Germany till the end of the 15th century; and some are still used in Switzerland at this day.

</table>
MEDALLION, or Medallion, is a medal of an extraordinary size supposed to be anciently struck by the emperors for their friends, and for foreign princes and ambassadors. But that the smallness of their number might not endanger the loss of the devices they bore, the Romans generally took care to stamp the subject of them upon their ordinary coins.

Medallions, in respect of the other coins, were the same as modern medals in respect of the modern money; they were exempted from all commerce, and had no other value than what was set upon them by the fancy of the owner. Medallions are so scarce, that there cannot be any set made of them, even though the metals and sizes should be mixed promiscuously.

MEDEA (Joseph), a very learned English divine of the 17th century, was educated at Cambridge, and soon distinguished himself to great advantage; for by the time he had taken the degree of master of arts in 1610, he had made an uncommon progress in all academic studies. His first appearance as a writer was by an address to Dr. Andrews, then bishop of Ely, in a Latin tract De Sanctorum Reliquiis, which was highly approved of by that prelate, who desired him to be his domestic chaplain. This Mr. Mede very civilly refused; valuing the liberty of his studies above all other value than what was set upon them by the fancy of the owner. He allowed himself little hopes of preferment, and estimating that freedom which he possessed (as) a matter serviceable to his purpose. He allowed him self little attention which Dr. Mede. very civilly refused; valuing the liberty of his studies above all other value than what was set upon them by the fancy of the owner. He allowed himself little hopes of preferment, and estimating that freedom which he possessed (as) a matter serviceable to his purpose. He allowed him self little attention which Dr. Mede. very civilly refused; valuing the liberty of his studies above all other value than what was set upon them by the fancy of the owner. He allowed himself little hopes of preferment, and estimating that freedom which he possessed (as) a matter serviceable to his purpose.

MEDEA, in fabulous history, a celebrated sorceress, daughter of Eetes king of Colchis. Her mother's name, according to the more received opinion of Hefiod and Hyginus, was Leuia, or, according to others, Ephyre, Hecate, Alterodia, Antiope, and Neaea. She was the niece of Circe. When Jason came to Colchis in quest of the golden fleece, Medea became enamoured of him, and it was to her well-directed labours that the Argonauts owed their preservation. Medea had an interview with her lover in the temple of Hecate; when they bound themselves by the most solemn oaths to eternal fidelity.

Mr. Mede was a curious inquirer into the most arduous parts of learning, and endeavoured after the knowledge of those things which were more remote from the vulgar track. Among other things, he spent no small pains and time in founding the depths of astrology, and blotted much paper in calculating the activities of his near relations and fellow-students; but he was in his younger years, and he afterwards discovered the vanity and weakness of this fanciful art. He applied himself to the more useful study of history and antiquities; particularly to those mysterious sciences which made the ancient Chaldeans, Egyptians, and other nations, so famous; tracing them as far as he could have any light to guide him in their oriental schemes and figurative expressions, as likewise in their hieroglyphics, not forgetting to inquire also into the oneirocritics of the ancients; which he did the rather, because of that affinity he conceived they might have with the language of the prophets. He was a curious and laborious searcher of antiquities relating to religion, ethnic, Jewish, Christian, and Mahometan; to which he added other attendants, necessary for understanding the more difficult parts of Scripture.

In 1620, he refused the provostship of Trinity college, Dublin, into which he had been elected at the recommendation of archbishop Usher, who was his particular friend; as he did also when it was offered to him a second time, in 1620. The height of his ambition was, only to have had some small donative fine cure added to his fellowship, or to have been thrown into some place of quiet; where, retired from the noise and tumults of the world, and possessed of a competency of fortune, he might have been entirely at leisure for study and acts of piety. In the mean time, although his circumstances were scanty, for he had nothing but his fellowship and a college lection, his charity was diffusive and uncommon; and, strange as it may now seem, he devoted the tenth of his income to pious and charitable uses. But his frugality and temperance always afforded him plenty. His prudence or moderation, either in declaring or defending his private opinions, was very remarkable; as was also his freedom from partiality, prejudice or prepossession, pride, anger, selfishness, flattery, and ambition. He was meek, patient, equally remote from superfluous and licentiousness of thinking; and, in short possessed every virtue. This great and good man died in 1630, in his 52d year, having spent above two-thirds of his time in college.

Mede.
MEDEA, Greek. To stop the pursuit of her father, the tore
pieces her brother Abiyturus, and left his mangled
limbs in the way through which Medea was to pass.
This act of barbarity, some have attributed to Jafon,
and not to her. When Jafon reached Iolchos his na-
tive country, the return and victories of the Argos-
naurs were celebrated with universal rejoicings; but
Eion the father of Jafon was unable to assist at the
solemnity on account of the infirmities of his age.
Medea, at her husband's request, removed the weak-
ness of Eion; and by drawing away the blood from
his veins, and filling them again with the juice of cer-
tain herbs, she restored him to the vigour and spright-
liness of youth. This sudden change in Medea aston-
i shed the inhabitants of Iolchos; and the daughters
of Pelias were determined to see their father restored
by the same power to the vigour of youth. Medea,
willing to revenge the injuries which her husband's fa-
mily had suffered from Pelias, increased their cru-
rité; and betrayed them into the murder of their fa-
ther as preparatory to his rejuvenescence, which she
afterwards refused to accomplish. This action greatly
irritated the people of Iolchos; and Medea with her
husband fled to Corinth to avoid their retribution. Here
they lived for 10 years with mutual attachment, when
the love of Jafon for Glauce the king's daughter inter-
rupted their harmony, and Medea was divorced. Me-
dea avenge the infidelity of Jafon, by causing the death
of Glauce, and the destruction of her family. She
also killed two of her children in their father's presence;
and when Jafon attempted to punish the barbarity of
the mother, she fled through the air upon a chariot drawn
by winged dragons. From Corinth Medea came
to Athens, where, after she had undergone the neces-
sary purification of her murder, the married king Agaeus,
or (according to others) lived in an adulterous manner
with him. From her conduct with Agaeus, Medea had
a son who was called Medus. Soon after, when The-
feus wished to make himself known to his father, Me-
dea, jealous of his fame and fearful of his power,
attempted to poison him at a feast which had been pre-
pared for his entertainment. Her attempts, however,
failed of success, and the sight of the sword which The-
feus wore by his side convinced Agaeus that the stran-
ger against whom the line had so safety confined was his
own son. The father and the son were reconciled; and
Medea, to avoid the punishment which her wickedness's
defended, mounted her fiery chariot and disappeared
through the air. She came to Colchis; where according
to some, she was reconciled to Jafon, while had fought
her in her native country after her sudden departure
from Corinth. She died at Colchis, as Justin mentions,
when she had been restored to the confidence of her
family. After death the married Achilles in the Elyrian
fields, according to the traditions mentioned by Simo-
nides. The murder of Mimerus and Pheres, the young-
eft of Jafon's children by Medea, is not to be attributed
to the mother, according to Elian; but to the Corin-
thians, who affiliated them in the temple of Juno Ac-
crea. To avoid the retribution of the gods, and to de-
liver themselves from the petulence which visited their
country after so horrid a massacre, they engaged the poet Eupriptes for five talents to write a tragedy, which
exposed them of the murder, and represented Medea as
the cruel assassin of her own children. And besides, that
this opinion might be the better credited, festivals were
appointed, in which the mother was represented with all
the barbarity of a fury murdering her own sons.

MEDUSA, climbing African asparagus, in
botany: A genus of the helianthus order, belong-
ing to the trigynia class of plants; and in the natural
method ranking under the 11th order, Solanaceous.
There is no calyx; the corolla is sepitate and revolu-
ted; the berry trifliform. Its characters are these:
The flower has no pistil; it has six oblong oval
petals, and six awl-shaped flaminia terminated by in-
cumbent summates; and three oromera germina termi-
nating the style; the gernina afterward turn to a roundish trifl berry with three cells, each contain-
ing one heart-shaped seed. There are two species.

MEDIA, now the province of Gilian in Persia, once
the seat of a potent empire, was bounded according
to Ptolemy, on the north by part of the Caspian Sea;
on the south by Parthia and Hyrcania; and on the west
by Armenia Minor. It was anciently divided into seve-
ral provinces, viz. Tropatene, Charomithrene, Darites, Parthia,
Armarioce, and Syro-Media. By a later division, how-
ever, all these were reduced to two; the one called Me-
dia Magna, the other Media Atropatene, or simple Atro-
patene. Media Magna was bounded by Persis, Parthia,
Hyrcania, the Hyrcanian Sea, at Atropatene, and
contained the cities of Ecbatan, Laodicea, Apamea,
Raga, Raelia or Rages, &c. Atropatene lay between
the Caspian mountains and the Caspian Sea.

This country originally took its name from Madai,
the third son of Jupitier; as is plain from Scripture,
where the Medes are constantly called Medini. Among
prophets authors, some derive the name Medini, from on-
Medus the son of Jafon and Medea; others from a city
called Medini. Sextus Rufus tells us that in his time it
was called Medilen, and from others we learn that it was
also called Arin. The most probable history of the Me-
des is as follows.

This people lived in subjection to the Assyrians till
the reign of Senacherib, when they threw off the yoke,
and lived for some time in a state of anarchy. But at
last, rapine and violence, the natural consequences of
such a situation, prevailed so much that they were con-
strained to have recourse to some kind of government,
that they might be enabled to live in safety. Accord-
ingly, about 699 B. C. one Dejoces having procured
himself to be chosen king, united the scattered tribes
into which the Medes were at that time divided; and
having applied himself as much as possible to the civi-
ization of his barbarous subjects, left the throne to his
son Phraortes, after a reign of 53 years.

The new king, who was of a warlike and enterprising
disposition, subdued almost all the Upper Asia lying be-
 tween Mount Tauros and the river Halys which runs
through Cappadocia into the Euxine Sea. Elated with
this good success, he invaded Assyria, the empire of
which was now much declined, and greatly weakened
by the revolt of many nations which had greatly followed
the example of the Medes. Nebuchadnezer or Chalidadiu,
however, the reigning prince, having assembled what
forces he could, engaged Phraortes, defeated, took him
prisoner, and put him to death; after which, entering
Media, he laid waste the country, took the metropolis
of Ecbatan itself, and levelled it with the ground.
MED

On the death of Phraortes, his son Cyaxares was placed on the throne. He was no less valiant and enterprising than his father, and had better success against the Assyrians. With the remains of that army which had been defeated under his father, he not only drove the conquerors out of Media, but obliged Chrysiladan to shut himself up in Nineveh. To this place he immediately laid close siege; but was obliged to give over the enterprise on account of an irritation of the Scythians into his own country. Cyaxares engaged these new enemies with great resolution; but was utterly defeated; and the conquerors over-ran not only all Media, but the greatest part of Upper Asia, extending their conquests into Syria, and as far as the confines of Egypt. They continued masters of all this vast tract of country for 28 years, till at last Media was delivered from their yoke by a general massacre at the instigation of Cyaxares.

After this deliverance, the Medes soon repopulated the territories which they had lost; and once more extended their frontiers to the river Halys, their ancient boundary to the westward. After this we find the Medes engaged in a war with the Lydians; which, however, ended without any remarkable transaction; but on the conclusion of it, Cyaxares having entered into a strict alliance with Nebuchadnezzar king of Babylon, returned in conjunction with the Babylonians before Nineveh; which they took and levelled with the ground, putting most of the inhabitants to the sword.

After this victory the Babylonian and Median empires seem to have been united; however, after, the death of Nebuchadnezzar, or rather in his lifetime, a war ensued, which was not extinguished but by the dissolution of the Babylonian empire. The Medes, under Alytages the son of Cyaxares I. withstood the power of the Babylonian monarchs; and under Cyrus and Cyaxares II. utterly destroyed their empire by the taking of Babylon, as is related under that article. After the death of Cyaxares, the kingdom fell to Cyrus, by whom the seat of the empire was transferred to Persia,

under which article the history of Media now falls to be considered, as also the manners, &c. of the inhabitants.

MEDIANA, the name of a vein or little vessel made by the union of the cephalic and basilic, in the bend of the elbow.

MEDIASTINUM, in anatomy, a double membrane, formed by a duplicature of the pleura; serving to divide the thorax and the lungs into two parts, and to sustain the vifera, and prevent their falling from one side of the thorax to the other. See Anatomy, n. 117.

MEDIATE, or INTERMEDIATE, something that stands betwixt and connects two or more terms considered as extremes; in which fence it stands opposed to immediate.

MEDIATOR, a person that manages or transacts between two parties at variance in order to reconcile them.

The word, in Scripture, is applied.

1. To Jesu Christ, who is the only intercessor and peace-maker between God and man, (1. Tim. ii. 5.) 2. To Moses, who interposed between the Lord and his people, to declare unto them his word; (Deut. v. 5. iii. 19.)

MEDITAGO, SNAIL-TREFOIL, in botany: A genus of the decandria order, belonging to the diadelpia class of plants, and in the natural method ranking under the 32d order, Papilionaceae. The legumen is compressed and screwed; the carina of the corolla luring down from the verillum. There are nine species, though only five are commonly cultivated in Britain. They are low trailing plants, adorned with small yellow flowers, succeeded by small, round, snail-shaped fruit, which are downy, and armed with a few short spines. They are all easily propagated by seeds. For the properties and culture of Lucern, a species of this genus, see Agriculture, n. 185.

MEDICINAL, any thing belonging to medicine.

MEDICAGO, a general name for any fountain, the waters of which are of use for removing certain disorders. They are commonly either chalybeate or sulphureous. See Springs and Water.

MEDINE.

MEDICINE is the art of preventing, curing, or alleviating, those diseases to which the human species are subjected.

History of Medicine.

The most ancient history of the ancients derives this art immediately from their gods; and, even among the moderns, some are of opinion that it may justly be considered as of divine revelation. But without adopting any supposition of which no probable evidence can be given, we may conclude that mankind were naturally led to it from casual observations on the diseases to which they found themselves subjected; and that therefore, in one sense at least, it is as ancient as the human race. But at what period it began to be professed as an art, by particular individuals following it as a profession, is not known. The most ancient physicians we read of were those who embalmed the patriarch Jacob by order of his son Joseph. The sacred writer styles these physicians Servants to Joseph; whence we may be assured that they were not priests, as the first physicians are generally supposed to have been; for in that age we know the Egyptian priests were in such high favour, that they retained their liberty, when, through a public calamity, all the rest of the people were made slaves to the prince.

It is not probable, therefore, that among the Egyptians religion and medicine were originally conjoined; and if we suppose the Jews not to have invented the art, but received it from some other nation, it is as little probable that the priests of that nation were their physicians as those of Egypt.

That the Jewish physicians were absolutely distinct from their priests, is very certain. Yet as the Jews resided for such a long time in Egypt, it is probable they would retain many of the Egyptian customs, from which it would be very difficult to free them.

We read, however, that when king Ahas was diseased...
in his feet, "he fought not to the Lord, but to the physicians." Hence we may conclude, that among the Jews the medicinal art was looked upon as a mere human invention; and it was thought that the Deity never cured diseases by making people acquainted with the virtues of this or that herb, but only by his miraculous power. That the same opinion prevailed among the heathens who were neighbours to the Jews, is also probable from what we read of Ahaziah king of Judah, who having sent messengers to inquire of Baal-seub god of Ekron concerning his disease, he did not derive any remedy from him or his priests, but simply to know whether he should recover or not.

What seems most probable on this subject therefore is, that religion and medicine came to be mixed together in consequence of that degeneracy into ignorance and superstition which took place among all nations. The Egyptians, we know, came at last to use emetics, and the herb verdigris, in their collection of cathartics, even pernicious. All of them, however, for all the heroes of antiquity are supposed to have discovered the use of verdigris in the cure of wounds, fractures, &c. Hence Hermes and his pupils Chiron, Macheon, and Podalirius, are mentioned as among all modern barbarians their priests or conjurors kept in the temples. The Egyptians, we are very certain; and indeed it seems to have been no less expert than in feats of arms. Several of them were transcribed by Agathodemon, or the second Mercury, the father of Tat, who is said to have composed books of them, that were kept in the most sacred places of the Egyptian temples. The existence of such a person, however, is very dubious, and many of the books ascribed to him were accounted forgeries as long ago as the days of Joseph; and very certain it is, that religion and barbarism to combine religion with physic, as it is for a civilized and enlightened people to keep them separate. Hence we see, that among all modern barbarians their priests or conjurors are their only physicians.

We are so little acquainted with the state of physic among the Egyptians, that it is needless to say much concerning them. They attributed the invention of medicine, as they did also of many other arts, to Thoth, the Hermes or Mercury of the Greeks. He is said to have written many things in hieroglyphic characters upon certain pillars, in order to perpetuate his knowledge, and render it useful to others. These were transcribed by Agathodemon, or the second Mercury, the father of Tat, who is said to have composed books of them, that were kept in the most sacred places of the Egyptian temples. The existence of such a person, however, is very dubious, and many of the books ascribed to him were accounted forgeries as long ago as the days of Joseph; and very certain it is, that religion and barbarism to combine religion with physic, as it is for a civilized and enlightened people to keep them separate. Hence we see, that among all modern barbarians their priests or conjurors are their only physicians.

After all, the Egyptian physic appears to have been little else than a collection of absurd superstitions. Origin informs us, that they believed there were 36 demons, or gods of the air, who divided the human body among them; that they had names for all of them; and that by invoking them according to the part affected, the patient was cured. Of natural medicines we hear of none recommended by the father of Egyptian physic; except the herb mulie, which he gave to Ulysses in order to cure him from the enchantments of Circe; and the herb mercury, of which he first discovered the use. His successors made use of venefication, cathartics, emetics, and Clysters. There is no proof, however, that this practice was established by Hermes: on the contrary the Egyptians themselves pretend that the origin of the art of physic was taken from some observations on brute animals. Veneration was taught them by the hippopotamus, which is said to perform this operation upon itself. On these occasions, he comes out of the river, and strikes his leg against a sharp pointed reed. As he takes care to direct the stroke against a vein, the consequence must be a considerable effusion of blood; and this being suffered to run as long as the creature thinks proper, he at last stops up the orifice with mud. The hint of clysters was taken from the ibis, a bird which is said to give itself clysters with its bill, &c. They used venefication, however, but very little, probably on account of the warmth of the climate; and the exhibition of the remedies above-mentioned, joined with abstinence, formed the most of their practice.

The Greeks too had several persons to whom they attributed the invention of physic, particularly Prometheus, Apollo or Pean, and Eucleapius; which last was the most celebrated of any. But here we must observe, that as the Greeks were a very warlike people, their physic seems to have been little else than what is now called surgery, or the cure of wounds, fractures, &c. Hence Eucleapius, and his pupils Chiron, Macheon, and Podalirius, are celebrated by Homer only for their skill in curing their, without any mention of their attempting the cures of internal diseases. We are not, however, to suppose that they confined themselves entirely to surgery. They no doubt would occasionally prescribe for internal disorders; but as they were most frequently conversant with wounds, we may naturally suppose the greatest part of their skill to have consisted in knowing how to cure those. If we may believe the poets, indeed, the knowledge of medicine seems to have been very generally diffused. Almost all the heroes of antiquity are reported to have been physicians as well as warriors. Most of them were taught physic by the centaur Chiron. From him Hercules received instructions in the medical art, in which he is said to have been no less expert than in feats of arms. Several plants were called by his name; whence some think it probable that he found out their virtues, though others are of opinion that they bore the name of this renowned hero on account of their great efficacy in removing diseases. Arisaenus king of Arcadia was also one of Chiron's scholars; and is supposed to have discovered the use of the drug called jophium, by some thought to be aphisita. Theseus, Talamon, Jason, Peleus, and his son Achilles, were all renowned for their knowledge in the art of physic. The last is said to have discovered the use of verdigris in cleansing foul ulcers. All of them, however, seem to have been inferior in knowledge to Palamades, who hindered the plague from coming into the Grecian camp after it had ravaged most of the cities of Hellas, and even Troy itself. His method was to confine his soldiers to a sparrow diet, and obligate them to use much exercise.

The practice of these ancient Greek physicians, notwithstanding the praises bestowed on them by their poets, seems to have been very limited, and in form-cures even pernicious. All the external remedies applied to Homer's wounded heroes were concoctions; while inwardly their physicians gave them wine, sometimes mingled
migled with others scraped down. A great deal of their physic also consisted in charms, incantations, amulets, &c., which, as they are common to all superstitious and ignorant nations, is superfluous to take any farther notice.

In this way the art of medicine continued among the Greeks for many ages. As its first professors knew nothing of the animal economy, and as little of the theory of diseases, it is plain, that whatever they did must have been in consequence of mere random trials, or empiricism, in the most rigid and proper sense of the word. Indeed, it is evidently impossible that this or almost any other art could originate from another source than trials of this kind. Accordingly, we find, that some ancient nations were accustomed to expose their sick in temples, and by the sides of highways, that they might receive the advice of every one who passed. Among the Greeks, however, Aesculapius was reckoned the most eminent practitioner of his time, and his name continued to be revered after his death. He was ranked amongst the gods; and the principal knowledge of the medical art remained with his family to the time of Hippocrates, who reckoned himself the seventeenth in a lineal descent from Aesculapius, and who was truly the first who treated of medicine in a regular and rational manner.

Hippocrates, who is supposed to have lived 400 years before the birth of Chriss, is the most ancient author whose writings expressly on the subject of the medical art are preserved; and he is therefore justly considered as the father of phyic. All the accounts which we have prior to this time, if not evidently fallacious, are at the utmost highly conjectural. Even the medical knowledge of Pythagoras, so much celebrated as a philosopher, can hardly be considered as resting on any other foundation. But from the time of Hippocrates, medicine, separated from philosophy and religion, seems to have assumed the form of a science, and to have been practiced as a profession. It may not, therefore, be improper to give a particular account of the state of medical knowledge as transmitted to us in his writings. The writings of Hippocrates, however, it may be remarked, are even more than preferred. Nor is it wonderful that attempts should have been made to increase the value of manuscripts, by attributing them to a name of such eminence. But although what are transmitted to us under the title of his works may have been written by different hands, yet the presumption is, that most, if not all of them, are of nearly as early a date, and contain the prevailing opinions of those times.

According to the most authentic accounts, Hippocrates was a native of the island of Cos, and born in the beginning of the 88th Olympiad. In the writings transmitted to us as his, we find a general principle adopted, to which he gives the name of Nature. To this principle he ascribes a mighty power. "Nature (says he) is of itself sufficient to every animal. She performs every thing that is necessary to them, without needing the least interposition from any one how to do it. Upon this footing, as if nature had been a principle endowed with knowledge, she gives her the name of God; and ascribes virtues or powers to her, which are her servants, and by means of which she performs all her operations in the bodies of animals; and distributes the blood, spirits, and heat, through all parts of the body, which by these means receive life and renovation. And in other places he tells us, that it is this faculty which gives nourishment, preservation, and growth, to all things.

The manner in which nature acts, or commands her processes, is by attracting what is good and agreeable to each species, and by retaining, preparing, and changing it; and on the other side in rejecting whatever is superfluous or hurtful, after she has separated it from the good. This is the foundation of the doctrine of depuration, concoction, and crises in fevers, so much inflicted upon by Hippocrates and most other physicians. He supposed also, that every thing has an inclination to be joined to what agrees with it, and to remove from every thing contrary to it; and likewise that there is an affinity between the several parts of the body, by which they mutually sympathize with each other. When he comes to explain what this principle called nature is, he is obliged to resolve it into boat, which, he says, appears to have something immortal in it.

As far as he attempts to explain the causes of disease, he refers much to the humours of the body, particularly to the blood and the bile. He treats also of the effects of sleep, watchings, exercise, and rest, and all the benefit or mischief we may receive from them. Of all the causes of diseases, however, mentioned by Hippocrates, the most general are diet and air. On the subject of diet he has composed several books, and in the choice of this he was exactly careful; and the more so, as his practice turned almost wholly upon it. He also considered the air very much; he examined what winds blew ordinarily or extraordinarily; he considered the irregularity of the seasons, the rising and setting of stars, or the time of certain constellations; also the time of the solstices, and of the equinoxes; those days, in his opinion, producing great alterations in certain distempers.

He does not, however, pretend to explain how, his divinities from these causes, that variety of distempers arises which is daily to be observed. All that can be gathered from him with regard to this is, that the different causes abovementioned, when applied to the different parts of the body, produce a great variety of distempers. Some of those distempers he accounted mortal, others dangerous, and the rest easily curable, according to the cause from whence they spring and the part on which they fall. In several places also he distinguishes diseases from the time of their duration, into acute or short, and chronic or long. He likewise distinguishes diseases by the particular places where they prevail, whether ordinary or extraordinary. The first, that is, those that are frequent and familiar to certain places, he called endemic diseases; and the latter, which ravaged extraordinarily sometimes in one place, sometimes in another, which feized great numbers at certain times, he called epidemic, that is, popular diseases; and of this kind the most terrible is the plague. He likewise mentions a third kind, the opposite of the former; and these he calls sporadic, or struggling diseases, that is, to include all the different sorts of distempers which invade at any one season, which are sometimes of one sort and sometimes of another.
Hippocrates remarked four stages in diseasements; viz. the beginning of the disease, its augmentation, its state or height, and its declination. In such diseases as terminate fatally, death comes in place of the declaration. In the third stage, therefore, the change is most considerable, as it determines the fate of the sick person; and this is most commonly done by means of a crisis. By this word he understood any sudden change in sickness, whether for the better or for the worse, whether health or death succeed immediately. Such a change, he says, is made at that time by nature, either aboliing or condemning the patient. Hence we may conclude, that Hippocrates imagined diseases to be only a disturbance of the animal economy, with which Nature was perpetually at variance, and using her utmost endeavours to expel the offending cause. Her manner of acting on these occasions is to reduce to their natural offences, either aboliing or condemning the patient. Hence we may conclude, that Hippocrates imagined diseases to be only a disturbance of the animal economy, with which Nature was perpetually at variance, and using her utmost endeavours to expel the offending cause.

Hippocrates remarks that nature has digested to fruits come to the market, and frequently the sick person is expected. He further says, "The fevers that come out upon the 3d, 5th, 7th, 9th, 11th, 14th, 17th, 21st, 27th, 31st, or 34th days, are beneficial; but those that come out upon other days signify that the sick shall be brought low, that his disease shall be very tedious, and that he shall subject to relapses." He further says, "That the fever which leaves the sick upon any odd day is usually apt to relapse." Sometimes, however, he contends that it is otherwise; and he gives an instance of a bilious crisis happening on the fifth day. But these are very rare instances, and therefore cannot, in his opinion, overthrow the general rule.

Besides the crisis, however, or the change which determines the fate of the patient, Hippocrates often speaks of another, which only changes the species of the disease, without restoring the patient to health; as when a vertigo is turned to an epilepsy, a tertian fever to a quartan, or to a continual.

But what has chiefly contributed to procure the vast respect generally paid to Hippocrates is his industry in observing the most minute circumstances of diseases, and his exactness in describing every thing that happened before, and every accident that appeared at the same time with them; and likewise what appeared to give ease, and what to increase the malady: which is what we call writing the history of a disease.—Thus he not only distinguished one disease from another by the signs which properly belonged to each; but by comparing the same sort of disorders which happened to several persons, and the accidents which usually appeared before and after, he could often detect a disease before it came, and afterwards give a right judgment of the event of it. By this way of prognosticating, he came to be exceedingly admired.
admiréd: and this he carried to such a height, that it may be justly be said to be his master-piece; and Celsius, who lived after him, remarks, that succeeding physicians, though they found out several new things relating to the management of diseases, yet were obliged to the writings of Hippocrates for all that they knew of signs.

The first thing Hippocrates considered, when called to a patient, was his looks.—It was a good sign with him to have a village resembling that of a perfom in health, and the fame with what the sick man had before he was attacked by the disease. As it varied from this, so much the greater danger was apprehended. The following is the description which he gives of the looks of a dying man. "When a patient (says he) has his nose sharp, his eyes funk, his temples hollow, his ears cold and contracted, the skin of his forehead tense and dry, and the colour of his face tending to a pale-green, or lead colour, one may give out for certain that death is very near at hand; unless the strength of the patient has been exhausted all at once by long watchings, or by a looseness, or being a long time without eating." This observation has been confirmed by those of succeeding physicians, who have, from him, denominated it the Hippocratic face. The lips hanging relaxed and cold, are likewise looked upon by this author as a confirmation of the foregoing prognostic. He took also his signs from the disposition of the eyes in particular. When a patient cannot bear the light, or that he sheds tears involuntarily; when, in sleeping, some part of the white of the eye is seen, unless he usually sleeps after that manner, or has a looseness upon him: these signs, as well as the foregoing ones, prognosticate danger. The eyes deadened, as it were with a mist spread over them, or their brightness loft, likewise signifies death, or great weakness. The eyes sparkling, fierce, and fixed, denote the patient to be delirious, or that he soon will be feized with a frenzy. When the patient fees any thing red, and like sparks of fire and lightning pafs before his eyes, you may expect an haemorrhagy; and this often happens before those crises which are to be attended by a lots of blood.

The condition of the patient is also shown by his polliure in bed. If you find him lying on one fide, his body, neck, legs, and arms, a little contracted, which is the polliure of a man in health, it is a good sign: on the contrary, if he lies on his back, his arms stretched out, and his legs hanging down, it is a sign of great weakness: and particularly when the patient di these or lets himself fall down towards the feet, it denotes the approach of death. When a patient in a burning fever is continually feeling about with his hands and fingers, and moves them up before his face and eyes as if he was going to take away something that paffed before them; or on his bed-covering, as if he was picking or seeking for little laws, or taking away some fift, or drawing out little flocks of wool; all this is a sign that he is delirious, and that he will die. Among the other signs of a present or approaching delirium he also adds this: When a patient who naturally speaks little begins to talk more than he used to do, or when one that talks much becomes silent, this change is to be reckoned a fort of delirium, or is a sign that the patient will soon fall into one.
of a consumption of the flesh and solid parts. The making of a great quantity of urine is the sign of a crisis, and sometimes the quality of it shows how the bladder is affected. We must also observe, that Hippocrates compared the state of the tongue with the urine; that is to say, when the tongue was yellow, and charged with bile, the urine he knew must of course be of the same colour; and when the tongue was red and moist, the urine was of its natural colour.

Hippocrates observed the excretions by stool are as follow. Those that are soft, yellowish, of some consistence, and not of an extraordinary ill smell, that answer to the quantity of what is taken inwardly, and that are voided at the usual hours, are the best of all. They ought also to be of a thicker consistence when the distemper is near the crisis; and it ought to be taken for a good prognostic, when some worms, round and long, are evacuated at the same time with them.

The prognostics, however, may still be favourable, though the matter excreted be thin and liquid, provided it ought always to be soft and even, as well on the right side as on the left. They are indispensible. That which is blackish, or of a lute hue, is the most pernicious. That which is pure black, and nothing else but a discharge of black bile, always prognosticates very ill; this humour, from what place never it comes, showing the ill disposition of the intestines. The matter that is of several different colours, denotes the length of the distemper; and, at the same time, that it may be of dangerous consequence. At Athens places in the fame clafs the matter that is bilious or yellow, and mixed with blood, or green and black, or like the dregs or scrapings of the guts. The stools that consist of pure bile, or entirely of phlegm, he also looks upon to be very bad.

Matter cast up by vomiting ought to be mixed with bile and phlegm; where one of these humours only is observed, it is worse. That which is black, livid, green, or of the colour of a leek, indicates alarming consequences. The fame is to be paid of that which smells very ill; and if at the same time it be livid, death is not far off. The vomiting of blood is very often mortal.

The spittings which give cause in diseases of the lungs and pleurisies, are those that come up readily and without difficulty; and it is good if they be mixed at the beginning with much yellow; but if they appear of the same colour, or are red, a great while after the beginning of the distemper, are falt and acrimonious, and cause violent coughings, they are not good. Spittings purely yellow are bad; and those that are white, vivid, and trothy, give no cause. Whitening is a good sign of conception in regard to spittings; but they ought not at all to be vicious, nor too thick, nor too clear. We may make the same judgment of the excrements of the nose according to their complexion and crudity. Spittings that are black, green, and red, are of very bad consequence. In inflammations of the lungs, tho' those that are mixed with bile and blood profuse well if they appear at the beginning, but are bad if they were not about the seventh day. But the worst sign in these distempers is, when there is no expectoration at all, and the too great quantity of matter that is ready to be discharged this way makes a rattling in the breast. After spitting of blood, the discharge of purulent matter often follows, which brings on a consumption, and at last death.

A kind good sweat is that which arises on the day of the crisis, and is discharged in abundance over all the body, and at the same time from all parts of the body, and thus carries off the fever. A cold sweat is alarming, especially in acute fevers, for in others it is only a sign of long continuance. When the patient sweats no where but on the head and neck, it is a sign that the disease will be long and dangerous. A gentle sweat in some particular part, of the head and breast, for instance, gives no relief, but denotes the heat of the distemper, or the weakness of the part. This kind of sweat was called by Hippocrates epistrophe.

The hypochondria, or the abdomen in general, ought always to be soft and even, as well on the right side as on the left. When there is any hardness or unevenness in those parts, or heat and swellings, or when the patient cannot endure to have it touched, it is a sign the intestines are indisposed.

Hippocrates also inquired into the state of the pulse, from the beating of the arteries. The most ancient physucians, however, and even Hippocrates himself, for a long time, by this word understood the violent pulsation that is felt in that inflamed part, without putting the fingers to it. It is observed by Galen, and other physicians, that Hippocrates touches on the subject of the pulse more slightly than any other on which he treats. But that our celebrated physician understood something even on this subject, is easily gathered from several passages in his writings; as when he observes, that in acute fevers the pulse is very quick and very great; and when he makes mention, in the same place, of trembling pulses, and those that beat slowly; when he observes, that in some diseases incident to women, when the pulse strikes the finger faintly, and in a languishing manner, it is a sign of approaching death. He remarks also, in the Cane Practitioner, that whose pulse is, that is to say, whole artery of the elbow, beats, is just going to run mad, or else that the person is at that time very much under the influence of anger.

From this account of Hippocrates, it will appear, that he was not near so much taken up with reasoning on the phenomena of diseases, as with reporting them. He was content to observe their phenomena accurately, to discern diseases by them, and judged of the event by comparing them exactly together. For his skill in prognostics he was indeed very remarkable, as we have already mentioned, from much that he and his pupils were looked upon by the vulgar as prophets. What adds very much to his reputation is, that he lived in an age when physic was altogether buried in superstitition, and yet he did not suffer himself to be carried away by it; on the contrary, on many occasions, he exposes his abhorrence of it.

Having thus seen in what Hippocrates makes the difference between health and sickness to consist, and likewise the most remarkable signs from whence he drew his prognostics, we must now consider the means he prescribed for the preservation of health, and the cure of diseases. One of his principal maxims was this,
**MEDICINE.**

**Hippocrates.**

**Humaxims we ought by no means to forget:**

1. This, that, to preserve health, we ought not to overcharge ourselves with too much eating, nor neglect the use of exercise and labour. In the next place, That which they struck forward with both their hands.

2. With regard to these things which ought to be

   **Excretions.**

   **Hippocrates observes, that people ought to take care not to load themselves with excrements, or keep them in too long; and besides the exercise abovementioned, which carries off one part of them, and which he prescribed chiefly on this account, he advises people to excite and route up nature when she flagged, and did not endeavour to expel the reft, or take care of the impediments by which she was resifted. For this reason he prescribed meats proper for loofening the belly; and when these were not sufficient, he directed the use of eylifiers and suppositories. For thin and emaciated persons he directed eylifiers composed only of milk and oily emulous substances which they mixed with a decoction of chick-pea; but for such as were plethoric, they only made use of salt or sea-water.

As preservative against distempers, Hippocrates also advised the use of vomits, which he directed to be taken once or twice a month during the time of winter and spring. The most simple of these were made of a decoction of hyfop, with an addition of a little vinegar and salt. He made those that were of a strong and vigorous constitution take this liquor in a morning fafting; but such as were thin and weakly took it after supper.—Venery, in his opinion, is wholesome, provided people consult their strength, and do not pursue it to excess; which he finds fault with on all occasions, and would have excess avoid ed also in relation to sleep and watching. In his writings are likewise to be found several remarks concerning good and bad air; and he makes it appear that the good or bad disposition of this element does not depend solely on the difference of the climate, but on the situation of every place in particular. He speaks also of the good and bad effects of the passions, and recommends moderation in regard to them.

From what we have already related concerning the opinions of Hippocrates, it may naturally be concluded, that for the most part he would be contented with observing what the strength of nature is able to accomplish without being affifted by the physician. That this was really the cafe, may be easily perceived from a perufal of his books entitled, "Of epidemical distempers;" which are, as it were, journals of the practice of Hippocrates; for there were find him often doing nothing more than describing the symptoms of a distemper, and informing us what has happened to the patient day after day, even to his death or recovery, without speaking a word of any kind of remedy. Sometimes, however, he did indeed make use of remedies; but these were exceedingly simple and few, in comparison of what have been given by succeeding practitioners. These remedies we shall presently consider after we have given an abridgment of the principal maxims on which his practice is founded.

**Hist.**

**Hippocrates observed in the first place, That contraries, or opposites, are the remedies for each other; and this maxim he explains by an aphorism in which he says, that evacuations cure those distempers which come from repletion, and repletion those that are caused..."
MEDICINE.

Hippocrates.

Medicine, as he first and principal, and often the only remedy made use of by this great physician to answer the greatest part of the intentions abovementioned: by means of it he opposed moist to dry, hot to cold, &c. and what he looked upon to be the most considerate point was, that thus he supported nature, and assisted her to overcome the malady. The dietetic part of medicine was so much the invention of Hippocrates himself, that he was very desirous to be accounted the author of it; and the better to make it appear that it was a new remedy in his days, he says expressly, that the ancients had wrote almost nothing concerning the diet of the sick, having omitted this point, though it was one of the most essential parts of the art.

The diet prescribed by Hippocrates for patients labouring under acute distempers, differed from that which he ordered for those afflicted with chronic ones. In the former, which require a more particular exactness in relation to diet, he preferred liquid food to that which was solid, especially in fevers. For these he used a sort of broth made of cleaned barley; and to this he gave the name of pífan. The manner in which the ancients prepared a pífan was as follows: They first steeped the barley in water till it was plumped up; and afterwards they dried it in the sun, and beat it to take off the husk. They next ground it; and having let the flour boil a long time in the water, they put it out into the sun, and when it was dry they pressed it close. It is properly this flour so prepared that is called pífan. They did almost the same thing with wheat, rice, lentils, and other grain: but they gave these ptisans the name of the grain from whence they were extracted, as pífan of kettle, rice, &c. whereas the ptisan of barley was called simply pífan, on account of the excellency of it. When they wanted to use it, they boiled one part of it in 10 or 15 of water; and when it began to grow plump in boiling, they added a little vinegar, and a very small quantity of anise or leek, to keep it from clogging or filling the stomach with wind. Hippocrates prescribes this broth for women that have pains in delivery. "Boil some of this pífan (says he), with some leek, and the fat of a goat, and give it to the woman in bed." This will not be thought very singular, if we reflect on what has been hinted above concerning the indiscriminate manner of living in those times. He preferred the ptisan to all other food in fevers, because it softened and moistened much, and was besides of easy digestion. If he was concerned in a continual fever, he would have the patient begin with a ptisan of a pretty thick constilution, and go on by little and little, leisening the quantity of barley-flour as the height of the distemper approached; so that he did not feed the patient but with what he called the juice of the pífan; that is, the ptisan strained, where there was but very little of the flour remaining, in order that nature being discharged in part from the care of digesting the aliments, they might more easily boil out to the end, and overcome the distemper, or the cause of it. With regard to the quantity, he caused the ptisan to be taken twice a-day by such patients as in health used to take two meals a-day, not thinking it convenient that those who were sick would eat oftener than when they were well. He also would not allow eating twice a-day to those who eat but once in that time when in health. In the paroxysm of a
MEDICINE.

Hippocrates, where there are exacerbations, he forbade nourishment while the exacerbations continued. He let children eat more; but those who were grown up to man’s estate, or were of an advanced age, less; making allowance, however, for the custom of each particular perion, or for that of the country.

But though he was of opinion that too much food ought not to be allowed to the sick, he was not of the mind of some physicians who prescribed long abstinence, especially in the beginning of fevers. The reason he gave for this was, that the contrary practice weakened the patients too much during the first days of the distemper, by which means their physicians were obliged to allow them more food when the illness was at its height, which in his opinion was improper. Besides, in acute distempers, and particularly in fevers, Hippocrates made choice of refreshing and moistening nourishment; and amongst other things prescribed orange, melon, spinach, gourd, and dock. This fort of food he gave to those that were in a condition to eat, or could take something more than a pittance.

The drink he commonly gave to his patients was made of eight parts of water and one of honey. In some distempers they added a little vinegar; but besides these, they had another fort named *exmidon*, or mixture. One prescription of this fort we find intended for a convulsive perfon; it consisted of rue, anise, coriander, juice of pomegranate, the roughest red wine, water, flour of wheat, and barley, with old cheese made of goats milk. Hippocrates did not approve of giving plain water to the sick; but though he generally prescribed the drinks abovementioned, he did not absolutely forbid the use of wine, even in acute distempers and fevers, provided the patients were not delirious nor had pains in their head. Besides, he took care to dilute the wines proper in these cases; preferring to all other forts white wine that is clear and has a great deal of water, with neither yellow milk, nor flavour.

There are the most remarkable particulars concerning the diet prescribed by Hippocrates in acute distempers; in chronic ones he made very much use of milk and whey; though we are not certain whether this was done on account of the nourishment expected from them, or that he accounted them medicines.

There were many dilecuses for which he judged the bath was a proper remedy; and he takes notice of all the circumstances that are necessary in order to cause the patient receive benefit from it, among which the following are the principal. The patient that bathes himself must remain full and quiet in his place without speaking while the officiants throw water over his head or are wiping him dry; for which last purpose he advised them to keep sponges, instead of that instrument called by the ancients *fregil*, which served to rub off from the skin the dirt and mafsines left upon it by unguents and oils with which they anointed themselves. He must also take care not to catch cold; and must not bathe immediately after eating and drinking, nor eat or drink immediately after coming out of the bath. Regard must also be had whether the patient has been accustomed to bathe while in health, and whether he has been benefited or hurt by it. Lastly, he must abstain from the bath when the body is too open, or too colivse, or when he is too weak; or if he has an inclination to vomit, a great loss of appetite, or bleeds at the nofe. The advantage of the bath, according to Hippocrates, consists in moistening and refreshing, taking away weariness, making the skin soft and the joints pliant; in provoking urine, making the nostrils open, and opening the other excretories. He allows two baths in a day to those who have been accustomed to it in health.

In chronic distempers Hippocrates approved very much of exercise, though he did not allow it in acute ones: but even in these he did not think that a patient ought always to lie a-bed; but tells us, that “we must sometimes pulse the timorous out of bed, and roufe up the lazy.”

When he found that diet and exercise were not sufficient to ease nature of a burden of corrupted humours, he was obliged to make use of other means, of purgation, which purgation was one. By this word he understood all the contrivances that are made use of to discharge the stomach and bowels; though it commonly signifies only the evacuation by the belly by stool. This evacuation he imagined to be occasioned by the purgative medicines attracting the humours to themselves. When first taken into the body, he thought they attracted that humour which was most similar to them, and then the others, one after another. — Most of the purgatives used in his time were emetics also, or at least were very violent in their operation downwards. These were the white and black hellebore; the first of which is now reckoned among the poisons. He caused also the Cnidian berries, which are nothing else but the seeds of thymelea or chamaelea; eunoroum peplium, which is a fort of milk-thistle; thapias; the juice of hippochae, a fort of rhamnus; elaterium, or juice of the wild cucumber; flowers of brais, coloquintida, scammony, the magneian stone, &c.

As these purgatives were all very strong, Hippocrates was extremely cautious in their exhibition. He did not prescribe them in the dog-days; nor did he prescribe long abstinence, or in children or old people. He principally used purgatives in chronic distempers; but was much more wary in acute ones. In his book entitled “Of Epidemical Distempers,” there are very few patients mentioned to whom he gave purgative medicines. He also takes notice expressly, that these medicines having been given in cases of the distempers of which he was treating, had produced very bad effects. We are not, however, from this to conclude, that Hippocrates absolutely condemned purging in acute distempers; for in some places he expressly mentions his having given them with success. He was of opinion, for instance, that purging was good in a pleurisy when the pain was seated below the diaphragm; and in this case he gave black hellebore, or some peplium mixed with the juice of *herpitiutum*, which is supposed to have been our aafetida.

The principal rule Hippocrates gives with relation to purging is, that we ought only to purge off the humours that are concocted, and not those that are yet crude, taking particular care not to do it at the beginning of the distemper, lest the humours should be...
be disturbed or stirred up, which happens pretty often
He was not, however, the first who remarked that
it would be of ill consequence to stir the humours in
the beginning of an acute distemper. The Egyptian
physicians had before observed the same thing. By
the beginning of a distemper, Hippocrates understood all
the time from the first day to the fourth complete.

Hippocrates imagined that each purgative medicine
was adapted to the carrying off some particular hu-
mour; and hence the division of purgatives into hy-
drogogue, cholagogue, &c. which is now justly explo-
ded. In consequence of this notion, which prevailed
long after his time, he pretended that we knew if a pur-
gative had drawn from the body what was fit to be eva-
cuated according as we found ourselves well or ill upon it.
If we found ourselves well, it was a sign that the
medicine had effectually expelled the offending humour.
On the contrary, if we were ill, he imagined, whatever
quantity of humour came away, that the humour which
caused the illness still remained; not judging of the
goodness or badness of a purge by the quantity of
matters that were voided by it, but by their quality
and the effect that followed after it.

Vomits were also pretty much used as medicines by
Hippocrates. We have already seen what those were
which he prescribed to people in health by way of pre-
ventatives. With regard to the sick, he sometimes ad-
vised them to the same, when his intentions were only
to cleanse the stomach. But when he had a mind to
recall the humours, as he termed it, from the immodi-
ately recedes of the body, he made use of brisker remedies.
Among these was white hellebore; and this indeed he
moft frequently used to excite vomiting. He gave
this root particularly to melancholy and mad people; to make them
vomit, and to draw the phlegm from the
vifed them to the same, when his intentions were only per-
s. For that purpofe he made ufe of the juices of

On these occasions Hippocrates proposed to purge
the head alone. This practice he employed, after pur-
ging the rest of the body, in an apoplexy, inveterate
pains of the head, a certain fort of jaundice, a con-
sumption, and the greatest part of chronic distem-
pers.

For that purpose he made ufe of the juices of
several plants, as cery; to which he sometimes added
aromatic drugs, making the patients snuff up this
mixture into their noftils. He ufed also powders com-
pounded of myrrh, the flowers of brafs, and white
hellebore, which he caufed them put up into the nofe,
to make them fneeze, and to draw the phlegm from
the brain.

Vomit was alfo pretty much ufed as
by the head alone. This
medicine was adapted to the carrying off hy-
drogogue, cholagogue, &c. which is now
justly exploded. In consequence of this

He commanded the patient to draw in
his breath, and in other chronical disor-
ders. lungs a liquor that irritated the part, which, ra-
iving a

But we do not find that he made ufe of it in acute di-
tempers, except in the cholera morbus, where he says
he prescribed it with benefit. Some took this medi-
cine failing; but molt took it after supper, as was com-
monly practifed with regard to vomits taken by way of
prevention. The reason why he gave this thing, which
Hippocrates and other ancient physicians, the phrase
to have need of hellebore, became a proverbial expre-
sion for being out of one's fenes. He gave it also in de-
fusions, which come, according to him, from the
brain, and throw themselves on the noftils or ears, or
fill the mouth with saliva, or that caufe stubborn pains
in the head, and a wearinefs or an extraordinary hea-
matter in the

Among thefe
to recall the courfe

As to the

Vessels that were

caufed them put up into the nofe,
to make them fneeze, and to draw the phlegm from
the brain.

For the fame purpose alfo he ufed what
he calls tetragonon, that is, "something having four
gles," but what this was, is now altogether un-
known, and was fo even in the days of Galen. The
latter physician, however, conjectures it to be antimo-
y, or certain flakes found in it.

In the diftemper called onypema (or a collection of
matter in the breast), he made ufe of a very rough me-
dicine. He commanded the patient to draw in his
tongue as much as he was able; and when that was
done, he endeavoured to put into the hollow of the
lungs a liquor that irritated the part, which, raising a
violent cough, forced the lungs to discharge the puru-
 lent matter contained in them. The materials that he
used for this purpose were of different forts; sometimes
he took the root of arum, which he ordered to be boil-
ted with a little falt, in a sufficient quantity of water
and oil; diluting a little hone with it. At other times,
when he intended to purge more strongly, he took the
flowers of copper and hellebore; after that he shook
the patient violently by the shouldcrs, the better to
loosen the pus.

This remedy, according to Galen,
he received from the Cnidian physicians; and it has
never been ufed by the succeeding ones, probably be-
cause the patients could notuffer it.

Blood-letting was another method of evacuation
pretty much ufed by Hippocrates. Another aim he re-
peating had in this, besides the mere evacuation, was to divert
blood
or to recall the courfe of the blood when he imagined it

ting

was going where it ought not.

A third end of bleed-
ing was to procure a free motion of the blood and pus,
Hippocrates had also a fourth intention for bleeding, and this was reinforcement. So in the iliac paffage, he ordered bleeding in the arm and in the head; to the end, says he, that the superior venter, or the breast, may cease to be overheated. With regard to this evacuation, his conduct was much the fame as to purging, in respect of time and perfon. We ought, says he, to let blood in acute diseases, when they are violent, if the party be lusty and in the flower of his age. We ought also to have regard to the time, both in respect to the disease and to the feafon in which we let blood. He also informs us, that blood ought to be let in great pangs, and particularly in inflammations. Among thefe he reckons such as fall upon the principal viscera, as the liver, lungs, and spleen, as also the quinsy and pleurisy. In the pain of the latter he above the dia­phragm. In thofe cases he would have the patients bled until they faint, especiaily if the pain be very acute; or rather he advifes that the orifice fhould not be closed till the colour of the blood alters, fo that from livid it turn red, or from red livid. In a quinsy he bled in both arms at once. Difficulty of breathing he also reckons among the diftempers that require bleeding; and he mentions another fort of inflammation of the lungs, which he calls a swelling or tumor of the lungs arifing from heat; in which cafe he advifes to bled in all parts of the body; and directs particularly to the arms, tongue, and noftrils. To make bleeding the more ufeful in all pangs, he directed to open the vein nearest the part affected; in a pleurisy he directs to take blood from the arm of the side affected; and for the fame reafon, in pangs of the head, he directs the veins of the nose and forehead to be opened. When the pain was not urgent, and bleeding was advifed by way of prevention, he directed the blood to be taken from the parts furthest off, with a defign to divert the blood infintly from the fear of pain. The highest burning fevers, which flow with fears of inflammation nor pain, he does not rank among thofe diftempers that require bleeding. On the contrary, he maintains that a fever itelf is in fome cafes a reafon againft bleeding. If any one, says he, has an ulcer in the head, he must bleed, unlefs he has a fever. He fays further, thofe that lose their speech from a sudden muff be bled, unlefs they have a fever. Perhaps he was afraid of bleeding in fevers, becaufe he fuppofed that they were produced by the bile and pituita, which grew hot, and afterwards heated the whole body, which is, fays he, what we call fever, and which, in his opinion, cannot well be evacuated by bleeding. In other places also he looks upon the prefeuce or abundance of bile to be an objeGion to bleeding; and he orders to forbear venéction even in a pleurisy, if there be bile. To this we must add, that Hippocrates di­stinguished very particularly between a fever which followed no other diftemper, but was itself the original malady, and a fever which came upon inflammation. In the early ages of phyfic, the firft were only properly called fevers: the others took their names from the parts affected; as pleurisy, perigemumany, hepatisitis, no­phritis, &c., which names signify that the pleura, the lungs, the liver, or the kidneys, are difeafed, but do not injufite the fever which accompanies the diftempe. In this latter fort of fever Hippocrates connantly ordered bleeding, but not in the former. Hence in his books Of Epidemical Diftempers, we find but few direc­tions for bleeding in the acute diftempers, and particular­ly in the great number of continual and burning fevers there treated of. In the firft and third book we find but one fingle infance of bleeding, and that in a pleurisy; in which, too, he flaid till the eighth day of the diftemper. Galen, however, and molt other commentators on Hippocrates, are of opinion that he generally bled his patients plentifully in the beginning of acute disorders, though he takes no notice of it in his writings. But had this been the cafe, he would not perhaps have had the opportunity of feeing fo many fevers terminate by crises, or natural evacuations, which happen of themfelves on certain days. Hippocrates, in fad, laid fo much weight upon the influance of nature and the method of diet, which was his favourite medicine, that he thought if they took care to diet the patients before mentioned, according to rule, they might leave the refi to nature. These are his principles, from which he never deviates; fo that his pieces Of Epidemical Diseases fefm to have been compafled only with an intention to leave to po­fterity an exact model of management in purfuance of thefe principles.

With regard to the rules laid down by Hippocrates for bleeding, we must further take notice, that in all diftempers which had their seat above the liver, he bled in the arm, or in fome of the upper parts of the body; but for thofe that were fittuated below it he directed the veins of the foot, ankle, or harm. If the belly was too laxative, and bleeding was at the fame time thought necessary, he ordered the leofensid to be stopped before bleeding.

Almost all these infances, however, regard fevere any thing but acute diftempers; but we find feveral con-

**History.**

Hippocrates.

Concerning chronic diseases. "A young man complained of great pain in his belly, with a rumbling while he was fasting, which ceased after eating; this pain and rumbling continuing, his meat did him no good; but, on the contrary, he daily wasted and grew lean. Several medicines, as well purges as vomits, were given him in vain. At length it was resolved to bleed him by intervals, first in one arm and then in the other, till he had scarce any blood left, and by this method he was perfectly cured."

Hippocrates let blood also in a drop by, even in a tympany; and in both cases he prescribes bleeding in the arm. In a disease occasioned by an overgrown spleen, he proposes bleeding several times repeated at a vein of the arm which he calls the spleenetic; and in a kind of jaundice, he proposes bleeding under the tongue. On some occasions he took away great quantities of blood, as appears from what we have already observed. Sometimes he continued the bleeding till the patient fainted; at other times he would bleed in both arms at once; at others, he did it in several places of the body, and at several times. The veins he opened were those of the arm, the hands, the ankles on both sides, the hams, the forehead, behind the head, the tongue, the nose, behind the ears, under the breasts, and those of the arms; besides which, he burnt others, and opened several arteries. He likewise used cupping-vesels, with intent to reac or withdraw the humours which fell upon any part. Sometimes he contended himself with the bare attraction made by the cupping-vesels, but sometimes also he made scarifications.

When bleeding and purging, which were the principal and most general means used by Hippocrates for taking off a plethora, proved insufficient for that purpose, he had recourse to diuretics and sudorifics. The former were of different sorts, according to the constitution of the person: sometimes baths, and sometimes sweet wine, were employed to provoke urine; sometimes the nourishment which we take contributes to it: and amongst those herbs which are commonly eaten, Hippocrates recommends garlic, leeks, onions, cucumbers, melons, gourds, fennel and all other things which have a biting taste and a strong smell. With these he numbers honey, mixed with water or vinegar, and all salt meats. But, on some occasions, he took four cantharides, and pulling off their wings and feet, gave them in wine and honey. These remedies were given in a great number of chronic dis-temperers after purging, when he thought the blood was overcharged with a sort of moisture which he calls kebor; or in impregnations of urine, and when it was made in lesser quantity than it ought. There were also some cafes in which he would force sweat as well as urine, but he neither mentions the diseases in which sudorifics are proper, nor lets us know what medicines are to be used for this purpose, except in one single passage, where he mentions sweating, by pouring upon the head a great quantity of water till the feet sweat; that is, till the sweat diffuses itself over the whole body, running from head to feet. After this he would have them eat boiled meat, and drink pure wine, and being well covered with clothes, lay themselves down to rest. The diseases for which he proposes the above-mentioned remedy is a fever; which is not, according to him, produced by bile or phlegm, but by mere altitude, or some other similar cause; from whence we may conclude that he did not approve of sweating in any other kind of fever.

Other remedies which Hippocrates tells us he made use of were those that purged neither bile nor phlegm, but act by cooling, drying, heating, moilting, or by closing and thickening, resolving and diluting. These medicines, however, he does not particularly mention; and it is probable they were only some particular kinds of food. To these he joined hypnoses, or such things as produce sleep; but these last were used very seldom, and, it is most probable, were only different preparations of poppies.

Lastly, besides the medicines already mentioned, which acted in a sensible manner, Hippocrates made use of others called specific; whose action he did not understand, and for the use of which he could give no reason besides his own experience, or that of other physicians. Thence he had learned from his predecessors the descendants of AEsclapius, who, being empirics, did not trouble themselves about inquiring into the operation of their remedies, provided their patients were cured.

Of the external remedies prescribed by Hippocrates, fomentations were the chief. These were of two kinds. The one was a sort of bath, in which the patient sat in a vessel full of a decocition of simples appropriated to his malady; so that the part affected was soaked in the decoction. This was chiefly used in distempers of the womb, of the arms, the bladder, the reins, and generally all the parts below the diaphragm. The second way of fomenting was to make a hot decoction of warm water and put it into a skin or a bladder, or even into a copper or earthen vessel, and to apply it to the part affected; as, for example, in a pleurisy. They used likewise a large sponge, which they dipped in the water, or other hot liquor, and squeezed out part of the liquor before they applied it. The same use they made of barley, vetches, or bran, which were boiled in some proper liquor, and applied in a linen bag. These are called moist fomentations. The dry ones were made of salt or millet, heated considerably, and applied to the part. Another kind of fomentation was the vapour of fome hot liquor; an infusion of which we find in his third book of Women's Distemperers. He calls, at several times, bits of red-hot iron into urine, and, covering up the patient close, caused her to receive the steam below. His design in these kinds of fomentations was to warm the part, to resolve or dilate, and draw out the pernicious matter, to mollify and affage pain, to open the passages, or even to hum them, according as the fomentations were emollient or astringent.

Fumigations were likewise very often used by Hippocrates. In the quinsy, he burned hyssop with sulphur and pitch, and caused the fume to be drawn into the throat by a funnel; and by this means he brought away abundance of phlegm through the mouth and through the nose. For this purpose he took nitre, marjoram, and cres-fleads, which he boiled in water, vinegar, and oil, and, while it was on the fire, caused the patient to draw in the fume by a pipe. In his works we find a great number of fumigants for the distemperers of women, to promote the menstrual flux.
flux, to check it, to help conception, and to ease pains in the matrix, or the correction of it. On these occasions he used such aromatics as were then known, viz. cinnamon, calamus, myrrh, and several odoriferous plants; likewise some minerals, such as nitre, sulphur, and pitch, and caused them to receive the vapours through a funnel into the uterus.

Gargles, a kind of fomentations for the mouth, were also known to Hippocrates. In the quinine he used a gargle made of marjoram, savoury, celery, mint and nitre, boiled with water and a little vinegar. When this was strained, they added honey to it, and wafted their mouths frequently with it.

Oils and ointments were likewise much used by Hippocrates, with a view to mollify and abate pain, to ripen boils, resolve tumors, refresh after weariness, make the body supple, &c. For this purpose, sometimes pure oil of olives was used; sometimes certain simples were infused in it, as the leaves of myrtle and roses; and the latter kind of oil was in much request among the ancients. There were other sorts of oils sometimes in use, however, which were much more compounded. Hippocrates speaks of one called fulnum, which were made of the flowers of the iris, of some aromatics, and of an ointment of narcissus made with the flowers of narcissus and aromatics infused in oil. But the most compounded of all his ointments was that called neotium, which he made particularly for women; and confituted, according to Hesychius, of a great number of ingredients. Another ointment, to which he gave the name of ceratum, was composed of oil and wax. An ointment which he recommends for the softening of a tumor, and the cleansing of a wound, was made by the following receipt; "Take the quantity of a nut of the marrow or fat of a sheep, of mastice or turpentine the quantity of a bean, and as some ointment, or juice of a plant, to make a solid or the quantity of a nut of the marrow or fat of a

Cataplasm were a sort of remedies less efficient than the two former. They were made of powders or tinctures or boiled in water or some other li­quor, to which sometimes they added oil. They were used with a view to soften or resolve tumors, ripen abscesses, &c. though they had also cooling cataplams made of the leaves of beets or oak, fig or olive-trees, boiled in water.

Collyria. Lastly, to complete the catalogue of the external remedies used by Hippocrates, we shall mention a sort of medicine called collyrium. It was compounded of powders, to which was added a small quantity of some ointment, or juice of a plant, to make a solid or dry mass; the form of which was long and round, which was kept for use. Another composition of much the same nature was composed of a small piece of money, which was burnt upon coals for a perfume, and powdered for particular uses. In his works we find likewise descriptions of powders for several uses, to take off fungous stich, and to blow into the eyes in ophthalmics, &c.

These were almost all the medicines used by Hip­pocrates for external purposes. The compound med­icines given inwardly were either liquid, solid, or lumbative. The liquid ones were prepared either by decoction or infusion in a proper liquor, which, when strained, was kept for use; or by macerating certain powders in such liquors, and so taking them together, or by mixing different kinds of liquors together. The solid medicines consisted of juices infused; of gums, resins, or powders, made up with them or with honey, or something proper to give the necessary consistence to the medicine. These were made up in a form and quantity fit to be swallowed with ease. The lumbative was of a consistence be­tween solid and fluid; and the patients were obliged to keep it for some time to dissolve in the mouth, that they might swallow it leisurely. This remedy was used to take off the acrimony of these humours which sometimes fall upon this part, and provoke coughing and other inconveniences. The basis of this last com­position was honey. It is worth our observation, that the compound medicines of Hippocrates were but very few, and composed only of four or five ingredients at most, and that he not only understood pharmacy, or the art of compounding medicines, but prepared such as he used himself, or caused his servants to prepare them in his house by his directions.

We have thus given some account of the state of medicine as practised and taught by Hippocrates, who, as we have already observed, has for many ages been justly considered as the father of physic. For when we attend to the state in which he found medicine, and the condition in which he left it, we can hardly bestow sufficient admiration on the judgment and accuracy of his observations. After a life spent in un­worned industry, he is said to have died at Larissa, a city in Thessaly, in the toad year of his age, 351 years before the birth of Christ.

After the days of Hippocrates, medicine in ancient Greece gradually derived improvement from the labours of other physicians of eminence. And we may particularly mention three to whom its future pro­gress seems to have been not a little indebted, viz. Praxagoras, Erasistratus, and Herophilus.

The first physician of eminence who differed con­siderably in his practice from Hippocrates was Praxa­goras. Celsus Aurelianus acquaints us, that he made great use of vomits in his practice, in so much as to exhibit them in the biception till the ex­crement were discharged by the mouth. In this dif­temper he also advised, when all other means failed, to open the belly, cut the intesine, take out the contents, and then to few up all again; but this practice has not probably been followed by any subsequent physician.

Erasistratus was a physician of great eminance, and flourished in the time of Seleucus, one of the successors of Alexander the Great. According to Galen, he entirely banished venefication from medicine; though some affirm that he did not totally dis­card it, but only used it less frequently than other physicians. His reasons for disapproving of venec­fication are as follow: It is difficult to succeed in vencefication, because we cannot always see the vein we intend to open, and because we are not sure but we may open an artery instead of a vein. We cannot ascertain the true quantity to be taken. If we take too little, the intention is by no means answered; if we take too much, we run a risk of destroying the patient. The evacuation of the venous blood also is
History.

MEDICINE.

Erasistratus succeeded by that of the spirits, which on that occasion pass from the arteries into the veins. It must likewise be observed, that as the inflammation is formed in the arteries by the blood coagulated in their orifices, venefection must of course be useless and of no effect.

As Erasistratus did not approve of venefection, so neither did he of purgatives, excepting very rarely, but exhibited enemias and vomits; as did also his master Chryippus. He was of opinion, however, that the enemias should be mild; and condemned the large quantity and acrid quality of those used by the ancients. The reason why purgatives were not much used by him was, that he imagined purging and venefection could answer no other purpose than diminishing the fulness of the vessels; and for this purpose he asserted that there were more effectual means than either phlebotomy or purging. He asserted that the humours discharged by cathartics were not the same in the body that they appeared after the discharge; but that the medicines changed their nature, and produced a kind of corruption in them. This opinion has since been embraced by a great number of physicians. He did not believe that purgatives acted by attraction; but substantiated in the place of this principle what Mr Le Clerc imagines to be the same with Aristotle's fuga vocis. The principal remedy substantiated by him in place of purging and venefection was absinence. When this, in conjunction with enemias and vomits, was not sufficient to eradicate the disease, he then had recourse to exercise. All this was done with a view to diminish the plentitude, which, according to him, was the most frequent cause of all diseases. Galen also informs us, that Erasistratus had so great an opinion of the virtues of succory in diseases of the viscerâ and lower belly, and especially in those of the liver, that he took particular pains to describe the method of boiling it, which was, to boil it in water till it was tender; then to put it into boiling water a second time, in order to destroy its bitterness; afterwards to take it out of the water, and preserve it in a vessel with oil; and lastly, when it is to be used, to add a little weak vinegar to it. Nay, so minute and circumstantial was Erasistratus with regard to the preparation of his favourite succory, that he gave orders to tie several of the plants together, because that was the more commodious method of boiling them. The art of Erasistratus's medicines consisted almost entirely of regimen; to which he added some topical remedies, such as cataplasms, fomentations, andunctions. In short, as he could neither endure compounded medicines, nor supurations and fine-pan reaoning, he reduced medicine to a very simple and comprehensible art.

With regard to surgery, Erasistratus appears to have been very bold; and as an anatomist he is said to have been exceedingly cruel, inasmuch as he is represented by some as having dissected criminals while yet alive *. In a fcarious liver, or in tumors of that organ, Celsus Aurelianus observes, that Erasistratus made an incision through the skin and integuments, and having opened the abdomen, he applied medicines immediately to the part afflicted. But tho' he was thus bold in performing operations on the liver, yet he did not approve of the paracentesis or tapping in the dropsy; because (said he) the waters being evacuared, the liver, which is inflamed and become hard like a stone, is more press'd by the adjacent parts which the waters kept at a distance from it; so that by this means the patient dies. He declared also against drawing teeth which were not loose; and used to tell those who talked with him on this operation, That in the temple of Apollo there was to be seen an instrument of lead for drawing teeth; in order to inculcate that we must not attempt the extirpation of any but such as are loose, and call for no greater force for their extirpation than what may be suppos'd in an instrument of lead.

Herophilus, the disciple of Praxagoras, and cotemporary of Erasistratus, followed a less simple practice: he made so great use of medicines both simple and compound, that neither he nor his disciples would undertake the cure of any disorder without them. He seems also to have been the first who treated accurately of the doctrine of purges, of which Hippocrates had but a superficial knowledge. Galen, however, affirms, that on this subject he involved himself in difficulties and advanced absurdities; which indeed we are not greatly to wonder at, considering the time in which he lived. He took notice of a disease at that time pretty rare, and to which he ascribes certain sudden deaths. He calls it a polypus of the heart; and perhaps it may be the same disease with what is now termed the angina pectoris.

According to Celsius, it was about this time that medicine was first divided into three branches, viz. the dietetic, the pharmaceutical, and the chirurgical medicine. The first of these employed a proper regimen in the cure of diseases; the second, medicines; and the third, the operation of the hands; and the same author informs us, that these three branches became now the bufines's of as many different classes of men; so that from this time we may date the origin of the three professions of physicians, apothecaries, and surgeons.—Before this division, those called physicians discharged all the several offices belonging to the three professions; and there were only two kinds of them, viz. one called ἄρτητοι, who only gave their advice to the patients, and directions to those of an inferior class, who were called διαφανται, and worked with their hands either in the performing operations, or in the composition and application of remedies.

The first grand revolution which happened in the Hippocratic medicinal art after the days of Herophilus and Erasistratus was occasioned by the founding of the empire of Alexandria about 284 years before Christ. The division into dogmatists and empirics had indeed subsisted before; but about this time the latter party began to grow strong, and to have champions publicly asserting its cauca. Galen informs us, that Scarpion used Hippocrates very ill in his writings, in which he discovered an excess of pride, self-sufficiency, and contempt for all the physicians that went before him. We have some sketches of his practice in Celsius Aurelianus, from which we may infer that he retained the medicines of Hippocrates and the other physicians who went before him, tho' he rejected their reasoning. We know not what arguments he advanced for the support of his sentiments, since his works are lost, as well as those of the other empirics; and we should know nothing at all of any

* See Anatomy, 63.
The empirics admitted only one general method of obtaining skill in the medical art, which was by experience, called by the Greeks ἀρετή. From this word they took their name, and refused to be called after the founder or any champion of their sect. They defined experience a knowledge derived from the evidence of senses. It was either fortuitous, or acquired by design. For acquiring practical skill they recommended what they called ἀρετή, or one's own observation, and the reading of histories or cures faithfully related by others. Hence they thought that we are enabled to know a disease by its resemblance to others; and, when new diseases occurred, to conclude what was proper to be done from the symptoms which they had in common with others that were before known. They asserted, that observation ought principally to be employed in two different ways; first in discovering what things are salutary, and what are of an indifferent nature; and, secondly, what particular disease is produced by a certain concurrence of symptoms; for they did not call every symptom a disease, but only such a combination of them as from long experience they found to accompany each other, and produced such disorders as began and terminated in the same manner.

On the other hand, the dogmatists affirmed, that there was a necessity for knowing the latent as well as the evident causes of diseases, and that the physician ought to understand the natural actions and functions of the human body, which necessarily presupposes a knowledge of the internal parts. By secret or latent causes they meant such as related to the elements or principles of which our bodies are composed, and which are the origin of a good or bad state of health. They asserted that it was impossible to know how to cure a disease without knowing the cause whence it proceeded; because undoubtedly it behoved them to vary prodigiously in themselves according to the different causes by which they were produced. Thus, the remarkable person in the history of phyle is Aesoppiades, who flourished in the century immediately preceding the birth of Christ. He introduced the philosophy of Democritus and Epicurus into medicine, and ridiculed the doctrines of Hippocrates. He asserted, that matter considered in itself was of an unchangeable nature; and that all perceptible bodies were composed of a number of smaller ones, between which there were interpenetrated an infinity of small places totally void of all matter. He thought that the foul itself was composed of these small bodies. He laughed at the principle called Nature by Hippocrates, and also at the imaginary faculties laid by him to be subservient to lesser and still more at what he called Aceldama. This last principle Aesoppiades denied in every instance, even in that of the loadstone and steel, imagining that this phenomenon proceeded from a concourse of corpuscles, and a particular disposition or modification of their pores. He also maintained, that nothing happened or was produced without some cause; and that what was called nature was in reality no more than matter and motion. From this last principle he inferred that Hippocrates knew not what he said when he spoke of Nature as an intelligent being, and ascribed qualities of different kinds to her. For the same reason he ridiculed the doctrine of Hippocrates with regard to crises; and asserted that the termination of diseases might be as well accounted for from mere matter and motion. He maintained, that we were deceived if we imagined that nature always did good; since it was evident that she often did a great deal of harm. As for the days particularly fixed upon by Hippocrates for crises, or those on which we usually observe a change either for the better or the worse, Aesoppiades denied that such alternations happened on those days rather than on others. Nay, he asserted that the crisis did not happen at any time of its own accord, or by the particular determination of nature for the cure of the disorder, but that it depended rather on the address and dexterity of the physician; that we ought never to wait till a dilemma terminates of its own accord, but that the physician by his care and medicines must hasten on and advance the cure. — According to him, Hippocrates and other ancient physicians attended their patients rather with a view to observe in what manner they died than in order to cure them; and this under pretence that Nature ought to do all herself, without any assistance.

According to Aesoppiades; the particular semblance of the various corpuscles abovementioned, and represented as of different figures, is the reason why there are several pores or interstices within the common mass, formed by these corpuscles; and why these pores are of a different size. This being taken for granted, as these pores are in all the bodies we observe, it must of course follow that the human body has some peculiar to itself, which, as well as those of all other bodies, contain other minute bodies, which pass and repass by those pores that communicate with each other; and as these pores or interstices are larger or smaller, to the corpuscles which pass through them differ proportionably as to largeness and to minuteness. The blood conflicts of the largest of these corpuscles, and the spirits, or the heat, of the smallest.

From these principles he infers, that as long as the corpuscles are freely received by the pores, the body remains in its natural state; and on the contrary, it begins to recede from that state, when the corpuscles find any obstacle to their passage. Health therefore depends on the just proportion between the pores and the corpuscles; they are destined to receive and transmit; as diseases, on the contrary, proceed from a disproportion between these pores and the corpuscles. The most usual obstacle on this occasion proceeds from the corpuscles embracing each other, and being retained in some of their ordinary passages, whether these corpuscles arrive in too large a number, are of irregular figures, move too fast or too slow, &c.

Among the disorders produced by the corpuscles, they drop offing of their own accord, Aesoppiades reckoned phrenies, lethargies, plagues and burning fevers. Pains, in particular, are clatified among the accidents which derive their origin from a stagnation of the largest of all the corpuscles of which the blood consists. Among the disorders produced by the bad state and disposition of the pores, he placed deliquiuums, languors, excretions, leannets, and dropsies. These last disorders he thought proceeded from the pores being too much relaxed and opened; the dropsy in
History.

Medicine.

Aesclepiades, in particular, thinks proceeds for the fist being perforated with various small holes, which convert the nourishment received into them into water. Hunger, and especially that species of it called fumes caninae, proceeds from an opening of the large pores of the stomach and belly; and thirst from an opening of their small ones. Upon the same principles he accounted for intermittent fevers. Quotidian fevers are caused by a retention of the largest corpuscles, those of the tertian kind by a retention of corpuscles somewhat smaller, and quartan fevers are produced by a retention of the smallest corpuscles of all.

The practice of Aesclepiades was suited to remove these imaginary causes of disorders. He composed a book concerning common remedies, which he principally reduced to three, viz. gelatination, friction, and the use of wine. By various exercises he proposed to render the pores more open, and to make the juices and small bodies, which cause feaftes by their retention, pass more freely; and while the former physicians had not recourse to gelatination till towards the end of long continued disorders, and when the patients, tho' entirely free from fever, were yet too weak for any vigorous exercise by walking; Aesclepiades used gelatination from the very beginning of the most burning fevers. He laid it down as a maxim, that one fever was to be cured by another; that the strength of the patient was to be exhausted by making him watch and endure thirst to such a degree, that, for the two first days of the disorder, he would not allow them to cool their mouths with a drop of water. Celsus also observes, that though Aesclepiades treated his patients like a butcher during the first days of the disorder, he induced them so far afterwards as even to give directions for making their beds in thefoleft manner. On several occasions Aesclepiades used frictions to open the pores. The droppy was one of the diitempers in which this remedy was used; but the most singular attempt was, by these means, to lull phrenetic patients to sleep. But though he enjoined patients abstinence to an extreme degree.

The next great revolution which happened in the medicinal art, was brought about by Themison, the disciple of Aesclepiades, who lived not long before the time of Celsus, during the end of the reign of Augustus, or beginning of that of Tiberius. The art founded by him was called methodic, because he endeavoured to find a method of rendering medicine more effectual, than former.

He maintained, that a knowledge of the caufes of these feaftes was not necessary, provided we have a due regard to what feaftes have in common and analogous to one another. In consequence of this principle, he divided all feaftes into two, or at most three, kinds. The fit included feaftes arising from friction; the second, those arising from relaxation; and the third, those of a mixed nature, or such as partook, both of friction and relaxation.

Themison also asserted, that feaftes are sometimes acute, and sometimes chronic; that for a certain time they increase, and at a certain time they are at their height; and that at last they were observed to diminish. Acute feaftes, therefore according to him, must be treated in one way, and chronic ones in another; one method must be followed with such as are in their augmentation, another with such as are at their height, and a third with such as are in their declension. He asserted, that the whole of medicine consisted in the observation of that small number of rules which are founded upon things altogether evident. He said, that all disorders, whatever their nature was, included under any of the kinds above-mentioned, ought to be treated precisely in the same way, in whatever country and with whatever symptoms they happen to arise. Upon these principles, he defined medicine to be a method of conducting to the knowledge of what feaftes have in common with each other, and which at the same time is evident.

Themison was old when he laid the foundation of the Methodic sect; and it was only brought to perfection by Theflalus, who lived under the emperor Nero. Theflalus, Galen and Pliny accuse this physician of intolerable in detail and vanity, and report that he gave himself the air of defpising all other physicians; and so intolerable was his vanity, that he assumed the title of the conqueror of physicians, which he caused to be put up on his tomb in the Appian way. Never was a more remarkable (say Pliny) attended by a greater number of followers than Theflalus had generally about him; and this circumstance is the less to be wondered at, if we consider that he promised to teach the whole art of medicine in less than six months. In reality, the art might be learned much sooner if it comprehended no more than what the methodics thought necessary; for they cut off the examination of the caufes of feaftes followed by the dogmatics; and substituted in the room of the laborious observations of the empirics, indications drawn from the analogy of feaftes, and the mutual resemblance they bear to each other. The most skilful of all the methodics, and he who put the last hand to it, was Soranus. He lived under the emperors Trajan and Adrian, and was a native of Ephesus.
tiquity was Celsus, whom we have already had occasion to mention. Most writers agree that he lived in the time of Tiberius, but his country is uncertain. It is even disputed whether or not he was a professed physician. Certain it is, however, that his books on medicine are the most valuable of all the ancients next to those of Hippocrates. From the latter, indeed, he has taken so much, as to acquire the name of the Latin Hippocrates; but he has not attached himself to him so closely as to reject the affinities of other authors. In many particulars he has preferred Aesculapiades. With him he laughs at the critical days of dogmatic, empiric, methodic, and other feists, had each their abettors. The methods were held in great esteem, and looked upon to be superior to the dogmatism, who were strangely divided among themselves, some of them following Hippocrates, others Erafiratus, and others Aesculapiades. The empirics made the least considerable figure of any. Galen undertook the reformation of medicine, and restored dogmatism. He seems to have been of that sect which was called celestial, from their choosing out of different authors what they esteemed good in them, without being particularly attached to any one more than the rest. This declaration he indeed fets out with; but, notwithstanding this, he follows Hippocrates much more than any of the rest, or rather follows nobody else but him. Though before his time several physicians had commented on the works of Hippocrates, yet Galen pretends that none of them had understood his meaning. His first attempt therefore was to explain the works of Hippocrates; with which view he wrote a great deal, and after this he undertakes the establishment of the science of medicine, and the physician ought to consider as found, as not found, or of a neutral and indifferent nature. These are the body itself, the signs, and the causes. He refuses the human body found, when it is in a good state or habit with regard to the simple parts of which it is composed, and when besides there is a just proportion between the organs formed of these simple parts. On the contrary, the body is reckoned to be unfound, when it recedes from this state, and the just proportion abovementioned. It is in a state of neutrality or indifference, when it is in a medium between soundness and its opposite state. The salutary signs are such as indicate present health, and prognosticate that the man may remain in that state for some time to come. The infalubrious signs, on the contrary, indicate a present disorder, or lay a foundation for suspecting the approach of one. The neutral signs, or such as are of an indifferent nature, denote neither health nor indisposition, either for the present, or for the time to come. In like manner he speaks of causes salutary, infalubrious, and indifferent.

These three dispositions of the human body, that is, soundness, its reverse, and a neutral state, comprehend all the difference between health and disorder or indifference.
HISTORY.

Upon these principles Galen defined a disease to be "such a preternatural disposition or affection of the parts of the body, or faculties of the soul, as is foreign to their natural and proper action." He established three principal kinds of diseases: the first relates to the similar parts; the second, to the organical; and the third is common to both these parts. The first kind of diseases consists in the intemperature of the similar parts; and this is divided into an intemperature without matter, and an intemperature with matter. The first discovers itself when a part has more or less heat or cold than it ought to have without that change of quality in the part being supported and maintained by any matter. Thus, for instance, a person's head may be overheated and indispensible by being exposed to the heat of the sun, without that heat being maintained by the continuance or conception of any hot humour in the part. The second fort of intemperature is when any part is not only rendered hot or cold, but also filled with a hot or cold humour, which are the cauages of the heat or cold felt in the part. Galen also acknowledged a simple intemperature: that is, when one of the original qualities, such as heat or cold, exceeds alone and separately; and a compound intemperature, when two qualities are joined together, such as heat and dryness, or coldness and humidity. He also established an equal and unequal temperature. The former is that which is equally in all the body, or in any particular part of it, and which creates no pain, because it becomes habitual, such as dryness in the hectic constitution. The latter is distinguished from the former, in that it does not equally suffit the whole of the body, or in the whole of a part. Of this kind of intemperature we have examples in certain fevers, where heat and cold, equally, and almost at the same time, attack the same part; or in other fevers, which render the surface of the body cold as ice, while the internal parts burn with heat; or lastly, in cases where the stomach is cold and the liver hot.

The second kind of disorders, relating to the organical parts, results from irregularities of these parts, with respect to the number, bulk, figure, situation, &c.; as when one has six fingers, or only four; when one has any part larger or smaller than it ought to be, &c. The third kind, which is common both to the similar and the organical parts, is a solution of continuity, which happens when any similar or compound part is cut, bruised, or corroded.

Like Hippocrates, Galen distinguished diseases into acute and chronic; and, with respect to their nature and genius, into benign and malignant; also into epidemic, endemic, and sporadic.

After having distinguished the kinds of diseases, Galen comes to explain the causes; which he divides into external and internal. The external causes of diseases, according to him, are six things, which contribute to the preservation of health when they are well disposed and properly used, but produce a contrary effect when they are imprudently used or ill disposed. These six things are, the air, aliments and drinks, motion and rest, sleeping and watching, retention and excretion, and lastly the passions. All these are called the procaartic or beginning causes, because they put the original source or principle of motion in all these faculties, Galen, as well as Hippocrates, defines to be Nature.
M E D I C I N E.

History.

Galen. in motion the internal causes; which are of two kinds, the anteculix and the conjunct. The former is discovered only by reasoning; and consists for the most part in a peculiarity of the humours, either by plentitude or catarachmy, i.e. a bad state of them. When the humours are in too large a quantity, the cafe is called a plethora; but we must observe, that this word equally denotes too large a quantity of all the humours together, or a redundancy of one particular humour which prevails over the rest. According to these principles, there may be a languid, a biliar, a pituitous, or a melancholy plentitude: but there is this difference between the languid and the three other plentitudes, that the blood, which is the matter of the former, may be discharged, whereas, if any of the three last mentioned ones do so, the cafe is no longer called plentitude, but catarachmy because the humours, abounding more than they ought, corrupt the blood. The causes he also divides into such as are manifest and evident, and such as are latent and obscure. The first are such as spontaneously come under the cognizance of our senses when they act or produce their effects; the second are not of themselves perceptible, but may be discovered by reasoning: the third fort, i.e. such as he calls occult or concealed, cannot be discovered at all. Among this last he places the cause of the hydrophobia.

He next proceeds to consider the symptoms of diseases. A symptom he defines to be "a preternatural affection depending upon a disease, or which follows it as a shadow does a body." He acknowledged three kinds of symptoms: the first and most considerable of these is the action of the parts being injured or hindered; the second in a change of the quality of the parts, their actions in the mean time remaining entire; the third related to defects in point of exertion and retention.

After having treated of symptoms, Galen treats of the signs of diseases. These are divided into diagnostic and prognostic. The first are so called because they enable us to know diseases, and distinguish them from each other. They are of two sorts, pathognomonic and adjunct. The first are peculiar to every disease, make known its specific species, and always accompany it, so that they begin and end with it. The second are common to several diseases, and only serve to point out the difference between diseases of the same species. In a pleurisy, for instance, the pathognomonic signs are a cough, a difficulty of breathing, a pain of the side, and a continued fever; the adjunct signs are the various sorts of matter expirated, which are sometimes bloody, sometimes bilius, &c.

The diagnostic signs were drawn from the defective or disordered disposition of the parts, or from the diseases themselves; secondly, from the causes of diseases; thirdly, from their symptoms; and lastly, from the particular dispositions of each body, from things which prove prejudicial and those that do service, and from epidemic diseases. The prognostic signs he gathered from the species, virulence, and peculiar genius of the disease: but as we have already spoken so largely concerning the prognostics of Hippocrates, it is superfluous to be particular on those of Galen.

His method of cure differed little from that of Hippocrates; but from the specimen already given of Galen's method of teaching the medical art, it is evident that his system was little else than a collection of speculations, definitions, and refinements; whereas that of Hippocrates was founded immediately upon facts, which he had either observed himself, or had learned from the observation of others.

The system of Galen, however, notwithstanding its defects and absurdities, remained almost uncontradicted for a very long period. Indeed it may be considered as having been the prevailing system till the inundation of the Goths and Vandals put an almost entire stop to the cultivation of letters in Europe. But during the general prevalence of the system of Galen, there appeared some writers to whom medicine was indebted for improvements, at least in certain particulars. Among the most distinguished of these we may mention Oribasius, Aetius, Alexander, and Paulus.

Oribasius flourished about the year 360, and was physician to the emperor Julian. He speaks very fully of the effects of bleeding by way of scarcification, a thing little taken notice of by former writers; from his own experience he affirms us that he had found it successful in a supputation of the menes, defluxions of the eyes, headach, and fraintness of breathing even when the person was extremely old. He tells his own case particularly, when the plague raged in Asia, and he himself was taken ill, that the second day he scarified his leg, and took away two pounds of blood; by which means he entirely recovered, as did several others who used it. In this author also we find the first description of a surprising and terrible distemper, which he termed lepra locularis, a species of melancholy and madness, which he describes thus. "The persons affected get out of their houses in the night-time, and in every thing imitate wolves, and wander among the sepulchres of the dead till day-break. You may know them by these symptoms: Their looks are pale; their eyes heavy, hollow, dry, without the least moisture of a tear; their tongue exceedingly parched and dry, no spittle in their mouth, extreme thirst; their legs, from the falls and the bruises they receive, full of incurable sores and ulcers."

Aetius lived very near the end of the fifth, or in the beginning of the sixth century. Many passages in his writings serve to show us how much the actual and potential caution were used by the physicians of that age. In the palsy, he says, that he should not at all hesitate to make an etchar either way, and this in several places; one in the nape, where the spinal marrow takes its rise, two on each side of it; three or four on the top of the head, one just in the middle, and three others round it. He adds, that in this case, if the ulcers continue running a good while, he should not doubt of a perfect recovery. He is still more particular when he comes to order this application for an invertebrate asthma, after all other remedies have been tried in vain. One, he says, should be made on each side near the middle of the joining of the clavicle, taking care not to touch the wind-pipe: two other little ones are then to be made near the carotids under the chin, one on each side, so that the cautle may penetrate no further than the skin; two others under the breasts, between the third and fourth ribs; and again, two more backwards towards the fifth and sixth ribs. Besides these there ought to be one in the middle...
middle of the thorax near the beginning of the xiphoid cartilage over the orifice of the stomach; one on each side between the eighth and ninth ribs; and three others in the back, one in the middle, and the other two just below it, on each side of the vertebræ. Those below the neck ought to be pretty large, not very superficial, not very deep: and all these ulcers should be kept open for a very long time.

Aetius takes notice of the worms bred in different parts of the body called dracunculi, which were unknown to Galen. He seems also to be the first Greek writer among the Christians, who gives us any specimen of medicinal spells and charms; such as that of a finger of St Blaffius for removing a bone which sticks between the eighth and ninth ribs; and another in relation to a fistula. He gives a remedy for the gout, which he calls the grand diver; the patient is to use it for a whole year, and observe the following diet each month. "In September, he must eat and drink milk; In October, he must eat garlic; In November, abstain from bathing; In December, he must eat no cabbage; in January, he is to take a glass of pure wine in the morning; in February, to eat no beer; in March, to mix sweet things both in eatables and drinkables; in April, not to eat horseradish, nor in May the fish called polpisus; in June, he is to drink cold water in the morning; in July, to avoid venery; and lastly, in August, to eat no mallow." This may sufficiently show the quackery of those times, and how superfluous was beginning to mix itself with the art.

Alexander, who flourished in the reign of Julianus, is a more original author than either of the two former. He confines himself directly to the transcribing the signs of diseases, and the methods of cure, without meddling with anatomy, the materia medica, or surgery, as all the rest did. He employs a whole book in treating of the gout. One method he takes of relieving this disease is by purging; and in most of the purges he recommends mermodactyls, of which he has a great opinion. In a caustic, or burning fever, where the bile is predominant, the matter fit for evacuation, and the fever not violent, he prefers purging to bleeding, and says that he has often ordered purging in acute fevers with surprising success. In the caustic also, if a syncope happens from crude and redundant humours, he recommends bleeding. In syncope succeeding the supputation of any usual evacuation, he recommends bleeding, with friction. The diagnostics upon which he founds this practice are the following: viz. a face paler and more swelled than usual, a bloated habit of body, with a little sluggish pulse, having long intervals between the strokes. In tertian, and much more in quartan fevers, he recommends vomiting above all other remedies, and affirms that by this remedy alone he has cured the most inveterate quartans. On the bulimus, or canine appetite, he makes a new observation, viz. that it is sometimes caused by worms. He mentions the case of a woman who laboured under this ravenous appetite, and had a perpetual gnawing at her stomach and pain in her head: after taking rhubarb, she vomited a worm above a dozen of cubits long, and was entirely cured of her complaints.—He is also the first author who takes notice of rhubarb; which he recommends in a weakness of the liver and styfenty.—Alexander is recommended by Dr Freind Alexander, as one of the best practical writers among the ancients, and well worthy the perusal of any modern.

Paulus was born in the island Zægina, and lived in Paulus, the 7th century. He transcribes a great deal from Alexander and other physicians. His descriptions are short and accurate. He treats particularly of women's disorders; and seems to be the first instance upon record of a professed man-midwife, for so he was called by the Arabsians: and accordingly he begins his book with the disorders incident to pregnant women. He treats also very fully of surgery; and gives some directions, according to Dr Freind, not to be found in the more ancient writers.

After the downfall of the Roman empire, and when the inundation of Goths and Vandals had almost completely exterminated literature of every kind in Europe, medicine, though a practical art, shared the same fate with more abstruse sciences. Learning in general, banished from the seat of arms, took refuge among the eastern nations, where the arts of peace still continued to be cultivated. To the Arabian physicians, as they have been called, we are indebted both for the preservation of medical science, as it subsisted among the Greeks and Romans, and likewise for the description of some new diseases, particularly the small-pox. Among the most eminent of the Arabsians, we may mention Rhazes, Avicenna, Albulcafas, and Avenzoar. But of their writings it would be tedious, and is unnecessary to give any particular account.—They were for the most part, indeed, only copiers of Rhazes the Greeks; we are, however, indebted to them for some improvements. They were the first who introduced chemical remedies, though of these they used but few, nor did they make any considerable progress in the chemical art. Anatomy was not in the least improved by them, nor did surgery receive any advancement till the time of Albulcafas, who lived probably in the 14th century. They added a great deal to botany and the materia medica, by the introduction of new drugs, of the aromatic kind especially, from the east, many of which are of considerable use. They also found out the way of making sugar; and by help of that, syrups; which two new materials are of great use in making up compound medicines.

With regard to their practice, in some few particulars they deviated from the Greeks. Their purging medicines were much milder than those formerly in use; and even when they did prefer the old ones, they gave them in a much less dose than formerly. The same reflection may be made concerning their manner of bleeding, which was never to that extreme degree practised by the Greeks. They deviated from Hippocrates, however, in one very trivial circumstance, which produced a violent controversy. The question was, Whether blood in a plentiful course ought to be drawn from the arm of the affected side or the opposite? Hippocrates had directed it to be drawn from the arm of the affected side; but the Arabsians, following some other ancient physicians, ordered it to be drawn from the opposite one. Such was the ignorance of those ages, that the university of Salamanca in Spain made a decree, that no one should dare to let blood but in the contrary arm; and endeavoured to procure an edict from the emperor Charles V to second it.
In consequence of the general decay of learning in the western parts of the world, the Greek writers became totally forgotten, because nobody could read the language; and the Arabians, though mostly copiers from them, enjoyed all the reputation that was due to the others. The Arabian physis was introduced into Europe very early, with the most extravagant applause; and not only this, but other branches of their learning, came into repute in the west; infomuch that in the 11th century, the studies of natural philosophy and the liberal arts were called the studies of the Saracens. This was owing partly to the crusades undertaken against them by the European princes; and partly to the settlement of the Moors in Spain, and the intercourse they and other Arabians had with the Italians. For, long before the time of the crusades, probably in the middle of the 7th century, there were Hebrew, Arabic, and Latin professors of physic settled at Salernum; which place soon grew into such credit, that Charles the Great thought proper to found a college there in the year 803; the only one at that time in Europe.

Confiantine the African flourished here towards the latter end of the 11th century. He was a native of Carthage; but travelled into the east, and spent 30 years in Babylon and Bagdad, by which means he became master of the oriental languages and learning. He returned to Carthage; but being informed of an attempt against his life, made his escape into Apulia, where he was recommended to Robert Guiscard, created in 1060 duke of that country, who made him his secretary. He was reputed to be very well versed in the Greek, as well as the eastern tongues; and seems to have been the first who introduced either the Greek or Arabian physic into Italy. His works, however, contain nothing that is new, or material; though he was then counted a very learned man, and for that age no doubt was so.

From this time to the end of the 15th and beginning of the 16th century, the history of physis furnishes us with no interesting particulars. This period, however, is famous for the introduction of chemistry into medicine, and the description of three new diseases, the sweating sickness, the venereal disease, and the fevers. The sweating sickness began in 1483, in the army of Henry VII. upon his landing at Milford-haven, and spread itself at London from the 21st of September to the end of October. It returned here five times, and always in summer; first in 1483, then in 1506, afterwards in 1517, when it was so violent that it killed many in the space of three hours, so that numbers of the nobility died, and of the commonalty in several towns often the half perished. It appeared the fourth time in 1528, and then proved mortal in six hours; many of the courtiers died of it, and Henry VIII. himself was in danger. In 1529, and only then, it infected the Netherlands and Germany, in which last country it did much mischief. The last return of it was in 1558, and in Westminister it carried off 130 in a day. Dr. Cains describes it as a pestilential contagious fever, of the duration of one natural day; the sweat be reckoned to be only a natural symptom, or crisis of the distemper. It first affected some particular part, attended with inward heat and burning, unquenchable thirst, restlessness, sickness at stomach, but seldom vomiting, headach, delirium, then faintness, and extreme drowines. The pulse was quick and vehement, and the breath short and laborious. Children, poor and old people, were less subject to it. Of others, scarce any escaped the attack, and most of them died. Even by travelling into France or Flanders they did not escape; and what is still more strange, the Scots were said not to be affected: abroad the English only were seized, and foreigners in England were free. At first the physicians were much puzzled how to treat this distemper. The only cure they ever found, however, was to carry on the sweat for a long time; for, if it stopped, it was dangerous or fatal. The way, therefore, was for the patient to lie still, and not expose himself to cold. If nature was not strong enough to force out the sweat, it was necessary to afflict her by art, with cloaths, wine, &c. The violence of the distemper was over in 15 hours; but there was no security for the patient till 24 were passed. In some strong constitutions there was a necessity to repeat the sweating, even to 12 times. The removing out of bed was attended with great danger; some who had not sweated enough fell into very ill fevers.

No flesh meat was to be allowed in all the time of the distemper; nor drink for the first five hours. In the seventh, the distemper increased; in the ninth the delirium came on, and sleep was by all means to be avoided. However terrible this distemper appeared at first, it seldom proved obdurate, if treated in the abovementioned manner.

In the beginning of the 16th century, the famous chemist Paracelsus introduced a new system into medicine, founded on the principles of his art. The Galenical system had prevailed till his time; but the practice had greatly degenerated, and became quite trifling and frivolous. The physicians rejected the use of opium, mercury, and other efficacious remedies. Paracelsus, who made use of thee, had therefore greatly the advantage over them; and now all things relating to medicine were explained on imaginary chemical principles. It was easily conceived that a practice founded in this manner could be no other than the most dangerous quackery. At this time, however, it was necessary; for now a new distemper over-ran the world, and threatened greater destruction than almost all the old ones put together, both by the violence of its symptoms, and its baffling the most powerful remedies at that time known.

This was the venereal disease, which is said to have been imported from the West-Indies by the companions of Christopher Columbus. Its first remarkable appearance was at the siege of Naples in 1494, from whence it was soon after propagated through Europe, Asia, and Africa. The symptoms with which it made the attack at that time were exceedingly violent, much more so than they are at present; and consequently were utterly unconquerable by the Galenists. The quacks and chemists, who boldly ventured upon mercury, though they no doubt destroyed numbers by their excessive use of it, yet showed that a remedy for this terrible distemper was at last found out, and that a proper method of treating it might soon be fallen upon. Shortly after, the West-Indian specific, guarana,
History.

MEDICINE.

Modern.

Cum, was discovered: the materia medica was enriched with that and many other valuable medicines, both from the East and West Indies: which contributed considerably to the improvement of the practice of physic. At this period, as its voyages of considerable duration became more frequent, the scurvy became more frequent distemper, and was of course more accurately described. But probably, from supposed analogy to the contusions which at that time were new in Europe, very erroneous ideas were entertained with regard to its being of an infectious nature. And it is not impossible, that from its being attended alo with ulcers, it was on some occasions confounded with syphilitic complaints.

The revival of learning, which now took place throughout Europe, the appearance of these new distempers, and the natural fondness of mankind for novelty, contributed greatly to promote the advancement of medicine as well as other sciences. While at the same time, the introduction of the art of printing rendered the communication of new opinions as well as new practices so easy a matter, that to enumerate even the names of those who have introduced the most eminent for medical knowledge would be a very tedious task. It was not, however, till 1628 that Dr. William Harvey of London demonstrated and communicated to the public one of the most important discoveries respecting the animal economy, the circulation of the blood. This discovery, more effectually than any reasoning, overturned all the old systems. The whole subject, however, for some time it may have seemed with its being attended to, the conduct of health and disease, on a more solid and rational foundation, has been so much improved by careful attention to the history, and practice of particular diseases, and by endeavours to ascertain from cautious observations the symptoms by which they are to be distinguished, the causes by which they are induced, and the means by which they are to be prevented, alleviated, or cured. On this footing, therefore, we shall endeavour to give a brief account of at least the most important affections to which the human body is subjected, delivering what appears to us to be the best established facts and observations respecting each.

But before entering on the consideration of particular diseases, on what has commonly been styled the practice of medicine, it is necessary to give a general view of the most important functions of the animal body, and of the chief morbid affections to which they are subjected; a branch which has usually been named the Theory or Institutions of Medicine.

THEORY OF MEDICINE, or an Account of the principal Functions of the Animal Body.

While the functions of living animals, but particularly of the human species, are very numerous, the accounts given of these both in a state of health and disease are very various. Without therefore pretending to enumerate the contradictory opinions of different authors, we shall here present the reader with a view of this subject, extracted from one of the latest and best publications respecting it, the Confessio Medica Theorica of Dr. James Gregory, formerly professor of the medical science in the university of Edinburgh, and now professor of practice. In this work, which was first published in 1780, and afterwards reprinted under an enlarged form in 1782, Dr. Gregory introduces his subject by observing, that some functions of the human body relate to itself only, and others to external things. To the latter classes belong those by which physicians are called, to explain and cure the animal functions; to which are to be referred all the natural functions, as well as the power of voluntary motion, by which we become acquainted with the universe, and enjoy this earth. Among the functions which relate to the body, only some have been named vital, such as the circulation of the blood and respiration; because, without the constant continuance of these life cannot subsist. Others, intended for repairing the waste of the system, have been termed the natural functions;
it, and when changed also changes it. There are no doubt, from the general constitution of the
cause, and come quite remote cause, also remote causes, which physicians have been
found. A disease therefore may happen to any part of the
cuise.

57

Diftribution
of
diseases
into
simple
and
complex.

We have examples of the most simple kinds of
diseases, in the rupture or other injury of any of the
corporeal organs, by which means they become les
fit for performing their offices; or, though the organs
themselves should remain found, if the solids or fluids
have degenerated from a healthy state; or if, having
lost their proper qualities, they have acquired others
of a different, perhaps of a noxious nature; or lastly,
if the moving powers shall become too weak or too
strong, or direct their force in a way contrary to what
nature requires.

The most simple diseases are either productive of
others, or of symptoms, by which alone they become
known to us. Every thing in which a sick per-
son is observed to differ from one in health is called
a symptom; and the most remarkable of these symp-
toms, and which most constantly appear, define and
constitute the disease.

The causes of diseases are various; often obscure,
and sometimes totally unknown. The most full and
perfect proximate cause is that which, when pre-
fixed, produces a disease, when taken away removes
it, and when changed also changes it. There are also
remote causes, which physicians have been ac-
customed to divide into the predisposing and exciting
ones. The former are those which only render the
body fit for a disease, or which put it into such a
state that it will readily receive one. The exciting
cause is that which immediately produces the disease
in a body already disposed to receive it.

The predisposing cause is always inherent in the
body itself, though perhaps it originally came from
without; but the exciting cause may either come from
within or from without.

From the combined action of the predisposing and
exciting causes comes the proximate cause, which nei-
ther of the two taken singly is able to produce; seeing
neither every exciting cause will produce a disease in
every person, nor will every one predisposed to a
disease fall into it without an exciting cause. A
body predisposed to disease therefore has already
declined somewhat from a state of perfect health,
although none of its functions are impeded in such a
manner that we can truly say the person is diseased.

Yet, sometimes the predisposing cause, by continuing
long, may arrive at such an height, that it alone
without the addition of any exciting cause, may pro-
duce a real disease. Of this we have examples in the

doility of the simple solids, the mobility of the
living solids, and in plague. The exciting cause
also, though it should not be able immediately to
bring on a disease; yet if it continues long, will by
degrees destroy the strongest constitution, and render
it liable to various diseases; because it either
produces a predisposing cause, or is converted into it,
so that the same thing may sometimes be an exciting
cause, sometimes a predisposing one; of which the
inclemencies of the weather, sloth, luxury, &c. are
examples.

Diseases, however, seem undoubtedly to have their
origin from the very constitution of the animal
machine; and hence many diseases are common to every
body when a proper exciting cause occurs, though
some people are much more liable to certain diseases
than others. Some are hereditary; for as healthy pa-
rents naturally produce healthy children, so diseased
parents as naturally produce a diseased offspring.
Some of these diseases appear in the earliest infancy; others
occur equally at all ages; nor are there wanting some
which lurk unsuspected even to the latest old age, at
last breaking out with the utmost violence on a proper
occasion. Some diseases are born with us, even though
they have no proper foundation in our constitution, as
when a focus receives some hurt by an injury done to
the mother; while others, neither born with us nor
having any foundation in the constitution, are sucked
in with the nurse's milk. Many diseases accompany
the different stages of life; and hence some are proper
to infancy, youth, and old age. Some also are proper
to each of the sexes; especially the weaker sex, pro-
ceeding, no doubt, from the general constitution of the
body, but particularly from the state of the parts sub-
vient to generation. Hence the diseases peculiar
to virgins, to menstruating women, to women with
child, to lying-in-women, to nurses, and to old
women. The climate itself, under which people live,
produces some diseases; and every climate hath an ten-
dency to produce a particular disease, either from its
excess of heat or cold, or from the mutability of the
weather. An immense number of diseases may be
produced by impure air, or such as is loaded with pu-
trid, marshy, and other noxious vapours. The same
thing may happen likewise from corrupted aliment,
whether meat or drink; though even the best and most
nutritious aliment will hurt if taken in too great quan-
tity; not to mention poisons, which are endowed with
such pernicious qualities, that even when taken in a
very small quantity they produce the most grievous
diseases, or perhaps even death itself. Lastly, from
innumerable accidents and dangers to which mankind
are exposed, they frequently come off with broken
limbs, wounds, and contusions, sometimes quite incur-
able; and these misfortunes, though proceeding
from an external cause at first, often terminate in internal
diseases.

Hitherto we have mentioned only the dangers which
come from without; but those are not les, nor fewer
in number, which come from within. At every breath,
man pours forth a deadly poison both to himself and
others. Neither are the effluvia of the lungs alone hurt-
ful; there flows out from every pore of the body a
molt intolerable and poisonous matter, perhaps of a ptre-
History.

Medicine.

Origin of Diseases.

Diseases from passions of the mind.

Diseases from parts of the body.

Flo medicatric nature.

PhyGicians therefore have a twofold error to avoid, namely, either despising the powers of natural cure too much, or putting too great confidence in them; because in many diseases these efforts are either too feeble or too violent, insomuch that sometimes they are more to be dreaded than even the disease itself. So far therefore it is from being the duty of a physician always to follow the footsteps of Nature, that it is often necessary for him to take a directly contrary course, and oppose her efforts with all his might.

After this general view of the functions of the animal body, of the nature and causes of diseases, and of the powers by which these are to be combated, Dr. Gregory proceeds to treat of the solid materials of which the body is formed. He tells us, that the animal solid, when chemically examined, yields earth, oil, salt, water, phlogiston or inflammable air, and a great quantity of mephitic air. These elements are found in various proportions in the different parts of the body; and hence these parts are endowed with very different mechanical powers, from the hardest and most solid bone to the soft and almost fluid retina. Nay, it is principally in this difference of proportion between the quantities of the different elements, that the difference between the solid and fluid parts of the animal consists, the former having much more earth and less water in their composition than the latter. The cohesion, he thinks, is owing to something like a chemical attraction of the elements for one another; and its cause is neither to be fought for in the gluten, fixed air, nor earth. This attraction, however, is not so strong but that even during life the body tends to diffusion; and immediately after death purifcation commences, provided only there be as much moisture in it as will allow an intestinal motion to go on. The greater the beat, the sooner does purifcation take place, and with the greater rapidity does it proceed; the mephitic air flies off, and together with it certain saline particles; after which, the cohesion of the body being totally destroyed, the whole falls into a putrid colliquing, of which at length all the volatile parts being deliquated, nothing but the earth is left behind.

This analysis, he owns, is far from being perfect; because nobody has ever been able, by combining the chemical principles of flesh, to reproduce a compound any thing like what the flesh originally was; but, however imperfect the analysis may be, it fell has the advantage of showing in some measure the nature and causes of certain diseases, and thus leads physicians to the knowledge of proper remedies.

The solid parts are fitted for the purposes of life in Qualities three several ways; namely, by their cohesion, their of the animal fluids.

The variations in flexibility, within certain limits,
regard to the health: though sometimes, by exceed-
ing the proper bounds, they may bring on real and
very dangerous diseases; and this either by an excess or
diminution of their cohesion, flexibility, or elaticity.
By augmenting the cohesion, the elaticity is also for
the most part augmented, but the flexibility dimin-
ished; by diminishing the cohesion, the flexibil-
ity becomes greater, but the elaticity is diminished.

The causes of these affections, though various, may
be reduced to the following heads. Either the
chemical composition of the matter itself is changed: or,
the composition remaining the same, the particles of
the solid may be so disposed, that they shall more or less
strongly attract one another. As to the composition,
almost all the elements may exist in the body in an un-
due proportion, and thus each contributes its share to
the general disorder. But of many of these things we
know very little: only it is apparent, that the fluid
parts, which consist chiefly of water, and the solid,
which are made up of various elements are often in
very different proportions; the more water, the less is
the cohesion or elaticity, but the greater the flexibil-
ity; and the reverse happens, if the solid or earthly
part predominates.

The remote causes of these different states, whether
predispoin or exciting, are various. In the first
place, idiosyncrasy itself, or the innate constitution of
the body, contributes very much to the above-
mentioned effects. Some have naturally a much harder
and drier temperament of the body than others; men,
for instance, more than women; which can with the
utmost difficulty, indeed scarce by any means what-
ever, admit of an alteration. The same thing takes
place at different periods of life; for, from first to last,
the human body becomes always drier and more rigid.

Much also depends on the diet made use of, which
always produces a corresponding state of the solids in
proportion to its being more or less watery. Whether
are there wanting strong reasons for believing, that not
only the habit of the body, but even the disposition
of the mind, depends very much on the diet we
make use of. The good or bad complexion of the aile-
ment, also the application of the nourishment prepared
from it, and likewise the state of the air with regard to
moisture or dryness, affects the temperament of the
body not a little; and hence those who inhabit
mountains or dry countries, are very different from
the inhabitants of low marshy places. Lastly, the
manner of living contributes somewhat to this effect:
Exercize prefered, the moisture of the body, if in too great quantity; on the contrary, little
and laziness produce an effect directly opposite, and
cause a redundancy of humour.

By the chemical composition of the solid parts out of the question altogether, they may be affected
by many other causes. The condensation, for
instance, or compaction of the particles, whether by
mechanical causes or by means of cold or heat, makes
a considerable alteration in the strength and elaticity
of every solid body. How much mechanical pressure
contributes to this may be understood from the expe-
riments of Sir Clifton Wintringham; and hence also
are we to deduce the reason of many facts of the high-
ly importance in the animal economy; namely, the
growth, state, decrease of the body; its rigidity
daily increasing; and at last the unavoidable death
incident to old age from a continuance of the same
causes.

Perhaps the different density of the solids is in some
measure owing to Nature herself; but it seems rather to
depend more on the powers of exercise or inactivity in
changing the state of the solids, the effects of which
on the body, whether good or bad, may hence be eas-
ily understood.

Heat relaxes and expands all bodies, but cold ren-
ders them more dense and hard; the effects of which
on the human body are well known to most people.
Though the body is found to preserve a certain de-
gree of heat almost in every situation, it is impossible
but that its surface must be affected by the tempera-
ture of the ambient atmosphere: and we have not the
least reason to doubt that every part of the body may
thus feel the effects of that temperature. What a dif-
ference is there between one who, exposed to the south-
wind, becomes lazy and languid, scarce able to
drag along his limbs; and one who feels the force of
the cold north-wind, which renders the whole body alert,
strong, and fit for action?

That these various causes, each of which is capable
of affecting the constitution of the body when taken
singly, will produce much greater effects when com-
bined, is sufficiently evident. The experiments of
Bryan Robinson, the effects of the warm bath, and
indeed daily experience, show it fully.

It is not yet certainly known what is the ultimate
structure of the minute parts of the animal solid;
whether it consists of straight fibres or threads, whose
length is very considerable in proportion to their
breadth, variously interwoven with one another, as
Boerhaave supposes; or of spiral ones, admirably con-
voluted and interwoven with one another, as some mi-
croscopical experiments seem to show, or whether the
cellular texture be formed of fibres and lamina, and
from thence the greatest part of the body, as the
celebrated Flahert had endeavoured to prove.

The cellular texture is disposed throughout the whole body: it surrounds and connects the fibres
themselves, which are sufficiently apparent in many of
the organs; and slightly joins the different parts which
ought to have any kind of motion upon the neighbour-
ing ones. By a condensation of the same substance
also, the strongest, and what seem the thickest, mem-
branes are joined; the most simple of which, being
accurately examined, discover the cellular structure.
This cellular substance sometimes increases to a surpris-
ing degree, and all parts formed of it, membranes,
veils, &c. especially by a gentle dilatation; for a
sudden and violent dilatation either breaks it alto-
gether, or renders it thinner. Sometimes also it grows
between neighbouring parts, and joins those which nature
has left free. Preternatural concretions of this kind
are often observed after an inflammation of the
lungs or of the abdominal visceræ; and these new
membranes are found to be truly cellular. This sub-
stance, when cut, or by any other means divided, grows
together of its own accord; but if, by reason of very
great inflammation and suppuration, a large portion of
the cellular texture has been destroyed, it is never
again renewed, and an ugly fear is left. It is even

Causes affecting the solids.
Theory.

Medical

said, that this substance, in certain cases, is capable of joining the parts either of the same body with one another, or of a foreign body with them: and upon this, if on any foundation, rests the art of Falloccitus, and that of transplanting teeth, lately so much talked of.

The cellular texture is in some places merely a kind of net-work, in others filled with fat. Wherever too great bulk or compulsion would have been inconvenient or dangerous, as in the head, lungs, eyes, eyebrows, penis, scrotum, &c. there it collects no fat, but is lax, and purely reticulated; but between the muscles of the body and limbs below the skin, in the abdomen, especially in the omentum and about the kidneys, very much fat is seereted and collected.

Animal fat. The fat is augmented by the use of much animal food, or of any other that is oily and nourishing, provided the digestion be good; by the use of strung drink, especially mul-tiquor; by much rest of body and mind, much sleep and inactivity, calibration, cold, repeated bloodletting, and in general by whatever diminishes the vital and animal powers. Much, however, depends on the constitution of the body itself; nor is it possible to fatten a human creature at pleasure like an ox. A certain degree of fatness, according to the age of the person, is a sign and effect of good health; but when too great, it becomes a disease of itself, and the cause of other diseases. It may always be very certainly removed by strong exercise, little sleep, and a spare and solid diet. The fat always makes up a considerable part of the bulk of the body, and very often by far the greatest part. Its use seems to be to make the motion of the body more easy and free by lessening the friction of the moving parts, and thus preventing the abrasion of the folds, which would otherwise happen. It is also of use to hinder the parts from growing together, which sometimes happens, when by an ulcer or other accident a part of the cellular texture containing the fat is destroyed. Besides all this, the fat contributes not a little to the beauty of the body, by filling up the large interfaces between the muscles, which would otherwise give the person a deformed and shocking appearance. It is thought to be nutritious, when absorbed from its cells by the blood; but of this we have no great certainty. It seems to have some power of defending from the cold, seeing nature has bestowed it in very great quantity on those animals which inhabit the colder regions.

Those parts of the body which enjoy sense and motility, are called living or vital folds. They are the lids, brain, cerebellum, medulla oblongata, spinal marrow, the nerves arising from these and diffused throughout the whole body, and which are distributed through the various organs of sense and through the muscles, and lastly the muscles themselves. Sensation is much more general than motility, as being common to all the parts already mentioned. Motility is proper to the muscular fibres alone; where there is sensation, therefore, we may believe that there are nerves; and wherever there is motility, we may believe that muscular fibres exist. Nay, even motility itself seems to originate from the connection which the muscles have with the nerves; for soon after the nerves are compressed, or tied, or cut, the muscles to which they are distributed lose their faculties; which happens, too, when the brain itself, or even only the nerves, is affected. Some reckon that the muscles are produced from the nerves, and of the same kind of matter. Both indeed have a similar structure, as being fibrous and of a white colour; for the muscles when well freed from the blood, of which they contain a great abundance, are of this colour as well as the nerves; neither can the nervous fibres by any means be distinguished from the muscular fibres themselves. Both have also sensitiveness; and both stimulants and sedatives act in the same manner, whether they be applied to the muscles themselves or to the nerves.

It is difficult for us to discover the origin of many parts of the body, or to ascertain whether they are produced all at the same time or one after another; yet it must be owned, that many of the muscular parts are obsered to have attained a remarkable degree of strength, while the brain is still soft and almost fluid; and that the action of these muscular parts is required for the action and growth of the brain. The muscles are also of a much firmer texture than the nerves; and enjoy a power of their own, namely, that of irritability, of which the nerves never participate. Of necessity, therefore, either the muscles must be constructed of some kind of matter different from that of the nerves; or if both are made of the same materials, their organization must be exceedingly different. But if the substance of the muscles and nerves be totally different, we may safely be convinced that much of the one is always mixed with the other; for it is impossible to prick a muscle even with the smallest needle, without wounding or lacerating many nervous fibres at the same time. Since, therefore, there is such a close connection between the muscles and nerves both as to their functions and structure, they are deferently reckoned by physiologists to be parts of the same genus, called the genus nervous, or nervous fyllem.

After treating of sense in general, Dr. Gregory proceeds to consider particularly each of the senses both external and internal. He begins with the sense of feeling, as being the most simple, and at the same time in common to every part of the nervous syllem. In some places, however, it is much more acute than in others; in the skin, for instance,
Medicine.

Pain.

From the sense of feeling, as well as all the other senses, either pain or pleasure may arise; nay, to this sense we commonly refer both pain and almost all other troublesome sensations, tho' in truth pain may arise from every vehement sensation. It is brought on by any great force applied to the sentient part; whether this force comes from within or without. Whatever, therefore, pricks, cuts, lacerates, diffuses bruises, stings, gnaws, burns, or in any manner of way stimulates, may create pain. Hence it is so frequently conjoined with so many diseases, and is often more intolerable even than the disease itself. A moderate degree of pain stimulates the affected part, and by degrees the whole body; produces a greater flux of blood and nervous power to the part affected; and often stimulates to such motions as are both necessary and healthful. Hence, pain is sometimes to be reckoned among those things which guard our life. When very violent, however, it produces too great irritation, inflammation and its consequences, fever, and all those evils which flow from too great force of the circulation; it disorders the whole nervous system, and produces spasms, watching, convulsions, delirium, debility, and fainting. Neither the mind nor body can long bear very vehement pain; and indeed Nature has appointed certain limits, beyond which the will not permit pain to be carried, without bringing on delirium, convulsions, syncope, or even death, to rescue the miserable sufferer from its torments.

Long continued pain, even though in a more gentle degree, often brings on debility, torpor, palsy, and rigidity of the affected part. But if not too violent, not accompanied with fever, fevers, or anxiety, it sometimes seems to contribute to the clearness and sweetness of the judgment, as some people tell us who have suffered on this account. Moreover, when the vital power may happen at that time, because the vital powers, unable to perform their functions, cannot make the blood circulate. But what kind of anxiety this is, the other signs of approaching death shows very evidently. Moreover, in the time of sleep, anxiety may arise from the same cause: hence frightful dreams, which frequently disturb our repose with fearful phantasms.

Itching. An uneasy sensation, with a desire of scratch. Itching is a sensation, which is often most uncomfortable, though it seems to be more akin to pleasure than to pain. As pain proceeds from too great an irritation, either chemical or mechanical, so does itching proceed from a flight one. Titillation, or friction, of a woolen shirt, 

Anxiety.

Anxiety is another disagreeable sensation, quite different from pain, as being more obtuse and less capable of being referred to any particular part, though frequently more intolerable than any pain. But we must take care to distinguish between this anxiety of which we treat in a medical sense, and that which is spoken of in common discourse. The latter does not at all depend on the state of the body, but belongs entirely to the mind; and arises from a sense of danger, or a foreboding of any misfortune. The former is truly corporeal, and derives, no less than pain, its origin from a certain state of the body. Notwithstanding this difference, however, it is very possible for both these kinds of anxiety to be present at the same time, or for the one to be the cause of the other. A very great bodily anxiety will strike fear and despondency into the most resolute mind; and mental anxiety, on the contrary, if very violent and long-continued, may induce the former, by destroying the powers of the body, especially those which promote the circulation of the blood.

Anxiety, in the medical sense of the word, arises in the first place from every cause disturbing or impeding the motion of the blood through the heart and large vessels near it. Anxiety, therefore, may arise from many diseases of the heart and its vessels, such as its enlargement, too great contraction, inflammation, polypus, palpitation, syncope, inflammation, debility, and also some affections of the mind. It is likewise produced by every difficulty of breathing, from whatever cause it may arise; because then the blood passes freely through the lungs: anxiety of this kind is felt deep in the breast. It is said also to arise from the difficult passage of the blood through the liver or other abdominal viscera.

A certain kind of anxiety is very common and troublesome to hypochondriacal people; and arises from the stomach and intestines being either loaded with indigestion and corrupted food, or diffused with air produced by fermentation and extracted from the alimentary parts. By such a load, or distension, the stomach, which is a very delicate organ, becomes greatly affected. Besides, the free interval of the diaphragm is thus hindered, and respiration obstructed. Anxiety of this kind is usually very much and suddenly relieved by the expulsion of the air; by which, as well as by other signs of a bad digestion, it is easily known. In these cases the anxiety is usually, though with little accuracy, referred to the stomach.

Anxiety also frequently accompanies fevers of every kind, sometimes in a greater and sometimes in a lesser degree. In this case it arises as well from the general debility as from the blood being driven from the surface of the body and accumulated in the large vessels; as in the beginning of an intermittent fever. Or it may arise from an affection of the stomach when overloaded with crude, corrupted aliment; or diffused and nauseated with too much drink, especially medicated drink. As the fever increases, the anxiety of the patient becomes greater and greater; remarkably so, according to the testimony of physicians, either immediately before the crisis or on the night preceding it; as before the breaking out of exanthemata, hemorhagias, fevers, or diarrhoeas, which sometimes remove fevers. The patient feels likewise an anxiety from the striking in of any eruption or critical metaffas. This sensation also accompanies fevers and most other diseases, when the vital power is exhausted, and death approaches, of which it is the forerunner and the sign. It happens at that time, because the vital powers, unable to perform their functions, cannot make the blood circulate. But what kind of anxiety this is, the other signs of approaching death shows very evidently. Moreover, in the time of sleep, anxiety may arise from the same cause: hence frightful dreams, which frequently disturb our repose with fearful phantasms.

Itching. An uneasy sensation, with a desire of scratch. Itching is a sensation, which is often most uncomfortable, though it seems to be more akin to pleasure than to pain. External senses.

Sens.
History.

MEDICINE.

External

Senses.

for instance, upon the skin of a person unaccustomed to it, and of a delicate constitution, excites itching; as do also many acrid fossils, vegetables, and animals. Hence an itching is the first sensation after the application of cantharides, although the same, when augmented, becomes painful. The same effect is produced by any thing acrid thrown out upon the skin; as in exanthematic fevers, the disease called the itch, &c. Lice, worms, especially acarides, irritating either the skin or the intestines, excite a troublesome itching. Certain species of internal itching excites people to many necessary actions both in a diseased and healthy state; such as the excresence of the faces and urine, coughing, freezing, and the like.

Too acute a sensation over the whole body is very rarely if ever observed. In a particular part the sense of feeling is often more acute than it ought to be, either from the cuticle itself being too thin and soft, or being removed; or from the part itself being inflamed, or exposed to too great heat. It becomes obtuse, or is even quite destroyed over the whole body, or in great part of it, from various affections of the brain and nerves; as when they are wounded, compressed, or defective in vital power. This is called anarthria, and sometimes accompanies palsy.

This sense may be deficient in a particular part, either from the nerve being defused, or from its being compressed or wounded, or from the part itself being exposed to too great a degree of cold;—or from the scarified skin which covers it being vitiated, either becoming too thick or hard, by the handling of too rough, or hard, or hot bodies, as is the cafe with glass-makers and smiths; or from the elevation of the cuticle from the subjacent cutis, or true skin itself; by the interposition of blood, serum, or pus; or from the cutis being macerated, relaxed, or become torpid, which sometimes happens to hydropic persons; or lastly, from the whole organ being corrupted by gangrene, burning, cold, or contusion. This sense is very rarely depraved, unless perhaps in the case of delirium, when all the functions of the brain are disturbed in a surprizing manner.

The sense next to be considered is that of taste, the principal organ of which is the tongue; the nearer the tip of it, the more acute is the sense, and the nearer the glosis so much the more obtuse. It must be owned, however, that some kind of acrid substances, the taste of which is scarce perceived upon the tip of the tongue, excite a most vehement sensation about its root; or even in the throat itself. The tongue is endowed with many large and beautiful nervous papilles, which seem to be the chief seat of this sense, and in the act of tasting are elevated and erected, in order to give the more acute sensation.

Nothing can be tasted which is not soluble in the saliva, that, being applied in a fluid form, it may pervade the involucra of the tongue, and affect its nervous pulp; and hence insoluble earths are quite insipid. Neither is it sufficient for a body to be soluble that it may be tasted; it must also have something in it acrid, or at least acrid, in order to vitiate the nervous substance; and hence, whatever has less salt than the saliva is totally insipid.

The taste is rarely found to be too acute, unless through a fault in the epidermis which covers the tongue. If this be removed or wounded, or covered with ulcers, aphthous, &c. then the taste, becoming too acute, is painful; or sometimes no other sensation than that of pain is felt. It may be impaired, as well as the sense of feeling, from various diseases of the brain and nerves; of which, however, the insipacies are but rare. In some people it is much more dull than in others; and in such the sense of smelling is usually deficient also. The taste is most commonly deficient on account of the want of saliva; for a dry tongue cannot perceive any taste: hence this sense is very dull in many diseases, especially in fevers, catarrhus, &c. as well on account of the defect of saliva as of appetite, which is of so much service in a state of health; or by reason of the tongue being covered with a viscid mucus.

The taste is frequently depraved; when, for example, we have a perception of taste without the application of any thing to the tongue: or, if any thing be applied to it, when we perceive a taste different from what it ought to be. This happens for the most part from a vitiated condition of the saliva, which is itself tasted in the mouth. Hence we may perceive a sweet, saline, bitter, putrid, or rancid taste, according to the state of the saliva: which may be corrupted either from the general vitiated condition of the mass of humours, or the glands which secrete it; of the mouth itself; or even of the stomach, the vapours and eruptions of which rise into the mouth, especially when the stomach is diseased.

Besides the faults of the saliva, however, the taste may be vitiated from other causes; as, for instance, the condition of the nervous papilles. This, however, is as yet but little known to us; for the taste is sometimes plainly vitiated when at the same time the saliva appears quite insipid when tasted by other people.

Physicians, in almost every disease, but especially in fevers, inquire into the state of the tongue; not, indeed, without the greatest reason: for from this they can judge of the condition of the stomach; of the thrill, or rather the occasion the patient has for drink, when, on account of his delirium or stupor, he neither feels his thirst nor is able to call for drink. And, lastly, from an inspection of the tongue, physicians endeavour to form some judgement concerning the nature, increase, and remission of the fever.

After the sense of taste, Dr Gregory next treats of smell, that of smell. Its seat is in that very soft and delicate membrane, filled with nerves and blood-vessels, which covers the internal parts of the nose, and the various sinuses and cavities proceeding from thence. This sense is more acute about the middle of the septum, and the ala frontalis, where the membrane is thicker and fitter, than in the deeper cavities, where the membrane is thinner, less nervous, and less filled with blood-vessels; although even these do not seem to be altogether destitute of the sense of smelling.

As by our taste we judge of the soluble parts of bodies, so by our smell we judge of those very volatile and subtle parts which fly off into the air; and like the organ of taste, that of smell is kepemnoit, that it may have the more exquisite sensation, partly by its proper mucus, and partly by the tears which descend from the eyes.
When the head is otherwise affected with inflammation, relaxation, or too great tension, by which it is impossible but the nerves, which constitute a great part of it, must be vitiated. It is evident also, that whatever obstructs the free entrance of the air into the nostrils, or impedes its passage through them, must prove detrimental to the sense of smelling.

The sense of hearing is more frequently vitiated than any other of the senses, as having a more delicate organ, and one composed of many and very small parts, of which an account is given under the article Anatomy. It frequently becomes too acute; either from the general habit of the body being too irritate, such as soon happens to hysterical and lying-in women; or from too great a sensibility of the brain itself, which is not unfrequently observed in fevers, as well as phrenitis, and sometimes in the true mania; or it may be from a disease of the ear itself, as when it is affected with inflammation, pain, or too great tension. It may be rendered dull, or even be altogether destroyed, so that the person shall become totally deaf from the same causes acting with different degrees of force. This happens especially from the want of the external ear; or from the meatus auditory being stopped up with mucus, wax, or other matters; or from the sides of the canal growing together, as sometimes happens after suppuration or the small-pox; or by the membrane of the tympanum becoming rigid or relaxed, or being eroded or ruptured; or the tympanum itself, or the Eustachian tube, may from certain causes be obliterated; or some of the little bones or membranes, or some of the muscles of the labyrinth itself, may be affected with concretion, spasm, palsy, or torpor; or lastly, it may happen from diseases from the brain and nerves, all the organs of hearing remaining sound. Hence deafness is often a nervous disease, coming suddenly on, and going off of its own accord. Hence also it is common in old people, all of whose solid parts are too rigid, while their nervous parts have too little sensibility.

Perfons labouring under fevers, especially of the typhous kind, often become deaf. When this comes on along with other signs of an oppressed brain, and a great prostration of strength, it may be a very bad sign; but for the most part it is a very good one, even though accompanied with some degree of torpor or sleepiness.

A very common disease in the sense of hearing is when certain sounds, like those of a drum, a bell, the falling of water, &c. are heard without any tremor in the air, or without a found person's hearing anything. This disease is called tinnitus aurium, of which various kinds have been observed. For the most part it is a very light transient disorder; but sometimes it is most obdurate, long-continued, and troublesome. It sometimes arises from the flighted caue, such as any thing partially stopping up the meatus auditorius or Eustachian tube itself, so that access is in part denied to the air; whence it happens that the latter strikes the membrane of the tympanum, or perhaps the interior parts, unequally, and with too much force. Hence bonsi, a kind of tinnitus, are heard even by the most healthy when they yawn.

A much more frequent and troublesome species of tinnitus accompanies many diseases both of the febile and nervous kind. This is occasioned by increased impetus of the blood towards the head, with an increase of sensibility in the nervous system itself, so that the very beatings of the arteries are heard; and partly from the increased sensation and mobility of the nerves and muscles of the labyrinth; whence it happens, that the parts which ought to be at rest until excited by the tremor of the air, begin to move of their own accord, and impart their motion to other parts which are already in a morbid state of too great sensibility.

A tinnitus sometimes arises from any vehement affectation of the mind; sometimes from a disorder in the stomach; sometimes from a rheumatic disorder affecting the ears and head; or from a catarrh, which commonly affects the tube. Sometimes, however, the tinnitus alone affects the patient; and even this is a disease of no small consequence. These various causes, however, both of this and other disorders of the hearing, are often very difficult to be distinguished, as well on account of the inaccessible situation of the organ, as on account of the little knowledge we have of its action. But from whatever cause it arises, both this and the other various affections of the hearing can neither be cured certainly nor easily.

Concerning the nature of the sense of sight, the sight reader may consult the articles Anatomy and Office. Of this sense some light disorders, or rather varieties, are often observed. These persons are called short-sighted who cannot see distinctly unless the object be very near them. This disorder arises from too great a refraction of the rays by reason of their being too soon collected into a focus by the crystalline lens, and diverging again before they fall upon the retina, by which means they make an indistinct picture upon it. The most usual cause is too great a convexity of the eye or some of its humours, as too prominent a cornea. It is a disorder common to young people, which is sometimes removed when they grow older. As soon as the first approaches of short-sightedness are observed, it is supposed it may be obviated by the person's accu-
MEDICINE.

The sight is liable to many and grievous disorders. It is sharpened beyond measure, so that the person either perceives nothing distinctly, or with great pain, from the same causes that induce a similar disorder in the other senses; namely, excessive sensibility in the general habit of body; or a particular state of the brain common in phrenitis, or even in those afflicted with fevers arising from inflammation or too great excitement; though more frequently from the condition of the eye itself, one becomes unable to bear the light. The inflammation of the tunica adventitia, and the forepart of the sclerotica, is communicated to the backparts of it, and from thence to the choroides and retina itself. Hence the light becomes intolerable, and vision is attended with pain and great irradiation, sometimes inducing or augmenting a delirium.

The sense of seeing is made dull, or even totally abolished, by age; the aqueous humour not being supplied in sufficient quantity, and the cornea and lens, or the vitreous humour, becoming thickened or decayed. It may likewise happen from the cornea becoming dry and opaque; which is too often imputed to the languid motion of the blood, and to great numbers of the small vessels being obstructed or having their sides concreted—or from the crystalline lens becoming yellow like amber, and the retina itself less sensible, for old age diminishes every sensation. It is totally abolished by injuries of the brain, the optic nerve, or the retina, even though the structure of the organ should remain found. This disease is called an amnopus; and is easily known by the dilatation and immobility of the pupil, the humour of the eye remaining clear. It is commonly owing to congestion of blood; and sometimes, where no congestion of blood can be shown, to mere torpor of the nerves. If it be only a torpor of part of the retina, we see black spots in those things at which we look; or flies seem to pass before our eyes, a very bad sign in fevers, and almost always mortal. The sight is abolished also by the obscurity or opacity of any of the parts through which the rays ought to pass and be refracted; as if the cornea lost its transparency by being covered with spots; or the aqueous humours become corrupted with blood, serous, or pus; or the lens (which often happens and which is called a cataara) becomes of a grey or brown colour, or the vitreous humour be in like manner corrupted; or lastly, when all the humours being disolved, confused, and mixed together, by inflammation and suppuration, either do not suffer the light to pass at all, or to pass imperfectly and unequally; whence either no image is formed on the retina, or it appears obscure, distorted, imperfect, and ill-coloured.

The sight is also depraved, when things appear to it of a colour different from their own, or even in another situation and of another shape than they ought to have. This happens from the humours being tinctured with any unusual colour, as is said to happen in some instances of jaundice; or from an extravasation and mixture of the blood with the aqueous humour. A surprising depravation also, or constant and perpetual defect of vision, is not uncommonly observed in men otherwise very healthy, and who see quite clearly; namely, that they cannot distinguish certain colours, green, for example, from red. Another deformity of vision is, when, without any light being admitted to the eyes, sparks, small drops of a flame or golden colour, and various other colours, are observed to float before us. This is generally a very frightful and transient disorder, common to those whose constitutions are very irritable; and arises from the flight impulses, as it would seem, on the retina, by the vessels bearing more vehemently than usual. A foreign circle is observed by pressing the eye with the finger after the eyelids are shut. The same reason, perhaps, may be given for those sparks which are seen by persons labouring under the falling sickness, and intermingled to the size of an immense and luminous beam before they fall down in convulsions. A similar beam those who have recovered from hanging or drowning testify that they have observed: for by reason of the respiration being suppressed, the vessels of the head swell and compress the whole brain and nervous parts of the head. Sparks of the same kind, and those too of no good omen, are observed in patients labouring under a fever, when phrenitis or fierce delirium is at hand: and likewise in those who are threatened with paralysis or epilepsy. A different but false perception, namely, of visible things which do not exist is to be imputed to some injury of the brain, to madness or a delirium, not to any defect of the eye.

A very frequent defect of vision remains to be mentioned; namely, squinting. A person is said to squint who has the axes of the eyes more oblique than usual, and directed to different points. Hence a great deformity, and often an imperfect and confused vision by which the objects are sometimes seen double. It is an evil for the most part born with the person, and often corrected by those attempts which an infant makes to see more pleasantly and distinctly; and this even without being conscious of its own defects. It is also easily learned, especially in infants, even without their own knowledge, by that kind of imitation which has a great influence over the human race, especially in their tender years. It is by no means, however, so easily unlearned.

Squinting is frequently occasioned by a pain, pull, or spasm.
rigidity, &c. of the muscles which manœuvre the eye; by epilepsy; by certain dilatations of the head, the hydrocephalus especially; or by any great injury done to the head. Sometimes, though very rarely, it comes on suddenly without any known cause. It is very probable, however, that squinting often arises from a fault of the retina, when their central points, for instance, and those similarly placed with respect to the centre, do not agree. In this case there must be a contortion of the eye, that the object may not be seen double. This seems also to be the reason why squinting is horribly increased when the person brings the object near his eye in order to view it more perfectly. Or if the central point of either, or both, of the retinas be insensible, or nearly so, it is necessary for the person to distort his eyes that he may have any distinct vision of objects. If the optic nerves had not entered the retina obliquely, but passed directly through its center, we would all either have squinted or seen double.

Physicians have referred to the sense of vision that most troublesome sensation which we call a vertigo; though it seems rather to belong to that of feeling, or of consciousness; for in many instances the disorder is not removed either in the dark or by shutting the eyelids. The vertigo takes place when external objects really at rest seem to reel, to whirl round, to tremble, or to move in any manner of way. If the disorder be very violent, the person is neither able to see, on account of a dimness of sight; nor can he stand, as the powers fail which ought to govern the limbs. A nausia also usually accompanies the vertigo, and the one generally produces the other.

This disorder is observed to be both the symptom and forerunner of some dangerous diseases; such as apoplexy, epilepsy, hysteria; hemorrhages from the nose and other parts; supplications of the meninges; plethora; fevers, as well such as are accompanied with debility as those in which there is an increased impetus of the blood towards the head. An injury done to the head also, but rarely one done to the eyes, unless in so far as it affects the whole head, brings on a vertigo. A vertigo may be likewise produced by a very great and sudden loss of blood or other fluid; by debility; syncope; various diseases of the alimentary canal, of the stomach especially; poisons admitted into the body, particularly of the narcotic kind, as opium, wine, &c. and hence vertigo is a symptom of every kind of drunkenness. Various motions also, either of the head or the whole body, being tossed in a ship, especially if the vessel be small and the sea runs high, produce a vertigo. In these and similar examples, the unusual and incoordinate motions of the blood are communicated to the nervous parts which are in the head; or else being affected by sympathies from the neighboring parts, produce a confused sensation as if of a rotary motion. Nay, it is often produced from an affection of the mind itself, as from beholding any thing turned swiftly round, or a great cataract, or looking down a precipice, or even by intense thought without looking at anything.

Though a vertigo be for the most part a symptom and concomitant of other diseases, yet it is sometimes a primary disease, returning at intervals, increasing gradually, and equally impeding and destroying the functions of the body and mind.

After having treated of the external senses, doctor Gregory next proceeds to consider those properly called internal; which are, the memory, the imagination, and the judgment. The first is lightened, disturbed, or even totally destroyed, in many diseases, especially those which affect the brain; as the apoplexy, palsy, internal tumors of the head, external violence applied, fevers, especially those in which there is an increased motion of the blood towards the head, or where the brain is any other way much affected. It is very rarely, however, deprived in such a manner that ideas are not represented to the mind in their proper order; or if at any time such a disorder occurs, it is considered rather as a disorder of the imagination, or as a delirium, than a failure of the memory. The mind is said to be disordered when the perceptions of memory or imagination are confounded with those of sense, and of consequence those things believed to be now present which are really past or which never existed; or when the sense of the peron concerning ordinary things is different from that of other people. The general name for such disorders is oyopia; if from fever, it is called delirium. A general fury without a fever, is called mania; but a partial madness, on one or two points, the judgment remaining found in all other respects, is called melancholia. There is, however, no exact and accurate limits between a fround mind and madness. All immoderate vivacity borders upon madness; and, on the other hand, a sorrowful and gloomy disposition approaches to melancholy.

Delirium accompanies fevers of many different kinds. Sometimes it is flight, easily removed, and scarce to be accounted a bad sign. Often, however, it is very violent, and one of the very worst of signs, requiring the utmost care and attention.

A delirium is either fierce or mild. The fierce delirium is preceded and accompanied by a redness of the countenance, a great beating of the arteries, and noise in the ears; the eyes in the mean time looking red, inflamed, fierce, shining, and unable to bear the light; there is either no sleep at all, or sleep troubled with horrid dreams; the wonded manners are changed; an unnatural peculiarity and ill-nature prevail. The deprivation of judgment is first observed between sleep and waking, and by the person's crediting his imagination, while the perceptions of sense are neglected, and the ideas of memory occur in an irregular manner. Fury at last takes place, and sometimes an untrivial and incredible degree of bodily strength, so that several people can scarce keep a single patient in his bed.

The mild delirium, on the contrary, is often accompanied with a weak pulse, a pale, collapsed countenance, and a vertigo when the patient fits in an erect posture; he is seldom angry, but often stupid, and sometimes remarkably grieved and fearful. The loss of judgment, as in the former kind, is first perceived when the patient is half awake; but a temporary recovery ensues upon the admission of the light and the conversation of his friends. The patient mutters much to himself, and attends little to the things around him; at last, becoming quite stupid, he neither feels the

Delirium. Facinations of hunger or thirst, nor any of the other propensities of nature, by which means the urine and excrements are voided involuntarily. As the disorder increases, it terminates in subsultus tendinum, tremors, convulsions, fainting, and death. The other species of delirium also frequently terminates in this, when the spirits and strength of the patient begin to fail.

The symptoms accompanying either of these kinds of delirium show an unusual, inordinate, and unequal motion of the blood through the brain, and a great change in that state of it which is necessary to the exercise of the mental powers. It is sufficiently probable, that an inflammation of the brain, more or less violent and general, sometimes takes place, although the other species of delirium also frequently terminates in Hence, if the epilepsy derives its origin that an inflammation of the brain, more or less violent and general, sometimes takes place, although the other species of delirium also frequently terminates in it.

The motion of the blood through the brain, and symptoms of its injuries plainly sooner and more general, sometimes takes place, although the other species of delirium also frequently terminates in this, when the spirits and strength of the patient begin to fail.

The pathology of melancholy and mania is much more obscure; as coming on without a fever, or disturbance in the blood's motion. Often also they are hereditary, depending on the original structure of the body, especially of the brain; the fault of which, however, cannot be detected by the nescient anatomist. But it is well known, that various diseases of the brain, obstructions, tumours, either of the brain itself, or of the cranium prefixed upon it, any injury done to the head, and, as some physicians relate, the hardness and dryness of the brain, and some peculiar affections affecting the nervous system, are capable of bringing on this malady. And indeed so great are the affections affecting the nervous system in mad people, that they often sleep little or none for a long time,—yet even this so defective and imperfect knowledge of the diseases of the brain and nerves, is by no means free from difficulties. For though we know that the brain, or a certain part of it, is hurt, or that it is irritated by a swelling, or a pointed bone growing into it, nobody can foretell how great, or what may be the nature of the malady from such a hurt; for examples are not wanting of people who, after losing a large part of the brain, have recovered and lived a long time; or of those who have perceived no inconvenience from a large portion of that viscera being corrupted, until at length they have fallen suddenly down and died in convulsions.

Another disease of the internal senses, quite different from these, is fatuity or idiotism. Those are called ides who are delinquent either of judgment or memory, or else have these faculties unequal to the common offices of life. A kind of idiotism is natural and common to all infants; neither is it to be accounted a disease: but if it lasts beyond the state of infancy, it is a real disease, and for the most part incurable. It has the same causes with the other diseases of the internal senses: although these can never be detected by the eye or by the knife of the anatomist. It frequently accompanies, or is the effect of, epilepsy. Hence, if the epilepsy derives its origin from causes not seated in the head, as from worms lodging in the intestines, the fatuity may be cured by dislodging these, and removing the epilepsy. It is not unlikely that the fatuity of children, and the dotage of old men, may arise from the brain being in the former too soft and in the latter too hard.

The muscular power may be diseased in a great number of ways. The mobility itself may be too great; but this must be carefully distinguished from vigour, or power. By mobility is meant the ease with which the muscular fibres are excited into contraction. The vigour, on the other hand, is that power with which the contraction is performed. They are sometimes joined, but more frequently separate, and for the most part the excises of each are causing to contrary causes.

Too great mobility is when motions are excited by too flight a stimulus, or when too violent motions are produced by the customary stimulus. A certain habit of body, sometimes hereditary, renders people liable to this disease. Women have a greater share of mobility than men have. Infants have a great deal of mobility, often too great; youth has less than infancy, but more than man's estate; though old age has commonly too little. A lazy, sedentary life, full diet, a supposition of the usual evacuations, fulness of the blood-vessels, and sometimes their being suddenly emptied, laxity, flaccidity of the solids in general, but sometimes too great a tension of the moving fibres, the use of diluents, especially when warm, or heat applied in any manner, produce too great mobility. And this may be either general or particular, according as the causes have been applied to the whole body or only to a part of it.

Vigour in general is rarely morbid; although sometimes certain muscular parts appear to have too great strength. In maniacs and phrenitics, an immense strength is observed in all the muscles, especially in those that serve for voluntary motion; which is not unjustly reckoned morbid. The reason of this excess is very obscure; however, it is plainly to be referred to a diseased state of the brain.

A more frequent and more important excess of vigour is observed in those muscular fibres that do not obey the will, such as those which move the blood. Its circulation is thus often increased, not without great inconvenience and danger to the patient. But a lighter excess of this kind, pervading the whole body, renders people apt to receive inflammatory diseases, and is usually called a phlegmatic disease. But this is better observed when local, as in inflammation itself.

Too great vigour of the muscular fibres may arise from the nervous power increased beyond measure, as in maniac, phrenitis, or violent affections of the mind; from too great a tension of the fibres, by which they more easily and vehemently constrict movements, as of the arteries when filled with too much blood; from catching cold, by being exposed either to cold or heat, as usually happens in the spring; or lastly, though the nervous power and tension of the fibres

L should
Debility. Debility takes place, when the motion of the muscles, either voluntary or involuntary, is not performed with sufficient strength. A greater or lesser share of debility, either general or of some particular part, accompanies almost all diseases, and is indeed no small part of them: for it is hardly possible that a disease can subsist for any length of time without inducing some degree of debility. When a state of debility is induced, it renders a man obnoxious to innumerable disorders, and throws him as it were defenceless in their way. It often depends on the original structure of the body, so that it can be corrected neither by regimen nor medicines of any kind. A greater debility is frequently called a paralytic debility. This proceeds from some injury of the brain: though a state very similar to it is induced by narcotics, opium, wine itself, or any generous liquor taken to excess; and lastly, by breathing in air corrupted by noxious impregnations, such as a large proportion of carbonic acid, hydrocyanic gas, or any similar active aetiform fluid.

Palsy. The highest degree of debility, namely, when the strength of the muscles is altogether or nearly destroyed, is called paralysis or palsy; and is either universal, or belonging only to some particular muscles. An universal palsy arises from diseases of the brain and nerves, sometimes very obscure, and not to be discovered by the anatomist; for the nervous power itself is often deficient, even when the structure of the nerves remains unhurt: yet often a compression, obstruction, or injury of the vessels, extravasation of blood, or serum, collections of pus, swellings, &c. are discovered. It frequently arises from certain poisons acting on the nerves; from the fumes of metals; from the diseases of parts, and affections of the muscles, very remote from the brain, as in the colic of Pott. A palsy of single muscles, but less perfect, often arises without any defect of the brain or nerves, from any violent and continued pain, inflammation, too great tension, relaxation, rest, or destruction of the structure of the parts, such as commonly happens after the

An universal palsy, however, as it is called, seldom affects the whole body, even though it should originate from a disease of the brain. We most commonly see those who are paralytic affected only on one side, which is called an hemiplegia. It is said that the side of the body opposite to the diseased side of the brain is most commonly affected. If all the parts below the head become paralytic, it is called a paraplegia. In these diseases the senses for the most part remain; though sometimes they are abolished, and at others rendered dull. Sometimes, though rarely, and which is an exceeding bad symptom, the motion, sensation, pulse, and heat of the paralytic limbs are lost; in which case the arteries themselves become paralytic. A palsy of the whole body, as far as regards the voluntary motions, with anaesthesia and sleep, is called an apoplexy. This proceeds from some injury of the brain: though a state very similar to it is induced by narcotics, opium, wine itself, or any generous liquor taken to excess; and lastly, by breathing in air corrupted by noxious impregnations, such as a large proportion of carbonic acid, hydrocyanic gas, or any similar active aetiform fluid.

Spasm. Spasm therefore is a violent, constant, and preternatural contraction of the muscular fibres; but a convolution is an uneful and violent contraction alternated with relaxation. People are rendered liable to spasm by too soluble an habit of body, or too great mobility; and hence it is a disease common in women, in infants, and in weak, luxurious, lazy, and plethoric people. It is brought on through the already predisposed to it, by any kind of stimulus applied to the brain, or to any nerve, muscle, or nervous part connected with it: of which we have examples in dentition; worms lodged in the intestines, and irritating them; any acid matter affecting the blood, or much affecting the stomach and intestines; the irritation of any nerve, or of the brain itself, by an exfoliation, swelling, too great fulness of the vessels, pain, vehement affections of the mind, sudden evacuation, or poisons admitted into the body. Frequently, however, the malady originates from flight causes, little known, and not easily observed.

Spasm is both the cause and effect, and frequently constitutes the greatest part, of most diseases. It is often very difficult either to be known or cured; because it is so multiform and produces as many different symptoms as there are organs affected; of which it surprizingly disturbs, impedes, or increases the functions. It is a disease feated in the original flamina of the constitution; and neither to be removed by flight remedies, nor in a short time.

With regard to sleep, Dr Gregory observes, that its use is sufficiently apparent from the effects which it produces in the body. It renews the powers both of mind and body when exhausted by exercise, giving vigour to the one, and reforming its wasted alarthy to the.
WANT of sleep is hurtful in a great many different ways, especially to the nervous system. It renders the organs of sense both external and internal, as well as those of every kind of motion, unfit for performing their purposes. Hence the sensations are either abolifhed, or become imperfect or depraved; and hence imbecility of mind, defect of memory, a kind of delirium, mania itself, pain of the head, weakness of the joints, an imperfect or inordinate action of the vital organs, quickness of pulse, heat, fever, depraved digestion, atrophy, leanness, and an increase or perturbation of the secretions and excretions.

Sleep may be prevented both in healthy and sick people from various causes; such as strong light, noise, pain, anger, joy, grief, fear, anxiety, hunger, thirst, vehement desire, motion of the body, memory, imagination, intense thought, &c. On the other hand, sleep is brought on by a flight impression on the organs of sense, or none at all; by the humming of bees, the noise of falling water, cold and thirst, of sense both external and internal, as well as by reason of the impetus of the blood towards the head being frequently increased; and likewise from the stomach being disorder'd, loaded with meat, or distended with drink. Hence too we may see the reason why many hypochondriac and hysteric patients sleep so ill: because they have a bad digestion, and their stomach is disposed to receive many though frequently flight disorders; the flightest of which, however, is sufficient to deprive the patient of rest, provided the body be already irritable, and endowed with too great a share of mobility.

Want of sleep will hurt in diseases as well as in health; and for the same reason; but in a greater degree, and more quickly, in the former than in the latter; and is therefore not only a very troublesome symptom of itself, but often produces other very dangerous ones.

Too much sleep, on the other hand, produces many mischiefs, rendering the whole body weak, torpid, and lazy; and it even almost takes away the judgment. It also disturbs the circulation, and diminishes most of the secretions and excretions. Hence plethora, fatness, flaccidity, and an inability for the common offices of life.—The causes of this excess are, either the usual causes of sleep abovementioned increased beyond measure, or some fault in the body; or some fault in the organs of sense, or depraved; and hence

Too great an impulse of the blood towards the head, such as often happens in fevers, prevents sleep; but a free and equal distribution of the blood through the whole body, especially the extreme parts, frequently brings it on. Whatever weakens the body also favours sleep; and hence various kinds of evacuations, the warm bath, fomentations, sometimes heat itself, are useful or producing it. It is also of use to drink tea, or take some strong nourishing medicine.

Cold produces a deep sleep of long continuance, not easily disturbed, and often terminating in death. Lastly, there are certain substances which, when applied to the body, not only do not excite the nervous system, but plainly lay us asleep, and render us unfit for sensation: of this kind are those called narcotics, as opium and the like; among which also we may reckon wine taken in too great quantity.

Lastly, watching itself is often the cause of sleep; because while a man is awake he always more or less exercises the organs of his body, by which the nervous influence is diminished, and thus the more violently the body is exercised, in the same proportion is the perfon under a necessity of sleeping.

Sleep is deficient in many diseases; for there are few which do not excite pain, anxiety, or uneasiness, sufficient to prevent the approach of sleep, or to disturb it. Fevers generally cause those who labour under them to sleep ill; as well on account of the uneasiness which accompanies this kind of disease,
The blood is also distributed in various proportions to the different parts of the body, and that proportion too differs at different periods of our lives. At first an immense quantity is sent to the head, because that part of the body is first to be evolved and fitted for its offices: but as soon as the parts begin to make a considerable refalliance to the efforts of the blood, and the vessels cannot easily be further dilated, it is necessarily sent off to other parts; by which means the rest of the body increases in bulk, and becomes fitted for performing its proper functions. The effect of this change is also very soon observed, namely, when none of the blood passes through the navel, and of consequence a sometimes produces a still more remarkable slowness of the pulse, as in the hydrocephalus, apoplexy, &c.—Sometimes also the pulse is too slow in those who are recovering from tedious fevers. But this is a matter of little moment, and seems to be owing to some kind of torpor. Indeed it has generally been considered as a mark of a thorough and complete solution of the fever; for it is commonly observed, that when this state of the pulse takes place, the patient seldom suffers a relapse.

While the frequency of the pulse continues the same, its strokes may be either full, great, strong, and hard; or soft, small, and weak. A full, great, and strong pulse takes place when the ventricle strongly and completely empties itself; throwing out a greater quantity of blood into the arteries, which fully dilates them and stimulates them to a strong contraction. A pulse of this kind is common in strong healthy men, and is seldom to be accounted a symptom of disease. But if it be too strong, and strike the finger of the person who feels it violently and sharply, it is called a hard pulse. This hardness is produced by a sudden and violent contraction of the heart and arteries, which dilates even the remote branches, as those of the wrist, too suddenly and smartly, and excites them also to sudden and violent contractions.

A hard pulse therefore denotes too great an action of the heart and arteries. It may arise from various causes: in the first place, from too great a tension of the vessels; for instance, from their being too full, and by that means more prone to motion, and the more fit for receiving violent motions. It may arise also from too great a density and firmness of the folae; and hence it is most frequent in cold countries, among strong robust people, and such as are accustomed to hard labour. It may likewise arise from various causes irritating the whole nervous system, or only the heart and arteries. Lastly, it accompanies many fevers, as well as most inflammatory disorders, whether the inflammation arises from a general stimulus applied to the whole body, or from the irritation of particular parts, by degrees extended over the whole body. In such a state of the circulation, the patient frequently faints in need of blood-letting, and almost always bears it well.
A small, weak, and soft pulse is generally owing to causes opposite to the foregoing, and indicates a contrary state of the circulation and nervous system. It frequently requires stimulants; nor does it generally require blood-letting, or easily bear it. Sometimes, however, a pulse of this kind is observed even in the case of a dangerous inflammation, of the stomack for instance, or intestines. But in these and the like examples, we ought to attend to the nature of the malady, much more than to the state of the pulse.

The pulse is said to intermit, when the stroke does not return after the usual interval, and perhaps not till after twice, thrice, or four times the usual space. A pulse of this kind seems to be almost natural and constant in some animals, and is common to some men even in the most perfect health; and if these happen to be seized with a fever, the pulse sometimes becomes equal, nor can the disease be removed before the intermission has returned.

Moreover, in some people, though their pulse beats equally while in health, yet the slightest illness makes it intermit; and in others, especially those who have a great deal of mobility in their constitution, such as hypochondriac and hysteric people, the intermission of the pulse is felt, without applying the finger to the carotid and femoral parts, and of consequence where the motion of the heart is emptied, the more quickly is the blood confirmed by the pulse, which indeed is a certain and definite distribution of the vital fluid frequently applied to the part itself, or to the brain, or at least to the lungs. Hence, varices, and congections of blood, especially in those parts of the body where the veins are distended and of confluence where the motion of the muscles cannot affect the circulation. Hence also arises dropsy from an impeded or languid motion of the blood; because the resistance of the veins being increased, the blood is received into them with the greater difficulty, and more of the thin humour is driven into the exhauling vessels, and by them deposited in such quantities as cannot be reabsorbed by the lymphatics. These diseases, as well as all others proceeding from defects of the circulation, are also more difficult of cure than others, because all the vital powers are weakened at the same time.

Another disorder of the circulation is where the blood is carried to one part of the body in too great quantity, by which means the other parts are deprived of their due proportion. This irregular distribution of the vital fluid frequently arises from a stimulus applied to the part itself, or to the brain, or at length acting on the mind, which, according to the laws of sympathy, produces a certain and definite distribution of the blood. It arises also not unfrequently from a spasm taking place in some other parts, which drives the blood out of its ordinary course.

In proportion to this irregularity of the circulation are the consequences; heat, swelling, redness, inflammation, ruptures of vessels, haemorrhages, effusion, secretion, corruption, and suppuration of the cellular texture and adjoining parts, &c. Even this evil, however, nature often converts into an excellent remedy; and physicians, following her steps, frequently attempt to direct the distribution of the blood in particular diseases, well knowing that a change in the distribution in the blood is frequently efficacious either for radically curing some diseases or relieving their most urgent symptoms.

Lastly, some disorders in the motion of the heart itself, and those of no small consequence, remain yet to be taken notice of, namely, palpitation and syncope. A palpitation is a violent and irregular action of the heart, such as for the most part is perceived by the patient himself, and that not without a great deal of uneasiness and oppression at his breast; and is also manifest to the bystanders if they apply their hands, or look...
 look at his naked breast; the pulse of the arteries in the mean time being weak, unequal, and intermitting. This is a spasmodic disorder; and is induced by various causes affecting either the nervous system in general, or the heart in particular. Every disease of the organ itself, such as a contraction of its valves and blood-vessels, and obliteratism, enlargement, or polypus, hindering the free action of the heart, and evacuation of blood from it, are capable of exciting it to violent and unusual contractions. The same effect will also follow plethysm, or too violent an impulse of the blood, &c. The heart will likewise frequently palpitate from a violent excitement of the nervous system, especially where the constitution is endowed with a great deal of mobility. Hence palpitations from any affection of the mind, and in hysterical women. Palpitation may likewise arise from an affection of the stomach, occasioned by worms, a surfeit, flatus, or fermentation by various acid substan- cies. It frequently also accompanies the gout when driven back, or even when a fit is coming on. Sometimes it arises from debility, whatever may be the cause; frequently from any difficulty in breathing; and many of these causes may be joined at the same time, or some of them produce others.

Hence we may see why the evil is sometimes flight and of short continuance; at other times altogether incurable, and certainly mortal in a long or shorter time; why it sometimes returns at intervals, often coming on and being increased by every kind of irritation and excircle, and sometimes relieved or totally removed by stimulants or exercise.

A syncope is when the action of the heart, and, along with it, that of the arteries, is suddenly and very much lef sen; whence the animal-powers, the senses, and voluntary motions, immediately cease. This may be produced by almost all the causes of palpitation; because whatever can disturb and disorder the motion of the heart, may also weaken or suspend it. The vitiated structure of the heart itself therefore, violent passions of the mind, whether of the depressing kind, or those which suddenly and vehemently excite, various kinds of nervous diseases, those of the stom- ach, every kind of debility and evacuation, especially a great loss of blood, excessive and unremitting labor, long watching, heat, pain, many kinds of poisons, &c. produce fainting.

Hence we see, that whatever weakens the motion of the blood through the brain tends to produce fainting; and, on the contrary, whatever tends to augment that motion, also tends to refresh, and prevent the person from fainting. Hence also we see how the mere posture of the body may either bring on or keep off fainting, or remove it after it has already come on. We likewise see how this disorder may sometimes be of little consequence and easily removed; at others very dangerous, not only as a symptom, but in even itself, as sometimes terminating in death; and lastly, how it may be used as a remedy by a skilful physician, and artificially induced, either to free the patient from violent pain, or to stop an inordinate effusion of blood to be restrained by any other method.

With regard to the disorders of the blood itself, Dr Gregory observes, that the glutinous part of it produces that buff-coloured appearance often seen upon blood drawn from people afflicted with inflammatory dis- orders, and even sometimes when no such diseases are present. This crust indeed is nothing else than the pure gluten of the blood taking longer time than usual to coagulate, by which means the red particles have an opportunity of falling to the bottom. This indicates no lenter, density, thickness, or tenacity of the blood, as was formerly thought; but rather its thinness, or at least a left tendency in it to coagulate. It arises for the most part from a violent agitation and con- summation of the blood within the body; and hence it accompanies many fevers, all inflammations, sometimes hemorrhages, exanthema, phlethora, pain, and many irritations. It must however be allowed, that in several of these diseases it is rendered highly probable, at least from experiments apparently accurate, that the quantity of the gluten of the blood is really encreased in the proportion which it bears to the other parts. This crust, however, is not always to be accounted morbid, as it often happens to the most healthy; and may even be produced or destroyed by the sight of cau-ses while the blood is flowing from the vein, so that frequently we shall see a very thick and tenacious crust on the blood flowing into one cup, while that which runs into another has little or none at all. In general, however, the appearance of this crust shows, that the patient will bear blood-letting well, though those have been in a great mistake who directed this operation to be repeated till no more crust appeared on the blood.

The glutinous part of the blood also frequently produces those masses called polypus, which sometimes take place during life, but more frequently after death, in the large vessels near the heart, or even in the cavities of that organ. Similar masses also are frequently formed in the uterus, and are called mole.

The quantity of blood contained in a healthy body is very various, and difficult to be ascertained. Many diseases, however, may arise from its being either too scanty or too abundant. Too great a quantity of blood is produced by the use of rich nourishing diet, strong drink, accompanied with a good digestion; from a lazy, sedentary life, or much sleep, especially in those who have been formerly acclimated to too much exercise; with many other causes of the same kind. It renders the person dull, weak, and languid, and sometimes almost totally oppresses him; nor are those organs defined for moving the blood sufficiently for driving forward such a load. The pulse sinks; and sometimes a syncope, vertigo, or palpitation takes place. More frequently, however, the vessels are too much diffused, and ready to be thrown into violent and irregular motions. Hence a disposition to fevers, inflammations, unequal distribution of the blood, unusual congections, rupture of the vessels, and hemorrhages. Moreover, by reason of the close connection between the languid and the nervous system, a fulness of blood produces a disposition to pain and other diseases of that kind.

Hence we may understand why a phlethora is sometimes accompanied with a weak and sometimes with a strong and hard pulse, why it is the cause as well as a part of so many distempers, why it is the effect of a high state of health, &c.
Theory.

MEDICINE.

Disorders of the blood.

The want of a due quantity of blood is no less pernicious than too great an abundance of it. It debilitates the person, and renders him unable to perform the proper offices of life; produces a languid circulation, syncope, spasm, and at last death itself. In a lighter degree of the dispa the body is emaciated through want of nourishment, and its functions are vitiated in various ways. It may arise from want, bad food, or such as affords little nourishment; from bad digestion, or the chyle being hindered from passing into the blood; from fevers, or other diseases which exhaust the body and hinder nutrition; or lastly, from various evacuations, particularly of blood: and that the more exhausted, the quantity left in them. Besides, if the body be great, it may either prove mortal in a short time, or break the constitution to a degree beyond recovery. Hence the blood becomes thin, pale, scarce capable of coagulation, or becoming very thin, pale, scarce capable of coagulation, or the blood concur.

The acrimony of the fluids has afforded a large field for declamation to the speculative physicians, and the more thinnes of the blood alfo proceeds from the increase of motion in the heart and arteries, and the familiar augmentation of the action of the secretory organs, from acid substan ces taken inwardly. The same thing also appears from the unusual acrimony of the secreted fluids in such cases, by which the vessels are sometimes greatly stimulated, and sometimes very much diffused. Very acrid substan ces, however, are daily taken into the stomach; so that there must either be corrected in the prime vitia, or changed by digestion before they pass into the blood; or at least by dilution with much water, or being blunted by an admixture with gluten, oil, or inflammable air; they must deposit much of their acrimony, and at last be thrown out of the body as noxious substances. Thus a vaf quantity of salts, acid, alkaline, and neutral, may pass through the body, without in the least affecting the health; though these salts, if taken in very large quantity, undiluted, or not thrown out of the body, will do much hurt.

Moreover, even while life continues, putrefaction is going on, and produces much of that substance called animal salt; for into this a great part of our food is converted, and passes off by the urine. But if this putrefactive disposition be too great, it will produce too much a quantity of animal salt; especially if much of any saline substance is otherwise thrown into the body without proper dilution; and this kind of disease is well known to sailors who have been long at sea without having any opportunity of getting fresh provisions.

For this spontaneous putrefaction, nature has suggested a proper remedy, namely, fresh meat, especially of the vegetable and acce dent kind, and such as is well impregnated with aerial acid, which it may impart to the body. But where this kind of food is wanting, the putrefaction goes on apace, and a very great thinness and acrimony of the juices take place; especially if there be also a scarcity of water, or the excretions which ought to carry the putrid matters out of the body languish, either from cold, faith, torpor, depressed passions of the mind, or from the constitution being broken by diseases; or lastly, from too great heat, which always favours putrefaction.
Diforders, of the Blood.

Besides, it would seem, that sometimes a disposition to putrefaction is much increased by the reception of a putrid ferment into the body; of which we have examples in some infectious fevers, where the contagion is very much afflicted by heat, animal-diet, certain kinds of feals, debility and malnaifes.

Lastly, any fingle part of the body may putrefy from various causes, as from inflammation, gangrene, cold, &c. and thus may the whole body be infected; although for the most part the difeafe proves fatal before the corruption has spread over the whole body.

But when the malady begins to putrefy greatly, it not only becomes very acid, but thin also, so that it either will not coagulate at all, or flows only a flight and very loofe cratfallent. Nay, even the red globules are broke down and destroyed; in which cafe it necessarily follows, that the blood must become very acid, as well on account of the evolution of the falt, as by reafon of the rancid and putrid glutfen, which stimulates, and frequently even erodes, the vellifer producing spots, first red, then livid and black, tumours, and ulcers scarce to be cured, without fight removing the putrefent disposition of the humours. From the fame caufe proceed hemorrhages from every part of the body, hardly to be refrained; a molt intolerable feg of the breath and all the excrementd; the highest debility and laxity of the folidf; the putrefation acting as a poison to the nervous fystem, and at length bringing on death.

An acrimony of the acid kind never takes place in the human blood, nor in any of the humours fecreted from it; though one of them, namely the milk, turns acid fecondarily in a very fhort time after it is drawn from the breast. Neither, indeed, does an alkaline acrimony feem ever to take place in the blood. Putrefacy indeed tends this way, and at laft terminates in it; but fearcely when the perfon lives, though the nature of the urine, even while recent, feems to be but little differ from that of an alkaH.

Many kinds of acrimony indeed may exif in the blood from too liberal anufe of spices, wine, &c. but of these we know nothing certain. We well know, however, that the body is often infested with various kinds of morbid acrimony, which bring on many and dangerous difeafes, as the small-pox, measles, feasures, lues veneris, &c. of which the origin and manner of acting are very little understood, though the effects are abundantly evident. In molt cafes, nature has taken no left care to provide againft the acrimony than against the too great thickness of the blood. Sometimes an antidote is afforded, either by the excitation of thirst, that the acid fubftance may be diluted with plenty of drink; or by increafing the evacuations, that it may be thrown out of the body; or laftly, by exciting various motions and actions of the vital powers, by which it may be either subdued, changed, rendered innocent, or expelled from the body by new and unwaited paffages.

With regard to refpiration, Dr Gregory obferves, that it may be obstructed from various causes fcaet either in the lungs themfelves or the surrounding parts. But from whatever cause this obftruction may arife, it undoubtedly produces all thofe difeafes which proceed from an interrupted circulation. The lungs themfelves alfo being at length comprifed, and not sufferfed to dilate fufficiently, cannot throw off the vapour which arises from them; and hence they are frequently oppreffed with moifure. At the fame time they are irritated, fo that a greater quantity of mucus, and that of a thicker kind than ufual, is fecreted; by which means the fages through which the air enters them are fpofled up, and a violent cough at length throws off the load.

The refpiration is alfo fubjeft to fonfe other diforders, as a cough and fneezing; which, though at first they may feem very dangerous, are not deftitute of life, and may even be reckoned among the molt falutary attempts of nature to relieve the patient. Often, however, they are attended with danger, or very great uneafinesf; namely, when they are either too violent or exerted in vain. At any rate, it is necejfary for a physician to know the nature, caufes, and effects, of thefe, that he may be enabled to promote them when necejfary, to moderate them when too violent, and to stop them when noxious or to no purpose.

A cough is a violent, frequently involuntary, and coughforous expiration, suddenly expelling the air with great force through the glottis somewhat contracted. The contraction of the muscles ferving for expiration, gives a great force to the air, while the contraction of the glottis produces the found. It is often long continued, being repeated at certain intervals, during each of which the inspiration is imperfect and obftructed by reafon of the contraction of the glottis. It is excited by any kind of acrid fubftance, either chemically or mechanically applied to thefe paffages through which the air enters. These are lined with a membrane fo exceedingly delicate and impatient of stimulus, that it cannot even bear the touch of the mildeft fubftance, fuch as a small drop of water, without throughfing the muscles ferving for expiration into a violent convulfion; the glottis at the fame time contracting by means of the sympathy between it and the neighbouring parts. Thus the air is thrown out with fuch violence, that it drives the irritating fubftance along with it; and thus a cough becomes not only ufeful, but absolutely necejfary for the prefervation of life, as being able to free the lungs from every kind of irritating fubftance or foulnefs, which might soon bring on a fuffocation. Hence a cough is almost an ineparable companion of every inflammation of the lungs, as well as every difficultly in refpiration; and even frequently accompanies the entrance of the pureft air when the trachea and bronchiae are excoriated, or become too fensible. Examples alfo are not wanting, where a violent and troublesome cough has arisen from an irritation of the nervous fystem, or even of some particular part, of the ear, for infance, the fafhaen and intestines by worms, the liver by inflammation, &c.

Coughing may alfo be voluntarily excited, and may then be managed at pleafure. Even when involuntary, it may be moderated, or fuppreffed, by a contrary ef- fott: though a violent fit of coughing cannot by any means be refuted. When it is once excited, the cough goes on till the irritating fubftance be expelled, or the feuds of irritation abolished, or perhaps overcome by a more uneafy fenfation than even the cough itfelf; af-

MEDICINE.

Theory.

Diforders.

Diforders. of Respiration.
A very violent cough is often dangerous. For by the retention of the breath, and the strong efforts made in coughing, a great quantity of blood is collected in the lungs, of which the vessels are dilated, and frequently broken; and hence there sometimes happens a violent and even fatal hemorrhage. More frequently, however, it is the cause of a flower, though equally fatal, disease. Nay, a frequent and troublesome cough, without any great hemorrhage, or even without any hemorrhage at all, may damage the lungs to such a degree, especially if they be of a more tender structure than usual, so as to lay the foundation of a phthisis almost always incurable.

Again, by a long-continued and violent cough, the passage of the blood through the lungs being impeded, it must necessarily flow through the veins towards the head: hence redness and lividness in the countenance, hemorrhages, pallies, apoplexies, and sometimes mortal convulsions. Lastly, by a violent cough the abdominal viscera are perpetually compressed with remarkable violence; and if any part happens to be weaker than usual, a hernia, prolapsus uteri, abortion, or similar accidents, may happen.

Even when the cough is more gentle, if it happens to be importunate and frequent, although we have nothing of this kind to fear, yet the patient is by no means free from danger; as he is thereby agitated, fatigued, has his constitution broken, is deprived of rest, and has a fever brought upon him, his lungs are faken and irritated, digestion and all the other functions are impeded, till at last he sinks under a complication of maladies.

Sneezing is somewhat akin to cough, as consisting of a very full inspiration, to which succeeds a most violent expiration, by which the air is driven out through the nostrils with immense violence, and sweeps the passage through them as it goes out. It is a con

The real part of Dr Gregory's treatise necessary to be taken notice of here, is that which considers diseases arising from a bad digestion, disordered motion of the intestines, and some of the principal secretions. The first of these, he says, are sometimes very troublesome, though seldom dangerous. The principal symptoms are oppression, anxiety, pain at the stomach; eructation, by reason of air extricated from the fermenting aliment, and irritating the stomach; nausea and vomiting, from the irritation and diffusion of the bile organ; the belly sometimes too colicky, and sometimes too loose; a defect of nourishment; a general debility; relaxation of the solid parts; too great thin

The consequences of long-continued colic, are first an affection of the alimentary canal, and, then of the whole body. The stomach is diseased, and does not digest the aliments properly; the whole body is left delirious of its usual stimulus; the blood is corrupted, perhaps from the restoration of the putrid matter into it. The circulation through the alimentary vasa is impeded; hence frequent and irregular convulsions, varices of the veins, hemorrhoids, &c. Nay the intestines themselves being overloaded, dilated and irritated by an heavy, acid, and putrid load of aliments or other matters, are excited to new and unusual contractions, which, if they do not get the better of the obstruction, bring on torments, colic, or an ileiac passion, inflammation and gangrene, fatal in a very short time.

Looseness, or diarrhea, is a malady extremely common, and sometimes only a symptom or an effect of others. Sometimes it is a salutary effort of nature, such as the physician ought to imitate and bring on by art. It is also familiar to infants, and to people of certain constitution; and to them colic and diarrhea is very prejudicial. It may arise, in the first place, from a fermenting taken into the body, or generated in the intestines; from a fermentation and corruption of the mucus of aliments; from the bile being too abundant and acid, or from blood or pus poured into the intestines; from the intestines themselves being eroded, or deprived of their natural mucus; from the humour's being driven from the surface of the body towards the inward parts, as by cold, especially when applied to the fist; or from a general corruption of the whole body, as in the phthisis, hectic, or putrid fever, especially towards the end of these disorders. In fevers it is sometimes fatal, or even puts an end to the disease altogether, or at least renders it milder: more frequently, however, deriving its origin from putrefaction, it is of no service, but rather exhausts the strength of the patients. A diarrhea likewise, almost incurable, and often mortal in a short time, frequently arises after the operation for the flatus in ano. Some have their intestines so extremely weak and moveable, that from the slightest cause, such as eating cold, any violent commotion of the mind, &c. they are subjected to a violent diarrhea. Lastly, whatever be its origin, if it has continued for a long time, the vasa are rendered too weak and its
Dysentery.

Dysentery is attended with very severe gripes in the belly, a frequent desire of going to stool, and vain efforts which excrete nothing belies the mucus of the intestines mixed with a little blood; and is accompanied with excessive debility, and frequently with putrefaction and fever. It is thought to arise from the contraction of some part of the intestines, of the colon especially, by which means the bowels, though ever so much irritated, can pass nothing; neither can the disease be removed until the belly has been well purged by proper medicines.

Teneusus.

Tenesmus is a frequent and insatiable propensity to stool without being able to pass any thing, notwithstanding the most violent efforts. It may be occasioned by any kind of irritation, either of the rectum itself or of the neighbouring parts, by acrid substances taken into the body; by some of the stronger purges, especially aloes, which is very difficult of solution, and will pass even to the rectum with very little alteration; by a violent and obstinate diarrhœa, dyentery, hemorrhoids, worms, flatus, calculus, ulcer in the bladder, urethra, &c. It is often very pernicious, both from the excessive uneasiness it occasions to the patient, and from its exhausting its strength, by the frequent and vain efforts bringing on a prolapus ani, and communicating the violent irritation to the neighbouring parts, as the bladder, &c.

A nausea and vomiting are disorders very common, and owing to almost innumerable causes: not only to affections of the thoracic heart, but also to affections and irritations of the remotest parts of the body which may act upon the thorax by sympathy. Every irritation and dilation of that viscus therefore, a load of crude aliment, an obstruction about the pylorus, all acrid substances taken into it, diseases of the liver, intestines, kidneys, uterus, the head, the feet, the skin or indeed the whole body, inflammation, the stone, king's evil, scirrhus, apoplexy, contraction of the brain, fracture of the skull, vertigo, syncope, violent pain, the gout, especially when repelled, fevers, paf-

Theodore.

Theodore, or the theory of the alimentary canal. It may originate from several causes, as too strong a dose of an emetic by which means a vast quantity of bile frequently ascends into the stomach, and is discharged by vomiting.

An excessive vomiting with loofenings is called a cholo-

Choleræ, when the matter discharged has a bilious appearance. It arises from a very great irritation of the alimentary canal without any obstruction; and is for the most part occasioned by too great a quantity, or from an acrimony of the bile, from whence it takes its name. It may originate from several causes, as too strong a dose of an emetic, and cathartic medicine, eating too great a quantity of summer-fruits, &c. and is a very violent malady, often killing the patient in a few hours, unless proper remedies be applied in time.

From a suppression of any of the secretions, or a Obstructed disorder of any of the secretory organs, many mischief may arise. A diminution of perspiration produces plethora, latitudo, languor, depression of mind, bad digestion, loss of appetite, and even a general corruption of the humours from the retention of such a quantity of putrefactive matter.—The more suddenly the diminution or suppression of the perspiration takes place, the sooner the mischief is produced, and the greater it is; not only by retaining the matter which ought to be thrown out, but by repelling the humours from the surface of the body, and directing them to other parts; whence fevers, inflammations, congections of the blood, &c. frequently take place.

Thus suppression of perspiration may arise from many different causes; as from cold suddenly applied to the body when very hot; sometimes from very violent passions.
Theory.

MEDICINE.

Diabetes of secretion, palpitations of the mind; or from spasmic diseases, as the
hysteric, &c. It may be suppressed also by that kind of
contraction of the vessels of the skin which is pro-
cuced by various kinds of fevers, the nature of which has
hitherto been but little known.

Excessive perspiration or sweating is injurious by de-
bitating the body, relaxing the skin, and expelling the
patient to all the

motions of urin, will certainly prove fatal. This disor-
der, which is call­
ed Urinaria, may arise from various diseases of the kid­
neys, ureters, bladder, urethra, &c. Thus any obstruc-
tion or irritation of one or other of the kidneys or ure-
thra, being secreted, or may give rise to a scanty or depraved

urine, or in some particular state of the neighbouring
parts, as of the uterus, vagina, urethra, prostate

Akin to the strangury is an incontinence of urine, in

which the patient's water either comes away against the
will, or altogether without his knowledge. This
disorder may arise from debility, pain, an ulcer or

wound, or any long-continued and violent irritation of
the bladder, especially of its splinter, as from a

stone, a general palsy, or in females, difficult labour

injuring the neighbouring parts.—This symptom oc-
curs in a great number of diseases, especially in

the hydrocephalus. Sometimes the urine is expelled

with violence, either by reason of universal spasms, or by

violent contractions of the muscles of respiration, as

in freezing, laughter, &c.

Among the disorders incident to the urine we Urinary
may reckon the production of calculi, which frequently
bring on the most excruciating and dangerous diseases.

The urine, besides the water and salt, contains no
small share of the glutinous part of the blood already
somewhat corrupted, and still inclined to further cor-

ruption. Hence the urine even of the most healthy
people deposits a sediment after it has stood for some

time; and though none of this sediment be formed in

an healthy body, yet if the smallest particle of foreign
matter be introduced into the bladder, a crust soon
gathers round it, and it is sure to become the basis of

a stone, which by degrees grows to a very great

size. It is not unlikely, also, that some unknown

fault of the fluids may contribute to the produc-
tion of these calculi, as the stone is well known to be an

hereditary disease, and to be born with the patient.

Calculous persons also are commonly subject to com-
plaints of the stomach, especially to an acidity of it;

and many have received no little relief from alkalis, or

alkaline medicines.—From the same causes may cal-
culi be formed in the kidneys; from which proceed a
horrid train of symptoms described in the subsequent
part of this treatise.

It is now found by accurate experiments of the
most able chemists, that urinary calculi do not, as was
once supposed, confit almost entirely of an earthly mat-

ter. Their principal constituent is a peculiar acid
approaching more nearly to the phosphoric found in
the bones than to any other. But the acid of cal-
culus being in some respects peculiar in its nature, has
among modern chemists obtained a peculiar name, and
been distinguished by the appellation of the lithic
acid.

It is highly probable that this acid present in the cir-
culating fluids, is precipitated and difengaged by the
introduction of other acids, and thus thrown off in
greater quantities by the kidneys. Thus then we can
understand the influence of acids as tending to the ge-
neration of calculi, and of alkalies as tending to
prevent it.

The last disorder here to be taken notice of is a
Strangury.

Scheirrus, disorder of the glands themselves, owing to some kind
of obstruction, and is one of the most dreadful dis-
eases incident to human nature. Hence happens a

great
great swelling and surprising hardness, not only without pain, but sometimes even with a diminution of sensation in the part affected; and when the gland is thus affected, it is called a tumor. Sometimes it remains in this state for a long time; but sooner or later produces the most excruciating torment. By degrees it is affected with a slow and malignant supputation, degenerating into an horrid ulcer, consuming not only the part itself, but eating away the neighbouring ones, and corrupting the whole body with the most acrid and incurable poison. This disease is called a cancer, of which the causes are very little known.

PRACTICE OF MEDICINE, or an Account of the principal Diseases to which the Human Body is subjected.

We have already defined medicine to be the art of preventing, curing, and alleviating, those diseases to which mankind are subjected. While these affections, however, are in number almost infinite, each in its progress is subjected to almost endless varieties from differences in climate, constitution, treatment, and a variety of other particulars. Hence we may readily explain both the difficulty of distinguishing morbid affections from each other in actual practice, and the diversity of names which have been affixed to them in the writings of ancient physicians. It may readily be supposed, that in this as well as other subjects, there has been a gradual improvement from the progressive labours of industrious and ingenious men. And although much yet remains to be done in the proper arrangement and distinction of diseases, or what has been called methodical nomenclature, yet there cannot be a doubt that during the course of the present century, this subject has received very great improvements. For these, we are in the first place highly indebted to the labours of Franciscus Boissier de Sauvages, an eminent professor of medicine at Montpellier, who, following out an idea suggested by the famous Dr Sydenham of England, first successfully attempted to arrange diseases as botanists have done plants, into classes, orders, genera, and species. Since the publication of the Nomenclature Methodica of Sauvages, this subject has been successfully cultivated by several ingenious men, particularly by Sir Charles Linnaeus of Upall, to whose genius for arrangement every branch of natural history, but botany in particular, has been so highly indebted; by Rodolphus Augustus Vogel, an eminent professor at Gottingham; and by John Baptist Sagar, a distinguished physician at Iglaw in Moravia: but of all the systems of arrangement yet presented to the medical world, that published by the late illustrious Dr William Cullen of Edinburgh, may justly be considered as the best. In treating, therefore, of the principal diseases to which the human body is subjected, we shall follow his plan, endeavouring to deliver the best established observations respecting the history, theory, and practice of each. And in treating of particular genera of diseases, although we follow the arrangement of Dr Cullen, yet for the satisfaction of the reader, we shall point out the classes to which the same affection is referred by the other eminent writers whom we have mentioned. And on this account, it may not be improper briefly to enumerate the general classes to which each of them have referred the affections of the human body.

The classes of Sauvages are,

1. Vitia.
2. Febres.
3. Phlegmasia.
4. Spasmis.
5. Anhelationes.

The classes of Linnaeus are,

1. Exanthematici.
2. Critici.
3. Phlogistici.
4. Dolores.
5. Mentesales.
6. Quietales.

The classes of Vogel are,

1. Febres.
2. Profuvia.
3. Episciehes.
4. Dolores.
5. Spasmis.

The classes of Sagar are,

1. Vitia.
2. Palgis.
3. Cachexiae.
4. Dolores.
5. Fluixus.
7. Spasmis.

After this short view of different classifications, we shall next present to our readers a more particular account of the arrangement of Dr Cullen; which, although it can by no means be represented as free from errors or imperfections, is yet in many respects the best that has hitherto been published.

CULLEN'S ARRANGEMENT.

CLASS I. PYREXIA. A frequent pulse coming on after an horror; considerable heat; many of the functions
Practice.

MEDICINE.

General

Arrangement

of

Diseases.

ctions injured; the strength of the limbs especially diminished.

ORDER I. Fevers. Pyrexia without any primary local affection, following languor, litharge, and other symptoms of debility.

Sect. I. Intermitentes. Fevers arising from the misfina of marshes; with an apyrexia, or at least a very evident remission; but the disease returns constantly, and for the most part with a horror or trembling. There is only one paroxysm in a day.

Genus I. Tertiana. Similar paroxysms at an interval of about 48 hours, coming on most commonly at mid-day. A tertian heat either;

I. An apyrexia interpofed;

1. Varying the duration of the paroxysms.

A. The tertian whose paroxysms are not extended beyond 12 hours;

B. The tertian with paroxysms extended beyond 12 hours.

2. Varying in the return of the paroxysms.

C. The tertian returning every day with unequal paroxysms alternately similar to one another.

D. The tertian returning every third day with two paroxysms on the same day.

E. The tertian returning every day, with two paroxysms on every third day, and only one on the intermediate ones.

F. The tertian returning every day, with a notable remission interpolated between the odd and the even days, but a less remarkable one between the even and the odd one.

3. Varying in its symptoms.

G. The tertian accompanied with a disposition to sleep.

H. Accompanied with spasm and convulsive motions.

I. Accompanied with an efflorescence on the skin.

K. With phlegmasia.

4. Varying in being complicated with other diseases.

5. Varying as to its origin.

II. With the interpolation only of a remission between the paroxysms.

Genus II. Quartana. Similar paroxysms, with an interval of about 72 hours, coming on in the afternoon.

I. With the interpolation of an apyrexia.

1. Varying in the type.

A. The quartan with single paroxysms, returning every fourth day, none on the other days.

B. With two paroxysms every fourth day, and none on the other days.

C. With three paroxysms every fourth day, and none on the intermediate days.

D. Of the four days having only the third free from fever, with similar paroxysms every fourth day.

E. The quartan coming on every day, with similar paroxysms every fourth day.

2. Varying in its symptoms.

3. Varying in being complicated with other diseases.

II. With a remission only between the paroxysms.

Genus III. Quotidiana. Similar paroxysms with an interval of about 24 hours, coming on in the morning.

I. With the interpolation of apyrexia.

1. Varies in being solitary.

A. Universal.

B. Partial.

2. Complicated with other diseases.

II. With a remission only between the paroxysms.

Sect. II. Continus. Fevers without any interpolation, and not occasioned by marsh miflams; attended with exacerbations and remissions, though not very remarkable.

Genus IV. Synocha. Great heat; a frequent, strong, and hard pulse; high-coloured urine; the functions of the fenforium a little disturbed.

Genus V. Typhus. A contagious disease; the heat not greatly above the natural; the pulse small, weak, and for the most part frequent; the urine little changed; the functions of the fenforium very much disturbed, and the strength greatly diminished.

The species are,

I. Typhus petechialis. Typhus for the most part with petechiae.

II. Typhus iterodes. Typhus with a yellowness of the skin.

Genus VI. Synochus. A contagious disease. A fever composed of a synocha and typhus; in the beginning a synocha, but towards the end a typhus.

ORDER II. Phlegmasia. A synocha fever, with inflammation or topical pain, the internal function of the part being at the same time injured; the blood covered with fize.

Genus VII. Phlegmosis. Pyrexia; redness, heat, and painful tension, of some external part.

The species are,

I. Phlegmosis (phlegmone) of a vivid red colour; a swelling well defined, for the most part elevated to a point, and frequently degenerating into an abscess, with a beating or throbbing pain.

The variations are, 1. In the form. 2. In the situation.

II. Phlegmosis (erythema) of a reddish colour, vanishing by pressure; of an unequal and creeping circulation, with scarce any swelling; ending in the scaling off the cuticle, in phlyctenae, or blisters.

The variations are, 1. In the degree of violence. 2. In the remote cause. 3. In being complicated with other diseases.

The consequences of a phlegmosis are, an impolhimine, gangrene, phlyctenae.

Genus VIII. Ophthalmia. A redness and pain of the eye, with an inability to bear the light; for the most part with an effusion of tears.

The species and varieties of the ophthalmia are,

I. Idiopathic.

1. Ophthalmia (membranacea), in the tunicza adnata, and the membranes lying under it, or the coats of the eye.

A. Varying in the degree of the external inflammation.

B. In the internal coats affected.

2. Ophthalmia (tarpe) of the eye-lids, with swelling, erosion, and glutinous exudation.

II. Symptomatic.

1. From a disease of the eye itself.

3. From...
MEDICINE.

Practice.

General Arrangement of Diseases.

I. Idiopathic.
II. Symptomatic.

Genus XIX. Phrenitis. Pyrexia; pain of the belly, exasperated by an upright posture, without the proper signs of other abdominal phlegmasia. If the diagnostics of the following disease are given, they may be reckoned as so many species of this genus.

I. Phrenitis (propria) situated in the peritoneum, properly so called, surrounding the inside of the abdomen.
II. Phrenitis (omenta) in the peritoneum extended through the omentum.
III. Phrenitis (mesenterica), in the peritoneum spread through the mesentery.

Genus XVI. Enteritis. Pyrexia of a typhous nature; pungent pain of the belly, stretching and twirling round the navel; vomiting; the belly obliquely bound.

I. Idiopathic.
1. From internal causes.
A. Gastritis (phlegmonoea) attended with acute pain and violent pyrexia.
2. From external causes.
B. Gastritis (erysipelatosa), with a less violent fever and pain; an erysipelatous redness appearing on the fauces.

II. Symptomatic.

Genus XV. Gastritis. Pyrexia inclining to a typhus; anxiety; pain and heat of the epigastrium, augmented when any thing is taken into the stomach; an inclination to vomit, and an immediate rejection of every thing swallowed; an hiccup.

I. Idiopathic.
1. From internal causes.
A. Gastritis (phlegmonoea) attended with acute pain and violent pyrexia.
2. From external causes.
B. Gastritis (erysipelatosa), with a less acute fever and pain; an erysipelatous redness appearing on the fauces.

General XX. Hyperitis. Pyrexia; heat, tenesmus, vomiting of the stomach; dyspncea; difficulty of breathing; cough; unequal pulse; palpitation of the heart, and fainting.

III. Peritonitis, with a difficulty of swallowing and breathing; an erysipelatous redness of the right hypochondrium, often following the course of the ureter; frequent making of water, either thin and colourless, or very red; vomiting; a leucorrhoea; with an immediate rejection of every thing swallowed; an hiccup.

I. Idiopathic.
1. From internal causes.
A. Peritonitis (phlegmonoea) attended with acute pain, violent fever, vomiting, and confiptation of the belly.
2. Enteritis (erysipelatosa) with less acute fever and pain, without vomiting; but accompanied with a diarrhea.

II. Symptomatic.

Genus XVII. Hepatitis. Pyrexia; tenesmus and pain of the right hypochondrium; sometimes pungent like that of a pleurisy, but more frequently obtuse; a pain reaching to the clavicle and top of the right shoulder; a difficulty of lying on the left side; dypnha; dry cough, vomiting, and hiccup.

Genus XVIII. Splenitis. Pyrexia; tenesmus, heat, and swelling of the left hypochondrium, the pain increasing by pressure; without the signs of nephritis.

Genus XIX. Nephritis. Pyrexia; pain in the region of the kidneys, often following the course of the ureter; frequent making of water, either thin and colourless, or very red; vomiting; a leucorrhoea; with a reaction or pain of the fullness of the same side. The species are,

I. Idiopathic. Spontaneous.
II. Symptomatic.

Genus XX. Cystitis. Pyrexia; pain and swelling of the hypogastrum, frequent and painful making of water, or itchuria; and tenesmus. The species are,

I. These arising from internal causes.
II. Those from external causes.

Genus XXI. Hyderitis. Pyrexia; heat, tenesmus, swelling.
MEDICINE.

General Arrangement of Diseases.

Day of the disease begins and on the fifth is finished, the eruption of inflammatory pustules, which suppurate in the space of eight days, and at last go off in crusts, frequently leaving depressed cicatrices or pock-pits in the skin. The species are,

I. Variola (diferta) with few, dilute, turgid pustules, having circular bases; the fever ceasing immediately after the eruption.

II. Variola (confuent) with numerous, confluent, irregularly shaped pustules, flaccid, and little elevated; the fever remaining after the eruption.

Genus XXIX. Varicella. Synocha; papulae breaking out after a short fever, similar to those of the small pox, but hardly ever coming to suppuration; after a few days going off in small scales, but never leaving any mark.

Genus XXX. Rubeola. A contagious Synocha, with freezing, epiphora, and dry hoarse cough. On the fourth day, or a little later, break forth small, flurried, and scarce elevated papulae: after three days going off in very small branny scales.

I. Rubeola (vulgaris) with very small confluent, corymbose papulae, scarce rising above the skin.

Varying,
1. In the symptoms being more severe, and the course of the disease less regular.
2. In being accompanied with a quinsy.
3. With a putrid diathesis.

II. Rubeola (variolodes) with dilute papulae, raised above the skin.

Genus XXXI. Miliaria. Synocha with anxiety, frequent lightheadings, feverish sweat, and spots on the skin. On an uncertain day of the disease break out red, small, dilute papulae, spread over the whole body as well as the face; the apices of which, after one or two days, become very small white pustules, remaining for a short time.

Genus XXXII. Scarlatina. A contagious Synocha. On the fourth day of the disease the face swells a little; at the same time an universal redness occupies the skin in large spots, at length running together; after three days going off in branny scales; frequently succeeded by anasarca. The species are,

I. Scarlatina (limplex), not accompanied with cyanche.

II. Scarlatina (cynanchica), with an ulcerous cyanche.

Genus XXXIII. Urticaria. An amphemera fever. On the second day of the disease, red spots resembling the stinging of nettles, almost vanishing during the day, but returning in the evening with the fever, and after a few days going off altogether in very small scales.

Genus XXXIV. Pemphigus. A contagious typhus. On the first, second, or third day of the disease, blisters break out in several parts of the body, of the bigness of a bean, remaining for many days, and at last pouring out a thin ichor.

Genus XXXV. Aphtha. Synochus; the tongue somewhat swelled and of a livid colour, as well as the fauces; effuses first appearing in the fauces, but at
length occupying the whole internal part of the mouth, of a white colour, sometimes distended, often running together; quickly growing again when taken off; and remaining for an uncertain time.

The species are, 1. Idiopathic. 2 Symptomatic.

ORDER IV. Hemorrhagia. Pyrexia, with a profusion of blood, without any external violence; the blood drawn from a vein hath the same appearance as in phlegmata.

Genus XXXVI. Epifaxis. Pain or weight of the head, redness of the face: a profusion of blood from the nose.

1. Idiopathic.

Varying according to the time of life.

1. Epifaxis of young people, with symptoms of an arterious plethora.
2. Epifaxis of old people, with symptoms of a venous plethora.

II. Symptomatic.

1. From internal causes.
2. From external causes.

Genus XXXVII. Hæmoptysis. Redness of the cheeks; a sensation of uneasiness, or pain, and sometimes of heat in the breast; difficulty of breathing; tickling of the fauces, either a severe or less violence, and sometimes of heat in the head, redness of the face: a profusion of blood without any external violence: the blood drawn from a vein hath the same appearance as in phlegmata.

1. From internal causes.
2. From external causes.

Genus XXXVIII. Hæmorrhagia. Weight and debility of the body, with a leucophlegmatia over the whole body, especially in old people.

Varying:

1. Accompanied with worms.
2. With the excretion of small fleshly or sebaceous bodies.
3. With an intermittent fever.
4. Without blood.
5. With a mililiary fever.

CLASS II. Neurosis. An injury of the fænæ and motion, without an idiopathic pyrexia or any local affection.

ORDER I. Comata. A diminution of voluntary motion, with sleep, or a deprivation of the senses.

Genus XL. Apoplexia. Almost all voluntary motion diminished, with sleep more or less profound; the motion of the heart and arteries remaining.

The idiopathic species are,

1. Apoplexia (fauina) with symptoms of universal plethora, especially of the head.
2. Apoplexia (tena) with a leucophlegmatia over the whole body, especially in old people.
3. Apoplexia (hydrocephalus) Coming on by degrees; affecting infants, or those below the age of puberty, first with inquietude, a flight fever and pain of the head, then with flow of the pus, dilatation of the pupil of the eye, and drouthiness.
4. Apoplexia (strabismaria) taking place in those of a melancholic constitution.
5. Apoplexia (traumatica) from some external injury mechanically applied to the head.
6. Apoplexia (venenata) from powerful sedatives taken internally or applied externally.

7. Apo-
MEDICINE.

Genus XLVIII. Tetanus:—a spastic rigidity of almost the whole body.

Varying according to the remote cause, as it arises either from something internal, from cold, or from a wound. It varies likewise from whatever cause it may arise, according to the part of the body affected.

Genus XLIX. Trismus. A spastic rigidity of the lower jaw.—The species are,

1. Trismus (nascentium), seizing infants under two months old.
2. Trismus (transversum), seizing people of all ages either from a wound or cold.

Genus LX. Convulsio.—An irregular tonic contraction of the muscles without sleep.

I. Idiopathic.
II. Symptomatic.

Genus LI. Chorea, attacking those who have not yet arrived at puberty, most commonly within the 10th or 14th year, with convulsive motions for the most part of one side in endeavoring the involuntary motion of the hands and arms, resembling the gesticulations of mountebanks; in walking, rather dragging one of their feet after them than lifting it.

Genus LI. Raphania. A spastic contraction of the joints, with a convulsive agitation, and most violent periodical pain.

Genus LIII. Epilepsia. A convolution of the muscles, with sleep.

The idiopathic species are,

1. Epilepsia (cerebralis), suddenly attacking without any manifest cause, without any sense of uneasiness preceding, excepting perhaps a slight vertigo or ecotomia.
2. Epilepsia (sympathica), without any manifest cause, but preceded by the sensation of a kind of air rising from a certain part of the body towards the head.
3. Epilepsia (acrophonia), arising from a manifest irritation, and ceasing on the removal of that irritation.

Varying according to the difference of the irritating matter. And thus it may arise,

From injuries of the head; pain; worms; poison; from the repulsion of the itch, or an effusion of any other acrid humour; from crudities in the stomach; from passions of the mind; from an immediate hemorrhagia; or from debility.

Sect. II. In the vital functions.

In the action of the heart.

Genus LIV. Palpitation. A violent and irregular motion of the heart.

In the action of the lungs.

Genus LV. Asthma. A difficulty of breathing returning by intervals, with a sense of strainers in the breast, and a noisy respiration with husting. In the beginning of the paroxysm there is either no cough at all, or coughing is difficult; but towards the end the cough becomes free, frequently with a copious spitting of mucus.—The idiopathic species are,

1. Asthma (spontaneum), without any manifest cause or other concomitant disease.
2. Asthma (exanthematicum), from the repulsion of the itch or other acrid effusion.
3. Asthma (plethoricum), from the supposition of some...
some customary sanguineous evacuation, or from a spontaneous pleurisy.

Genus LVI. Dyphnia. A continual difficulty of breathing, without any sense of straitness, but rather of fullness and shortness in the breath; a frequent cough throughout the whole course of the disease.

The idiopathic species are,

1. Dyphnia (catarrhalis), with a frequent cough, bringing up plenty of viscid mucus.
2. Dyphnia (fica), with a cough for the molo part dry.
3. Dyphnia (aborea), increased by the least change of weather.
4. Dyphnia (terrea), bringing up with the cough an earthly or calculous matter.
5. Dyphnia (aqua), with scanty urine and oedematous feet, without any fluctuation in the breast, or other signs of an hydrothorax.
6. Dyphnia (pneumonica), in very fat people.
7. Dyphnia (thoracica), from an injury done to the parts surrounding the thorax, or from some bad conformation of them.
8. Dyphnia (ehrinea), from evident external causes.

The symptomatic species of dyphnia are symptoms,

1. Of diseases of the heart or large vessels.
2. Of a swelling in the abdomen.
3. Of various diseases.

Genus LVII. Pertussis. A contagious disease; convulsive frangulating cough reiterated with noisy inspiration; frequent vomiting.

Genus LVIII. Pyrofis. A burning pain in the abdomen, especially about the navel; vomiting; a contusion.

The idiopathic species are,

1. Colica (padmodica), with retention of the navel, and spasms of the abdominal muscles.

Varying, by reason of some symptoms superadded.

Hence,

1. Colica, with vomiting of excreta, or of matters injected by the anus.
2. Colica, with inflammation supervening.
3. Colica (pelionum), preceded by a sense of weight or uneasiness in the belly, especially about the navel; then comes on the colic pain, at first slight and interrupted, chiefly augmented after meals: at length more of limpid urine, for the nature of chyle is passed.
4. Colica (catarrhalis), with a bloody evacuation, in which a frequent cough, part of the abdomen, and calculi sometimes passing by the anus.

Genus LX. Cholera. A vomiting of bilious matter, especially in the nature of the remote cause; idiopathic species; but, by Dr Cullen, only varieties of the same species.

A. From a retention of the menses.
B. From a menorrhagia cruenta.
C. From a menorrhagia ferrea, or flour albus.
D. From an obstricition of the vescera.
E. From a fault of the stomach.
F. From too great fatacity.

Genus LXIII. Hydropsy. A disfife and horror at any kind of drink, and occasioning a convulsion of the pharynx; induced, for the most part, by the bite of a mad animal. The species are:

1. Hydro-
I. Hydrophobia (rabies), with a desire of biting the bylanders; occasioned by the bite of a mad animal.

II. Hydrophobia (sinais), without madness, or any desire of biting.

Order IV. Vefaniæ. Diforders of the judgment, without any pyrexia or coma.

Genus LXV. Amentia; an imbecility of judgment, by which people either do not perceive, or do not remember, the relations of things. The species are,

I. Amentia (sogenina), continuing from a person's birth.

II. Amentia (fania), from the diminution of the perceptions and memory through extreme old age.

III. Amentia (acquista), recurring in people formerly of a sound mind, from evident external causes.

Genus LXVI. Melancholia; a partial madness, without dysepia.

Varying according to the different subjects concerning which the person raves; and thus it is,

1. With an imagination in the patient concerning his body being in a dangerous condition, from flight causes; or that his affairs are in a desperate state.

2. With an imagination concerning a proferous state of affairs.

3. With violent love, without satyrisis or nymphomania.

4. With a superfluous fear of a future state.

5. With an aversion from motion and all the offices of life.

6. With refleffes, and an impatience of any situation whatever.

7. With a weariness of life.

8. With a deception concerning the nature of the patient's species.

Dr Cullen thinks that there is no such disease as that called damonomania, and that the diseases mentioned by Sauvages under that title are either,

1. Species of melancholy or mania; or

2. Of some disease by the speculators falsely ascribed to the influence of an evil spirit; or

3. Of a disease entirely feigned; or

4. Of a disease partly true and partly feigned.

Genus LXVII. Mania; universal madness.

1. Mania (mental), arising entirely from passions of the mind.

2. Mania (corpora), from an evident disease of the body.

Varying according to the different diseases of the body.

3. Mania (obscuri), without any passion of mind or evident disease of the body preceding.

The symptomatic species of mania are,

1. Paraphreny from poisons.

2. Paraphreny from fumom.

3. Paraphreny from febries.

Genus LXVIII. Oneirodynia. A violent and troublesome imagination in time of sleep.

1. Oneirodynia (alvea), exciting to walking and various motions.

2. Oneirodynia (gravans), from a sense of some weight incumbent, and preliding on the breast especially.

CLASS III. Cachexia; a depraved habit of the whole or greatest part of the body, without primary pyrexia or neuritis.

Order I. Marceors: a walking of the whole body.

Genus LXIX. Tubæ. Leanesis, athenia, hectic pyrexia. The species are,

1. Tubæ (purulenta), from an external or internal ulcer, or from a vomit.

Varying in its situation: hence,

2. Tubæ (serophylaios), in serpulphous constitutions.

3. Tubæ (venenata), from poison taken inwardly.

Genus LXX. Atrophy. lzanneis and atheenia, without hectic pyrexia. The species are,

1. Atrophy (inanitorum), from too great evacuation.

2. Atrophy (famiteorum), from a deficiency of nourishment.

3. Atrophy (ensymnina), from corrupted nourishment.

4. Atrophy (aboliium), from the functions of nutrition being depraved, without any extraordinary evacuation or caecohymia having preceded.

Order II. Intumescentia. An external tumor of the whole or greatest part of the body.

Sect. I. Alipotes.

Genus LXXI. Polyatarca; a troublesome swelling of the body from fat.

Sect. II. Fatuses.

Genus LXXII. Pneumatolus; a tense elastic swelling of the body, cracking under the hand. The species are,

1. Pneumatolus (ponạma), without any manifest cause.

2. Pneumatolus (traumatice), from a wound in the breast.

3. Pneumatolus (venenata), from poison injected or applied.

4. Pneumatolus (hydreras), with hysteric.

Genus LXXIII. Tymparnates; a tense, elastic, flororous swelling of the abdomen; colicnavis; a decay of the other parts. The species are,

1. Tymparnates (tentillina), with a tumor of the abdomen frequently unequal, and with a frequent evacuation of air relieving the tension and pain.

2. Tymparnates (abdominata), with a more evident noise, a more equable tumor, and a less frequent emission of flatus, which also gives less relief.

Genus LXXIV. Pneumometra; a flight elastic swelling in the epigaltrium, having the figures and situation of the uterus.

Sect. III. Aquosse or Hydroses.

Genus LXXV. Anasarca. A soft, inelastic swelling of the whole body, or some part of it. The species are,

1. Anasarca (fibia), from a retention of serum on account of the suppression of the usual evacuations, or from an increase of the serum on account of too great a quantity of water taken inwardly.

2. Anasarca (applicata), from a compression of the veins.

3. Anasarca (exanthematica), arising after exanthemata, especially after the erythelles.

4. Anasarca
MEDICINE.

Genus LXXXIV. Scrophula. Swellings of the conglobate glands, especially upon the neck; swelling of the upper lip and support of the nose; the face florid, skin thin, abdomen swelled. The species are,

1. Scrophula (vulgaris), simple, external, and permanent.
2. Scrophula (mesenterica), simple, internal, with paleness of the face, want of appetite, swelling of the abdomen, and unusual fetor of the extremities.
3. Scrophula (sphenidis), most simple, appearing only about the neck, for the most part proceeding from the resorption of the matter of ulcers in the head.
4. Scrophula (Americana), joined with the yaws.

Genus LXXXV. Syphilis. A contagious disease, after impure venery, and a disorder of the genitals; ulcers of the tonsils; of the skin, especially of the margin of the hair; scrophulo papule, ending in crusts and crusty ulcers; pains of the bones; exanthema.

Genus LXXXVI. Scrophula; in cold countries, attacking after putrefactive diet, especially such as is faind and of the animal kind, where no supply of fresh vegetables is to be had; athelias; stomachae; spots of different colours on the skin, for the most part livid, and appearing chiefly among the roots of the hair.

Varying in degree.

a. Scrophula incipiens.
b. Scrophula crescentis.
c. Scrophula inverteratus.
d. Varying also in symptoms.
e. Scrophula lvidus.
f. Scrophula petechialis.
g. Scrophula pallidus.
h. Scrophula ruber.
i. Scrophula calidus.

Genus LXXXVII. Elephantiasis; a contagious disease; thick, wrinkled, rough, unctuous skin, deformed of hairs, anaesthesia in the extremities, the face deformed with pimples, the voice hoarse and nasal.

Genus LXXXVIII. Lepra; the skin rough, with white, branny, and chapped ecchymoses, sometimes moist beneath, with itching.

Genus LXXXIX. Frambesis; swellings resembling fungi, or the fruit of the mulberry or raspberry, growing on various parts of the skin.

Genus XC. Trichoma; a contagious disease; the hairs thicker than usal, and twisted into inextricable knots and cords.

Genus XCI. Icterus; yellowness of the skin and eyes; white faces; urine of a dark red, tinged what is put into it of a clay colour.

The idiopathic species are,

1. Icterus (calculeus), with acute pain in the epigastric region, increasing after meals; biliary concretions voided by stool.
2. Icterus (psoridicus), without pain, after psoridic diseases and passions of the mind.
3. Icterus (hepaticus), without pain, after diseases of the liver.
4. Icterus (gravidum), arising during the time of pregnancy, and going off after delivery.
5. Icterus (infantilis), coming on in infants a few days after birth.

CLASS
M E D I C I N E.

Genus XCVI. Dysea. A diminution or total abolition of the sense of hearing. The species are,
1. Dysea (organica), from a disease in the organs transmitting sounds to the internal ear.
Varying according to the nature of the disease of the part affected.
2. Dysea (atonia), without an evident disease of the organs transmitting the sounds.
Varying according to the nature of the cause.
Genus XCVII. Paracusis; a deprivation of the hearing. The species are,
1. Paracusis (imaginaria), in which sounds coming from external objects are heard, yet it is neither distinctly nor in the usual manner.
Varying.
   a. With a dulness of hearing.
   b. With an hearing too acute and sensible.
   c. When a single external sound is doubled by some internal causes.
   d. When the sounds which a person desires to hear are not perceived, unless some other violent sound is raised at the same time.
2. Paracusis (imaginaria), in which sounds not exciting externally are excited from internal causes.
Varying according to the nature of the sound perceived, and according to the nature of the remote cause.
Genus XCVIII. Anosmia; a diminution or abolition of the sense of smell. The species are,
1. Anosmia (organica), from a disease in the membrane lining the internal parts of the nostrils.
Varying according to the nature of the disease.
2. Anosmia (atonia), without any evident disease of the membrane of the nose.
Genus XCIX. Aghellitia; a diminution or abolition of the sense of taste.
1. Aghellitia (organica), from a disease of the membrane of the tongue, keeping off from the nerves those substances which ought to produce taste.
2. Aghellitia (atonia), without any evident disease of the tongue.
Genus C. Anæsthesia; a diminution or abolition of the sense of feeling. The species from Sauvages, adopted by Dr Cullen, are,
1. Anæsthesia a spina bifida.
2. Anæsthesia plethorica.
3. Anæsthesia nafcentium.
4. Anæsthesia melanochola.

ORDER II. Dyseoria: error or defect of appetite.
Sect. I. Appetitio erronei.
Genus Cl. Bulimia; a desire for food in greater quantities than can be digested.
The idiopathic species are,
1. Bulimia (bulivum), an unusual appetite for food, without any disease of the stomach.
2. Bulimia (syncope), a frequent desire of meat, on account of a sensation of hunger threatening syncope.
5. Bulimia (emetic), an appetite for a great quantity of meat, which is thrown up immediately after it is taken.
Genus CII. Polydipsia; an appetite for an unusual quantity of drink.
The polydipsia is almost always symptomatic, and varies
Medicine.

2. Paraphonia (refracta), in which, by reason of an obstruction in the nostrils, the voice becomes hoarse, with a sound hissing through the nostrils.
3. Paraphonia (alterata), in which, on account of a defect or division of the uvula, for the most part with an hare-lip, the voice becomes obscure, harsh, and unpleasant.
5. Paraphonia (calva), in which, the voice is changed to one acute, thrill, and small.
6. Paraphonia (comata), in which, from a relaxation of the velum palati and glottis, a sound is produced during inspiration.

Genus CXIII. Pneumonia; a defect in the articulation of words. The species are,
1. Pneumonia (dyspnea), in which, the words, especi­ally the first ones of a discourse, are not easily pronounced, and not without a frequent repetition of the first syllable.
2. Pneumonia (sestam), in which, the found of the letter R is always aspirated, and, as it were, doubled.
3. Pneumonia (talis), in which, the found of the letter L becomes more liquid, or is pronounced instead of R.
4. Pneumonia (mollis), in which, the hard letters are changed into the softer ones, and thus the letter S is much used.
5. Pneumonia (balantium), in which, by reason of the tongue being large, or swelled, the labial letters are better heard, and often pronounced instead of others.
6. Pneumonia (aebeitus), in which, the labial letters cannot be pronounced at all, or with difficulty.
7. Pneumonia (tegulum), in which, on account of the division of the palate, the guttural letters are less perfectly pronounced.

Genus CXIV. Strabismus, the optic axes of the eyes not converging. The species are,
1. Strabismus (bilateralis), from a bad custom of using only one eye.
2. Strabismus (commutus), from the greater debility or mobility of one eye above the other; so that both eyes cannot be conveniently used.
3. Strabismus (acceius), from a change in the situation or shape of the parts of the eye.

Genus CXV. Contracutura; a long-continued and rigid contraction of one or more limbs. The species are,
1. Contracutura (primaria), from the muscles becoming contracted and rigid.
a. From the muscles becoming rigid by inflammation.
b. From muscles becoming rigid by fatum,
c. From muscles contracted by reason of their antagonists having become paralytic.
7. From muscles contracted by an irritating actini­mony.
2. Contracutura (articularia), from stiff joints.

Order IV. Apocynophyse. A flux either of blood or some other humour flowing more plentifully than usual, without pyrexia, or an increased impulse of fluids.

Genus CXVI. Profusio; a flux of blood.

Genus CXVII. Ephedrophia; a precursory evacuation of sweat.

Symp-
MEDICINE

Practise.

General Arrangement of Diseases.

Symptomatic epidroes vary according to the nature of the diseases which they accompany, the different nature of the sweat itself, and sometimes the different parts of the body which sweats most.

Genus CXVIII. Epiphora; a flux of the lacrimal humour.

Genus CXIX. Psalifismus; a flux of saliva.

Genus CXX. Enuresis; an involuntary flux of urine without pain. The species are,
1. Enuresis (atonicus), after diseases injuring the sphincter of the bladder.
2. Enuresis (irritata), from a compression or irritation of the bladder.

Genus CXXI. Gonorrhoea; a preternatural flux of humour from the urethra in men, with or without a desire of venery. The species are,
1. Gonorrhoea (cura) in which, without any impure venery having preceded, a humour resembling pus, without dilution or propensity to venery, flows from the urethra.
2. Gonorrhoea (impura), in which, after impure venery, an humour like pus flows from the urethra with dyuria. The consequence of this is.

Genus CXXII. Mucorrhoea; a mucous humour flows from the urethra with little or no dyuria.

3. Mucorrhoea ( laxorum), in which an humour for the most part peculiar, without any erection of the penis, but with a propensity to venery, flows from the urethra while the person is awake.

4. Gonorrhoea (dermatium), in which the seminal liquor is thrown out, with erection and desire of venery, in those who are asleep and have lascivious dreams.

ORDER V. Epifcheses; suppressions of evacuations.

Genus CXXII. Obstipation; the stools either suppressed or fewer than usual. The species are,
1. Obstipation (debilium), in lax, weak and for the most part dyspeptic persons.
2. Obstipation (rigidum), in people whose fibres are rigid, and frequently of an hypochloriac disposition.
3. Obstipation (addictus), with symptoms of the colic ill, 2d, 4th, and 7th, abovementioned.

Genus CXXIII. Ichuria; an absolute suppression of urine. The species are,
1. Ichuria (renalis), coming after a disease of the kidneys, with pain, or troublesome sense of weight in the region of the kidneys, and without any swelling of the hypogallithum, or desire of making water.
2. Ichuria (urethralis), coming after a disease of the kidneys, with a sense of pain or uneasiness in some part of the ureter, and without any tumor of the hypogallium, or desire of making water.
3. Ichuria (vesicula), with a swelling of the hypogallium, pain at the neck of the bladder, and a frequent stimuli to make water.
4. Ichuria (urethralis), with a swelling of the hypogallium, frequent stimuli to make water, and pain in some part of the urethra.

All these species are subdivided into many varieties, according to their different causes.

Genus CXXIV. Dyuria; a painful, and somehow impeded emission of urine. The species are,
1. Dyuria (ardens), with heat of water, without any manifest disorder of the bladder.

2. Dyuria (irritata), with signs of a stone in the bladder.

3. Dyuria (compressiva), from the neighbouring parts pressuing upon the bladder.

4. Dyuria (bolegilia), from an inflammation of the neighbouring parts.

5. Dyuria (irritata), with signs of a stone in the bladder.

6. Dyuria (mucofa), with a copious excretion of mucus.

Genus CXXV. Dysermatismus; a flux, impeded, and insufficient emission of semen in the venereal act. The species are,
1. Dyspermatismus (urethralis), from discharges of the urethra.

2. Dyspermatismus (nodosus), from knots on the cavernous bodies.

3. Dyspermatismus (propiorum), from too narrow an orifice of the prepuce.

4. Dyspermatismus (mucofa), from mucus obstruing the urethra.

5. Dyspermatismus (hypertonicus), from too strong an erection of the penis.

6. Dyspermatismus (epilepticus), from a spasmodic epilepsy happening during the time of coition.

7. Dyspermatismus (episodius), from an imbecility of the parts of generation.

8. Dyspermatismus (rifluous), in which there is no emission of semen, because it returns from the urethra into the bladder.

Genus CXXVI. Amenorrhoea. The menses either falling more sparingly than usual, or not at all, at their usual time, without pregnancy. The species are,
1. Amenorrhoea (amastis), in those arrived at puberty, in whom, after the usual time, the menses have not yet made their appearance, and many different morbid affections have taken place.

2. Amenorrhoea (suppressalis), in adults, in whom the menses which had already begun to flow are suppressed.

3. Amenorrhoea (difficultis), in which the menses flow sparingly, and with difficulty.

ORDER VI. Tumores; and increased magnitude of any part without phlogosis.

Genus CXXVII. Aneurisma; a soft tumour, with pulsation, above an artery.

Genus CXXVIII. Varix; a soft tumor, without pulsation, above a vein.

Genus CXXIX. Ecchymosis, a diffused, and scarce eminent, livid tumor.

Genus CXXX. Scirrhus; an hard tumor of some part, generally of a gland, without pain, and difficultly brought to suppuration.

Genus CXXXI. Cancer. A painful tumor of a scirrhous nature, and degenerating into an ill-conditioned ulcer.

Genus CXXXII. Bubo; a suppurating tumor of a conglobate gland.

Genus CXXXIII. Sarcoma; a soft swelling, without pain.

Genus CXXXIV. Verruca; a harder scabrous swelling.

Genus CXXXV. Clavus; a hard, lamellated thicknes of the skin.

Genus
MEDICINE.

Genus CXXXVI. Lupia. A moveable, soft tumour below the skin, without pain.

Genus CXXXVII. Ganglion. An harder moveable swelling, adhering to a tendon.

Genus CXXXVIII. Hydatis; a cuticular vessel filled with aqueous humour.

Genus CXXXIX. Hydrarthrus; a most painful swelling of the joints, chiefly of the knee, at first scarce elevated, of the same colour with the skin, diminishing the mobility.

Genus CXLI. Hernia; an elevation of some part out of its proper situation.

Genus CXL. Exfoliosis; a hard tumor adhering to a bone.

ORDER VII. Exacerbatos.

Genus CXLII. Tinea; the removal of the mobility.

Genus CXLIII. Luxatio; the removal of a joint.

Genus CXLIV. Ulcus.

Genus CXLV. Vomitus; a profuse vomiting of a fluid part.

Genus CXLVI. Peritonitis; a fullness of the abdomen, adhering to a tendon.

ORDER VIII. Diaphragm.

Genus CXLVII. Tumors, infected; a fluid tumour, which changes to a white friable scurf.

Genus CXLVIII. Phlegmon; a large swelling, adhering to a tendon.

Genus CXLIX. Fractura; bones broken into large fragments.

Genus CLI. Caries an exulceration of a bone.

Having thus presented to our readers Dr Cullen's general systematic view of all the diseases to which the human body is subjected, we come next to give a more particular account of the most important affections, treating of them in the order which Dr Cullen has arranged them.

CLASS I. PYREXIAE, or the Febrile Diseases.

ORDER I. FEVERS.

Or FEVERS strictly so called.

Continue, Fag. Clas. I. Order II.
3. Causes of this disease, and proper subject to it. The
   genuine tertian attacks men rather than women, young
   people rather than old; the latter being more subject to
   anomalous tertians. It likewise affects the fiery and aciel, rather than the lazy and indolent.
   Thos., however, who are apt to nauseate their meat,
   fall easily into a tertian fever. The cause, according to
   Dr Cullen, is the miasma of marathes, and that
   only. Other physicians have taken in many more
   causes, almost every thing which debilitates the
   body: but the Doctor denies that any of these,
   though they may dispoile the body for receiving the
disease or may augment it, can by any means pro-
duce it without the concurrence of the marsh miasma;
and it cannot be denied, that it is a disease almost
peculiar to marathes. Thus we find it very fre-
quent in the fenny counties of Britain, although in
other parts of the island it may be considered as a
rare disease.

3. Prognosis. The genuine simple tertian, unless
improper medicines be administered, is generally very
easily cured; nay, the vulgar reckon it of such a fa-
luatory nature, that after it they imagine a person be-
comes more strong and healthy than before. Hippo-
crates has observed, that these fevers terminate of
their own accord after seven or nine paroxysms.
Juncker tells us, that it frequently terminates before
the seventh paroxysm, but rarely before the fourth.
He also denies that any thing critical is to be ob-
served in its going off; but in this he differs from Vogel,
who tells us, that the urine, for some days after the
fever is quite gone off, appears flimsy, and lets fall much
sediment. The latter also informs us, that besides the
common crisis by sweat and urine, the tertian hath one
peculiar to itself, namely, dry feebly ulcers breaking
out upon the lips. These sometimes appear about the
third or fourth paroxysm; and then we may venture
to foretell that the disease will go off spontaneously
after the seventh. But though the disease be never
dangerous, in cold climates at least, when properly
reated; yet the improper use of hot and stimulat-
ing medicines may change it into a continued fever, more
or less dangerous according to the quantity of medi-
cines taken and the constitution of the patient; in
which case the prognosis must be regulated by the
particular symptoms which occur. In warm climates,
however, the tertian fever may be considered as a
much more dangerous disease; and unless the most
powerful medicines be employed, the patient is in dan-
ger of falling a victim to every paroxysm.

A variety of theories have been proposed for ex-
plaining the phenomena of this affection; but we may
easily affirm, that every thing hitherto said upon the sub-
ject is highly unsatisfactory. For although it be now
almost universally admitted, that this fever does arise
from the effluvia of marathes, yet in what manner the
action of these effluvia induces fever, and particularly
why this fever returns in regular paroxysms, are ques-
tions with regard to which we are still totally in the
dark. Dr Cullen, with much ingenuity, attempted to
prove, that the remote causes of this; as well as of
other fevers, operated by inducing a state of debility;
that this debility gives rise to ipasm, induces increased
action, from which the phenomena are to be explained.

This theory is liable to no less numerous and unfor-
table objections than the exploded hypotheses
which have before been propounded by others. For it is
an undeniable truth, that debility often exists, even to
the highest imaginable degree, without any fever; and,
that when fever has taken place, the debility is often much
greater after it is entirely gone than at any period
during its course. When ipasm and increased action do
take place, we have no reason to view them in any other
light than merely as symptoms of the disease; and
while they are often absent in this affection, they fre-
cquently occur in others where the fevers, anxiety,
and other characteristic symptoms of fever are entirely
absent; and, upon the whole, a probable or rational
theory of intermittents, as well as of other fevers, still
remains to be discovered.

Care. The treatment of all genuine intermittent
diseases whether tertiana, quotidian, or quartana,
being almost precisely the same, the general method of cure appli-
cable to them all may here be given, to which it will be
easier to refer when we come to describe the others.

In treating intermittent fevers, physicians have
formed indications of cure according to their dif-
frent theories. The followers of Boethave, Stahl,
&c., who imagined that the disease proceeded from
a former or other disorders in the blood, always thought it
necessary to correct and evacuate these pessant humours
by emetics and purgitives before they attempted
to stop the disease by the peruvian bark or any
other medicine. The bark, indeed, among some,
forms to be held in very little estimation by them; since
Vogel affirms, that this medicine, instead of delivering
the preference to have the preference of all other febrifuge medicines,
ought rather to be ranked among the lowest of the whole;
and for this reason he ascribes the cures, said
to be obtained by the use of the Peruvian bark, entirely
to nature.

According to Dr Cullen, the indications of cure in
intermittent fevers may be reduced to the following.

1. In the time of intermission, to prevent the return
   of the paroxysms.

2. In the time of paroxysms, to conduct the patient
   in such a manner as to obtain a final solution of the
disease.

3. To take off certain circumstances which might
   prevent the fulfilling of the two first indications.

The first indication may be answered in two ways.
1. By increasing the action of the heart and arteries
   some time before the period of accession, and support-
   ing that increased action till the period of accession be
   over, and thus to prevent the recurrence of that atony.
   and ipasm of the extreme vessels, which he thinks give
   occasion to the recurrence of paroxysms. 2. By sup-
   porting the tone of the vessels, and thereby preventing
   atony and the consequent ipasm, without increasing
   the action of the heart and arteries, the recurrence
   of paroxysms may be prevented.

The action of the heart and arteries may be increas-
ed, 1. By various stimulent remedies internally given
or externally applied, and that without exciting sweat.
2. By the same remedies, or others, managed in such
   a manner as to excite sweating and to support that
sweating till the period of accession be for some time past. 3. By emetics, supporting for the same time the tone and action of the extreme vessels.

The tone of the extreme vessels may be supported without increasing the action of the heart and arteries, by various tonic medicines; as, 1. Altrigents alone. 2. Bitters alone. 3. Altrigents and bitters conjointly. 4. Altrigents and aromatics conjointly. 5. Certain metallic tonics: and, 6. Opiates. A good deal of exercise, and as full a diet as the condition of the patient's appetite and digestion allow of will be proper during the time of intermission, and may be considered as belonging to this head. Although many particulars in this plan of cure are deduced from Dr Cullen's theory, yet there can be no doubt that the object chiefly to be aimed at is to employ such remedies during the intermissions as will prevent a recurrence of the paroxysm. Of all the remedies hitherto employed with this intention, the most celebrated, perhaps the most certainly effectual, is the Peruvian bark; or, to speak more properly, the bark of the Cinchona officinalis of Linneus. But it must be observed that good effects are only to be expected from this medicine when given in subhaunces and in large quantity; and for its use the following rules or observations have been given.

1. The bark may safely be employed at any period of interrupting fevers, providing that at the same time there be neither a phlegmatis diathesis prevailing in the system, nor any considerable or fixed congestion present in the abdominal viscera.

2. The proper time for exhibiting the bark in intermittent fevers is during the time of intermission, and it is to be obtained from in the time of paroxysms.

3. In the case of genuine intermitents, while a due quantity of bark is employed, the exhibition of it ought to be brought as near to the time of accession as the condition of the patient's stomach will allow.

4. In all cases of intermitents it is not sufficient that the recurrence of paroxysms be stopped for once by the use of the bark; a relapse is commonly to be expected, and should be prevented by the exhibition of the bark repeated at proper intervals.

The advantage of administering the bark as early as possible, was fully ascertained by Dr Lind in the year 1765, 66, and 67, during an uncommon prevalence of intermitents. When the disease was stopped by the bark immediately after the first or second fit, which was the case with 200 of the Doctor's patients as well as himself, neither a jaundice nor dropsy ensued; whereas, when the bark could not be administered, on account of the imperfect remission of the fever, or when the patient had neglected to take it, either a dropsy, jaundice, or continual head-ach, were the certain confquences; and the violence of the disease was in proportion to the number of the preceding fits, or to the continuance of the fever. By every paroxysm the dropical swellings were visibly increased, and the colour of the skin rendered of a deeper yellow. When the fever continued a few days without remission, the belly and legs generally swelled; a violent head-ach, likewise, and vertigo; for the most part deftroyed the patience, so that some, even after the fever had left them, were not able to walk across their chamber for a fortnight or three weeks. When the returns of the fever were regular and even, but flight, four or five fits of a simple tertian were sometimes followed by the most dangerous symptoms; especially in the year 1765, when these fevers raged with the greatest violence. If, as frequently happened, a dropical patient relapsed into the ague, there was an absolute necessity for putting an immediate flrop to it by the bark; and in upwards of 70 such patients, Dr Lind observed the most beneficial effects to accrue from this practice. He never prescribed the bark until the patient was free from all symptoms of the fever; but in that case, without regard to a cough, or any other chronic indisposition, he ordered it to be given in large doses.

The bark has been often observed to fail in removing intermitents, from not continuing the use of it for a sufficient length of time, from administering it in too small a dose, or from giving it in an improper form. It was a prevailing opinion, that an ounce, or an ounce and a half, of the bark, taken during one intermission, is sufficient to prevent the return of another paroxysm. But this is not always the case; for a severe fit will often attack a patient who has taken such a quantity. When this happens the patient ought to persevere during the following intermissions, with an increase of the dose, till five or six ounces at least have been taken. The medicine also ought not to be omitted as soon as one fit is stopped, but should be continued in a smaller dose, and after longer intervals, for at least ten days or a fortnight. Even for several months after the disease is entirely removed, it would be advisable to take a little bark occasionally in damp weather, or during an easterly wind, to prevent a relapse. Where the intervals between the fits are short, as in quotidiens and double tertians, from one to two drachms of it ought to be taken every two or three hours.

The form in which this medicine is administered is of some consequence. Mucilages and syrups have been recommended to conceal the taste of it; but, from various experiments, Dr Lind found nothing more effectual for this purpose than small-beer or milk, especially the latter. A drachm of bark mixed with two ounces of milk, and quickly drank, may easily be taken by a person of the most delicate taste, and by washing the mouth afterwards with milk there will not remain the least flavour of the bark; but if the mixture be not drank immediately, the bark will impart a bitter taste to the milk. This medicine is commonly given in electuaries or bolufes; but Dr Lind observes, that in these forms it proves much less efficacious than when administered in juleps or draughts, with the plentiful addition of wine or spirits. He has remarked, that six drachms of powdered bark, given in a julep, confisting of one fourth or one third of brandy, is as effectual as an ounce of the powder in the form of an electuary, and proves less disagreeable to the stomach. For patients unaccustomed to wine or spirits, each draught should be warmed with spiritus failis ammoniacci, or tinct. myrrh. by both of which the efficacy of the bark is increased. Dr Lind is also fully convinced that wine or spirits improve the virtues of the bark much more than elixir vitrioli, tinct. rofar. or such other medicines as have been recommended by different physicians.

For those who nauseate the bark from a weakness of
Practice.  

MEDICINE:  

Febra.

of the stomach or other cause, he advises it to be given in clysters, in which form it is as efficacious as when taken by the mouth. For this purpose the extract is most proper with the addition of a sufficient quantity of the tinctura thebaica, in order to its being longer retained. For children labouring under intermittents in children, even when externally applied, the magnesia frequently

by putting the powder of it into a quilted waistcoat. Of it he used; if this with more certainty than an ounce of the bark is found to remove the disease. It generally gives a

relief to the head, takes off the burning heat of the fever, and occasions a profuse sweat. This sweat is attended with an agreeable soothness of the skin, instead of the burning fenation which effects patients sweating in the hot fit, and is always much more copious than in those who have not taken opium.

It often produces a soft and refreshing sleep to a patient tortured in the agonies of the fever from which he awakes bathed in sweat, and in a greater measure free from all complaints.

The Doctor has always observed, that the effects of opium are more uniform and constant in intermittent fevers than in any other disease, and are more quick and sensible than those of any other medicine. An opiate thus given soon after the commencement of the hot fit, by abating the violence and lessening the duration of the fever, preserves the constitution so entirely uninjured, that, since he used opium in agues, a dropsey or jaundice has seldom attacked any of his patients in those diseases. When opium did not immediately abate the symptoms of the fever, it never increased their violence. On the contrary, most patients reaped some benefit from an opiate given in the hot fit, and many of them bore a larger dose at that time than they could do at any other. The Doctor affures us, that even a delirium in the hot fit is not increased by opium, though opium will not remove it. Hence he thinks it probable, that many symptoms attending these fevers are phaenomonic; but more especially the head-ach. However, if the patient be delirious in the fit, the administration of the opiate ought to be delayed until he recovers his senses, when it will be found greatly to relieve the weakness and faintness which commonly succeed the delirium. Dr. Lind is of opinion, that opium in this disease is the balm preparative for the bark; as it not only produces a complete intermixture, in which case alone that remedy can be safely administered; but occasions such a salutar and copious evacuation by sweat, as generally to render a much less quantity of bark requisite. He commonly prescribes the opiate in about two ounces of tinctura thebaica, when the patient is convulsive, who is to take the bark immediately after the fit. By these means the paroxysm is shortened, and the intermissions are cleansed,
previous to the administration of the bark; as the opiate doth not prevent, but only somewhat retards, the operation of the purgative. When a vomit is given immediately before the paroxysm, the administration of the opiate should be postponed till the hot fit is begun.

In the administration of the Peruvian bark, care should be taken that it be of a good quality. And different opinions have been entertained with respect to the choice, even where there is no reason to believe that it has been adulterated by the mixture of other articles. For a long time, the preference was given to small quilled pieces of a pale coloured bark; but of late the red bark, which is generally in larger masses, or of an apparently coarser texture, and evidently of a more relinous nature, has been highly celebrated by Dr Saunders and others. And in cases where it does not disagree with the stomach or cause loose motions, it is admitted by the most accurate observers to be more powerful in preventing the return of intermittents. Whether the red bark be the product of a different species of the cinchona, or be obtained as well as the pale quilled bark from the cinchona officinalis, is not yet ascertained with sufficient accuracy.

A species of cinchona, distinguished by the title of cinchona Jamaicensis, has been discovered in Jamaica and other islands in the West Indies. A very accurate description of it has been given by Dr Wright of Jamaica in the Philosophical Transactions of London. The bark of this species also has been recommended in the cure of intermittents; but the advantages of it have not hitherto been sufficiently confirmed by experience.

See CINCHONA AND JAMAICAN BARK.

The barks of various trees readily cultivated in Britain, particularly different species of the salix, the prunus, the fraxinus, and the quercus, have by some been represented as no less efficacious than the Peruvian bark. But we may safely venture to assert, that although several of them may produce some power in stopping intermittents, yet that none hitherto tried can be considered as in any degree approaching to the elachona in point of efficacy.

But although the Peruvian bark be the best cure for intermittents hitherto discovered, yet while it can by no means be represented as the only cure, it is very certain that other remedies have in different cases succeeded after the cinchona has failed. Cures have often been obtained by the use of different aromatic, bitters, and astringent. Many articles from the mineral kingdom also have been employed with advantage. And intermittents have unquestionably been in certain cases stopped by different preparations of iron, zinc, copper, lead, and mercury. But all of the articles of this nature, arsenic has of late been the most celebrated. Arsenic is on good grounds conjectured to be the basis of an article much employed in the cure of intermittents in some of the countries where they are most prevalent, and sold under the title of the toffelfe afque drop. The great success attending the use of this article, led Dr Fowler, an ingenious physician of Stafford, to examine it with particular attention. And in a treatise which he has lately published, entitled Medical Reports on the effects of arsenic in the cure of agues, he has given a formula for an arsenical solution, which he has found very successful in affections of this kind, and which is probably very nearly Tertian;

the same with the talfelfs aque drop. Dr Fowler's mineral solution, as he styles it, is found by dissolving 64 grains of arsenie and as much fixed vegetable alkaline salt in a pound of distilled water. This solution is given in doses from three to 12 drops, varied according to the condition of the patient, and repeated two or three times a-day. And where the Peruvian bark has failed in stopping intermittents, it seems to be one of the most powerful remedies yet discovered. But after all remedies prove ineffectual, intermittents are often stopped by change of season and of situation.

But besides the remedies employed in tertian fevers and other intermittents, with the view of preventing the return of paroxysms, it is often also necessary to employ powerful articles with other intentions, particularly to mitigate and shorten the paroxysm when present; to obviate urgent symptoms, especially those of an inflammatory or putrid nature; and to obtain a complete appresia or intermission from fever after the paroxysm has ceased. With these intentions, recourse is not unfrequently had to emetics, laxatives, blood-letting, blisters, opium, diuretics, and sudorifics, as the circumstances of the case may require.

The Irregular or Spurious Tertian.

Sp. I. var. 1. B.

The characteristic marks of this fever are, that its paroxysms last longer than 12 hours, and consequently its inclines more to the quotidian or continued fever than the former. Its paroxysms have no stated hour of attacking. The cure, however, is precisely the same with that above described, observing the proper caution already mentioned with regard to the use of the bark.

The Double Tertian.

Sp. I. var. 2. C.

Duplicata, Lin. 18.

The double tertian comes on every day; but differs from the quotidian in so far, that its paroxysms do not answer to each other singly, but alternately. The first day, for instance, the fit will come on in the forenoon, the second in the afternoon, the third in the forenoon, and the fourth in the afternoon.

Of these fevers we shall give the following description from Cieghorn's treatise on the diseases of Minorca: "They are called double tertians when there are two fits and two intervals within the time of each period. But commonly there is some difference between the two fits, either in respect of the hour they come at, the time of their duration, or the nature and violence of their concomitant symptoms. Some double tertians begin in this manner:—On the evening of Monday, for example, a slight fit comes on; and goes off early next morning; but on Tuesday, towards the middle of the day, a more severe paroxysm begins, and continues till night. Then there is an interval to Wednesday evening, when a slight fit commences a new period of the fever, which proceeds in the same manner as the first; so that (according to the way physicians calculate the days of disease, by beginning
to reckon from the first hour of their invasion, both paroxysms happen on the odd days, while the greatest part of the even days is calm and undisturbed. But in most double tertians the patient has a fit every day of the disease; the severest one commonly appearing at noon upon the odd days, the flight one towards evening on the even days; though sometimes the worst of the two fits happen on the even days.

There is a tertian fever sometimes to be met with, during each period of which there are three different fits, and as many intervals. For example, towards Monday noon the patient is feized with a paroxysm, which declines about five or six o'clock the same evening: a few hours after, another fit begins, and continues until morning; from which time there is an interval to Tuesday evening, when a third fit comes on, and lasts most part of the night. On Wednesday there are again two paroxysms, as on Monday and on Thursday, like that of Tuesday; and thus the fever goes on with a double fit on each of the odd days, and a single fit on the even days.

In double tertians, that interval is the most considerable which follows the severer fit; for the flight fit oftener ends in a remission than intermission, and frequently lingers till the other approaches: Hence it is, that the night preceding the violent fit is much more restless than that which comes after it, as has been observed by Hippocrates. In double tertians, the violent fit often comes on a little earlier in each period, than the other, which increases the disease.

Concerning the cure of these fevers Dr. Cullen observes, that though no entire apyrexia occurs, the bark may be given during the remissions; and it should be given even though the remissions be incomconsiderable; if, from the known nature of the epidemic, intermissions or considerable remissions are not to be expected, and that great danger is apprehended from repeated exacerbations.

The Sleepy Tertian. Sp. l. var. 3. G.

Tertiana carotica, Sauv. fp. 10. Werdlaph.

Tertiana hemiplusica, Sauv. fp. 20. Werdlaph.

Quotidiana fopora, Sauv. fp. 8 Car. Pif.

February caput impetens, Sydenham, ep. ad R. Brady.

This, according to Vogel, is a most dangerous species, and very commonly fatal; for which reason he ranks it among those intermitents which he calls magnum. Sometimes he tells us the alarming symptom of a sleepiness comes on, not at the beginning of the disease, but will unexpectedly occur during the third fourth, fifth, or sixth paroxysm. It commonly begins with the cold fit, and continues during the whole time of the paroxysm, and, becoming stronger at every succeeding one, at last terminates in a mortal apoplexy. Sometimes fevers of this kind rage epidemically. Vogel relates, that he saw a simple tertian change into one of these dangerous fevers. The patient was a woman of a delicate constitution, and the symptom appeared in consequence of her being put in a violent passion: however, it occurred but once, and he recovered.

Hoffman mentions a carus in a double tertian occurring seven times without proving mortal; though Vogel says, that the powers of nature are very seldom sufficient to conquer the disease.

In 1678, Dr. Sydenham tells us that intermitents raged epidemically at London, where none had appeared before from 1664. Of them "it is to be noted (says he), that though quartains were most frequent formerly, yet now tertians or quotidiens were most common, unless the latter be intituled double tertians; and likewise, that though these tertians sometimes began with chills and shivering, which were succeeded first by heat, and soon after by sweat, and ended at length in a perfect intermission, returning again after a fixed time, yet they did not keep this order after the third or fourth fit, especially if the patient was confined to his bed and used hot cardinals, which increase the disease. But afterwards this fever became so unusually violent, that only a remission happened in the place of an intermission; and approaching every day nearer the species of continued fevers, it seized the head, and proved fatal to abundance of persons."

From this description of Sydenham's we may have an idea of the nature of the disease. As to its cure,
he strongly recommends the bark; telling us, that, even in the most continued kind of intermittent s, "the nearer the intermittent approaches to a continued fever, either spontaneously, or from using too hot a regimen, so much the more necessary is it to exhibit larger quantity of the bark; and that he took advantage of a remission, though ever so small.

The Spasmodic or Convulsive Tertiana. Sp. I. var. 3. II

Tertiana hysterica, Sauv. fp. 8. Wedel. A. N. C.

Hysteria fibrifica, Sauv. G. 135. fp. 8. A. N. C.
Dec. I. Ann. II

The patient was a farmer's son about 26 years of age, of a strong plethoric habit of body. He had laboured under an ague half a years, and had taken a great deal of bark. While he was telling his case to the surgeon (Mr Baine of Pembroke), he was suddenly taken with a violent flamping of his feet; and the convulsions gradually ascended from the soles of the feet to his legs, thighs, belly, back, and shoulders. His head was then most violently convulsed, with a total deprivation of speech; but he had a moist discoloured vescication, that might have been heard in the soles of the feet, as well as in his legs, thighs, belly, back, and shoulders. His head was then most violently convulsed, and the next symptoms of asthma, in others with those of hysteric, in others with convulsions. Where the symptoms of asthma occur, the disease must be treated with diuretics and antispasmodics joined with the bark. In the hysteric asthma the fit comes on with cold, yawning, cardialgia, terror and dejection of mind. The disease is to be removed by mild aperients and antihysteric joined with the bark.

Of the convulsive tertian we have a most remarkable instance in the Edinburgh Medical Essays, Vol. V.

The patient was a farmer's son about 26 years of age, of a strong plethoric habit of body. He had laboured under an ague about 2 years, and had taken a great deal of bark. While he was telling his case to the surgeon (Mr Baine of Pembroke), he was suddenly taken with a violent flamping of his feet; and the convulsions gradually ascended from the soles of the feet to his legs, thighs, belly, back, and shoulders. His head was then most violently convulsed, with a total deprivation of speech; but he had a moist discoloured vescication, that might have been heard in the soles of the feet, as well as in his legs, thighs, belly, back, and shoulders. His head was then most violently convulsed, and the next symptoms of asthma, in others with those of hysteric, in others with convulsions. Where the symptoms of asthma occur, the disease must be treated with diuretics and antispasmodics joined with the bark. In the hysteric asthma the fit comes on with cold, yawning, cardialgia, terror and dejection of mind. The disease is to be removed by mild aperients and antihysteric joined with the bark.

The Eruptive Tertian. Sp. I. var. 3. I

Tertiana petechialis, Sauv. fp. 3. Donati. Lauter.
Tertiana scorbutorica, Wedel. A. N. C. Doc. I. A.

This species of tertian is accompanied with red or livid blotches on the skin, or an eruption like that occasioned by the stinging of nettles. In the latter case Dr Clegborn says the disease is very dangerous; and as the former indicates an incipient dilution and putrefaction of the blood, it must also be reckoned of very dangerous tendency.

The Inflammatory Tertian. Sp. I. var. 3. K

Tertiana arthritica, Sauv. fp. 5. Morton. Lautt.

Sauvages informs us, that he has seen a true and genuine pleurisy having all the pathognomonic signs of the disease, but assuming the form of an intermittent; that is, the patient is one day affected with the pleuris, and the next seemingly in perfect health. He also tells us, that in the month of May 1760 a tertian raging epidemically, which after the third fit imitated a pleuris, the pain of the side and difficulty of breathing coming regularly on, and the fever from an intermittent becoming remittent; the blood had also the same appearance with that of pleuritic persons, and the dæmper yielded to bleeding and gentle cathartics.—Morton also informs us, that he has observed similar disorders an hundred times over, which were always certainly and safely cured by the Peruvian bark.

The Tertian complicated with other Disorders, Sp. I. var. 4.

Tertiana fpphilistica, Sauv. fp. 17. Deidier.

The scorbustic tertian, according to Sauvages, is exceedingly anomalous, its periods being sometimes much anticipated, and sometimes much postponed. It is exceedingly obllinate, and will return if the body be not cleared of its febrifuge taint. The patient is affected with lancinating pains of a wandering nature. The urine lets fall a dusky red sediment, or a thick branny matter is copiously scattered up and down in it, feemingly tinged with blood. The usual symptoms of scurvy, viz. livid spots, and rotten fetid gums, also frequently occur. For this the Peruvian bark, is very useful, both as a febrifuge and antificrotic.

A tertian accompanied with worms is taken notice of by Sir John Pringle in his treatise on the diseases of the army. The worms, he tells us, were of the round kind; and though we are by no means to reckon them the cause of the fever, they never failed to make it worse, occasioning obstinate gripings or fieknefs at stomach. In these cases fitches were frequent; but, being flatulent, were not often relieved by bleeding. The worms were discharged by vomiting
as well as by foool. For discharging these worms, he commonly gave half a drachm of rhubarb with 12 grains of calomel; without observing any inconvenience from such a large dose of mercury. Anthelmintics, which act slowly, had little chance of doing good; for though worms will sometimes lie long in the bowels without giving much uneasiness to a person otherwise well, yet in fever, especially one of a putrid kind (to which his intermitents always seemed to incline), the worms being disturbed by the increase of heat, and the corruption of the humour in the prime viti, begin to move about, and struggle to get out. Lancifus, who makes this remark, adds, that upon opening the bodies of some who had died at Rome of fevers of this kind, wounds were found in the intellines made by the biting of the worms; nay, many cafes in which the worms escaped by the patient's mouth, though there had been no previous retching to bring them up. One soldier was thrown into violent convulsions, but was cured by the above-mentioned powder.

The Tertian varied from its Origin. Sp. I. var. 5.

Hoffman, II. p. 12.

The existence of fevers of this kind, as we have already observed, is denied by Dr Cullen; the accidental fever of Sauvages was said to arise from any flight error in the non-naturals, and consequently was very eaily cured. That which arose from the repetition of the itch, was cured as soon as the eruption returned.

The remittent fevers are much more dangerous than the true intermittents, as being generally attended with much greater debility of the nervous system and tendency to putrefaction in the fluids than the latter. Sauvages divides his tritephusa, a remittent tertian, into the following fpecies.

1. *Tritephusa fynceopalis,* or that attended with fainting. It begins like a tertian, with cold succeeded by heat and profuse sweating; but attended with much more dangerous symptoms, such as cardialgia, enormous vomiting, great weakness, small contracted pulse, coldness of the extremities, and, unless timely affilience be given, kills during the second or third paroxism.

2. The *caufa,* or burning fever of Hippocrates, returns every third day without any new fenation of cold; and is attended with great thirst, heat, but without diarrhrea or sweat, and continues only for one week or two at the utmost. It attacks chiefly young people of a robust and bilious habit of body, who have been accusto med to much exercife, and exposed to the fun during the heats of summer, and have also used a phlogiflic regime. The tongue is dry, sometimes black; the urine of a red or flame colour; together with pain of the head, anxiety, and sometimes other symptoms ill more dangerous.

3. *Tritephusa Vratilavieffis,* was a pestifential difeafe occasioned by famine, during which the people fed on putrid aliment: the air was infected by the vaft numbers of bodies of thofe slain in battle, and the inhabitants were also dejected by reafon of being deprived of their harvest and other calamities; to all which was added the continuance of a calm in the atmosphere for a long time. It began with an acute fever, lepia or coldness of the external parts and fenation of burning heat inwardly; general weakness, pain of the head and pre cordia; feros or bilious diarrhrea; a delirium, in some pursuance, and accompanied with a dread of being exposed to the air; on the second day the thirt was violent, attended with a bilious vomiting as well as diarrhrea, tough vifcid fputting, fainting, burning heat in the bowels, the tongue dry and feeming as if burnt with a hot fyrup, a fuppression of the voice, anxiety, fuppor; after which quickly followed convulsions and death. In some fevers a lepia came on with an exceeding great cold of the extremities, prefently followed by an intolerable heat of the vitfera, with symptomatic fweats, violent diarrhrea, followed by a very ichy military eruption. On the fourth day came on with the copious fweats, fphism of the lower jaw, naufea, involuntary paffing of urine, flight delirium, a flux of ichorous matter from the noftrils, and exceeding tough fputting, an epilepsey, and death. Profeflor Hahn, who gives the Hiftory of this difeafe, was himself attacked by it, and fuffered in the following manner. On the first day was a violent feverish paroxism without rigor, a sharp pain in the occiput, and immediately an inflammatory pain over the whole head; the feet were extremely cold, and the extremities rigid with fphism. The pain continued to increafe daily to such a degree, that the patient took his own life.

4. *Tritephusa typhodes.* The principal fymptom of this fever was a continual fweat with which the patients were almoft always wet; with paroxysms returning every third day. Sauvages tells us, that he had twice an opportunity of obferving this fever; one was in the teacher of an academy, about 40 years of age, and of a melancholic temperament. He fweated every other night fo plentifully, that he was obliged to change his linen nine times; and even on the intermediate days was never perfectly free of fever, and had his skin moistened with fweat. The other was a woman who went about in man's cloathes, and was disco vered only after her death. The difeafe began with a flight fenation of cold, after which the fweat left for eight hours. It was attended with the highest debility, anxiety, and at the fame time an infatiable hunger.

5. *Tritephusa eludes,* was an inflamatory epidemic, but not contagious, terminating about the 14th or 21st day. The difeafe came on in the night-time, with disturbed reft, universal weakness, watchings, great heat and fweat, redness of the face and almoft of the whole body, fparking eyes, the tongue dry and white; a hard, tender, and coupled pulse; about the third day a kind of frenzy frequently came on with the feverish paroxysm, the forerunner of an universal military eruption; or, what was worse, with purple spots to clofe together, that they looked like an erupfion...
of the whole body. Sometimes blisters of the size of small pearls, filed with acrid serum, appeared on the neck, armpits, and trunk of the body, which were of all others the most dangerous. There was a variety of the disease, which our author calls the bama-ras, and in which the pulse was felt and feeble, with greater weakness over the whole body, and the disposition to sleep more frequent than in the other; the eyes languid; the tongue very white, but not dry; and worms were discharged.

6. Tritreophya affideus. This species arose from a fountein of the prime vice, and the effluvia of waters in which hemp had been steeped. It began with rigor, followed by great heats, restlessness, toffing of the limbs, terrible faintings, immoderate thirst, dryness of tongue, delirium, and at length excessive watchings; these last, however, were less dangerous than vertigoes or convulsions, which brought on convulsions or apoplexies.

7. Tritreophya caroala. This had exacerbations every other evening; and its distinguishing symptom was an excessive inclination to sleep, preceded by a severe headache, and followed by delirium, and sometimes convulsions; the tongue was black, and the patient insensible of sight after the delirium came on. In those cases where the disease proved fatal, a delirium, tertius tendinum and other grievous symptoms came on.

8. Tritreophya laiyria is only a variety of the tritreophya eufus, already described.

9. Tritreophya delphitu. This species at first assumes the appearance of a continued fever; but afterwards degenerates into a remittent, or even an intermittent. It is described by Sydenham, but attended with no remarkable symptoms.

11. The last of Sauvages's species of Tritreophya belonging to the remittent tertian is the Americana. This, according to Sauvages, is the ardent fever with which the Europeans are usually seized on their first coming to America, and generally carries off one half of them. Of this there are two varieties, the very acute and the acute. The very acute ends before the seventh day. It comes on a few days after the person's arrival, with loss of appetite, with dyspepsia and sighing from weakness, head-ach, latitude, pain of the loins: a pyrexia succeeds, with great thirst, sweat, and heat; the sickness increases, nausea comes on, with vomiting of porridous bile; the tongue rough, the extremities often cold; watching, furious delirium; and the patient frequently dies on the third day. Copious sweats, and a plentiful hemorrhage from the nose on the fifth day, but not sooner, are serviceable; but a bilious diarrhoea is the best crisi of all.

The acute kind terminates most frequently on the ninth, but very rarely goes beyond the fifteenth day. Death frequently comes on between the fourth and seventh days. It begins with head-ache, pain in the loins, and sometimes heaving; great latitude, dyspepsia, thirst; burning fever, increasing every third day; inflation of the abdomen, pain at the pit of the stomach, nausea, and bilious vomiting. Such is the state of the disease within twenty-four hours. The eyes are red, and full of tears; the urine pellucid; there is a low delirium, and continual anxiety: the tongue is dry and red, and sometimes, though rarely, black, which is a still worse sign; the pulse, formerly strong and full, sinks about the fourth day, and becomes tenesmus and pulsemodic: if a carus then comes on, the patient dies the fifth or sixth day; but if the pulse keeps up, and no carus comes on, a crisis is to be expected by sweat, by a copious hemorrhage from the nose, or, which is still more safe, by a bilious diarrhoea, which is never fatal if it comes on before the fifth day.

To the Remitting tertian also belong the following species mentioned by Sauvages, viz.

1. Tertiana fubacuminus. This begins like a genuine tertian, and at first hath distinct paroxysms; but these grow gradually more and more obscure, the disease acquiring daily more of the appearance of continued fever, by which it is to be distinguished from the other varieties of this species. It is not unfrequently joined with those symptoms which attend the fatal fever already mentioned; as cardialgia, cholera, syncope, &c. but in a much less degree. The disease commonly begins with little or no sense of cold, but rather a sensation of heat; when the tertian is doubled, it has first a slighter and then a more severe fit; and thus goes on with an exacerbation on the even days: and though it should change from a double into a single tertian, we are still to expect it, if a weak fit is the forerunner of a very strong one. This change of the tertian into a continued fever is also to be prognosticated if a heat remarkable to the touch is perceived on the day of intermission, together with some disturbance of the pulse, thirst, and dryness of the tongue; all of which show an univerbal tendency to inflammation: the same is foretold by the urine being in small quantity, and very red, or of a faffron colour; also an ulcerous or aphthous inflammation of the throat, with difficulty of swallowing, or any very severe symptom coming on in the beginning of the disease, excepting only a delirium, which is easily removed.

2. Quotidiana deceptiva. This is a disorder of an inflammatory kind, with a strong tendency to putrefaction, and sometimes assumes the form of a quotidian. In it the patient frequently complains of cold when he really is hot, and the remission is very indistinct; and the disease is known by the great languor of the patient and the foulness of his tongue.

3. Amphimerina cardiaca is an acute malignant fever, with daily exacerbations, attended with fainting and vomiting of green bile. Afterwards, the weakness increasing, the patient's extremities grow cold, and a profuse sweat comes on, which is frequently succeeded by death on the fourth day. Another species resembling this Sauvages calls the fyncopa1s; but the cardiaca differs from it in being attended with cardialgia.

3. Amphimerina paludosa. This is the fever described by the British physicians under many different names, and appearing under various forms, according to the different conditions of the patients. This fever in the East Indies, according to Dr. Lind of Windfor, generally comes on suddenly, and begins with a sense of debility and very great lenows of spirits. These symptoms are attended with a greater or less degree of chillines, a dizziness, a nausea, very acute pains in the head and loins, and a trembling of the hands; the countenance is pale, the skin commonly very dry and corrugated, the eyes dull and heavy, the pulse quick and small, the breath generally difficult, and interrupted with hicouche.
As the paroxysm increases, the chilliness now and then gives way to irregular heats, which soon become violent and permanent; the nausée likewise increases; and in some there comes on a vomiting, in which they throw up a great deal of bile. Sometimes bile is likewise voided by foal. The skin grows red; the eyes small, and sometimes not a little inflamed. The pulse becomes fuller, and the breathing more difficult, attended with great restlessness and a troublesome thirst; notwithstanding which (so great is the nausée) the patient cannot endure any kind of liquids. The tongue becomes foul; and the pain of the head and loins more violent; a delirium then follows; a flight moisture appears on the face, and from thence spreads to the other parts; whilst the violence of the other symptoms abates, and shows the beginning of a remission, which is completed by plentiful sweats.

On the fever's remitting, the pulse returns almost to its natural state; the pains of the head and loins still continue, though somewhat less violent, as likewise the nausée and want of appetite. When the disease gains strength, the remission is scarcely obvious, and is immediately followed by another paroxysm; which begins, not indeed with so great a shivering, but is attended with a greater pain of the head, the greatest anxiety, a heartburn, nausées, vomiting, and bilious fumes. The matter most commonly evacuated by vomit and ftool is whitish like chalk and water, or curdled milk which is vomited by sucking children, when the curd is much broken down. A heat, immediate thirst, and delirium, now come on. The tongue becomes more foul; the teeth and inside of the lips are covered with a black crust; the breath grows hot and fetid; another remission ensues, attended with a sweat; but this remission is both shorter and less obvious than the first.

This second remission is succeeded by a paroxysm, in which the symptoms are far more violent than in the former; that which the patient discharges by vomiting and purging is more feit; the mouth, teeth, and inside of the lips, are not only covered with a black crust, but the tongue becomes fo dry and fetid, that the patient's voice can scarce be heard. Violent delirium, with restlessness and anxiety, come on chiefly during the paroxysm; nor do these symptoms abate till the fever remits, and the patient sweats.

When the fever becomes so violent, during the third fit, as to end in death, which is generally the case, some of the sick have a coma; in others the delirium becomes more violent. The discharges now become more fetid, and have a cadaverous smell; the stools are involuntary; the pulse is fo quick, small, and irregular, that it is scarce to be counted, or even felt; a cold sweat is diffused over the whole body, especially the head and neck; the face becomes Hippocratic and convulsed; the patient picks the bed-clothes; a fapheus tendinum comes on; the fick lie confantly on their backs, and insensibly slide down to the foot of the bed; their extremities grow cold; they are then seized with convulsions, with which the scene closes.

In this fever, the urine, which at the beginning is pale, becomes of a deeper colour by degrees, but without deposing any sediment. There seldom or never appear any petechiae, and the prickly heat which was before on the skin vanishes on the first appearance of the fever. But though these were the general symptoms of this disorder, they varied in the different subjects, and at different seasons of the same year. The pulse, for example, in some, was quick in the beginning of the disorder; in others, it varied with the other symptoms. The skin was generally dry in the beginning of the fit; but in some it was moist, and covered with sweat from the very first beginning of the disease. In the month of September, when the disorder raged most, the remissions were very imperfect and obscure; but, on the return of winter and the healthy season, they became more regular, and the disease assumed the appearance of an intermittent fever, to such a degree as at length not to be distinguished from it. In some the remissions could scarce be perceived, and the fever continued for two weeks without any material change for the better or the worse. At this time numbers were seized with it. When the disorder continued for any time without a change, it generally ended in death; while the weather grew better, it sometimes, in the space of a few days, from a common fever became an intermitting one, and the patient recovered, unless his liver, which was sometimes the cafe, happened to be affected.

The cure of an inflammation of the liver proved uncertain and tedious; as it was commonly followed by a colliquative diarrhœa, which generally endangered the patient's life. Every succeeding paroxysm was observed to be more dangerous than the preceding; the third generally proved fatal; some died during the fit. When this happened, the fever, in the language of the country, was called pucea, that is a strong fever.

This disease, according to Dr. Lind of Haflar hospital, is the autumnal fever of all hot countries, the epidemic disease between the tropics, and the disease most fatal to Europeans in all hot and unhealthy climates. All authors agree that intermittents in general, but particularly this dangerous kind of them, are produced by heat and moisture. Dr. Lind of Windermund remarks, that the European seamen are very subject to the fever above-mentioned when they happen to arrive at Bengal in autumn. They are predisposed to it from the nature of their food, their confinement on board, the very great heats to which they are exposed during the voyage, and their lying for hours together exposed to the night colds.

Most of the meat used by the crews of these ships is salted, and often in a putrid state, without any fresh vegetables, they having only biscuits, and some other farinaceous matters. The quantity of the vinous or spirituous liquors allowed them is by far too small to subsist the putrefcent disposition of their animal-food. Their fluids consequently become, from day to day; more and more putrefcent, and of course the more apt to breed and contract this disorder. This disposition is likewise induced by their being flown very close together, and that for a considerable length of time, and in a foul air, especially when the weather happens to be too stormy to permit the hatches and port-holes to be kept open.

Though the heats they endure in the voyage to India are less considerable than those of the country itself, yet they are too much for an European constitution
Practice. M E D I C I N E.

The general heat at sea within the tropics is about 84° of Fahrenheit's thermometer, which is sufficient to relax them, and promote a corruption of their humours, especially when it coincides with the above causes. It likewise creates a languor and indolence, which alone are sufficient to increase that putrefection. These causes are apt to be considerably aggravated by the masts being often exposed, when on duty, for hours together, to rain, damp, and cold air; a circumstance which frequently happens to them when working their ships up the river Ganges in the night-time. Hence the perpiration is checked, and the excrementitious fluid which used to be discharged by the skin being retained in the body, contributes, he thinks, very much towards the predisposition to this disease.

But the most powerful of all the remote causes is jutly thought to be the effluvia of marshes replete with putrid animal-substances. We have not, however, been able to determine from what kind of putrid animal-substances these effluvia arise. For that every kind of putrefaction has not such an effect appears from this, that neither practical anatomists, nor those who by their trades are exposed to the putrid effluvia of animals, for instance such tanners and butchers as keep their shops and stalls very dirty, are more subject than others to putrid diseases. Nor are the ship'swards and their servants, whose business it is to deliver out their provisions to the ships crews, and who spend the most of their time amongst the putrid and rank effluvia of the places in which those provisions are kept, more subject to putrid fevers than their ship-mates. But whatever be in this we are well assured that some particular putrid fermentations produce noxious vapours, which, united with those of marshes, render them more pernicious. Hence evidently proceeds the extreme unhealthfulness of a place called Culpis, on the eastern bank of the Ganges. The shores about it are full of mud, and the banks covered with trees. Opposite to the place where the ships lie there is a creek, and about a mile from its entrance stands the town of Culpis; the ships lie about a mile from the shore. None of the sailors on board the ships stationed at this place enjoyed their health. The burying ground also contributed not a little to spread the infection. The ground being marshy, the putrid water flowed from the old graves into the new ones, which infected the grave-diggers and those that attended the funerals; and from this cause many were suddenly seized while they were performing the last duty to their companions. This place has ever been remarkable for the unhealthfulness of its air. It was once customary to send some of the Company's servants here to receive the cargoes of the ships, and send them to Calcutta; but so many of them died on this duty that the Company was at length obliged to discontinue it.

Hence it plainly appears, how apt putrid animal and vegetable substances are to render the effluvia of fenny places more pernicious than they would otherwise be. The reason why great inundations of the Nile and Ganges are followed by a healthy season, is, that by this means the putrid animal and vegetable substances dispersed over the contiguous countries are carried off into the sea. The noxious vapours arising from dens spread but a little way. Dr Lind has often known ships crews at a very little distance from the shore quite free from this disorder. But although these marsh marshmata first bring on the disease, yet contagion is particularly spread by it, and renders it more epidemic. Thus the Drake East Indianmen continued free from the disorder for two weeks together, when she had no communication with the other ships; whereas as soon as the disorder was brought on board, many were seized with it within a few days in such a manner as to leave no room to entertain the least doubt concerning its pestilential nature.

Dr Lind of Haflar hospital has given a very curious and learned account of the appearance of this fever throughout the various parts of the globe. It was very common in England in the years 1763 and 1766, one obvious cause of which was the prevalence of the easterly wind. This wind in England is often said to bring with it a fog from the sea; but the truth of the matter is, that in many places of that island the easterly wind frequently raises a copious vapour from water, mud, and all marshy damp places. To this exhaling quality of the easterly wind Dr Lind has often been an eye-witness. When the wind changes to the east, the mud sometimes sends up a vapour as thick as smoke; and the doctor has observed two fishy ponds in his neighbourhood one of fresh and the other of salt water, which on the approach of an easterly wind sometimes emit a dense vapour, as from a pot of boiling water. In order to view this phenomenon distinctly, the person should stand at about 100 yards distance from the mud or ponds. If the sun shines when the wind changes to the east, he will observe a constant stream of vapours arising out of the ponds, from about five to ten yards in height, while the air about him remains serene. As the vapour or fog arising from other bodies glides along the surface of the earth, and is brought by the easterly wind to the ponds, he will still be able, for some time, to distinguish the vapours ascending perpendicularly out of the ponds from those which are carried in an horizontal direction by the wind: especially if the sun continues to shine, though faintly.

This evaporating quality of the easterly wind seems to manifest itself also by its effects both on the thermometer and the human body; for a thermometer hung over a damp piece of ground during the fogs or exhalations arising from it, will often indicate a degree of cold below the freezing point. The chilliness of the body, so sensibly perceived when in this situation, seems to proceed from the same cause, and to produce nearly the same sensations, which the damp arising from the wet floor in a chamber communicates to those who happen to be in it.

Winds are not constant in their effects. As we have sometimes warm weather with a north-wind, and sometimes very little heat with one blowing from the south; so the fogs attending an easterly wind are not constant, neither is the evaporation abovementioned at all times to be perceived. It is possible, however, that in all this there may be a deception; and that instead of supposing the quantity of vapours exhaled to be increased by an easterly wind, the coldness of that wind may only condense and render visible the vapours in the air at that time. But even this supposition is liable to great objections, as our coldest north-winds seldom or never produce such an effect, but on the contrary are attended with dry and serene weather.
Be this as it will, however, an east-wind is usually accompanied with a cold, damp, and unwholesome vapour, which is observed to affect the health both of animals and vegetables, and in many places to produce oblitinate intermitting fevers, and also to occasion frequent attacks. In particular spots of the low damp island of Portsea, the ague frequently prevails during the autumnal season, and in some years is much more frequent and violent than in others. It is also observable, that this disease always attacks strangers, or those who have formerly lived on a drier soil, and in a more elevated situation, with greater severity than those who are natives of the island.

The year 1765 was remarkable, not only for the long continuance of the easterly wind, but for an excessive degree of heat, which produced a more violent and general rage of those diseases than had been known for many years before. In the month of August the quicksilver in Fahrenheit's thermometer often rose to 82° in the middle of the day. This considerable addition of heat, together with the want of refreshing rains, greatly spread the fever, increased its violence, and even changed its form in many places. At Portsmouth, and throughout almost the whole island of Portsea, an alarming continual or remitting fever raged, which extended itself as far as Chichester. At the same time, the town of Gosport, though distant only one mile from Portsmouth, enjoyed an almost total exemption from sickness of every kind; whereas in the neighbouring villages and farm-houses, a mild regular tertian ague distilled whole families. The violence of the fever, with its appearances in a continued, remitting, or intermitting form, marked in some measure the nature of the soil. In Portsmouth the symptoms were bad, worse at Kingston, and full more dangerous and violent at a place called Half-way House; a street so named, about half a mile from Portsmouth, where fearfully one in a family escaped this fever, which generally made its first attack with a delirium. In the large suburb of Portsmouth called the Common, it seemed to rage with more violence than in the town, some parts excepted; but even whole streets of this suburb, together with the howies in the dock-yard, escaped the attack.

The Marines, who were three times a-week exercised early in the morning on South Sea beach, suffered much from the effect of the stagnant water in an adjoining marsh. Half a dozen of them were frequently taken ill in their ranks when under arms; some being feized with such a giddiness of their head, that they could fearlessly stand; while others fell down speechless, and upon recovering their senses complained of a violent head-ache. When such patients were received into the hospital, it was observed that some few had a regular ague, but that far the greater number laboured under a remitting fever, in which sometimes indeed there was no perceptible remission for several days. A constant pain and giddiness of the head were the most inseparrable and distreasing symptoms of this disease. Some were delicious, and a few vomited up a quantity of bile; but in all the countenance was yellow. A long continuance of the fever produced a dry, or jaundice, or both. Even a slight attack reduced the most robust constitution, to a state of extreme debility; and this weakness, together with the giddiness, continued for a long time after the fever.

Such is the appearance of the remitting fever occasioned by marsh miasmata in England. In the Netherlands its symptoms are not much different. Dr Wind informs us, that at Middleburg, the capital of Zeelend, a sicknes generally reigns towards the latter end of August, or the beginning of September, which is always most violent after hot summers. It commences after the rains which fall in the end of July; the sooner it begins the longer it continues, and it is only checked by the coldness of the weather. Towards the end of August and the beginning of September it is a continual burning fever, attended with a vomiting of bile, which is called the gall-sickness. This fever, after continuing three or four days, intermits, and assumes the form of a double tertian; leaving the patient in a fortnight, or perhaps sooner. Strangers that have been accustomed to breathe a dry pure air do not recover so quickly. Foreigners in indigent circumstances, such as the Scots and German soldiers, who are garrisoned in the adjacent places, are apt after those fevers to have a swelling in their legs and a dropsy of which many die.

These diseases, the Doctor observes, are the same with the double tertians common within the tropics. Such as are feized with the gall-sickness have at first some fluxes of heat over the body, a loss of appetite, a white fowl tongue, a yellow tint in the eyes, and a pale colour in the lips. Such as live well, drink wine, and have warm clothes and good lodgings, do not suffer so much during the sickly season as the poor people; however, these diseases are not infectious, and seldom prove mortal to the natives.

Sir John Pringle observes, that the prevailing epidemic of autumn in all marshy countries, is a fever of an intermitting nature, commonly of a tertian form, but of a bad kind; which, in the dampest places and worst feasons, appears as a double tertian, a remitting, or even an ardent fever. But however these fevers may vary in their appearance according to the constitution of the patient and other circumstances, they are all of a familiar nature. For though, in the beginning of the epidemic, the heat or rather the putrefaction in the air is the greatest, they assume a continued or a remitting form, yet by the end of autumn they usually terminate in regular intermitents.

In Zeelend, where the air is more corrupted than in other parts of the Netherlands, this distemper, as we have already observed, is called the gall-sickness; and indeed both the redundancy and depravation of the gall is sometimes so great, that it has been generally ascribed to the corruption and overflow of that humour. But though it cannot with justice be said to originate from corrupted gall or bile, it is certain that the disease may be continued, and the symptoms aggravated, by an increased secretion and putrefaction of the bile occasioned by the fever. In proportion to the coolness of the season, to the height and dryness of the ground,
ground, this distemper is milder, remits or intermits more freely, and removes further from the nature of a continued fever. The higher ranks of people in general are least liable to the diseases of the marshes; for such countries require dry houses, apartments raised above the ground, moderate exercise, without labour in the sun or evening damps, a just quantity of fermented liquors, plenty of vegetables, and fresh meats. Without such helps, not only strangers, but the natives themselves are sickly, especially after hot and close summers. The hardiest constitutions are very little excepted more than others; and hence the British in the Netherlands have always been subject to fevers.

By this distemper the British troops were harassed throughout the whole of the war from 1743 to 1747. It appeared in the month of August 1743; the paroxysms came on in the evening, with great heat, thirst, a violent headache, and often a delirium. These symptoms lasted most of the night, but abated in the morning, with an imperfect sweat, sometimes with a hemorrhagy of the nose or a looones. The stomach from the beginning was disordered with a nausea and sense of oppression, frequently with a bilious and offensive vomiting. If evacuations were either neglected, or too sparingly used, the patient fell into a continued fever, and sometimes grew yellow as in a jaundice. When the season was further advanced, this fever was attended with a cough, rheumatic pains, and fiery blood. The officers being better accommodated than the common men, and the cavalry who had cloaks to keep them warm, were not so subject to it: and others who belonged to the army, but lay in quarters, were least of all affected; and the left in proportion to their being little exposed to heats, night-damps, and the other fatigues of the service.

In this manner did the remitting fever infect the army for the remaining years of the war; and that exactly in proportion to their distance from the marshy places, of which we have several notable instances in Pringle's observations. In Hungary the same disease appears with still more violence, and is readily contracted by sickly constitutions, by which means it becomes extremely dangerous. Hungary is acknowledged to be the most sickly climate in Europe, and indeed as bad as any in the world. Here it was where the crusaders, in only marching through the country to invade Aflia, often lost half their number by fevers; and where the Austrians not long since buried, in a few years, above 40,000 of their best troops, who fell a sacrifice to the malignant disposition of the Hungarian air. The reason of this uncommon malignity is, that Hungary abounds with rivers, which, by often overflowing, leave that low flat country over-spread with lakes and ponds of stagnating water, and with large unhealthy marshes. So great is the impurity of these stagnated waters, that by them the rivers, even the Danube, whose course is flow, becomes in some places corrupted and offensive. The air is moist, and in summer quite sultry. In the nights of harvest, Krumper tells us, it was so very damp, that the Austrian soldiers could not secure themselves from the moisture even by a triple tent-covering. Here epidemic disturbances begin constantly to rage during the hottest months of the year; which are July, August, and September: and these complaints, according to the observations of the physician abovementioned, are the same with those which are epidemic upon the coast of Guinea, and in the sickly climates of the East and West Indies, of which malignant fevers of the remitting and intermitting kind are the most common and dangerous.

The heat of the sun in Hungary, according to the same author, is more intense than in any other country of Europe; and in proportion to the heat is the pestilential quality of the marshy exhalations. It is constantly observed, that the nearer any city or fort is to a marsh or a large river with foul and oozy banks, the more unhealthy are the inhabitants. At such feasons and places, the air swarms with numberless insects and animalcules, a sure sign of its malignant disposition; and the hotter the summer, the more frequent and mortal are the diseases. In short, this country, on account of its unhealthy air, has been termed the grave of the Germans; and in Italy, the Campania of Rome is almost equally unhealthy. Lancilius, physician to Pope Clement XI., furnishes us with a very striking instance of the malignant quality of the air of Campania. Thirty gentlemen and ladies of the first rank in Rome having made an excursion, upon a party of pleasure, towards the mouth of the Tyber, the wind suddenly shifting blew from the south over the putrid marshes, when 25 were immediately seized with a tertian fever, only one escaping.

The island of Sardinia is annually visited with an epidemic sickness, which rages from June to September, and is called by the natives the intermitent. In some years there is a want of rain for four or five months; and then it is that this sickness exerts its utmost violence, being always more fatal in some places than in others, and in particular to strangers. Of this the British had a severe proof in 1758. Admiral Broderick, in the Prince ship of war, anchored, in the bay of Orifaltani, where 27 of his men, sent ashore on duty, were seized with the epidemic distemper of this island; twelve of them in particular, who had slept on shore, were brought on board delicious. All of them in general laboured under a low fever, attended with great oppression at the breast and at the pit of the stomach, a constant retching, and sometimes a vomiting of bile; upon which a delirium often ensued. These fevers changed into double tertians, and terminated in obitinate quartan agues. It is worthy of remark, that in this ship, which lay only two miles from the land, none were taken ill but such as had been on shore, of whom seven died. The prior of a convent, making a visit to the English officers, informed them, that the intermitenties of the island was a remitting or intermitting fever, and that he himself had suffered several attacks of it. Sardinia was formerly so remarkable for its unhealthy air, that the Romans used to banish their criminals thither; and it is at present but thinly peopled, owing to the mortality occasioned by this annual sickness. For although it is about 140 miles long, and in several places 75 miles broad, yet it is computed that the whole number of its inhabitants does not exceed 250,000; an inconsiderable number, when compared with the inhabitants of the lefser, but comparatively more healthful, island of Corsica; though even there the French lost a number of their troops by intermitting and remitting fevers.
In the island of Minorca, too, Dr Cleghorn informs us, that fevers of this kind prevail exceedingly; that their types are various, their symptoms violent, the intermissions fallacious, and that they frequently and suddenly prove fatal. It is more than probable, he adds, from the accounts of several physicians and travellers, that epidemic terns are not wholly confined to the coasts and islands of the Mediterranean, but that they are equally frequent and destructive in many other parts of the globe; and perhaps may be deemed the anniversary autumnal distempers of most hot countries in the world. And though in the mild climate of Britain, a tertian may always easily be cured when once it is discovered; yet in warm climates, such is the rapid progress of the distemper, that it is necessary to know it in the very beginning, which is very difficult for those who have never seen any but the tertians usually met with in Britain.

From Dr Cleghorn's account of Minorca, however, it doth not appear why that island should be so much infected with fevers of this kind, since it is far from being a marshy country; may, on the contrary, it is very dry. The south wind, he observes, is very unhealthy; and it is the prevalence of this wind which brings on the fever: but still the difficulty is not removed, because the sea-air is so far from bringing on such dangerous diseases, that it is one of the greatest preservatives against them when it can be had. As to the moisture which must necessarily accompany an insular situation, that cannot reasonably be admitted as a cause of this or any other disease. In the London Medical Observations we find a paper on a subject very similar to the present, namely, the mischief produced by lying in damp sheets, or being exposed to moist vapour. The author tells us, that he hardly knows a distemper the origin of which hath not by some been ascribed to lying in a damp bed, or sitting in a wet room; and yet he does not know any one which will certainly be produced by these causes, and people frequently expose themselves to such causes without suffering any ill effects. "It must be owned indeed, (says he), that the vapours arising from the bilge waters of ships tend to produce a scurvy. The swampy plains also near the mouths of great rivers which are often overflowed, and low grounds which cannot readily be drained, and those tracts of land where the thickness and extent of the woods keep the ground moist and half putrid for want of ventilation, are destructive to the neighbouring inhabitants, by occasioning obdurate intermittents in the colder climates, and pestilential fevers in the hotter regions. But all this mischief arises not merely from moisture, but from an unventilated and putrid moisture; for the inoffensive fumes of mere wetness, untainted with putridity, may be reasonably inferred from the following considerations. The air is often fully saturated with moisture, and could not be more filled by the vapours arising from a chamber covered with water; and yet neither is any epidemic distemper produced by it, nor are they remarkably aggravated with which the sick happen at that time to be afflicted. The air from rivers and from the sea is probably more replenished with vapours than inland countries cleared of their woods; yet the most celebrated of the ancient physicians recommended the bank of a running river for the situation of a house, on account of its peculiar healthfulness; and many invalids are sent by the modern physicians to the sea side, only for the benefit of the sea air.

"Where the sailors are cleanly, and not too much crowded, they are often as healthy during long voyages at sea, as they would have been upon any part of the land. Venice is not observed to be less healthy than London or Paris."

"Those who are much disposed to sweat, lie many hours in bed-clothes impregnated probably with a less wholesome moisture than would have been left in the sheets half-dried after washing; and I have not yet had reason to think that any remarkable injury was done to the health by the continuance of such sweats almost every night for weeks, and for months, except what arose from the too great copiousness of this evacuation.

"Children, and such as are troubled with the stone, and those who, from other infirmities or age, constantly wet their beds with their urine, do not appear to suffer in their health on this account.

"It is a common practice, in some disorders, to go to bed with the legs or arms wrapped in linen cloths thoroughly soaked in Malvern water, so that the sheets will be in many places as wet as they can be; and I have known these patients and their bedfellows receive no harm from a continuance of this practice for many months. Nor can it be said that the Malvern water is more innocent than any other water might be, on account of any ingredients with which it is impregnated; for the Malvern water is purer than that of any other spring in England I ever examined or heard of.

"The greatest valetudinarians do not scruple to sprinkle lavender-water upon their sheets; and yet, when the spirit is flown off, there is left what is as truly water as if it had been taken from the river.

"Is it observed, that laundresses are peculiarly unhealthy by reason of the water, though they live half their time in the midst of wet linen, in the air fully saturated with vapours? Many other employments might be mentioned, the persons occupied in which must be exposed to wet floors or pavements, or to be surrounded with watery vapours, or to have their clothes often wet for many hours together.

"Is it the coldness of wet linen which is to be feared? But shirts and sheets, colder than any unfrozen water can be, are safely worn and lain in by many persons, who, during a hard frost, neither warm their shirts nor their sheets.—Or does the danger lie in the dampness? But then how comes it to pass, that a warm or cold bath, and long-continued fomentations, can be used, without the destruction of those who use them? Or is it for both together? Yet we have long heard of the thickness and continuance of the cold fogs in the seas north-west of England, but have never yet been told of any certain ill effect which they have upon those that live in these countries."

"With regard to the causes of fevers, however, Dr Lind is of opinion, that noxious vapours arising from the earth are for the most part to be blamed. Even in countries seemingly dry, and where violent rains are
not frequent, he thinks that the air may load itself with putrid exhalations from the ground; and that, except in the burning desarts of Arabia or Africa, people are nowhere exempt from diseases occasioned by putrid moisture. In most of the hot countries, however, the noxious effects of the putrid vapours are by no means equivocal. In Guinea, they seem to be more extraordinary than any where else in the world; neither indeed can it be supposed, that a hot and moist atmosphere can be without putrefaction. It may in general be remarked, that in sultry climates, or during hot weather, in all places subject to great rains, where the country is not cleared and cultivated, but is overrun with thickets, shrubs, or woods, especially if there are marshes or swamps, even in the huts or houses. But of all the parts of Guinea, where travellers are obliged to be denom's dominions at Benin (the most unhealthy part of Guinea), where travellers are obliged to be carried on mends backs for several days journey, through swampy grounds, and over marshes, amidst flinking oozes, and thickets of mangrove trees which are annually overflowed. These vapours come up the coast to a surprising distance, with the south-east and north-east winds; and it has been observed, that in their progress they have often changed both the course of the winds and of the sea currents. The times of their appearance at Cape Coaft are the months of December, January, or February. The north-east and south-east winds are always unhealthy, but particularly so during the harramattans: Some years this vapour is fearely perceptible; but in others it is thick, noxious, and destructive to the blacks as well as whites. The mortality is in proportion to the density and duration of the fog. It has a raw putrid smell; and it is sometimes so thick, that a person or house cannot be discerned through it, at the distance of 15 or 20 yards; and it continues so for 10 or 15 days; during which it opens the seams of tiles, splits or opens the crevices of wood as if burned, or dried with a great fire, and destroys both man and beast. In the year 1751 or 1755, the mortality occasioned in Guinea by this sinking fog was so great, that in several negro towns the living were scarce sufficient to bury the dead. Twenty women brought over from Holland by a new governor to the Cattle del Mina, perished, together with most of the men in the garrison. The gates of Cape Coast castle were shut up for want of centinels to do duty; the blacks dying at this time as well as the white people. It is lucky that it is only in some years that harramattans are so very thick and noxious, otherwise that part of the country would be depopulated. It is observed that all fogs are extremely unhealthy in those parts, particularly before and after the rainy seasons; but the above account of the harramattans appeared so very extraordinary and incredible to some of Dr. Lind's readers, that he thought proper to publish a further corroboration of the facts above-mentioned. A gentleman (says he), who had long resided at Cape Colle, informed me, that during the time of this fog, being in the upper chambers of the fort, the boards of the floor shrunk so much, that he could discern the candles burning in the apartments below him (there are no plaster ceilings used in those hot countries), and that he could then even distinguish what people were doing in the apartments below; the rooms of the floor having opened above half an inch, while the fog lasted which afterwards, upon its being diffused, became close and tight as before.

In this country the rains and dews seem to be possessed of qualities almost equally pernicious with the fogs. This much is certain, that in Guinea, many of the principal negroes, and especially of the mulatto Portuguese, take the utmost precaution to avoid being wet with these rains, especially such as fall first. At the setting in of the rainy season, they generally shut themselves up in a close well-thatched hut, where they keep a constant fire, smoke tobacco, and drink brandy, as preservatives against the noxious quality of the air at that time. When wet by accident with the rain, they immediately plunge themselves into salt-water, if near it. Those natives generally bathe once a-day, but never in the fresh water rivers when they are overflowed with the rains; at such times they prefer for that purpose the water of springs. The first rains which fall in Guinea are commonly supposed to be the most unhealthy. They have been known, in 48 hours, to render the leather of the shoes quite mouldy and rotten; they thin clothes more than any other rain; and soon after their commencement, even places formerly dry and parched swarm with fogs. At this time skins, part of the traffic of Senegal, quickly generate large worms; and it is remarked, that the fowls, which generally prey on other insects, refuse to feed on these. It has been farther observed, that woollen cloths wet in these rains, and afterwards hung up to dry in the sun, have sometimes become full of maggots in a few hours. It is also probable, that as in some of these countries the earth, for six or eight months of the year, receives no moisture from the heavens but what falls in dews, which every night renew the vegetation, the surface of the ground in many places becomes hard and incrusted with a dry flour, which pens up the vapours below; until by the continuance of the rains for some time, this crust is softened, and the long pent up vapours set free. These dews do not penetrate deep into the earth; they are eviden from the constant dryness and hardness of such spots of ground in those countries as are not covered with grass and other vegetables. Thus the large rivers in the dry season being confined within narrow bounds, leaving a great part of their channel uncovered, which having its moisture totally exhaled, becomes a solid hard crust; but no sooner the rains fall, than by degrees this long parched up crust of earth and clay gradually soften, and the ground, which before had not the left smell, begins to emit a fench, which in four or five weeks becomes exceedingly noifome, at which time the sickness is generally most violent.

This sickness, however, is not different from the remitting...
remitting fever which has been described under so many various forms and names. An inflammatory fever is seldom observed, during the season of sickness, in this part of the world; and we shall conclude our description of the *amphiocerina paludos* with some extracts from the surgeon’s journal of a ship that sailed up the rivers of Guinea.

“On the 5th of April we sailed up the river of Gambia, and found all the English in the fort in perfect health. The surgeon of the factory informed me, that a relaxation of the stomach, and consequently a weakened digestion, seemed to bring on most of the diseases so fatal to Europeans in the sickly season. They were generally of a bilious nature, attended with a low fever, sometimes of a malignant, at other times of a remitting kind. On the 12th of April, after 30 miles up the river St Domingo, we came to Cachou, a town belonging to the Portuguese, in Lat. 20° N. In this town were only four white people, the governor and three friars. The number of whites in the trading ships were 51. One morning, towards the latter end of April, a little rain fell. On the 13th of May there was a second shower, accompanied with a tornado. On the 18th of May it rained the whole day; and the rain continued, with but short intervals, until the beginning of October.

“In the month of June, almost two-thirds of the white people were taken ill. Their sickness could not be well characterized by any denomination commonly applied to fevers: it however approached nearest to what is called a nervous fever, as the pulse was always slow, and the brain and nerves seemed principally affected. It had also a tendency to frequent remissions. It began sometimes with a vomiting, but oftener with a delirium. Its attack was commonly in the night; and the patients, being then delirious, were apt to run into the open air. I observed them frequently recover their senses for a short time, by means of the heavy rain which fell upon their naked bodies. But the delirium soon returned: they afterwards became comatose, their pulse funk, and a train of nervous symptoms followed; their skin often became yellow; bilious vomitings and froths were frequent symptoms. The fever reduced the patient's strength so much, that it was generally six weeks or two months before he was able to walk abroad. A confining flux, a jaundice, a dropsey, or obstructions in the bowels, were the consequences of it. Of 51 white men, being the companies of four ships which were at Cachou, one-third died of the fever, and one-third more of the flux, and other diseases consequent upon it; and of these not one was taken ill till the rains began.

“I believe, on the whole face of the earth, there is scarce to be found a more unhealthy country than this during the rainy season: and the idea I then conceived of our white people was by making a comparison of their breathing such a noisily air, with a number of river-fish put into flagrant water; where, as the water corrupts, the fish grow less lively, take, droop, pine away, and many die.

“Thus some persons became dull, inactive, or slightly delirious at intervals; and, without being so much as confined to their beds, they expired in that delirious and comatose state in less than 48 hours, after being in apparent good health. The white people in general became yellow; their stomack could not receive much food without loathing and retchings. Indeed it is no wonder that this sickness proved so fatal, that recoveries from it were so tedious, and that they were attended with fluxes, dropsey, the jaundice, ague-cakes, and other dangerous chronic distempers. It seemed more wonderful to me that any white people recovered, while they continue to breathe so pestiferous an air as that at Cachou during the rainy season. We were, as I have already observed, 30 miles from the sea, in a country altogether uncultivated, overflowed with water, surrounded with thick impenetrable woods, and over-run with slime. The air was vitiated, noisome, and thick; insomuch that the lighted torches or candles burnt dim, and seemed ready to extinguish; even the human voice lost its natural tone. The smell of the ground and of the houses was raw and offensive; but the vapour arising from putrid water in the ditches was much worse. All this, however, seemed tolerable, when compared with the infinite numbers of insects swarming every where, both on the ground and in the air; which, as they seemed to be produced and cherished by the putrefaction of the atmosphere, so they contributed greatly to increase its impurity. The wild bees from the woods, together with millions of ants, over-ran and destroyed the furniture of the houses; at the same time swarms of cockroaches often darkened the air, and extinguished even candles in their flight; but the greatest plague was the musquetos and sand-flies, whose incessant buzz and painful stings were more inhuman than any symptom of the fever. Besides all these, an incredible number of frogs on the banks of the river made such a constant and disagreeable croaking, that nothing but being accustom to such a hideous noise could permit the enjoyment of natural sleep. In the beginning of October, as the rains abated, the weather became very hot; the woods were covered with abundance of dead frogs, and other vermin, left by the reces of the river; all the man­groves and shrubs were likewise over-spread with flinking slime.”

After so particular a description of the remitting fever in many different parts of the world, we presume it will be needless to take notice of any little varieties which may occur in the warm parts of America, as both the nature and cure of the distemper are radically the same; neither shall we lengthen out this article with further descriptions of remitting fevers from the works of foreign authors, as, from what we have already said, their nature cannot well be mistaken.

Cure. The difficulty in the cure of remitting fevers arises from their not being simple diseases, but a complication of several others. Fevers, properly speaking, have but three or four different appearances which they can assume without a complication. One is, when they are attended with a phlogistic diaphresis; another is, when they assume the form of genuine intermittent; a third is, when they produce a great debility of the nervous system; and the fourth is, when along with this debility there is also a rapid tendency to putrefaction. If, therefore, all these species happen to make an attack at once, the most dangerous fever we can imagine will be produced; and however contrary it may be to our theories to admit the possibility of such
such an attack, the truth of the fact is too often confirmed by fatal experience. In the beginning of remittent fevers, for instance, the symptoms indicate a high degree of inflammation: but if the practitioner attempts to remove this inflammation by blood-letting or other evacuations, the pulse sinks irrecoverably, and the person dies with such symptoms as show that the nervous system has been from the beginning greatly affected; at the same time the high stimulants and cordials, or the balsam, which would have conquered the nervous part of the disease, increase the inflammatory part of it to such a degree, that, by a too early exhibition of them the patient also dies, but after another manner.

In the remitting fever of the East Indies, Dr Lind of Windsor formed the following indications of cure.

1. To allay the violence of the fever.
2. To evacuate the putrid humours, and take great care to prevent the body from inclining to putrefaction.
3. To keep up the strength of the patient as much as possible during the disorder.
4. To lose no time in preventing the return of the paroxysms.

To allay the violence of the fever, everything that can contribute to increase it ought to be carefully avoided or removed; such as great heat, too strong a light falling on the eyes, noise, and motion. If during the paroxysm the head and loins be affected with violent pains, the pulse be full and hard, and the heat intense, bleeding may be used, but with the greatest caution; for, however useful this operation may be in cold climates, the success of it in warm ones is so far from being certain, that the lives of the patients have been often very much endangered, and even destroyed by it. Dr Balenoch, and the surgeon of the Pondborne, endeavoured each of them to relieve two patients by blood-letting; and the consequence was that each of them lost one patient. Dr Lind bled two patients, one of whom was Mr Richardson, the first mate of the ship, who complained of a most violent pain in his head with a full hard pulse. About four or five ounces of blood were taken from him, by which he was greatly relieved; nor was the cure returned by its means, the fever afterwards became laborious. At the time the other patient was bled, the disease was exceedingly frequent and violent. He was so earnest for bleeding, that he fired all the rest with the same desire, swearing, that by refusing them this only remedy, every one of them would be sent to their graves. To quiet them, therefore, and get quit of their importunities, the Doctor complied with their request, and took about five or six ounces from him who had been the first to require it. The consequence was, that he immediately lost his strength; and in less than an hour, during which time he made his will, was carried off by the next fit. It is necessary, however, to observe, and indeed the Doctor himself makes the observation, with regard to this patient, that he was bled at an improper time, namely, between the fits, whereas, had he been bled in the hot fit, it is possible he might have been relieved.

In support of the advantages to be derived from bleeding under proper circumstances, we have the authority both of Cleghorn and Pringle. As Dr Cleghorn practised in a very hot country, his observations must in the present case have greater weight than those of Pringle, who practised in a colder one. The former acquaints us, that if he was called in early enough, unless there was a strong contraindication, he always used to take away some blood from people of all ages; namely, from robust adults, 10 or, 12 ounces; from others a smaller quantity, in proportion to their strength and years. And further, if a violent head-ache, obliate delirium, and great heat or pains of the bowels, were urgent, the bleeding was repeated within a day or two. By this seasonable evacuation, he found the remission of all the paroxysms followed by diminished; the apoplexies became more complete; the operation of emetics and cathartics rendered safer and more successful; and the terrible symptoms which happenings about the height of the distemper, such as raging febrifor, difficulty of breathing, inflammations of the abdominal viscera, &c. were either prevented or mitigated. But if the fever had continued for some time before he was called, and the mass of blood appeared to be too much melted down or inclined to a putrid dilution, he either abstained from bleeding entirely, or took away a very small quantity, though some important symptoms might seem to require a larger evacuation. As to the time of performing the operation, he acquaints us, that it is safe enough, except when the cold fit lasts or is soon expected, or while the skin is covered with critical sweats; and that he usually opened a vein in the beginning of the hot fit; by which means the sick were relieved, the immediate heat of the body, which is often productive of fatal effects, was diminished, and the critical sweats brought on sooner and in greater abundance.

But though Dr Lind found venesection to be of such pernicious tendency in his patients, cooling acidulated liquors were of the utmost service, as they correled the putrid humours, lefened the heat and thirst, and of course prevented the fever from arriving at so great an height as it would otherwise have done. Those cooling liquids are the best which are made up with some stimulating substance, as they most easily unite with our fluids. Puddled acids and, in crystals of tartar, especially the latter, are of considerable use, not only in this but in other fevers. The neutral salts, prepared with the juice of lemons, were likewise given with success during the heat of the fever. They lessen the nausea, the fits become more regular, and the remissions more full; and they are particularly grateful when given in a state of effervescence. The good effects of these draughts we are in a great measure to ascribe to the antiseptic quality of the fixed air extirpated from them during the effervescence; of which we shall speak more fully when speaking of the typhous fevers.

During the remission, it is proper to evacuate the putrid humours by small doses of ipecacuanha, or rather tartar emetic. The tartar emetic indeed appears to be endowed with some kind of febrifuge virtue, which Dr Cullen thinks is owing to its relaxing the febrile spasm taking place in the capillary vessels. But should there appear any symptoms of a topical inflammation in some of the abdominal viscera, a thing which never happens unless the disorder has been of some standing, vomiting is to be avoided, and we are to depend upon purgatives alone for the
evacuation of the putrid bile, which are always useful in the cure of this disorder. But all acid and strong purgatives are to be carefully avoided, and only the mild antiseptic ones made use of, such as crystalline tartar, or tamarinds made up with manna or with Glauber’s salt.

Under the article Gall, we have observed, from Dr Percival, the effect which vegetable acids have in sweetening putrid bile; whence it seems probable, that a liberal use of these acids would be much more serviceable than a repetition of any kind of purgatives. Though in these diseases there is a great quantity of putrefcent bile collected in the body, yet it seems much more probable that this is the effect rather than the cause of the disorder; and therefore, though we carry off the quantity collected ever so often, more of the same kind will still be produced by the putrefcent disposition of the other fluids, at the same time that the strength of the patient must necessarily be diminished by repeated evacuations, when it ought rather to be kept up by all possible means. We ought well to observe, however, that the mineral acids have not that property of sweetening putrid bile which the vegetable ones have; and therefore the same relief will not be given by them which might reasonably be expected from vinegar or lemon-juice.

In order to keep up the strength of the patient, good food is absolutely necessary. Dr Lind allowed the sick small messes of panada made with boiled rice and barley mixed with currants or raisins and prunes, seasoned with sugar and a little wine, especially clarat. During the paroxysms, they had gruel made of flour and rice, with sugar and the juice of acid fruit; and when the fit went off, a little wine was more bleeding. A physician unacquainted with the use of the bark, and informed that there is a tendency to inflammation, by increasing the fluid of the body, yet he supposes the actions of these flies to operate usefully in the same manner in which volatile alkalies, that is, by dissolving and putrefying the blood still farther. But Sir John Pringle has shown, that, in inflammatory fevers as well as those of the putrid kind, both blisters and volatile falls may be of service; the latter, particularly, he hath experimentally proved to be so far from promoting putrefaction, that they are exceedingly strong antiseptics.

In the East Indies, Dr Lind found it absolutely necessary to exhibit the bark in large quantities, and as early as possible. By this method he not only cured the patient from the imminent danger of death Tertians, to which he was exposed at every fit, but likewise conquered those obstructions which were apt to enfee in the abdominal viscera, and which are to be attributed to the continuance of the disorder, and not to the bark employed to cure it. He always gave the bark during the second remission, as all his care was during the first to cleanse the prime vies. He observes, however, that it is to no purpose to give the bark till the necessary purgations are over; but assures us, that it never fails, unless from the coming on of a vomiting or diarrhoea it cannot be taken in sufficient quantities before the return of a paroxysm. To prevent the medicine from vomiting or purging, he mixed a few drops of liquid laudanum with every dose of it. Half a drachm was given every half hour in some convenient vehicle, beginning as soon as the fever had considerably abated, and the pulse was returned nearly to its natural rate; both which generally happened before the sweats were over. An ounce of the bark was sometimes found too little to check the fever, but an ounce and a half never failed. It must be continued daily in small doses till the patient has recovered his strength, and then a greater quantity must be given, especially at the season when the rivers overflow the country.

Dr Pringle found the autumnal remittents in the Netherlands complicated with a great many inflammatory symptoms; for which reason it was generally found necessary to open a vein in the beginning. The verbal and later autumnal remitting fevers are accompanied with pleuritic and rheumatic pains from the coldness of the weather, and on that account require more bleeding. A physician unacquainted with the nature of the disease, and attending chiefly to the paroxysms and remission would be apt to omit this evacuation entirely, and give the bark too soon, which would bring on a continued inflammatory fever. In these countries a vein may be safely opened either during the remission or in the height of a paroxysm; and our author also found good effects resulting from bleeding in the hot fits of the marsh-fever, even after it had almost come to regular intermissions. After bleeding a purgative was usually exhibited, of which he gives us the following formula.

R. Infiţi fæce commun. ʒ.iij.
Elefl. Leminiv. ʒ.ii.
Nitr. pur. ʒi
Tinœ. fæ. ʒ.ii. M.

Of this only one half was taken at once: and if it did not operate twice in four hours, the remainder was then taken. This potion agreed with the flow, much, purged plentifully, and therefore was a very useful composition. Next morning, when there was almost always some remission, he gave one grain of emetic tartar rubbed with 2 grains of crabs-eyes, and repeated the dose in two hours, if the first had little or no effect; or at any rate in four hours. This medicine was intended not only to vomit, but also to operate by stool, and excite a sweat. If these evacuations were procured, the fever generally became easier, and was even sometimes cured. This he prefers to the ipecacuanha, and therefore in the latter years of his practice infused that root entirely. The same medicine was repeated next day or the day following; or if
not, a laxative clyster was thrown in: and this method was continued till the fever either went off altogether, or intermitted in such a manner as to be cured by the bark.

A similar method was followed by Dr Huck in the remitting fevers of the West Indies and North America. In the beginning he let blood; and in the first remission gave four or five grains of ipecacuanha, with from half a grain to two grains of emetic tartar. This powder he repeated in two hours, taking care that the patient should not drink before the second dose; for then the medicine more readily passed into the bowels after it had operated by vomiting. If after two hours more the operation either way was small, he gave a third dose, which commonly had a good effect in opening the first passages; and then the fever either went quite off, or intermitted in such a manner as to yield to the bark. On the continent, he found little difficulty after the intermission; but in the West Indies, unless he gave the bark upon the very first intermission, though imperfect, the fever was apt to assume a continued and dangerous form.

In the remitting fevers of hot countries, however, it must be observed, that the lancet must in all cases be much more sparingly used than in similar diseases of the colder regions; and we must also be sparing of venesection in those countries where the marsh effusions are very strong and prevail much. For this reason Dr Lind of Halifax greatly condemns the practice of indiscriminate bleeding when people first arrive in hot climates. The first diseases indeed which occur in a voyage to the southward are for the most part of an inflammatory nature, and owing to a sudden transition from cold to hot weather. This occasions a fulness and dilatation of the vessels; whence all Europeans, on their first arrival under the tropic, bear evacuations much better than afterwards. The practice of indiscriminately bleeding, however, a number of the ship's company when they first come into a warm latitude, is by no means found to answer the purpose of a preventive. In such cases, indeed, as plainly indicate a plethoric disposition brought on by the heat, blood-letting is certainly useful. The signs of this are a pain and giddiness in the head; a heaviness and dulness of the eyes, which sometimes appear slightly inflamed; there is also commonly a sense of weight and fulness in the breast; the pulse at the same time being quick and oppressed.

But the case is quite different after a longer continuance of sultry weather, and when the constitution is in some measure habituated to the hot climate. For it is then observed, that the symptoms of inflammations in the bowels, even the most dangerous, are not near so severe in such climates as in cold countries; nor can the patients bear such large evacuations. The physician, however, must take care not to be misled by the apparent mildness of the symptoms: for he will find, notwithstanding such deceitful appearances, that the inflammation makes a more rapid progress in hot countries than in cold, suppurations and morbidions being much more suddenly formed; and that in general all acute diseases come sooner to a crisis in the warm southern than in colder regions. Hence it is an important rule of practice in those climates, to seize the most early opportunity, in the commencement of all threatening inflammations, to make frequent though not copious evacuations by blood-letting. For by delaying the inflammation quickly passes from its first to its last or fatal stage; at least an imperfect crisis in such inflammatory fevers ensues, which fixes an obstruction in the viscera extremely difficult to remove.

It is indeed a general maxim with some physicians in the West Indies, that in most acute diseases bleeding in that country is prejudicial. This is founded upon a supposition that the cressamentum of the blood is thinned, and the solids greatly weakened, by the heat of the climate. It is therefore objected, that bleeding in such an habit of body weakens the powers of nature, and withdraws the strength which is requisite to support the patient until the crisis of the fever.

This reasoning is partly just; but, like all general maxims, will admit of exceptions. First with regard to sailors, it is to be remembered, that they are more exposed to quick vicissitudes of heat, cold, damp, and to various changes of the air and weather, than most of the other inhabitants of the Torrid Zone. Add to this, that their intemperance, and the excesses they are apt to fall into whenever it is in their power to commit them, render them more liable to inflammations than any other set of people. Hence their diseases require more plentiful evacuations than the inhabitants of those parts of the world, and generally they bear them better. But with regard to the natives of the country, or those who have remained long there, it must be proper to bleed them very sparingly, making a small allowance for the different feasons of the year, the temperature of the air, and the situation of the places where they reside. Thus, in some parts, even on the island of Jamaica, at particular seasons, the weather is cool; wherefore, in these places, and at such seasons, the inhabitants having their fibres more rigid, and a firmer crasis of their blood, bear venesection much better.

In cold countries the state of the air greatly assists in restoring the impaired spring of the fibres; whereas every thing alike in warm weather, such as heat, moisture, &c. concur to relax and weaken the habit of body. Thus we may daily see persons in Britain, after having suffered a most severe fit of sickness, recover their strength and spirits in a few days, and in a very short time their natural constitution. But the case is very different in the sultry regions of the Torrid Zone, or indeed in any part of the world where the heat of the season causes the mercury to stand on any length of time at the 77th degree and upward of Fahrenheit's thermometer. During such an excess of heat, debility after fevers is apt to remain with European constitutions for several months. In Jamaica, the convalescents are sent to the cool summits of the mountains; but a retreat to a more northern climate is often absolutely necessary to recover their wonted tone and vigour of body. It is a well-established observation, that the negroes and aborigines of the Torrid Zone cannot bear plentiful evacuations by the lancet. They commonly mix the most stimulans zones with their ordinary light food; and this is found by experience suitable to their constitutions.

As proper preventives for the dangerous fevers of which:
which we are treating, Dr Lind on all occasions recommends the avoiding of Ranciant water, or putrid marlhes; the use of proper food, cleanliness, and sobriety. Of the propriety of removing from the neighbourhood of those places whose pestidical effluvia produce the disorders, we cannot possibly entertain a doubt; and of the efficacy of proper food in preventing putrid disorders he gives a remarkable instance in the Sheerness man of war, bound to the East Indies. As they went out, the men being apprehensive of sickness in foing a voyage, petitioned the captain not to oblige them to take up their salt provisions, but rather to permit them to live upon the other species of their allowance. It was therefore ordered, that they should be served with salt-meat only once a-week; and the consequence was, that, after a passage of five months and one day, the ship arrived at the Cape of Good Hope without having a single person sick on board. As the use of Sutton's pipes had been then newly introduced into the king's ships, the captain was willing to afcribe part of such an uncommon healthfulness to their beneficial effects; but it was soon discovered, that, by the neglect of the carpenter, the cock of the pipes had been all this while kept shut. This ship remained in India some months, where none of the men, except the boat's crew, had the benefit of going on shore; notwithstanding which, the crew continued to enjoy the most perfect state of health; they were, however, well supplied with fresh meat. On leaving India, knowing they were to stop at the Cape of Good Hope, and trulling to a quick passage, and the abundance of refreshments to be had there, they eat their full allowance of salt-meats, during a passage of only 10 weeks; and it is to be remarked the air-pipes were now open. The effect of this was, that when they were arrived at the Cape, 20 of them were afflicted in a most miserable manner with scurvy and other disorders. These, however, were speedily recovered by the refreshments they met with on shore. Being now thoroughly sensible of the beneficial effects of eating, in these southern climates, as little salt meat as possible when at sea, they unanimously agreed, in their voyage home from the Cape, to refrain from their too plentiful allowance of salt flesh. And thus the Sheerness arrived at Spithead, with her full complement of 150 men in perfect health and with unbroken constitutions; having in this voyage of 14 months and 15 days buried but one man, who died in a merciful fulfilment.

Thus we see, that a free and pure air is not a sufficient preservative against a putrescent state of the fluids, without proper food; and, on the other hand, we have a very remarkable instance of the inefficacy of the most salutary food to prevent putrid diseases, in a very noxious state of the atmosphere. In the year 1717, at the siege of Belgrade in Hungary, the fever of the country, and the flux, occasioned a most extraordinary mortality among the troops. The dread of these diseases caused every one, as may naturally be supposed, to have recourse to different precautions for self-preservation. Prince Eugene, the commander in chief, had water and the provisions for his table sent him twice a-week from Vienna. The pure stream of the river Kahlenberg was regularly brought to him; he avoided all excusses, and lived regularly, or rather abstemiously; refreshed himself often by eating a cool makan, and mixed his usual wine, which was Burgundy, with water. Yet notwithstanding his utmost care, he was seized with a dysentery; which would have quickly put an end to his life, had not the speedy conclusion of that campaign permitted him to make a quick retreat.

At this unhealthy season, when hardly-one imperial officer, much less their several domestics, escaped those malignant diseases, the renowned Count Bonneval and his numerous retinue continued in perfect health, to the surprise, or, to use the words of Dr Kramer, to the envy, of all who beheld him. The only precaution he used was to take, two or three times a-day, a small quantity of brandy in which the bark was infused; and he obliged all his attendants and domestics to follow his example. It is no less remarkable that the count, placing his certain prevetation in the use of this single medicine, lived for many years afterwards in the most unhealthy spots of Hungary, without any attack or apprehension of disease; and continued to enjoy a perfect state of health during the hottest and most sickly seasons. And thus, with an unbroken and found constitution, which is seldom the case of those who reside long in such climates, he lived to a great age. There is an instance produced by the fame author of a whole regiment in Italy having been preserved by the use of the bark from the attack of those malignant diseases, viz. the flux, and Lilis fever as it is frequently called, when the rest of the Austrian army, not pursuing that method, became greatly annoyed with them.

The intemperance and irregular living of those Europeans who visit the hot climates is frequently accused as the cause of their destruction; but, our author thinks, without sufficient reason: for though intemperance will make the body more liable to receive such diseases, it will not bring them on. It must by no means, however, be imagined, that in these climates Europeans may with impunity be guilty of excesses in eating or drinking; for the least error in that way will often prove fatal by debilitating the body, whose utmost strength in time of full health was perhaps scarce sufficient to resist the pestilential miasmas of the atmosphere.

It appears, therefore, from the concurrent testimony of the most eminent physicians, that the most proper medicine to be used, either as a preventive or cure for remitting and intermitting disorders is the Peruvian bark, administered with proper precautions, and after the prime use have been evacuated of the putrid biliary matter collected in them. In those species of *triaephoxy,* &c. belonging to this class, enumerated by Sauvages, the fame remedies only were useful; but in that pestilential diitterem which he calls *triaephoxy Priaflavienis,* he tells us, that washing the body with water sometimes hot sometimes cold, watery clysters, and plenty of aqueous drink, were likewise of use.

**Genus II. Quartan Fever.**

|--------------|--------------------------------------------------|

**Description**
The genuine quartan, according to Juncker, keeps its form more exactly than other intermittents; scarcely coming on at any other time than four or five in the afternoon. The cold is less violent than in the tertian; but is very perceptible, though it do not proceed to such a height as to make the limbs shake; and continues for about two hours. It is preceded and accompanied by a languid both of body and mind. There is seldom any vomiting unless when the stomach is manifestly overloaded with aliment; neither is there any diuresis, but the belly in general is rather bound, not only on the days on which the paroxysm takes place, but also on the intermediate ones. The heat, which swiftly succeeds the cold, is less troublesome to the patient by its violence than by the uneasy dryness of the skin, which is scarce ever moistened with sweat. This heat rarely continues longer than four or six hours, unless perhaps at the first or second paroxysm. It is accompanied also with a giddiness and dull pain of the head. On the termination of the paroxysm, the patient returns to a middling state of health, and continues in the same for the rest of the intermediate days; only there remains something of a loathing, and a deep-felt pain as if the person was all over bruised or broken, which kind of inflammation the physicians are wont to call postparoxysmus. The fit returns every fourth day, and that precisely at the same hours, being rarely postponed.

Causes of, and persons subject to, this Disorder. The same general causes concur in producing this as in other intermittents, namely, marsh miasmata, and whatever can duple the body to be easily affected by them. Studious people, and those of a melancholic turn, are said to be particularly subject to quartans; but what are the immediate causes which produce a return of the fits every fourth day, instead of every day, or every third day, must probably lie for ever concealed, as depending upon the secret and inexplicable mechanism of the human body.

Pregnomy. A simple quartan, where there is no reason to dread any induration of the viscera, may very certainly admit of a cure; and the prognosis can never be unfavourable, unless in cases of extreme weakness, or where the diætemper has been unskillfully treated.

Cure. This does not in the least differ from that which hath been fully laid down for the simple tertian, and which it is needless therefore to repeat here.

The Duplicated QUARTAN. Sp. I. var. 1. B Quarta duodecima, Sayw. sp. 4. Bonet. This is entirely similar to the duplicated tertian already mentioned; proper allowance being made for the difference between the type of a tertian and quartan.

The TRIPLED QUARTAN. Sp. I. var. 1. C. Quartana triplicata, Sayw. sp. 16. This hath three paroxysms every fourth day, while the intermediate days are entirely free from fever.

The Double QUARTAN. sp. I. var. 1. D. Quarta duodecima, Sayw. sp. 13, Voss. sp. 13. In the double quartan, the fits come on every day except the third; but so that the first paroxysm answers to the third, the second to the fourth, and so on.
MEDICINE.

Sect. II. CONTINUED FEVERS.

The Genuine QUOTIDIAN. Sp. i. var. i. A.

The Partial Quotidian. Sp. i. var. i. B.

The Remitting Quotidian. Sp. II.

Concerning these all nothing remains necessary to be mentioned in this place, having already so fully discussed the remitting fevers in all the different parts of the world. Many other varieties of these fevers mentioned by different authors are to be accounted merely symptomatic.

The Genuine QUOTIDIAN. Sp. i. var. i. A.

The Partial Quotidian. Sp. i. var. i. B.

The Remitting Quotidian. Sp. II.

Concerning these all nothing remains necessary to be mentioned in this place, having already so fully discussed the remitting fevers in all the different parts of the world. Many other varieties of these fevers mentioned by different authors are to be accounted merely symptomatic.
of certain humours; wounds, fractures, luxations, &c.; so that in general we may reckon every thing tending to increase the action of the arterial sytem to be in certain circumstances a cause of inflammatory fever.—Hence we find those are most subject to the synocha whose constitution is either naturally robust, or who are exposed to those cause which tend to produce an increased action of the arterial sytem; such as hard labour, high living, &c.

Prognosis. The most simple kind of synocha, that is, the ephemera or diary fever, is commonly cured without the assistance of medicine, and therefore the prognosis is for the most part favourable; yet, if it be improperly treated by heating medicines, it may easily be converted into the other kind; or, if there be a putrid disposition of the fluids, into a fever of a very dangerous nature. The same thing is to be understood even of the most violent kind; for simple inflammatory fevers are not dangerous unless complicated with an affection of some particular part, as the pleura, stomach, &c.

Dr. Cullen objects to the plan of those who are for leaving the cure of continued fevers to the operations of nature; because these operations are neither certain in themselves, nor are they so well understood as to enable us to regulate them properly; and it is likewise possible to supercede them by art. The plan therefore on which he proceeds is, to form his indications of cure upon the means of obviating the tendency to death in fevers; and these he reduces to three.

1. To moderate the violence of re-action.
2. To remove or obviate the causes of debility; and,
3. To obviate or correct the tendency of the fluids to putrefaction.

The first indication may be answered, 1. By all those means which diminish the action of the heart and arteries. 2. By those which take off the spasm of the extreme vessels, which, according to his theory, is the chief cause of violent re-action.

The action of the heart and arteries may be diminished, 1. By avoiding or moderating those irritations which, in one degree or other, are almost constantly applied to the body. 2. By the use of certain sedative powers. 3. By diminishing the tension or tone of the arterial sytem.

The second method of moderating the violence of re-action is by the employment of certain sedative powers, with a view to diminish the activity of the whole body, and particularly that of the sanguiferous sytem. The first of these to be mentioned is the application of cold. Heat is the chief support of the activity of the animal-sytem; and the sytem is therefore provided with a power of generating heat in itself; but at the same time we may observe, that this would go to excess, were it not constantly moderated by a cooler temperature in the surrounding atmosphere. When, therefore, the generating power of heat in the sytem is increased, as is commonly the case in fevers, it is necessary not only to avoid all further means of increasing it, but also to apply air of a cooler temperature; or at least to apply it more entirely and freely than in a state of health. This is shown, from some late observations, to be a very powerful means of moderating the violence of re-action; but what is the mode of its operation, to what circumstances of fever it particularly applies, or what limitations it requires, are not yet fully ascertained.

Another sedative power very frequently employed in fevers, is that of certain medicines known in the materia medica by the name of refrigerants. The chief of these are acids of all kinds when sufficiently diluted, and which are, in several respects, remedies adapted to continued fevers. Those especially in use...
are the vitriolic and vegetable; and on many accounts the latter are to be preferred. Another set of refrigerants are the neutral salts formed of the vitriolic, nitrous, or vegetable acids, with alkalies either fixed or volatile. All these neutrals, while they are dissolved in water, generate cold; but as that cold ceases soon after the dissolution is finished, and as the salts are generally exhibited in a dissolved state, their Refrigerant power in the animal body does not all depend upon their power of generating cold with water. Nitre is the refrigerant chiefly employed; but all the others, compounded as abovementioned, partake more or less of the same quality. Besides these neutrals, some metallic salts have also been employed in fevers, particularly the sugar of lead: but the Refrigerant powers of this salt are by no means ascertained, and its deleterious qualities are too well known to admit of its being freely used.

[3.] The third general method of diminishing the reaction of the system, is by leaching the tension, tone, and activity of the sanguiferous system. As the activity of the system in a great measure depends upon the tone, and this again upon the tension, of the vessels, given to them by the quantity of fluids they contain, it is evident, that the diminution of the quantity of these mull diminish the activity of the sanguiferous system. The most efficacious means of diminishing the quantity of fluids is by the evacuations of blood-letting and purging. The former is evidently one of the most powerful means of diminishing the activity of the whole body, and especially of the sanguiferous system; and it mull therefore be the most effectual means of moderating the reaction in fevers. When the violence of reaction, and its constant attendant a Phlogistic diathesis, are sufficiently evident; when these constitute the principal part of the disease, and may be expected to continue through the whole of it, as in the cases of Synocha; then blood-letting is the principal remedy, and may be employed as far as the symptoms of the disease may seem to require, and the constitution of the patient will bear. It mull, however, be remarked, that a greater evacuation than is necessary may occasion a fever recovery, and render the person more liable to a relapse, or bring on other diseases. It is also to be observed, that this evacuation is more effectual, as the blood is more suddenly drawn off, and as the body is at the same time more free from all irritation, and therefore when it is in a posture in which the fewest muscles are in action.

With regard to purging, when we consider the quantity of fluids constantly present in the cavity of the intestines, and the quantity which may be drawn off from the innumerable excretories that open into this cavity, it will be obvious, that a very great evacuation may be made in this way; and if this be done by a stimulus that is not at the same time communicated to the rest of the body, it may, by emptying both the cavity of the intestines and the arteries which furnish the excretions poured into it, induce a considerable relaxation in the whole system; and is therefore fitted to moderate the violence of reaction in fevers. But it is to be observed, that as the fluid drawn from the excretories opening into the intestines is not all drawn immediately from the arteries, and as what is even more immediately drawn from these is drawn off slowly; so the evacuation will not, in proportion to its quantity, occasion such a sudden depletion of the fluids as blood-letting does; and therefore cannot act so powerfully in taking off the phlogistic diathesis of the system.

At the same time the evacuation may induce a considerable degree of debility; and therefore, in those cases in which a dangerous state of debility is likely to occur, purging is to be employed with a great deal of caution; and this caution is more difficult to be observed than in the case of blood-letting: and it is further to be noticed, that as purging takes off in some measure the determination of the blood to the vessels on the surface of the body, it seems to be an evacuation not well adapted to the cure of fevers.

II. The other method of moderating the violence of reaction in fevers is by the exhibition of those remedies suited to take off the spasm of the extreme vessels, supposed to be the irritation which chiefly supports the reaction. The means to be employed for this purpose are either internal or external.

Firft, The internal means are, 1. Those which determine the force of the circulation to the extreme vessels, on the surface of the body, and, by restoring the tone and activity of these vessels, overcome the spasm on their extremities. 2. Those medicines which have the power of taking off spasm in any part of the system, and which are known under the title of Antispasmodics.

(i.) Those remedies which are fit to determine to the surface of the body are, 1. Dluaments. 2. Neutral salts. 3. Sudorifics. 4. Emetics.

1. Water enters, in a large proportion, into the composition of all the animal fluids, and a large quantity of it is always diffused through the whole of the common mafs. In a sound state, the fluidity of the whole mafs depends upon the quantity of water present in it. Water is therefore the proper diluent of our mafs of blood, and other fluids are dilute only in proportion to the quantity of water they contain.

In a healthy state, also, the fulness of the extreme vessels and the quantity of excretion are in proportion to the quantity of water present in the body. But in fever, though the excretions be in some measure interrupted, they continue in such quantity as to exchale the more fluid parts of the blood; and, while a portion of them is at the same time necessarily retained in the larger vessels, the smaller, and the extreme vessels, both from the deficiency of fluid and their own contracted state, are less filled, and therefore allowed to remain in that condition. To remedy this contracted state, nothing is more necessary than a large supply of water or watery fluids taken in by drinking or otherwise; for as any superfluous quantity of water is forced off by the several excretories, such a force applied may be a means of diluting the extreme vessels, and of overcoming the spasm affecting the extremities. Accordingly, the throwing in of a large quantity of watery fluids has been, at all times, a remedy much employed in fevers; and in no instance more remarkably than by the Spanish and Italian physicians, in the use of what they call the dieta aqua. This practice consists in taking away every other kind of aliment and drink, and in giving, in divided portions,
M E D I C I N E.

Practice.

every day for several days together, fix or eight pounds of plain water, generally cold, but sometimes warm. All this, however, is to be done only after the disease has continued for some time, and at least for a week.

7. A second means of determining to the surface of the body, is by the use of neutral salts. These neutrals, in a certain dose, taken into the stomach, produce soon after a sense of heat upon the surface of the body; and, if the body be covered close and kept warm, a sweat is readily brought out. The same medicines taken during the cold stage of a fever, very often put an end to it, and bring on the hot one; and they are also remarkable for stopping the vomiting which so frequently attends the cold stage of fevers.

All this shows, that neutral salts have more or less of the same virtue; and perhaps some of them, particularly the ammoniacal salts, possess it in a stronger degree. As cold water taken into the stomach often shows the same diaphoretic effects with the neutral salts, it is probable that the effect of the latter depends upon their refrigerant powers.

3. A third method of determining to the surface of the body, and taking off the ipam which subsists there in fevers. The neutral most commonly employed in fevers, is that formed of an alkali with the native acid of vegetables. But all the other neutrals have more or less of the same virtue; and perhaps some of them, particularly the ammoniacal salts, possess it in a stronger degree. As cold water taken into the stomach often shows the same diaphoretic effects with the neutral salts, it is probable that the effect of the latter depends upon their refrigerant powers.

3. That, when excited by art, is has been found useful at certain periods, and in certain species of fever.—On the other hand, it may be urged against the practice of sweating. 1. That in fevers, as a spontaneous sweating does not immediately come on, there are some circumstances different from those in the state of health, and which may render it doubtful whether the sweating can be safely excited by art. 2. That in many cases the practice has been attended with bad consequences. The means commonly employed have a tendency to produce an inflammatory diathesis; which, if not taken off by the sweat proceeding, must be increased with much danger. Thus sweating employed to prevent the accessions of intermittent fevers has often changed them into a continued form, which is always dangerous. 3. The utility of the practice is doubtful, as sweating, when it happens, does not always give a final determination, as must be manifest in the case of intermittent; and in many continued fevers which are sometimes in the beginning attended with sweatings which do not prove final; and, on the contrary, whether they be spontaneous or excited by art, they seem often to aggravate the disease.

From these considerations, it is doubtful if the practice of sweating can be admitted very generally; but, at the same time, it is also very doubtful if the failure of the practice, or the mischief thus to avoid from it, have not been owing to the improper conduct of the practitioner. With respect to the last, it is almost agreed among physicians, 1. That sweating has been generally hurtful when excited by stimulant, heating, and inflammatory medicines. 2. That it has been hurtful when excited by much external heat, and continued with a great increase of the heat of the body.

In these cases, it is probable, that either an inflammatory diathesis is produced, which increases the ipam on the extreme vessels; or that, from other causes, the ipam is too much fixed to yield easily to the increased action of the heart and arteries; and upon either supposition it must be obvious, that urging the sweat may produce determinations to some of the internal parts, with very great danger.

Notwithstanding these doubts, however, it still remains true, 1. That sweating has been often useful in preventing the accessions of fevers when they have been certainly foreseen, and a proper conduct employed. 2. That even after fevers have in some measure come on, sweating has interrupted their progress when properly employed, either at the very beginning of the disease, or during its approach and gradual formation. 3. That even after pyrexia have continued for some time, sweating has been successfully employed in curing them, as is particularly exemplified in the case of a rheumatism. 4. That certain fevers produced by a very powerful sedative contagion, have been generally treated most successfully by sweating.

These instances are in favour of sweating, but give no general rule; and it must be left to further experience to determine how far any general rule can be established in this matter. In the mean time, if the practice of sweating is to be attempted, the following rules may be laid down for the conduct of it. 1. That a sweat should be excited without the use of stimulant inflammatory medicines. 2. That it should be excited with as little external heat, and with as little increase of the heat of the body as possible. 3. That, when excited, it should be continued for a due length of time; not less than 12 hours, and sometimes for 24 or 48 hours; always, however, supposing that it proceeds without the dangerous circumstances already mentioned. 4. That for some part of the time, and as long as the person can easily bear, it should be carried on without admitting of sleep. 5. That it should be rendered universal over the whole body; and therefore particularly that care should be taken to bring the sweating to the lower extremities. 6. That the practice should be rendered safer by moderate purging excited at the same time. 7. That it should not be suddenly checked by cold any how applied to the body.

When attention is to be given to these rules, the sweating may be excited, 1. By warm bathing, or a fomentation of the lower extremities. 2. By frequent draughts of tepid liquors, chiefly water, rendered more grateful
grateful by the addition of a light aromatic, or more powerful by that of a small quantity of wine. 3. By giving some doses of neutral salts. 4. Moit effectually, and perhaps most safely, by a large dose of an opiate, joined with a portion of neutral salts, and of an emetic.

The fourth mean of determining to the surface of the body, and thereby taking off the spasm affecting the extreme vessels, is by the use of emetics. Their, particularly of the antimonial kind, have been employed in the cure of fevers ever since the introduction of chemical medicines; and though of late their use has become very general, their efficacy is still diffused, and their manner of operating is differently explained.

Vomiting is in many respects useful in fevers; as it evacuates the contents of the stomack, as it enuleges the biliary and pancreatic ducts, and evacuates the contents of the duodenum, and perhaps also of a larger portion of the intestines; as it agitates the whole of the abdominal visceras, it expedites the circulation in them, and promotes their several secretions; and lastly, as it agitation the visceras of the thorax, it has like effects there.

It is not to this cause, however, that we are to impute the effect of vomiting has in determining to the surface of the body. This must be attributed to the particular operation of emetics upon the mucular fibres of the stomack, whereby they excite the action of the extreme arteries on the surface of the body, and this means effectually determine the blood to these vessels, remove the atony, and take off the spasm affecting them. For this purpose they are exhibited in two different ways; that is, either in such doses as may excite full and repeated vomitings, or in such doses as may excite sickness and nausea only, with little or no vomiting at all.

Full vomiting is well suited to determine to the surface of the body, and therefore to obviate the atony and spasm which lay the foundation of fever. Thus, vomiting excited a little before the expected accession of the paroxysm of an intermittent, has been found to prevent the paroxysm altogether. It has been observed also, that when contagion has been applied to a person, and if it discovers its operation, a vomit given has prevented the fever which might otherwise have been expected.

There are the advantages to be obtained by exciting vomiting at the first approach of fevers, or of the paroxysm of fevers; and they may also be applied after fevers are formed, to take off, perhaps entirely, the atony and spasm, or at least to moderate them, so that the fever may proceed more gently and safely. It is seldom, however, that vomiting is found to produce a final solution of fevers; and after they are once formed, it is commonly necessary to repeat the vomiting several times; but this is attended with inconvenience, and sometimes with disadvantage. The operation of full vomiting is transitory, and the exercise of vomiting is a debilitating power; and therefore, when the vomiting does not remove the atony and spasm very entirely, it may give occasion to their recurrence with greater force. For these reasons, after fevers are fully formed, some physicians have thought proper to employ emetics in nauseating doses only. These are capable of exciting the action of the extreme vessels, and their operation is more permanent. At the same time they often show their power: by exciting some degree of sweat, and their operation is rendered more safe by their commonly producing some evacuation by stool. But nausea continued for any great length of time, is to moit patients a fenfation highly distasteful, and almost insufferable.

The emetics chiefly in use at present are, ipecacuanha and antimony. The former may be employed for determining to the surface of the body: but, even in very small doses, it do readily excites vomiting, that it is with difficulty employed for the purpose of nauseating only; and in whatever manner employed, there is reason to suspect that its effects are left permanent, and left powerfully communicated from the stomack to the rest of the system, than those of antimony. This last is therefore generally preferred; and its preparations, seemingly various, may all be reduced to two heads; one comprehending those in which the reguline part is in a condition to be acted upon by acids, and therefore on meeting with acids in the stomack it becomes active; and another, comprehending those preparations in which the reguline part is already joined with an acid, rendering it active. Of each kind there are great numbers, but not differing essentially from one another; the two most worthy of notice are, the calx nitrata antimonii and emetic tartar or antimonium tartarifatum, of the Edinburgh dispensatory. Both these are very efficacious medicines; but the latter seems preferable, because its dose is capable of being better CERTAINT; though the former, on account of its slower operation, may have some advantages, and in certain cases be more efficacious as a purgative and sudorific.

The calx nitrata antimonii, when first introduced into the pharmacopoeia of the Edinburgh college, was supposed to be very nearly, if not precisely, the same with a medicine which has of late been highlycelebrated in the cure of fevers, Dr James's powder. But from later and more accurate observations, there is now reason to believe that the pulvis antimonialis of the London pharmacopoeia, formed by the calculation of antimony with hartsthorn, approaches more nearly to that celebrated arcanum. But at any rate, the calx antimonii nitrata, the pulvis antimonialis, and James's powder, are probably not essentially different from each other. The two latter, however, have the most near resemblance; and accordingly the Edinburgh college in the laft edition of their pharmacopoeia have introduced an article under the title of antimonium calcaris phosphoratum, which they consider as so much fimilar to James's powder, that they have used it as a synonyme, for the title of pulvis Jacobi.

The time most proper for exhibiting these medicines is a little before the accession, when that can be certainly known. In continued fevers the exacerbations are not always very observables; but there is reason to believe, that one commonly happens about noon or noon after it; and that these, therefore, are the most proper times for exhibiting emetics.

With respect to the manner of administration, that of the calx nitrata is simple, as the whole of what is thought a proper dose may be given at once; and no more can be properly given till the next accession. The administration of the emetic tartar is different. It is to be given in small doses, not sufficient to excite vomiting.
M E D I C I N E.

Typhus.

Practice.

Fevers of the skin; and these doses are to be repeated after short intervals for several times, till sickness, nausea, and vomiting come on. The difference of administration must depend upon the dose, and the length of the interval at which it is given. If it be intended that the medicine should certainly penetrate by flood, the doses are made small, and the intervals long. On the contrary, when vomiting is proper, or when much purging ought to be avoided, and therefore some vomiting must be admitted, the doses are made larger, and the intervals shorter. With respect to both kinds of preparations, the repetition is to be made at the times of accession, but not very often: for if the first exhibitions, duly managed, have little effect, it is seldom that the after exhibitions have much; and it sometimes happens that the repeated vomiting, and especially repeated purging, does harm by weakening the patient.

(2.) The other fact of internal medicines which are frequently useful in taking off the spasm of the extreme vessels, is that named antispasmodic. But whatever may be the virtues of some of them in this way, such is their power of stimulating at the same time, that very few of them can with safety be administered in fevers of an inflammatory nature. Almost the only one which can with safety be exhibited in these cases is camphor; and the operations of this are by no means well ascertained. Dr. Huxham mentions it as a correc- tor of the acrimony of cantharides; and affirms us, that it very effectually promotes a diaphoreis. But from the remarks of other practitioners, we have no just reason to suppose that it acts perceptibly in a dose of five or six grains, though in 15 or 20 it produces a particular kind of intoxication:

Secondly. The external means suited to take off the spasm of the extreme vessels, are blistering and warm bathing.

1. What are the effects of blistering so frequently employed in fevers, is not yet agreed upon among physicians. Dr. Cullen is of opinion, that the small quantity of cantharides absorbed from a blistering plaister, is not sufficient to change the confidence of the mafs of blood; and therefore, that such a quantity can neither do good by resolving phlegmatic fentor if it exists, nor do harm by increasing the dissolution of the blood arising from a putrid tendency in it. The effects of cantharides upon the fluids, therefore, may be entirely, neglected. The inflammation produced by the application of cantharides to the skin, affords a certain proof of their stimulant power: but in many person the effect of that stimulus is not considerable; in many it is not communicated to the whole fystem; and even when it does take place in the whole fystem, it seems to be taken off very entirely by the evaporation and evacuation of furm from the blistered part. It may be concluded, therefore, that neither much good is to be expected nor much harm to be apprehended, from the stimulant power of blistering; and the certainty of this conclusion is established by the great benefit arising from the proper practice of blistering in inflammatory diseases. Much has been imputed to the evacuation made by blistering; but it is never so considerable as to affect the whole fystem; and there can neither be a sudden deploration relax the subcutaneous fystem, nor by any

revulsion affect the general distribution of the fluids. The evacuation, however, is so considerable as to cause a little swelling about it, and the manifest utility of blistering near the paraffected inflammatory diseases leads us to think, that blistering, by deriving to the skin, and producing and effusion there, relaxes the spasm of the deeper vessels. It is in this manner, most probably, that the tumor of a joint, from an effusion into the cellular textures under the skin, takes off the rheumatic pain formerly affecting that joint. Analogous to this, probably, is the good effect of blistering in continued fevers; and arises from the relaxation of the spasm of the extreme vessels by a communication of the blistered part with the rest of the skin. A blister may be employed at any period in continued fevers; but it will be of most advantage in the advanced state of such fevers, when the re-action being weaker, all ambiguity from the stimulating power of blistering is removed, and when it may best coincide with other circumstances tending to a final solution of the spasm.

From this view of the matter, it will appear, that the part of the body to which blisters ought to be applied is indifferent, except upon the suspicion of topical affection, when the blistering is to be made as near as possible to the part affected. Whether sinapisms and other rubefcentia act in a manner analogous to what has been supposed of blistering may be doubtful; but their effects in rheumatism and other inflammatory diseases render it probable.

2. The other external means of taking off the spasm of the extreme vessels is warm bathing. This was frequently, and in different circumstances, employed by the ancients; but has, till very lately, been neglected by modern physicians. As the heat of the bath stimulates the extreme vessels, and, with the concurrence of moiture, also relaxes them, it seems to be a fain stimulus, and well suited to take off the spasm affecting these vessels. It may be applied to the whole body by immersion; but this is in many respects inconvenient; but whether some of the inconveniences of immersing might not be avoided by a vapour-bath, is not yet determined by experience; but from extensive experience it appears, that most of the purpofes of warm bathing can be obtained by a fomentation of the legs and feet, if properly administered, and continued for a due length of time, not less than an hour. The marks of the good effect of such a fomentation are, the patient's bearing it easily, its relieving delirium, and inducing sleep.

Fever, or Typhus. --v----

Typhus, Savin, fp. 10.

Typhus comatus, Savin, fp. 3.

Trizephyra typhodes Mangeti, Savin, fp. 19. Raym.

The fever, or Typhus, is a disorder of the nervous system, characterized by delirium, headache, and general debility.

Description.

The symptoms of the fever, or Typhus, are

1. Delirium, affecting the patient in various ways.

2. Headache, usually located in the back or top of the head.

3. Nausea and vomiting.

4. Rigors and chills.

5. Pain and coldness in the extremities.

6. Restlessness and agitation.

7. Loss of appetite.

8. Changes in the skin, such as blisters or eruptions.

The fever is often accompanied by a rise in temperature, and the patient may experience delirium, confusion, or disorientation.

The fever, or Typhus, is a contagious disease, and precautions should be taken to prevent its spread.
Practice.

MEDICINE.

out of much affecting the state of the blood or juices, though the latter are greatly affected in the putrid malignant fevers.

In nervous fevers, the prognosis is very much the fame as that with the putrid malignant kind. And although death be not so frequent as in that modification of fever, yet it may justly be considered as a very fatal disease.

Cure. As this fever is produced by a contagion affecting the nervous fystem of a person already debilitated, and thus producing weaknees in an extreme degree, we have now occasion to consider Dr Cullen's two indications of cure omitted under the Synoeha; namely, to remove the caufe and obviate the effects of debility, and to correct the putrifent tendency of the fluids; for though, in the beginning of nervous fevers, the tendency to putrefaction be not remarkablc, it becomes exceedingly great towards their conclusion.

As in anfwering the first indication, Dr Cullen observes, that most of the fedative powers inducing debility cease to act foon after they have been applied; and therefore the removing of them is not an object of the prefent indication. There is only one which may be fuppofed to continue to act for a long time, and that is the contagion applied; but we know nothing in the nature of contagion that can lead us to any measures for removing or correcting it. We know only its effects as a fedative power inducing debility, or as a ferment inducing a tendency to putrefaction in the fluids, the former of which at prefent falls under our consideration. The debility induced in fevers by contagion, or other caufes, appears especially in the weaker energy of the brain; but in what this conftits, or how it may be reftored, we do not well know; but as nature, seemingly for this purpofe, excites the motion of the heart and arteries, we muft attribute the continuance of the debility to the weaker re-action of the fanguiferous fystem: the means, therefore, which we employ for obviating debility, are immediately directed to fupport and increase the action of the heart and arteries; and the remedies employed are tonics or fimi­lants.

In contagious difeafes we know, both from the effects which appear, and from diffeffections, that the tone of the heart and arteries is considerably diminished; and that tonic remedies are therefore properly indicated. We are to consider these remedies as of two kinds; 1. The power of cold; 2. That of tonic medicines.

The power of cold as a tonic in fevers may be employed in two ways: either as thrown into the stomach, or as applied to the surface of the body. As we have already obferved that the power of cold may be communicated from any one part to every other part of the fystem, fo it will be readily allowed that the ftomach is a part as fitt as any other for this communication, and that cold drink taken into the ftomach may prove an useful tonic in fevers. This the experience of all ages has confirmed; but at the fame time it has been frequently obferved, that, in certain circumstances, cold drink taken into the ftomach has proved very hurtful; and therefore that its ufe in fevers requires fome limitations. What these limitations should be, and what are the circumftances which may forbid the ufe of cold drink, it is difficult to determine; but it seems clearly forbidden in all cafes where a phlogifit diathesis prevails in the fystem, and more efpecially when there are topical affections of an inftammatory nature.

The other method of employing cold as a tonic, is by applying it to the surface of the body, as a refrigerant power fit to moderate the violence of re-action; but probably it may here also be considered properly as a tonic, and useful in cafes of debility. Not only cool air, but cold water alfo may be applied to the surface of the body as a tonic. The ancients frequently applied it with advantage to particular parts as a tonic; but it is a discovery of modern times, that, in the cafe of putrid fevers attended with much debility, the body may be washed all over with cold water. This was firft practiced at Breflaw in Silefia, as appears from a difcourfe under the title of Epidemia Verna, que Wafterflauam anno 1737 of­fer­tis est, & ad usus medicos muta­l: 1. This increa­fed the circulation of blood; and a general debility was not fo frequent.

The medicines which have been employed in fevers as tonics are various. If the faccharum faturi hath been found ufeful, it is probably as a tonic rather than as a refrigerant; and the caracxi, or other preparations of iron which have been employed, can act as tonics only. The preparations of copper, from their effects in epilepsy, are presumed to proffefs a tonic power; but whether their ufe in fevers be founded on their tonic or emetic powers, is uncertain.

The bark has commonly been considered as a specific, or a remedy of which the operation was unfound. We muft obferve, however, that, as in many cafes the effects of the bark are perceived foon after its being taken into the ftomach, and before it can poibibly be conveyed to the mafs of blood, we may conclude, that its effects do not arife from its operating on the fluids; and mutt therefore depend upon its operating on the nerves of the ftomach, and being thereby communicated to the reft of the nervous fystem. This operation seems to be a tonic power, the bark being a remedy in many cafes of debility, particularly in gangrene; and if its operation may be explained from its poffeffing a tonic power, we may easily perceive why it is improper when a phlogifit diathesis prevails; and from the fame view we can acertain in what cafes of continued fever it may be admitted. These cafes are either where coniderable remissions have appeared, when it may be employed to prevent the return of exacerbations, on the fame footing as it is ufed in intermitting fevers; or in the advanced flate of fevers, when all fufpicion of an inftammatory flate is removed, and a general debility prevails in the fystem; and its being then employed is sufficiently agreeable to the prefent practice.

Another fet of medicines to be employed for obviating debility and its effects, are the direft fimul­lants.
MEDICINE.

Febre. Thefe, in some meafure, increafe the tone of the moving fibres; but are different from the tonics, as they more directly excite and increafe the action of the heart and arteries. This mode of their operation renders their ufe ambiguous; and when an inflammatory diathesis is prefent, the effects of the stimulants may be very hurtful; but it is ftill probable, that in the advanced state of these fevers, when debility prevails, they may be ufeful.

Of all the stimulants which may be properly employed, wine feems to be the moft eligible. It has the advantage of being grateful to the palate and stomach, and of having its stimulant parts fo much diluted, that it can be conveniently given in small doses; and therefore it may be employed with fufficient caution; but it is of little service unlefs taken pretty largely.—It may be influfped that wine has an operation analogous to that of opium; and on good grounds. But we can pretty largely.—It may be

operation analogous to that of opium; and on good
delirium manifefHy hurtful; and in the mild
cure, namely to
the fluids to
matter already prefent in the body. 3. By
the violence of
tone of the
by diluents and antifeptics. 4. By fupporting the

The progrefs of
putrefaction. -
ber. 4. By avoiding
accumulation of the patients own effluvia, by a confiant
removal of all excremental matters from the patient's
and body-linen.
The putrid or putrefcent matter already prefent
may be evacuated partly by frequent
and various

and innocent by the ufe of diluents, or may be
which

are of many
applicable, or more particularly fuited to the cafe of
as already mentioned. The violence
of re-action, confidered as a means of increafing
putrefaction.
The further application of putrid or putrefcent matter
may be avoided, 1. By removing the patient from
places filled with corrupt air. 2. By preventing the
accumulation of the patients own effluvia, by a conflant
ventilation, and by a frequent change of bed-clothes
and body-linen. 3. By the careful and speedy removal
of all excremental matters from the patient's chamber.
4. By avoiding animal-food.
The putrid or putrefcent matter already prefent in the
body, may be evacuated partly by frequent
exafinations of the contents of the intestines; and more
effentially by influffing the exfcreta of diluents. That
which remains in the body may be rendered more mild
and innocent by the ufe of diluents, or may be corrected
by the ufe of antifeptics. Thisleft are of many
and various kinds; but which of them are conveniently
applicable, or more particularly fufet to the cafe of
fevers, is not well ascertained. Thofe most certain
applicable and ufeful are acetic aliments, acids of
all kinds, and neutral falt.
The progrefs of putrefaction may be coniderably
retarded, and its effects obferved, by influffing the
tone of the veffels; and this may be done by
tonic medicines, of which the chief are cold, and the
Peruvian bark, as already mentioned. The violence
of re-action increafing the tendency to putrefaction,
may be moderated by the means already mentioned
under fyncope.

These are the proper indications to be obferved in
the cure of the fnow nervous fever. Dr Harham
observes, that evaucations (efpecially bleeding) are
improper even at the beginning. Even a common purgative
given at this time hath been followed by surprifing
langsions, fyncope, and a train of other ill fymptoms. However, it may fometime be neceffary to
cleane the fomach and prime vief by a gentle emetic,
or a mild rarificative. Indeed where nausea, fick-
feness, and load at fomach are urgent, as is frequently
the cafe in the beginning of this fever, a vomit is nece-
cary. Clysters of milk, sugar, and salt, may be
injected with safety and advantage every second or
third day, if nature wants to be prompted to ftool.
The temperate, cordial, diaphoretic medicines, are
certainly, according to our author, moft proper in
these fevers; and a well-regulated, fupporting,
diluting diet, is neceffary. The latter of itself, ju-
dicilly managed, will go a great way in the cure,
especially affifted by well-timed and well-applied
blifters, and a due care to keep the patient as
quiet as poflible both in body and mind. But it
should be obferved, that any ftrong opiates are commonly
very pernicious, however, much the want of sleep and
reflelifines may feem to demand them. Mild dia-
phoretics, such as neutral draughts or elixir paregori-
cum, have much better effects; which, by raising a
gentle easy sweat, or at leat a plentiful perpiration,
keep the hurry of the spirits, and a refufling sleep en-
ues. Where the confufion and dejection of spirits
are very confiderable, blifters have been advifed to be
applied to the neck, occiput, or behind the ears;
and during all this a free ufe of thin wine-whey,
some pleafant ptifan or gruel, with a little foft wine,
mufi be indulged. Indeed the patients, in this cafe,
should drink frequently; though fuch quantities may
not be neceffary as in the ardent, or even putrid mal-
ignant fevers; yet they fhould be fufficient to carry
on the work of dilution, fupport the fweats, and
supply the blood with fresh and wholesome fluids, in
place of that noxious matter which is continually
paffing off. In this view also a thin chicken-broth is
a very ufeful service, both as food and phyfic, efpecially towards
the vital power, and are followed
of fpirits

the vital power, and are followed
of fpirits
dehiscion of fpirits, tremors,
devises the swells, supports the patient, and keeps up the military pressure if they happen to attend. Towards the decline of the fever also, where the swells are abundant and weakening, small doses of the tincture of the bark with saltness and saucy root were given with the greatest advantage, frequently interposing a dose of rhubarb to carry off the putrid colluvings in the first passages; which vital sickness makes the remission or intercalations that often happen in the decline of nervous disease more distinct and manifest, and gives a safer opportunity of throwing in the bark; for in the proper exhibition of this medicine we are to place our chief hopes of curing both the nervous and putrid malignant fevers.

R. Pulv. contrayerv. comp. gr. xv.
Croc. Angl. gr. iii.
Coc. C. C. 3 grs.
Syr. Croc. q.t.
M. f. Balsam.

If great tremors and sublunus tendimium came on, he substituted half a scruple of mulk instead of the contrayerv in the bolus, with advantage. One or other of these, or similar prescriptions, are to be taken every fifth, sixth, or seventh hour, and a temperate cordial julep may be now and then given out of thin wine or cider whey, or, which is in many cases better, out of mustard-whey; which last is by no means a contemptible medicine. The saline draught made as above, is much more apt to pass through the pores of the skin when made with sixt of wormwood, which rather moves through the urinary passages.

The above mentioned difficulty of breathing, anxiety, and opression, many times precede a military eruption, which often appears on the seventh, ninth, or eleventh hour of the fever, and sometimes later. Indeed great anxiety and opression on the precordia always precede pustular eruptions of any kind in all sorts of fevers. This eruption should be promoted by 1 or 2 easy cordials and proper infusions; to which should be sometimes added some gentle aromatics. These tend to calm the universal uneasiness commonly complained of, and also very effectually. promote a diaphoresis, or breathing kindly swells, with which the military eruptions freely and easily advance. But however advantageous these commonly are, profuse swells are seldom or never so, even though attended with a very large eruption. Two or three crops of these military pustules have been known to succeed one another, following profuse swells, not only without advantage, but with great detriment to the patients, as they were thereby reduced to an extreme degree of weakness; so that they may jutly be reckoned symptomatical rather than any thing else, and the consequent eruption is often merely the symptom of a symptom; for the military glands of the skin appear very turgid, and mimic a rash, after profuse sweating, even in the worst healthy.

In these profuse colliquative sweatings a little generous red wine (diluted somewhat, if necessary) may be given with the greatest advantage; as it presently mo-
Hence fever is a disease of the most dangerous nature, as, that both frequently originate from a contagion precicely of the same nature. In the same manner we see, during different feasons, and in different circumstances, various degrees of malignity in small-pox. Though every instance of the disease depends on the introduction of a peculiar and specific contagion into the body, yet this contagion in particular epidemics evidently poises peculiar malignancy. The same is probably the case with the typhoid fever: But whether this observation be well founded or not, there cannot be a doubt that the typhus gravior or putrid fever is a disease of the most dangerous nature, as, besides the extreme debility of the nervous system, there is a rapid tendency of the fluids to putrefaction, which sometimes cuts off the patient in a few days, nay, in the warm climates, in 12 or 14 hours; or if the patient recovers, he is for a long time, even in this country, in an exceedingly weak state, and requires many weeks to recover his former health.

The putrid fevers, according to Huxham, make their attack with much more violence than the flow nervous ones; the rigor are sometimes very great, though sometimes scarce felt; the heats much sharper and permanent; yet, at first, fudden, transient, and resurgent; the pulse more tenax and hard, but commonly quick and small; though sometimes flow, and seemingly regular for a time, and then fluttering and unequal. The head-ach, nausea, and vomiting, are much more considerable even from the beginning. Sometimes a severe fixed pain is felt in one or both temples, or over one or both eyes-brows; frequently in the bottom of the orbits of the eyes. The eyes at times appear very dull, heavy, yellowish, and very often a little inflamed. The countenance seems bloated, and more dead-coloured than usual. Commonly the temporal arteries throb much, and tinnitus aurium is very troublesome; a strong vibration also of the carotid arteries frequently takes place in the advance of the fever, though the pulse at the wrist may be small, nay, even feeble: this is a certain sign of an impending delirium, and generally proceeds from some considerable obstructions in the brain.

The prostration of spirits, weakness, and faintness, are often surprizingly great and sudden, though no inordinate evacuation happens; and this too sometimes when the pulse seems tolerably strong. The respiration is most commonly laborious and interrupted with a kind of sighing or sobbing, and the breath is hot and offensive.

Few or none of these fevers are without a sort of lumbago, or pain in the back and joints; always an universal weariness or soreness is felt, and often much pain in the limbs. Sometimes a great heat, load, and pain, affect the pit of the stomach, with continual vomiting of porridgeous or black choler, and a most troublesome fignum; the matter discharged is frequently of a very nauseous smell. The tongue, though only white at the beginning, grows daily more dark and dry; sometimes of a shining livid colour, with a kind of dark bubble at top; sometimes exceeding black; and so continues for many days together; nor is the tint to be got off many times for several days, even after a favourable crisis: at the height of the disease, it generally becomes very dry, stiff, and black, or of a dark pomegranate colour. Hence the speech is very inarticulate, and scarce intelligible. The thirst in the increafe of the fever is commonly very great, sometimes unquenchable; and yet no kind of drink pleases, but all seem bitter and mawkish; at other times, however, no thirst is complained of, tho' the mouth and tongue are exceedingly foul and dry; this is always a dangerous symptom, and ends in a frenzy or coma. The lips and teeth, especially near the height, are furred up with a very black tenacious matter. At the onset of the fever, the urine is often crude, pale, and rapid, but grows much higher-coloured in the advance, and frequently resembles a strong lixivium, or citrine urine, tinged with a small quantity of blood; it is without the least sediment or cloud, and so continues for many days together; by degrees it grows darker, like dead strong high-coloured beer, and finally very rank and offensive. In petechial fevers, the urine hath often been seen almost black and very feitid. The foids, especially near the height, or in the decline of the fever, are for the most part intolerably fetid, green, livid, or black, frequently with severe gripes and blood. When they are more yellow or brown, the fea the danger; but the height when they run off infeffibly, whatever their colour may be. It is likewise a very bad symptom when the belly continues teetle, swollen, and hard, after profuently foids; for this is generally the consequence of an inflammation or mortification of the intestines. A gentle diarrhoea is often very beneficial, and sometimes seems to be the only way which nature takes to carry off the morbiferous matter.
Practice.

Sometimes black, livid, dun, or greenish spots appear, which always indicate a high degree of malignity; however, the more florid the spots are, the less danger is to be feared. It is also a good sign when the black or violet petechiae become of a brighter colour. The large, black, or livid spots, are almost always attended with profuse hemorrhages; and the small, dusky, brown spots, like freckles, are not much less dangerous than the livid or black; though they are seldom accompanied with fluxes of blood: excessively profuse, cold, clammy sweats are often concomitant, by which also they sometimes vanish, though without any advantage to the patient. The eruption of the petechiae is uncertain; sometimes they appear on the fourth or fifth day, though sometimes not till the eleventh, or even later. The ulcers, or large dark, blue, or greenish marks, seldom appear till very near the fatal period. Frequently also we meet with an efflorescence like the measles in malignant fevers, but of a much more dull and livid hue; in which the skin, especially on the breast, appears as it were marble'd or variegated. This in general is an ill symptom, and is often attended with fatal consequences.

Sometimes about the 11th or 14th day, on the occurrence of profuse sweats, the petechiae disappear, and vail quantities of white milky pur turds break out. This is seldom found of any considerable advantage; but an itching, smarting, red rash, commonly gives great relief; and so do the large, fretting, watery bladders, which many times rise upon the back, breast, shoulders, &c. A scabby eruption-like about the lips and nose is certainly one of the salutary symptoms; and the more hot and angry it is, so much the better. But of much more uncertain and dangerous event are the brown-coloured aphyres; nor are those that are exceeding white and thick, like lard, of a very pleasing aspect. They are soon succeeded by great difficulty of swallowing, pain and ulceration of the faucies, oesophagus, &c. and with an incessant singulitus: the whole prime view become at last affected; a bloody dyentery comes on, followed by a phacelation of the intestines; as is evident from the black, fanning, and bloody fluids, extremely fetid and infectious. Vomits, or large, black, and bluish marks resembling bruises, are frequently seen towards the close of the fever; and, when attended with lividity and coldness of the extremities, are certain tokens of approaching death. In some cases, the blackness hath been known to reach almost to the elbows, and the hands have been dead-cold for a day or two before the death of the patient.

Such are the general appearances of the putrid malignant fever in this country, among those who enjoy a free air, and are not crowded together, or exposed to the causes of infection: but in jails, hospitals, or other places where the sick are crowded, and in some measure deprived of the benefit of the free air, the symptoms are, if possible, more terrible. Sir John Pringle, who had many opportunities of observing it, tells us, that the jail or hospital fever, especially in the beginning, is not easy to be distinguished from a common fever. The first symptoms are light interchanges of heat and cold, a trembling of the hands, sometimes a feint of numbness in the arms, weakness of the limbs, loss of appetite; and the disorder increasing towards night, the body grows hot, the sleep is interrupted, and not refreshing. With these symptoms, for the most part, there is some pain or confusion in the head; the pulse at first is a little quicker than natural, and the patients find themselves too much indisposed to go about business, though too well to be wholly confined.

When the fever advances, the abovementioned symptoms are in a higher degree; and in particular, the patient complains of a languid, nervous, pains in his back, a more constant pain and confusion in his head, attended with an uncommon deviation of spirits. At this time the pulse is never faint, but beats quick, and often varies in the same day both as to strength and fulness. It is little affected by bleeding once, if a moderate quantity of blood be taken away; but if the evacuation be large, and especially if it be repeated, to answer a false indication of inflammation, the pulse, increasing in frequency, is apt to sink in force, and often irrecoverably, whilst the patient becomes delirious. But whilst we must observe, that, in every case, independent of evacuations, the pulse sooner or later sinks, and then gives certain intelligence of the nature of the disease. The appearance of the blood is various; for though it be commonly little altered, yet sometimes it will be puffy, not only on the first attack, but after the fever is formed. The work appearance is when the rash is indolent; though this does not happen till the advanced state of the fever: though indeed this feems not easy to be ascertained, as blood has been so seldom taken away at that time.

The urine is also various. Sometimes it is of a reddish or flame colour, which it preserves a long time; but it is oftener pale, and changes from time to time in colour as well as crudity, being sometimes clear, sometimes clouded: towards the end, upon a favourable crisis, it becomes thick, but does not always deposit a seminum. If the sick lie warm, and have had no preceding flux, the belly is generally bound; but when they lie cold, as they often do in field-hospitals, the pores of the skin being that; a diarrhoea is a common symptom, but is not critical. In the worst cases, a flux appears in the last stage; then the fluids are incontinent, collapacous, behavous, and have a cadaverous smell; the effects of a mortification of the bowels, and the signs of approaching death. When the hospitals are filled with dyfenteric patients, some of the nurses will be infected with the flux only, and others with this fever, ending in these bloody and gangrenous fluids.

In the beginning the heat is moderate; and even in the advanced state, on first touching the skin, it seems inconsiderable; but upon feeling the pulse for some time, we are sensible of an uncommon ardeur (the color nordinus, as it has been called), leaving an unpleasant sensation on the fingers for a few minutes after. A day or two before death, if care be not taken, the extremities become cold, and the pulse is then hardly to be felt. The skin is generally dry and parched, though sometimes there are longer or shorter sweats, especially in the beginning. Such as are produced by medicine are of no use, except on the first attack, at which time they will often remove the fever; and natural sweats are never critical till the dillenper begins to decline. These last are rarely profuse.
profuse, but gentle, continued, and equally diffused
over the body; sometimes the disease will terminate
by an almost imperceptible moisture of the skin; the
sweats are usually fetid, and offensive even to the pa-
tient himself.

The tongue is commonly dry; and, without constant
care of the nurse, becomes hard and brown, with deep
chops: But this symptom is common to most fevers.
At other times, though rarely, the tongue is soft and
moist to the lilt, but with a mixture of a greenish or
yellowish colour. The breath is sometimes great, but
more frequently moderate. In the advanced stage, the
breath is offensive, and a blackish, furring gathers about
the roots of the teeth.

Soms are never delirious, but all lie under a stupor
or confusion; few retain their senses till death; many
lose them early, and from two causes; either from im-
moderate bleeding, or the premature use of warm and
spiritious medicines. They rarely sleep, and, unless delirious,
have more of a dejected and thoughtful lool than what is
commonly seen in other fevers. The face is late in acquiring either a ghastly or a very morbid
appearance; yet the eyes are always muddy, and gen-
erally the white is of a reddish cast as if inflamed.
The confufion of the head generally rises to a delirium,
especially at night; but, unless by an unreasonable hot
regimen, it seldom turns to rage, or to those high
flights of imagination common in other fevers. When
the delirium comes to that height, the face is flushed,
the eyes red, the voice is quick, and the patient struggles
to get up. But when that symptom is owing to large
evacuations, or only to the advanced stage of the dis-
case, the face appears meagre; the eye-kids in flammers
are only half flult; and the voice, which is commonly
low and flow, sinks to a degree fcarce to be heard.
From the beginning, there is generally a great dejec-
tion and failure of strength. A tremor of the hands
is more common than a flattering of the tendons; or if the
subfultus occurs, it is in a lefser degree than in many
other fevers. In every stage of the disease, as the pulse
sinks, the delirium and tremor increafes; and in pro-
portion as the pulse rises, the head and fpirits are re-
lieved. Sometimes in the beginning, but for the moft
part in the advanced stage, the patient grows dull of
hearing, and at last almost deaf. When the fever is
protracted, with a flow and low voice, the fick have a
particular craving for fomething cordial, and nothing
is fo cordial or fo acceptable as wine. They long for
no food, yet willingly take a little panada if wine be
added. But fuch as are delirious, with a quick voice,
with fuch a fubfultus tendium, or violent actions,
though their pulse be fink, yet bear neither hot medi-
cines, wine, nor the common cordials.

Vomiting, and complaints of a load and ficknefs at
the stomach, though usual symptoms, are not efential to
the disease; nor are pleuritic diftiffies, difficulty in
breathing, or flying pains, to be referred so much to
it as to the continuation of the patient, or to a prece-
ding cold.

A pectinal effuence is a frequent, though not
an ineparable, attendant of this fever. It sometimes
appears of a brighter or paler red, at other times of a
livid colour, but never rises above the skin. The spots
are small; but generally fo confluent, that at a little di-
fance the skin appears only somewhat redder than or-
dinary, as if the colour was uniform; but upon a nearer
inspection there are interlaced fmall fquares or dots.

The hofpital fever, though accounted one of the con-
tinued kind, yet has generally some exacerba
tion at night, with a remiffion and often partial sweats in
the day; and after a long continuance it is apt to change
into a hectic, or an intermitting form. The length of
the disease is uncertain. Sometimes it terminated
either in death or recovery, in feven days after the pa-
tient took to his bed; but in the hofpitals it generally
continued from 14 to 20, and fome died or recovered
after four weeks. From the time of the finking of the
pulse until death or a favourable crisis, there is per-
haps lea? change to be seen from day to day in this
than in molt other fevers. When its course is long, it
sometimes terminates in fuppurations of the parotid
or auxiliary glands; and when these do not appear, it
is probable that the fever is kept up by the formation
of some internal afscefs. The parotid glands themselves
do not fuppurate, but only three of the lymphatic glands
that lie over them. Sir John Pringle obferved one in-
fance of a swelling of this kind on both fides, with-
out any previous indifpofition, when the perfon, not
feeking the caufe, and applying diftifeent cau-
als, was, upon the tumour fubfliding, fezed with the
hufpital-fever. Many patients after the crisis of
this fever comain of a pain in the limbs and want of
refi; and almost all of them mention great wea-
kness, confufion in their head, vertigo, and a noise in
their ears.

Ten of the bodies of thofe who died of this diftem-
er in Houghton's regiment were opened. In fome
of them, all the cavities were examined; in others, only
the brain or the bowels. In fome of them, the brain ap-
peared to be fuppurated. The fift of this kind Sir John
Pringle met with at Ghent; but the man being brought
into the hufpital from the barracks no earlier than two
days before he died, he could only conjecture from the
symptoms and the imperfect accounts he had of him,
that his death was owing to a fever of this kind, after
lirting near a month in it. About three ounces of
purulent matter was found in the veficles of the
brain, and the whole cortical and medullary fubflance
was uncommonly f leaked and tender; nay, fome of
the fame kind of matter was found in the fubflance of
the upper part of the cerebellum; yet this perfon, with
fome fupur and deftrines, had his fenses till the night
before he died; fo far, at leaft, that he anfwered di-
finitely when roufed and fpoken to; but about that

wine, reticled on common
the ho2pital-fever. Many patients after the crisis of
this fever complain of a pain in the limbs and want of
rest; and almost all of them mention great weakness,
confusion in their head, vertigo, and a noise in their
time the muscles of his face began to be convulsed. Of
two other instances of men who undoubtedly died of
this fever, in one the cerebrum was suppurred, in the
other the cerebellum. In the former cafe, the patient
was under a stupor, with deafness from the beginning;
but was never delirious, nor altogether insensible. His
pulse funk early; and about ten days before his death
his head began to swell, and continued very large till
within two days before he died, when it subsided a little.
For several days before his end, he would taffe nothing
but cold water, and during his illness he lay conftantly
upon one fide. The head being opened, an abfcess as
large as an egg was found in the fubftance of the fore-
part of the right hemifphere of the brain, full of thin
matter like whey. At
afterwards, in which the cortical
abfcesses in both orbits, the brain was found flaccid, and
marfhes that had been made
the contagion. As to the
ill
about its
cerebellum. In the former
case, the abfcess in the cere-

Thefe fuppurations, however, were not
for another who died about the fame time and had
been ill about the fame number of days with the like
symptoms, the pale water excepted, had no abfcess ei-
ther in the brain or cerebellum. And two were opened
afterwards, in which the cortical fubftance of the brain had an inflammatory appearance, but no fuppura-
tion. In one of them the large inflations were cor-
ruped; that man went off with a loofeness; and juft
before he died, an ichorous matter was discharged from
his nofe. In the military hospital at Ipswich, one
who unexpectedly died of this fever after having been
feemingly in a fair way of recovery, had no fuppura-
tion in his brain; but in another, who died after an
abfcess in both orbits, the brain was found flaccid, and
about two ounces of a thin ferum in the ventricles.

Cauces of, and persons subject to, this disorder. The
caufe of this fever, as well as that of the flow nervous
fever, is an infection or contagion from fome difeafe
animal-body, or from corrupted vegetables; and there-
fore is very little, if at all, different from thofe
peftilential disorders which have arifen after battles, when
great numbers of dead bodies were left unburi'd, and
infected the air with their effluvia. This is con-
mifed by an obfervation of Forelhus, who was eye-
 witnefes to a diftemper of this kind (which indeed he
calls a fbounding) owing to the fame caufe, attended with
buboes and a high degree of contagion. The fame au-
thor also gives an account of a malignant fever break-
ning out at Egmont in North-Holland, occafioned by
the rotting of a whale which had been left on the shore.
We have a like obfervation of a fever affecting the
crew of a French fhip, by the putrefadion of fome
cattle which they had killed on the ifland of Nevis in
the Wett Indies. Thofe men were feized with a pain
in their head and loins, great weaknefs, and a difor-
der of the stomach, accompanied with fever. Some
died of carbuncles; and on others purple spots appeared
after death.

Galen affigns two caufes for peftilential fever's:
1. The great heat of the weather, when the humours
happen to be in a more putrefacent state than usual.
2. A putrid flate of the air, arifing either from a mul-
titude of dead bodies left unburi'd, as after a battle,
or from the evaporation of corrupted lakes and
marshes.

One of the moft remarkable difeafes incident to an
army is related by Diodorus, as breaking out among
the Carthaginians at the siege of Syracufa. That au-
tor not only relates fome of its moft diftinguifhing
symptoms, but reafons well about its caufe. He ob-
erves, that fome in the back and eruptions (\textit{\textcopyright})
were common; that fome had bloody floods; that oth-
ers were feized with a delirium, fo as to run about
and beat all that came in their way; that the physici-
ans knew no cure; and that it was the more fatal as
the fick were abandoned by every body on account of
the contagion. As to the caufe, the author takes no-
tice of the multitude of people confined within a nar-
row compass; of the fiation of the camp in a low
and wet ground; of the fcorching heats in the middle
of the day, fucceeded by the cold and damp air from
the marshes in the night-time; to thofe he adds, the
putrid flames arifing from the marshes, and afterwards
from the bodies of thofe who lay unburi'd.—This
diftemper feems to have been a compound of the
marsh and peftilential fever.

Forelhus remarks, that, from the putrefadion of
the water only, the city of Delit, where he prahifed,
was fcarce ten years together free from the plague or
peftilential disorder. He adds, that the mag-
illrates, upon their reprefentation of the caufe, erect-
ed a wind-mill for moving and refrefhing the water.
At that time Holland was much more fubject to in-
flations and the fagnation of water than preftent.
In 1694, a fever broke out at Rochfert in France,
which, on account of the uncommon symptoms and
great mortality, was at first believed to be the plague.
But M. Chiras, who was fent by the court to inquire
into its nature, found the caufe to arife from fome
marshes that had been made by an inftigation of the
seas; and obferved, that the corrupted flreams, which
flmed like gun-powder, were carried to the town by
the wind, which had long blown from that quarter.
About two-thirds of thofe who were taken ill died.
In fuch as were opened, the brain was found either
infamed or loaded with blood; the fibres of the body
were uncommonly tender; and the bowels had either
difcharges or were filled with matter.

It is needful to mention more inftances of peftil-
elial fever's being brought on by the flreams of
corrupted flufances, whether animal or vegetable. In
general it may be remarked, that the putrefadion of
fuch flufances in a dry air is more apt to bring on a
fever of the continued form; but in a moif air hath
a greater tendency to produce remitting fervers. But
it muft alfo be obferved, that, even in cafes where the
moft malignant fever's prevail, all perfons are not
equally difposed to receive the infection, though
equally exposed to it with others. Some, through
mere vigour of body and mind, cannot be infected with
the moft contagious difeafes; whiles, on the other
hand, thofe whole bodies are defribed by a former
difeafe, by fudy, low diet, or war, or thofe who
have laboured under any of the defpefting pains of
the mind for fome time, feldom or never escape. Men,
therefore, who have been weakened by accidents (as
thofe who have undergone a mercurial fublimation)
are very apt to fall into this diftemper. Thofe who are
taken into crowded hospitals, ill of the small-po

Practise.

however good the fort may be, fall readily into this fever, and run a greater risk of dying of it than others. The second fever is attended with double danger, fearing the patient has been so much weakened by the first. A sure sign of the corruption of the air in an hospital is when many of the nurses fall sick.

Prognosis. In these fevers we cannot draw a prognostic from any symptom by itself; and perhaps all of them together are more fallible than in others. Generally the following are good: to have little delirium; the strength little impaired; turbid urine in the decline of the disease; and at that time a gentle sweat or moisture diffused over the body, or even the skin soiled and the tongue moist; or to have some loose stools succeeded by a diaphoresis; the pulse to rise by wine or cordials, with an abatement of the flour, tremor, and other affections of the brain. Deafness is rather a good sign. A sediment in the urine, without other changes to the better, is no sure sign of recovery; and some have recovered in whose urine there was no sediment.—The bad signs are, a subfultus tendinum; the patient complains of blindness; when he swallows with difficulty, or cannot put out his tongue when desired to do it; when he can lie on his back only, and pulls up his knees; or when insensible he endeavours to uncover his breast, or makes frequent attempts to get out of bed without affigning any reason. If to any of these are added ichorous, cadaverous, and putrid stinks, frequent stools, with a sinking pulse, and the day, from such a sandy soil, is always hot, disagreeable, and unhealthy; these fogs may be compared to that of a new cleaned ditch. Diffuses therefore, arising from this cause, generally take place in the night, or before sun-rising.

Numerous fwarms of flies, gnats, and other insects which attend the corrosion of the air and unhealthy places covered with wood.

4. When all butchers meet soon corrupts, and in a few hours becomes full of maggots; when metals are quickly corroded on being exposed to the air; and when a corpse becomes intolerably offensive in less than six hours; these are proofs of a close, hot, and unhealthy country. And in such places, during excessive heats and great calms, it is not altogether uncommon for Europeans, especially such as are of a gross habit of body, to be seized at once with the most alarming and fatal symptoms of what is called the yellow fever, without even any previous complaint of biliousness or other symptoms of the disease. There has first been perceived an uneasy itching sensation, commonly in the legs; and upon pulling down the stockings, streams of thin discolored blood followed, a ghastly yellow colour quickly diffused itself over the whole body, and the patient has been carried off in less than forty-eight hours.

5. A fort of sandy soil, commonly a small, loose, white sand, as that at Pensacola, Whydah, and the island of Bonavista, which is found by experience to be injurious to health. The pestiferous vapour arising, during the summer months and in the heat of the day, from such a sandy soil, is best characterized by its effects in the extensive deferts of Asia and Africa. It there constitutes what is called the semel-awin; a blast which, in the parched deserts, proves insupportable to man and beast: but when it passes over a soil well covered with grass and vegetables, has its effects greatly mitigated; it is, however, even then, productive of sickness; thus the southerly winds, while they blow from the deserts of Libya during the summer, at Algiers, Tunis, and Tripoli, produce an unhealthy season; and at Madras the winds, which, in the months of April and May, pass over a large tract of sand, are always hot, disagreeable, and unhealthy.

During these land-winds, sudden gusts of a more hot and suffocating nature are often observed to come from these sands once or twice, or even more frequently, in a day, which seem to be this vapour in a purer form. These gusts pass very quickly, and affect persons who happen to stand with their faces towards them in the same manner as the hot air which issues from a burning furnace, or from a heated oven, and obliges them immediately to turn away from it in order to recover breath. The effect of this hot suffocating blast or vapour on the human body, even when mitigated by passing through a moist atmosphere, is the same as that of intense cold; it flushes up every pore of the skin, and entirely stops the perspiration of such
The heat of the season is increased; but the opposite winds, arising from the opposite parts of India, are a wholesome check to this increase of heat and suffocating quality of these winds, which accompany them, proceed from sand heated in the desert of Nubia and the deserts of Arabia, and other places of Africa, where the sun, is evident from experience, is confirmed by the experience of Europeans, who have often been obliged to die from this dangerous work; the captain and 11 of his men being seized with violent fevers, which terminated in obliterating intermittent, and of which several died. The survivors suffered so much in their constitutions, that, even after they came to England, the return of an east wind was apt to bring on a violent fit of the ague. The Ludlow-Castle, a ship of war of 40 guns, in a voyage to the coast of Guinea, also lost 5 of her men at Sierra Leone, who were employed in cutting down wood for the ship. This is an occupation which has often proved destructive to Europeans in those climates, and in which they ought never to be employed, especially during the rainy season. There being numberless instances of white persons, when cutting down the woods at that season, who have been taken ill in the morning, and dead before night.

Another evil, less known, and less suspected, but no less dangerous, is the sending of Europeans in open boats after fish, where the soil is swampy, or where there are great night-fogs. The tingle duty alone of fetching fresh-killed butchers meat at night for the use of our ships companies in the East and West Indies, has destroyed every year several thousand seamen. In those parts of the world, butchers meat must be brought on board at night immediately after it is killed, otherwise it will not be fit for use the next day; but a contract made with the natives to send it on board at that time, which might be done for a trifling sum, would be the means of preserving many useful lives. During the sickly season at Batavia, a boat belonging to the Medway, which attended on shore every night, was three times successively manned, not one having survived that service. They were all taken ill in the night, when on shore, or when returning on board; so that at length the officers were obliged to employ none but the natives on that business. Great numbers of men have perished from being employed in this manner at Bengal, where the European ships often anchor in the most unhealthy spots of the river; and even when the great night-fogs arise, after the rainy season, the men are often obliged to perform such night-services in boats.
boats. Now since it is so dangerous for Europeans in unhealthy countries, particularly during a season of sickness, to be exposed in an open boat to the foggy night-air, it must appear, that sending them unsheltered, in open boats, far up rivers, in unhealthy southern climates, for the sake of wood, water, trade, or other purposes, must be attended with the most destructive and fatal consequences.

Burying the dead in swampy countries is another occupation which has proved fatal to many, and which ought to be entailed on negroes or the natives of the country. The effluvia from the ground when newly opened, whether from graves or ditches, are far more dangerous than from the same swampy soil when the surface is undisturbed; nay, in some places, it has been found almost certain death for an European to dig a grave, unless long feasoned to the country. In such a place, the attendance of friends at funerals ought to be dispensed with.

In all cases where it is practicable, the ships which visit these unhealthy countries should anchor as at great a distance as possible from shore; or if obliged to anchor near marshy grounds or swamps, especially during summer or in hot weather, and when the wind blows directly from thence, the gun-ports which would admit the noxious land-breeze ought to be kept shut, especially at night. Or if the ship rides with her head to the wind, a thick sail ought to be put upon her forecastle, along which the smoke from the fire-place might be made conveniently to play and ascend. If the sails should occasion a little smoke between decks, this inconvenience will be sufficiently compensated by its keeping off the direct stream of the swampy shore effluvia; which now being obliged to form a curve before they reach the more distant parts of the vessel, must needs be greatly diverted and scattered.

The best preservative against the mischievous impressions of a putrid fog, or of a marshy exhalation, is a close, sheltered, and covered place; such as the lower apartments in a ship, or a house in which there are no doors or windows facing the swamps. If an open place a fire be kept, either at the doors and other inlets to a house, or in the chambers, as is practised in some unhealthy countries during the rainy or foggy season, it will prove an excellent and effectual protection against the injuries of a bad air. On board of ships also fires may be made at the hatchways; and of the good effects of this we have the following example.

When the Edgar, a ship of war of 60 guns, was upon the coast of Guinea in the year 1768, her men were very sickly, and many of them died; however it was observed, that in a flood of war, which was constantly in company with her, few were taken ill, and not one died during the whole voyage. This could be ascribed to no other cause, but that in the flood the fire-place for cooking victuals was on the same level with the deck where the men lay; and every morning when the fire was lighted, especially when there was but little wind, the smoke from the cook-room spread itself all over the ship, and particularly over those parts where the men lay; but from the constriction of the fire-place of the Edgar, no smoke from it ever came between her decks.

Persons on board any ship whatever, are much more safe, and their situation is much more preferable to that of those who make distant inland excursions in small boats upon the rivers, and who are for the most part ignorant of the cause of those maladies which destroy them. The intolerable heat at noon often obliges such persons to go in a manner half-naked; while a free and plentiful perspiration issues from every pore. A near approach to putrid swamps at this time is apt to produce an immediate sickness, vomiting, and afterwards a low nervous or malignant fever. But if they happen to pass them at night, or lie near them in an open boat, the air from those swamps is perceived to be quite chill and cold; in so much that warm thick clothing becomes absolutely requisite to guard the body against the impressions of so great an alteration in the air, and against its cold and indecent quality: for the effects of it then, even on the most healthy and vigorous constitution, is frequently a chilling cold fit of an ague, terminating in a fever with delirium, bilious vomitings, a flux, or even death itself. But where such exposure becomes unavoidable, the only method is then to defend the body as much as possible against the pernicious manifesta with which the air abounds. All those who are employed in cutting down woods, or in other laborious and dangerous services in hot climates, during the heat of the day ought to have their heads covered with a bladder dipped in vinegar, and to wash their mouths often with the same liquid; never to swallow their spittle, but rather to chew a little rubarb or some other bitter, and spit it out frequently; to stop their nostrils with a small bit of linen or tow dipped in camphorated vinegar; and to infuse some bark, garlic, and rubarb, in brandy, of which a dram is to be taken, either by itself or diluted with water morning and evening.

In the evening before sunset they should leave off work, and not return to their labour in the morning till the sun has dispersed the unhealthy vapours. Those who must of necessity remain on shore, and sleep in dangerous places, must take care not to lie upon the ground exposed to the dew, but in hammocks in a close tent, standing upon a dry sand, gravel, or chalk, near the sea shore, and where there is no subterraneous water for at least four feet below the surface of the ground. The door of this tent should be made to open towards the sea; and the back part of it, which receives the land breeze, must be well secured by double canvas, or covered with branches of trees. But in such circumstances, a hut, when it can be procured, is preferable to a tent, especially if it be well thatched, so as to prove a defence both against the excessive heat of the sun by day, and the noxious dew which falls at night. Here the men may be enjoined to smoke tobacco. When the air is thick, moist, and chill, the earth being overspread with cold dew, a constant fire must be kept in and about the tent or hut, as the most excellent means of purifying such unhealthy air, and of preserving the health of those who either sleeping or waking are exposed to its influence. The centinels who guard the water-casks, ought likewise at such a time to have a fire burning near them. All old and forsaken habitations, natural caves and grottos in the earth, where the men may be induced to take up their abode, must before their admission be perfectly dried and purified.
with sufficient fires. Fire and smoke are undoubtedly the great purifiers of all tainted and unwholesome air, and the most excellent preservatives against its noxious influence. It is the custom of the negroes in Guinea, and also of some Indians (who both sleep for the most part on the ground), to have a fire producing a little smoke, constantly burning in their huts where they sleep. This not only corrects the moisture of the night, but also, by occasioning more smoke than heat, renders the damp from the earth less noxious; of which Dr Lind gives the following remarkable instance.

A Guinea ship being up one of the rivers for the sake of trade, it was found to be very dangerous to sleep on shore; without which their trade could not be so conveniently carried on. First the captain, then the mate, and two or three of the seamen, were taken ill; each of them the morning after they had lain on shore. By these accidents the men were greatly intimidated from lying abroad; till the surgeon boldly offered to try the experiment on himself. Next morning when he waked, he found himself greatly relieved, especially by breathing some smoke, and in the head, &c. He immediately acquainted one of the negroes with his condition, who carried him to his hut, and set him down in the smoke of it; when his giddiness and shiverings soon left him. He then took a dram of the bark bitter; and found himself greatly relieved, especially by breathing some time in the smoke.—Thus instructed by the negro, he ordered a large fire to dry the hut he slept in; and afterwards had every night a small fire sufficient to raise a gentle smoke, without occasioning a troublesome heat: and by this means he and several others, using the same precautions, slept many nights on shore without any inconvenience.

Fire and smoke indeed are found to be certain correctors, or rather destroyers, of infection in all cases, whether arising from the noxious effluvia of marshes, or from the contagion of diseased bodies. Thence most extraordinary and fatal damps called harnamattas, are unable to refift the salutary effects of smoke. In other cases, Dr Lind remarks, that, under some circumstances, the source of an infection in a sick chamber or any other place, may be removed or destroyed by accidental means, for which we cannot account, and which we often cannot ascertain. But it oftener happens, that it is very difficultly rooted out; and that exaet cleanliness, with the benefit of a pure air, often proves insufficient to remove the evil. Smoke, however, has never been known to fail. It is not to be doubted, that excepting the true plague, there has been an infection fully as pestilential and as mortal in some ships as in any other place whatever; yet it has never been heard, that any ship, after having been carefully smoked, did not immediately become healthy; and if afterwards they turned fickly, it was easy to trace that sickness from other infected ships, jails, and the like places.

There are three methods practised for purifying vessels after the men have been removed out of them. The first is by burning of tobacco. A quantity of tobacco is spread on several fires, made with such old pieces of rope as are called junk. These are dispersed into different places of the ship, and their heat and smoke afterwards closely confined below for a considerable time.—The second method is by charcoal fires drewed with brimstone. The heat and flem of these burning materials must also be long and close; but, although this furnance properly applied, has been found by experience to purify most efficiently tainted apartments, ships, clothes, &c. yet there are some kinds of vermin which it will not destroy, particularly lice. The third method of purification is performed by the addition of arsene to the materials of the second process, in the following manner. After carefully fopping up all the openings and every small crevice of the ship (as was also necessary in the preceding processes), a number of iron pots, properly secured, are to be placed in the hold, orlopes, gun-deck, &c. Each of these to contain a layer of charcoal at the bottom, then a layer of brimstone, and so alternately three or four layers of each, upon which the arsenic is to be sprinkled; and on the top of it some oakum dipped in tar is to be laid to serve as a match. The men, upon setting fire to the oakum, must speedily leave the place, shutting close the hatchway by which they came up.

From the small and experienced efficacy of these processes, it appears, that fire and smoke are the most powerful agents for annihilating infection; and, it may be presumed, even the plague itself. This is in some measure agreeable to what we learn from the ancient records of physic. But the preposterous use, or rather abuse, of fire on such occasions, has caused its effects to be disregarded by some, and to be suspected of mischief by others. The modern practice of burning large fires in the open air, in the streets, and about the walls of towns infected with the plague or other contagion, is founded on principles groundless and erroneous; and has therefore been found by experience not only unsuccessful, but hurtful. But though this must be allowed, it doth not thence by any means follow, that when once a house hath been fumck, the patients removed from it, the doors and windows at the same time being shut, that such fires will then prove hurtful; or that, by this method of purification, all the seeds of contagion will not be effectually destroyed. Whenever, therefore, perons die of a spotted fever, a malignant sore throat, the small-pox, or any other disease found to be communicable from the sick to others, the corpse ought quickly after death to be removed into another room; that in which the person died should be well aired, by having the windows opened, till a charcoal-fire be kindled, with some rolls of sulphur upon it; after which, both doors and windows should be kept shut for a considerable time, not less than eight or ten hours, till the room be thoroughly smoked. In several ships, where there are the fairest opportunities of trying and judging things of this nature, the contagion of the small-pox has been entirely expelled by wood fires, sprinkled with brimstone, kept burning and closely confined in the infected place. In a word, a judicious and proper application of fire and smoke is the best means for the destruction and utter extirpation of the most malignant sources of disease; and they are besides the greatest purifiers of all bad and tainted air.

Next to the smoke of wood for purifying a tainted air, that of gun-powder is to be esteemed the best; and it has this further good property, that it is entirely inoffensive to the lungs. The cacteilla-bark, when burning, gives a most agreeable fcent to the chamber of the sick; so is at least an elegant preservative, and may prevent
Such slight degrees of infection have been often observed to be derived from patients of a gross habit of body when labouring under inflammatory distempers, and even other complaints. A man was sent to Hal­lar Hospital supposed to have a fever. He was furiously delirious, with a quick full pulse. Notwithstanding plentiful evaporation, this delirium continued for two months with short intervals; when the case was found to be plainly maniacal. A nurse, upon rais­ing this person up in her arms, perceived an intoler­ably bad smell, and was instantly seized with shiverings, sicknese, and head-ach. Finding herself very ill, she took a vomit in fix hours afterwards, and passed the night in profuse sweats by means of a sudorific draught.

Next morning the violence of the head-ach was but little abated; upon every attempt to move, she com­plained of a burning heat and pain in her forehead, and became giddy. Her inclination to drink was frequent, and her pulse low and quick. A blister was im­mediately applied to the back; as soon as the blister took effect, the head-ach and thirst entirely left her, and the pulse was calm. Next day the afe and was well.

Many similar instances of infection have been ob­served from putting the dead into their coffins. In par­ticular, one man, who, from performing that duty to his mate, was so ill, even after the operation of the vomit, as to require a blister. In the course of one week two nurses were infected by a person in the small­pox. Both were seized in like manner with shiverings, sicknes, and head-ach; the one upon receiving the patient's breath, the other upon making his bed. In the one, a pain darted into her breast; in the other, into the breast and in the small of the back. The com­plaints of the former were speedily removed by a vomit, though the continued to have irregular returns of shiverings for three days afterwards. But in the latter, though the head-ach, sicknes, and rigors, were greatly abated by the vomit, yet a constant heat and thirst, with a low pulse, and a violent pain in the breast, indi­cated the necessity of applying a blister to the affected parts, which next morning removed all her com­plaints.

A person is often immediately sensible of his having received an infection from the first attack: they gene­rally compare the first impression to an earthy, dif­agreeable smell, reaching down as they express it, into their throats, as from a grave newly opened, but not quite so raw as the cadaverous fcent, and the effects of it, shivering and sicknes, are instan­taneous. It is a smell difficult to describe; but it is well known to the nurses and attendants about the sick, as it usually accom­panies fevers of extreme malignity, and, with the peculiar discharges from the blistered parts, may be reckoned among the most con­stant symptoms of a bad fever. Some compare the smell to that of rotten straw. It often resembles the disagreeable fcent of a perfum labouring under the con­stant small-pox at their turn, though not so strong. One person, on receiving the infection, was sensible of something like an electric shock through his body. But many are not sensible of any effect from an infection at first; and an infection from a fever will sometimes continue for many days, nay weeks, discovering itself chiefly by irregular shiverings, sometimes so severe as to oblige the patients to have
in the delirium with a sunk pulse, even leeches were hurtful. Many recovered without letting blood, but few who lost much of it.

Vomits also must be used with caution; for though they may be of use by way of prevention, yet in the advanced state of the disease, when the patient has all along complained of sickness at stomach, they are evidently unsafe. Here the antilptic quality of fixed air is of much use, and the neutral draughts given in the act of effervescence are generally attended with happy effects. Nay, clysters of fixed air itself have been found very serviceable. Even in very bad flages of the delirium, where a putrid and colloquate looefet has taken place, clysters of fixed air have been known to alleviate the symptoms. We must not, however, put too much confidence in medicines of this kind. Mild astringent cordials, especially wine and Peruvian bark, are the only resources in these disorders. Concerning the former, Sir John Pringle observes, in the low state of these fevers, and in great sicknesses, which either come after unseasonable bleedings or long want of nourishment, it was a most grateful and efficacious cordial, to which nothing was comparable. The common men had an allowance, from a quarter to half a pint in a day, of a strong kind, made into whey, or added to the panada which was their ordinary food. But to others out of the hospital, he usually prescribed Rhenish or a small French wine, whereof some consumed near a quart per day, and part of that undiluted. Nay, fo great was the virtue of wine in this stage of the fever, that several were known to recover from the lowest condition, when refusing the bark on account of its taste, they took nothing but a little panada with wine and a volatile diaphoretic mixture every two or three hours by turns. Perhaps there is no rule more necessary in this state, than not to let the patient when low remain long without taking something cordial and nourishing: as many have been observed past recovery, by being suffered to pass a whole night without any support about the time of the crisis. In the advanced state of this fever the sick are remarkably low; and therefore Hoffmann advises in such cases, that they should be constantly kept in bed, and not permitted even to sit up in it. In the last stage of this fever, as well as in that of the sea-scurvy, it would seem that the force of the heart was too small to convey the blood to the brain, except when the body is in a horizontal posture.

But, however necessary wine and the bark may be in the low state of this fever, we must remember, that these remedies are to be administered only as antileptics and supporters of the ditto wine, without aiming at thoroughly raising the pulse or relieving the head, or at forcing a sweat by them, before nature points that way, and which Sir John Pringle seldom observed before the 14th day. For though the patient may die before that time if he has been largely bled, or if the cordial medicines have been given him too freely, yet such means as he made use of were not powerful enough to bring on a crisis sooner.

In the low state of the hospital-fever, a florup was a constant attendant, which was very apt, in the evening, to change to a slight delirium. If this was all, as being in the common course, nothing was done. But if the delirium increased upon ufing wine, if the eyes
eyes looked wild, or the voice became quick, there was reason to apprehend a phrenitis; and accordingly it was observed, that at such times all internal heating medicines aggravated the symptoms; and in these cases blisters were of the greatest service. Fomentations of vinegar and warm water for the feet, our author is of opinion would answer better than either snipums or blisters, provided they were long enough and often enough applied. In the inflammatory fevers, he has known thefe fomentations have little effect for the fifth hour, and yet succeeded afterwards. For internal medicine the bark was omitted for some time, but the patient was continued with an acidulated drink, viz. barley-water and vinegar; and treated also with camphire, pubis confreyera campfta, and nitre, as was usual in the beginning of the fever. If the delirium was of the low kind, a decoction of the bark and wine were the only remedies; for in no instance was the delirium perfectly removed till the time of the crisis. It must also be observed, that a delirium may arise in putrid fevers from two opposite errors; one from large and repeated bleedings, and the other from wine and the cordial medicines being taken too early. It appears therefore how nice the principles are that regard the cure; as neither a hot nor a cool regimen will answer with every patient, or in every flate of the disease.

If a diarrhoea came on in the decline of the fever, it was moderated, but not suppreffed, by adding an opiate to the usual medicines. For though the loofenefs may be considered as critical; yet as the fick were too low to bear evacuations, there was a necessity for refraining it in some measure; and it has often been observed, that when it has been treated in this manner, the usual time of the crisis, the patient has fallen into a gentle sweat, which has carried off the disease. In the worst cafes of this fever, and especially when it coincides with the dysentery, the fowls are frequently bloody; in which dangerous flate, if any thing could be done, it was attempted by medicines of the fame kind. In proportion to the putrid nature of the fowls, opiates and astringents were used with the greater caution.

If the disease terminate in a fuppuration upon one of the parotid glands (for the gland itself does not suppurate), the abfcess was opened without waiting for a fluctuation, which might never happen; the pus being often here fo vifcid, that after it was rife the part felt nearly as hard as if the fuppuration had not begun. Almost every patient, after the fever, complained of want of reft, frequently of a vertigo or confusion of the head, of a continuation of the deafness, or of other symptoms commonly called nervous. An opiate was then given at night; and in the day some strengthening medicines, fuch as the bark and the elixir of vitriol. In these cafes, the bark was found not only to be the belt ftrenger, but the fureft prefervative againft a return of the disease. For this laft intention the convalefcent was ordered about three draffms a-day for fix or seven days together; and afterwards, if he remained longer in the hospital, fome smaller quantity daily. But if there was any appearance of a hectic fever from an inward abfcess, the cafe was treated accordingly. Upon comparing fome of the remaining symptoms of thofe who recovered, with the condition of the brain in thofe who died and were opened, Sir John Pringle was induced to think, that fome part even of that fubflance might fuppurate, and yet the person recover.

Sometimes the patient falls into an irregular intermittent; which, if not of a hectic nature from an internal abfcess, may proceed from neglecting to clear the prima via. For it is easy to conceive, that after a long fever of fuch a putrid nature, often attended with languor of the bowels, the faces may be fo much accumulated, and fo corrupted, as to occasion new disorders. In fuch cafes, after proper evacuation by a purge, the bark was almofl an infallible remedy.

The Yellow Fever.

Typhus cum flavidine cutis. Typhus icteroides, Sawa, fp. 7.

Mackittrick de febre flavo India Occidentalis, Edin. 1766.

Definition. This is one of the most fatal diseases to which the inhabitants of warm climates are subject, and is the fame with that called, from one of its worst symptoms, the black vomit, which is fo terribly deftructive in fome of the warm parts of America, particularly at Carthageana. According to Dr. Hilliard, the yellow or putrid fever most commonly feizes the patient at fift with a faintnefs, then with a fickness at fometime, accompanied moftly with a giddinefs of the head; foon after with a flight chillnefs and horror, very rarely with a rigor, which is foon followed by a violent heat and high fever, attended with acute darting pains in the head and back. A flushing in the face, with an inflamed rednefs and a burning heat in the eyes, great anxiety and oppreffion about the precordia, are the pathognomonic signs of the diftemper; fpecially when attended with fickness at fomach, violent retching, and bilious yellow vomitings, with frequent fighing. The pulse is now generally very quick, high, foft, and fometimes throbbing, but neverhard: in fome it is very quick, foft, low, and oppreffed; the respiration quick, full, and fometimes difficult; the skin very hot, and fometimes dry, though more frequently moist. Blood taken from the patient, even at the very beginning of the difafe, is often of an exceedingly florid red colour; much rareded and thin, and without the leaft appearance of fize; and the craffamentum, when it has flood till it is cold, will fcarce cohere, but fluctuates; the serum is very yellow.

Moft of the abovementioned symptoms continually increase, and are much aggravated; the retching and vomitings become almofl incessant; the anxiety great, and fighing frequent; great rednefs; continual toiling; no eafe in any posture; little sleep, and that disturbed and uneasy; and without any refreshment to the fick: and when they are fainting, they turn yellow about the face and neck, instead of turning pale; and as the fainting goes off, they recover their natural colour. These symptoms generally continue to the third day, though fometimes not longer than the fift or second, in others to the end of the fourth: the fift shows the greater defolution of the blood, and the greater malignity of the disease; the laft, the contrary; which
which the improper manner of treating the disease sometimes hastes and increases, or the proper method retards. This may be called the first stadium of the disease, and generally ends on the third day.

Blood taken from the sick on the second or third day, is much more discolored, the serum more yellow, and the cagamentum florid, loofe, scarce cohering, but undulates like fify water when shaken, and sometimes has dark blackish spots on its surface, showing a strong gangrenous diathesis.

About the third day, the pulse, which was quick and full before, now generally sinks greatly, and becomes very low; though sometimes it remains very quick, yet in others it is not much quicker than when the patient is in health, but is always low, the vomiting becomes almost incessant if not so before, and the matter thrown up is black; the patient then becomes comatose, with interrupted delirium. The thirst in some is very great, in others but little; the pulse still low and quick, attended with cold clammy sweats, and sometimes with delirium. The eyes, which were inflamed and red before, and began to be of a more dusky colour, now turn yellow; and this yellowness also soon appears round the mouth, eyes, temples, and neck, and in a short time diffuses itself all over the body.

But this yellowness is so far from being always an encouraging prognostic, as some would have it, that it most commonly proves a mortal symptom. Sometimes indeed, though seldom, this suffusion of bile upon the surface has proved critical; but then it did not come on till the eighth or ninth day, nor appear till the coma and all the other bad symptoms began to abate; and then in proportion as the yellowness increases, all the bad symptoms decrease. But the case is most commonly quite the reverse; especially when the yellowness comes on soon; and then it is not only symptomatical, but ufhers in the most fatal symptoms of the disease, viz. a deep coma, a low, vermicular, and intermitting pulse, great hemorrhages from various parts of the body, a delirium with laborious and interrupted respiration, great anxiety, deep sighing, refltilleshns, a subfultus tendinum, coldness of the extreme parts, and then all over the body, a faltering of the speech, tremors, and convulsions, which are soon after followed by death. So that from the first appearance of the yellowness we may say the patient is in the last stage of the disease, whether it terminates in death or recovery.

It has been observed, that, in some strong sanguine constitutions, when the patients have not been bled to a sufficient quantity in the beginning of the disease, the pulse has continued full, strong, and rapid, but never hard; the face flushed, eyes inflamed; the tongue dry, with great thirst and heat, till the second or last stage of the fever is come on, when the pulse has suddenly sunk, and death soon after ensued. Yet in others, who seemed to be of a phlegmatic habit, the tongue has been moist all along, though they have been delirious most of the time, and the heat of their skin and the strength and quickness of their pulse have continued, after the first stage of the disease was over, pretty near to that of their natural state in health, till within a few hours of their death; and when they have had a coma on them, one who is not well acquainted with the nature of this disease would, from their pulse, heat, breathing, and other symptoms, have taken them to be in a natural sleep. Others, when the pulse has begun to sink, and the fatal period seemed to be just approaching, to the great surprize of all present have recovered their senses, sat up, and talked pretty cheerfully for an hour or two, and in the midst of this seeming security have been suddenly seized with convulsions, which carried them off immediately.

In the latter stage of this fever, the blood is so attenuated and discolored, that we frequently fee it flowing not only out of the nose and mouth, but from the eyes, and even through the pores of the skin; also great quantities of black, half-baked, or half-mortified blood, are frequently voided both by vomiting and by stool, with great quantities of yellow and blackish putrid bile by the same passages; and the urine, which was before a high fetiduous colour, is now almost black, and is frequently mixed with a considerable quantity of half-dissolved blood.

The pulse, which was much sunk before, now becomes very low, unequal, and intermitting; the breathing difficult and laborious; and the anxiety inexpressible; an oppression with a burning heat about the precordia comes on, tho' the extremities are cold, and often covered with cold clammy sweats; a constant delirium follows; and then a total loss of the outward senses as well as the judgment, with livid spots in many parts of the body, especially about the precordia; and sometimes gangrenes in other parts of the body, which are very soon succeeded by death.

In a short time after death, the body appears much more full of livid, large, mortified spots, particularly about the precordia and hypochondres, especially the right; which parts seem, even from the first seizure, to be the principal seat of this terrible disease; and, upon opening the bodies of those who die of it, we generally find the gall-bladder and biliary ducts turgid, and filled with a putrid blackish bile; and the liver, stomach, and adjoining parts, full of livid or blackish mortified spots; and the whole corpse soon putsrefies after death, and can be kept but a few hours above ground.

Dr Lind is of opinion, that the remarkable diffusion of the blood, the violent hemorrhages, black vomit, and the other symptoms which characterize the yellow fever, are only accidental appearances in the common fever of the West Indies; that they are to be esteemed merely as adventitious, in the same manner as purple spots and bloody urine are in the small-pox, or as an hiccup in the dysentery: like these they only appear when the disease is attended with a high degree of malignity, and therefore always indicate great danger. This opinion, he thinks, is confirmed by an observation of Dr Wind's, that in 1750 the crew of a Dutch ship of war were distempered by the yellow fever, accompanied with the black vomit; but when the ship left the harbour, and changed the noxious land-air for one more healthy, the fever continued, but was not accompanied with the black vomit.

Diseases similar to this fever, Dr Lind informs us, may arise in any part of the world where the air is intensly hot and unwholesome; and therefore he treats
treats as chimerical the notion of its being imported
from one part of the world to another. An example
of this happened at Cadiz in Spain, in the months
of September and October 1764, when excessive heat,
and want of rain for some months, gave rise to viol-
ent, epidemic, bilious disorders; resembling those of
the West Indies, of which 100 persons often died in a
day. At this time the winds blew principally from
the south, and after sun-fet there fell an unusual and
very heavy dew.

This disease began commonly with alternate flight
chills and heats, nausea, pains of the head, back, loins,
and at the pit of the stomach. These symptoms were often
fellowed, in less than 24 hours, with violent retchings,
and vomiting of a green or yellow bile, the smell of
which was very offensive. Some threw up an hontour
as black as ink, and died soon after in violent convul-
sions and in a cold sweat. The pulse was sometimes
fast, sometimes quick, but often varying. After the
first day, the surface of the body was generally either
cold, or dry and parched. The head-ache and flupor
often ended in a furious delirium, which quickly proved
fataL. The dead bodies having been examined by
order of the court of Madrid, the stomach, intestines,
and orifices, were found covered with gangrenous
spots. The orifice of the stomach appeared to have
been greatly affected, the spots upon it being ulcer-
ated. The liver and lungs seemed to be putrid, both
from their texture and colour. The stomach con-
tained a quantity of an atrodiabulous liquor, which, when
poured on the ground, produced a sennible efferv-
cia; and, when mixed with spirit of vitriol, a vio-
lent exultion ensued. The dead bodies do quickly
turned putrid, that at the end of six hours their feter
was intolerable; and, in some of these, worms were
found already lodged in the stomach. His Britannic
majesty’s ship the Tweed being at that time in Cadiz bay,
several of her men were taken ill when on shore, but
by being carried on board, all of them recovered.
Neither did the black vomit, or any other deadly
symptom of that fever, make its appearance in any of
the ships.

It has been a matter of much dispute, whether the
yellow fever is of an infectious nature or not. Some
time ago it became an object of considetation before
the Right Hon. the Lords Commissioners of Trade
and Plantations, where it was urged, among other reasons,
for not removing the seat of government and justice
in the island of Jamaica from Spanish Town to King-
ston, that there was danger from Greenwich hospital,
situated near Kingston, of an infection from the yellow
fever being frequently communicated to that town.
On this affair a physician was consulted, who had long
practised in that island, and who gave it as his opini-
on, that from the yellow fever in that island there
was no infection. This was the opinion not only of
that gentleman, but of many others who had an oppor-
tunity of being well acquainted with this fever in
Jamaica. Dr Lind, however, gives a remarkable in-
stance of its being of an infectious nature. A gent-
leman dying at Barbades of a yellow fever, his
wearing apparel and linen, packed up in a chest, were
sent to his friends at Philadelphia; where, upon open-
ing the chest, the family were taken ill; and the clothes
being unluckily hung abroad to be aired, they pre-
ently diffused the contagion of the yellow fever over the
whole town, by which 200 persons died. These
contradictions, Dr Lind thinks, can only be reconciled,
by supposing the yellow fever in the West Indies to be
sometimes of an infectious nature and sometimes not.

In the description of the same fever by Dr Lining,
as it appears in South Carolina, there are several
particulars considerably different from that by Dr
Hillary. According to the former, people complained
for a day or two before the attack; of a head-ach, pain
in the loins and extremities, especially in the knees
and calves of the legs, loss of appetite, debility, and a
spontaneous latitude. Some, however, were seized
suddenly, without any such previous symptoms. After
a chilliness and horror, with which this disease gene-
really invades, a fever succeeded. The pulse was very
frequent, till near the termination of the fever, and
was generally full, hard, and consequently strong: in
some, it was small and hard; in others, soft and small;
but in all those cases, it frequently varied in its full-
ness and hardness. Towards the termination of the
fever, the pulse became smaller, harder, and less fre-
quent. In some there was a remarkable throbbing
in the carotids and in the hypochondria; in the latter
of which it was sometimes so great, that it caufed a
confiant tremulous motion of the abdomen. The heat
generally did not exceed 102 degrees of Fahrenheit’s
thermometer; in some it was less; it varied frequently,
and was commonly nearly equal in all parts, the heat
about the precordia being seldom more intense than
in the extremities when these were kept covered.
In the frjl day of the disease, most had frequent returns
of a fenfe of chillinefs, though there was not any abate-
ment of their heat. In a few, there happened to great
remiffion of the heat for some hours; when at the
same time the pulse was soft and lefs frequent; and
the skin was moist, that one from these circumstances
might reasonably have hopfed that the fever would only
prove a remittent or intermittent. About the end of:
the second day, the heat began to abate. The skin was
sometimes (though rarely) dry; but oftener, and in-
deed generally, it was moist, and difcharged to sweat.
On the first day, the sweating was commonly profuse
and general; on the second day, it was more mo-
dest; but on both these, there happened frequent short
remissions of the sweatings; at which times the febile
heat increased, and the patient became more une-
sely. On the third day, the disposition to sweat
was so much abated, that the skin was generally dry;
only the forehead and backs of the hands continued
moist. The respiration was by no means frequent or
difficult; but was soon accelerated by motion, or the
fatigue of drinking a cup of any liquid. The tongue
was moist, rough, and white, even to its tip and edges.
On the second day, its middle in some was brown.
On the third day, the whitening and roughness of the
tongue began to abate. The thirst in very few was
great. A nausia, vomiting, or frequent retchings to
vomit, especially after the exhibition of either medi-
cines or food, came on generally the third day, as the
fever began to lessen; or rather as the fulness of the
pulse, heat, and disposition to sweat, began to abate.
Some indeed, but very few, on the first day, had a
vomiting, either bilious or phlegmatic. Very few
complained of anxiety or oppression about the precor-
dia.

Pratt's Practice.

Fever accompanied with this affection, was often attended with great dependency, and the strength was greatly prostrated from the first attack. The patient had complained before the attack, and then the pain in the head, loins, &c. of which they had complained before the attack, and then the pain in the head, which was very acute and darting, but those pains went generally off the second day. The face was flushed, and the eyes were hot, inflamed, and unable to bear much light. On the first day, many of them at times were a little delirious, but afterwards not until the recess of the fever. The blood often at venereal affection had not any inflammatory crust; in warm weather, it was florid like arterial blood, and continued in one soft homogeneous-like mass, without any separation of the serum after it was cold. When there was no separation, the effaancement was of a very lax texture. The stools, after the first day, were fetid, inclined to a black colour, and were very rarely bilious, soft, or liquid, excepting when forced by art; for an obstinate colliquia adhered and obstructed the fleshy flange.

The urine was discharged in a large quantity, was pale, sometimes limpid, and rarely of a higher than a straw colour, except when the weather was very warm, and then it was more saturated, of a deep colour, and discharged in smaller quantities. It had a large cloud, except when it was very pale or limpid; but more generally it had a copious white sediment, even on the first day of the fever. On the second day, the urine continued to be discharged copiously; in some it was then turbid, and deposited a more copious sediment than on the first day: this sediment was sometimes of a brownish colour; in which case it was generally followed by bloody urine, either about the end of the second or beginning of the third day.

The colour and quantity of the urine, discharged in equal times, were remarkably variable, being now limpid, then of a deeper colour, now discharged in a larger, then in a smaller quantity; which could not be accounted for by any change made either in the quantity or equality of the drink, &c.

The fever accompanied with those symptoms terminated on the third day, or generally in less than 72 hours from the first attack, not by any amelioration or cessation of the morbid matter: for if by the latter, there would have been some critical discharge by sweat, urine, stool, or otherwise, none of which happened; and if by the former, nothing then would have remained but great debility. This fever, however, did not terminate in either of these salutary ways, excepting in some, who were happy enough to have the disease conquered in the beginning by proper evacuations, and by keeping up a plentiful sweat, till the total solution of the fever, by proper mild diaphoretics and diluents. But those who had not that good fortune, however tranquil things might appear at this period (as great debility, and a little yellowness in the white of the eyes, seemed then to be the chief complaint, excepting when the vomiting continued), yet the face of affairs was quickly changed: for this period was soon succeeded by the second fatidum; a state, though without any fever, much more terrible than the first: the symptoms in which were the following. The pulse, immediately after the recess of the fever, was very little more frequent than in health, but hard and small. However, though it continued small, it became, soon afterwards, slower and very soft; and this softness of the pulse remained as long as the pulse could be felt. In many, in this stage of the disease, the pulse gradually subsided, until it became scarce perceptible; and this, notwithstanding all the means used to support and fill it; and when this was the case, the interminable-like suffocation, the vomiting, delirium, reflexes, &c. increased to a high degree. In some, the pulse, after being exceedingly small and scarce perceptible, recovered considerably its fullness; but that favourable appearance was generally of but short continuance. The heat did not exceed the natural animal-heat; and when the pulse subsided, the skin became cold, and the face, breath, and extremities acquired somewhat of a livid colour. The skin was dry when the weather was cold, but moist and clammy when the weather was hot. The respiration was natural, or rather slow. The tongue was moist, and much cleaner than in the former stage; its tip and edges, as also the gums and lips, were of a more florid red colour than usual. Very few complained of thirst, though they had a great desire for cold liquors. The vomiting or retching to vomit increased, and in some was so constant that neither medicines nor aliment of any kind were retained. Some vomited blood; others only what was left undigested, mixed with phlegm, and others again had what is called the black vomit (A). The retching to vomit continued a longer or shorter time according to the state of the pulse; for as that became fuller, and the heat greater, the retching to vomit abated, and de contra. The inquietude was very obstinate; and when they did, their flumbers were but short and unrefreshing. There were some who were drowsy; but these always awakened, after the shortest slumber, with a great dejection of spirits and strength.

(A) That which is called the black vomit at first sight appears to be black; but on a more careful examination, it was observed that this colour proceeded from a great quantity of small flaky black substances which floated in the liquor thrown up by vomiting; but the colour of this liquor was much the fame with that which the patient had last drank, and was by no means black. Those black flaky substances are the bile mixed with, or adhering to the mucus which lined the stomach. For, upon digestion of those who died of this disease, it was always observed that the mucus of the stomach was sometimes very viscid. In a lad who died of this disease in the beginning of the fourth day, and who was immediately opened, the bile was not only black, but had the confluence of thick venous-turpentine, and was exceedingly tough. On the inside of the stomach, there were several carbuncles or gangrenous specks. And in all those who were dissected, and had died of this disease, the same appearances were not only always observed, but likewise the blood was very fluid, and the vessels of the viscera were much distended.
The jaundice or jaunty were surging: it was frequently scarce possible to keep the patients in bed; though, at the same time, they did not complain of any anxiety or uneasiness; but if asked how they did, the reply was, Very well. The debility was so great, that, if the patient was raised on the pillow, or, in some, if the head was only raised from the pillow, while a cup of drink was given, the pulse sunk immediately, and became sometimes so small, that it could scarcely be felt; at this time, they became cold, as in a horripilation, but without the anæmis-like skin, their lips and skin, especially about the neck, face, and extremities, together with their nails, acquired a livid colour. The delirium returned and increased; it was generally constant in those whose pulse was small and subsiding. The inflammation of the conjunctiva or white of the eyes increased much, but without pain. A yellowness in the white of the eyes, if it did not appear before in the febrile state, became now very observable, and that ëtirous-like colour was soon diffused over the whole surface of the body, and was continually acquiring a deeper farron-like colour. In some indeed no yellowness was observable, except in the white of the eyes, until a little before death, when it increased very quickly, especially about the breast and neck. There were many small specks, not raised above the skin, which appeared very thick in the breast and neck, and less so in the extremities, and were of a scarlet, purple, or livid colour. In women the menstrua flowed, and sometimes excessively, though not at their regular period.

There was such a putrid dissolution of the blood in this flatus of the disease, that, beside the vomiting of blood formerly mentioned, and the bloody urine soon to be taken notice of, there were hemorrages from the nose, mouth, ears, eyes, and from the parts which were blistered with cantharides. Nay, in the year 1739 and 1745, there were one or two instances of an hemorrage from the skin, without any apparent puncture or lacer of any part of the tear-skin.

An obstinate constipation continued in some; in others, the stools were frequent and loose; in some they were black, liquid, large, and greatly fatiguing; in others, when the stools were moderate, even though they were black, they gave great relief; in others, again, the stools nearly resembled tar in smoothness, tenacity, colour, and consistence.

The urine was discharged in a large quantity, in proportion to the drink retained by the patient: it was pale if the patient was not yellow; but if yellow, then it was of a deep farron-colour: in either case, it had a sediment, or at least a large cloud, which remained at the bottom of the glass; in some it was very turbid; in others it was bloody; and the quantity of blood discharged with the urine bore always some proportion to the state of the pulse; when that became fuller, the quantity of blood in the urine was diminished; when the pulse subsided, the bloody urine increased, and even returned after it had ceased some days, soon after the pulse became smaller. This stage of the disease continued sometimes seven or eight days before the patient died.

When this flatus of the disease terminated in health, it was by a reces or abatement of the vomitings, hemorrages, diastem, inquietude, jaundices, and ëtirous-like suffusion of the skin and white of the eyes; while, at the same time, the pulse became fuller, and the patient gained strength, which, after this disease, was very slowly. But when it terminated in death, those symptoms not only continued, but sooner or later increased in violence, and were succeeded with the following, which may be termed the third flatus of the disease, which quickly ended in death. The pulse, though faint, became exceedingly small and unequal; the extremities grew cold, clammy, and livid; the face and lips, in some, were flushed; in others they were of a livid colour; the livid specks increased to faint, that in some the whole breast and neck appeared livid; the heart palpitated strongly; the heat about the precordia increased much; the respiration became difficult, with frequent sighting; the patient now became anxious, and extremely relatives; the sweat flowed from the face, neck, and breast; blood flowed from the mouth, or nose, or ears, and in some from all those parts at once; the deglutition became difficult; the hiccoughs and fulfultus of the tendons came on, and were frequent; the patients trifled with their fingers, and picked the maps of the bed-clothes; they grew comatous, or were constantly delirious. In this terrible state, some continued eight, ten, or twelve hours before they died, even after they had been so long speechless, and without any perceptible pulsation of the arteries in the wrists; whereas, in all other acute, diseases, after the pulse in the wrists ceased, death follows immediately. When the disease was very acute, violent convulsions seized the unhappy patient, and quickly brought this flatus to its fatal end. After death, the livid blotches increased fast, especially about the face, breast, and neck, and the putrefaction began very early, or rather increased very quickly.

This was the progress of this terrible disease through its several flatus. But in hot weather, and when the symptoms in the first stage were very violent, it passed through those stages with such precipitation that there was but little opportunity of distinguishing its different flatus, the whole tragedy having been finished in less than 48 hours. It was remarkable, that 1. The infection was increased by warm and lented by cold weather. 2. The symptoms in the several flatus were more or less violent, according to the heat or coolness of the weather. In hot days, the symptoms were not only more violent, but in those who seemed in moderate weather to be on the recovery, or at least in no danger, the symptoms were also greatly heightened, when the weather grew considerably warmer, as frequently to become fatal. In cool days, the symptoms were not only milder, but many who were apparently in great danger in hot days were faved from the very jaws of death by the weather becoming happily cooler. The disease was generally more fatal to those who lay in small chambers not conveniently fitted for the admis of fresh air, to those of an athletic and full habit, to strangers who were natives of a cold climate, to those who had the greatest dread of it, and to those who before the attack of the disease had overheated themselves by exercise in the sun, or by excessive drinking of strong liquors; either of which, indeed
Practice.

MEDICINE.

Indeed seemed to render the body more susceptible of the infection. Lastly, the disease proved most certainly fatal to valetudinarians, or to those who had been weakened by any previous disease.

Although from the description which has now been given of the yellow fever, it may appear to be in many particulars very different from the remittent fever of warm climates; yet it is the opinion of many late writers of great accuracy, particularly of Dr John Hunter in his Observations on the Diseas of the Army in Jamaica, that it is to be considered only as a more dangerous form of the same disease. And there can be no doubt that the remittent fever not only appears in different feasons and situations with very different degrees of severity; but also that while the remittent fever prevails in its usual form in the West India islands, some individuals, particularly those who are newly arrived, will be affected with very remarkable yellowness, as well as bilious and black vomitings.

Causes of, and effects subject to, this disease. The yellow fever attacks principally Europeans, especially those who have but lately arrived in the hot climates. Negroes are entirely exempt from it, though the mulattoes and tawnies are as liable to be seized with it as the whites themselves. The cause of the disease seems to be a particular kind of contagion; but Dr Lind seems to be of opinion, that the immediate cause of the symptoms is a disposition in the glutinous part of the blood to separate from the others, and to become purulent. In some persons who have been bled in the yellow fever, the blood hath been observed prodigiously viscid; the cæmentum covered with a yellow gluten half an inch in thickness, and impenetrable to the finger unless cut by the nail; the serum being at the same time of the consistence of a thin syrup, and of a deep yellowish tinge. This serum tasted bitter, and was taken for a composition of foot. The appearances on diffusion, with his conclusion from them, we shall give in his own words: "In a man who died on the eleventh day of a yellow fever, whose body emitted no bad smell 36 hours after death, and was still yellow, I found all the bowels of the abdomen found; the liver and spleen were remarkably fo; as also the stomach and intestines. There was no suffusion of the bile either in the intestines or stomach. The gall-bladder, of the natural size, contained the usual quantity of bile, somewhat thicker than common, and gramineous (a)."

Upon examining further, this disease was found to have lain wholly on the left side, where, within the breast, was found near a quart of yellowish water, in which were many large flakes of yellowish gluten, appearing, by comparison, precisely the same with the thick pellicle which had covered the blood taken from his arm. These flakes bore in several places a resemblance to a membranous substance beginning to be converted into a purulent jelly. The pleura, both on its inside and outside, as also its continuation, the invading membrane of the lungs (which in some parts was greatly thickened), were covered with cakes of this gluten, hanging in some places loosely, in others adhering more strongly; and all in different states of yellow or purulent corruption. The right cavity of the breast, and all the other parts of his body, were found entirely free from disease.

His complaints had been chiefly in his breath; and a small quantity of blood, taken from him two days before his death, was covered with an impenetrable, yellow, thick gluten; the red portion below it being quite loose.

In those fevers, I have also seen the disease entirely confined to the heart and pericardium. In one who died the tenth day of the fever, without having been yellow, a quantity of pus and purulent eruits were found mixed with the water of the pericardium. The heart in different places was excoriated; and, together with the inside of the pericardium, was lined with a thick membranous cake, similar to that already mentioned on the lungs and pleura. In some places this cake had a purulent, in others a gelatinous, appearance, exactly resembling the coagulum of the blood. His complaints had been, a great oppression on the breast, and an extreme difficulty of breathing. In a third person, who died on the thirtieth day of the fever, above two quarts of pus and purulent jelly were found in the cavity of the belly. The source of such an extraordinary quantity of matter was not from any preceding inflammation, nor any impolthume, that we could discover; but from innumerable ulcerations on the surface of the intestines, omentum, mesentery, an peritoneum. Neither did those ulcerations (or excoriations, as they rather appeared in several places) seem to be the primary fountains of the matter, but to have been occasioned by its acrimony.

This purulent appearance seems to arise merely from an extravasation of one of the component parts of the blood, the gluten or coagulable lymph. Blood taken from persons in a fever, and frequently even from persons in perfect health, after standing in a clean vessel for a short time, commonly separates into three distinct portions; viz. the serum, or water of the blood, the red concreted mass, and a viscid pellicle termed the face, which spreads itself on the top of the red concretion. Some time ago, when making experiments with the blood taken from persons in the fevery, I was surprized to find it often covered with that fazy crust. This induced me to extend my experiments to large quantities of blood from different subjects, which I had opportunities of inspecting at once in a large hospital. For this purpose I one morning ordered ten patients in the fevery to be bled, taking two ounces from each. A larger quantity was taken, for its inspection, from two men in health. That day I had occasion to preferibe bleeding to a woman in labour, two hours before her delivery; to a girl of sixteen years of age afflicted with a luminary proceeding from the chlorosis; to three patients in the rheumatism; and to a person labouring under an irritation of the liver.

From.

(a) In others who died in this yellow state, the bile in the gall-bladder was found of a thick ropy consistence like pitch, but the liver never appeared in the least affected. Dr Lind at first in several bodies opened the head only; but afterwards judged that all the cavities ought to be inspected.
From a nice examination, and an examination of the different blood, I found in general, that the more
size there was on the top, and the thicker and more
viscid this white 'pellicle' showed itself, the concretion
below it was of a more loose coherence. This was not
so observable when only some slight white streaks appeared
on the top. But when much size had separated itself, the red mass became very soft at the bottom of
the vessel, and less compact in its different parts, in proportion to their distance from the surface, towards
which this whitish portion had ascended.

From this and from other experiments it appears,
that this crust or pellicle is the natural gluten or ce-
ment of the blood (called by some the coagulable
lymph), which becomes strongly dispersed, in certain
circumstances and diseases, to separate itself. And
whereas the serum and red concretion are easily incor-
pored together, it will be found, that this glue, af-
ter its separation, becomes immitachable with either.
We have, by gentle drying, converted it into a perfectly
tough elastic membrane; and, by the means of a small
portion of the red mass being left adhering to it, into
a substance resembling muscular flesh; and it is capable
of undergoing various changes into corruption, in the
same manner as of either of the two.

Now I can see no reason why this gluten, in its
morbid state, may not separate itself from the circu-
lating blood, and be deposited in the cavities of the
body, as readily as the serum does in dropsies; the
former having always a less disposition than the latter
to incorporate with the mass.

In different persons who died of fevers in Lon-
don and Minorca, and where no infection was suspected,
appearances similar to these have also fallen under
the inspection of those accurate anatomists Drs Hun-
ter and Claghnorn. Hence it may be presumed very
difficult to distinguish fevers that are produced by
infection, from some others. I cannot; however, be
induced to think, as those gentlemen seem to do, that
these preternatural substan ces which were found in the
cavities of the body are the consequence, but rather
that they are the cause of the inflammation and ex-
coriation. I believe these substances to have been
dis charged at first diseased extravasated gluten, and conjecture their different
states greatly to depend upon the different times
at which they were deposited.

I have remarked in a variety of dead bodies,
three different kinds of extravasation; those occurred
in fluid as had died of the fever, of the consumption,
and of fevers. In the former of those diseases, red
coagulated blood is found extravasated in almost all
parts of the body, not only into the tela cellulosa,
but into the bellies of the muscles, particularly of the
legs and thighs, which often become quite inflated and
even distended with large granular masses. The intestines and meconium are often spotted with
extravasated blood; and I have seen large ecchymoses on
the thorax. These appearances at first sight rumbl-
ed so many different modifications; and by this ap-
pearance some anatomists have been deceived; but,
upon a nice examination, the texture, of the parts is
found to be loose and firm. There is likewise, in
that disease, sometimes, an extravasation of water,
chiefly collected in, and always when in the legs con-
fined to, the tela cellulosa.

But whereas, in the limbs of scurvy patients,
it is extremely difficult to make a good distinction by
reason of such quantities of extravasated blood that
every where obstruct the operator; for, upon the con-
trary, the lower extremities of those whose had died
consumptive, with swelled legs, are of all other sub-
jects, in the best state to afford a satisfactory view of
the muscles. The water inclosed in their legs having
infalinated itself, by passing the tela cellulosa, into
the spaces between the muscles, the muscles are easily sepa-
rated from each other, and their several origins and
insertions may be distinctly traced by means of their
having been cleaned and washed by the water in the
invelling cellular membrane. Thus there are extrava-
sations of three sorts; viz. first, the granular mass in
the scurvy; and this I have often remarked where no
serum was observed. Secondly, the serum alone in
anaceous swellings. The third and last is what was
taken notice of in those who died of fevers, being the
granular of the blood, accompanied for the most part
with some serum; both of them altogether confined
in the large cavities of the body.

I conjecture, that in these fevers there is always
an ulcerous or purulent disposition in the blood; and
that this gluten or coagulable lymph is greatly dis-
eased. I have frequently seen it have a true purulent
appearance soon after it was drawn off, when the pa-
tient seemed not very ill.

And I further conjecture, that the Mitchief often
lies within the breath; and also, that the great benefit de-
ferred from the early application of blisters, in a
great measure flows from so many ulcerations and vents
being timely provided for the free discharge of those
purulent and tainted particles from the body.

If an infection depends, as many have imagined,
on the admission of certain foreign particles into the
blood, this gluten seems to be its more immediate
seat, and to be primarily affected by it; and a dis-
charge of this, as though by washing those particles
out of the body, tends in a great measure to remove the
disease.

It is an observation of the best practical writers,
that ifuses and fetons are most excellent preservatives
against receiving an infection, nay, even that of the
plague itself. And indeed a suppuration and plentiful
discharge from a proper ulcer, whether produced by
nature or by art, seems to open a channel the belh appr-
propriated for an exit out of the body to some of the
tous malignant poisons. Thus the most favourable
crisis in the plague, and in most pestilential fevers,
happens when nature excites tumours kindly suppura-
ting in the groin or arm pits, by which beneficial and
plentiful discharge the deadly poison is expelled from
the constitution.

I have observed it to be amongst the most certain
characteristics of the worst fevers, that the blisters ei-
er do not rise and fill, or discharge such yellow,
greenish, fetid, and highly offensive fluid, that even
experienced nurses could give a pretty certain conjectu-
re from the blisters, of the different degrees of mal-
dignity in the fever. We have more than once en-
dangered to conceal the bad state of some patients in the
hospital; but a discovery was always made of their
condition in the wash-houses, from the linen sent there
stained with the discharges from the blistered parts.

And
Fever.

The cure of this terrible disease, according to Dr. Hillery, is very easy and simple. His indications are, 1. To moderate the too great and rapid motion of the fluids, and abate the too great heat and violence of the fever in the two first days of the disease, as much and as safely as we can. 2. To evacuate and carry out of the body as much of the putrid bile and other humours, and as expeditiously and safely as possible. 3. To put a stop to the putrefactive disposition of the fluids, and to prevent the gangrenes from coming on, by suitable antiseptics.

The first indication is answered by bleeding, which, in the first stage of this fever, is absolutely necessary in some degree: the quantity to be taken away must be determined by the age and strength of the patients, the degree of plethora, fulness of the pulse, &c. When called in at the beginning, he orders 12, 14, 16, 18, or 20 ounces of blood to be taken away on the first or second day: and if the patient's pulse rise after the first bleeding, or if the fever still continue high and the pulse full, he repeats the bleeding once on the days above mentioned. But bleeding a third time is seldom or never required: neither is bleeding on the third day almost ever necessary: and when it is performed on that day, it ought to be done with the greatest caution and judgment; neither should a vein be opened after the third day in this fever, unless some very extraordinary symptoms and circumstances require it; which seldom or never happen. On that day, indeed, the pulse generally sinks, and the blood is in such a dilated state, that bleeding must be accounted highly pernicious. Nevertheless, it is indispensably necessary in the beginning of the disease; and if omitted at that time, the violent heat and motion of the blood increase the putrefaction of the humours to such a degree as to bring on the fatal consequences much sooner than would otherwise have happened.

After bleeding, we come to the second indication of cure, namely, to evacuate as much of the bilious and putrid humours as soon and as safely as we can. The great irritation of the stomach, by the putrid bilious humours constantly attending this fever, with almost continual retchings and violent vomitings, seem to indicate the giving of an emetic: but the stomach is always observed to be so violently inflamed and irritated and most commonly inflamed by the acrimony of the putrefacient bile, that any emetic, even the most mild and gentle, given in the smallest dose, brings on an inceffant vomiting, which continues, in spite of all remedies, till a mortification and death ensue. Instead of this, it is proper to give large draughts of warm water, which, without any additional stimulus to the coats of the stomach, evacuates its acid and putrid contents, commonly with great relief to the patient; the warm water also acts as an emollient fatus to the inflamed coats of the stomach; and thus abates the inflammation, and prevents the gangrene and mortification from coming on.

After the patient has by this means vomited seven or eight times or oftener, and discharged a great quantity of yellow and black bilious matter as they often do; a grain or a grain and a half of thebeic extract is given in order to procure some respite from the violent retching, vomiting, and anxiety. The person is defir'd to take nothing into his stomach for two hours after this, by which means it is seldom or never rejected; and thus all the symptoms are considerably abated, the retching and vomiting either totally cease or are very much lessened, so that medicines may now be exhibited which the stomach would not have retained before. These are cooling acid juleps, or other antiseptic remedies; but neither nitre nor any of its preparations will commonly be found to stay on the stomach; nor are the nitrous medicines, or even the common anti-emetic draughts, proper to be given in this disease, even though they should agree with the stomach, on account of their attenuating property. If the patient has not a feoul or two after drinking the warm water and vomiting, it is necessary to give a gentle purging (quality; and when six or eight hours have been obtained, a gentle antiphlogistic and antiseptic purge, in order to evacuate by stool as much of the bilious matter as we possibly can. Or if the patient has a purging before, which sometimes though very rarely happens, a dose of toasted rhubarb is given and an antiseptic anodyne after it has operated, to abate and check the too great purging, but not to stop it, as this evacuation has been always observed to be of service, provided it be not too violent.

After this indication is completely answered, the next is to exhibit such proper antiseptic medicines as may stop the putrefactive disposition of the fluids. Here the Peruvian bark would seem to be the most proper remedy, but unluckily the stomachs of the patients in this disease are so much irritated, and so apt to reject every thing, that the bark cannot be retained in any form whatever. In this case Dr. Percival recommends columnb-root, the infusion of which is found to be a powerful anti-emetic and antiputrefactive medicine, and might perhaps so far alter the state of the stomach as to make it bear the bark. Dr. Hillary, however, who was ignorant of the virtues of columbo, substituted the radix serpentaria Virginiana with success. A slight infusion of this root not only soothes entirely on the stomach of the patients, but moderately raises the pulse and fever, both of which are now too low. The following receipt was found most agreeable and efficacious.

By the use of this medicine, and soft light nourishment taken in small quantities, the pulse is usually kept up.
Being called out of the town, I did not see him till the fourth morning after; he said that he had followed my directions; and I found him free from the fever and all its symptoms, but weak and low, and his skin a little yellow, but much less so than usual, uncle's when the bilious matter is thus carried off. I ordered him to take euc. virreli acidi. got. 1x, three or four times a-day for a few days, in an infusion of mint-leaves with a little snake-root, made as tea; which he did, and four recovered perfectly well in seven or eight days time.

"This patient being fixed in so violent a manner, and recovering in so short a time, and so near to the rule which the elegant Celsius recommends Lib. tabo, et jucum'ves, not only confirmed the above manner of reasoning on the cause and nature of this disease to be right, but made me determine to follow the same method as near as I possibly could ever since, and I must add, with the same good success also, when I am called so early in the disease that I can distinctly perceive it: which is too seldom the case; for in general the physician is not called till the fourth or fifth day, or after, when the putrid, acid, bilious matter is a great part of it carried into the blood, which it has been dissolved and brought into a colliquated, putrid, gangrenous state, that the best of methods, and the most efficacious medicines, however judiciously timed and applied, are precarious and uncertain; or sometimes it is so far advanced, that the ablest physician can do no more than tell the relations of the sick that it is too late, and that they can live but a few hours: for I know no disease in which the recovery of the patient so much depends upon the right or wrong method of treating it, at the very first attack or beginning of the disease, as this fever does: for by thus discharging and carrying the putrid, acrimonious, bilious matter, out of the body before much of it is carried into the blood, not only most of the bad symptoms which attend the second stage of the fever are prevented from coming on, but the hemorrhages, and the yellowness of the skin, &c. also, and the fever been taken off too; for I have never seen any hemorrhoagy come on, but little yellowness, or in some cases, when they were thus treated.

"And when the last stage of this fever is come on before we are called in, provided that it is not at the very latter end of it, I have always found that this method of gentle purging, whenever the beforementioned symptoms indicate it, and a liberal use of the anti septic medicines in the intervals, has been so successful, that I have seen but two patients that have died in this fever during the eight years past in which I treated it in this manner; and one of them was so weak that he could not take a spocial of any thing, and so near his end that he died about two hours after without taking any medicine; and the other killed himself by drinking a gallon of cold water in less than three hours time (after taking half an ounce of manna in the morning), which struck such a coldness into his whole body that he died; though I have visited several every year, and in some years a great many; therefore I take the liberty of recommending this method to others, and with it to be successful to all."

To the genus of typhus also belong all those fevers attended with very profuse and debilitating sweats, and which
when the patient is very ill, it will return so frequent;

The urine in a true intermittent is clear in the fits and turbid in the intervals; but in the hectic fever it is liable to all kinds of irregularity. It will be equally clear or turbid in both stages; or turbid in the fits and clear in the intervals; and sometimes it will be, as in a true intermittent, clear during the fever, and thick at the going off.

Hectic patients often complain of pains like those of the rheumatism, which either affect a part of the body, or else return constantly to the same place; which is often at a great distance from the seat of the principal disorder, and, as far as is known, without any peculiar connection with it. Those pains are so violent in some patients, as to require a large quantity of opium. As far as Dr Heberden has observed, they are most common, where the hectic arises from some ulcer open to the external air, as in cancers of the face, breast, &c. Joined with this fever, and arising probably from one common cause, he has been surprised to see swellings of the limbs, neck, or trunk of the body, rise up almost in an instant, as if the part was all at once grown fatter. These swellings are not painful, hard, or discoloured, and they continue for several hours.

Dr Heberden has seen this fever attack those who seemed in tolerable health, in a sudden and violent manner, like a common inflammatory one; and like that, also, in a very short time bring them into imminent danger of their lives; after which it has begun to abate, and to afford hopes of a perfect recovery. But though the danger might be over for the present, and but little of a fever remain; yet that little has soon demonstrated, that it was kept up by some great mischief within, and, proving unconquerable by any remedies, has gradually undermined the health of the patient, and never ceased except with his life. This manner of its beginning, however, is extraordinary. It much often differs in its strength at first, and creeps on so slowly, that the subjects of it, though they be not perfectly well, yet for some months hardly think themselves ill; complaining only of being sooner tired with exercise than usual, of want of appetite, and of falling away. But gentle as the symptoms may seem, if the pulse be quicker than ordinary, so as to have the artery to beat 90 times and perhaps 120 times in a minute, there is the greatest reason to be apprehensive of the event. In no disorder, perhaps, is the pulse of more use to guide our judgment than in the hectic fever; yet even here we must be upon our guard, and not trut entirely to this criterion; for one in about twenty patients, with all the worst signs of decay from some incurable cause, which irresistibly goes on to destroy his life, will show not the smallest degree of quickness, nor any other irregularity of the pulse, to the day of his death.

Cauti, &c. This fever will suprervene whenever there is a great collection of matter formed in any part of the body; but it more particularly attends upon the
Inflammation of a fibrous gland, and even upon one
that is slight and only just beginning; the fever growing
worse in proportion as the gland becomes more in-
flamed, ulcered, or gangrenous. And such is the ling-
ering nature of those glandular disorders, that the first
of those stages will continue for many months, and the
second for some years.

If this fibrous inflammation be external, or in the
lungs, or some of the abdominal visera, where the dis-
turbance of their functions plainly points out the
seat of the disorder, no doubt can be entertained con-
cerning the cause of the fever. But if the part affec-
ted be not obvious to the senses, and its precise func-
tions be not known, the hectic, which is there only part
of the train of another disease, may be mistaken for
the primary or only one.

Lying-in women, on account of the violence suf-
tained in delivery, generally die when affected with
this fever. Women of the age of near 50 and upwards
are particularly liable to it. For, upon the cellu-
tation of their natural discharge, the glands of the
breasts, ovaries, or womb, too commonly begin to
grow fibrinous, and proceed to be cancerous. Not
only there, but the glandular parts of all the abdo-
ninal visera, are disposed to be affected at this part
icular time, and to become the seats of incurable disor-
ders.

The injuries done to the stomach and liver by hard
drinking are attended with similar symptoms, and ter-
minate in the same manner.

Dr Heberden observes, that the slightest wound by
a fine pointed instrument is known upon some occa-
sions to bring on the greatest disturbances, and the most
alarming symptoms, may even death itself. For
not only the wounded part will swell and be painful, but
by turns almost every part of the body; and very dif-
tant parts have been known to come even to suppura-
tion. These symptoms are constantly accompanied
with this irregular intermittent, which lasts as long as a
part of the breast.

Fregigns. This anomalous fever is never less dan-
gerous than when it belongs to a kindly suppuration, in-
to which all the diseased parts are melted down, and for
which there is a proper outlet.

The symptoms and danger from some small punctures,
with their concomitant fever, most frequently give way in
a few days; though in some persons they have continued for
two or three months, and in others have proved fatal.

The inflammation of internal fibrous glands, or of
those in the breasts, sometimes goes off, and the fever,
which depended upon it, ceases; but it much oftener
happens, that it proceeds to cancerous and gangrenous
ulcers, and terminates only in death. Death is also
almost universally, the consequence of hectic fever
from tubercles of the lungs, which have in general at
least been considered as glandular bodies in a fibrous
state.

Cure. It is not to be expected that the same re-
medies will in every case be adapted to a fever which,
arising from very different causes, is attend-
ed with such a variety of symptoms. A mixture
of afebrin and opium has in some persons seemed
singularly serviceable in this fever, when brought on
by a small wound; but in most other cases the princi-
pal if not the sole attention of the physician must be
Hectics.

The phlegmasia, or topical inflammations, are a
very numerous assemblage of diseases. Their great
char-
When a tendency to suppuration is perceived, the proper indication is to promote the production of perfect pus as much as possible. For this purpose various remedies, supposed to possess a specific power, have been proposed; but it does not appear that any of them are possessed of a virtue of this kind; and, in Dr Cullen's opinion, all that can be done is to favour the suppuration by such applications as may support a moderate heat in the part, by some tenacity confine the perforation, and by an emollient quality may weaken the cohesion of the teguments, and favour their erosion. As all abscesses are occasioned by the effusion of fluids and as in the case of certain effusions a suppuration becomes not only unavoidable but desirable, it may be supposed that most of the means of procuring a resolution by diminishing the force of circulation, &c. ought to be avoided, but as we observe on the one hand, that a certain degree of increased impetus, or of the original symptoms of inflammation, is necessary to produce a proper suppuration; so it is then especially necessary to avoid those means of resolution which may diminish too much the force of circulation. And on the other hand, as the impetus of the blood, when violent, is found to prevent the proper suppuration; so, in such cases, though a tendency to suppuration may have begun, it may be proper to continue those means of resolution which moderate the force of the circulation. With respect to the opening of abscesses when completely formed, see the article Surgery.

When an inflammation has taken a tendency to gangrene, that event is to be prevented by every possible means; and these must be different according to the nature of the several causes: but after a gangrene has in some degree taken place, it can be cured only by the separation of the dead from the living parts. This in certain circumstances can be performed, and most properly, by the knife. In other cases it can be done by exciting a suppuratory inflammation on the verge of the living part, whereby its cohesion with the dead part may be every where broken off, so that the latter may fall off by itself. While this is doing, it is proper to prevent the further propagation of the part, and its spreading wider. For this purpose various antifeptic applications have been proposed: but Dr Cullen is of opinion, that while the teguments are entire, these applications can hardly have any effect; and therefore, that the fundamental procedure must be to scarify the part so as to reach the living subcutis; and, by the wounds made there, to excite the suppuration required. By the same incisions also we give access to antiseptics, which may both prevent the progress of the putrefaction in the dead, and excite the inflammation necessary on the verge of the living parts.

When the gangrene proceeds from the loss of tone, and when this communicat d to the neighbouring parts prevents that inflammation which, as we have said, is requisite to the separation of the dead parts from the living, it will be necessary to obviate this loss of tone by tonic medicines given internally; and for this purpose the Peruvian bark has been found to be most effectual. But when the gangrene arises from the violence of inflammation, the bark may not only fail of proving a remedy, but may do harm; for its power as a tonic is especially suited to those cases of gangrene which proceed from an original loss of tone, as in the

When an inflammation has taken a tendency to gangrene, that event is to be prevented by every possible means; and these must be different according to the nature of the several causes: but after a gangrene has in some degree taken place, it can be cured only by the separation of the dead from the living parts. This in certain circumstances can be performed, and most properly, by the knife. In other cases it can be done by exciting a suppuratory inflammation on the verge of the living part, whereby its cohesion with the dead part may be every where broken off, so that the latter may fall off by itself. While this is doing, it is proper to prevent the further propagation of the part, and its spreading wider. For this purpose various antifeptic applications have been proposed: but Dr Cullen is of opinion, that while the teguments are entire, these applications can hardly have any effect; and therefore, that the fundamental procedure must be to scarify the part so as to reach the living subcutis; and, by the wounds made there, to excite the suppuration required. By the same incisions also we give access to antiseptics, which may both prevent the progress of the putrefaction in the dead, and excite the inflammation necessary on the verge of the living parts.

When the gangrene proceeds from the loss of tone, and when this communicat d to the neighbouring parts prevents that inflammation which, as we have said, is requisite to the separation of the dead parts from the living, it will be necessary to obviate this loss of tone by tonic medicines given internally; and for this purpose the Peruvian bark has been found to be most effectual. But when the gangrene arises from the violence of inflammation, the bark may not only fail of proving a remedy, but may do harm; for its power as a tonic is especially suited to those cases of gangrene which proceed from an original loss of tone, as in the
calf of palsy and oedema; or in those cases where a
loss of tone takes place while the original inflammatory
symptoms are removed.

On the other hand, Mr Bell is of opinion, that in-
cisions made with a view to admit the operation of an-
ti-lytic remedies in gangrene, as well as the remedies
themselves, must be peminous from the irritation they
occasion, and from the danger of wounding blood-
veins, nerves, or tendons, and also by allowing a free
passage for the putrefcent fluids into the parts not
yet affected. And unless they be carried so deep as
to reach the found parts, applications of the anti-lytic
kind can never have any effect in answering the pur-
pose for which they were intended. The same author
also remarks, that all the advantages commonly observed
from the great number of applications recommended for
gangrenes, are obtained with more ease, and generally
too with more certainty, from the use of some gentle
stimulating embrocation; which, by exciting a slight
irritation upon the surface, especially when allided
by a free use of the Peruvian bark, produces for the moft
part such a degree of inflammation as is wished for.
With this view he has frequently known a
reduction of the degree of inflammation to its
normal state, and has in due course of time seen the
condition return to that which it was in before the
coward was applied.

Whenever, either by the means recommended, or by
a natural exertion of the system, a slight inflammation
appears between the diseased and found parts, we may
in general, with tolerable certainty, expect, that in due
time the parts will be separated; and when a full sup-
rupation is once fairly established, there can be little
doubt that the mortified parts will be soon and easily
removed.

A complete separation being effected, the remaining
fore is to be treated in the manner described under the
article SURGERY; with a proper attention, at the same
time, to the support of the general system by the con-
imination of a nourishing diet, and the bark with such
quantities of wine as may seem necessary.

With regard to the bark, however, it is proper to
note, that in the use of it in the manner in which it is
likewise unsuccessfull, as well as in that attended with
an high degree of inflammation; and that is, in those
mortifications of the toes and feet, common in old
people, or which arise from any cause increaing the
rigidity of the vessels to such a degree as to prevent
the motion of the fluids through them. In this case
Mr Pott has discovered, that all kinds of warm applica-
tions are very unsuccessfull; but that by the free use
of opium, together with sedatives and relaxants exter-
nally applied, he has frequently seen the tumefaction
of the feet and ankles subsided, the skin recover its
natural colour, and all the mortified parts separate in a
very short time, leaving a clean fore. But what to
elvations, or any other attempt to separate artificially
the mortified from the found part, he thinks them
very prejudicial, by giving pain; which is generally of
itself violent in this dis ease, and which seems to have a
great share in producing the other evils.

The other terminations of inflammation either do
not admit of any treatment except that of preventing
them by resolution, or properly belong to the article Phtbosia.

Erythema symptomaticum, Sauv. f p. 6.

The word erythema doth not apply to any primary dis-
 ease, but to a great number of those cutaneous inflam-
mations denominated by another general term, viz. the
erysipelas, or " St Anthony's fire;" and which being
commonly symptomatic, of some other inflammation or
disorder, are to be removed only by removing the
primary disease; the erythema is found scarcely to bear
any kind of warm application to itself; and is very apt,
if treated as a primary disea, to terminate in a gan-
grene of the part affected, or some other disorder fell
more dangerous. The difference between the phleg-
mon or preceding species, and erythema, according to Dr
Cullen, is, that, in the former, the inflammation seems
particularly to affect the vessels on the internal surface
of the skin, communicating with the l ax adjacent cel-
ular texture; whereas a more copious effusion, and that
too of serum convertible into pus, takes place. In
the erythema the affection is of the vessels on the ex-
ternal surface of the skin communicating with the rete
suctosum, which does not admit of any effusion but
what separates the cuticle and gives occasion to the
formation of a blister, while the smaller size of the
veins admits only of the effusion of a thin fluid very
f seldom convertible into pus. For the cure of the fever
attended with erythema or cef fe, see below; and
for the external treatment of erythema, see the article
SURGERY.

GENUS VIII. OPHTHALMIA.

Inflammation of the Eye.

Chemosis, V sq. 46.
Oph-
Ophthalmia, \textit{Vog.} 47.  
Ophthalmia \textit{ocularum}, \textit{Flemm.} II. 165.  
Ophthalmia ad natum, \textit{Sauv.} \textit{f.p.} 16.  
Ophthalmia ab escocata, \textit{Sauv.} \textit{f.p.} 18.  
Ophthalmia uvea, \textit{Sauv.} \textit{f.p.} 22.  

From reading this long list of distinctions which authors have invented in the ophthalmia, it is evident, that by far the greatest part of them are symptomatical, or merely the consequences of other disorders present in the habit; and therefore the remedies must be directed towards the removal of the primary disorder; and when they are gone the ophthalmia will be removed of course. Dr Cullen observes, that the inflammation of the eye may be considered as of two kinds; according as it is seated in the membranes of the ball of the eye, when it is named \textit{ophthalmia membranarum}; or as it is seated in the subcutaneous glands placed in the tarsus, or edges of the eyelids, in which case it may be termed \textit{ophthalmia tarso}. These two kinds are very frequently connected together, as the one may excite the other; but they are full to be distinguished according as the one or the other may happen to be the primary affection.

7. The inflammation of the membranes of the eye affects especially, and most frequently, the adnata, and appears in a turgescence of its vessels; so that the red vessels which are naturally there, become not only increased in size, but many more appear than in a natural state. This turgescence of the vessels is attended with pain, especially from the motion of the ball of the eye; and this irritation, like every other, applied to the surface of the eye, produces an effusion of tears from the lacrymal gland.

The inflammation commonly, and chiefly, affects the adnata spread on the anterior part of the bulb of the eye; but usually spreads also along the continuation of the adnata on the inside of the palpebra, and as that is extended on the tarsus palpebrarum, the excretories of the subcutaneous glands opening there are also frequently affected. When the affection of the adnata is considerable, it may be communicated to the subjacent membranes of the eye, and even to the retina itself; which thereby acquires so great sensibility, that every impression of light becomes painful. The inflammation of the membranes of the eye is in different degrees, according as the adnata is more or less affected, or according as the inflammation is either of the adnata alone, or of the subjacent membranes also; and upon these differences, different species have been established; but they seem all to differ only in degree, and are to be cured by the same remedies more or less employed.

The proximate cause of ophthalmia is not different from that of inflammation in general; and the different circumstances of ophthalmia may be explained by the difference of its remote causes, and by the different parts of the eye which it happens to affect; as may be understood by what has been already said. We shall therefore proceed to give an account of the method of cure.

The great objects to be aimed at in the treatment of ophthalmia, are, in the first place, the resolution of the inflammation which has already taken place; and, secondly, the removal of those consequences which frequently arise from the inflammation, especially if it have been of long standing. But besides these, while it has appeared from former observation, that there is a peculiar disposition to the disease, practices may often be successfully employed to combat this disposition, and thus prevent the return of the affection.

The ophthalmia membranarum requires the remedies proper for inflammation in general; and when the deeper-seated membranes are affected, and especially when a pyrexia is present, large general bleedings may be necessary. But this is seldom the case; and, for the most part, the ophthalmia is an affection merely local, accompanied with little or no pyrexia. General bleedings therefore have little effect upon it, and the cure is chiefly to be obtained by topical bleedings, that is, blood drawn from the vessels near the inflamed part; and opening the jugular vein, or the temporal artery, may be considered as some measure of this kind. It is commonly sufficient to apply a number of leeches round the eye; but it is perhaps still better to draw blood by cupping and scarifying upon the temples. In many cases, the most effectual remedy is to scarify the internal surface of the inferior eye-lid, and to cut the turgid vessels upon the adnata itself.

Besides the blood-letting, purging, as a remedy suited to inflammation in general, has been considered as peculiarly adapted to inflammation in any part of the head, and therefore to ophthalmia; and it is sometimes useful: but, for the reasons given before with respect to general bleeding, purging in the case of ophthalmia does not prove useful in any proportion to the evacuation excited. For relaxing the pangs in the part, and taking off the determination of the fluids to it, blistering near the part has commonly been found useful. When the inflammation does not yield to the application of blisters after topical bleeding, great benefit is often obtained by supporting a discharge for the blistered part, under the form of an issue, by which means a more permanent determination of blood from the part is obtained.

It is probably also on the same principle that the good effects obtained from the use of ointment medicines in obliterative cases of ophthalmia are to be accounted for. By these ointments, in particular, which occasion and
and support for some time a great discharge from the nofe, great benefit has often been obtained. The powder of aftarbacca, or the infusion of hippocastanum, fluftup the nofe at bed-time in proper doses, are often productive of the bleft effects, when many other remedies have been tried in vain.

Ophthalmia, as an external inflammation, admits of topical applications. All thofe, however, which in creafe the heat and relax the vessels of the part, prove hurtful; and the admission of cool air to the eye, and the application of cooling and altirgent medicines which at the fame time do not produce irritation, prove ufeful. All thofe the folution of acetated lead, affiduously applied, is perhaps the more generally adapted to this purpose.

Before the ufe of this dilatemper, indeed, all irritation must carefully be avoided, particularly that of light; and the only certain means of doing this is by keeping the patient in a very dark chamber.

The flighter kinds of inflammations from the dust or the fun may be removed by fomenting with warm milk and water, adding a small portion of brandy; and by anointing the borders of the eye-lids with unguentum tufts, or the like, at night, especially when thofe parts are excoriated and fore. But in bad cafes after the inflammation has yielded a little to evaucations, the cataplasma aluminis of the London pharma­topia spread on lint, and applied at bed-time, has been found the beft external remedy. Before the ufe of the latter, the folution of white vitriol is prefcribed with advantage; and in violent pains it is of fervice to foment frequently with a decoction of white poppy heads. One of the moft common and moft disagreeable confequences of ophthalmia, is an oifudation of the cornes, fo far obstructing the passage of light as to diminish or prevent vision. This is fometimes fo confeiderable as to admit of removal by operation: but in flighter cafes it may often be removed by the application of different gentle eicharotics; and in this way, without the leaft danger of any inconvenience, good effects are often obtained, from gently introduc­ing into the eye at bed-time a powder confifting of equal parts of crystals of tartar and fuugar.

Where there is a propensity to frequent returns of this affection, the Peruvian bark is often employed with fuccefs in combating it: But nothing in general answers better than frequent and regular cold bathing of the eyes.

**GENUS IX. PHRENITIS.**

**PHRENEX**, or Inflammation of the Brain.

Cephalitis cerebelli, Sauv. fp. 8.
Phrenitis miliaris, Sauv. fp. 3.
Phrenitis variolosa, Sauv. fp. 5.
Phrenitis morbillosa, Sauv. fp. 6.
Phrenitis a plica, Sauv. fp. 8.
Phrenitis aphrodisifica, Sauv. fp. 9.
Phrenitis hydrophobica, Sauv. fp. 15.
Phrenitis a dolore, Sauv. fp. 13.
Cephalitis traumatica, Sauv. fp. 2.

**Description.** The figns of an impending phrenitis are, immoderate and continual watchings; or if any fleep be obtained, it is disturbed with dreams and gives no refreshment; acute and lafiting pains, especially in the hind part of the head and neck; little thirt; a great and low respiration, as if proceeding from the bottom of the breath, the pulse fometimes small and low, fometimes quick and frequent; a fup­preffion of urine; and forgetfulness. The dilatemper when prefent may be known by the following figns:

The veins of the head swell, and the temporal arteries throb much; the eyes are fixed, sparkle, and have a fierce afpect; the fpeech is incoherent, and the pa­tient behaves very roughly to the by-fanders, with furious attempts to get out of bed, not indeed con­nually, but returning as to admit of removal by operation; the tongue is dry, rough, yellow, or black; there is a coldnef of the external parts; a promenea to anger; chattering of the teeth; a trembling of the hands.
with which the sick seem to be gathering something and actually do gather the mumps off the bed clothes.

Causes of, and persons subject to, this disorder. People of a hot and bilious habit of body, and such as are of a passionate disposition, are apt to be affected with phrenitis. In the former danger are those who use much spices, or are given to hot and spirituous liquors; who have been exposed more than usual to the sun, or obliged to undergo inordinate studies or watchings; who are subject to head-aches, or in whom some customary hemorrhages have been stopped; or the disease may arise from some injury offered to the head externally. Dr Pringle observes, that the phrenitis, when considered as an original disease, is apt to attack soldiers in the summer season when they are exposed to the heat of the sun, and especially when asleep and in liquor. A symptomatic phrenitis is also more frequent in the army than elsewhere, on account of the similar cases, a hate of phrenitis. In the same danger are those who use much coffee and bilious habit of digestion, the disease is apparently critical, breaking out suddenly, with watching; thin watery urine, white and frothy, running off involuntarily from the part affected, and the patient dies delirious. The following symptoms: Sweats, especially those from the feet and soles, are a symptom of danger; and, unless removed before the fourth day, are the cause of death. An abatement of strength, the mind, we are still totally in the power of the disease, and particularly that peculiar delirium which characterizes it. But in what manner local diseases, even of the brain itself, produce affections of the mind, are we still totally in the dark.

Progress. Every kind of phrenitis, whether idiopathic or symptomatic, is attended with a high degree of danger; and, unless removed before the fourth day, a gangrene or phacelus of the meninges readily takes place, and the patient dies delirious. The following are the most fatal symptoms: A continual and furious delirium, with watching; thin watery urine, white faces, the urine and fowls running off involuntarily or a total suppression of these excretions; a ready disposition to become insipid, or to faint; trembling, rigor, chattering of the teeth, convulsions, hic-cough, coldness of the extremities, trembling of the tongue, shrill voice, a sudden cessation of pain, with apparent tranquillity. The following are favourable: Sweats, apparently critical, breaking out; a ceasing effort of nature to terminate the disease by a diarrhoea; a large hemorrhoagy from the nose; swellings of the glands behind the ears; hemorrhoids.

Cure. From what has been said of the theory of this disease, the cure must entirely depend on obtaining a resolution of the inflammation. The objects chiefly to be aimed at with this view are, 1. The removal of such exciting causes as continue to operate. 2. The diminution of the momentum of the blood in the circulating system in general. 3. The diminution of impetus at the brain in particular; and, 4. The avoiding circumstances which tend either to accelerate the motion of the blood or to give determination to the head.

Different practices may be used with these intentions; but here the most powerful remedies are to be immediately employed. Large and repeated bleedings are especially necessary; and these too, taken from well-fed as near as possible to the part affected. The opening the temporal artery has been recommended and with some reason: but as the practice is attended with some inconveniences, perhaps the opening of the jugular veins may prove more effectual; with which, however, may be joined the drawing of blood from the temples by cupping and scarifying. It is also probable, that purging may be of more use in this than in some other inflammatory affections, as it may operate by resolution. For the same purpose of resolution, warm pediluvia are a remedy, but rather ambigious. The taking off the force of the blood in the veins of the head by an erect posture is generally useful. Blisters are also useful, but chiefly when applied near to the part affected. In short, every part of the antiphlogistic regimen is here necessary, and particularly the admission of cold air. Even cold substances applied to the head have been found useful; and the application of such refrigerants as vinegar is certainly proper. Opiates are thought to be hurtful in every inflammatory state of the brain. On the whole, however, it must be remarked, that practitioners are very uncertain with regard to the means proper to be used in this disease; and the more so, that the symptoms by which the disease is commonly judged to be present, appear sometimes without any internal inflammation; and on the other hand, diffuse signs have shown that the brain has been inflamed, where few of the peculiar symptoms of inflammation had appeared before.

Genus X. Cynanche.
Cynanche, Sauv. gen. 110. Lim. 33. Syst. gen. 300.
Angina inflammatoria, Boerh. 798.

Sp. I. Cynanche tonsillaris.

The Inflammatory Quinsy.
Cynanche tonsillaris, Sauv. sp. 1.
Angina inflammatoria, sp. 5. Boerh. 805.

Description. This is an inflammation of the mucous membrane of the fauces, affecting principally that congeries of mucous follicles which forms the tonsils; and from thence spreading along the velum and uvula, so as frequently to affect every part of the mucous membrane. The disease appears by some tumour and redness of the parts; is attended with a painful and difficult deglutition; a troublesome clamminess of the mouth and throat; a frequent but difficult excretion of mucus; and the whole is accompanied with pyrexia. The inflammation and tumor are commonly at first most considerable in one tonsil; and afterwards, abating in that, increase in the other. This disease is not contagious.

Causes of and persons subject to, this disorder. This disease is commonly occasioned by cold externally applied, particularly about the neck. It affects especially the young and sanguine; and a disposition to it is often acquired by habit. It occurs especially in the spring and autumn, when vicissitudes of heat and cold frequently take place.

Progress. This species of quinsy terminates frequently by resolution, sometimes by suppuration, but hardly ever by gangrene; though in some cases fleshy spots appear on the fauces: the prognosis in these cases is generally favourable.

Cure. As the principal morbid affection in this disease, on which all its characterizing symptoms im-
Angina maligna, probably the more apt to Phlegm as tonsils and neighbouring parts, the object first and principally to be aimed at in the cure is to obtain a resolution of this inflammation. Sometimes, however, it is necessary to have recourse to practices, with the view of obviating urgent symptoms before a resolution can be effected: and in other cases, where a resolution cannot be obtained, it must be the aim of the practitioner to promote a speedy and favourable suppuration.

After suppuration has taken place, the proper treatment is to promote a speedy and favourable evacuation. Here some bleeding may be necessary; but large and general evacuations are seldom beneficial. The opening of the ranular veins seems to be an insignificant remedy, according to Dr Cullen but is recommended as efficacious by Sir John Pringle: more benefit, however, may in general be derived from leeches to the external fauces. The inflammation may be often relieved by moderate astringents, and particularly by acids applied to the parts affected. In many cases, nothing has been found to give more relief than the vapour of warm water received into the fauces.

Besides these, blistering, and still more frequently rubeficient medicines, are applied with success, as well antiphlogistic purgatives; and every part of the antiphlogistic regimen is to be observed, except the application of cold. Sir John Pringle recommends a thick piece of flannel moistened with two parts of common sweet oil, and one of spirit of hartshorn (or in a larger proportion, if the skin will bear it), to be applied to the throat, and renewed once every four or five hours. By this means the neck, and sometimes the whole body, is put into a sweat, which after bleeding either carries off or lefbens the inflammation. When the disease takes a tendency to suppuration, nothing will be more useful than the taking into the fauces the steam of warm water. Benefit is also obtained from poultices applied to the external fauces. When the abscess is attended with much swelling, if it break not spontaneously, it ought to be opened by a lancet; and this does not require much caution, as even the inflammatory state may be relieved by some scarification of the tonsils. When this disease runs very rapidly to such a height as to threaten suffocation, it is sometimes necessary to have recourse to bronchotomy as the only mean of saving the life of the patient. But there is reason to believe that this operation has sometimes been employed where it was not necessary; and we may safely venture to say, that it is but seldom requisite; infomuch that Dr Cullen tells us, that he has never in his practice seen any case requiring bronchotomy.

History and description. This disease is not particularly described by the ancient physicians; though perhaps the Syrian and Egyptian ulcers mentioned by Aretas Cappadox, and the pestilent ulcerated tonsils we read of in Actius, Amideus were of this nature. Some of the scarlet fevers mentioned by Morton seem also to have approached near to it. In the beginning of the last century, a disease exactly similar to this is described by the physicians of that time, as raging with great violence and mortality in Spain and some parts of Italy; but no account of it was published in this country till the year 1748, when a very accurate one was drawn up by Dr Fothergill, and in 1752 by Dr Huxham. The latter observes, that this disease was preceded by long, cold, and wet seafons by which probably the bodies of people were debilitated, and more apt to receive contagion, which possibly also might be produced by the flagrant and putrid waters.

The attack of this disease was very different in different persons. Sometimes a rigor, with fulnes and foreheads, and painful stiffness of the neck, were the first symptoms complained of. Sometimes alternate chills and heats, with some degree of giddiness, drowsiness, or head-ach, ushered in the disease. It feized others with much more severity; great pain of the head, back, and limbs; a vall oppression of the precordia, and continual fighting. Some grown persons went about for some days in a drooping state with much uneasiness and anxiety, till at last they were obliged to take to their beds. Thus various was the disease, says Dr Huxham, at the outset. But it commonly began with chills and heats, load and pain of the head, foreheads of throat, and hoarseness; some cough, sickness at stomach, frequent vomiting and purging, in children especially, which were sometimes very severe; though a contrary state was more common to the adult. There was in all a very great dejection of spirits, very sudden weakness, great heaviness on the breast, and faintness, from the very beginning. The pulse in general was quick, small, and fluttering, though sometimes heavy and undulating. The urine was commonly pale, thin, and crude; however in many grown persons, it was passed in small quantities and high-coloured, or like turbid whey. The eyes were heavy, red, and as it were weeping; the countenance very often full, flushed, and bloated, though sometimes pale, and funk.

How long ever the disorder might appear in the day time, at night the symptoms became greatly aggravated, and the feverish habit very much increased, nay, sometimes a delirium occurred on the very first night; and this exacerbation constantly returned thro' the whole course of the disease. Indeed, when it was considerably on the decline, our author says he has been often pretty much surprized to find his patient had
had passed the whole night in a phrenzy, whom he had let tolerably cool and fedate in the day.

S me few hours after the seizure, and sometimes cotemporary with it, a swelling and foreness of the throat was perceived, and the tonsils became very tumid and inflamed, and many times the parotid and maxillary glands swelled very much, and very suddenly, even at the very beginning; sometimes so much as even to threaten strangulation. The fauces also very soon appeared of a high florid red, or rather of a bright crimson colour, very shining and glossy; and moist commonly on the uvula, tonsils, velum palatini, and back part of the pharynx, several whitish or ash-coloured spots appeared scattered up and down, which oftentimes increased very fast, and soon covered one or both the tonsils, uvula, &c.; those in the event proved sloughs of superficial ulcers (which sometimes, however, eat very deep into the parts). The tongue at this time, though only white and moist at the top, was very foul at the root, and covered with a thick yellowish or brown coat. The breath also now began to be very nauseous; which offensive smell increased hourly, and in some became at length intolerable, and that too sometimes even to the patients themselves.

The second or third day every symptom became much more aggravated, and the fever much more considerable; and those that had struggled with it tolerably well for 30 or 40 hours, were forced to submit. The relievness and anxiety greatly increased, as well as the difficulty in swallowing. The head was very giddily, pained, and loaded; there was generally more or less of a delirium; sometimes a pervigilium and perpetual phrenzy; though others lay very stupid, but often startling and muttering to themselves. The skin was very hot, dry, and rough; there was very rarely any disposition to sweat. The urine was pale, thin, crude; often yellowish and turbid. Sometimes a vomiting was urgent, and sometimes a very great looseness, in children particularly. The sloughs were now much enlarged, and of a darker colour, and the surrounding parts tended much more to a livid hue. The breathing became much more difficult; with a kind of a rattling flteror, as if the patient was actually strangling, the voice being excessively hoarse and hollow, exactly resembling that from vesere ulcers in the fauces: this noise in speaking and breathing was so peculiar, that any person in the least conversant with the disease might easily know it by this odd noise; from whence indeed the Spanish physicians gave it the name of garruolis, expressing the noise made by persons when they are strangled by a rope. Our author never observed in one of them the thriling barking noise that we frequently hear in inflammatory quinsies. The breath of all the diseased was very nauseous; of some insufferably fetid, especially in the advance of the delirium to a crisis; and many about the fourth or fifth day spit off a vast quantity of thinning purulent mucus tinged sometimes with blood; and sometimes the matter was quite livid, and of an abominable stench. The nostrils likewise in many were greatly inflamed and ex-coriated, continually dripping down a most sharp ichor or fanguineous matter, so excessively acrid, that it not only corroded the lips, cheeks, and hands of the children that laboured under the disease, but even the fingers and arms of the very nurses that attended them: as this ulceration of the nostrils came on, it commonly caused an almost incessant sneezing in the children; but few adults were affected with it, at least to any considerable degree. It was surprising what quantities of matter some children discharged this way, which they would often rub on their face, hands, and arms, and blister them all over. A sudden stoppage of this rhum from the mouth and nostrils actually choked several children; and some swallowed such quantities of it, as occasioned excoriations of the interines, violent gripings, dysenterie, &c. nay, even excoriations of the anus and buttocks. Not only the nostrils, fauces, &c. were greatly affected by this extremely sharp matter, but the wind-pipe itself was sometimes much corroded by it, and pieces of its internal membrane were spat up, with much blood and corruption; and the patients lingered on for a considerable time, and at length died tabid; though there were more frequent influences of its falling suddenly and violently on the lungs, and killing in a peripneumonic way.

Dr Huxham was astonifhied sometimes to see several swallow with tolerable ease, though the tumour of the tonsils and throat, the quantity of thick mucus, and the rattling noise in breathing, were very terrible; which he thinks pretty clearly shows, that this malignant quinsy is more from the armaancy and abundance of the humours than the violence of the inflammation.

Most commonly the angina came on before the exanthemata; but many times the cuticular eruption appeared before the sore-throat, and was sometimes very considerable, though there was little or no pain in the fauces: on the contrary, a very severe angina seized some patients that had no matter of eruption; and yet, even in these cases, a very great itching and desquamation of the skin sometimes ensued; but this was chiefly in grown persons, very rarely in children. In general, however, a very considerable efflorescence broke out on the surface of the body, particularly in children; and it most commonly happened the second, third, or fourth day: sometimes it was partial, sometimes it covered almost the whole body, though very seldom the face; sometimes it was of an erythematous kind: sometimes more pustular: the pufules frequently eminent, and of a deep fery red colour, particularly on the breast and arms; but oftentimes they were very small, and might be better felt than seen, and gave a very odd kind of roughness to the skin. The colour of the efflorescence was commonly of a crimson hue, or as if the skin had been smeared over with juice of rubberries, and this even to the fingers ends; and the skin appeared infamed and inflamed, as if it were; the arms, hands, and fingers, were often evidently so, and very stiff, and somewhat painful. This crimson colour of the skin seemed indeed peculiar to this disease. Though the eruption seldom failed of giving some manifest relief to the patient, as to anxiety, lickenes at stomach, vomiting, purging, &c. yet there was observed an universal fery eruption on some persons, without the least abatement of the symptoms, nay almost every symptom seemed more aggravated, particularly the fever, load at breast, anxiety, delirium; and our author knew more than one or two patients die in the most raging phrensy, covered with the most universal fery rash whatever. Saw fo that, as in the
the highly contained smallpox, it seemed only to denote the quantity of the disease, as he terms it.

He had under his care a young gentleman, about 12 years of age, whose tongue, fauces, and tonsils, were as black as ink, and he swallowed with extreme difficulty; he continually spit off immense quantities of black, fomaceous, and very fetid matter, for at least eight or ten days:—about the seventh day, his fever being somewhat abated, he fell into a bloody dysentery, though the bloody, fomaceous, fetid expectation still continued, with a most violent cough. He at length indeed got over it, to the very great surprise of every one that saw him. Now, in this patient, a fever and universal rash broke out upon the second and third day; and the itching of his skin was so intolerable, that he tore it all over his body in a most shocking manner: yet this very great and timely eruption very little relieved his fever and phrenzy, or prevented the other dreadful symptoms mentioned.

An early and kindly eruption, however, was most commonly a very good omen; and, when succeeded by a very copious desquamation of the cuticle, one of the most favourable symptoms that occurred; but when the eruption turned of a dusky or livid colour, or prematurely or suddenly receded, every symptom grew worse; and the utmost danger impended, especially if purple or black spots appeared up and down, as sometimes happened: the urine grew limpid, and convulsions came on, or a fatal suffocation soon closed the tragedy.

The disease was generally at the height about the fifth or sixth day in young persons, in the elder not so soon; and the crisis many times was not till the 11th or 12th, and then very imperfect: some adults, however, were carried off in two or three days; the distemper either falling on the lungs, and killing in a peripneumonic manner; or on the brain, and the patient either died raving or comatose. In some, the disease brought on a very troublesome cough, purulent expectoration, haemoptoe, and hectic; in which they lingered on for several weeks, and then died tabid.

If a gentle easy sweat came on the third or fourth day; if the pulse became more flow, firm, and equal; if the fomaces called off in a kindly manner, and appeared at the bottom tolerably clean and florid; if the breathing was more soft and free, and some degree of vigour and quickness returned in the eyes; all was well, and a salutary crisis followed soon by a continuance of the sweat, and a turbid, subfiding, farinaceous urine, a plentiful expectoration, and a very large desquamation of the cuticle. But if a rigor came on, and the exanthemata suddenly disappeared or turned livid; if the pulse grew very small and quick, and the skin remained hot and parched as it were, the breathing more difficult, the eyes dead and glassy, the urine pale and limpid, a phrenzy or coma succeeded, with a coldish clammy sweat on the face or extremities; life was despaired of; especially if a singultus and choking or gulping in the throat attended, with fomaceous liquid, involuntary, livid froths, intolerably fetid. In some few patients Dr Huxham observed, some time before the fatal period, not only the face bloated, hollow, flaming, and greyish as it were, but the whole neck very much swollen, and of a cadaverous look; and even the whole Cynanchus, body became in some degree adenoma; and the impulsion of a finger would remain fixed in a part, the skin not returning again as usual; an indication that the blood stagnated in the capillaries, and that the extensibility of the fibres was quite lost.

Medical writers are still much divided in opinion, whether the cynanche maligna is to be considered as the same disease with the scarlatina anginosa, afterwards to be treated of, or not. This question will afterwards come to be more fully discussed. At present we may only observe, that although ulcerous sore throats of a malignant nature often appear sporadically, yet that the disease above described appears only as an epidemic, and is always the consequence of contagion.

Prognostic. This may be easily gathered from the above description. The malignant and putrid tendency of the disease is evident, and an increase of the symptoms which arise from that putrefactive disposition of the body must give an unfavourable prognostic; as, on the contrary, a decrease of these, and an apparent increase of the vis viva, are favourable: in general, what is observed to be favourable in the nervous and putrid malignant fevers, is also favourable in this and vice versæ.

Causes. Since the accurate accounts given by Dr Fothergill and Huxham of the epidemics which prevailed about 30 years ago, this disease has frequently been observed at times epidemic in almost every different part of Britain. Like smallpox, measles, and chinchough, it seems in every case to be the effect of a peculiar and specific contagion. It has been observed to prevail, equally generally in every situation, and at every season; and on exposure to the contagion, no age, sex, or condition, is exempted from it. But the having once had the disease, seems in this affection to afford the same security against future contagion as in the smallpox: at least infinaces, where it can be said that the same individual has been twice affected with it, are both very rare and very doubtful, as well as in smallpox. Cure. Like other febrile contagious, the malignant ulcerous sore throat is terminated only by a natural course; and the chief business of the practitioner is to combat unfavourable occurrences. In this the septic tendency of the disease is chiefly to be kept in view. The debility with which it is attended renders all evacuations by bleeding and purging improper, except in a few instances where the debility is left, and the inflammatory symptoms more considerable. The fauces are to be preferred from the effects of the acid matter poured out upon them, and are therefore to be frequently washed out by antiseptic gargles or injections; and the putrid flate of the whole system should be guarded against and corrected by internal anti-fevers, especially by the Peruvian bark given in the beginning and continued through the course of the disease. Great benefit is also often derived from the liberal use of the mineral acids. Both the vitriolic and muriatic, in a state of proper dilution, have been highly extolled by different medical writers, and are productive of the best effects in actual practice, when they can be introduced to a sufficient extent. Emetics, both by vomiting and nauseating, prove useful. When any considerable tumor occurs, blisters applied

MEDICINE.

Practice.
Irac 1: ice.

Very lately, the internal use of the capricum annum, or Cayenne pepper as it is commonly called, has been highly celebrated in this affection; and it is particularly said to have been employed with singular success in the West Indies.

Angina polypora in membranacea. Michelis. Argentorati 1778, et autores ab eo allegati.

The best description of this disease we have in Dr Cullen's Practice of Physic. He informs us, that it consists in an inflammation of the glottis, larynx, or upper part of the trachea, whether it affect the membranes of these parts or the muscles adjoining. It may arise first in these parts, and continue to fubflit in them alone; or it may come to affect these parts from the cynanche tonnllarisis, or m greatest, spreading into them.

In either way it has been a rare occurrence, and few instances of it have been marked and recorded by physicians. It is to be known by a peculiar croaking sound of the voice, by difficult respiration, with a sense of straining about the larynx, and by a pyrexia attending it.

From the nature of these symptoms, and from the description of the body of persons who died of this disease, there is no doubt of its being of an inflammatory kind. It does not, however, always run the course of inflammatory affections; but frequently produces such an obstruction of the passage of the air, as suffocates, and thereby proves suddenly fatal.

It is particularly hazardous, in consequence of the trachea being obstructed by a membranous substance lining the inside of it, and very nearly approaching in appearance to the inflammatory exudation often discovered on the intellecal canal in those dying of catarrhus.

If we judge rightly of the nature of this disease, it will be obvious, that the cure of it requires the most powerful remedies of inflammation to be employed upon the very first appearance of the symptoms. When a suffocation is threatened, whether any remedies can be employed to prevent it, is not yet determined by sufficient experience: but it is evident, that in certain cases the life of the patient can be preserved only by the removal of that matter which obstructs the passage of air through the trachea.

The accounts which books have hitherto given us of inflammations of the larynx and the parts connected with it, amount to what we have now said; and many instances are recorded of this disease happening in adult persons: but there is a peculiar affection of this kind happening to infants which has been little taken notice of till lately. Dr Home is the first who has given any distinct account of this disease; but since he wrote, several other authors have taken notice of it, and have given different opinions concerning it.

This disease seldom attacks infants till after they have been weaned. After this period, the younger they are, the more they are liable to the disease. The frequency of it becomes less as children become more advanced; and there are few instances of children above 12 years of age being affected with it. It attacks children of the midland countries, as well as those who live near the sea; but it occurs much more frequently at certain places than at others. It does not appear to be contagious; and its attacks are frequently repeated in the same child. It is often materially effects of cold applied to the body; and therefore appears most frequently in the winter and spring seasons. It very commonly comes on with the ordinary symptoms of a catarh; but sometimes the peculiar symptoms of the disease flow themselves at the very first.

These peculiar symptoms are the following: A hoarseness, with some thrillings and ringing found, both in speaking and coughing, as if the noise came from a brzen tube. At the same time, there is a sense of pain about the larynx, some difficulty of respiration, with a whistling found in inspiration, as if the passage of the air were straitened. The cough which attends it, is commonly dry; and if anything be spit up, it is a matter of a purulent appearance, and sometimes films resembling portions of a membrane. With all these symptoms, there is a frequency of pulse, a reflexibility, and an uneasy sense of heat. When the internal fauces are viewed, they are sometimes without any appearance of inflammation; but frequently a redness, and even swelling, appears; and sometimes there is an appearance of matter like to that rejected by coughing, together with the symptoms now described, and particularly with great difficulty of breathing, and a sense of strangling in the fauces, by which the patient is sometimes suddenly taken off.

Many divisions have been made of infants who had died of this disease, and almost constantly there has appeared a preternatural substance, apparently membranous, lining the whole internal surface of the upper part of the trachea, and extending in the same manner.
This preternatural membrane may be easily separated, and sometimes has been found separated in part, from the subjacent proper membrane of the trachea. This latter is commonly found entire, that is, without any appearance of erosion or ulceration; but it frequently shows the vestiges of inflammation, and is covered by a matter resembling pus, like to that rejected by coughing; and very often a matter of the same kind is found in the bronchi, sometimes in considerable quantity.

From the remote causes of this disease; from the catarrhal symptoms commonly attending it; from the pyrexia constantly present with it; from the same kind of preternatural membrane being found in the trachea when the catarrhal maligna is communicated to it; and from the vestiges of inflammation on the trachea discovered upon exudation; we must conclude, that this disease consists in an inflammatory affection of the mucous membrane of the larynx and trachea, producing an exudation analogous to that found on the surface of inflamed vidiæ, and appearing partly in a membranous crust, and partly in a fluid form resembling pus.

Though this disease consists in an inflammatory affection, it does not commonly end either in suppuration or gangrene. The troublesome circumstance of it appears first as a pain in the muscles of the glottis, threatening suffocation.

When this disease terminates in health, it is by resolution of the inflammation, by ceasing of the pain of the glottis, by an expectoration of the matter exuding from the trachea, and of the crusts formed there, and frequently it ends without any expectoration, or at least with fuch as only attends an ordinary catarrh. But in some instances, a fulatory termination has very speedily taken place, in consequence of the discharge of the membranous substance from the trachea, even under its proper tubular form.

When the disease ends fatally, it is by a suffocation, seeming depending upon a pain affecting the glottis; but sometimes, probably, depending upon a quantity of matter filling the bronchi, or obstructing the trachea.

As we suppose the disease to be an inflammatory affection, so we attempt the cure of it by the usual remedies of inflammation. Bleeding, both general and topical, has often given immediate relief; and by being repeated, has entirely cured the disease. Blistering also, near to the part affected, has been found useful. Upon the first attack of the disease, vomiting, immediately after bleeding, seems to be of considerable use, and sometimes suddenly removes the disease. But emetics are still more useful in advanced periods. By the employment of these, the matter obstructing the trachea, and inducing phlegmotic affections, has often been successfully removed, when the situation of the patient seemed to be almost desperate. And as in the progress of the disease fresh effusions of this matter are very apt to take place, the frequent repetition of emetics becomes necessary. It is often necessary to have recourse to those operating the most expeditiously, such as vitriolated zinc even in large doses. In every stage of the disease, the antiphlogistic regimen is necessary, and particularly the frequent use of laxative glyters. Though we suppose that a pain affecting the glottis is often fatal in this disease, antiphlogistic medicines have not in general been found of great service. Some, however, have strongly recommended the use of aspirin in the form of injection; others place great confidence in oil, or oily mixtures taken by the mouth: but more immediate benefit is derived from tepid bathing, and the employment of vitriolic ether, both externally and internally.

**Sp. IV. CYNANCHE PHARYNGEA.**

Cyananche pharyngea, Sawv. sp. 6. Eller de cogn. et cur. foè. 7.

Angina inflammatoria, sp. 4. Boerh. 804.

This is not materially different from the cyananche tonsilaris; only that the inflammation is said to begin in the pharynx, though Dr Cullen says he never knew an instance of it. The symptoms are almost the same, and the cure is precisely so with that of the cyananche tonsilaris.

**Sp. V. CYNANCHE PAROTIDEA.**

This is a disease well known to the vulgar, but little taken notice of by medical writers. It is often epidemic, and manifestly contagious. It comes on with the usual symptoms of pyrenia, which is soon after attended with a considerable tumour of the external fauces and neck. The swelling appears first as a glandular moveable tumour at the corner of the lower jaw; but it soon becomes uniformly diffused over a great part of the neck, sometimes on one side only, but more commonly on both. The swelling continues to increase till the fourth day; but from that period it declines, and in a few days more goes off entirely. As the swelling of the fauces recedes, it not unfrequently happens that some tumour affects the teeths in the male sex, or the breasts in the female. These tumours are sometimes large, hard, and somewhat painful; but are seldom either very painful or of long continuance. The pyrexia attending this disease is commonly slight, and goes off with the swelling of the fauces; but sometimes, when the swelling of the teeths does not succeed to that of the fauces, or when the one or the other has been suddenly reprieved, the pyrexia becomes more considerable, is often attended with delirium, and has sometimes proved fatal.

As this disease commonly runs its course without either dangerous or troublesome symptoms, so it hardly requires any remedies. An antiphlogistic regimen, and avoiding cold, are all that will be commonly necessary. But when, upon the receding of the swellings, the pyrexia comes to be considerable, and threatens an affection of the brain, it will be proper, by warm fomentations,
mentations, to bring back the swelling; and by vomiting, bleeding, or blistering, to obviate the consequences of its absence.

Under the general head of *Pneumonia*, Dr Cullen comprehends all inflammations of the thoracic visera, or membrane lining the inside of that cavity; as the symptoms do not sufficiently distinguish the seat of the affection, nor does a difference in the situation of the affected place make any difference in the cure.

Description. Pneumonic inflammation, however various in the seat, always discloses itself by pyrexia, difficult breathing, cough, and pain in some part of the thorax. It almost always comes on with a cold stage, and is accompanied with the other symptoms of pyrexia; though in some few instances the pulse may not be more frequent, nor the heat of the body increased beyond what is natural. Sometimes the pyrexia is from the beginning accompanied with the other symptoms; but frequently it is formed some hours before them, and particularly before the pain be felt. The pulse for the most part is frequent, full, strong, hard, and quick; but, in a few instances, especially in the advanced state of the disease, it is weak, soft, and at the same time irregular. The difficulty of breathing is most considerable in inspiration, both because the lungs do not easily admit of a full dilatation, and because the dilatation increases the pain attending the disease. The difficulty of breathing is also greater when the patient is in one posture of the body rather than another. It is generally greater when he lies on the side affected; though sometimes the contrary happens. Very often the patient cannot lie easy upon either side, and can find ease only when lying on the back; and sometimes he cannot breathe easily, except when in some fashion of an erect posture. The cough, in different cases, is more or less urgent or painful. It is sometimes dry, or without any expectoration, especially in the beginning of the disease; but more commonly it is, even from the beginning, moist, and the matter spit up various both in consistence and colour, and frequently it is streaked with blood. The pain is also different in different cases, and felt in different parts of the thorax, but most frequently in one side. It has been said to affect the right side more frequently than the left; but this is uncertain, and we are sure that the left side has been very often affected. Sometimes it is felt as if it was under the sternum; sometimes in the back between the shoulder blades; and when in the sides, its place has been higher or lower, more forward or backward; but the place of all most frequently affected is about the sixth or seventh rib, near the middle of its length, or a little more forward. The pain is often severe and pungent; but sometimes more dull and obtuse, with a sense of weight rather than of pain. It is most especially severe and pungent when occupying the place last mentioned. For the most part it continues fixed in one part, but sometimes shoots from the side to the stappula on one hand, or to the sternum and clavicle on the other.

Dr Cullen supposes that the disease is always feated, or at least begins, in some part of the pleura, taking that membrane in its greatest extent, as now commonly understood; that is, as covering not only the internal surface of the cavity of the thorax, but also as forming the mediastinum, and as extended over the pericardium, and over the whole surface of the lungs. But as the symptoms never clearly indicate
where the seat of the disease is, there is but little foundation for the different names by which it has been distinguished. The term pleurisy is improperly limited to that inflammation which begins in and chiefly affects the pleura costalis. This our author thinks is a rare occurrence; and that the pneumonia much more frequently begins in the pleura, involving the lungs, producing all the symptoms which belong to what hath been called the pleuritis vera. The word peripneumony has been applied to an inflammation beginning in the parenchyma, or cellular texture of the lungs, and having its seat chiefly there. But to Dr Cullen it seems very doubtful if any acute inflammation of the lungs, or any disease which has been called peripneumony, be of that kind. It seems probable, that every acute inflammation begins in membranous parts; and in every dissection of persons who have died of peripneumony, the external membrane of the lungs, or some part of the pleura, has appeared to have been considerably affected. An inflammation of the pleura covering the upper surface of the diaphragm, has been distinguished by the appellation cephalophrenitis, as supposed to be attended with the peculiar symptoms of delirium, rigors, and convulsive motions; but it is certain, that an inflammation of that portion of the pleura, and affecting also even the muscular substance of the diaphragm, has often taken place without any of the symptoms above-mentioned; and neither the dissections which have fallen under Dr Cullen's observation, nor any accounts of dissections, support the opinion that an inflammation of the pleura covering the diaphragm is attended with delirium more commonly than any other pulmonary inflammation.

It is to be observed however, that though the inflammation may begin in one particular part of the pleura, the morbid affection is commonly communicated to the whole extent of the membrane. The pneumonia inflammation, like others, may terminate by resolution, suppuration or gangrene: but it has also a termination peculiar to itself; namely, when it is attended with an effusion into the cellular texture of the lungs, which, soon interrupting the circulation of the blood through the vices, produces a fatal suffocation. This indeed appears to be the most common termination of pneumonia inflammation when it ends fatally; for upon the dissection of almost every person who has died of this disease, it appears that such an effusion had happened. From the same dissections we learn, that pneumonia inflammation commonly produces an exudation from the internal surface of the pleura, which appears partly as a soft viscid crust, often of a compact membranous form, covering every where where the surface of the pleura, and particularly those parts where the lungs adhere to the pleura costalis, or mediastinum; and this crust seems always to be the cement of such adhesion. The same exudation flows itself also by a quantity of a serous fluid, commonly found in the cavity of the thorax; and some exudation or effusion is usually found to have been made into the cavity of the pericardium. It seems likewise probable, that an effusion of this kind is sometimes made into the cavity of the bronchi; for in some persons who have died after labouring under a pneumonia inflammation for a few days only, the bronchi have been found filled with a consider-
Pneumonia.

Practice.

MEDICINE.

The pulfe, heat of the body, and other febrile symptoms. Although, from the history now given, it appears that pleurisy and pneumonia cannot with propriety be considered as different diseases, yet it is certain that in different cases this affection occurs with an assemblage of symptoms separate and distinct.

Thus even Dr. Cullen himself, in his Neology, has defined pleurisy to consist in pyrexia, attended with a pungent pain of the side, painful respiration, difficulty of lying down particularly on the affected side, and distempering cough, in the beginning dry, but afterwards humid, and often with bloody expectoration. While again he has defined pneumonia to consist in pyrexia, attended with a dull pain under the sternum and between the shoulders, anxiety, difficulty of breathing, humid cough, expectoration generally bloody, a soft pulfe, and a turgid livid appearance of the countenance. It is highly probable, that the first of these sets of symptoms chiefly arises from a state of active inflammation, and the second from effusion. Thus, in certain cases the symptoms may appear perfectly separate and distinct; but more frequently both inflammation and effusion are united; and thus the symptoms in both definitions are in general combined in the same patient.

Cough, and perform subject to, this disorder. The remote cause of pneumonia inflammation is commonly cold applied to the body, obstructing perspiration, and determining to the lungs, while at the same time the lungs themselves are exposed to the action of cold. These circumstances operate chiefly when an inflammatory diathesis, prevails in the system; and therefore those principally affected with the disease are persons of the greatest vigour, in cold climates, in the winter season, and particularly in the spring, when vicissitudes of heat and cold are frequent. This disease, however may arise in any season when such varieties take place. Other remote causes also may have a share in producing this distemper; such as every means of obstructing stratification, or otherwise injuring, the pneumonic organs. The pneumatic inflammation has sometimes been so much an epidemic, that it hath been suspected of depending on a specific contagion; but Dr. Cullen never met with an instance of its being contagious.

Prognosis. In pneumatic inflammations, a violent pyrexia is always dangerous. The danger, however is chiefly denoted by the difficulty of breathing. When the patient can lie on one side only; when he can lie on neither side, but only on his back; when he cannot breathe with tolerable ease, except when the trunk of his body is erect; when even in this posture the breathing is very difficult, and attended with a turgescence and flush of the face, partial sweats about the head and neck, and an irregular pulfe; these circumstances mark the difficulty of breathing in different degrees and, consequently, in proportion, the danger of the disease. A frequent violent cough, aggravating the pain, is always the symptom of an oblique disease; and as the disease is seldom or never resolved without some expectoration, so a dry cough must always be an unfavourable symptom.

The proper characteristics of the expectoration have been already laid down; and though an expectoration which has not these marks must indicate a doubtful state of the disease, yet the colour alone can give no certain prognostic. An acute pain, very much interrupting inspiration, is always the mark of a violent disease but not of a more dangerous disease than an obtuse pain attended with very difficult respiration.

When the pains, which had at first affected one side only, shall afterwards spread into the other; or when, leaving the side first affected, they pass entirely into the other; these are always marks of a dangerous disease. A delirium coming on during a pneumatic inflammation is always a symptom denoting much danger.

When pneumatic disorders terminate fatally, it is on one or other of the days of the first, week, from the third to the seventh. This is the most common case; but, in a few instances, death has happened at a later period. When the disease is violent, but admitting of resolution, this also happens frequently in the course of the first week; but in a more moderate disease the resolution is often put off to the second week. The disease generally suffers a remission on some of the days from the third to the seventh: which, however, may be often fallacious, as the disease sometimes returns again with as much violence as before; and in such a case with great danger. Sometimes it disappears on the third day, while an erysipelas makes its appearance on some external part; and if this continue fixed, the pneumatic inflammation does not recur. If the disease continue beyond the 14th day, it will terminate in a suppuration, or Putrescence. The termination by gangrene is much more rare than has been imagined: and when it does occur, it is usually joined with the termination by effusion: the symptoms of the one being hardly distinguishable from those of the other.

Cure. This must proceed upon the general plan mentioned under Synochia; but, on account of the importance of the part affected, the remedies must be employed early, and as fully as possible; and these are chiefly directed with one of three views, viz, for obtaining a resolution of the inflammation in the thorax, for mitigating the urgent symptoms before a resolution can be effected, and for counteracting or obviating the consequences of an effusion. Venesection is the remedy chiefly to be depended on; and may be done in either arm, as the surgeon finds most convenient; and the quantity taken away ought in general to be as large as the patient's strength will allow. The remission of pain, and the relief of respiration, during the flowing of the blood, may limit the quantity to be then drawn; but if these symptoms of relief do not appear, the bleeding should be continued to a considerable extent unless symptoms of a beginning syncope come on. It is seldom that one bleeding, however large, will cure this disease; and though the pain and difficulty of breathing may be much relieved by the first bleeding, these symptoms commonly and after no long interval recur, often with as much violence as before. In this case the bleeding is to be repeated even on the same day, and perhaps to the same quantity as before. Sometimes the second bleeding may be larger than the first. These are persons whose constitution, are ready to faint, even upon a small bleeding; and in such persons this may prevent the drawing to much blood at first as a pneumatic inflammation may require: but as the pains are
Phlegmatics have plenty of warm diluting drinks, disease emetics have been found to be dangerous; but in a somewhat advanced state they should have procured some remission, yet upon the return of the urgent symptoms, bleeding may be repeated at any time within the first fortnight, or even after that period, if a fluctuation be not evident, or if after a feeming solution the disease shall have returned.

With respect to the quantity of blood which may be taken away wit.its safety, no general rules can be given; as it must be very different according to the state of the disease, and the constitution of the patient. In an adult male of tolerable strength a pound avoidance of blood is a full bleeding. Any quantity above 20 ounces is a large, and any quantity below 12 is a small, bleeding. An evacuation of four or five pounds in the course of two or three days, is generally as much as most patients will bear; but if the intervals between the bleedings, and the whole of the time during which the bleedings have been employed, have been long the quantity taken upon the whole may be greater.

When a large quantity of blood hath been taken from the arm, and it is doubtful if more can be taken in that manner with safety, some blood may still be taken by cupping and scarifying. This will especially be proper, when the recurrence of the pain, rather than the difficulty of breathing, becomes the urgent symptom; and then the cupping and scarification should be made as near as possible to the painful part.

An expectoration sometimes takes place very early in this disease; but if the symptoms continue urgent, the bleedings must be repeated notwithstanding the expectoration: but in a more advanced state, and when the symptoms have suffered a considerable remission, we may then trust the cure to the expectoration alone. It is not observed that bleeding, during the first days of the disease, stops expectoration; on the contrary, it hath been often found to promote it; and it is only in a more advanced state of the disease, when the patient has been already exhausted by large evacuations and a continuance of his illness, the bleeding seems to put a stop to expectoration; and even then, this stoppage seems not to take place so much from the powers of expectoration being weakened by bleeding, as by its favouring the feterous effusion in the bronchise, already taken notice of.

Bleeding every part of the antiphlogistic regimen ought here to be carefully employed: the patient must keep out of bed as much as he can bear; must have plenty of warm diluting drinks, impregnated with vegetable acids, accompanied with nitre or some other cooling neutral falt; and the belly also ought to be kept open by emollient, glisters or cooling laxative medicines. Vomiting in the beginning is dangerous; but in a somewhat advanced state of the disease emetics have been found the best means of promoting expectoration. Fomentations and poultices to the painful part have been found useful; but blisters are found to be much more effectual. A blister, however, ought not to be applied till at least one bleeding hath been primed, as venesection is less effectual when the irritation of a blister is present. If the disease be moderate, a blister may be applied immediately after the first bleeding; but in violent cases, where it may be presumed that a second bleeding may soon be necessary after the first, it will be proper to delay the blister till after the second bleeding, when it may be supposed that the irritation occasioned by the blister will be over before another bleeding becomes necessary. It may frequently be of use in this disease to repeat the blisters; and in that case the blisters should always be applied somewhere on the thorax, for when applied to more distant parts they have little effect. The keeping the blistered parts open, and making what is called a 'perpetual blister', has much less effect than a repeated blistering.

Many methods have been proposed for promoting expectoration, but none appear to be sufficiently effectual; and some of them, being acrid stimulating substances, are not very safe. The gums usually employed seem to be too heating; the squills less so; but they are not very powerful, and sometimes inconvenient, by the constant nausea they occasion. The volatile alkali may be of service as an expectorant, but it ought to be reserved for an advanced state of the disease. Musculinuous and oily demulcents appear to be useful, by allaying that acrimony of the mucus which occasions too frequent coughing; and which coughing prevents the flagration and thickening of the mucus, and thereby its becoming mild. The receiving into the lungs the steams of warm water, impregnated with vinegar, has often proved useful in promoting expectoration; and, for this purpose, the machine called the INHALER, lately invented by Dr Mudge of Plymouth, promises to be of great service. But of all others, the antimonial emetics given in nauseating doses, promise to be the most powerful for promoting expectoration. The kermes mineral has been greatly recommended; but doth not seem to be more efficacious than emetic tartar or antimonial wine; and the dose of the kermes is much more uncertain than that of the others.

Though this disease often terminates by a spontaneous sweating, the evacuation ought not to be excited by art, unless with much caution. When, after some remission of the symptoms, spontaneous sweats arise, they may be encouraged; but it ought to be without much heat, and without stimulant medicines. If, however, the sweats be partial and clammy only, and a great difficulty of breathing still remain, it will be very dangerous to encourage them.

Physicians have differed much with regard to the use of opiates in pneumonic affections. It appears, however, that, in the beginning of the disease, and before bleeding and blistering have produced some remission of the pain, and of the difficulty of breathing, opiates have a bad tendency, by their increasing the difficulty of breathing and other inflammatory symptoms. But in a more advanced state of the disease, when the difficulty of breathing has abated, and when the urgent symptom is a cough, proving the chief cause of the continuance of pain and want of

ref
Practise.

Medicine.

VOMICA, or Affections of the Lungs.

Vomica, Boerh. 835, fmalc. 35.

Pleurodyne vomica, Sauv. fp. 21.

This sometimes follows pneumonia, though the cafee is not frequent. The symptoms of it so much re semble the phthisis, that it can mofl properly be treated of under that head.

EMPHYEMA.

This is another consequence of a pneumonia terminating unfavourably, and is occasioned by the effufion of a quantity of purulent matter into the cavity of the thorax, producing a lingering and painful disorder, very often incurable.

Description. The firft sign of an emphyema is a effufion of the pain in the breath, which before was continual; this is followed by a effufion of weight on the diaphragm, and a fluctuation of matter, sometimes making a noise that may be heard by the bystanders; the acute fever is changed into a hectic, with an exacerbation at night: a continual and troublefome night-sweats is danger of fufFocation when they ascend. Thefe fymptoms are accompanied with great anxiety, palpitations of the heart, and faintings. Sometimes the patients have a fefuation like a hot vapour effuding from the cavity of the thorax to their mouth. Others, in a more advanced f fate of the disease, have a putrid taste in the mouth. At the fame time, profuse night-sweats waftes the body, and greatly weaken the patient. The face at firft grows red on that fide where the matter lies, at laft the Hippocratic face comes on, and the eyes become hollow. The pulse, especially on the affected f ide, is quick, but more frequently intermitting. Sometimes the nails are crooked, and pulsules appear on the thorax; and frequently, according to the testimony of Hippocrates, the feet fwell, and, on the affected f ide of the breath, there is an inflammation and swelling of the skin.

Causes, &c. An emphyema may arife either from Empyema, the burbling of a vomica of the lungs, or from a suppuration taking place after the inflammatory flag of the pneumonia; or sometimes from a suppuration in the cafe of a quincy, when the inflammation had extended to the alveolar arteries, from whence arifes a kind of bloody f pittle, and the patients are afflicted with an emphyema, unless they die on the 7th day of the disease, according to the obervation of Hippocrates. It may arife also from external violence, as wounds of the thorax, &c. blood extravafated, corrupted, or changed into pus. Like the vomica, it is a rare diftemper, but may attack all thofe fubjeft to pneumonia.

Prognosis. Very few recover after an emphyema has been once formed, efpecially if the operation of paracentesis be neglected. After this operation is performed, if a great quantity of bloody f eftid pus be discharged, if the fever continue, and if the patient fipt up a purulent, pale, frothy, livid, or green matter, with a decay of strength, there is no hope: But when a small quantity of pus, of a white colour, not very f eftid, is discharged; when the fever and thifty moment ceafe, the appetite returns, and faces of a good confidence are discharged, the strength also returning in fome degree, there is then hope of a perfect recovery. If the matter be not dried up in f even weeks time, the disease readily changes to a f uitulous ulcer which is very difficult to cure. An emphyema affecting both fides of the thorax is more dangerous than that which affects only one.

Cure. This confists in evacuating the purulent matter contained in the cavity of the thorax, which is best done by the operation of paracentesis. See the article Surgery. Afterwards the ulcer is to be treated with abftrangent and confolidating medicines, and the fame internal ones are to be given as in a Phthisis.

Gen. XIII. CARDITIS.

Infammation of the Heart.

Carditis, Sauv. gen. 111. Vgg. 54.

Pericarditis, Vgg. 53.

Eryhipelas pulmonis, Lomn. Obcrv. lib. ii.

Description. This disease is attended with all the fymptoms of pneumonia, but in a higher degree; it is besides f aid to be accompanied with hydrophobic fymptoms, fainting, palpitation of the heart, a heatening madness, a funk and irregular pulse, watery eyes, and a dejected countenance, with a dry and black tongue. On defiication, the heart and pericardium are found very much inflamed, and even ulcerated, with many polynomial concerations.

Causes, &c. The fame as in the pneumonia.

Prognosis. In the carditis the prognosis is more unfavourable than in the pneumonia; and indeed, unless the disease very quickly terminates, it muft prove fatal, on account of the confluitant and violent motion of the heart, which exaitiates the inflammation, and increafes all the fymptoms.

Cure. Here bleeding is neceffary in as great a degree
external injuries, such as wounds, contusions, &c. It affects chiefly those of a plethoric habit and hot bilious constitution.

**Prognosis.** This disease is always very dangerous, and the prognosis doubtful, which also must always be in proportion to the severity of the symptoms. A cessation of pain, coldness about the precordia, great debility, with a languid and intermitting pulse, with an abatement of the hicchough, denote a gangrene and speedy death. From the sensibility of the stomach also, and its great connection with the reft of the system, it must be obvious, that an inflammation of it, by whatever causes produced, may be attended with fatal consequences; particularly, by the great debility it produces, it may prove suddenly fatal, without running through the usual course of inflammations. Its tendency to admit of resolution may be known by its having arisen from no violent cause, by the moderate state of the symptoms, and by a gradual remission of these symptoms in the course of the first or at most of the second week of the disease. The tendency to gangrene may be suspected from the symptoms continuing with unremittent violence notwithstanding the use of proper remedies, and a gangrene already begun may be known by the symptoms abovementioned, particularly great debility and sudden cessation of pain. The tendency to suppuration may be known by the symptoms continuing, but in a moderate degree for more than one or two weeks, and by a considerable remission of the pain while a sense of weight and anxiety still remain. When an abscess has been formed, the frequency of the pulse is first abated; but soon after it increases, with frequent cold shivering, and an exacerbation in the afternoon and evening; followed by night-sweats, and other symptoms of hectic fever. These at length prove fatal, unless the abscess open into the cavity of the stomach, the pus be evacuated by vomiting, and the ulcer soon healed.

**Cure.** It appears from dissections, that the stomach may very often be inflamed when the characteristic marks of it have not appeared; and therefore we are often exposed to much uncertainty in the cure. But when we have sufficient evidence that a state of active inflammation has taken place in the stomach, the principal object to be aimed at is to obtain a resolution. Before, however, this can be accomplished, it will often be necessary to employ measures with the view of obviating urgent symptoms. When the symptoms appear in the manner above described, the cure is to be attempted by large and repeated bleedings employed early in the disease; and from these we are not to be deterred by the weakness of the pulse, for it will commonly become fuller and softer after the operation. A blister ought also to be applied to the region of the stomach; and the cure will be assisted by fomentations of the whole abdomen, and by frequent enemata of laxative glyters. The irritability of the stomach in this disease will admit of no medicines being thrown into it; and if any can be supposed necessary, they must be exhilarated in glyters. Diluting drinks may be tried; but they must be of the very mildest kind, and given in very small quantities at a time. Opiates, in whatever manner exhibited, cannot be retained in the stomach during the first days of the disease; but when the violence of the disease shall have abated, and when the pain and vomiting
vomiting recur at intervals only, opiates given in glbtides may frequently be employed with advantage; and after bleeding and blisters no remedy is more effective either in allaying the pain or vomiting. As soon as the stomach will retain any laxative, gentle refrigerant cathartics, taken by the mouth, such as the soda phosphorata, soda tartarifata, or the like, are productive of great benefit. A tendency to gangrene in this disease is to be obviated only by the means just now mentioned; and when it does actually suppurate, it admits of no remedy. A tendency to supuration is to be obviated by the same means employed early in the disease. After a certain period it cannot be prevented by any means whatever; and, when actually begun, must be left to nature; the only thing that can be done by art being to avoid all irritation.

B. GASTRITIS ERYSPELATOSA, or the Eryspelatous Gastritis.

Description. This species of inflammation takes place in the stomach much more frequently than the former. From dissections it appears that the stomach has been often affected with inflammation, when neither pain nor fever had given any notice of it; and such is justly looked upon to have been of the eryspelatous kind. This kind of inflammation also is especially to be expected from acrimony of any kind applied to the stomach; and would certainly occur more frequently, were not the interior surface of this organ commonly defended by mucus exuding in large quantity from the numerous follicles placed immediately under the villous coat. On many occasions, however, the exudation of mucus is prevented, or the liquid poured out is of a less vivid kind, so as to be less fitted to defend the subjacent nerves; and it is in such cases that acid matters may readily produce an eryspelatous affection of the stomach.

In many cases, however, this kind of inflammation cannot be discovered, as it takes place without pain, pyrexia, or vomiting; but in some cases it may; namely, when it spreads into the oesophagus, and appears on the pharynx and on the whole internal surface of the mouth. When therefore an eryspelatous inflammation affects the mouth and fauces, and there shall be at the same time in the stomach an unusual sensibility to all acrids, and also a frequent vomiting there can be little doubt of the stomach's being affected in the same manner. Even when no inflammation appears in the fauces, if some degree of pain be felt in the stomach, if there be a want of appetite, an anxiety and frequent vomiting, an unciall sensibility with regard to acrids, some thirst, and frequency of pulse, there will then be room to suspect an inflammation in the stomach; and such symptoms, after some time, have been known to discover their cause by the inflammation rising to the fauces or mouth. Inflammation of this kind is often disposed to pass from one place to another on the same surface, and, in doing so, to leave the place it had at first occupied. Such an inflammation has been known to spread successively along the whole tract of the alimentary canal; occasioning, when in the intestines, diarrhoea, and in the stomach vomitings; the diarrhoea ceasing when the vomitings came on, and the vomitings on the coming on of the diarrhoea.

Causes, &c. An eryspelatous inflammation may arise from acrid matters taken into the stomach; or from some internal causes not yet well known. It frequently occurs in putrid diseases, and in those recovering from fevers.

Cure. When the disease is occasioned by acid matters taken internally, and these may be supposed still present in the stomach, they are to be washed out by drinking a large quantity of warm and mild medicines, and exciting vomiting. At the same time, if the nature of the acrimony and its proper corrector be known, this should be thrown in; or if a specific corrector be not known, some general demulcent should be employed.

These measures, however, are more suited to prevent than to cure inflammation after it has taken place. When this last may be supposed to have happened, if it be attended with a sense of heat, with pain and pyrexia, according to the degree of these symptoms, the measures proposed for the cure of the other kind are to be more or less employed. When an eryspelatous inflammation of the stomach has arisen from internal causes, if pain and pyrexia occur, bleeding may be employed in persons not otherwise weakened; but in cases of its occurring in putrid diseases, or where the patients are already debilitated, bleeding is inadmissible; all that can be done being to avoid irritation, and only throwing into the stomach what quantity of acids and aseptic aliments it shall be found able to bear. In some conditions of the body in which this disease is apt to occur, the Peruvian bark and bitters may seem to be indicated; but an eryspelatous flame of the stomach will seldom allow them to be used.

Genus XVI. ENTERITIS,

Inflammation of the Intestines.

Intestinalis inflammatorius, Boerh. 959.

Febris intestinorum inflammatoria ex mense ferentio, Hoffm. II. 170.

Sp. I. ENTERITIS PHLEGMONOSA, or the Acute Enteritis

Enteritis iliacas, Sauv. sp. 1.

Enteritis colica, Sauv. sp. 2. Boerh. 963.

Description. This disease shows itself by a fixed pain in the abdomen, attended with fever, vomiting, and colic.

Causes, &c. Inflammations of the intestines may arise from the same causes as those of the stomach; though commonly the former will more readily occur from cold applied to the lower extremities, or to the belly itself. It is also found suppurating on the inflammatory colic, incarcerated hernia, and volvulus.

Prognosis. Inflammations of the intestines have the same terminations with those of the stomach, and the prognosis in both cases is much the same.

Cure. The cure of enteritis is in general the fame with that of gastritis: but in this disease there is commonly more opportunity for the introduction of liquids, of acids, aseptic, and other cooling remedies, and even of laxatives; but as a vomiting frequently attends the enteritis, care must be taken not to excite that vomiting by the quantity or quality of any thing thrown
MEDICINE.

Phlegmoe.

thrown into the stomach. With regard to the suppuration and gangrene of the intestines following the enteritis, the observations, made respecting these terminations of gaitritis are equally applicable in this disease.

Sp. II. Enteritis Erysipelas, or Erysipelas Enteritis.

Concerning this nothing farther can be said, than what hath been already delivered concerning the gaitritis.

Genus XVII. HEPATITIS.

Inflammation of the Liver.

Description. The inflammation of the liver is thought to be of two kinds, acute and chronic; but the latter very often does not discover itself except by an abscess found in the liver after death, and which is supposed to have been occasioned by some degree of inflammation; for this reason the chronic inflammation often escapes observation, and we shall here only treat of the acute hepatitis.

The acute hepatitis is attended with considerable fever; a frequent, strong, and hard pulse; high coloured urine; an acute pain in the right hypochondrium, increased by pressing upon the part. The pain is very often in such a part of the side as to make it appear like a pleurisy; and frequently, like that, is increased on inspiration. The disease is also commonly attended with a cough, which is generally dry, but sometimes moist; and when the pain thus ressembles a pleurisy, the patient cannot lie easily except upon the side affected. The pain is frequently extended to the clavicle, and to the top of the shoulder; and is attended sometimes with hiccup, and sometimes with vomiting. Some have added jaundice, or a yellowness of the eyes, to the symptoms of this distemper; but experience shows that it has often occurred without any such symptom.

When hepatitis is of the chronic kind, depending more on the accumulation and effusion in the liver than in an increased action of its small vessels, the patient complains rather of a sense of weight than of pain; and the fever is by no means either acute, or constant: but it often returns in paroxysms somewhat resembling the attacks of an intermittent. This disease is very florid in its progress, frequently continuing for many months, and at last terminating in a very considerable suppuration. In most cases however, it may be discovered by careful examination of the region of the liver externally. By this means, a considerable enlargement of that viscus may in general be discovered.

Cauters, &c. The remote causes of hepatitis are not always to be disbelieved, and many have been assigned on a very uncertain foundation. It has been supposéd that the disease may be an affection either of the extremities of the hepatic artery, or those of the vena portarum; and the supposition is by no means improbable. The opinion, however, most commonly adopted is, that the acute hepatitis is an affection of the external membrane of the liver, and the chronic kind an affection of the parenchyma of that viscus. The acute disease may be seated either on the convex or concave surface of the liver; and in the former case a more pungent pain and hiccup may be produced, and the respiration is more considerably affected. In the latter there occurs less pain; and a vomiting is produced, commonly by some inflammation communicated to the stomach. The inflammation on the concave surface of the liver may be readily communicated to the gall-bladder and biliary ducts; and this, perhaps, is the only case of idiopathic hepatitis attended with jaundice.

Prognosis. The inflammation of the liver, like others, may end by resolution, suppuration, or gangrene; and the tendency to one or to the other of these events may be known from what has been already mentioned concerning the gaitritis. The resolution of hepatitis is often the consequence of or is attended with, evacuations of different kinds. A hemorrhage, sometimes from the nose, and sometimes from the hemorrhoidal vessels, gives a solution of the disease. Sometimes the same thing is accomplished by a bilious diarrhoea; and sometimes the resolution is attended with sweats, and an evacuation of urine containing a copious sediment. Sometimes it may be cured by an erysipelas appearing in one external part.

When the disease has ended in suppuration, the pus collected may be discharged by the biliary ducts; or, if the suppurated part does not adhere any where closely to the neighbouring parts, it may be discharged into the cavity of the abdomen: but if, during the first state of inflammation, the affected part of the liver shall have formed a close adhesion to some of the neighbouring parts, the discharge after suppuration may be various, according to the different seat of the abscess. When feated on the convex part of the liver, if the adhesion be to the peritoneum lining the common teguments, the pus may make its way through these, and be discharged outwardly: or if the adhesion shall have been to the diaphragm, the pus may penetrate through this, and into the cavity of the stomach, from whence it may be discharged by coughing. When the abscess is seated on the concave part of the liver, in consequence of adhesions, the pus may be discharged into the stomach or intestines; and into these last, either directly, or by the intervention of the biliary ducts. Upon a consideration of all these different circumstances therefore, together with the general principles of inflammation, must the prognosis of this disease be established.

Cure. For the cure of hepatitis, we must have recourse to the general means of removing other inflammatory disorders. Bleeding is to be used according to the degree of fever and pain. Blistering are to be applied: fomentations of the external parts, emollient gluters, gentle laxatives, drenches and refrigerants, are also useful. The cure, however, particularly in warm climates, where the disease is much more common than it is in Britain, is chiefly trusted to mercury. Not only in cases of the chronic kind, but in acute hepatitis also, after an attempt has been made to alleviate the urgent symptoms by bleeding and blistering, recourse is immediately had to this powerful mineral. It is employed by different practitioners, and in different cases, under various forms. Some are very
very fond of the use of calomel. But the preference is in general given, and perhaps with justice, to friction with mercurial ointment over the region of the liver. But under whatever form it may be employed, it is necessary that it should be introduced to such an extent as to keep the patient on the verge of suffocation for some length of time; the duration being regulated by the circumstances of the case.

From the liberal use of mercury, there can be no doubt that a successful resolution has been obtained in many cases, which would otherwise have infallibly terminated in suppuration. But notwithstanding the most careful employment of it in some cases, suppuration will ensue; and then it is very doubtful whether any benefit will be derived from the continuance of it. But when a suppuration has been formed, and the abscess points outwardly, the part must be opened, the pus evacuated, and the ulcer healed according to the ordinary methods in use for healing abscesses and ulcers in other parts.

Genus XVIII. SPLENITIS.

Description. This disease, according to Juncer, comes on with a remarkable shivering succeeded by a most intense heat and very great thirst; a pain and tumor are perceived in the left hypochondrium, and the paroxysms for the most part assume a quartan form. When the patients expose themselves for a little to the free air, their extremities immediately grow very cold. If an hemorrhage happens, the blood flows out of the left nostril. The other symptoms are the same with those of the hepatitis. Like the liver, the spleen often is also subject to a chronic inflammation, which often happens after agues, and is called the ague cake, though that name is also frequently given to a falsehood tumour of the liver succeeding intermittents.

Causes, &c. The causes of this distemper are in general the same with those of other inflammatory disorders; but those which determine the inflammation to that particular part more than another, are very much unknown. It attacks persons of a very plethoric and fangineous habit of body rather than others.

Prognosis. What has been said of the inflammation of the liver applies also to that of the spleen, tho' the latter is less dangerous than the former. Here also a vomiting of black matter, which in other acute diseases is such a fatal omen, sometimes proves critical, according to the testimony of Juncer. Sometimes the hemmorhoids prove critical; but very often the inflammation terminates by farinthus.

Genus XIX. NEPHRITIS.

Nephritis vera, Sauw. sp. 1.

Description. The nephritis has the same symptoms in common with other inflammations; but its distinguishing mark is the pain in the region of the kidney, which is sometimes obtuse, but more frequently pungent. The pain is not increased by the motion of the trunk of the body so much as a pain of the rheumatic kind affecting the same region. It may also frequently be distinguished by its shooting along the course of the ureter, and it is often attended with a drawing up of the testicle, and a numbness of the limb on the side affected; though indeed these symptoms most commonly attend the inflammation arising from a calculus in the kidney or ureter. The disease is also attended with frequent vomiting, and often with coldness and colic pains. The urine is most commonly of a deep red colour, and is voided frequently and in a small quantity at a time. In more violent cases the urine is commonly coloured.

Causes, &c. The remote causes of this disease may be various; as external contusion, violent or long-continued riding; strains of the muscles of the back incumbent on the kidneys; various acids in the course of circulation conveyed to the kidneys; and perhaps some other internal causes not yet well known: the most frequent is that of calculous matter obstructing the tubuli uriniferi, or calculi formed in the pelvis of the kidneys, and either flicking there or falling into the ureter.

Prognosis. This is not different from that of other inflammatory diseases.

Cure. When any of those causes operating as inducing the inflammation still continue to act, the first object in the cure must be the removal of those; but the principal intention to be had in view, is the revolution of the inflammation which has already taken place. But when, notwithstanding efforts for this purpose, the disease terminates in suppuration, it must be the endeavour of the practitioner to promote the discharge of purulent matter, and the healing of the ulceration in the kidney.

These different objects are principally accomplished by bleeding, external fomentation, frequent emollient glycerins, antiphlogistic purgatives, and by the free use of mild and demulcent liquids. The use of blisters is scarce admirable, or at least will require great care to avoid any considerable absorption of the causticides.

The other species of nephritis enumerated by authors are only symptomatic.

Genus XX. CYSTITIS.

Inflammation of the Bladder.

Inflammation vesicae, Hoffm. II. 157.

The Cystitis from Internal Causes.

Cystitis spontanea, Sauw. sp. 1.

The Cystitis from External Causes.

Cystitis a cantharidibus, Sauw. sp. 2.

Cystitis traumatica, Sauw. sp. 3.
Phlegm: inflammation of the bladder from internal causes is a very rare distemper; and when it does at any time occur, is to be cured in the same manner with other inflammations, avoiding only the use of cantharides. When the disease arises from the internal use of those flies, camphor is recommended, besides other cooling medicines, and particularly cooling and emollient glycers.

Genus XXI. HYSTERITIS. Inflammation of the Uterus. Hyysteris, Lin. 38. Vog. 63. Metritis, Sauv. gen. 107. Sag. gen. 315. Inflammatio et febris uterina, Hoffm. II. 156. Description. This disease is often confounded with that called the peripetal or child-bed fever; but is essentially distinct from it, as will be shown in its proper place. The inflammation of the uterus is apt to terminate by gangrene: there is a pain in the head, with delirium; and the uterine region is so exceedingly tender, that it cannot bear the least gentle pressure without intolerable pain. When the fundus uteri is inflamed, there is great heat, throbbing, and pain, above the pubes; if its posterior part, the pain is more confined to the loins and rectum, with a tenesmus; if its anterior part, it shoots from thence towards the neck of the bladder, and is attended with a frequent irritation to make water, which is voided with difficulty; and if its sides or the ovaria are affected, the pains will then dart into the inside of the thighs. Causer, &c. Inflammation of the uterus, and indeed of the rest of the abdominal visceræ, are very apt to take place in child-bed women; the reason of which seems to be the sudden change produced in the habit, and an alteration in the course of the circulating blood by the contraction of the uterus after delivery. The preffure of the gravid uterus being suddenly taken off from the aorta defendens after delivery, the resistance to the impulse of the blood passing through all the vessels derived from it, and distributed to the contiguous visceræ, will be considerably lessened: it will therefore rush into those vessels with a force superior to their resistance; and, by putting them violently on the stretch, may occasion pain, inflammation, and fever. This contraction of the uterus also renders its vessels impervious to the blood which had freely passed through them for the service of the child during pregnancy; and consequently a much larger quantity will be thrown upon the contiguous parts, which will still add to their diffusion, and increase their tendency to inflammation.

Prognosis. An inflammation of the uterus generally may be expected to produce an obstruction of the lochia; but the fever produced seldom proves fatal, unless the inflammation be violent, and end in a gangrene.

Cure. This is to be attempted by the same general means already recommended, and the management of this disorder entirely coincides with that of the peripetal fever.

Dolores rheumatici et arthritici, Hoffm. II. 317. Myolitis, Sag. gen. 301.

The Acute Rheumatism. Rheumatismus acutus, Sauv. sp. 1. Rheumatismus vulgaris, Sauv. sp. 2.

A. The Lumbago, or Rheumatism in the muscles of the Loins.

Rheumatismus febricola, Sauv. sp. 9. Lumbago febrilis, Sauv. sp. 4.

Description. The rheumatism is particularly distinguished by pains affecting the joints, and for the most part the joints alone; but sometimes also the muscular parts. Very often they shoot along the course of the muscles.
Practice.

MEDICINE.

Phlegma-

muscles from one joint to another, and are always much increased by the action of the muscles belonging to the joint or of joints affected. The larger joints are those most frequently affected, such as the hip-joint and knees of the lower extremities, and the shoulders and elbows of the upper ones. The ankles and wrists are also frequently affected; but the smaller joints, such as those of the toes or fingers, seldom suffer. Sometimes the diseaè is confined to one part of the body, yet very frequently it affects many parts of it; and then it begins with a cold stage, which is immediately succeeded by the other symptoms of pyrexia, and particularly by a frequent, full, and hard pulse. Sometimes the pyrexia is formed before any pains are perceived; but more commonly pains are felt in particular parts before any symptoms of pyrexia occur. When no pyrexia is present, the pain may be confined to one joint only; but when any considerable pyrexia takes place, though the pain may chiefly be felt in one joint, yet it seldom happens that the pains do not affect several joints, often at the very same time, but for the most part shifting their place, and having abated in one joint they become more violent in another. They do not commonly remain long in the same joint, but frequently shift from one to another, and sometimes return to joints formerly affected; and in this manner the diseaè often continues for a long time. The fever attending these pains has an exacerbation every evening, and is most considerable during the night, when the pains also become more violent; and it is at the same time that the pains shift their place from one joint to another. These seem to be also increased during the night by the body being covered more closely, and kept warmer.

A joint, after having been for some time affected with pain, commonly becomes also affected with some swelling and redness, which is painful to the touch. It seldom happens that a swelling coming on does not take off the pain entirely, or secure the joint again until a return of it. This diseaè is commonly attended with more or less sweating, which occurs early, but is seldom free or copious, and seldom either relieves from the pains or proves critical. The urine is high in not either relieves from the swelling and redness, which is

when the application of the cold is long continued, as when moist or wet clothes are applied to any part of the body.—These causes may affect persons of all ages; but the rheumatism seldom appears either in very young or in elderly persons, and most commonly occurs from the age of puberty to that of 35. These causes may also affect persons of any constitution, but they most commonly affect those of a fane temperament.

With respect to the proximate cause of rheumatism, there have been various opinions. It has been imputed to a peculiar astringency; of which, however, there is no evidence; and the consideration of the remote causes, the symptoms, and cure, render it very improbable. A disease of a rheumatic nature, however, may be occasioned by an acrid matter applied to the nerves, as is evident from the tooth-ach, a rheumatic affection generally arising from a carious tooth. Pains arising from deep-seated suppurations may also resemble the rheumatism; and many cases have occurred in which such suppurations occasioned pains resembling the lumbago and ischias; but from what hath been already said, it seems improbable that ever any rheumatic case should end in suppuration.

The proximate cause of rheumatism hath by many been supposed to be a leucorrhea in the fluids obliterating the vessels of the part; but in the former part of this treatise, sufficient reasons have been already laid down for rejecting the doctrine of leucorrhea. While we cannot therefore find either evidence or reason for supposing that the rheumatism depends on any change in the state of the fluids, we must conclude that the proximate cause of it is the same with that of other inflammations not depending upon a direct stimulus.

In the case of rheumatism, it is supposed that the most common remote cause of it, that is, cold applied, operates especially on the vessels of the joints, these being less covered by a cellular texture than those of the intermediate parts of the limbs. It is farther supposed, that the application of cold produces a constriction of the extreme vessels, and at the same time an increase of tone of phlogistic diathesis in the course of them, from which arises an increased impetus of the
the blood, and at the same time a resistance to the free passage of it, and consequently inflammations and pain. It is also supposed, that the resistance formed, excites the vis medica rix to a further increase of the impetus of the blood; and to support this, a cold stage arises, a spasm is formed, and a pyrexia and phlogistic diathesis are produced in the whole system.

Hence the cause of rheumatism appears to be exactly analogous to that of inflammations depending on an increased influx of blood to a part while it is exposed to the action of cold. But there seems to be further in this disease some peculiar affection of the muscular fibres. These seem to be under some degree of rigidity; and therefore less easily admit of motion, and are gained upon the exertions of it. This also seems to be the affection which gives opportunity to the propagation of pains from one joint to another, and which are most severely felt in the extremities terminating in the joints, because beyond these the oscillations are not propagated. This affection of the muscular fibres explains the manner in which strains and spasms produce rheumatic affections; and, on the whole, shows, that with an inflammatory affection of the sanguiferous system, there is also in rheumatism a peculiar affection of the muscular fibres, which has a considerable share in producing the phenomena of the disease. And it would even appear, that in what has commonly been called acute rheumatism, in contradistinction to the chronic, of which we are next to treat, there exists not only a state of active inflammation in the affected parts, but also of peculiar irritability; and that this often remains after the inflammation is very much diminished or has even entirely ceased. Hence a renewal of the inflammation and recurrence of the pain take place from very slight causes; and in the treatment of this disease both the state of inflammation and irritability must be had in view.

Cure. For countering the state of active inflammation, the chief aim of the practitioner must be to diminish the general impetus of the circulation, and the impetus at the part particularly affected. For countering the state of irritability, he must endeavour to remove the disposition to increased action in the vessels; to prevent the action of caustics exciting painful sensations; and to obviate their influence on the part. The cure therefore requires, in the first place, an antiphlogistic regimen, and particularly a total abstinence from animal-food, and from all fermented or spirituous liquors; substituting a mild vegetable or milk diet, and the plentiful use of soft diluting liquors. On this principle also, blood-letting is the chief remedy of acute rheumatism. The blood is to be drawn in large quantity; and the bleeding is to be repeated in proportion to the frequency, fulness, and hardness of the pulse, and the violence of the pain. For the most part, large and repeated bleedings during the first days of the disease seem to be necessary, and accordingly have been very much employed; but to this some bounds are to be set; for very profuse bleedings occasion a flow recovery, and if not absolutely effectual, are ready to produce a chronic rheumatism.

To avoid that debility of the system which general bleedings are apt to occasion, the urgent symptom of pain may be often relieved by topical bleedings; and when any swelling or redness have come upon a joint, the pain may very certainly be relieved by topical bleedings: but as the pain and continuance of the disease seem to depend more upon the phlogistic diathesis of the whole system than upon the affection of particular parts, so topical bleedings will not supply the place of the general bleedings proposed above.

To take off the phlogistic diathesis prevailing in this disease, purging may be useful, if produced by medicines which do not stimulate the whole system, as neutral salts, and other medicines which have a refrigerant power. Purging, however, is not so useful as bleeding in removing the phlogistic diathesis; and when the disease has become general and violent, frequent stools are inconvenient, and even hurtful, by the motion and pain which they occasion.

Next to blood-letting, nothing is of so much service, both in alleviating the pains in this disease and in removing the phlogistic diathesis, as the use of sudorifics; and of all the medicines belonging to this class, what has commonly been known by the name of Dover's powder, a combination of powder of sanguis and opium, is the most convenient and the most effectual. Copious sweating, excited by this medicine, and supported for 10 or 12 hours by tepid diluents, such as decoction of the woods, or the like, will in most instances produce a complete remission of the pain: and by this practice, combined with blood-letting and proper regimen, the disease may often be entirely removed.

If, however, after complete intermissions from pain for some length of time have been obtained by these means, it be found that there is a great tendency to a return of the pains without any obvious cause, recourse may be had with very great benefit to the use of the Peruvian bark. By the early use of this, where a complete intermission from pain is obtained, the necessity of repeated blood-letting and sweating is often superseded; but where a complete remission cannot be obtained, it has been suspended by some to be hurtful: and in these cases, when blood-letting and sudorifics have been pushed as far as may be thought prudent without being productive of the desired effect, very great benefit is often obtained from the use of calomel combined with opium, as recommended in the Edinburgh Medical Commentaries by Dr Hamilton of Lynn-regs.

In this disease, external applications are of little service. Fomentations in the beginning of the disease, rather aggravate than relieve the pains. The rubefacients and camphire are more effectual: but they, commonly only shift them from one part to another, and do not prove any cure of the general affection. Blistering may also be very effectual in removing the pain from a particular part; but will be of little use, except where the pains are much confined to one place.

**ARTHRODYNA, or Chronic Rheumatism.**

Rheumatism chronicus Auctorum.

Description. When the pyrexia attending the acute rheumatism has ceased; when the swelling and redness of the joints are entirely gone, but pains still continue to affect certain joints, which remain stiff, feel uneasily upon
Phlegmasia upon motion, changes of weather, or in the night-time, the disease is then called the chronic rheumatism, as it often continues for a very long time.

The limits between the acute and chronic rheumatisms are not always exactly marked. When the pains are still ready to shift their place; when they are especially severe in the night-time; when, at the same time, they are attended with some degree of pyrexia, and with some swelling, and especially some redness of the joints; the disease is to be considered as partaking of the nature of the acute rheumatism. But when there is no longer any degree of pyrexia remaining; when the pains of these are increased by cold, and relieved by heat, applied to them; the case is to be considered as that of a purely chronic rheumatism; or perhaps more properly the first of the conditions now described may be termed the state of irritability, and the second state of atony.

The chronic rheumatism, or rather the atonic, may affect different joints; but is especially apt to affect those which are surrounded with many muscles, and those of which the muscles are employed in the most constant and vigorous exertions. Such is the case of the vertebrae of the loins, the affection of which is named lumbago; or of the hip-joint, when the disease is named ischias or sciatica.

Violent strains and spains occurring on sudden and somewhat violent exertions, bring on rheumatic affections, which at first partake of the acute, but very soon change into the nature of the chronic, rheumatism. Such are frequently the lumbago, and other affections, which seem to be more seated in the muscles than in the joints. The distinction of the rheumatic pains from those resembling them which occur in the fibrisis and scurvy must be obvious, either from the seat of the pains, or from the concomitant symptoms peculiar to those diseases. The distinction of the rheumatism from the gout will be more fully understood from what is laid down under the genus Podagra.

G. XXIV. ODONTALGIA, the Tooth-ach.

For answering these purposes, a great variety of remedies, both external and internal, are had recourse to. The chief of the external are, the supporting the heat of the part, by keeping it constantly covered with flannel; the increasing the heat of the part by external heat, applied either in a dry or humid form; the diligent use of the flesh-brush, or other means of friction; the application of electricity in sparks or shocks; the application of cold water by affusion or immersion; the application of officinal oils of the moist warm and penetrating kind; the application of salt brine; the employment of the warm bath or of the vapour baths, either to the body in general or to particular parts; and lastly, the employment either of exercise of the part itself as far as it can easily bear, or by riding or other modes of gentle motion.

The internal remedies are, Large doses of officinal oils drawn from resinous substances, such as turpentine. Substances containing pitch oils, as guaiac. Volatile alkaline salts. These or other medicines are directed to procure sweat; and calomel, or some other preparation of mercury, in small doses, may be continued for some time. Besides these, there are several others recommended. The cicuta, aconitum, and hyosciamus, have in particular been highly extolled; and an infusion of the rhododendron corymbosum is said to be employed by the Siberians with very great success. An account of the Siberian mode of practice is given by Dr Matthew Guthrie of Peterburgh, in the fifth volume of the Edinburgh Medical Commentaries, and has been followed with success at other places.

Description. This well-known disease makes its attack by a most violent pain in the teeth, most frequently in the malaris, more rarely in the incisivis, reaching sometimes up to the eyes, and sometimes backward into the cavity of the ear. At the same time there is a manifest determination to the head, and a remarkable tension and inflation of the ear; the patient often feels and inflammation of the inner ear, together with a sense of oppression and choking in the throat. The pain is most frequently at the height of pregnancy, and takes place in some nervous disorders; it may attack persons at any time of life, tho' it is most frequent in the young and plethoric.

Cura. From the view just now given of the proximate cause of chronic rheumatism, the chief indication of cure must be, to restore the activity and vigour of the part, which is principally to be done by increasing the tone of the moving fibres, but which may sometimes also be aided by giving condensation to the simple solid. When, however, the disease has degenerated into the state of paralysis, the objects to be aimed at are, the restoration of a due condition to the nervous energy in the part affected; the obtaining free circulation of blood through the vessels of the part; and the removal of rigidity in membranes and ligaments.
Cure. Many empirical remedies have been proposed for the cure of the tooth-ach, but none have in any degree answered the purpose. When the affection is purely rheumatic, blushing behind the ear will almost always remove it; but when it proceeds from a carious tooth, the pain is much more obstinate. In this case it has been recommended to touch the painful part with a hot iron, or with oil of vitriol, in order to destroy the aching nerve; to hold strong spirits in the mouth; to put a drop of oil of cloves into the hollow of the tooth, or a pill of equal parts of opium and camphire; but one of the most useful applications of this kind is strong nitrous acid, diluted with three or four times its weight of spirit of wine, and introduced into the hollow of a tooth from which great pain arises, either by means of an hair pencil or a little cotton. The Peruvian bark has also been recommended, and perhaps with more justice, on account of its tonic and antifeptic powers; but very often all these remedies will fail, and the only infallible cure is to draw the tooth. See Surgery.

Description. What we call a paroxysm of the gout is principally constituted by an inflammatory affection of some of the joints. This sometimes comes on suddenly, without any warning, but is generally preceded by several symptoms; such as the ceasing of a sweating which the feet had been commonly affected with before; an unusual coldness of the feet and legs; a frequent numbness, alternating with a sense of prickling along the whole of the lower extremities; frequent cramps of the muscles of the legs, and an unusual turgescence of the veins.

While these symptoms take place in the lower extremities, the body is affected with some degree of torpor and languor, and the functions of the stomach in particular are more or less disturbed. The appetite is diminished; and flatulency, or other symptoms of indigestion, are felt. These symptoms take place for several days, sometimes for a week or two, before a paroxysm comes on; but commonly, upon the day immediately preceding it, the appetite becomes keener than usual.

The circumstances of paroxysms are chiefly the following. They come on most commonly in the spring, and sooner or later according as the vernal heat succeeds sooner or later to the winter's cold; and, perhaps, sooner or later also, according as the body may happen to be more or less exposed to vicissitudes of heat and cold.

The attacks are sometimes felt first in the evening, but more commonly about two or three o'clock in the morning. The paroxysm begins with a pain affecting one foot, most commonly in the ball or first joint of the great toe, but sometimes in other parts of the foot. With the attack of this pain, there is commonly more or less of a cold shivering; which, as the pain increases, gradually ceases; and is succeeded by a hot sweat of pyrexia, which continues for the same time with the pain itself. From the first attack, the pain becomes, by degrees, more violent, and continues in this state with great restlessness of the whole body till next midnight; after which it gradually remits; and, after it has continued for 24 hours from the commencement of the first attack, it commonly ceases almost entirely; and, with the coming on of a gentle sweat, allows the patient to fall asleep. The patient, upon coming out of this sleep in the morning, finds the painful part affected with some redness and swelling, which, after having continued for some days, gradually abates.

When a paroxysm has thus come on, although the violent pain after 24 hours be considerably abated, the patient is not entirely relieved from it. For some days he has every evening a return of more considerable pain and pyrexia, and these continue with more or less violence till morning. After going on in this manner for several days, the disease sometimes goes entirely off, not till after a long interval.

When the disease, after having thus remained for some time in a joint, ceases entirely, it generally leaves the person in very perfect health, enjoying greater ease and alacrity in the functions of both body and mind than he had for a long time before experienced.

At the beginning of the disease, the returns of it are sometimes only once in three or four years; but as it advances, the intervals become shorter, and at length the attacks are annual; afterwards they come twice each year; and at length recur several times during the course of autumn, winter, and spring; and as, when the fits are frequent, the paroxysms become also longer, so, in the advanced state of the disease, the patient is hardly ever tolerably free from it, except perhaps for two or three months in summer.

The progress of the disease is also marked by the parts which it affects. At first, it commonly affects one foot only; afterwards every paroxysm affects both feet, the one after the other; and as the disease proceeds, it not only affects both feet at once, but, after having ceased in the foot which was secondly attacked, returns again into the first, and perhaps a second time also into the other. Its changes of places are not only from one foot to another, but from the feet into other joints, especially those of the upper and lower extremities; so that there is hardly a joint of the body, which,
Of such irregular gout there are three different states, which may be named the astatic, the retrocedent, and the misplaced gout.

The first is, when the gouty diathesis prevails in the system; but from certain causes, does not produce the inflammatory affection of the joints. In this case, the morbid symptoms which appear, are chiefly affections of the stomatch, such as loss of appetite, indigestion, and its various attendants of sickness, nausea, vomiting, flatulency, acid eruptions, and pains in the region of the stomatch. These symptoms are frequently accompanied with pains and cramps in several parts of the trunk and the upper extremities of the body, which are relieved by the discharge of wind from the stomatch. Together with these affections of the stomatch, there commonly occurs a colicene, but sometimes a looseness, with colic pains. These affections of the alimentary canal are often attended with all the symptoms of hypochondria, such as dejection of mind, a constant and anxious attention to the lightest feelings, an imaginary aggravation of these, and an apprehension of danger from them.

In the same astatic gout, the vasa of the thorax also are sometimes affected, and palpitations, faintings, and asthma, occur.

In the head also occur headaches, giddinefs, apoplectic and paralytic affections.

When the several symptoms now mentioned occur in habits having the marks of a gouty disposition, this may be suspected to have laid the foundation of them; and especially when either, in such habits, a manifest tendency to the inflammatory affection has formerly appeared, or when the symptoms mentioned are intermixed with and are relieved by some degree of the inflammatory gout. In such cases there can be no doubt of considering the whole as a state of the gout.

Another state of the disease we name the retrocedent gout. This occurs when an inflammatory state of the joints has, in the usual manner, come on, but without arising to the ordinary degree of pain and inflammation; or at least without these continuing for the usual time, or without their receding gradually in the usual manner; these affections of the joints suddenly and entirely cease, while some internal part becomes affected. The internal part most commonly attacked is the stomatch; which then is affected with anxiety, sickness, vomiting, or violent pain; but sometimes the internal part is the heart, which gives occasion to a syncope; some times it is the lungs, which are affected with asthma; and sometimes it is the head, giving occasion to apoplexy or palsy. In all these cases there can be no doubt that the symptoms are all a part of the same disease, however different the affection may seem to be in the parts in which it attacks.

The third state of irregular gout, which we name the misplaced, is when the gouty diathesis, instead of producing the inflammatory affection of the joints, produces an inflammatory affection of some internal part, and which appears from the same symptoms that attend the inflammations of those parts arising from other causes.

Whether the gouty diathesis does ever produce such inflammation of the internal parts without having first produced it in the joints, or whether the inflammation
of the internal part be always a translation from the joints previously affected, we dare not determine; but, even supposing the latter to be always the case, we think the difference of the affection of the internal part must still distinguish the misplaced from what we have named the retrograded gout.

With regard to the misplaced gout, Dr Cullen, whom we here follow, tells us, that he never met with the pneumonic inflammation. of which is an

The other is an hemorrhoidal affection indicated by pain alone in that part, and sometimes by hemorrhoidal symptoms. In gouty persons such affections have been known to alternate with inflammatory affections of the joints; but whether these belonged to the retrograded or to the misplaced gout, our authors pretend not to determine.

It is commonly supposed, that there are some cases of rheumatic which are scarcely to be distinguished from the gout: but these, Dr Cullen thinks, are but few; and that the two diseases may be for the most part distinguished with great certainty, by observing the predisposition, the antecedent circumstances, the parts affected, the recurrences of the disease, and its connection with the system; which circumstances, for the most part, appear very differently in the two diseases.

Causes, &c. The gout is generally an hereditary disease: but some persons, without any hereditary disposition, seem to acquire it; and some an hereditary disposition may be counteracted from various causes. It attacks the male sex especially; but it sometimes, more rarely, attacks also the female. The females liable to it are those of the more robust and full habits; and it very often happens to those before the menstrual evacuation had ceased. Dr Cullen has also found it occurring in several females whose menstrual evacuations were more abundant than usual.

The gout seldom attacks children; and when it does, seem to fall upon those who happen to be of a robust habit, to lead an indolent life, and to live very full. It attacks especially men of robust and large bodies, those of large heads, are of full and copulent habits, and whose skins are covered with a thicker rete mucosum, which gives a coarser surface. To speak in the style of the ancient physicians, the gout will seldom be found to attack those of a fanguiine, or such as are of a purely melancholic temperament; but very readily those of a phlegmatis-fanguiine temperament. It is, however, very difficult to treat this matter with precision. The gout seldom attacks persons employed in constant bodily labour, or those who live much upon vegetable aliment. It does not commonly attack men till after the age of 35; and generally not till a still later period. There are indeed instances of the gout appearing more early; but these are few in comparison of the others. When the disease does appear early in life, it seems to be in those who have the hereditary disposition very strong, and to whom the remote causes hereafter mentioned have been applied in a very considerable degree.

As the gout is an hereditary disease, and affects men particularly of a certain habit, its remote causes may be considered as predisposing and occasional. The predisposing cause, as far as expressed by external appearances, has been already marked; and physicians have been very confident in affiguing the occasional causes: but in a disease depending so much upon a predisposition, the affiguing occasional causes must be uncertain; as in the predisposing the occasional causes may not always appear, and in persons not predisposed they may appear without effect; and this uncertainty must particularly affect the cause of the gout.

The occasional causes of the disease seem to be of two kinds. First, those which induce a phlegmatic state of the body. Secondly, those which in plethoric habits, induce a state of debility. Of the first kind are a sedentary, indolent manner of life, and a full diet of animal-food. Of the second kind of occasional causes which induce debility are excess in venery; intemperance in the use of intoxicating liquors; indigestion, produced either by the quantity or quality of the aliments; much application to study or business; the latter are common in the gout: a sudden change from a very full to a very spare diet; the large use of acids and astringents; and lastly, cold applied to the lower extremities. The former seem to act by increasing the predisposition; the latter are commonly the exciting causes, both of the first attacks, and of the repetitions of the disease.

With respect to the proximate cause of the gout, it has generally been thought that it depends on a certain morbid matter always present in the body; and that this matter, by certain causes, thrown upon the joints or other parts, produces the several phenomena of the disease.

This doctrine, however ancient and generally received, appears to Dr Cullen to be very doubtful. For,

First, there is no direct evidence of any morbid matter being present in persons disposed to the gout. There are no experiments or observations which show that the blood or other humours of gouty persons are in any respect different from those of others. Previous to attacks of the gout, there appear no marks of any morbid state of the fluids; for the disease generally attacks those persons who have enjoyed the most perfect health, and appear to be in that state when the disease comes on. At a certain period of the disease, a peculiar matter indeed appears in gouty persons; but this, which does not appear in every instance, and which appears only after the disease has subsided for a long time, seems manifestly to be the effect, not the cause, of the disease. Further, though there be certain acids which, taken into the body, seem to excite the gout, it is probable, that these acids operate otherwise in exciting the disease, than by affording the material cause of it. In general, therefore, Dr Cullen thinks there is no proof of any morbid matter being the cause of the gout.

Secondly, the suppositions concerning the particular nature of the matter producing the gout, have been so various, and so contradictory, as to allow us to conclude, that there is truly no proof of the existence of
of any of them. With respect to many of these suppositions, they are inconsistent with chemical philosophy, and with the laws of the animal economy, that they must be entirely rejected. Thirdly, the supposition of a morbific matter as the cause is not consistent with the phenomena of the disease, particularly with its frequent and sudden translations from one part to another. Fourthly, the supposition is further rendered improbable by this, that, if a morbific matter did exist, its operation should be similar in the several parts which it attacks; whereas it seems to be very different, being stimulant, and exciting inflammation, in the joints; but sedative and destroying the tone in the stomach: which, upon the supposition of the same particular matter acting in both cases, is not to be explained by any difference in the part affected. Fifthly, Some facts all aged in proof of a morbific matter, are not sufficiently confirmed; such as those which would prove the disease to be contagious. There is, however, no proper evidence of this, the facts given being not only few, but exceptional, and the negative observations innumerable. Sixthly, Some arguments brought in favour of a morbific matter are founded upon a mistaken explanation. The disease has been supposed to depend upon a morbific matter, because it is hereditary. But the inference is not just; for most hereditary diseases do not depend upon any morbific matter, but upon a particular conformation of the structure of the body transmitted from the parent to the offspring; and this last appears to be particularly the case in the gout. It may be also observed, that hereditary diseases depending upon a morbific matter, appear always much more early in life than the gout commonly does. Seventhly, The supposition of a morbific matter being the cause of the gout, has been hitherto useless, as it has not suggested any successful method of cure. Particular theories of gout have often corrupted the practice, and have frequently led from those views which might have been useful, and from that practice which experience had approved. Further, though the supposition of a morbific matter has been generally received, it has been as generally neglected in practice. When the gout has affected the stomach, nobody thinks of correcting the matter supposed to be present there, but merely of restoring the tone of the moving fibres. Eighthly, The supposition of a morbific matter is quite superfluous; for it explains nothing without supposing that matter to produce a change in the state of the moving powers; and a change in the state of the moving powers, produced by other causes, explains every circumstance without the supposition of a morbific matter; and it may be observed, that many of the causes exciting the gout, do not operate upon the state of the fluids, but directly and solely upon that of the moving powers. Lastly, Dr Cullen contends that the supposition of a morbific matter is superfluous; because, without that, the disease can be explained, he thinks, in a manner more consistent with its phenomena, with the laws of the animal economy, and with the method of cure which experience has approved. We now proceed to give this explanation; but, before entering upon it, we must premise some general observations which Dr Cullen states. The first observation is, That the gout is a disease of the whole system, or depends upon a certain general conformation and state of the body, which manifestly appears from the facts abovementioned. But the general state of the system depends chiefly upon the state of its primary moving powers; and therefore the gout may be supposed to be an affection of these chiefly. The second observation is, That the gout is manifestly an affection of the nervous system; in which the primary moving powers of the whole system are lodged. The occasional or exciting causes are almost all such as act directly upon the nerves and nervous system; and the greater part of the symptoms of the atomic or retrodental gout are manifestly affections of the same system. This leads us to seek for an explanation of the whole of the disease, in the laws of the nervous system, and particularly in the changes which may happen in the balance of its several parts. The third observation is, That the stomach, which has to universal a connex with the rest of the system, is the internal part that is most frequently, and often very considerably, affected by the gout. The paroxysms of the disease are commonly preceded by an affection of the stomach; many of the exciting causes act first upon the stomach, and the symptoms of the atomic and retrodental gout are most commonly and chiefly affections of the same organ. This observation leads us to remark, that there is a balance subsisting between the state of the internal and that of the external parts; and in particular that the state of the stomach is connected with that of the external parts, so that the state of tone in the one may be communicated to the other. These observations being premised, Dr Cullen offers the following pathology of the gout. In some persons there is a certain vigorous and phlegmatic state of the system, which at a certain period of life is liable to a loss of tone in the extremities. This is in some measure communicated to the whole system, but appears more especially in the functions of the stomach. When this loss of tone occurs while the energy of the brain still retains its vigour, the vis medicastris naturae is excited to restore the tone of the parts; and accomplishes it, by exciting an inflammatory affection in some part of the extremities. When this has fulfilled for some days, the tone of the extremities and of the whole system is restored, and the patient returns to his ordinary state of health. This is the course of things in the ordinary form of the disease, which we name the regular gout; but there are circumstances of the body, in which this course is interrupted or varied. Thus, when the atony has taken place, if the reaction do not succeed, the atony continues in the stomach, or perhaps in other internal parts; and produces that state which Dr Cullen, for reasons now obvious, named the atomic gout. A second cause of variation in the course of the gout is, when to the atony the reaction and inflammation have to a certain degree succeeded, but from causes either internal or external the tone of the extremities and perhaps of the whole system is weakened; so that the inflammatory state, before it had either proceeded to the degree, or continued for the time, requisite for restoring
A third case of variation from the ordinary course of the gout, is, when to the atony, uttally preceding, an inflammatory reaction fully succeeds, but has its usual determination to the joints by some circumstances prevented; and is therefore directed to some internal part, where it produces an inflammatory affection, and that state of things which we have named the misplaced gout.

Though this theory of Dr Cullen's be supported with much ingenuity, yet we may confidently venture to assert, that on this subject he has been less successful in establishing his own opinion, than in combating those of others; and this theory, as well as others formerly propounded, is liable to numerous and unfirmamentable objections. According to the hypothesis, a vigorous and phlethoric habit should in every case exist prior to the appearance of gout; which is by no means consistent with fact; nor is it true that a vigorous and phlethoric habit is liable at a certain age to a loss of tone in the extremities; which is another necessary condition in the hypothesis. Loss of tone often occurs in the extremities without exercising any peculiar influence on the stomach; and why a loss of tone in the stomach should excite the vis medicatrix naturee, to restore it by exciting an inflammatory affection in some part of the extremities, is very inconceivable. Were the hypothesis true, every dyseptic patient should infallibly be affected with gout; which, however, is by no means the case. In short, every step in the theory is liable to unfirmamentable objections; and it by no means, any more than former hypotheses, explains the phenomena of the disease, particularly what Dr Cullen has himself so accurately pointed out, the connection of gouty with calculous complaints.

A very ingenious work has lately been published by an anonymous author, entitled "A Treatise on Gravel and upon Gout," in which the features of each are investigated, and effectual means of preventing or removing these diseases recommended. In this treatie an attempt is made to prove, that both diseases depend upon a peculiar concretion acid, the acid of calculus, or the lithic acid, as it has been styled by some. He supposes this acid, constantly present to a certain degree in the circulating fluids, to be precipitated by the introduction of other acids; and in this manner he explains the influence of acid wines and other liquors, as claret, cyder, &c inducing gout; for he considers the circumstance chiefly constituting the disease as being an inflammation in parts of which the functions have been interrupted by the redundant acid precipitated. Although this theory be supported with much ingenuity, yet it is also liable to many objections. The sudden attack of the affection; its sudden transition from one part of the body to another; the infant relief of one part when another comes to be affected; and the various anomalous forms which the disease puts on, having an exact resemblance to different affections; are altogether irreconcileable to the idea of its depending on any fixed obstruction at a particular part arising from concreting acid. Nor does the plan of prevention and cure which he proposes, and which consist chiefly in abstinence from acid and in the deftruction of acid, by any means correspond in every particular to be felt established facts respecting the treatment of gout; to which we next proceed.

Cure. In entering upon this, we must observe, in the first place, that a cure has been commonly thought impossible; and we acknowledge it to be very probable, that the gout, as a disease of the whole habit, and very often depending upon original conformation, cannot be cured by medicines, the effects of which are always very transitory, and seldom extend to the producing any considerable change of the whole habit.

It would perhaps have been happy for gouty persons if this opinion had been implicitly received by them; as it would have prevented their having been so often the dupes of self-interested pretenders, who have either amused them with inert medicines, or have rashly employed those of the most pernicious tendency. Dr Cullen, who has treated of the cure of the disease with great judgment, as he has done the theory with much ingenuity, is much disposed to believe the impossibility of a cure of the gout by medicines; and more certainly still inclined to think, that, whatever may be the possible power of medicines, yet no medicine for curing the gout has hitherto been found. Although almost every age has presented a new remedy, all hitherto offered have, very soon after, been either neglected as useless, or condemned as pernicious.

But, though unwilling to admit the power of medicines, yet he contends, that a great deal can be done towards the cure of the gout by a regimen: and he is firmly persuaded, that any man who, early in life, will enter upon the constant practice of bodily labour and of abstinence from animal-food, will be preserved entirely from the disease.

Whether there be any other means of radically curtailing the gout, the Doctor is not ready to determine. There are histories of cases of the gout, in which it is said, that by great emotions of mind, by wounds, and by other accidents, the symptoms have been suddenly relieved, and never again returned; but how far these accidental cures might be imitated by art, or would succed in other cases, is at least extremely uncertain.

The practices proper and necessary in the treatment of the gout, are to be considered under two heads; firstly, As they are to be employed in the intervals of paroxysms; or, secondly, As during the time of these. In the intervals of paroxysms, the indications are, to prevent altogether the return of paroxysms; or at least to render them less frequent, and more moderate. During the time of paroxysms, the indications are, to moderate the violence and shorten the duration of them as much as can be done with safety.

It has been already observed, that the gout may be entirely prevented by constant bodily exercise, and by a low diet; and Dr Cullen is of opinion that this prevention may take place even in persons who have a hereditary disposition to the disease. Even when the disposition has discovered itself by several paroxysms of inflammatory gout, he is persuaded that labour and abstinence will absolutely prevent any returns of it for the
the rest of life. These, therefore, are the means of an-
swering the first indication to be pursued in the intervals of paroxyms.

Exercise in persons disposed to the gout, in Dr Cull-
len’s opinion, has effect by answering two purpotes: One of these is the strengthening of the tone of the extreme vessels; and the other, the guarding against a plethoric state. For the former, if exercise be em-
ployed early in life and before intemperance has wea-
kened the body, a very moderate degree of it will an-
swer the purpose; and, for the latter, if abstinence be at the same time observed, little exercise will be ne-
necessary.

With respect to exercise, this in general is to be ob-
erved, that it should never be violent; for, if violent it cannot be long continued, and must always endan-
ger the bringing on an atony in proportion to the violence of the preceding exercise.

It is also to be observed, that the exercise of ge-
station, though considerable and constant, will not, if it be entirely without bodily exercise, answer the purpose in preventing the gout. For this end, therefore, the exercise must be in some measure that of the body, and must be moderate, but at the same time constant and continued through life.

In every case and circumstance of the gout in which the patient retains the use of his limbs, bodily exer-
cise, in the intervals of paroxyms, will be always use-
ful; and in the beginning of the disease, when the disposition to it is not yet strong, exercise, may prevent a paroxysm which otherwise might have come on. In more advanced states of the disease, however, when there is some disposition to a paroxysm, much walking will bring it on, either as it weakens the tone of the lower extremities, or as it excites an inflammatory dis-
position in them; and thus it seems to be that strains or contusions often bring on a paroxysm of the gout.

Abstinence, the other part of the proper regimen for preventing, the gout is of more difficult applica-
tion. If an abstinence from animal food be entered upon early in life, while the vigour of the system is yet entire, Dr Cullen has no doubt of its being both safe and effectual; but if the motive for this diet shall not have occurred till the constitution has been broken by intemperance or by the decline of life, a low diet may then endanger the bringing on an atomic state.

Further, if a low diet be entered upon only in the decline of life, and be at the same time a very great change from the former manner of living, the with-
drawing of an accustomed stimulus of the system may readily throw this into an atomic state.

The safety of an abstemious course may be greater or less according to the management of it. It is ani-
mal food which especially disposes to the plethoric and inflammatory state, and that food is to be therefore especially avoided; but, on the other hand, vegetable aliment of the lowest quality is in danger of weak-
ening the system too much by not affording suffi-
cient nourishment, and more particularly of weaken-
ning the tone of the stomach by its aecency. It is therefore a diet of a middle nature that is to be cho-

As approaching to the nature of milk, and as being a vegetable matter containing the greatest portion of nourishment, the farinaceous foods are next to be cho-

With respect to drink, fermented liquors are useful only when they are joined with animal food, and that by their acceancy; and their stimulus is only neces-
sary from custom. When, therefore, animal food is to be avoided, fermented liquors are unnecessary; and by increasing the acceancy of vegetables, these liquors may be hurtful. The stimulus of fermented or spirit-
luous liquors is not necessary to the young and vigo-
rous; for, when much employed injures the tone of the system. These liquors, therefore, are to be avo-
ded, except so far as custom and the declining state of the system may have rendered them necessary. For pre-
venting or moderating the regular gout, water is the only proper drink.

With respect to an abstemious course, it has been sup-
posed, that an abstinence from animal food and fer-
m ented liquors, or the living upon milk and farina,
alone for the space of one year, might be sufficient for a radical cure of the gout; and it is possible that, at a certain period of life, in certain circumstances of the constitution, such a measure might answer the purpose. But this is very doubtful; and it is more probable, that the abstinence must, in a great measure, be con-

It has been alleged, that, for preventing the return of the gout, blood-letting or scarifications of the feet, frequently repeated, and at stated times, may be prac-
ticed with advantage; but of this Dr Cullen tells us he has had no experience; and the benefit of the prac-
tise is not, as far as we know, confirmed by the obser-
vation of any other practitioner.

Exercise and abstinence are the means of avoiding the plethoric state which gives the disposition to the gout; and are therefore the means proposed for pre-
venting the paroxyms, or at least for rendering them less frequent and more moderate. But many circum-
stances prevent the readiness necessary in pursuing these measures; and therefore, in such cases, unless great care be taken to avoid the exciting causes, the disease may frequently return; and, in many cases, the preventing of paroxyms is chiefly to be obtained by avoiding those exciting causes already men-
Phlegmatic fures necessary for this purpose will, in most cases, be pursued with difficulty, and even with reluctance, men have been very desirous to find a medicine which might answer the purpose without any restraint on their manner of living. To gratify this desire, physicians have proposed, and, to take advantage of it, empirics have feigned, many remedies. Of what nature several of these remedies have been, it is difficult to say; but of those which are unknown, we conclude, from their having been only of temporary fame, and from their having been fallen into neglect, that they have been either inert or pernicious, and therefore shall make no inquiry after them, and shall now remark only upon one or two known remedies for the gout which have been lately in vogue.

One of these is what has been named in England the Portland powder. This is not a new medicine, but is mentioned by Galen, and, with some little variation in its composition, has been written by the writers of almost every age since that time. It appears to have been at times in fashion, and to have again fallen into neglect; and Dr Cullen thinks that this laft has been owing to its having been found to be, in many instances, pernicious. In every instance which he has known of his exhibition for the length of time prescribed, the persons who had taken it were indeed afterwards free from any inflammatory affection of the joints; but they were affected with many symptoms of the atonic gout; and all, soon after finishing their course of the medicine, have been attacked with apoplexy, asthma, or dropsy, which proved fatal.

Another remedy which has had the appearance of preventing the gout, is an alkali in various forms; such as the fixed alkali, both mild and caustic, lime-water, soap, and absorbent earths; and of late the alkaline aerated water has been more fashionable than any other. Since it became common to exhibit these medicines in naphritic and calculous cases, it has often happened that they were given to those who were at the same time subject to the gout; and it has been observed, that under the use of these medicines, gouty persons have been longer free from the fits of their disease. That, however, the use of these medicines has entirely prevented the returns of gout, Dr Cullen does not know; because he never pufhed the use of those medicines for a long time, being apprehensive that the long-continued use of them might produce a hurtful change in the state of the fluids.

As the preventing the gout depends very much on supporting the tone of the stomach, and avoiding indigestion; so colchicines, by occasioning this, is very hurtful to gouty persons. It is therefore necessary for such persons to prevent or remove colchicines, and by a laxative medicine, when needful; but it is at the same time proper, that the medicine employed should be such as may keep the belly regular, without much purging. Aloetis, rhubarb, magnesia alba, oleum ricini, or flowers of sulphur, may be employed, as the one or the other may happen to be best suited to particular persons.

These are the several measures to be pursued in the intervals of the paroxysms; and we are next to mention the measures proper during the time of them.

As during the time of paroxysms the body is in a feverish state, no irritation should then be added to it; every part, therefore, of the antiphlogistic regimen except the application of cold, ought to be strictly observed.

Another exception to the general rule may occur when the tone of the stomach is weak; and when the patient has been before much accustomed to the use of strong drink; for then it may be allowable, and even necessary, to give some animal-food and a little wine.

That no irritation is to be added to the stylen during the paroxysms of gout, except in the cases mentioned, is agreed upon among physicians; but it is a more difficult matter to determine, whether, during the time of paroxysms, any measures may be pursued to moderate the violence of reaction and of inflammation. Dr Sydenham has given it as his opinion, that the more violent the inflammation and pain, the paroxysm will be the shorter, as well as the interval between the present and the next paroxysm longer: and, if this opinion be admitted as just, it will forbid the use of any remedies which might moderate the inflammation; which is, to a certain degree, undoubtedly necessary for the health of the body. On the other hand, acute pain presides for relief; and although a certain degree of inflammation may seem absolutely necessary, it is not certain but that a moderate degree of it may answer the purpose; and it is even probable, that in many cases the violence of inflammation may weaken the tone of the parts, and thereby invite a return of paroxysms. It seems to be in this way, that, as the disease advances, the paroxysms become more frequent.

From these last considerations, it seems probable, that during the time of paroxysms, some measures may be taken to moderate, the violence of the inflammation and pain, and particularly, that in first paroxysms, and in the young and vigorous, blood-letting at the arm may be practised with advantage; but this practice cannot be repeated often with safety; because blood-letting not only weakens the tone of the gouty, but may also contribute to produce plethora. However, bleeding by leeches on the foot, and upon the inflamed part, may be practised and repeated with greater safety; and infusions have been known of its having been employed with safety to moderate and shorten paroxysms; but how far it may be carried, we have not had experience enough to determine.

Besides blood-letting and the antiphlogistic regimen, it has been proposed to employ remedies for moderating the inflammatory pain of the part affected, such as warm bathing and emollient poultices. These have sometimes been employed with advantage and safety; but at other times, have been found to give occasion to a retrocession of the gout.

Blistering is a very effectual means of relieving and discharging a paroxysm of the gout; but has also frequently had the effect of rendering it retrocedent. The flogging with nettles is analogous to blistering; and probably would be attended with the same danger. The burning with moxa, or other substances, is a remedy of the same kind; but though not found hurtful, there is no sufficient evidence of its proving a radical cure.

Camphir, and some aromatic oils, have the power of
of allaying the pain, and of removing the inflammation from the part affected: but these remedies commonly make the inflammation only shift from one part to another and therefore with the hazard of its falling upon a part where it may be more dangerous, and they have sometimes rendered the gout retrocedent.

From these reflections it will appear, that some danger must attend every external application to the parts affected during a paroxysm; and that therefore the common practice of committing the person to patience and flannel alone, is established upon the best foundation. Opium gives the most certain relief from pain but, when given in the beginning of gouty paroxysms, it has by some been thought that they occasion these to return with greater violence. When, however, the paroxysms shall have abated in their violence, but still continue to return, so as to occasion painful and refl€ct nights, opium may be given with safety and advantage; especially in the case of persons advanced in life, and who have been often affected with the disease. When, after paroxysms have ceased, some swelling and stiffness still remain in the joints, these symptoms are to be diffused by the diligent use of the flesh-brush. Purging immediately after a paroxysm will be always employed with the hazard of bringing it on again.

Thus far of the regular gout. We now proceed to consider the management of the disease when it has become irregular.

In the atomic gout, the cure is to be accomplished by carefully avoiding all debilitating causes; and by employing, at the same time, the means of strengthening the system in general, and the stomach in particular.

For strengthening the system in general, Dr Cullen recommends frequent exercise on horseback, and moderate walking. Cold bathing also may answer the purpose, and may be safely employed, if it appear to be powerful in stimulating the system, and be not applied when the extremities are threatened with pain.

For supporting the tone of the system in general, when threatened with atomic gout, some animal food ought to be employed, and the more acentic vegetables ought to be avoided. In the same cafe, some wine also may be necessary; but it should be in moderate quantity, and of the least acentic kinds; and if every kind of wine shall be found to increase the acidity of the stomach, ardent spirits and water must be employed.

For strengthening the stomach, bitters and the Peruvian bark may be employed; but care must be taken that they be not constantly employed for any great length of time.

The most effectual medicine for strengthening the stomach is iron, which may be employed under various preparations; but the best appears to be the rust in fine powder, which may be given in large doses.

For supporting the tone of the stomach, aromatics may be employed; but should be used with caution, as the frequent and copious use of them have an opposite effect; and they should therefore be given only in compliance with former habits, or for palliating present symptoms.

When the stomach happens to be liable to indige-
M E D I C I N E.

Practice.

The case was that of Mr James Roebuck, surgeon and apothecary in Upper Shadwell, of about 45 years of age, a sober, temperate man, of a good habit of body, accustomed to no disease but the gout; the returns of the fits whereof had never been more frequent than once in 12 or 14 months, about the month of June 1752, was seized with a very severe paroxysm of the gout. As I had known some extraordinary effects proceeding from a vegetable diet in that distemper, particularly in one gentleman, who, by a total abstinence from all manner of food except cow's milk, and that without bread, had cured himself of this disease; and who, at the time I mentioned the cafe to my friend, was in the 13th year of his milk-diet; I persuaded Mr Roebuck to try what vegetables would do for him: he readily complied, and entered upon it immediately, with a resolution, that, if it answered his expectation, he would renounce fish and flesh for ever.

But after the most religious abstinence from animal food of every kind for eleven weeks, being visited by a gentle paroxysm, the fit of the gout went off in half a minute, the part affected, no sooner, and in three days disappeared.

The urine was tinged as with saffron; and his urine very high coloured, of almost as deep a red as claret; but, upon the critical vomitings, every one of these symptoms disappeared with the disease.

Mr Roebuck had experienced so great and happy effects from the former critical vomitings, he was greatly disappointed upon finding the quantity evacuated...
Phlegma-

"During the first of these fits, in the year 1752, a hard tumor had appeared on the side of the meta-
tarsus near the middle of the right foot, which con-
tinued till after the third critical vomiting; when it
was resolved, and totally disappeared, upon the dis-
charge of a viscid matter like the white of an egg, with
a few small chalk-stones from the end of the middle
toe of the same foot. This disease happened about
four or five days before the patient was seized with
a regular fit in April 1755. But it is to be remark-
ed, that this last fit continued three or four weeks, and
went off in the common way, without any of the
discharges of vomiting, urine or sweat; but left on one hand three, and on the other two, fingers
loaded with chalk-stones; with this peculiar symptom,
that when the weather was cold those fingers were
affected with a most exquisite pain, which was always
removed by heat.

"But not long after this last mentioned fit, a large
quantity of chalk-stones were extracted from the bot-
tom of the left foot, near the ball of the great toe, and
that from time to time for about three or four months.
On the 10th of January 1756 (the wound occasion-
ed by the chalk-stones being still open), he was seized
with a fever, without any symptom of the gout: the
fever went off on the third day, with the same kind
of critical sweat and urine as always accompanied the
acid vomitings in the forementioned fits. On the fourth
day from the attack of the fever, a fit of the
gout came on, with the common symptoms, in both
feet; which continued with frequent retching and vomiting, but without bringing up more than the common contents of the stomach.
At this time an uncommon itching in the
bottom of the foot and ball of the great toe from
whence the chalk-stones had been extracted, torment-
ed the patient for five or six hours; upon his gently
rubbing the part, he was very sensible of a fluctuation
of some matter, which soon appeared to flow at first
in small quantities from the open orifice in the ball
of the toe: upon pressing the part, about a tea-cup
full of a liquid chalky matter was collected. The next
morning the patient made a large opening with an im-
opollume knife, which produced more than half a pint
of a bloody serous matter, full of chalk-stones, which
proved as truly critical as the vomitings of the corro-
five acid did in the cases above-mentioned; for the
orifice from whence the chalk-stones first issued, was
very soon healed, and the gentleman continues in per-
fect health."

c. xxxii.

This is a disease very much resembling the rheuma-
tism; but differing from it and the gout, in that
it occasions suppuration, which they seldom or never
do. It frequently, according to Sauvages, attacks the
piaos muscle; and occasions excruciating pains, and
then collections of matter.

The only cure is, if suppuration cannot be prevent-
ed, to lay open the part where the matter is contain-
ed, which would otherwise be absorbed, and occasion
a fatal hæmorrhage.

**Description.** The eryspilas of the face, where this
affection very frequently appears, comes on with a
cold shivering, and other symptoms of pyrexia. The
hot flush of this is frequently attended with a con-
fusion of the head, and some degree of delirium; and
almost always with drowsiness, and perhaps coma.
The pulse is always frequent, and commonly full and
hard.—When these symptoms have continued for one
two, or at most three days, an erytheumat appears on
some part of the face. This at first is of no great
extent, but gradually spreads from the part it first
occupied to the other parts of the face, till it has
affected the whole; and frequently from the face it
spreads over the hairy scalp, or extends on some
part of the cheek. As the redness spreads, it com-
monly leaves, or at least is abated in the parts it had
before occupied. All the parts which the redness
affects are also affected with some swelling, which
continues for some time after the redness has abated.
The whole face becomes considerably turgid; and
the eye-lids are often so much swelled as entirely to
shut up the eyes. When the redness and swelling
have continued for some time, there commonly arise,
a sooner or later, blisters of a larger or smaller size on
several parts of the face. These contain a thin colour-
less liquor, which sooner or later runs out. The sur-
fice of the skin in the blistered places, sometimes
becomes livid and blackish; but this seldom goes
deeper, or discovers any degree of gangrene affecting
the skin. On the parts of the face not affected with
blister, the cuticle suffereth, towards the end of the
disease, a considerable desquamation. Sometimes the
tumor of the eye-lids ends in a suppuration.

The inflammation coming upon the face does not
produce any remission of the fever which had before
prevailed; and sometimes the fever increases with the
spreading and increasing inflammation. The inflamma-

An erysipelas frequently appears on other parts of the body besides the face, and such other erysipelas inflammations frequently end in suppuration; but these cases are seldom dangerous. At coming on they are sometimes attended with drowsiness, and even with some delirium; but this seldom happens, and these symptoms do not continue after the inflammation is formed; and Dr Cullen does not remember to have seen an instance of the translation of an inflammation from the limbs to an internal part; and though these inflammations of the limbs be attended with pyrexia, they seldom require the same evacuations as the erysipelas of the face.

History. Of this distemper Dr Cullen declines giving any particular history, because he never saw it; from the accounts of other authors, however, he is of opinion, that the circumstances peculiarly characteristic of it, especially of its more violent and dangerous states, are, 1. The great loss of strength in the animal function, which often appears early in the disease. 2. The stupor, giddiness, and consequent staggering, which resembles drunkenness, or the head-ach and various delirium all of them denoting a great disorder in the functions of the brain. 3. Anxiety, palpitation, syncope, and especially the weakness and irregularity of the pulse, denoting a considerable disturbance in the action of the heart. 4. Nausea and vomiting, particularly the vomiting of bile, which shows an accumulation of vitiated bile in the gall-bladder and biliary ducts, and from thence derived into the intestines and stomach; and which denote a considerable pain, and loss of tone in the extreme vessels on the surface.
Practice.

MEDICINE.

5. The buboes and carbuncles, which denote an action prevailing in the fluids and, lastly, the petechiae, hemorrhages, and colliquative diarrhoea, which denote a putrefactive tendency prevailing in a great degree in the mafs of blood.

To these characteristics of the plague enumerated by Dr Cullen, we shall add one mentioned by Sir John Pringle, which though perhaps less frequent than the others, yet seems worthy of notice. It is this, that in the plague there is an extraordinary enlargement of the heart and liver. In nine differences of bodies dead of the plague at Marfselles, this extraordinary enlargement of the heart is taken notice of in all of them, and of the liver in seven of them. The account was sent to the Royal Society by M. Didier, one of the physicians to the king of France, and has been published in the Philosophical Transactions. In the first case, the author takes notice, that "the heart was of an extraordinary bigness; and the liver was of double the natural size."—Case 2. The heart was of a prodigious size, and the liver much enlarged.—Case 3. The heart double the natural bigness.—Case 4. The heart was very large, and the liver was bigger and harder than ordinary.—Case 5. The heart was of a prodigious bigness.—Case 6. The heart was larger than its natural state; the liver also was very large.—Case 7. The heart was of a prodigious size, and the liver very large.—Case 8. The heart was much larger than natural, and the liver of a prodigious size.—Case 9. The heart was double the natural bigness, and the liver was larger than ordinary."—

This preternatural enlargement Dr Pringle thinks is owing to the relaxation of the solid parts, by which means they become unable to resist the impetus of blood, and therefore are easily extended; as in the case of infancy, where the growth is remarkably quick. And a similar enlargement he takes notice of in the scurvy, and other putrid diseases.

A very elaborate work has lately been published on the subject of the plague by Dr Patrick Ruffel, formerly physician to the British Factory at Aleppo. In this work, a very full history is given of the various forms and varieties of the disease. He makes particular observations on the following symptoms, which, in addition to the putrid eruptions, he considers as the most important concomitants of plague, viz. fever, delirium, coma, impediment or lofs of speech, deafness, mudrines of the eyes, white tongue, state of the pulse, respiration, anxiety, pain at the heart, inquietude, debility, fainting, convulsion, appearances of the urine, perforation, vomiting, looseness, and hemorrhagy; and he concludes those remarks with some observations on the occurrence of the plague with pregnant women. To point out more distinctly the flable varieties of the disease, he arranges the putridal cases which fall under his observation at Aleppo under six clasfes: and he concludes his description with a very minute and particular account of the putridal eruptions, appearing under the form either of buboes, carbuncles, or other exanthemata. The prefer of the two first, he observes either separately or conjundly, leaves the nature of the diftemper unequivo-

ence. Buboes affected the inguinal, axillary, parotid, maxillary, and cervical glands. But the first were the moft commonly affected, and the two latter seldom observed to swell, without either the parotid swelling at the time or soon after. Of the carbuncles, Dr Ruffel describes five different varieties. The other exanthemata, which he observed sometimes, though less frequently, attending the plague, were petechiae, a marbled appearance of the skin, an erysipelas dusky, streaks of a reddish purple or livid colour, vices or weals, and large blue or purple spots, the macule magne of authors. In some cases, an extraordinary concurrence of eruptions took place, which was chiefly observed among children under 10 years of age.

Causes, &c. From a consideration of the symptoms abovementioned, Dr Cullen concludes, that the plague is owing to a specific contagion, often suddenly producing the most considerable debility in the nervous system or moving powers, and a general putrefactive in the fluids. Dr Ruffel also considers the disease as being universally the consequence of what may be called putridal contagion; and has judiciously repelled the objections which have been brought against this doctrine.

Prevention. Here we must refer to all those methods of preventing and removing the incipient contagion of putrid fevers, which have been so fully enumerated. Dr Cullen is persuaded that the disease never arises in the northern parts of Europe, but in consequence of being imported from some other country. The magistrate's first care therefore ought to be to prevent the importation; and this may generally be done by a due attention to bills of health, and to the proper performance of quarantines. With respect to the latter, he is of opinion, that the quarantines of persons may with safety be much less than 40 days; and if this were allowed, the execution of the quarantine would be more exact and certain, as the temptation to break it would be in a great measure avoided. With respect to the quarantine of goods, it cannot be perfect unless the suspected goods be unpacked, duly ventilated, and other means be employed for curtailing the infection they may carry; and if all this be properly done, it is probable that the time commonly prescribed for quarantine may be also shortened.

A second measure in the way of prevention is required, when an infection has reached and prevailed in any place, to prevent that infection from spreading into others. This can only be done by preventing the inhabitants or the goods of any infected place from going out of it till they have undergone a proper quarantine.

The third measure, and which ought to be employed with great care, is to prevent the infection from spreading among the inhabitants of a place in which it has ariien. And in this case, a great deal may be done by the magistrate. 1. By allowing as many of the inhabitants as are free from infection, and are not necessary to the service of the place, to go out of it. 2. By discharging all assemblies, or unnecessary intercourse of the people. 3. By ordering some necessary communications to be performed without contact. 4. By making such arrangements and provisions...
MEDICINE.

Practise.

The fourth and last part of the business of prevention respects the conduct of persons necessarily remaining in infected places, especially those obliged to have some communication with persons infected. Thefe obliged to remain in places infected, but not to have any near communication with the fick, muft avoid all near communication with other persons or their goods; and it is probable, that a small distance will serve, if, at the fame time, there be no stream of air to carry the effluvia of persons or goods to some distance. Thofe who are obliged to have a near communication with the fick ought to avoid any of the debilitating caufes which render the body infusceptible of infection, as a fpare diet, intemperance in drinking, excess in venery, cold, fear, or other deprefling paffions of the minds. A full diet of animal food is alfo to be avoided, becaufe it increases the irritability of the body, and favours the operation of contagion; and indigefion, whether from the quantity or quality of the food, contributes very much to the fame.

Besides thefe, it is probable that the moderate ufe of wine and fpirituous liquors, moderate exercife, and the cold bath, may be of ufe; tonic medicines alfo, of which the Peruvian bark is defervedly accounted the chief, may likewise be ufed with fome probability of fuccefs. If any thing is to be expected from antifeptics, Dr Cullen thinks campbhor preferrable to any other. In general, however, every one is to be indulged in the ufe of all medicines of which he has the beft opinion, provided it is not evidently hurtful. Whether fuccefs in preventing from the effects of contagion, is a matter of doubt. Dr Ruffel in his treatment enters very fully into the consideration of the means of prevention, both with refpect to quarantines, lazarettoes, and bills of health. He is of opinion, that the prefent laws on this fubjeét are in many places, efpecially in the United States, defective; and he thinks, that a fet of new regulations would have the beft chance of a deliberate and impartial diftribution in the fenate, if the inquiry were taken at a time free from any apprehenfion of immediate danger.

Cure. Here according to Dr Cullen, the indications are the fame as in fever in general, but are not all equally important. The meafures for moderating the violence of reaction, which operate by diminishing the action of the heart and arteries, have feldom, he fays, any place here, excepting that the antiphlogific regimen is generally proper. Some phyficians have recommended bleeding, and Sydenham even fays, to think it an effectual cure; but Dr Cullen fuppofes, that for the moft part it is unnecessary, and in many cafes might do much hurt. Dr Ruffel, however, who on this fubjeét fpeaks from experience and actual obfervation, is of a different opinion. With moft of his patients, a fingle bleeding was employed with advantage; and even where the fick under his inspection were bled oftener than once, he did not find that the low state was thereby hurried on. Purging has also been recommended; and in fome degree it may be ufeful in driving off the putrefcent matter frequently prefent in the intelleus; but a large evacuation this way may certainly be hurtful.

The moderating the violence of reaction, as far as it can be done, by taking off the fpasm of the extreme vessels, is a meafure, in Dr Cullen's opinion, of the utmost neceffity in the cure of the paffion; and the fourth of the means formerly mentioned, as joined to this indication, are extremely proper. The giving an emetic, at the first approach of the difeafe, would probably be of great fervice; and it is probable that, at fome other periods of the difeafe, emetics might be ufeful, both by evacuating bile abounding in the alimentary canal, and by taking off the fpasm of the extreme vessels. Indeed Baron Asf, and fome other of the Russian practitioners, represent the early and repeated ufe of emetics as the only effectual mode of cure.

**Description.** In the difcrtc small-pox, the difeafe begins with a fynochus or inflammatory fever. It generally comes on about mid-day, with fome symptoms of a cold fit, and commoniy with a confiderable languor and drowfiness. A fhort fit isfoon formed, and becomes more confiderable on the second and third day. During this courfe children are liable to frequent flatings from their flulls; and adults, if they are kept in bed, are difposed to much sweating.

On the third day, children are fometimes affected with one or two epileptic fits. Towards the end of the third day the eruption commonly appears, and gradually increafes during the fourth; appearing firft on the face, and fucceffively on the inferior parts, fo as to be completed over the whole body on the fifth day. From the third day the fever abates, and again the fifth it entirely ceafes. The eruption appears firft in small red spots hardly eminent, but by degrees rifting into pimples. There are generally but few on the face; but, even when more numerous, they are separable and diffufed from one another. On the fifth or fith day, a small vehicle, containing an almost colourless fluid, appears on the top of each pimple. For two days these vehicles increafes in breadth only, and there is a small hollow pit in their middle, fo that they are not raised into frouruoidal pufifules till the eighth day. Thesef pufifules from their firft formation continue to be surrounded with an exadly circular in-flamed margin, which when they are numerous diffufs feome inflammation over the neighbouring skin; fo as to give fomewhat of a damniff-robe colour to the spaces between the pufifules. As the pufifules increafes in fize, the face fwell incread if the matter are numerous on it; and the eyes, particularly, in fevefle of the matter which they covered becomes degrccs more opaque and white, and at length affumes a yellowish colour. On the elimin day the swelling of the face is abated, and the pufifules seem quift full. On the top of each a darker spot appears; and at this place the pufifule, on the 11th day, or fon after, is spontaneoufly broken, and a portion of the matter oozes out; in confequence of which the matter is ferviled, and fufible; while the matter remaining out drys, and forms a crust upon its surface. Sometimes only a little of the matter oozes out, and what remains in the pufifule becomes thick and even hard. After some days, both the crusts and the hardened pufifer fall off, leaving the skin which they covered of a brownifh red colour; nor doth it refume its natural colour till many days after. In fome cafses where the matter of the pufifules has been more liquid, the crusts formed from it are later in falling off, and the part they covered fuffers fome defquaframion, which occasions a small hollow or pit in it.

On the legs and hands the matter is frequently absorbed; fo that at the height of the difeafe, their pufifules appear as empty as vehicles. On the 10th and 11th days, as the swelling of the face rufides, a swelling arifes in the hands and feet; but which again rufides as the pufifules come to maturity. When the pufifules on the face are numerous, some degree of pyrexia appears on the 10th and 11th days; but disappears again after the pufifules are fully ripened, or perhaps remains in a very light degree till the pufifules on the feet have finished their courfe; and it is feldom that any fever continues longer in the difcrtc small-pox. When the pufifules are numerous on the face, upon the fifth or fith day, fome uneafiness of the throat, with a hoarnefnes of the voice, comes on, and a thin liquid is poured out from the mouth. These symptoms increafe with the swelling of the face; and the liquids of the mouth and throat be coming thicker are with difficulty thrown out; and there is at the fame time fome difficulty in swallowing, fo that liquids taken in to be swallowed are frequently rejected or thrown out by the nofe. But all these af- fections of the fauces are abated as the swelling of the face rufides.

In the confluent small-pox all the symptoms above-mentioned are much more fevere. The eruptive fever particularly is more violent; the pufifer is more frequent and more contracted, approaching to that state of pufifer which is obferved in typhus. The coma is more confiderable, and there is frequently a delirium. Vomiting also frequently attends, efpecially at the beginning of the difeafe. In very young infants, epileptic fits are fometimes frequent on the firft days of the difeafe, and fometimes prove fatal before any eruption appears, or they uffer in a very confluent and putrid small-pox. But at the fame time, it has been fully remarked by Dr Sydenham, and other accurate obervers, that epileptic attacks more frequently precede difcrtc and mild than malignant and confluent small-pox. The eruption appears in the confluent more early on the third day, and it is frequently preceded or accompanied with an eryphthalmous effufion. Sometimes the eruption appears in chifters, like the measles. When the eruption is completed, the pufifer are always more numerous upon the face, and at the fame time smaller and lefs eminent. Upon the eruption the fever fuffers fome remiffion, but never goes off entirely; and after the fifth or fith day it increafes again, and continues to be confiderable throughout the remaining part of the difeafe. The vehicles formed on
the top of the pimples appear sooner; and while they
increase in breadth, they do not retain a circular, but
are every way of an irregular figure. Many of them
run into one another, inflating that very often the face
is covered with one vesicle rather than with a
number of pustules. The vesicles, as far as they are
any way separated, do not arise to a spherical form,
but remain flat, and sometimes the whole of the face
is of an even surface. When the pustules are in any
measure separated, they are not bounded by an
inflamed margin, but the part of the skin that is free
from pustules is commonly pale and flaccid. The li-
quor that is in the pustules changes from a clear to an
opaque appearance, and becomes whitish or brownish,
but never acquires the yellow colour and thick con-
sistency that appears in the distinct small-pox. The
swelling of the face, which only sometimes attends
the distinct small-pox, always attends the confluent
kind; it also comes on more early, and arises to a
greater height, but abates considerably on the tenth
or eleventh day. At this time the pustules or vesicles
break and thrive; pouring out at the same time a
liquor, which is formed into brown or black crusts,
which do not fall off for a long time after. Those
of the face, in falling off, leave the skin subject to a
defquamation, which pretty certainly produces pit-
tings. On the other parts of the body the pustules of
the confluent small-pox are more distinct than on
the face; but never acquire the same maturity and
consistency of pus as in the properly distinct kind.
The vesicles, which only sometimes attend the
distinct small-pox, very constantly attend the con-
fuent; and both the vesicles and the affection of the
sides abovementioned are, especially in adults, in a
degree higher. In infants a diarrhoea comes frequently
in place of a vesication.

In this kind of small-pox there is often a very con-
siderable putrefcency of the fluids, as appears from
petechiae, from serous vesicles, under which the skin
swells a disposition to gangrene, and from bloody urine
or other hemorhages; all of which symptoms fre-
quently attend this disease. In the confluent small-
pox alfo, the fever, which had only suffered a remission
from the eruption to the maturcation, at or immedi-
ately after this period, is renewed again with
considerable violence. This is what has been called
the secondary fever, and is of various duration and
event.

casus, &c. It is evident, that the small-pox is ori-
ginally produced by contagion; and that this conta-
gion is a ferment with respect to the fluids of the
human body, which affinimates a great part of them to
its own nature; or, at least, we have every reason to
believe that a small quantity of contagious matter in-
troduced, is somehow multiplied and increased in the
circulating fluids of the animal body. This quantity
passes again out of the body, partly by insensible per-
piration again, and partly by being deposited in pustules.
The causes which determine more of the variolous
matter to pass by perspiration, or to form pustules, are
probably certain circumstances of the skin, which de-
termines more or less of the variolous matter to flock in
it, or to pass freely through it. The circumstance of
the skin, which seems to determine the variolous
matter to flock in it, is a certain state of inflammation de-
pending much on the heat of it; thus we have many
inflances of parts of the body, from being more heated,
having a greater number of pustules than other parts.
Thus parts covered with pustules, especially those of
the stimulant kind, have more pustules than others.

—Certain circumstances, also, such as adult age,
and full living, determining to a phlogistic diathesis,
seem to produce a great number of pustules, and

varia. foil. It is therefore probable, that an inflam-
matory state of the whole system, and more particu-
larly of the skin, gives occasion to a greater number of
pustules; and the causes of this may produce molt of
the other circumstances of the confluent small-pox,
such as the time of eruption, the continuance of the
fever; the effusion of a more putrefcent matter, and
lefts to be converted into pus, together with the form
and other circumstances of the pustules.

Properties. The more exactly the disease retains
the form of the distinct kind, it is the safer; and
the more completely the disease takes the form of the
confluent kind, it is the more dangerous. It is only
when the distinct kind shows a great number of pustu-
les on the face or otherwise, by fever or putre-
fecy, approaching to the circumstances of the con-
fuent, that the distinct kind is attended with any
danger.

In the confluent kind the danger is always very
considerable; and the more violent and permanent
the fever is, the greater the danger; and especially
in proportion to the increafe of the symptoms of put-
refcence. When the putrid disposition is very great,
the disease sometimes proves fatal before the eighth
day; but in most cases death happens on the
eleventh, and sometimes not till the fourteenth or seven-
teenth.

Though the small-pox may not prove immediately
fatal, the more violent kinds are often followed by a
morbid state of the body, sometimes of very dan-
gerous event. These consequences, according to Dr.
Cullen, may be imputed sometimes to an acrid matter
produced by the preceding disease, and deposited in
different parts; and sometimes to an inflammatory
diathesis produced and determined to particular parts
of the body.

Care. The art of medicine hath never yet afforded
a method of preventing the eruption of the small-pox
after the contagion is received; all that can be done is,
to render the disease more mild, which is generally ef-
pected by inoculation. It is not to be supposed that
the mere giving of the infection artificially could make
any difference in the nature of the disease, was it not
that certain precautions are commonly used in the case
of those who are inoculated, which cannot be used
in the case of those who receive them naturally.—
These measures, according to Dr. Cullen, are chiefly
the following:

1. The choosing for the subject of inoculation per-
sons whose age is not; the children, and not liable
from their age or otherwise to any incidental disease.

2. The choosing that time of life which is most fa-
vourable to a mild disease.

3. The choosing for the practice a season most
favourable to a mild disease.

4. The
Practice.

**MEDICINE.**

4. The preparing the person to be inoculated, by enjoining abstinence from animal food for some time before inoculation.

5. The preparing the person by courses of mercurial and antimonial medicines.

6. The taking care at the time of inoculation to avoid cold, intemperance, fear, or other circumstances which might aggravate the future disease.

7. After these preparations and precautions, the choosing a fit matter to be employed in inoculation, by taking it from a person of a sound constitution and free from any disease, or suspicion of it; by taking it from a person who has had the small-pox of the most benign kind; and lastly, by taking the matter from such person as soon as it has appeared in the pustules, either on the part inoculated, or on other parts of the body.

8. The introducing, by inoculation, but a small portion of the contagious matter.

9. After inoculation, the continuing of vegetable diet, and the employment of mercurial and antimonial medicines, and at the same time employing frequent purging.

10. Both before and after inoculation, taking care to avoid external heat, either from the sun, artificial fires, warm chambers, much clothing, or being much in bed; and on the contrary, exposing the person to a free and cool air.

11. Upon the appearance of the eruptive fever, the rendering that moderate by the employment of purgatives; by the use of cooling and antiseptic acids; and especially by exposing the person frequently to a cool and even a cold air, at the same time giving freely of cold drink.

12. After the eruption, the continuing the application of cold air, and the use of purgatives, during the course of the disease, till the pustules are fully ripened.

On these measures Dr Cullen observes, that, as the common infection may often seize persons under a diseased state, which may render the small-pox more violent, it is evident that inoculation must have a great advantage by avoiding such concurrence. But as the avoiding of this may in the mean time frequently leave persons exposed to the common infection, it is well worth while to enquire what are the diseased states which should refrain from the practice of inoculation. This is not yet sufficiently ascertained; for it hath been observed, that the small-pox has often occurred with a diseased state of the body, without being thereby rendered more violent; and it hath also been observed, that some diseases of the skin are equally innocent.

Dr Cullen is of opinion that they are diseases of the febrile kind, or such ailments as induce or aggravate a febrile state, that especially give the concurrence which is most dangerous with the small-pox. He is also of opinion, that though a person be in a diseased state, if that state be of uncertain nature and effect, and at the same time the small-pox are very common in the neighbourhood, so that it must be extremely difficult to guard against the common infection it will always be safer to give the small-pox by inoculation than to leave the person to take them by the common infection.

Though inoculation has been practised with safety upon persons of all ages, yet there is reason to conclude, that adults are more liable to a violent disease than persons of younger years. At the same time it is observed, that children, in the time of their first dentition, are liable, from the irritation of that, to have the small-pox rendered more violent; and that infants, before the time of dentition, upon receiving the contagion of the small-pox, are liable to be afflicted with epileptic fits, which frequently prove fatal. Hence it is evident, that though circumstances may admit and approve of inoculation at any age, yet for the most part it will be advantageous to choose persons after the first dentition is over, and before the time of puberty. But in large cities in particular, if the operation be delayed till after dentition, the patient must run many risks of accidental infection, and thus many will be cut off by the natural small-pox who might have been saved by early inoculation. Accordingly, in towns especially, it is now the common practice to inoculate infants when only three or four months old; and indeed accidents so rarely happen, that it is almost impossible to conceive that greater success can be obtained at any other period of life.

The operation of inoculation may be performed at any season of the year; yet as it is certain that the cold of winter may increase the inflammatory, and the heats of summer increase the putrescent state of the small-pox it is highly probable that inoculation may have some advantage from avoiding the extremes either of cold or heat.

As the use of animal-food may increase both the inflammatory and putrescent state of the human body so it must render persons, in receiving the contagion of the small-pox, less secure against a violent disease; and therefore inoculation may derive some advantage by enjoining abstinence from animal-food for some time before the operation is performed; But Dr Cullen is of opinion, that a longer time is necessary than what is commonly prescribed.

Mercurial and antimonial preparations may have some effect in determining to a more free perspiration and therefore may be of some use in preparing a person for the small-pox; but there are many observations which render their use doubtful. The quantity of both these medicines, particularly the antimony, commonly employed, is too inconsiderable to have any effects. Mercurials indeed have been often employed more freely; but even their salutary effects have not been evident, and they have sometimes been manifestly productive of mischief. It is therefore much to be doubted, whether inoculation really derives any benefit from these preparatory courses or not.

It has been often observed, in the case of almost all contagions, that cold, intemperance, fear, and some other circumstances, concurring with the application of the contagion, have greatly aggravated the future disease; it must undoubtedly be the same in the case of the small-pox: and it is certain that inoculation must derive a great advantage, perhaps its principal one, from avoiding the concurrences above mentioned.

It has commonly been supposed, that inoculation derives some advantage from the choice of the matter employed in it; but it is very doubtful if any choice...
be here necessary, or can be of any benefit in determining the state of the disease. It is not indeed probable that there is any difference of contagion producing the small-pox; for there are innumerable instances of the contagion, arising from a person who labours under the distinct small-pox producing the constant kind, and the contrary. Since the practice of inoculation hath been introduced, it has also been observed that the same variolous matter would in one person produce the distinct and in another the confluent small-pox. It is therefore highly probable, that the difference of the small-pox does not much depend upon any difference of the contagion, but upon some difference in the state of the persons to whom it is applied, or in the state of certain circumstances concuring with the application of the contagion.

Some have supposed, that inoculation has an advantage over the natural infection, by introducing only a small portion of contagious matter into the body; but this is by no means well ascertained. It is not known what quantity of contagion is introduced into the body by the common infection of the small-pox; and it is probable the quantity is not great; nor, though it were larger than that thrown in by inoculation; is it certain what the effects would be. A certain quantity of ferment may be necessary to excite fermentation in a given mass; but when that quantity is given the fermentation and inflammation are extended to the whole mass; and we do not find that a greater quantity than is just necessary, either increases the activity of the fermentation, or more certainly secures the inflammation of the whole. In the case of the small-pox a considerable difference in the quantity of the contagion introduced hath not shown any effects in modifying the disease.

Purging has the effect of diminishing the activity of the fanguiferous system, and of obliterating the inflammatory state of it; and therefore it is probable that the frequent use of cooling purgatives gives a considerable advantage to the practice of inoculation and probably this is also obtained by diminishing the determination to the skin. It seems also probable, that mercurials and antimonials are useful only as they make part of the purging course.

It is probable that the state of the small-pox depends very much upon the state of the eruptive fever, and particularly in avoiding the inflammatory state of the skin; and therefore it is also probable that the measures taken for moderating the eruptive fever, and inflammatory state of the skin, are the greatest improvement which has been made in the practice of inoculation. The tendency of purging, and the use of acids to this purpose, is sufficiently obvious; and upon the same grounds we should suppose blood-letting might be useful; but probably this has been omitted, and perhaps other remedies might be so, since we have found a more powerful and effectual one in the application of cold air and the use of cold drink.

It hath been the practice of inoculators to continue the use of purgatives and the application of cold air after the eruption; but it cannot be said to give any particular advantages to inoculation, and the employment of purgatives seems often to have led to an abuse. When the state of the eruption is determined, when the number of pustules is very small, and the fever has entirely ceased, the safety of the disease may be said to be ascertained, and further remedies absolutely superfluous; in such cases therefore the use of purgatives is unnecessary, and may be hurtful.

It remains now only to consider the treatment of the small-pox, when the symptoms are violent, as they sometimes happen, even after inoculation and every remedy and precaution have been used. The cause of this is not ascertained, but it seems to be a putrefactive tendency of the fluids. When therefore, from the prevailing of small-pox as an epidemic, and more especially when it is known that a person not formerly afflicted with the disease has been exposed to the infection if such person should be attacked with the symptoms of fever, there can be little doubt that it is the fever of the small-pox, and therefore he is to be treated in every respect as if he had received the disease by inoculation. He is to be freely exposed to cool air, to be purged, and to have cooling acids given liberally. If these measures moderate the fever, nothing more is necessary: but if the nature of the fever be uncertain; or if, with suspicions of the small-pox, the fever be violent; or even if, knowing the dilatometer to be the small-pox, the measures above-mentioned do not moderate the fever sufficiently; venesection will be proper; and more especially if the person be an adult, of a plethoric habit, and accustomed to full living: in the same circumstances it will always be proper to give a vomit which is useful in the beginning of all fevers, and especially in this, where a determination to the stomach appears by pain and spontaneous vomiting.

It frequently happens, especially in infants, that, during the eruptive fever of the small-pox, convulsions occur. Of these, if only one or two fits appear on the evening preceding the eruption, they give a prognostic of a mild disease, and require no remedy: but if they occur more early, are violent, and frequently repeated, they are very dangerous, and require a speedy remedy: and here bleeding and blistering are of no service, the only effectual medicine is an opiate given in a large dose.

These are the remedies necessary during the eruptive fever; and if upon the eruption, the pustules on the face are difficult and their number few, the disease requires no further remedies. But when, upon the eruption, the number of pimples on the face is considerable, when they are not difficult, and especially if, upon the fifth day, the fever does not suffer a considerable remission; the disease still requires a great deal of attention.

If, after the eruption, the fever shall fall continue the avoiding of heat and the continuing to expose the body to a cool air will still be proper. If the fever be considerable, with a full hard pulse, in an adult person, a bleeding will be necessary, and more certainly a cooling purgative; but it will be seldom necessary to repeat the bleeding, as the loss of strength very soon comes on; but the repetition of a purgative, or the frequent use of laxative glisters, is commonly advantageous.

When a loss of strength, with other marks of a putrefactive tendency of the fluids, appears, the Peruvian bark must be given in substance, and in large quantity,
quantity. In the same cafe, the use of acids and of nitre is advantageous, and commonly it is proper also to give wine very freely. From the fifth day of the disease throughout the whole course of it, it is proper to give an opiate once or twice a day; taking care at the same time to obviate colic in the bowels, by purgatives, or by laxative gyllers. From the eighth to the eleventh day of a violent disease, it will be proper to lay on blisters successively on different parts of the body, and that without regard to the parts being covered with pustules. Blisters are also to be applied to the external parts, in cafe of difficult deglutition, and vilicid tilla and mucus, which are thrown out with difficulty, at the same time that detergent gargles are to be delicately used. During the whole course of this disease, when a considerable fever is present, antimonial medicines, in nauseating doses, have by some been alleged to be employed with advantage; and in this way they have often the effect of moving the belly. But the great differees which patients suffer from a state of constant nausea is hardly to be borne; and every advantage which can be had from this practice may be obtained by easier means.

The remedies above-mentioned are frequently proper from the fifth day till the suppuration be finished. But after that period the fever is sometimes continued and increased; or sometimes, when there was little or no fever before, a fever now arises and continues with considerable danger; this is called the secondary fever, and requires a particular treatment.

When the secondary fever follows the distinct small-pox, and the pulse is full and hard, the cafe is to be treated as an inflammatory affection, by bleeding and purging; but the secondary fever which follows the confluent kind is to be considered as a putrid disease and bleeding is improper. Some purging may be necessary, but the remedies chiefly to be depended upon are the Peruvian bark and acids. When the secondary fever first appears, whether after a distinct or confluent small-pox, it is useful to exhibit an antimonial emetic in nauseating doses, but in such a manner as to produce some vomiting. For avoiding the pits which frequently follow the small-pox, no method hitherto proposed seems to be sufficiently certain.

On the subject of inoculation, Baron Dimfdale, a very celebrated writer, informs us, that were it left to his choice, he would decline inoculating children under two years old; because within that period they are exposed to all the dangers of diphtheria, fevers, fluxes, convulsions, and other accidents, sufficiently difficult in themselves to manage in such tender subjects.

In regard to constitution, Baron Dimfdale observes, that greater liberties may be taken than were formerly judged admissible. Persons afflicted with various chronic complaints, of phrenological scrobutic and arthritic habits; persons of unwieldy corpulence, and of intertemperate irregular lives; have all passed through this disease with as much facility as the most temperate healthy, and regular. But those who labour under any acute or critical disease, or its effects, are obviously unfit and improper subjects. So likewise are those in whom are evident marks of corrosive acrimonious humour's, or who have an evident debility of the whole frame from inanition or any other cause. All such require to be treated in a particular manner previous to the introduction of this disease. Constitutions disposed to frequent returns of intermitments, seem likewise justly exceptional; especially as the preparatory regimen may in some habits increase this tendency.

Baron Dimfdale, however, has known instances of severeague fits attacking persons between the infection of the matter and the eruption of the small-pox, and even during maturation, when the Peruvian bark has been given liberally and with much success; the principal business, in the mean time, suffering no injury or interruption.

Among the circumstances generally considered as more or less propitious to inoculation, the season of the year has been reckoned a matter of some importance. Spring and autumn have been generally recommended, as being the most temperate seasons; the cold of winter and the warmer heats having been judged unfavourable for this purpose. But Baron Dimfdale remarks, that experience does not justify those opinions; for, according to the best observations he has been able to make, inoculated persons have generally had more pustules in spring than at any other time of the year; and epidemic diseases being commonly most frequent in autumn, especially fluxes, intermitments, and ulcerated fore throats (all which are liable to mix more or less with the small-pox), the autumn, upon this account does not seem to be the most favourable season in general.

Baron Dimfdale's opinion is, that considering the surprising and indubitable benefits arising at all times to patients in the small-pox, from the free admission of fresh cool air and evacuations, we may safely inoculate at all feasons, provided care be taken to screen the patients as much as possible from heat in summer, and to prevent them from keeping themselves too warm and too much shut up, as they are naturally disposed to do, from the weather in winter. When feasons, however, are marked with any peculiar epidemics, of such a kind especially as may render a mild disease more untractable, it may perhaps be most prudent not to inoculate while such diseases are prevalent.

In directing the preparatory regimen, Baron Dimfdale principally aims at the following points, viz. To reduce the patient, if in high health, to a lower and more secure state; to strengthen the constitution, if too low; to correct what appears vitiated; and to clear the stomach and bowels as much as may be, from all crudities and their effets. With this view he orders such of his patients as constitute the first class above-mentioned, and who are by much the majoritv, to live in the following manner: To abstain from all animal food, including broths, and likewise butter, and cheese, from all fermented liquors, excepting small-beer, which is allowed sparingly; and from all juices, and whatever is ended with a manifest heating quality. The diet is to consist of pudding, gruel, fago, milk, rice-milk, fruit-pies, greens, roots, and vegetables of any of the kinds in feason, prepared or raw. Eggs, though not to be eaten alone, are allowed in puddings, and butter in paste-crust. The patients are to be careful that they do not eat much a quantity as to overload their stomachs, even of this kind of food. Tea, coffee, or chocolate, are permitted for breakfast; to those who choose or are accustomed to them.
In this manner they are to proceed about nine or ten days before the operation; during which period, at nearly equal distances, they are directed to take three doses of the following powder, either made into pills or mixed with a little syrup or jelly, at bedtime, and a dose of Glauber’s salts dissolved in thin water-gruel, each succeeding morning.

The powder is composed of eight grains of calomel, the same quantity of the compound powder of crab’s claw’s, and one eighth part of a grain of ermetic tartar. Instead of the latter, Baron Dimfdale has sometimes substituted two grains of precipitated sulphur of antimony. In order to facilitate the division of the doses, a large quantity is prepared at once, and great care taken that the several ingredients be well mixed.

This quantity is usually sufficient for a healthy strong man; and the dose must be allowed for women or children, according to their age and strength, as well as for persons advanced in years.

The first dose is generally ordered at the commencement of the course; the second three or four days after; and the third about the eighth or ninth day. The Baron chooses to inoculate the day after the last dose has been taken. On the days of purging, broths are to be allowed, and the patients are dehord to abstain from unprepared vegetables.

What has been said concerning the preparation, must be considered as proper only for the young or middle-aged, in a good state of health; but among those who are deficient in inoculation, are often found tender, delicate, and weak women; men of bad dispositions, valetudinarians by constitution, by illness, or intemperance; also aged persons, and children; and for all such a very different treatment must be directed. Here a milder course of medicine, rather of the alterative than purgative kind, is preferable; and in many instances, an indulgence in some light animal-food, with a glass or two of wine in cafe of lowness, is not only allowable, but necessary to support a proper degree of strength, especially in advanced age.

Children, whose bowels are often tender, and ought not to be ruffled by strong purges, yet require a mild mercurial and bear it well. Besides emptying the bowels of crudities, it is a good security against worms and their effects, which sometimes produce very alarming and even fatal disorders.

Inattention to the particular state of health of those who are entering upon the preparatory course, has been productive of great mischief. This is chiefly observable respecting the indiscreet use of mercurials, by which a salivation has often been raised, to the risk of impairing good constitutions, and the ruin of such as were previously weak and infirm. The difficulties and treatment necessary, will be obvious to those who are acquainted with the animal economy and medical practice.

The time of menstruation has generally been the guide in respect to the inoculation of women, that the whole of the disease may be over within the menstrual period. Baron Dimfdale informs us, that he observes this rule, when he can choose his time without any inconvenience, and he inoculates soon after the evacuation ceases; though he has no reason to decline performing the operation at any time.

Women with child have likewise been inoculated, and done well; but the state of pregnancy seems unfavourable to the process, which ought therefore not to be hazarded without some urgent reason. Baron Dimfdale has not inoculated any woman whom he knew to be pregnant; but on some who concealed their pregnancy he has performed the operation, without producing a miscarriage; the hope of which event, he suspects, had rendered them delirious of the process.

One of those had a child born nine weeks after inoculation at the full time, with distinct marks of the disease, though the mother had very few pustules.

The manner most commonly practiced in Britain, for communicating the small-pox by inoculation, has of late been the following: a thread was drawn thro’ a ripe pustule, and well moistened with matter. A piece of this thread was infused into a superficial incision made in one or both arms, near the part where the females are usually fixed; and being covered with a plaster, was three left for a day or two.

Very different methods of inoculation, however, are pursued; two of which Baron Dimfdale has frequently practiced and describes; but he informs us, that the following has proved so invariably successful, as to induce him to give it the preference.

The patient to be inoculated being in the same house, and if no objection be made to it, in the same room, with one who has the disease, a little of the various matter is taken from the place of infection, if the subject be under inoculation; or a pustule, if in the natural way, on the point of a lancet, so that both sides of the point are moistened.

With this lancet an incision is made in that part of the arm where the pustules are usually placed, deep enough to pass through the scar-skim, and just to touch the skin itself; and in length as short as possible, not more than one eighth of an inch.

The little wound being then stretched open between the finger and thumb of the operator, the incision is moistened with the matter, by gently touching it with the flat side of the infected lancet. This operation is generally performed in both arms, and sometimes in two places in one arm; a little distant from each other. For as Baron Dimfdale has not observed any inconvenience from two or three incisions, he seldom trifles to one; that neither he nor his patient may be under any doubt about the success of the operation from its being performed in one place only.

Baron Dimfdale has also tried the following method, with the same success as that above described; but he does not so much approve of it, because he has been credibly informed that it has sometimes failed in the practice of others. A lancet being moistened with the various fluid in the same manner as in the former, is gently introduced, in an oblique manner, between the scar and true skin, and the finger of the operator is applied on the point, in order to wipe off the infection from the lancet, when it is withdrawn. In this method, as well as in the former, a little blood will sometimes appear; but Baron Dimfdale neither draws blood with design, nor does he think there is any necessity of wiping it off before the matter is introduced.

In both these ways of inoculating, neither plaster, bandage,
bandage, nor covering is applied, nor in any respect necessary.

Baron Dimfdale informs us, that those methods of producing this disease have never once failed him; and experience has sufficiently proved that there is no danger from additional infection by the natural disease at the same time. He therefore makes no scruple of having the person to be inoculated, and the person from whom the infection is to be taken, in the same room; nor has he ever observed any ill consequence attending this practice. But he advises the inoculated patients (though perhaps there be no necessity for that precaution) to be afterwards separated from places of infection till certain signs of success appear, when all restraints are removed, there being then no danger from accumulation.

Baron Dimfdale remarks, that it seems to be of no consequence whether the infecting matter be taken from the natural or inoculated small-pox. He has used both, and never has been able to discover the least difference, either respecting the certainty of infection, the progress, or the event. He therefore takes the infection from either, as opportunity offers, or at the option of the patients or their friends.

Neither is it of any consequence whether the matter be taken before, or at the crisis of, the distemper. It is generally supposed, that the small-pox is not infectious till after the matter has acquired a certain degree of maturity; and in the common method of inoculation this is so much attended to, that when the operation has proved ineffectual, the failure has been ascribed to the unripeness of the matter.

But, as the author remarks, it appears very clearly from the present practice of inoculation, that so soon as any moisture can be taken from the infected part of an inoculated person, previous to the appearance of any pustules, and even previous to the eruptive fever, this moisture is capable of communicating the small-pox with the utmost certainty. Baron Dimfdale has taken a little clear fluid from the elevated pellicle on the incised part, even so early as the fourth day after the operation; and has at other times used matter tullly digested at the crisis, with equal success. In general, however, he prefers taking the matter for infection during the eruptive fever, as he supposes it at that time to have its utmost activity.

In all cases, when he takes matter from an inoculated person, it is from the place where it was infected; as he is always sure to find infection there if the disease succeeds, and always of sufficient energy.

It may appear strange that no bandage, dressing, or application whatsoever, is used to the part infected; but that the most simple incision being made, and moistened with the smallest particle of the recent fluid matter, the whole is committed to nature. This method, however, the Baron observes, is perfectly right: because the application of either plaster or unguent, as is the usual practice, will occasion an inflammation on some skins; and, in all, tend to disfigure the natural appearance of the incision, and prevent our forming a proper judgment of the progress of the infection.

If neither an inoculated patient be at hand, nor any one in the neighbourhood has a distinct kind of the natural disease, a thread may be used as in the common manner, provided it be very recently infected; but Baron Dimfdale is of opinion, that the thread ought to be used as soon as possible after being charged with the infecting matter.

The method of inoculation recommended by Baron Dimfdale is now almost universally adopted; or at least if any change has taken place, the operation is, if possible, still more simplified. Without the trouble of bringing to the same house both the person from whom the contagion is to be taken and the person to whom it is to be given, the operator in general carries the matter about with him on what is called a refervoir lancet. For this purpose a common lancet may be employed; but one, the blade of which is accurately inlaid in a metallic case, so constructed as to prevent the access of the air, and at the same time not to rub off the matter, is certainly preferable.

The infectious matter on this lancet is gently moistened by holding it for a few seconds over the steam of warm water; and by rubbing on it the point of another lancet, as much is taken off as is sufficient for giving the disease, which is done by introducing this infected point under the scurf-skin, in the manner Baron Dimfdale has recommended. Where fresh matter can be had, it is always preferable; but where this cannot be obtained, a lancet may be infected from a dry pustule, though kept for many months, by moistening it in warm water; particularly if care has been taken to preserve it from the action of external air by keeping it in a close phial.

A due attention to the progress of infection, discoverable by the part where the operation was performed, is a necessary circumstance; because a just prognostic may thence be sometimes formed of the future state of the distemper, and indications may be taken from the different appearances on the arm, that will enable us to prevent inconveniences.

Baron Dimfdale observes, that the former method of covering the place of incision with a plaster, and continuing upon it dressings of one sort or other, prevented much useful information of this kind. They precluded any judgment by the touch, and sometimes rendered that by the eye equivocal.

The day after the operation is performed, though it takes effect, little alteration is discoverable. On the second day, if the part be viewed with a lens, there generally appears a kind of orange-coloured stain about the incision, and the surrounding skin seems to contract. At this time Baron Dimfdale usually gives the following medicine at going to bed, either mixed with a little of any kind of jelly, or more frequently made into a pill.

Calomel, and compound powder of crab's-claws, of each three grains; emetic tartar, one-tenth of a grain.

A quantity of this medicine should be carefully prepared at once, in order to make the division more exact.

On the fourth or fifth day, upon applying the finger, a hardness is perceptible to the touch. The patient feels an itching on the part, which appears slightly inflamed; and under a kind of vesication is seen a little clear fluid, the part resembling a superficial burn. About the sixth, most commonly some pain and stiffness is felt in the axilla; a circumstance which not only foretells the near approach of the eruptive symptoms,
but is a sign of a favourable progress of the disease. Sometimes on the seventh, oftener on the eighth day, symptoms of the eruptive fever appear; such as light remittent pains in the head and back, succeeded by transient shivering and alternate heats, which continue in a greater or less degree till the eruption be perfected. At this time also it is usual for the patient to complain of a very disagreeable taste in his mouth, the breath is always fetid, and there ensues a smell peculiar to the variolous eruptive fever.

The inflammation in the arms at this time spreads fast; and, upon viewing it with a good glass, the incision for the moat part appears surrounded with an infinite number of small confluent pustules, which increase in size and extent as the disease advances. On the tenth or eleventh day, a circular or oval efflorescence is usually discovered surrounding the incision, and extending sometimes near half round the arm, but more frequently to about the size of a shilling; and being under the cuticle, is smooth to the touch and not painful. This appearance also is favourable. It accompanies eruption; every disagreeable symptom ceases; and at the same time it certainly indicates the whole affair to be over, the pain and flatness in the axilla also going off.

The feverish symptoms are for the most part so mild, as seldom to require any affliction, except a repetition of the same medicine that was directed on the second night after the operation; and next morning the following laxative draught should be given, to procure three or four fowls.

Infusion of fenna two ounces, manna half an ounce, tincture of jalap two drachms.

These are given as soon as the eruptive symptoms are perceivable, if they seem to indicate any uncommon degree of vehemence.

It has been observed, that by attending to the progress of infection, we may in general be able to prognosticate with some degree of certainty the issue of the distemper. Particular incidents will ever happen, but not sufficient to invalidate the propriety of general rules.

If the appearances already described are observed early, a very favourable event may be expected; but it happens in some cases, that the success of the inoculation is barely perceptible, the colour about the wound remaining pale, instead of changing to red or inflamed; the edges of the incision spread but little; they remain almost entirely flat, and are attended neither with itching nor uneasiness of any kind. Nay, sometimes on the fifth, and even the sixth day, the alteration is so little as to render it doubtful whether the infection has taken place.

When matters are in this state, Baron Dimidale observes the appearance is unfavourable, implying a late and more untoward disease: To prevent which, he directs the powder or pill to be taken every night, and in came it fails to operate by itself, or there be the least difficulty to collectives, an ounce of Glauber’s falls, or more commonly the laxative draught already mentioned, is given in the morning, once or twice, as the case may require. This course forwards the inflammation, which is always a desirable circumstance; it being in general observed, that an early progress on the arm, and an early commencement of the eruptive complaints, portend that the distemper will be mild and favourable; and on the contrary, when both are late, the symptoms he tells us are usually more irregular and unfavourable.

Further experience, however, has by no means fully confirmed his opinion in this particular. On the contrary, even where the progress of infection in the arm has been uncommonly slow, a disease in the mildest possible form has succeeded. There is therefore no good reason why a practitioner should be alarmed at an unusually slow progress, or should in such instances employ more internal remedies than he would do in other cases. And some, whose practice in inoculation has been very extensive, have even remarked, that when infants are inoculated, they have never observed epileptic accessions, the most alarming forerunners of the disease, in thoee cases where the progress of the arm has been slow.

The management recommended by Baron Dimidale at the period of eruption differing essentially from that of former practitioners, and being a matter of great importance, he gives the following explicit directions on this head, advising that they may be pursued with firmness and moderation.

Instead of the patient being confined to his bed or his room, when the symptoms of the eruptive fever come on, he is directed, as soon as the purging medicine has operated, to keep abroad, as much as he can bear, in the open air, be it ever so cold; always taking care not to stand still, but to walk about moderately while abroad. He is also directed, if thirsty, to drink cold water.

Baron Dimidale observes, that this treatment seems as hard at first to the patients as it must appear singular to those who are unacquainted with such practice; but the effects are so salutary, so constantly confirmed by experience, and an easy progress through every stage of the disease depends so much upon it, that he admits of no exception, unless the weather be extremely feverish and the constitution very delicate. He adds, it is indubitably true, that in the few instances where the symptoms of eruption have run very high, the patients being averse to any motion, and fearing the cold as the greatest evil; yet when, under those circumstances, he has persuaded them to rise out of bed, and go out of doors, though led sometimes by two attendants, and has allowed them to drink as much cold water as they chose, they have not suffered the least unfavourable accident: on the contrary, after they have been prevailed upon to comply with those directions, they find their spirits revived; an inclination for nourishment returns; they rest well; a gentle sweat succeeds, accompanied with a favourable eruption; and the fever seems to be entirely extinguished.

Cool regimen during the eruptive fever is now almost universally adopted; but like other useful remedies it has not unfrequently been abused: And practitioners ought never to forget, that inoculated patients are not, more than the rest of the human species, exempted from injuries from cold, which is unquestionably a powerful cause of disease. Unless, therefore, in cases where very considerable morbid heat is induced by the eruptive fever, by which a temporary defence is unquestionably afforded against the action of external
external cold, the bad effects which may result from it are never to be overlooked. And there is reason to believe, as may indeed be inferred from Baron Dimfdale's observations, that the disease is more moderated by the action of pure and free air than by cold. Accordingly inoculation is performed with very great success even in the warmest seasons and situations of warm climates.

In general, the complaints in this disease are very moderate, and attended with so little illness that the patient eats and sleeps well the whole time. A few pustules appear, sometimes equally disposed; sometimes the inflammations on the arms spread, and are surrounded with a few pustules, which gradually advance to maturity; during which time, for the most part, the eruption proceeds kindly, and there is much more difficulty to restrain the patients within due bounds, and prevent their mixing with the public, thereby spreading the infection, than there was at first to prevent them to go abroad. During this time medicine is seldom wanted; the coolest air seems the best cordial; and if any uncommon languor happens, a glass of wine is allowed in the day, or some white-wine whey at bed-time; which are indeed at any time allowed to tender, aged or weakly persons.

With these exceptions, the patients are hitherto kept very scrupulously to the diet at first directed. But after the eruption is completed, they are, if occasion requires, indulged in a little well boiled meat of the lightest kind, as chicken, veal, or mutton.

The above mentioned regimen, the cooling alterations, and the free use of cool air at the season of eruption, almost universally prevent either alarming symptoms or a large crop of pustules. Baron Dimfdale has seen a few with such a quantity of pustules, though deficient that he has neither advised nor allowed them to go out of the house. But the generality of his patients, where the eruptions are few, assume themselves abroad, within proper limits, with the pustules upon them.

This practice, however, the Baron neither enjoins nor maintains to be necessary; but he has not been able to observe that any inconvenience has arisen from it. He also informs us, that, how strange severer it may appear, those who are most adventurous, seem to enjoy better spirits, and are more free from complaints, than others who are inclined to keep within doors.

Those who have the disease in the slightest manner first described viz. without any appearance of eruption but on the inoculated part, are soon permitted to go about their usual affairs: and many instances have happened of very industrious poor men, who have immediately returned to their daily labour, with a caution not to intermix with those who have not had the distemper, for fear of spreading it; and with injunctions to take, two or three times, of the purge already directed, or as many doses of Glauber's salts. Those who have the disease in a greater degree, are confined somewhat longer; and, if there be the least suspicion of convulsions, a very mild laxative is now and then exhibited; as the progress to maturation appears rather to be advanced than retarded by such means.

When the maturation is completed, and there is nothing farther to fear from the distemper, Baron Dimfdale allows his patients gradually to change their course of diet, from the perfectly cooling kind, to one a little more generous; recommending firstly to all a return to their ordinary animal-diet, with much caution and restraint upon their appetites, both in respect of food and fermented liquors.

He observes it is not often that we are under the necessity of making any application to the part where the infection of the various matter was made. It most commonly heals up, and is covered with a scab, about the time when, in a natural way, all the small-pox would have been dried up. But in some cases the infusions continue to discharge a purulent matter a longer time. In these instances it is sufficient to cover the part with the white cerate, or any other mild emollient substance, which may at once prevent the linen from adhering to the scab, and defend it from the air. As in these cases the part remains unhealed from some peculiar cause in the habit, it will be necessary to give gentle purgatives, and proper alternatives, as particular exigencies may require.

After describing the usual progress of the small-pox from inoculation, Baron Dimfdale remarks that there are frequent deviations from this course, which may embarrass an inexperienced practitioner, and create a real difficulty, as well as apprehensions of danger. He therefore proceeds to relate the means for removing those symptoms, and the doubts respecting the event.

The symptom he first notices, and which, though it very rarely happens, sometimes gives much trouble, is great fickliness, accompanied with vomiting, in the eruptive state of the disease. For this complaint it is always necessary in the first place to clear the stomach, which may be effected, either by ordering the patient to drink plentifully of warm liquids to promote vomiting; or perhaps more properly, by giving to an adult one grain of tartarised antimony, mixed with ten grains of compound powder of crab's-claws; taking care to diminish the dose for very young and weak subjects.

This usually throws off some bilious matter by vomiting, sometimes produces flosses, or occasions a moderate sweat, and generally administers relief. If, however, no flosses should follow from this medicine, and the fickliness should remain, a gentle laxative almost certainly procures a respite, and the appearance of the eruption entirely removes the complaint.

Another deviation, of yet greater consequence, which sometimes happens towards the times of the eruption, and is often, though not always, accompanied with great sickliness, is an erythematous efflorescence. If this shows itself on the skin partially, and here and there in patches, it is not very alarming, and soon wears off. But sometimes the whole surface of the body is covered with a rash intimately mixed with the various eruption, and so much resembling the most malignant kind of confluent small-pox as scarcely to be distinguished from it. In some such cases, accompanied with petechial and livid spots, Baron Dimfdale has been much alarmed; not being able by inspection only, though assisted by glasses, to determine whether what he saw was an inoffensive rash, or tokens of the greatest malignity. Very strict attention, however, has
enabled him to distinguish the difference clearly; and for afflicting others in such a discrimination, he makes the following remarks.

The real and essential differences to be gathered from the concomitant symptoms. In the erythematous or variolous rash, there is not so much fever, nor is the redness, or pain of the head, or loins, so considerable; neither is there that general prostration of strength; all which are usual attendants on a confluent small-pox especially when accompanied with such putrid appearances. Besides, upon a careful examination, there may sometimes be discerned a few distinct pustules, larger than the rest, mixed with the rash, which are the real small-pox. In these cases the patients are ordered to refrain from cold water, or any thing cold and to keep within doors, but not in bed. If any sickness yet remains, a little white-wine whey, or other temperate cordial, is advised; and this method has been so generally successful, as to prevent any alarming complaint. After two or three days, the skin changes from a florid to a dusky colour, a few distinct pustules remain and advance properly to maturation without any farther trouble ensuing from this formidable appearance.

This rash has often been mistaken for the consequence it so much resembles; and has afforded occasion for some practitioners, either ignorantly or diligenously, to pretend, that, after a very copious eruption of the confluent pox, they can by a specific medicine, discharge the greater part of the pustules, leaving only as many distinct ones as may satisfy the patient that he has the distemper.

Baron Dimidale informs us, that rashes of the kind above described frequently happen during the preparation (whether owing to the regimen, or medicine, or both, he does not determine), and cause the operation to be postponed. But he has observed, that in such cases they are apt to return at the time of the eruption of the small-pox.

In general, as has been already said, the symptoms which precede eruption commence at the end of the seventh or on the eighth day inclusive from the operation; but it often happens that they appear much sooner, and sometimes much later than this period. Baron Dimidale has seen some cases in which the distemper has come on so suddenly after infection, and with so little complaint or uneasiness, that the whole affair has been terminated, purges taken and the patient returned home perfectly well, in a week; before others, inoculated at the same time, from the same patient, and under the same circumstances, have begun to complain.

In this case, the inoculated part shows early certain marks of infection, sometimes on the very next day, or the day after, when the incision will often appear considerably inflamed and elevated. The patient about this time frequently makes some of the following complaints, viz. chilliness, itchings and flight prickings, pains in the parts, and sometimes on the shoulders; giddines, drowsines, and a flight head-ache, sometimes attended with a feverish heat, but often without any. The account which patients themselves give of their feelings is, in some, as if they had drank too much, and in others, as if they had caught a cold. Tho' these complaints seldom last 24 hours, often not so long, and with frequent intermissions; never, so far as our author remembers, rising to a degree that requires confinement. During the continuance of those complaints, the inflammation of the arm advances space, and feels hard to the touch: but upon their wearing off, the inflamed appearances gradually diminish, and the part dries to a common scab; the skin, that was before red, turns livid, and the distemper entirely vanishes. In some instances, tho' symptoms attack much later; even on the seventh or eighth day, when an eruption might be expected in consequence of them, yet none appears; but the arm gets well very soon, and the distemper is at an end.

In this irregular sort of the disorder there have, however, been some examples where a few eruptions have appeared, and probably in consequence of the inoculation; yet the pustules have not looked like the true small-pox, neither have they maturated like them nor lasted longer than three days; about which time for the most part, they have dried away.

When this irregular kind of the distemper first occurred in Baron Dimidale's practice, he was in doubt whether the patients were quite secure from any future attacks of the distemper. In order to be satisfied of this point, he inoculated them a second time, causing them to associate with persons in every stage of the distemper, and to try all other means of catching the infection. This method has been practiced with the generality of such patients ever since, yet without a single instance of its producing any disorder. Baron Dimidale, therefore, now makes no scruple of pronouncing them perfectly safe; and experience has enabled him to foretell, for the most part, in two or three days after the operation, whether the distemper will pass in this flight manner.

Upon the second inoculation, however, the incised parts are commonly inflamed for a day or two, just in the same manner as has in numerous instances been observed, as well in those who, though certain of having had the small-pox in the natural way, have submitted to inoculation for the sake of experiment, as in others, who being doubtful whether they have had the distemper or not, have been inoculated in order to be satisfied. But in all such cases, the parts soon became well; nor did any of those appearances which have been described as the constant attendants on inoculation, as pain in the head, giddines, marks of infection, in the arm, &c. ensue. Neither can those appearances ever be produced upon a person who has had the small-pox before, either in the natural way, or by inoculation.

Another irregularity deserving notice is, that some times upon the abatement of the fever and other symptoms, after the appearance of several pustules, and when the eruptive stage of the distemper seems completed, it nevertheless happens that fresh eruptions come out, and continue doing so daily, for four, five, or even six days successively; preceded sometimes by a flight pain in the head, though more frequently they appear without any new disturbance. Tho' these are generally few, of short duration, and seldom come to maturity. Baron Dimidale, however, has seen four cases in which, after a cessation of complaints, and an appearance of few pustules, the eruptive stage of the distemper was thought to be over, yet in two or three days
a fresh fit of fever has attacked the patients, and after a short illness a quantity of new pustules has broke out far exceeding the first number, and those remained and matured completely.

Some of the Baron's own patients, and, as he has been credibly informed, those of other inoculators, have had considerable eruptions of this kind after they returned home; which have probably given occasion for the reports of several having had the disease in the natural way after inoculation. But in confirmation that those reports are ill-grounded, he observes, that in all the cases of this sort which have occurred in his own practice, or as far as he can learn, in that of others, the second or latter crop of pustules has always happened within the time usually allowed for the progress of the small-pox from inoculation; before the inflammation on the arm has ceased, and sooner than we can suppose them to have been produced by inoculation received in the natural way. When this has happened, it has been to persons in whom, after a flight eruption and abatement of symptoms, the disease has prematurely been judged to be quite over, and they have therefore been permitted to return to their families.

An appearance, more alarming and more dangerous than any of those which have already been taken notice of, is the occurrence of epileptic fits. For although it has been remarked, that these are often the forerunners of a mild disease, both in cases of accidental and likewise of intentional contagion; yet it is undeniable, that in not a few instances they have of themselves proved fatal. Wherever, therefore, an epileptic fit occurs, it naturally claims the attention of the practitioner. The occurrence of future fits is best prevented by the employment of tincture of opium, taking off the tendency to inordinate action by giving at first a temporary diminution of irritability; and on the same principle, when during a fit the patient is able to swallow, nothing is more effectual either in shortening the fit or diminishing its severity, than a dose of laudanum accommodated to the age and condition of the patient. Considerable benefit may be derived from any volatile alkaline spirit, such as spirit of hartshorn, the favourite remedy of Dr. Sydenham in such cases. But the best effects may be obtained from the use of the tepid bath, which is not only of service in such cases from its action as an antisyphilitic, but which also, by producing relaxation of the skin facilitates and promotes the eruption. And even allowing that, as some imagine, the number of pustules should be increased by heat applied in this manner; yet much less is to be dreaded from thence than from the continuance of the fits.

Baron Dimfoldale next considers the consequences that arise from this very cool and repelling method and how far the patients future state of health may be affected by a practice so opposite to what was formerly employed.

It has been the general opinion, that in most or all eruptive complaints, especially the small-pox, the rational method of cure was to forward, by every gentle means, the efforts of nature in producing an eruption and on the contrary, that there was danger in checking it, either by cold air, cold drink, or any considerable evacuations. For this purpose the use of warm diluents, and the lying in bed, especially if the fever and symptoms run high, or at least confining to the house, have been generally approved and recommended. Experience, however, has now sufficiently confirmed the advantage of a different kind of treatment.

While the old methods prevailed of conducting inoculation, the patients, particularly children, after passing through the disease in a very favourable manner, were frequently liable to abscesses in the axilla and other parts, tedious ophthalmies, and troublesome ulcerations in the place of infection; which though they could not be foreseen nor prevented, yet often gave more pain and vexation to the patients, and trouble to the operator, than the disease itself had done. But on inquiry into the state of those who have been treated in the cool way, or according to the new method, Baron Dimfoldale affirms, that in more than 1500 there has been only one who has had so much as a boil in the axilla; and this was a child who had in the same arm an idium, which was at that time dried up. He has seen only two very small superficial boils in others near the place of infection; and those seemed to be occasioned rather by an irritation from the discharge than by any other cause, and were all soon healed with very little trouble.

In a few instances also, there has been a slough in the incised part, which has caused a fore of short duration; but not one instance of an ulcer of any continuance. Such like breakings out too, and scabs as frequently succeed the mild natural small-pox, sometimes though rarely happen to those inoculated in the new way; and, as they are of little consequence, are generally cured by the same method, the use of a few gentle purges.

In regard to ophthalmies from this kind of practice, Baron Dimfoldale has never known an instance of one truly deferving that name. The coats of the eye have been a little inflamed in a very few, but they soon cleared, without any means used for that purpose. He knows but two cases where he thought the discharges produced some inconvenience, and these were sand in two cafes where he thought the inflammation great enough to require bleeding; and not one where a blister was necessary. Those complaints, therefore, which were formerly so frequent and troublesome, seem to be much reduced by the new method, the great utility of which is now universally acknowledged.

When the benefits of inoculation have now been demonstrated to be so great, it is truly surprising that the practice has not yet become general. Even its wonderful success, however, particularly when contrasted with the natural small-pox, has not been sufficient to remove every prejudice against it; and in many parts of Britain, the lower classes are deterred from it by scruples even of a religious nature, by which means the state annually suffers a very considerable loss. It is, however, but just to observe, that in many parts, both the medical practitioners and the clergy have done all in their power to remove every difficulty.

At Edinburgh, the colleges of physicians and surgeons annually make an offer of their assistance and advice gratis to all the poor who submit to this operation during certain months; and a most respectable clergyman has been at the expense of publishing a plain and sensible discourse, not only calculated to remove every religious doubt or scruple which can be entertained on
MEDICINE.

Exanthematous eruptions are sometimes so common among children, as to excite the doubts and fears of parents; and I have been frequently consulted on the subject of the chicken-pox, by persons who have been sufficiently cautioned against the small-pox; and, by the accidental rubbing of the face, and.

This is in general a very slight disease; and is attended with so little danger, that it would not merit any notice, if it were not apt to be confounded with the small-pox, and thus give occasion to an opinion that a person might have the small-pox, twice in his life; or that they have apt to deceive into a false security those who have never had the small-pox, and make them believe that they are safe when in reality they are not. This eruption breaks out in many, according to Dr Heberden, without any illness or previous sign; in others it is preceded by a little degree of chilliness, latiitude, cough, broken sleep, wandering pains, loss of appetite, and feverish state for three days.

In some patients the chicken-pox make their first appearance on the back; but this perhaps is not constant. Most of them are of the common size of the small-pox, but some are large. Dr Heberden never saw them confluent, nor very numerous. The greatest number was about 12 in the face, and 200 over the rest of the body.

On the first day of the eruption they are reddish. On the second day there is at the top of most of them a very small bladder, about the size of a millet-seed. This is sometimes full of a watery and colourless, sometimes of a yellowish liquor contained between the cuticle and skin. On the second, or at the farthest, on the third day from the beginning of the eruption, as many of these pocks as are not broken seem arrived at their full maturity; and those which are full of that yellow liquor very much resemble what the genuine small-pox are on the fifth or sixth day, especially where there happens to be a larger space than ordinary occupied by the extravasated serum. It happens to most of them, either on the first day that this little bladder arises, or on the day after, that its tender cuticle is burst by the accidental rubbing of the clothes, or by the patient's hands to allay the itching which attends this eruption. A thin scab is then formed at the top of the pock, and the swelling of the other part abates, without its ever being turned into pus, as it is in the small-pox. Some few escape being burst; and the little drop of liquor contained in the vehicle at the top of them, grows yellow and thick, and dries into a scab. On the fifth day of the eruption they are almost all dried and covered with a light crust.

This eruption is preceded for three or four days by all the symptoms which forewarn the chicken-pox; but in a much higher degree. On the fourth or fifth day the eruption appears, with very little abatement of the fever; the pains likewise of the limbs and back still continue, to which are joined pains of the gums. The pocks...
pocks are redder than the chicken-pox, and spread wider; and hardly rise so high, at least not in proportion to their size. Instead of one little head or vesicle of a serous matter, these have from four to ten or twelve. They go off just like the chicken-pox, and are distinguishable from the small-pox by the same marks; besides which, the continuance of the pains and fever after the eruption, and the degree of both these, though there be not above 20 pocks, are circumstances never happening in the small-pox.

Genus XXX. Rubeola.

Measles.

Exantheme.

Var. 1. The Anomalous Measles.

Rubeola anomala, Sauv. sp. 2. Morbilli anomali. Syden. lec. v. cap. 3.

Var. 2. The Measles attended with Quinsy.

Var. 3. The Measles with Putrid Diathesis of the Blood.

Sp. II. The Variolodes.

In Scotland commonly called the Nirles.

Rubeola variolodes, Sauv. sp. 3.

Description. This disease begins with a cold stage, which is soon followed by a hot, with the ordinary symptoms of thirst, anorexia, anxiety, and vomiting; and these are more or less considerable in different cases. Sometimes from the beginning the fever is sharp and violent; often, for the first two days, it is obscure and inconsiderable; but always becomes violent before the eruption, which commonly happens on the fourth day. This eruptive fever, from the beginning of it, is always attended with hoarseness, a frequent hoarse dry cough, and often with some difficulty of breathing. At the same time, the eyes are somewhat swollen; the eyes are a little inflamed, and pour out tears; and with this there is a coryza, and frequent sneezing. For the most part, a continual drounness attends the beginning of the disease. The eruption, as we have said, commonly appears upon the fourth day, first on the face, and successively on the lower parts of the body. It appears first in small red points; but, soon after, a number of these appear in clusters, which do not arise in visible pimplies, but, by the touch, are found to be a little prominent. This is the cæfe on the face; but, in other parts of the body, the promineney, or roughness, is hardly to be perceived. On the face, the eruption retains its redness, or has it increased for two days; but on the third, the vivid redness is changed to a brownish red; and in a day or two more the eruption entirely disappears, while a mealy desquamation takes place. During the whole time of the eruption, the face is somewhat turgid, but seldom considerably. Sometimes, after the eruption has appeared, the fever ceases entirely: but this is seldom the case; and more commonly the fever continues or is increased after the eruption, and does not cease till after the desquamation. Even then the fever does not always cease, but continues with various duration and effect. Though the fever happen to cease upon the eruption's taking place, it is common for the cough to continue till after the desquamation, and sometimes much longer. In all cases, while the fever continues, the cough also continues, generally with an increase of the difficulty of breathing; and both of these symptoms sometimes arise to a degree which denote a pneumatic affection. This may happen at any period of the disease; but very often it does not come on till after the desquamation of the eruption.

After the same period, also, a diarrhœa frequently comes on, and continues for some time.

It is common for measles, even when they have not been of a violent kind, to be followed by inflammatory affections, particularly ophthalmia and phthisis. If blood be drawn from a vein in the meaules, with circumstances necessary to favour the separation of the glutton, this always appears separated and lying on the surface of the cæramentum, as in inflammatory diseases. For the most part, the meaules, even when violent, are without any putrid tendency; but in some cases, such a tendency appears both in the course of the disea על and especially after the ordinary course of it is finished.

Causa. The meaules are occasioned by a peculiar kind of contagion, the nature of which is not understood; and which, like that of the small-pox, affects a person only once in his life.

Prognosis. From the description of this distemper already given, it appears that the meaules are attended with a catarrhal affection, and with an inflammatory diathesis to a considerable degree; and therefore the danger of them is to be apprehended chiefly from the coming on of a pneumatic inflammation.

Care. In meaules, as well as in small-pox, the disease from its nature must necessarily run a determined course; and therefore the sole aim of a practitioner is to conduct this course in the easiest manner, by preventing and obviating urgent symptoms.

From the consideration mentioned in the prognosis, it will be obvious, that the remedies especially necessary are those which may obviate and diminish the inflammatory diathesis; and therefore, in a particular manner, blood-letting. This remedy may be employed at any time in the course of the disease, or after the ordinary course of it is finished. It is to be employed more or less, according to the urgency of the symptoms of fever, cough, and dyspnoea; and generally may be employed very freely. But as the symptoms of a pneumatic inflammation seldom come on during the eruptive fever, and as this is sometimes violent immediately before the eruption, though sufficiently mild disease be to follow; bleeding is seldom very necessary during the eruptive fever, and may often be desired for the times of greater danger which are perhaps to follow.

In all cases of meaules, where there are no marks of putreency, and where there is no reason, from the known nature of the epidemic, to apprehend putrefency, bleeding is the remedy most to be depended upon:
uppon: but allusion may also be drawn from cooling purgatives; and particularly from blisters on the fides or between the shoulders. The dry cough may be alleviated by the large use of demulcent peptoria, mucilaginous, oily, or sweet. It may, however, be observed with respect to these demulcents, that they are not so powerful in involving and correcting the acrimony of the masts of blood as has been imagined; and that their chief operation is by soothing the fauces, and thereby defending them from the irritation of acrides, either arising from the lungs or difilling from the head. For moderating and quieting the cough in this disease, opiates certainly prove the most effectual means, whenever they can be safely employed.

In the meahes, in which an inflammatory state prevails in a considerable degree, opiates have indeed by some been supposed to be inadmissible: but experience abundantly demonstrates, that the objection made to their use is merely hypothetical; and even in cases where, from a high degree of pyrexia and of dyspnoea, there is reason to fear the preference, or at least the danger, of pneumatic inflammation, opiates are highly useful; after bleeding, to obviate or abate the inflammatory state, has been duly employed in such cases, while the cough and watchfulnes are the urgent symptoms, opiates may be safely exhibited, and with great advantage. In all the exanthemata, there is an acrimony diffused over the system, which gives a considerable irritation: and, for obviating the effects of this, opiates are useful, and always proper, when no particular contra-indication prevails.

When the desquamation of the meahes is finished, though then there should be no disorder remaining, phyaicians have thought it necessary to purge the patient several times, with a view to draw off what has been called the drugs of this disease; that is, a portion of the morbid matter, which is supposed to remain long in the body. Dr Cullen does not reject this supposition; but at the same time cannot believe that the remains of the morbid matter diffused over the whole mass of blood, can be wholly drawn off by purging; and therefore thinks, that, to avoid the consequence of the meahes, it is not the drawing off the morbid matter which we need to study, so much as to obviate and remove the inflammatory state of the system which had been induced by the disease. With this last view indeed, purging may still be a proper remedy; but bleeding, in proportion to the symptoms of inflammatory disposition is still more so.

From our late experience of the use of cold air in the eruptive fever of the small-pox, some physicians have been of opinion that the practice may be transferred to the meahes; but this point has not yet been determined by sufficiently extensive experience. We are certain, that external heat may be very hurtful in the meahes, as in most other inflammatory diseases; and therefore, that the body ought to be kept in a moderate temperature during the whole course of the disease: but how far, at any period of the disease, cold air may be applied with safety, is still uncertain. Analogy, though so often the resource of physicians, is frequently fallacious; and further, though the analogy with the small-pox might lead to the application of cold air during the eruptive fever of the meahes, the analogy with catarh feems to be against the practice.

When the eruption is upon the skin, there are many instances of cold air making it disappear, and thereby producing much disorder in the system; and there are also frequent instances of this disorder's being removed by retuming the heat of the body, and thereby again bringing out the eruption.

Upwards of 20 years ago, inoculation for the meahes was proposed, and practiced in several instances with success, by Dr Home of Edinburgh. His method of communicating the infection was, by applying to an incision in each arm cotton moistened with the blood of a patient labouring under the meahes; but with others who have made similar trials, the attempt has not yet succeeded. And attempts have been made to inoculate this disease by means of the fluid discharged under the form of tears, the sm镭e falling from the surface, and the like; but there is reason to believe, that where it was imagined the infection had thus been communicated, the contagion was only carried about the person inoculating, and communicated in the ordinary way.

From inoculation of the meahes, it is imagined that several advantages may be obtained, and among others, it is thought the forenes of the eyes may be mitigated, the cough abated, and the fever rendered less severe. But the practice was never much in fashion, and now is scarce ever heard of.

**Hiflory and Description.** This disease is said to have been unknown to the ancients, and that it appeared for the first time in Saxony about the middle of the last century. It is said to have since spread from thence into ail the other countries of Europe; and, since the period mentioned, to have appeared in many
From the time of its having been first taken notice of, it has been described and treated of by many different writers; and by all of them, till very lately, has been considered as a peculiar idiopathic disease. It is said to have been constantly attended with peculiar symptoms. It comes on with a cold stage, which is often considerable. The hot stage, which follows, is attended with great anxiety, and frequent sighing. The heat of the body becomes great, and soon produces profuse sweating, preceded, however, with a sense of pricking, as of pin points in the skin; and the sweat is of a peculiar rank and disagreeable odour.

The eruption named milia is said to be of two kinds: the one named the red, the other the white miliaria. The former, which in English is strictly named a rubo, is commonly allowed to be a symptomatic affection; and as the latter is the only one that has any pretensions to be considered as an idiopathic disease, it is this only that we shall more particularly describe and treat of under this genus.

What is then called the white miliaria eruption, appears at first like the red, in very small red pimples for the most part distinct, but sometimes clustered together. Their little prominence is better distinguished by the finger than by the eye. Soon after the appearance of this eruption, and, at least, on the second day, a small veicle appears upon the top of the pimples. At first the veicle is whey-coloured: but soon becomes white, and stands out like a little globule on the top of the pimple. In two or three days these gloubules break, or are rubbed off; and are succeeded by small crusts, which soon fall off in small scales. While one set of pimples take this course, another set arise to run the same; so that the disease often continues upon the skin for many days together. Sometimes when one crop of this eruption has disappeared, another, after some intervals, is produced. And it has been further observed, that in some persons there is such a disposition to this disease, that they have been affected with it several times in the course of their lives.

This disease is said to affect both sexes, and persons of all ages and constitutions; but it has been observed at all times to affect especially, and most frequently, lying-in women.

It is often accompanied with violent symptoms and has frequently proved fatal. The symptoms, however attending it are very various; and they are, upon occasions, every one attending febrile diseases; but no symptom, or concourse of symptoms, are steadied the same in different persons, so as to give any specific character to the disease. When the disease is violent, the most common symptoms are phrenetic comatose, and convulsive affections which are also symptoms of all febrile diseases treated by a very warm regimen.

When there is such a variety of symptoms appearing in this disease, it is not to be expected that any one particular method of cure can be proposed; and, accordingly, we find in different writers different methods and remedies prescribed; frequent disputes about the most proper; and those received and practised by some, opposed and deferted by others.

It appears, however, to Dr Cullen, very improbable, that this was really a new disease, when it was first considered as such. There are very clear traces of it in authors who wrote long before that period; and though there were not, we know that ancient descriptions were often inaccurate and imperfect, particularly with respect to cutaneous affections; and we know also that those affections which commonly appeared as symptomatic only, were often neglected, or confounded together under a general appellation.

The antecedent symptoms of anxiety, sighing, and pricking of the skin, which have been spoken of as peculiar to this disease, are, however, common to many others; and perhaps to all those in which sweatings are forced out by a warm regimen. Of the symptoms said to be concomitant of this eruption, there are none which can be affirmed to be confant and peculiar but that of sweating. This, indeed, always precedes and accompanies the eruption; and, while the miliaria eruption attends many different diseases, it never, however, appears in any of these but after sweating; and in persons labouring under the same diseases it does not appear, if in such persons sweating be avoided. It is therefore probable, that the eruption is the effect of sweating; and that it is the effect of a matter not before prevailing in the mafs of blood, but generated under particular circumstances in the skin itself. That it depends upon particular circumstances of the skin, is also probable from its being observed that the eruption seldom or never appears upon the face, although it affects the whole of the body besides; and that it comes upon those places especially which are more closely covered; and that it can be brought out upon particular places by external applications.

It is to be observed, that this eruptive disease differs from the other exanthemata in many circumstances, especially the following; that it is not contagious, and therefore never epidemic; that the eruption appears at no determined period of the disease; that the eruption has no determined duration; that successive eruptions frequently appear in the course of the same fever, and that such eruptions frequently recur in the course of the same person's life. All this renders it very probable, that, in the miliaria fever, the morbid matter is not a subsisting contagion communicated to the blood, and thence, in consequence of fever and assimilation, thrown out upon the surface of the body, but a matter occasionally produced in the skin itself by sweating.

This conclusion is further rendered probable from hence, that, while the miliaria eruption has no symptoms or concourse of symptoms peculiar to itself, it, upon occasions, accompanies almost every febrile disease, whether inflammatory or putrid, if these happen to be attended with sweating; and from thence it may be presumed, that the miliaria eruption is a symptomatic affection only, produced in the manner we have said.

But as this symptomatic affection does not always accompany every instance of sweating, it may be proper to inquire, what are the circumstances which especially
Exantemata. Dr Cullen gives no full and proper answer. He cannot say that there is any one circumstance which in all cases gives occasion to this eruption; nor can he say what different causes, in different cases, may give occasion to it. There is only one observation that can be made to the purpose of this inquiry; and it is, that these perimetric sweats, under febrile diseases are especially liable to the military eruption, who have been previously weakened by large evacuations, particularly of blood. This will explain why it happens to lying-in women more frequently than to any other persons; and to confirm this explanation, he has observed, that the eruption has happened to other women though not in child-bed, but who had been much subjected to a frequent and copious menstruation, and to an almost constant nitric album. He has also observed it to have happened to men in fevers, after wounds from which they had suffered a great loss of blood.

Further, that this eruption is produced by a certain state of debility, is, he thinks, probable, from its often attending fevers of the putrid kind, which are always attended with great debility. It is true, that it also sometimes attends inflammatory diseases, when it cannot be accounted for in the same manner; but he believes it may be observed, that it especially attends those inflammatory diseases in which the sweats have been long protracted, or frequently repeated, and which have thereby produced a debility, and perhaps a debilitating putrid diathesis.

That, however, the military eruption is not necessarily or even generally connected with a certain state of debility, is abundantly evident from its being entirely wanting in by much the greater number of instances of typhoid fever, and in a variety of other diseases, where every possible degree of debility occurs: And that it is not connected with any certain state of debility, till farther appears, both from the condition of those afflicted with it in different instances, which in point of strength is very various; and likewise from the continuance of fresh eruptions with the same individual, although during that time in very different states with respect to debility. It appears, therefore, much more probable, that it depends on some peculiar state of the surface, induced by the concurring influence of certain predisposing and occasional causes.

It appears so clearly that this eruption is always a symptomatic and factitious affection that Dr Cullen is persuaded it may be, in most cases, prevented merely by avoiding sweats. Spontaneous sweats, in the beginning of diseases, are very rarely critical; and all sweats not evidently critical, should be prevented, or at least moderated; and the promoting them, by increasing external heat, is commonly very pernicious. Even critical sweats should hardly be encouraged by such means. If, therefore, spontaneous sweat arise, they are to be checked by the coolness of the chamber; by the lights and loofeness of the bed-cloaths; by the persons laying out their arms and hands; and by their taking cold drink; and in this way Dr Cullen thinks he has frequently prevented military eruptions, which were otherwise likely to have appeared, particularly in puerperal women.

But it may happen, when these precautions have been neglected, or from other circumstances, that a military eruption does actually appear; and the question will then be put, how the case is to be treated? This in a question of consequence; as there is reason to believe that the matter here generated is often of a virulent kind; it is often the offspring of putrefacence; and, when treated by increasing the external heat of the body, it seems to acquire a virulence which produces those symptoms mentioned above, and proves certainly fatal.

It has been an unhappy opinion with most physicians, that eruptive diseases were ready to be hurt by cold; and that it was therefore necessary to cover up the body very closely, and thereby increase the external heat. We now know that this is a mistaken opinion; that increasing the external heat of the body is very generally pernicious; and that several eruptions not only admit, but require the application of cold air. Dr Cullen is persuaded, therefore, that the practice which formerly prevailed in the cafe of military eruptions, of covering up the body closely, and both by external means and internal remedies encouraging the sweats which accompany this eruption, was highly pernicious, and commonly fatal. He is therefore of opinion, that even when a military eruption has appeared, in all cases in which the sweating is not critical, we should employ all the means of stopping the sweating that are mentioned above; and he has sometimes had occasion to observe, that even the admission of cool air was safe and useful.

This is, in general the treatment of military eruptions: but at the same time, the remedies suited to the primary diseases are to be employed; and, therefore, when the eruption happens to accompany inflammatory affections, and the fullness and hardness of the pulse or other symptoms show an inflammatory state present, the case is to be treated by blood-letting, purging and other antiphlogistic remedies.

Upon the other hand, when the military eruption attends diseases, in which debility and putrefacence prevail, it will be proper to avoid all evacuations, and to employ tonic and antiseptic remedies, particularly the Peruvian bark, cold drink, and cold air.

The most difficult circumstance attending this affection, is the almost unsupported sickness at first which frequently occurs, and which is often observed to precede fresh eruptions taking place during the course of the disease. With the view of counteracting and alleviating this symptom, recourse is had to wine and other cordial medicines. But with many patients nothing is found to have so much influence as the use of camphor, particularly when introduced gradually in small doses, under the form of the miliaria camphorata, of the London Pharmacopeia, or the emulsio camphorata of that of Edinburgh.

We shall conclude this subject with observing, that the venerable octogenarian practitioner, de Fischer, when treating of this subject, in laying down the indications of cure, has given this as one of them: "Excretions peripherica non primarium habere rationem."

Practice.

Sp. I. The Mild SCARLET FEVER.
Scarlatina febris, Sav. sp. 1. Sydenham, sect. vi. cap. 2.

Sp. II. The SCARLET FEVER with ulcerated Sore Throat.
Scarlatina aniginosa. Withering on the SCARLET FEVER.

The mild scarlet fever is described by Sydenham, who tells us that he can scarce account it a disease; and indeed nothing more seems to be necessary in the treatment of it than an antiphlogistic regimen, avoiding the application of cold air and cold drink. The disease however sometimes rages epidemically, and is attended with very alarming symptoms, bearing no small resemblance to the coryza maligna, in which case it is called scarlatina aniginosa.—The best description of this distemper has been published by Dr Withering in the year 1778. This disease made its appearance, we are told, at Birmingham and the neighbouring villages, about the middle of May 1778. It continued in all its force and frequency to the end of October; varying, however, in some of its symptoms, as the air grew colder. In the beginning of November it was rarely met with; but towards the middle of that month, when the air became warmer, it increased again, and in some measure resumed those appearances it boistered in the summer-months, but which it had lost during the cold winds in October.

It affected children more than adults; but seldom occurred in the former under two years of age, or in the latter if they had passed their fifteenth year.

Description. With various general symptoms of fever, the patient at first complains of a dejection of spirits, a slight fever, or rather flatness in the neck, with a sense of straitness in the muscles of the neck and shoulders, as if they were bound with cords. The second day of the fever this sense of the throat increases, and the patients find a difficulty in swallowing; but the difficulty seems less occasioned by the pain excited in the attempt, or by the straitness of the passage, than by an inability to throw the necessary muscles in action. The skin feels hot and dry, but not hard; and the patients experience frequent, small, pungent pains, as if touched with the point of a needle. The breath is hot and burning to the lips, and thirst makes them wish to drink; but the tendency to sleep, and the exertions necessary in deglutition, are so unpleasant, that they seldom care to drink much at a time. They have much uneasiness also from want of rest during the night. In the morning of the third day, the face, neck, and breast, appear redder than usual; in a few hours this redness becomes universal; and increases to such a degree of intensity, that the face, body, and limbs, resemble a boiled lobster in colour, and are evidently swollen. Upon pressure the redness vanishes, but soon returns again. The skin is smooth to the touch, nor is there the least appearance of pimples or pustules. The eyes and nostrils partake more or less of the general redness; and in proportion to the intensity of this colour in the eyes, the tendency to delirium prevails.

Vol. XI.

Things continue in nearly this state for two or three days longer, when the intense scarlet gradually abates, a brown colour succeeds, and the skin becoming rough, peels off in small scales. The tumefaction subdues at the same time, and the patients gradually recover their strength and appetite.

During the whole course of the disease, the pulse is quick, small, and uncommonly feeble; the urine small in quantity; the sub-maxillary glands somewhat enlarged and painful to the touch. The velum palatini, the uvula, the tonsils, and gullet, as far as the eye can reach, partake of the general redness and tumefaction; but although collections of thick mucus, greatly resembling the iphecks or fluids in the putrid sore throat, sometimes occur, yet those are easily washed off, and real ulcerations of those parts were never observed.

These are the most usual appearances of this disorder; but it too frequently assumes a much more fatal form. In some children the delirium commences in a few hours after the first attack; the skin is intensely hot; the scarlet colour appears on the first or second day, and they die very early on the third. Others again, who survive this rapid termination, instead of recovering, as is usual, about the time the skin begins to get its natural colour, fall into a kind of lingering, and die at last in the course of six or eight weeks.

In adults, circular livid spots were frequently observed about the breath, knees, and elbows; also large blotches of red, and others of white intermixed, and often changing places.

In the month of October, when the air becomes colder, the scarlet colour of the skin was both less frequent and less permanent. Many patients had no appearance of it at all; whilst others, especially adults, had a few minute red pimples, crowned with white pellicular heads. The inside of the throat was considerably tumefied; its colour a dull red, sometimes tending to a livid. The pulse beat in general 130 or 140 strokes in a minute; was small, but hard, and sometimes sufficiently so to justify the opening of a vein; and the blood thus taken away, in every instance when cool, appeared fizzly, and the whole ccaffamentum firm.

Happy would it be, Dr Withering observes, if the baneful influence of this disorder terminated with the febrile symptoms. But in ten or fifteen days from the cessation of the fever, and when a complete recovery might be expected, another train of symptoms occur, which at last frequently terminate fatally. The patients, after a few days amendment, feel something that prevents their further approach to health; an unaccountable languor and debility prevails, a stiffness in the limbs, an accelerated pulse, disturbed sleep, disfolfie to food, and a scarcity of urine. These symptoms, we are told, are soon succeeded by swellings of a real dropical nature, forming sometimes an anasarca, and on other occasions an ascites; and not unfrequently scarlatina has proved fatal, from supervening hydrothorax in consequence of the effusion of water into the chest. It is unnecessary to remark, that when this happens, a fatal termination is more sudden than from any other modification of dropy.

Dd Dr
Dr Withering, after examining the accounts given of this disease by different authors, proceeds to the diagnosis. It may be distinguished, he observes, from the petechial fever, by the eruption appearing seldom before the fourth day, by the regularity and distinctness of the spots, and by its principally occupying the neck, the back, and the loins. On the other hand, in the scarlet fever, the eruption generally appears about the third day; confls either of broad blotches, or else one continued redness, which spreads over the face and the whole body. In the fever called purpura, the pustules are prominent, keep their colour under pressure, and never appear early in the disease; whereas in the scarlet fever, the eruption appears more early, is not prominent, but perfectly smooth to the touch, and becomes quite white under pressure.

Although the purple fever and scarlatina may be connected by some general cause, yet our author takes occasion to observe, that they cannot be more modifications of the same eruption: for examples occur, he says, of the same person being first feigned with one of these disorders, and afterwards with the other; but he never met with an instance of the same person having the scarlet fever twice; and he believes it to be as great an improbability as a repetition of the small-pox.

This disorder is particularly distinguished from the measles, we are told, by the want of that cough, watery eye, and running at the nose, which are known to be the predominant symptoms in the early state of the measles, but are never known to exist in the scarlatina.

From the erysipelis this disease is distinguishable, by the limited seat of the former, together with its not being contagious.

The ulcerated sore throat, however, is more difficult to distinguish from this disease than any other; and yet the distinction is a matter of the greatest importance, as the method of treatment, according to Dr Withering, ought to be extremely different.—But although, in a number of circumstances, these two diseases bear a very great resemblance, yet, with a little attention, the one may in general, he thinks, be distinguished from the other. From Dr Fothergill’s account of the sore throat attended with ulcers, our author has made out the following characteristic circumstances of the two diseases, contrasted to one another.

**Scarlata Anginofa.**

**Season.** Summer. Autumn.

**Air.** Hot. Dry.

**Place.** High. Dry.

**Gravely.**

**Subject.** Vigorous.

**Sexes alike.** Robust in most danger...

**Skin.** Full scarlet smooth. If pimply, the pimples white at the top.. Always dry and hot.

**Angina Gangrenofa.**

**Season.** Spring. Winter.

**Air.** Warm. Moist.

**Place.** Clofe. Low.

**Damp.** Marshy.

**Subject.** Delicate. Women and female children. Robust adults not in danger.

**Skin.** Red. Ate pimply. The pimples redder than the interstices bedewed with sweat toward morning.

Scarlata Anginofa.

Eyes. Shining, equable, intense redness, rarely watery.

**Throat.** In summer, tonsils, &c. considerably swelled and ulcerated... Sloughs dark brown.

**Breath.** Very hot, but not fetid.

**Voice.** In summer, natural.

**Bowsels.** Regular at the accession.

**Blood.** Buffy. Firm.

**Termination.** The 3d, 5th, 8th, or 11th day.

**Nature.** Inflammatory.

Angina Gangrenofa.

Eyes. Inflamed and watery, or foul and dead.

**Throat.** Tonsils, &c. considerably swelled and ulcerated... Sloughs white.

**Breath.** Offensive to the patients and attendants.

**Voice.** Flat and ratling.

**Bowsels.** Purging at the accession.

**Blood.** Florid. Tender. Natural.

**Termination.** No settled period.

**Nature.** Putrid.

It is not pretended, Dr Withering remarks, that all the above contrasted symptoms will be met with in every case. It is enough, he observes, that some of them appear; and that if joined with the consideration of the prevailing constitution, they enable us to direct that mode of treatment which will most contribute to the relief of the sick.

But notwithstanding the attention which Dr Withering has bestowed upon this subject, we are still inclined to think, that the disease which he has accurately described under the title of *scarlatina anginosa,* is in reality the same affection with the malignant ulcerous sore throat of Huxham and Fothergill. During different epidemics, this disease, like small-pox and measles in different seasons, is considerably varied in its appearance. But still there occurs such a similarity as clearly marks the sameness of the affection. And indeed this, as in the case of the small-pox, is abundantly demonstrated, by infection from one contagion giving protection against succeeding ones, although the appearances be much varied. This has particularly appeared at Edinburgh, where the disease has of late prevailed as an epidemic on three different years, viz. 1774-5, 1782-3, and 1789-90. During the first of these, in the greater part of patients, the sore throats were of a very gangrenous and malignant nature: during the second, the disease more commonly appeared under the form of what might be called *simple scarlatin:* and during the third epidemic, the contagion was, if we may be allowed the expression, of an intermediate nature. But it is farther to be remarked, that during every one of these epidemics, when several children of a family were at the same time subjected to the infection, in one the disease would have been attended with almost all the symptoms mentioned in the column of *scarlatina anginosa,* with respect to skin, eyes, throat, breath, bowels, termination of the afections, &c. In another, would have occurred all the symptoms with respect to those particulars which he has mentioned under the column of *angina gangrenosa.* While at the same time, in numberless instances, even in the same patient, the disease at its commencement has shown evident marks of such inflammatory, and at its termination of a putrid tendency. And there cannot be a doubt, that both the scarlatina anginosa,
angina spasmodica, and angina gangrenosa, as described by
Thomson and Hueham have occurred in every season
and situation, and have affected persons of every age
and constitution not before subjected to either di-
cese.

Cures. Dr Withering affirms, that the immediate
cause of this disease is a poison of a peculiar kind,
communicable by contagion.

1. That this poison first takes possession of the
mucous membrane lining the fauces and the nose;
and either by its action upon the secretory glands;
or upon the mucus itself, assimilates that mucus to its
own nature.

2. That it is from this beginning, and from this
only, that it spreads to the stomach, &c. and at length
acts upon the system at large.

3. That its first action upon the nerves is of a de-
finately or debilitating nature.

4. That in consequence of certain laws of the ner-
vous system, when the debilitating effects operate upon
the fenso-rium commune, a reaction takes place;
and that this reaction is, ceteris paribus, proportioned to
the debilitating power.

5. That, in consequence of this reaction of the ner-
vous system, the vibratory motion of the capillary
blood vessels dependent thereon is greatly encreased;
an unusually large quantity of blood is accumulated
in those vessels; the heart and large blood-vessels are
deprived of their customary proportion; and hence,
though stimulated to more frequent contraction, the
pulse must necessarily be feeble.

6. That as violent exertions are followed by debility,
upon the cessation of the fever, the capillary vessels,
which had acted with such unusual violence, are left
in a state of extreme debility, and are long in reco-
viving their tone; hence it is that so many patients
afterwards become deracial.

Dr Withering next proceeds to the consideration of
the different remedies, which either are at present in
common use or have been recommended as proper in
this disease.

Cure. Blood-letting has been recommended by
authors; but such was the state of the pulse in this
disease, at least during the summer months, that it
was not in any instance thought advisable to take
away blood. In some cases, indeed, where the fiery
redness of the eyes seemed to demand the use of leeches,
they were had recourse to, but never with any
advantage. In the harvest months, when the
pulse was more firm, and when suffocation seemed to
be threatened from the swelling in the fauces, blood-
letting was sometimes advised; but still with less
advantage than one would have expected in almost any
other situation.

Vomiting. This, our author observes, seems to be the
remedy of nature; and he is surprised how it should
have been omitted by several authors who have gone
before him. Vomiting, he says, most amply fulfills
the indications arising both from a consideration of the
cause and of the effects; and a liberal use of the
remedy he holds forth as the true foundation for suc-
cessful practice in scarlet fever and sore throat. His
common form of emetic is a combination of tartar
etemic and ipecacuanha, given in pretty smart doses;
and these are to be repeated at least once in 48 hours,
and in the worst cases so often as twice in 24 hours.

Purgings.] The action of purgatives is considered
by Dr Withering as altogether repugnant to the cu-
rative indications in this disease; for the poisonous,
formerly remarked, being received into the system by
the fauces, the operation of a purge, instead of dis-
charging it, can only promote its diffusion along the
alimentary canal; and in fact, we are told, that when
even a spontaneous purging supervenes in this disease,
the patients sink so amazingly fast, that it is not with-
in the reach of art to support them. When, how-
ever, a considerable quantity of acid matter pass-
ing from the fauces into the bowels, makes its way to the
remedy, a considerable degree of toxemica often takes
place. And although evacuations from the system in
general by means of cathartics may be useful, yet
patients are often obtained great relief from a free dis-
charge of this matter; and by discharging it, purgatives have
the effect even of preventing an evacuation from the
system, which would otherwise take place.

Sudorifics. Cordials, Alexipharmics. None of these
remedies were found beneficial. With respect to cord-
dials, Dr Withering observes, that although they seem to
be indicated by the great loss of strength and feeble
pulse, yet the certain confluence of their use always
was, an increase of restlessness, of the delirium and of
the heat.

Diuretics. These were found very beneficial. The
vegetable fixed alkalii is recommended as the most
proper article of this kind; a dram or two may be
easily swallowed every 4 hours, by giving a small
quantity in every thing the patient drinks. Diure-
tics, however, have been found principally serviceable
by practitioners in general in those cases where the
urine is observed to be scanty, and where dropical
symptoms have taken place.

Peruvian bark. No medicine, we are told, ever
had a fairer trial in any disease than the Peruvian bark
had in this epidemic; for the feeble pulse, great
proliferation of strength, with here and there a livid
spot were thought to be such undeniable evidences of
a putrid tendency, that the bark was poured down
not with a sparing hand. But this was only at first;
for these livid spots and the loughs in the throat be-
ing found to be the effects of inflammation instead of
putrefaction, and the bark instead of diminishing,
rather increasing these symptoms, it was at last entire-
ly laid aside by Dr Withering in his practice. But
although Peruvian bark may not have been successful
with a particular epidemic at a particular place; yet
from the concurrent testimony of many practitioners,
it is very commonly found to be productive of good
effects: And there is perhaps no remedy in which
greater dependence is in general put, particularly in
the advanced periods of the disease, where the factor
is considerable.

Upon the same principles that the bark was pre-
fixed, flammable air was at first likewise advised, but
with no evident effects either one way or another.
Dulcified acids were also had recourse to, but with no
advantage.

Opiates. These, although recommended by some
authors

Genus XXXIII. URTICARIA, NETTLE-RASH.

Febris urticaea, Vog. 40.
Urado, Lin. 8.
Scarlatina urticaea, Jand. 75.
Scarlatina urticaea, Sauv. p. 2.
Erythelatis species altera, Sydenham, s. e. vi. cap. 6.

Febris scarlatina, et febris urticaea, Meyferry, Mal. des armées, 291 et seq.

Description. This disease has its English name from the resemblance of its eruption to that made by the flogging of nettles. These little elevations upon the skin in the nettle-rash often appear instantaneous, especially if the skin be rubbed or scratched, and seldom stay many hours in the same place, and sometimes not many minutes. No part of the body is exempt from them; and where many of them rise together, and continue an hour or two, the parts are often considerably swelled, which particularly happens in the face, arms, and hands. These eruptions will continue to infest the skin, sometimes in one place and sometimes in another, for one or two hours at a time, two or three times every day, or perhaps for the greatest part of the 24 hours. In some persons they last only a few days, in others many months; and sometimes the disease has lasted for years with very short intervals.

But though the eruption of the urticaria resembles, as already observed, that produced by the flogging of nettles, it is sometimes accompanied with long wheals, as if the part had been struck with a whip. Whatever be the shape of these eminences, they always appear solid, without having any cavity or head containing either water or any other liquor: and this affords an easy mark whereby this disease may be distinguished from the itch. For it often happens, that the inoffensive itching with which this eruption is attended, provokes the patient to scratch the parts so violently, that a small part of the cuticle on the top of these little tumours is rubbed off; a little scab succeeds; and when the swelling is gone down, there is left an appearance hardly to be distinguished from the itch, but by the circumstance just now mentioned. The nettle-rash also further differs from the itch, in not being infectious.

Cauttes, &c. Dr Heberden is inclined to ascribe this distempers to some mechanical cause outwardly applied to the skin. He observes that most people suffer in a similar manner from the real flogging of nettles. Cowhage, or, as it is corruptly called, cow-itch, a sort of phaeolus, or French bean, the pod of which is covered over with a kind of down or hair, and the effect of which upon the skin is much the same as that of nettles; and almost any hairs cut equally short, and sprinkled upon the skin, whenever they happen to stick in it, will make the part itch or smart in such a manner as to give great uneasiness; it is also a considerable time before the skin can be cleared of the finer ones, when once they are stirred upon it.

Reaumur, in the fourth memoir of his History of Insects, describes a species of caterpillars to which be-
long a sort of hairs almost invisible to the naked eye, which are easily detached, and frequently float in the air round their nest, though they have not been at all disturbed. The touch of these hairs has a similar effect with the cow-itch; that is, they occasion intolerable itchings, with little bumps and redness, arising sometimes to a slight inflammation. These he found all disturbed. The touch of but for a shorter time. These hairs of cantharides: but though it has continued many weeks the cantharides over the readily be carried to other parts of the body. But it had a violent itching, attended with great heat and pain: the skin would then be almost as red as vermillion, and thicken like leather; and this remained till he went out of the open air, and then abated in about 15 or 20 minutes. This happened only when the fun was above the horizon; at other times he was what he called quite well.—But it was not owing to the heat of the sun; for the sun in winter affected him as much, if not more, and the heat of the fire had no such effect. This he was confined to the house for 10 years. He tried several hospitals, and had advices from many physicians, without the least abatement of his complaints. At last it was agreed by a consultation of physicians, that he should try dipping in salt-water; which he did at Yarmouth for 13 weeks, without any visible amendment. One hot day, having pulled off his clothes and gone into the sea in the middle of the day, the heat diffused itself so violently all over his body, that, by the time he had put on his clothes, his eye-sight began to fail, and he was compelled to lie down upon the ground to save himself from falling. The moment he lay down, the faintness went off: upon this he got up again; but had no sooner arisen, than he found himself in the former condition; he therefore lay down again, and immediately recovered. He continued alternately getting up and lying down, till the disorder began to be exhausted, which was in about half an hour; and he was frequently obliged to have recourse to the same expedient.

Dr Heberden asks, Is it impossible that the nettle-rash should arise from the same causes, or from others similar, which we meet by looking too deeply for them in the blood and humours? Such (says he) may have been its origin in some instances, where it has lasted only a few days; but where this affection has continued for some years, in persons who change their linen every day, and who bathe frequently all the time, it can hardly be ascribed to such an external cause. He has observed it frequently to arise from cantharides: but though it has continued many weeks after the removal of the blister, yet it might be suspected that this arose from the fine spicule of the cantharides sticking all this time about the skin; it being customary to burn much of the dry powder of the cantharides over the blister-plaster, whence it may readily be carried to other parts of the body. But it is certain that similar effects will sometimes follow the internal use of wild valerian root, or the eating of fish not sufficiently dried; muscles, shrimps, and even honey, and the kernels of fruits, will also sometimes produce symptoms of a similar kind. But whatever be its cause, Dr Heberden never saw any reason to suppose that the nettle-rash had in any way vitiated the humours to such a degree as to require the use of internal remedies; and if the itching could be certainly and expeditiously allayed, there would be no occasion for any farther cure. He concludes this history of the disorder with a case communicated to him by Dr Monfey, physician of Chelsea-college, and in which the disease appeared with uncommon violence.

W. A. aged near 30, of a thin spare habit, was seized with a disorder attended with symptoms of a very uncommon kind. Whenever he went into the air, if the sun shined bright, he was seized with a tickling of his flesh on those parts exposed to the sun: this tickling, by his continuing in the air, increased to a violent itching, attended with great heat and pain: the skin would then be almost as red as vermillion, and thicken like leather; and this remained till he went out of the open air, and then abated in about 15 or 20 minutes. This happened only when the sun was above the horizon; at other times he was what he called quite well.—But it was not owing to the heat of the sun; for the sun in winter affected him as much, if not more, and the heat of the fire had no such effect. This he was confined to the house for 10 years. He tried several hospitals, and had advices from many physicians, without the least abatement of his complaints. At last it was agreed by a consultation of physicians, that he should try dipping in salt-water; which he did at Yarmouth for 13 weeks, without any visible amendment. One hot day, having pulled off his clothes and gone into the sea in the middle of the day, the heat diffused itself so violently all over his body, that, by the time he had put on his clothes, his eye-sight began to fail, and he was compelled to lie down upon the ground to save himself from falling. The moment he lay down, the faintness went off: upon this he got up again; but had no sooner arisen, than he found himself in the former condition; he therefore lay down again, and immediately recovered. He continued alternately getting up and lying down, till the disorder began to be exhausted, which was in about half an hour; and he was frequently obliged to have recourse to the same expedient.

Having at last accidentally met with Dr Monfey, this physician questioned him concerning the cause of the disorder; but nothing could be guessed at, excepting that the patient owned he had one winter lived entirely upon bullock's liver and porter, from inability to purchase better vi{uals. A comrade lived with him at that time, on the same provisions; and he also was affected in a similar manner, though in a less degree, and had recovered. This patient was then first put upon a course of Dover's sweating powder without any effect, and, afterwards tried a course of nitrous ones with the same bad success. At last Dr Monfey determined to try the effect of mercury, which happily proved effectual in removing this intractable and uncommon distemper. The patient began with taking five grains of calomel for three nights running, and a cathartic next morning. In this course he went on for near a fortnight, at the end of which he found himself very sensibly relieved. This encouraged him to go on rather too boldly, by which means a slight salivation ensued; however, that went off soon, and in about six weeks he was quite well.—Some time after, he was threatened with a return of his disorder; but this was effectually relieved by a dose of calomel, which he had afterwards occasion to repeat for the same reason, and with the same success;

Pemphigus Helveticus, Sauv. sp. 3. Langbain in
Ad. Helvet. vol. ii. p. 260. et in Byfchreibung
des Siementhalis, Zurich 1753.

This is a very rare disease, insomuch that Dr Cul-
len declares he never saw it. He declines taking the
descriptions of foreign physicians: we shall therefore
content ourselves with giving an instance of this very
uncommon disemper, as it was observed in the infir-
mary at Aberdeen, and was treated by the late Dr
David Stuart, then physician to that hospital, who
soon after published an account of it in the Edinburgh
Medical Commentaries. A private soldier of the 3d
regiment, aged eighteen years formerly a pedlar,
and naturally of a fvery healthy constitution, was
David
Mary at Aberdeen, and
his whole body, and the pustules continued every day
flill,
and rigiditv of his knees and other joints. The surgeon of the
regiment vifited him: he was purged, but with little
benefit. About ten days before, he observed on the
inner side of his thighs a number of very small, disfance,
red spots, a little elevated above the surface of the
skin, and much resembling the first appearance of
small-pox. This eruption gradually spread itself over
his whole body, and the pultules continued every day
to increase in size.

Upon being received into the hospital, he complained
of head-ach, fickness at stomach, opprefion about the
precordia, head-ach, laatitude, and wearineffes,
on the left exertion; with liffness and rigidity of his knees and other joints. The surgeon of the
regiment vifited him: he was purged, but with little
benefit. About ten days before, he observed on the
inner side of his thighs a number of very small, disfance,
red spots, a little elevated above the surface of the
skin, and much resembling the first appearance of
small-pox. This eruption gradually spread itself over
his whole body, and the pultules continued every day
to increase in size.

Upon being received into the hospital, he complained
ed of head-ach, fickness at stomach, opprefion about the
precordia, thrift, fore throat, with difficulty of
swallowing; his tongue vvas foul, his skin felt hot and
feveriith; pulse from 110 to 120, rather depreffed;
belly conflive; eyes dull and languid, but without deli-
rium. The whole surface of his skin was interfpered
with vehicles, or phlydias, of the size of an ordinary
walnut; many of them were larger, efpecially on the
arms and breast. In the interftices, between the vehi-
cles, the appearance of the skin was natural, nor was
there any redneff round their base: the diftance from
one to another was from half an inch to a hand-
breadth or more. In fome places two or three were
joined together, like the pultules in the confluent small-
pox. A few vvefles had burst of themelves, and form-
ed a whitifh fcrab or crust. These were mostly on the
neck and face; others showed a tolerably laudable pus.
However, by far the greatest number were perfectly
entire, turgid, and of a blulfh colour. Upon opening
them, it was evident that the cuticle elevated above the
cutis, and diftended with a thin, yellowish, femipelle-
ucid fcrum, formed this appearance. Nor was the sur-
face of the cutis ulcerated or livid; but of a red florid
colour, as when the cuticle is interfolated by a blister,
or superficial burning. No other perfon laboured un-
der a similor difeafe, either in the part of the country
from which he came, or when he resided in Aberdeen.
This cafe was treated in the following manner. The
largest of the vehicles were flipped, and defribed with
arquant. e lap. calaminari. In the evening he was
vomited with a folution of tartar emetic, given in small
quantities and at intervals. This also procured two
loofe ffools. And he was ordered for drink, water-
grel aciuated with lemon juice.

"April 16. He still complained of fickness, some
oppreffion about his brefth, and fore throat; he had
fept little during the night; his tongue was foul and
blackish; his skin, however, was not fo hot as the pre-
ceeding day; his urine was high-coloured, but had the
appearance of separation; his pulse go, and foft; most
of the fores on the trunk of the body looked clean.
Others, particularly where the vehicles were confluent,
seemed beginning to ulcerate, and to have a blutfh sub-
livid appearance. They were defribed after with ce-
tre, and he was ordered the following medicines:
3ii. M. Hujus mixtura capiat 35l. tertia quaque hora
hora
His aciuated drink was continued; and on ac-
count of the very offensive fhmell on approaching near
him, fome vinegar was placed in a bafon before the
bed, and sprinkled on the floor; and the room was
keperd properly aired.

"April 17. His fores looked tolerably clean, un-
feles on his arms and thighs; where they were livid, a
little ulcerated, and difcharged a bloody ichor.

"April 18. The little ulcers in his arms and thighs
flill difcharged a bloody ichor, and looked ill; his
other complaints were better; pulse 82. The bark
had not nafeated him, and it was continued as well
as his former drink.

"April 19. His fores looked much cleaner and
better; the fever was gone, his pulse natural, and he had
no complaint but weakness and troubleome itching
of the skin: The Peruvian bark, &c. were continued.

"April 20. Some of the ulcers still poured forth a
bloody ichor; molt of them, however, looked well,
and had begun to heal—fever gone—medicines con-
tinued.

"From the 21st of April he went on gaining strength,
and his fares appeared to heal fast; he was defired to
practice.
take only four doses every day; and by the 27th his fores, &c. were totally dried up—he had no complaint, and was diffimil cured.

Since the publication of this case of pemphigus by Dr Stuart, observations on this disease have been published by Dr Stephen Dickson of Dublin in the Transactions of the Royal Irish Academy. In the observations, an account is given of six different cases which Dr Dickson has had an opportunity of seeing. Judging from these, Dr Dickson thinks that Dr Cullen's definition of this disease requires correction; and that it ought to be defined, "a fever accompanied with the succedaneum eruption, from different parts of the body, internal as well as external, of vesicles about the size of an almond, which become turgid with a faintly yellowish serum, and in three or four days subside."

From the cases which have been published under Dr Dickson's observation, he concludes, that the disease varies considerably as to its mildness or malignity. In three of the cases which he has seen, the symptoms were extremely mild, but in the other three strong symptoms of putrefaction were manifell, and the life of the patient was in great danger. With respect to the method of cure, he is of opinion, that the general symptoms of weakness, and tendency to putrefaction, obviously point out the proper treatment. Nourishment must be supplied, and the Peruvian bark and wine carefully administered; and when vesicles appear on internal parts, irritation must be guarded against by opiates, demulcent, and gentle laxatives.

Some additional observations on the subject of pemphigus have lately been published in the London Medical Journal by Mr. Thomas Chriftie. From a cafe which Mr. Chriftie describes, he is disposed to agree with Dr Dickson in thinking that sometimes at least pemphigus is not contagious. He remarks, however, that the pemphigus described by some foreign writers was extremely infectious; which he thinks this may lead to a division of the disease into the two species, the pemphigus simplex and complicatus; both of which, but especially the latter, seem to vary much with respect to mildness and malignity.

**GENUS XXXV. APHTHA.**

The Thrush.

Febris aphthosa, Feg. 44.

The only idiopathic species is the thrush to which infants are subject; (Aphtha lacticius, Sauv. 6. 1.)

The aphthae are whitish or ash-coloured vesicles, invading the uvula, fauces, palate, tonsils, inside of the cheeks, gums, tongue, and lips. They may on the most part begin at the uvula, sending forth a glutinous mucus, and the vesicles covering all or the greatest number of the parts abovementioned with a thick whitish crust adhering most tenaciously. This crust does not induce an echar on the parts on which it lies by eating into them, but comes off in whole pieces after the vesicles have arrived at maturity. This will often happen in a short time, so that the throat and internal parts of the mouth are frequently observed to be clean which a few years before were wholly covered with white crusts. Neither is this disease confined to the thr. as and fauces, but is said to affect the esophagus, thorax, and all parts of the alimentary canal. Of this indeed there is no other proof, than that, after a great difficulty of swallowing, there is sometimes an immense quantity of aphtha evacuated by stool and vomiting, such as the mouth could not be thought capable of containing.

**Caufes, &c.** The aphthae fever seems to be produced by cold and moisture, as it is found only in the northern countries, and especially in marshy places; and in them the aphthae often appear without any fever at all.

**Progress.** There is no symptom by which the coming out of aphtha can be foretold, though they are common in many fevers; but they themselves are in general a bad symptom, and always signify a very tedious disorder: the danger denoted by them is in proportion to the difficulty of abatement and a discharge accompanying them is likewise bad. This indeed generally carries off old people when they become afflicted with aphtha. The dark-coloured aphtha also are much more dangerous than such as are of a brown or ash colour; but it is a good sign when the ap­petite returns, and the dark-coloured ones are succeeded by others of a whiter colour. Neither are those which are unaccompanied with fever so dangerous as the other kind.

**Care.** As the aphthae are seldom a primary disease, we must generally endeavour to remove the disorder upon which they depend, after which they will fall off; but in the mean time we are not to neglect applications to the aphthae themselves, such as detergent and softening gargles made of the decoction of figs, with the addition of honey of roses, a little vinegar, and some tincture of myrrh.

**Bleeding at the Nose.**

**Hæmorrhagia narium, Hoffm. II. 196. Junck. 6.**

**Hæmorrhagia plethorica, Sauv. Ord. 2. Hoffm. II. 198.**

The other species enumerated by authors are all symptomatic.

**Description.** The milder species of this hæmorrhagy comes on more frequently in summer than in winter, and for the most part without giving any warning, or being attended with any inconvenience; but the lea benign kind is preceded by several remarkable symptoms. These are, congestions of the blood sometimes in one part and sometimes in another, and which are often very troublesome in the sides of the head; there is a redness of the cheeks; an inflammation of the face, and of the vessels of the neck and temples; a thuribus aurium; a heavy pain of the eyes, with a promincence
MEDICINE.

Practice.

Epistaxis.

Hemorrhagiae minence, dryness, and sparks; there is a vertiginous affection of the head, with an itching of the nostrils, and a feeble of weight, especially about the root of the nose. In some the sleep is disturbed with dreams about blood, fire, &c. Frequently the belly is cold, there is a diminution of the quantity of urine, a suppression of sweat, coldness of the lower extremities, and tension of the hypochondria, especially the right one.

Casus, &c. This hemorrhagia may occur at any time of life; but most commonly happens to young persons, owing to the peculiar state of the system at that time. Sometimes, however, it happens after the 

\[ \text{exsanguination} \] and during the state of manhood, at which time it is to be imputed to a plethoric state of the system; to a determination of the blood, by habit, to the vessels of the nose; or to the particular weakness of these vessels.

In all these cases the disease may be considered as an arterial hemorrhagia, and depending upon an arterial plethora; but it sometimes occurs in the decline of life, and may then be considered as the sign of a venous plethora in the vessels of the head. It often happens at any period of life in certain febrile diseases, which are altogether or partly of an inflammatory nature, and which show a particular determination of the blood to the vessels of the head. As this evacuation, other diseases are often removed, it may on these occasions be deemed truly critical. It happens to persons of every constitution and temperament; but in all cases it should be moderated by keeping the patient in cool air, by giving cold drink, by keeping the body and head erect, by avoiding any blowing of the nose, speaking, or other irritation; and if the blood has flowed for some time without showing any tendency to stop, we are to attempt the suppression of the hemorrhagia, by pressing the nostrils from which the blood flows, washing the face with cold water, or applying this to some other parts of the body. Thse measures Dr Cullen judges to be proper even on the first attacks, and in young persons where the disease is the least hazardous; but they will be more requisite if the disease frequently recurs without any external violence; if the returns happen to persons disposed to a plethoric habit; and more particularly if the signs of plethora appear in the symptoms preceding the discharge.

When the bleeding is so profuse that the pulse becomes weak and the face pale, every means must be used to put a stop to it, and that whether the patient be young or old. Besides those methods above-mentioned, we must use astringents both internal and external; but the latter are the most powerful, and the choice of these may be left to the surgeon. The internal astringents are either vegetable or solid; but the vegetable astringents are seldom powerful in the cure of any hemorrhagies except those of the alimentary canal. The solid astringents are more active, but differ considerably in strength from one another.—The child bearing may have little strength, the preparations of lead are more powerful; but cannot be employed, on account of their pernicious qualities, unless in cases of the utmost danger. The \text{fruits} \text{furninae}, \text{or antiphlogistica}, is a medicine of very little efficacy, either from the small quantity of lead it contains, or from the particular state in which it is. The safest and at the same time the most powerful astringent seems to be alum.

For suppressing this and other hemorrhagies, many suppuritious remedies and charms have been used, and said to have been employed with success. This has probably been owing to the mistake of the by-flanders, who have supposed that the spontaneous cessation of the hemorrhagia was owing to their remedy. At the same time Dr Cullen is of opinion, that such remedies have sometimes been useful, by improving the mind with horror or dread. Opiums have sometimes proved successful in removing hemorrhagies; and when the fulness and inflammatory diathesis of the system have been previously taken off by bleeding, they may, in Dr Cullen’s opinion, be used with safety and advantage. Ligatures have been applied upon the limbs, for retarding the return of the venous blood from
from the extremities; but their use seems to be ambiguous. In the case of profuse hemorrhages, no care is to be taken to prevent the patient from fainting, as this is often the most certain means of stopping them.

Sp. V. **The Picaeious Hemoptysis.**
Hemoptysis catamenialis, Sauv. sp. 4.
Hemoptysis periodica, Sauv. sp. 5.

**Description.** This hemoptysis commonly begins with a sense of weight and anxiety in the chest, some uneasiness in breathing, pain of the breast or other parts of the thorax, and some sense of heat under the sternum; and very often it is preceded by a faintish taste in the mouth. Immediately before the appearance of blood, a degree of irritation is felt at the top of the larynx. The person attempts to relieve this by hawking, which brings up a little florid and somewhat frothy blood. The irritation returns; and in the same manner blood of a similar kind is brought up, with some noise in the wind-pipe, as of air palling through a fluid. Sometimes, however, at the very first, the blood comes up with coughing, or at least somewhat of coughing, and accompanies the hawking above-mentioned. The blood is sometimes at first in very small quantity, and soon disappears; but in other cases, especially when it frequently recurs, it is in greater quantity, and often continues to appear at times for several days together. It is sometimes profuse, but rarely in such quantity as either by its excess or by a sudden suffocation to prove immediately mortal.

It is not always easy to discover whether the blood evacuated by the mouth proceeds from the internal surface of the mouth itself, from the faucies or adjoining cavities of the nose, from the pharynx, or from the lungs. It is, however, very necessary to distinguish the different cases; and for this Dr Cullen offers the following considerations.

1. When the blood proceeds from some part of the internal surface of the mouth, it comes out without any hawking or coughing; and generally, upon inspection, the cause is evident.
2. When blood proceeds from the faucies, or adhering cavities of the nose, it may be brought out by hawking, and sometimes by coughing. In this case there may be a doubt concerning its real source, and the patient may be allowed to please himself with the thoughts that the blood does not come from the lungs. But the physician must remember that the lungs are much more frequently the source of an hemorrhagia than the faucies. The latter seldom happens but to persons who have before been liable to an hemorrhagia from the nose, or to some evident cause of erosion; and in most cases, by looking into the faucies, the distillation of the blood from thence will be perceived.

3. When blood proceeds from the lungs the manner in which it is brought up will commonly shew from whence it comes; but, independent of that, it may also be known from the causes of hemoptysis from the lungs, to be afterwards mentioned, having preceded.

4. When vomiting accompanies the throwing out of blood from the mouth, we may generally know the source from whence it proceeds, by considering that blood does not proceed so frequently from the stomach as from the lungs; that blood proceeding from the stomach commonly appears in greater quantity than from the lungs. The pulmonary blood also is usually of a florid colour, and mixed with a little frothy mucus only; but the blood from the stomach is of a darker colour, more grumous, and mixed with the other contents of the stomach. The coughing or vomiting, as the one or the other happens first to arise, may sometimes point out the source of the blood; and this hath also its peculiar antecedent signs and causes.

**Causes, &c.** An hemoptysis may be produced at any time of life by external violence; and, in adult persons, while the arterial plethora prevails in the vitium, i.e. from the age of 16 to 35, an hemoptysis may at any time be produced merely by a plethoric state of the lungs. More frequently, however, it arises from a faulty proportion between the capacity of the lungs and that of the rest of the body. Thus it is often an hereditary disease, which implies a peculiar and faulty conformation.

This disease especially happens to persons who discover the smaller capacity of their lungs by the narrowness of their chest, and by the prominence of their shoulders; which last is a mark of their having been long liable to a difficulty of respiration. In such cases, too, the disease very frequently happens to persons of a fagacious temperament, in whom particularly the arterial plethora prevails. It happens also to persons of a tender delicate make, of which a long neck is a mark; to persons of much sensibility and irritability, and therefore of quick parts; to persons who have formerly been liable to hemorrhages from the nose; to those who have suffered a suppression of any uterine hemorrhagia; to those who have suffered a suppression of their menstrual flux; and, lastly, to persons who have suffered the amputation of any considerable limb.

All this constitutes the predispontion cause of hemoptysis; and the disease may happen merely from the predispontion cause arising to a considerable height. But in those who are already predisposed, it is often brought on by the concurrence of various occasional
and exciting causes. One of these, and perhaps a frequent one is external heat; which, even when in no great degree, brings on the disease in spring, and the beginning of summer, while the heat rarifies the blood more than it relaxes the solids, which had before been contracted by the cold of winter. Another exciting cause is a sudden diminution of the weight of the atmosphere, especially when concurring with any effort in bodily exercise. The effort too, alone, may often be the exciting cause in those who are already predisposed; and more particularly any violent exercise of respiration. In the predisposed, also the disease may be occasioned by any degree of external violence.

Progress. Hæmoptysis may sometimes be no more dangerous than a hemorrhagy from the nose; as when it happens to females, in consequence of a supposition of their menicles; when, without any marks of predisposition, it arises from external violence; or, from whatever cause arising, when it leaves no cough, dyspnoea, or other affection of the lungs, behind it. But, even in these cases, a danger may arise from too large a wound being made in the vessels of the lungs, from any quantity of red blood being left to stagnate in the cavity of the bronchus, and particularly from any determination of the blood being made into the vessels of the lungs, which by renewing the hemorrhagy may have these consequences.

Cure. In the treatment of this disease, with a view of stopping the discharge, it is first necessary to have recourse to those measures which tend to diminish the impetus by which the blood is expelled. This is to be effected by a removal of plethora when it exists; by diminishing the general impetus of circulation; by diminishing local increased action when it takes place in the vessels of the lungs; and by producing a determination of blood to other parts of the system remote from the lungs. But besides practices diminishing impetus, it is often also necessary to employ such as augment the reluctance to the passage of blood through the ruptured vessels of the lungs. With these views a variety of practices may be employed, particularly blood-letting, astringents, refrigerants, sedatives, and the like.

On this subject Dr Cullen differs from those who prescribe chalybeates and the Peruvian bark in the cure of hæmoptysis. Both of these, he observes, contribute to increase the phlogistic diathesis then prevailing in the system, and the hæmoptysis from predisposition is always accompanied with such a diathesis. Instead of these, therefore, he recommends blood-letting in greater or smaller quantity, and more or less frequently repeated as the symptoms shall direct. At the same time cooling purgatives are to be employed, and every part of the antiphlogistic regimen is to be strictly enjoined. In the London Medical Observations, the use of nitre is greatly recommended by Dr Dickson, to whom its efficacy was made known by Dr Letherland, physician to St Thomas's hospital. The most commodious method of exhibiting it he found was in the spring.

Practice.

MEMORANDA. 3. A catarrh. 4. An asthma; and, 5. Tubercles.

1. When a phthisis arises from an hemoptysis, it is probable that it is occasioned by particular circumstances; and what these circumstances are, may not always be easily known. It is possible, that merely the degree of rupture, or frequently repeated rupture, preventing the wound from healing, may occasion an ulcer; or it is possible, that red blood effused, and not brought up entirely by coughing, may, by flaginating in the lung, become acrid, and erode the parts. But these hypotheses are not supported by any certain evidence; and from many observations we are led to think, that several other circumstances must concur in producing the dilacée from hemoptysis.

2. The second cause of an ulceration of the lungs mentioned above is a suppuration formed in consequence of pneumonia. When a pneumonia, with symptoms neither very violent nor very light, has continued for many days, it is to be feared it will end in a suppuration: but this is not to be determined by the number of days; for, not only after the fourth, but even after the tenth day, there have been examples of a pneumonia ending by a resolution; and if the disease has differed from the previous, and again recurred there may be instances of a resolution happening at a much later period from the beginning of the disease than that just now mentioned. But, if a moderate dilacée, in spite of proper remedies employed, be protracted to the 14th day without any considerable remission, a suppuration is pretty certainly to be expected; and it will be more certain still, if no signs of resolution have appeared, or if an expectoration which had appeared shall have again ceased, and the difficulty of breathing has continued or increased, while the other symptoms have been rather abated.

That in a pneumonia, the effusion is made which may lay the foundation of a suppuration, may be concluded from the difficulty of breathing becoming greater when the patient is in a horizontal posture, or when the patient can lie more easily on the affected side. That, in such cases, a suppuration is actually begun, may be inferred from the patient's being frequently affected with flight cold shiverings, and with a sense of cold felt sometimes in one sometimes in another part of the body. We form the same conclusion also from the state of the pulse, which is commonly less frequent and softer, but sometimes quicker than before. That a suppuration, is already formed, may be inferred from there being a considerable remission of the pain which had before subsisted; while with this the cough especially the dilacée continue, and are rather increased. At the same time the frequency of the pulse is rather increased, the feverish state fullers considerable exacerbations every evening, and by degrees a hectic fever in all its circumstances comes to be formed.

In this state of symptoms, we conclude very confidently, that an abscess, or, as it is called, a vomica, is formed in some part of the pleura, and most frequently in that portion of it involving the lungs. Here purulent matter frequently remains for some time, as if enclosed in a cyst; but commonly not long before it comes to be either absorbed and transferred to some other part of the body, or breaks through into the cavity of the lungs, or into that of the thorax. In the latter case it produces the dilacée called empyema, but it is when the matter is poured into the cavity of the bronchiae that it properly constitutes the phthisis pulmonalis. In the case of empyema, the chief circumstances of a phthisis are indeed also present: but we shall here consider only that case in which the abscess of the lungs gives occasion to a purulent expectoration.

An abscess of the lungs, in consequence of pneumonia, is not always followed by a phthisis; for sometimes a hectic fever is not formed; the matter poured into the bronchiae is a proper and benign pus, which frequently is coughed up very readily, and spat out; and though this purulent expectoration should continue for some time, if it be without hectic fever, the ulcer soon heals, and every morbid symptom disappears.

This has so frequently happened, that we may conclude, that neither the access of the air, nor the constant motion of the lungs, will prevent an ulcer of these parts from healing if the matter of it be well conditioned. An abscess of the lungs, therefore, does not necessarily produce the phthisis pulmonalis; and if it be followed by such a dilacée, it must be in consequence of particular circumstances which corrupt the purulent matter produced, render it unfit for the healing of the ulcer, and at the same time make it afford an acrimony, which, absorbed, produces a hectic fever and its consequences.

The corruption of the matter of such abscesses may be owing to several causes; as, 1. That the matter effused during the inflammation had not been a pure serum fit to be converted into a laudable pus, but had been joined with other matters which prevented that and gave a considerable acrimony to the whole. Or 2. That the matter effused and converted into pus, merely by long flagination in a vomica, or by its connection with an empyema, had been so corrupted as to become unfit for the purpose of pus in the healing of the ulcer. Thence seem to be possible causes of the corruption of matter in abscesses, so as to make it the occasion of a phthisis in persons otherwise found; but it is probable that a pneumatic abscess especially produces phthisis when it happens to persons previously disposed to that dilacée, and therefore only as concurring with some other causes of it.

3. The third cause suppos’d to produce a phthisis is a catarrh; which, in many cases, seems in length of time to have the expectation of mucus proper to it gradually changed to an expectoration of pus; and at the same time by the addition of a hectic fever, the dilacée which was at first a pure catarrh, is changed into a phthisis. But this supposition is, in the opinion of least of some physicians, liable to several difficulties. The catarrh is properly an affection of the mucous glands of the trachea and bronchiae analogous to the coryza and less violent kinds of cypanche tonsillaris, which very seldom end in suppuration. And although a catarrh should be disposed to do so, the ulcer produced might readily heal up, as it does in the case of a cypanche tonsillaris; and therefore should not produce a phthisis.

Further, he catarrh, as purely the effect of cold, is generally a mild dilacée as well as of short duration; and, according to Dr Cullen, there are at meath but very few of the numerous cases of it, which can be said.
to have ended in a phthisis. In all these cases in which this seems to have happened, he thinks it probable that the persons affected were peculiarly predisposed to phthisis; and the beginning of phthisis is often resembles a catarrh, that it may have been mistaken for such a disease. It often happens also, to increase the fallacy, that the application of cold, which is the most frequent cause of catarrh, is also frequently the exciting cause of the cough, which proves to be the beginning of a phthisis.

Many physicians have supposed that an acrimony of the fluids eroding some of the vessels of the lungs is a frequent cause of ulceration and phthisis; but this appears to Dr Cullen to be a mere supposition. He acknowledges, that in many cases an acrimony subsisting in some part of the fluids is the cause of the disease; but observes that it is at the same time probable, that this acrimony operates by producing tubercles, rather than by any direct erosion.

But notwithstanding these objections, experience affords numerous examples of cases in which a disease long subsisting under the form of catarrh has at last degenerated into phthisis, and proved fatal from subsisting long hectic fever. To this must, however, at the same time be allowed, that catarrh, degenerating into a chronic state after subsisting for many years, has itself often proved fatal without inducing phthisis.

4. If phthisis does not frequently follow catarrh, it is still more rarely a consequence of asthma. Innumerable examples are unquestionably afforded of that disease subsisting for many years without any symptom whatever of phthisis as a consequence of it. But at the same time, there are unquestionable examples of phthisis deriving its origin from asthma; which, however, probably happens only in cases where a peculiar state of the lungs at the same time takes place: But without the concurrence of asthma, this state would not of itself have been sufficient for inducing the affection.

5. Of all the causes formerly mentioned, phthisis most frequently arises from tubercles. Dr Simmons informs us, that he has had opportunities of inspecting the bodies of many people who died in this way, and never found them totally abstinent. He has likewise seen them in subjects of different ages, who had been troubled with no symptoms of an affection of the breath during their lifetime. In these, however, they were small, and few in number. This proves that they may exist without inconvenience till they begin to disturb the functions of the lungs by their size and number; or till some degree of inflammation be excited, either by accidental causes, or by certain changes that take place within their substance; for as yet we know but little of their true nature. These little tumors vary in their consistence; in some they are composed of a pulpy substance, and in others approach more to the nature of fibrous. They are most commonly formed in consequence of a certain constitutional predisposition; but whatever is capable of occasioning a morbid irritability of the lungs seems also to be capable of generating them. Thus the spasmodic asthma frequently ends in tubercles and consumption; and it is not unusual for millers, stone-cutters, and others, to die consumptive, from their being constantly exposed to dust, which in these cases probably acts by producing similar concretions; and Dr Kirkland observes, that the grinders rot-tubercles, however, in by much the greater number of instances, have their source from a scrophulous disposition; and some eminent physicians have supposed that the generality of pulmonary consumptions are of this kind. This notion, however, they have perhaps carried too far: they have probably been misled by these tuberculous concretions which, without good reason, have been supposed to be diseased glands, and of course analogous to the glandular affections we meet with in the scrophula. Tubercles may likewise sometimes be owing to the sudden repulsion of cutaneous eruptions, or of the matter of exanthemata, &c. or to other causes.

The persons who are most liable to consumption are those of a fair complexion, fine and soft skin, florid cheeks, and a slender make; with high cheek-bones, hollow temples, long neck, shoulders standing out like wings, narrow chest, and a remarkable prominence of the processes of the os sacrum. To these marks we may add, that of found teeth, which, as the disease advances, usually become of a milky white colour, and more or less transparent. Of those who are carried off by this disease, Dr Simmons afferts, the greater number will be found never to have had a carious tooth. This circumstance, however, does not seem to us to hold so generally as Dr Simmons is disposed to imagine; and instances not unfrequently occur of patients dying of phthisis, although they have had many teeth subjected to caries; and some of these beginning even at an early period of life.

Perons of the above description often remain for a long time without feeling any other inconvenience than some oppression at the breast in moist weather, or in hot apartments. Their breathing is easily hurried, sometimes by the slightest motion; and they become languid, paler, and thinner. All this time, however, they feel no heat or painful sensation in the breast. As the evil increases, the patient begins to be attacked with a flight, frequent, and dry cough, which is most troublesome in the night-time. But this, by proper care, is often relieved; and the patient remains in this state for a considerable time, and even for many years, if he be sensible of his danger, and careful to guard against it by a suitable manner of living. More commonly, however, we find the cough increas'd, and sometimes accompanied with more or less catarrh. This is usually ascribed to cold; and but too generally neglected, till the disease become alarming by its obstinacy and its effects. This may be considered as the beginning, or first period, of the disease. During this stage, the cough is sometimes dry from the first; and sometimes, when it begins in the form of a catarrh, is attended with more or less expectoration of mucus.

When the cough begins in the form of a catarrh, and appears to be occasioned by an increased secretion of a thin faltih mucus irritating the membrane of the trachea, all judicious practitioners agree in recommending an attention to regimen, the free use of diluting liquors, bland emulsions, small doses of nitre, the taking away a few ounces of blood if there be much in
inflammation, the inhaling the steam of warm water by means of the machine contrived for that purpose, and occasional use of such a dose of elixir paregoricum as, will be sufficient to allay the irritation of the bronchial, and to promote a gentle moisture on the skin. These methods will generally be found to be efficacious, especially if the patient's chamber be of a moderate temperature, and he carefully avoid exposure to a cold, damp, or raw air, till the complaint be removed. In cafes in which the cough has been obstinate, and the inflammatory symptoms considerable, Dr Simmons has often experienced the great advantages of the warm bath, the heat of which did not exceed 92. When this is had recourse to, the patient should remain in it only a very few minutes, and go soon afterwards to bed; but not with a view to force sweat by an increased weight of bed-clothes, as is too often injudiciously practised.

Patients of a consumptive habit, who have had an attack of this kind at the beginning of winter, are particularly liable to a return of the complaint during the continuance of the cold season, on the slightest occasion and with greater violence. A relapse is therefore to be carefully guarded against; and nothing will be found to do this more effectually than the use of foots and a flannel under-waiftcoat. The use of flannel has been condemned by several medical writers as increasing the infeebil temperature; but in the present cafe, to say nothing of some others in which it may be useful, it will in general be found to have the best effects. It will prevent a too great determination to the lungs, and should not be left off till the approach of summer. In some feve infancies in which flannel was found to have a disagreeable effect, a piece of dimity, worn over the breast next the skin, prevented the return of colds and coughs in persons of a delicate habit, who had before been liable to them on the slightest occasions. Shirts made of cotton cloth are much more effectual than linen in preserving an equable temperature of the surface, and guarding against the action of external cold; while at the same time they are much more pleasant to most people than even the finest flannel. In these cases, circumstances that are seemingly of the most trivial nature become of importance.

Sometimes the cough is occasioned by an immediate inflammation of some part of the lungs, from some of the usual causes of inflammation; and when this happens no time is to be lost in removing it. To do this will perhaps require more than one bleeding, together with a strict attention to a cooling plan of diet diluting drinks, the inhalation of warm items, and if convenient the use of the warm bath: but above all, the speedy application of a large blister as near as may be to the supposed seat of the inflammation. The cough, in this cafe, will often remain after the original complaint is abated. A prudent use of opiates at bed-time, either by themselves or combined with gummy and mucilaginous medicines, will then generally be used as a sedative and antispasmodic.

In this, as well as in the catarrhal cough just now mentioned, many practitioners are too eager to administer the Peruvian bark, with the view, as they term it, of bracing the patient: but this never fails to increase the cough, and of course to do great and very often irreparable mischief.

And here it will not be foreign to our subject to observe, that a symptomatic cough, which has its rise not from catarrh or from an immediate inflammation of the lungs, but from their sympathy with the stomach, has sometimes laid the foundation of phthisis, from its being miftaken, and of course improperly treated. It seems to be owing to a redundancy or vitiated state of the bile or to some affection of the stomach, which it is perhaps not easy to define. It is sometimes a concomitant of other bilious symptoms; and when this happens to be the cafe, it cannot easily be mistaken, but we sometimes find it occurring fingly, and in general attacking persons of a sedentary life. Dr Stoll of Vienna, who has noticed this cough, has very properly given it the name of tussis flumachiæ. This complaint is so far from being relieved by bleeding, that it constantly grows worse after it, especially if the evacuation be in any considerable quantity. The oily medicines seldom fail to exasperate this cough, which at first is dry, frequent, and often extremely violent, but which seldom fails to give way to one or two gentle pukes, and the occasional use of mild cathartics. The cough, in other cafes, often continues from habit after the cause that gave rise to it has been removed, and may then be checked by opiates.

When the disease has been neglected, or our attempts to remove it in the beginning have failed, both of which circumstances but too frequently happen, the patient begins to complain of a looseness, of the face, which usually accompanies the beginning of the disease, to which succeeds the supplicative stage. In the latter, the expectoration becomes more copious and purulent, the breath proportionably offensive, and the exacerbations of the hectic fever more considerable: an increased quinckeus of the pulse comes on about the middle of the day; but the most considerable paroxysm of the fever is at night, and at first continues till towards morning, commonly till three or four o'clock, when it terminates in a sweat, which usually begins upon the breast. As the disease advances, these sweats become more profuse, and some times come on almost as soon as the pulse begins to quicken, but without affording any relief to the patient. During the exacerbations, we observe a circumflibed redness of the cheeks, while the rest of the face is pale, and appears as if it were not clean washed. The colic which commonly accompanies the beginning of the disease is usually succeeded by a diarrhea; the spitting lefens and
and all the putrid matter seems to be carried downwards. The walking of the fat, and the loss of nourishment occasion the nails to curve inwards, the hair to fall off, and the eyes to sink in their sockets. In the mean time, the legs commonly swell; till at length death closes a scene which is melancholy to all but the patient himself, who in general continues sensible to the last moment, and even then indulges a vain hope of prolonging a miserable existence. In some cases, and that not unfrequently, a delirium comes on towards the close of the disease.

The hectic fever that attends this and some other chronic diseases is evidently the effect of acrimony, and most commonly of pus absorbed and carried into the circulation. The nature of this acrimony, and the different irritability of different patients, are probably the sources of the variety we observe in fevers of this denomination; a variety which is doubtless much greater than we are aware of. Thus we find that the matter of the small-pox excites a fever and the different irritability of different individuals who are placed in different circumstances; nor does the latter correspond with that which sometimes accompanies the suppuration of a cancerous ulcer. In the pulmonary consumption, or at least in the third stage of it, the fever induced often appears to be of the putrid kind, and has been denominated fœbris hætica parvîa by the judicious Morton, who considers it as being combined with a peripneumonic or inflammatory fever, which recur so often as fresh tubercles begin to inflame. For although we have named one period of the disease the inflammatory, and another the suppurative period, yet we are not to suppose that the latter is exempt from inflammation. While matter is poured into the bronchies, or absorbed and carried into the system from one part of the lungs, other parts are in a crude state of inflammation, or advancing towards suppuration; so that, on examining the lungs of persons who die consumptive, we find some tubercles that are small and just formed, some that are large and full of matter, and others that are in a state of ulceration. This easily accounts for the occasional combination of inflammatory symptoms with those of the putrid hectic. When the matter absorbed is a laudable pus, as in the case of a pinæ abscess, we find the form of the hectic fever differing from either of those we have mentioned.

Cure. In these different periods of the disease, the curative indications are sufficiently obvious. To prevent the formation of fresh tubercles; to obviate the inflammation of those already formed; to promote their resolution; to allay morbid irritability, the cough, and other troublesome symptoms; and, above all, to check the tendency to the hectic state, are the views that every rational physician propounds to himself in the treatment of the genuine consumption. We know of no medicines that can exert their specific effects upon the lungs by dissolving tuberculous concretions; nor is it probable, from what we know of the animal economy, that any such will ever be discovered. Yet medicines that operate in a general manner upon the system, may, by promoting absorption, and diminishing the determination to the lungs, tend to diffuse tubercles, or to prevent their formation. There are not wanting instances of wonderful recoveries in cases where the evil was supposed to be beyond the power of physic; and in some, where nature was left to herself; so that a physician who has observed the various and powerful resources nature has within herself, will be very cautious how he afferts that a disease is incurable.

The most fruitful effects of ulcerated lungs are the absorption and consequent hectic. It seems evident, that, in many cases, death is brought on by this, rather than by the lungs themselves being rendered unfit for the purposes of respiration. So that if we can obviate the effects of the absorption, diminish the preternatural determination to the lungs, and fill up the other general indications just now mentioned, we may very often enable nature to recover herself. It may be alleged indeed, that the physician’s art has hitherto proved very unsuccessful in these cases; but may not this be owing to the remedies that are employed being very often such as are inimical to the cure.

The Peruvian bark is, perhaps, the most commonly employed of any, and often confided in as an ultimate resource in consumption cases. But besides this, the elixir of virioll, the balsams, and frequent bleedings, have each had their partizans. The use of blisters and infusions, opiates, a milk and vegetable diet, exercise, and change of air, are pretty generally recommended by all. Concerning the bark, Default long ago observed, that it had been productive of great mischief in consumptive cases; and Dr Fothergill, in a paper lately published by him on this subject, very judiciously remarks, that the bark is so far from curing the hectic fever arising from diseased lungs, that according to the best of his observations, it not only takes up that time which might probably have been better employed in the use of other medicines, but for the most part aggravates the disease beyond remedy. Indeed it has been the opinion of several attentive observers, that, whenever pus or any kind of matter excites an hectic fever, by being absorbed and carried into the circulation, the Peruvian bark will never fail to exasperate the complaint, especially if it be accompanied with any degree of inflammatory diathesis, unless the matter has a free outlet from the system; as in the case of abscesses, for instance, in which we often find the bark productive of excellent effects. It is likewise well known to be used as a tonic, to obviate the effects of fluor albus, or any other immediate evacuation in delicate persons, which, by enfeebbling the system, very often lays the foundation of phthisis; but the moment we have reason to suspect that the lungs are ulcerated, especially if this ulceration be attended with an inflammatory disposition; or if the separation of vitiated pus be the consequence of a peculiar increased morbid action of the vessels at the part, it ought to be laid aside; and in the genuine tuberculous consumption, perhaps it is at all times inadmissible.

Dr Fothergill, however, observes, that there are two causes of consumption, which often produce symptoms similar to those of the genuine phthisis, as sometimes to have misled him to make use of the bark in apparent tendencies to a genuine pulmonary consumption with advantage.

One of these causes is, the suckling of children longer than is consistent with the mother’s ability. This
Phthisis.

Practice.

Hemorhagia.

This case frequently occurs among the middling and lower classes of females of constitutions naturally delicate and tender. In such a state of weakness, some slight cold brings on a cough, which increases gradually, till at length it produces the true pulmonary consumption. Here the bark given early, in moderate doses, and merely as a tonic remedy, is often of excellent use.

Another cause is, any weakening discharge, either from abscences, the greater operations of surgery, a copious and constant flor albus, or similar ensuing evacuations. That the bark is, for the most part, of use in these cases, when the lungs are not inflamed, is indubitable; and if they be so affected, but not beyond a certain degree, it is also efficacious in preventing the progress of the consumption.

In phthisical complaints succeeding such situations, a prudent trial of the bark seems necessary. Small doses of the decoction, either alone, or joined with the saline mixture or such other additions as the physician thinks proper, may be given. But if the breath becomes more tight and dry, the pulse more quick and hard, and especially if flight traumato pains or fitches about the throat are more frequently complained of, a perseverance in the use of the bark will increase the difficulty. If this also should be the appearances in the progress of the disease, or, from whatever cause, if the bark be accompanied with such effects, the use of it ought to be withheld.

If, on the other hand, no pain, tightness, or oppression is perceived, and there appears a manifest abatement of the symptoms, it will be advisable to proceed. The administration of this medicine, however, requires a judicious observer; and it ought neither to be given in the early inflammatory stage of the disease, nor be continued in any subsequent period, if it produce the effects above-mentioned.

By its tonic virtues it will often enable nature to conquer many difficulties. In confirmation of this remark, Dr Eatherall further observes, that he has seen it of use in promoting expectoration, when this became deficient from want of strength towards the end of peripneumonic fevers; but that if it stops this discharge, changes flight wandering pains into such as are fixed, and increases them with all their consequences, in a variety of cases.

The elixir of vitriol, or the pure vitriolic acid properly diluted, though in many instances a highly useful remedy, is often exhibited in consumptive cases with no less impropriety than the bark. This medicine, from its alteregy, is obviously improper in the inflammatory stage of the disease. But in the latter stage, when a general tendency to putrefaction takes place, it is serviceable in retarding the effect; it restrains the colliquitive sweats; and if the lungs be not injured past reparation, it is allowed to be a very useful auxiliary.

Various are the opinions concerning the efficacy of Britol-water in this disease. The experienced author last mentioned informs us, that he has seen many persons recover from pulmonary diseases after drinking these waters, whose cure seemed to be doubtful from any other process; and he thinks this circumstance, added to the general reputation of Britol-waters in phthisical cases, affords sufficient inducement to recommend the trial of them in the early stages of such complaints. It is, however, before the approach of a confirmed phthisis that patients ought to repair to Britol; otherwile a journey thither will not only be without benefit, but may even prove detrimental.

Some have imagined, that the journey, a better air, change of situation and of objects, have contributed to the patient's recovery; and these may doubtless be of advantage. It seems, however, that the water drank fresh at the pump, actually contains principles conducive to the recovery of patients affected with phthisical complaints. It seems to poetles a flight calcareous, diphthletic, and perhaps the air it contains may also have an antiseptic quality. On the whole, it appears to be an efficacious medicine, and is often found of remarkable benefit to consumptive patients.

Change of air, particularly from good to bad, is of great consequence in all chronic diseases of the lungs. In consumptive cases, the air of all large cities is found to be particularly injurious.

A sea-voyage has been much recommended in the cure of this disease. The benefit of exercise has also been strongly urged by many writers; but, however falutary when properly used, it certainly ought to be regulated with discretion. Dr Dickson declares himself of opinion, that riding on horseback in consumptive cases is most commonly hurtful, without such regulations as in general have been little regarded. For instance, he has known a person who, by a ride of an hour or two in the morning, was very much recruited, and who, at another time, in the afternoon and evening, without undergoing more bodily motion, has returned faint and languid, and apparently worse. This observation on the same person has been so frequently made, as to point out clearly the times when this exercise shall not do hurt in consumptive cases. In this disease, the pulse, however calm in the morning, becomes more frequent in the afternoon and night, attended with heat and other feverish symptoms. Exercise therefore at this time, can only add to the mischief of the fever. For this reason he prudently recommends to all hectic persons, especially those who shall travel to distant places on account of a better air, or the benefit expected from any particular water, that their travelling should be slow, confined to a very few hours, and only in the morning.

Exercise on horse-back seems to be chiefly beneficial in those cases where consumption is a secondary disease. For example, in the nervous atrophy; in the hypochondriacal consumption; or when it is the effect of long continued intermittents, or of congestions in any of the abdominal viscera; or, in a word, whenever the consumption is not attended with an inflamed or ulcerated state of the lungs; long journeys on horseback will be beneficial. Such a practice may likewise be highly useful in obviating an attack of phthisis, or in carrying off a dry husky cough in a person of a consumptive habit, when there is reason to suppose that no tubercles are as yet formed. On the other hand, in the confirmed phthisis, when the lungs are inflamed or ulcerated, much or violent exercise will be improper; and there have been instances where the death of the patient was evidently accelerated by
The exercise therefore should be gentle, proportioned to the strength of the patient, and employed only in the morning. In fine weather, an easy open carriage is perhaps the most eligible, not only on account of its being open to the air, but because it affords that kind of agitation which is most wanted in these cases. For if we consider the different modes of exercise, we shall find that walking, though the best exercise in health, as it employs the most muscles, is the worst for the sickly, who should have the benefit of exercise without fatigue. Riding on horseback agitates the viscera more than walking, and is therefore preferable to it in many chronic diseases; but when a preternatural determination to the lungs has taken place; it will be liable to increase the evil, and may likewise be hurtful by the fatigue that attends it. For these reasons it will be prudent to begin with a carriage; and if the patient gain strength, and the disease abates, recourse may afterwards be had to horse-exercise.

The gentle motion of a coach has been often found of great utility in pulmonary complaints. Its efficacy seems to depend chiefly on its increasing the determination to the surface of the body. The nausea which this motion excites in some persons is an effect of this increased determination. It has therefore been found beneficial in hemorrhys; and Dr Simmons mentions the case of a lady, who, after trying various remedies to no purpose, was cured of this complaint by travelling several hundred miles through different parts of England in her own coach. At first, whenever she tarried three or four days in any place, the disorder began to return again; but at length by persevering in her journeys, it gradually went off. Default, who practiced at Bordeaux about 40 years ago, tells us, he sent several consumptive patients to Bareges, and with good success; but that in these cases his reliance was not so much upon the Bareges waters, as upon the motion of the carriage and the change of air in a journey of more than 100 leagues.

It is now pretty generally acknowledged, that the good effects of sea-voyages in consumptive cases depend more upon the constant and uniform motion of the ship, than upon any particular impregnation of the sea-air; although this from its coolness and purity may likewise be of great use, especially in the hot months, when sea-voyages are generally undertaken by consumptive patients. The ancients were no strangers to this remedy; and amongst the Romans it was no unusual thing for consumptive persons to sail to Egypt. Pliny observes, that this was done not for the sake of the climate, but merely on account of the length of the voyage.

Many of the English physicians have recommended a voyage to Liben in these cases. When this is done, the proper season of the year should be carefully attended to. Dr Simmons knew a gentleman who went thither with symptoms of incipient phthisis, and who experienced some relief during the course of the voyage; but happening to arrive at Liben at the beginning of a rainy season, the patient died, his cough greatly increased, and terminated fatally.

Another species of motion has of late been extolled as highly useful in consumptive cases. Dr James Carmichael Smyth of London, has lately published an account of the effects of swinging, employed as a remedy in the pulmonary consumption and hectic fever. In this treatise Dr Smyth contends, that sea-air, in place of being of advantage is constantly prejudicial to hectic and consumptive patients, and even to those who have a tendency to such complaints. He thinks, therefore, that the benefit derived from sea-voyages must certainly be referred to some other cause. In flattering his sentiments on this subject, he attempts to establish a distinction between exercise and motion. By exercise, he understands muscular action, or the exertion of the loco-motive powers of the body either alone or combined. This he represents as increasing the force and frequency of the heart's contraction, the velocity and momentum of the blood, the quickness of breathing, the heat, the irritability, and the transpiration of the whole body. By motion, in contradistinction to exercise, he means such motion as is not necessarily accompanied with any agitation or excitation of the body, and which is totally independent of any muscular exertion. The effects of this, both on the heart, the lungs, and indeed on the system in general, he considers as of the sedative kind; thus it subsists the action of coughing, and lessens the frequency of the pulse. He is, therefore, led to refer the good effects of sea-voyages entirely to this cause. And on these grounds he was led to conclude, that the motion given by swinging might be of equal if not greater service. This conclusion, we are told, in the treatise above alluded to, experience in many cases has fully confirmed. And he recommends it as a mode of cure which may be employed with advantage in every stage of phthisis. While, however, the reasoning of Dr Smith on this subject seems to be liable to many objections, we are sorry to add, that his observations in practice have by no means been confirmed by those of others, who have had recourse to this mode of cure.

The best adapted diet in consumptive cases is milk, particularly that of calves. It may however be remarked, that there are constitutions in which this salutary nutriment seems to disagree. A propensity to generate bile, or too strong a disposition to acidity from a weakness of the digestive organs, both merit attention. Whey, either from cows or goat's milk, appears to be more salutary in the former case; and for correcting acidity, lime-water may be added to milk. The method of adding rum or brandy to calves or cow's milk, should be used with great caution; for when added beyond a certain quantity, as is often the case, they not only congeal the milk, but heat the body; by which means the former disagrees with the patient, and the spirit augments the disease.

In consumptive cases, Dr Simmons observes, that the patient's table should be consulted; and says that a moderate use of animal food, where the falted and high-seasoned kinds are avoided, is not to be denied. Shell-fish, particularly oysters, are useful as well as finals swallowed whole, or boiled in milk.

Repeated bleedings, in small quantities, are considered in consumptive cases as highly advantageous; and in particular circumstances they undoubtedly are so; for instance, when the constitution apparently abounds with blood; when the fluid drawn off is extremely fizy; when there is much pain in the breast; and
and when venefaction is followed by an abatement of every symptom. In these cases, bleeding is certainly proper, and ought to be repeated so long as it seems to be attended with advantage. In very delicate constitutions, however, even where the pulse is quick, with some degree of fulness, and the blood last drawn considerably fizy, it may not prove equally serviceable.

It deserves to be remarked, that the inflammatory appearance of the blood is not alone a sufficient reason for bleeding; but, in determining the propriety of this evacuation, all other circumstances should be considered; such as the patient's age, strength, habit, and the state of the diseased.

A remark which has been judiciously made by Dr Fothergill, ought not to be omitted in the account of this disease. It is, that young delicate females, from the age of 15 or 16, and upwards, are often subject to consumptions. When the disease has advanced considerably, the medicines have sometimes been administered, which, without obtaining this end, have tended to aggravate the dislemer. This deficiency is often of no real disadvantage in those cases; and in many the evacuation would prove injurious, by diminishing the strength, which is already too much impaired. Even small bleedings at the regular periods have often done more harm than good. A sudden supression may require bleeding; but when the evacuation fails through want of strength, and from poverty of blood, the renewal of it increases the disease.

Besides these remedies, Dr Simmons strongly recommends a frequent repetition of vomits. Many physicians have supposed, that where there is any increased determination to the lungs, vomits do mischief; but Dr Simmons is persuaded, that instead of augmenting they diminish this determination; and that much good may be expected from a prudent use of this remedy, than which none has a more general or powerful effect on the system. If any remedy be capable of dispersing a tubercle, he believes it to be vomits. The affections of the liver, that sometimes accompany pulmonary complaints, give way to repeated emetics sooner than to any other remedy. In several cases where the cough was expectorated, the flushing heats, loss of appetite, and other symptoms, threatened the most fatal event; the complaints were greatly relieved, and in others wholly removed, by the frequent use of emetics. Other suitable remedies were indeed employed at the same time; but the relief the patients generally experienced after the emetic, was a sufficient proof of its salutary operation. By this, however, he does not mean that vomits will be useful in every period of the disease, or in every patient. In general, it will be found that the earlier in the disease emetics are had recourse to, the more likely they will be to do good and the less likely to do harm. The cafes in which emetics may be reckoned improper, are commonly those in which the disease is rapid in its progress; or in that stage of it when there is great delicacy, with profuse colloquative sweat.

In these cases, when an emetic has been administered twice a-week, and the cough is mitigated, the evacuation facilitated, and the other symptoms relieved, both the patient and the physician will be encouraged to proceed, and to repeat the vomit every second day, or even every day, for several days together, as Dr Simmons has sometimes done when the good effects of it were obvious.

The choice of emetics to be employed in these cases is by no means a matter of indifference. Carduus tea, camomile tea, warm water, and others that act by their bulk, and by exciting nausea, relax the tone of the stomach when they are frequently repeated, and of course will be improper. More active emetics are therefore to be preferred; and here some of the preparations of antimony might naturally be thought of. But the operation of these is not confined to the stomach. They produce evacuations by food, and a defquamation of the lungs; and are therefore improper in the pulmonary hectic. The mildness and excellence of ipecacuana as an emetic, are well known; but in these cases, Dr Simmons has often employed the blue vitriol and the emetic distempers.

More active emetics are therefore to be preferred; and here some of the preparations of antimony might naturally be thought of. But the operation of these is not confined to the stomach. They produce evacuations by food, and a desquamation of the lungs; and are therefore improper in the pulmonary hectic. The mildness and excellence of ipecacuana as an emetic, are well known; but in these cases, Dr Simmons has often employed the blue vitriol and the emetic distempers.

Another remedy which Dr Simmons strongly recommends in consumptive cases, both from his own observation and on the authority of many other eminent practitioners is gum myrrh. This given by itself to the extent of a scruple or half a dram for a dose, two or three times a-day, or, if there be much inflammatory tendency, combined with a proportion of nitre or of cream of tartar, has often been serviceable.
able in cases which were apparently instances of incipient phthisis even of the tuberculous kind. But when the disease is far advanced, or even decidedly marked, as far as our experience goes it has rarely if ever been productive of any benefit.

Besides the use of internal remedies in pulmonary affections, physicians have often prescribed the fumes of resinous and balsamic substances to be conveyed into the lungs. The vapour of dulcified spirit of vitriol, dropped into warm water, has likewise been used in these cases, and is advertised as a nostrum under the name of ether. The inhaling of fixed air has also been spoken of as an useful practice. Dr. Simmons has seen all of these methods tried at different times; but without being able to perceive any real advantages from them in the suppurative stage of the disease, where they might be expected to be of the greatest use; and in the beginning he has often found the two first to be too stimulating. He therefore preferred the simple vapour of warm water, and has experienced its excellent effects in several instances; but when the complaint has made any considerable progress, its utility is less obvious; and when the patients have been much weakened, he has seen it bring on profuse sweats, especially when used in bed, and therefore generally recommended it to be used in the daytime. Formerly he made use of a fumigating machine, described in the Gentleman's Magazine for 1748, in which the air, inspired by the patient, is made to pass through hot water by means of a tube that communicates with the external air, and with the bottom of the vessel: but we have now a more elegant and (on account of the valve and mouth-piece) a more useful instrument of this kind, the inhaler, invented by the ingenious Dr. Mudge.

Another remedy recommended by some as a specific in consumptions is the earth-bath. Van Swieten, in his Commentaries on Boerhaave, tells us, from the information of a person of credit, that in some parts of Spain they have a method of curing the phthisis pulmonary by the use of this remedy; and he quotes the celebrated Solano de Laque in confirmation of this practice. Solano speaks of the "baños de tierra," or earth-baths, as a very old and common remedy in Granada and some parts of Andalusia; in cases of hectic fever and consumptions; and relates several instances of their good effects in his own practice. The method he adopted on these occasions was as follows: He chose a spot of ground on which no plants had been fown, and there he made a hole large and deep enough to admit the patient up to the chin. The interior of the pit were then carefully filled up with the fresh mould, so that the earth might everywhere come in contact with the patient's body. In this situation the patient was suffered to remain till he began to shiver or felt himself uneasy; and during the whole process, Solano occasionally administered food or some cordial medicine. The patient was then taken out, and, after being wrapped in a linen cloth, was placed upon a matras, and two hours afterwards his whole body was rubbed with an ointment, composed of the leaves of the jujnum nigricum and hog's lard. He observes, that a new pit must be made every time the operation is repeated; and advices the use of these baths only from the end of May to the end of October.

Dr. Fouquet, an ingenious French physician, has tried this remedy in two cases. In one, a confirmed phthisis, he was unsuccessful; but the remedy had not a fair trial. The patient, a man 50 years of age, had been for several months afflicted with cough, hectic fever, and profuse colliquative sweats. He was first put into the earth in the month of June; but soon complained of an uneasy oppression at his stomack, and was removed at the end of seven minutes. The second time he was able to remain in it half an hour, and when taken out was treated in the way prescribed by Solano. In this manner the baths were repeated five times, and the patient was evidently relieved; but having conceived a dislike to the procés, he refused to submit to any further trials, and died some months afterwards. In the second case he was more fortunate: the patient, a girl 11 years of age, had been for three months troubled with a cough brought on by the measles, which was at length attended with a purulent expectoration, hectic fever, and night-sweats. She began the use of the earth-bath in August, and repeated it eight times in the space of 20 days. At the end of that time the fever and disposition to sweat had entirely ceased, and by the use of the common remedies the patient was perfectly restored. A physician at Warsaw has likewise prescribed the earth-bath with good success in cases of hectic fever. The Spaniards confine it entirely to such cases; but in some other parts of the world we find a similar method employed as a remedy for other diseases, and particularly for the sea-scurvy. Dr. Priestley observes, that the Indians, he has been told, have a custom of burying their patients labouring under putrid diseases up to the chin in fresh mould, which is also known to take off the feator from flesh-meat beginning to putrify. The racioidity of a ham for example, may be corrected by burying it for a few hours in the earth. The efficacy of this remedy in the sea-scurvy has, it is said, frequently been experienced by the crews of East India ships.

Solano, who is fond of philosophizing in his writings, is of opinion, that the earth applied in this way absorbs the morbid taint from the system; but does not seem more probable, that the effe&s of the earth, by being absorbed and carried into the circulation, corrects the morbid state of the fluids, and thus are equally useful in the fea-scurvy and in the pulmonary hectic. That the earth when moistened does emit a grateful odour is a fact generally known; and Baglivi long ago gave his testimony in favour of the grateful effects of the effluvia of fresh earth. He ascribes these good effects to the nitre it contains.

The earth-bath, both in consumptive cafes and likewise in a variety of other affections, has of late been extensively employed in Britain by a celebrated empiric. But, as far as we can learn, in most cafes it produced to the patient a very distressing sensation of cold; in some, it seemed to be productive of bad effects, probably in consequence of this cold; and we have not heard of any consumptive cases in which good effects were decidedly obtained from it.

With regard to the drains, such as blisters, ifusses, and fotons, that are so frequently recommended in pulmonary complaints, there is least danger of abuse from them than from the practice of venfication. The discharge they excite is not calculated to weaken the patient.
tient much; and the relief they have so often been found to afford, is a sufficient reason for giving them a trial. Blisters, as is well known, act in a twofold manner; by obviating pain, and producing resolution: Iffues and setons act chiefly in the latter of these two ways; and in this respect their effects, though not sudden and not powerful at first, are more durable from the continuance of the discharge they occasion. It is perhaps hardly necessary to remark, that, if much service is to be expected from either of these remedies, they should be applied early in the disease. The ingenious Dr Mudge, who experienced the good effects of a large scapulary iffue on his own perfon, very properly observes, that the discharge in these cases ought to be considerable enough to be felt. But it is seldom possible for us to prevail on the delicate persons, who are most frequently the victims of this disease, to submit to the application of a cautery between the shoul- ders. The discharge produced by a seton is by no means incon siderable; and as in these cases there is generally some inflammatory fitch, some part of the breath that is more painful or more affected by a deep inspiration than the rest, a seton in the fide, as near as can be to the seat of the inflammation, will be an useful auxiliary. Dr Simmons has seen it evidently of great use in several cafes.

**Description.** The discharge of blood from small tumors on the verge of the anus constitutes what is called the hæmorrhoides or piles. They are distinguished into the external and internal, according to the situation of the tumors, either without or within the anus. Sometimes, however, these tumors appear without discharging any blood; and in this case they are called the hæmorrhoides inae or blind piles. Sometimes the disease appears without the verge of the anus in dilated separate tumors; but frequently only one tumid ring appears, seeming as it were the anus pushed without the body. Sometimes these tumors appear without any previous disorder of the body; but more frequently, before the tumors are formed and sometimes even before the blood begins to flow, various affections are perceived in different parts of the body; as head-ache, vertigo, flufor, difficulty of breathing, fickness, colic pains, pain of the back and loins, and frequently a considerable degree of pyrexia; while along with these symptoms there is a tene of fullness, heat, itching, and pain in and about the anus. Sometimes the disease is preceded by a ferosus discharge from the anus; and sometimes this ferosus discharge, accompanied with swelling, seems to come in place of the discharge of blood, and to relieve the abovementioned disorders of the syslem. This ferosus discharge hath therefore been named the hæmorrhoides albus.

In this disease the quantity of blood discharged is different upon different occasions. Sometimes it flows only when the perfon goes to stool, and commonly follows the discharge of faces. In other cafes it flows without any discharge of faces; and then generally in confequence of the disorders abovementioned, when it is alfo commonly in larger quantity. This is often very considerable; and, by the repetition, fo great, that we could hardly fuppofe the body to bear it but with the hazard of life. Indeed, though rarely, it has been fo great as to prove suddenly fatal. These considerable discharges occur especially to persons who have been frequently liable to the disease. They often induce great debility, and frequently a leucopuficmatia or dropy which proves fatal. Sometimes the tumors and discharges of blood in this disease recur exactly at flated periods. In the decline of life it frequently happens that the hæmorrhoidal flux, formerly frequent, ceases to flow; and in that cafe it generally happens that the persons are affected with apoplexy or palsy. Sometimes hæmorrhoidal tumors are affected with inflammation, which ends in suppuration, and gives occasion to the formation of fitious ulcers in those parts.

The hæmorrhoidal tumors have often been confidered as varices or dilatations of the veins; and in some cafes various dilatations have appeared upon defcription. These, however, do not appear in the greater part of cafes; and Dr Cullen is of opinion that they are ufually formed by an effufion of blood into the cellular texture of the intine near to its extremity. When recently formed, they contain fluid blood; but after they remain for some time they are usually of a firmer confistence, in confequence of the blood being coagulated.

**Confus, &c.** It would seem probable, that the hæmorrhoidal tumors are produced by some interruption of the free return of the blood from the rectum, by which a rupture of the extremities of the veins is occasioned. But considering that the hæmorrhagia occurring here is often preceded by pain, inflammation, and a fribile flate, and with many other symptoms which show a connection of the topical affection with the state of the whole syslem, it is probable that the interruption of the blood in the veins produces
produces a considerable resitance to the motion of the blood through the arteries, and consequently that the discharge of blood is commonly from the latter. Some have thought, that a difference of the hemorrhoids, and of its effects upon the system, might arise from the difference of the hemorrhoidal vessels from whence the blood issued. But Dr. Cullen is of opinion, that we can scarce ever distinguish the vessels from which the blood flows, and that the frequent inculcations of both arteries and veins belonging to the lower extremity of the rectum, will render the effects of the hemorrhagy much the same, from whatever source it proceeds.

With regard to the hemorrhoids, however, he is of opinion, that they are, for the most part, merely a topical affection. They take place before the period of life at which a venous plethora happens. They happen to females, in whom a venous plethora determined to the hemorrhoidal vessels cannot be supposed to occur; and they happen to both sexes, and to persons of all ages, from cauces which do not affect the system, and are manifestly suited to produce a topical affection only.

These causes are, in the first place, the frequent voiding of hard and bulky feces, which, by their long friction in the rectum, and especially when voided, must necessarily press upon the veins of that part, and interrupt the course of the blood in them. For this reason the disease so frequently happens to those who are habitually collique. From the same causes, the disease happens frequently to those who are subjected to a prolapsus ani. In voiding the feces, it almost always happens that the internal coat of the rectum is more or less protruded; and, during this protrusion, it sometimes happens that the sphincter ani is contracted: in consequence of this, a strong constriction is made, which preventing the fallen-out gut from being replaced, and at the same time preventing the return of blood from it, occasions a considerable swelling, and the formation of a tumid ring round the anus.

But when the sphincter's being a little relaxed, as it is immediately after its strong contraction, the portion of the gut which had fallen out is commonly taken into the body again; but by the frequent repetition of the accident, the size and fulness of the ring formed by the prolapsed intestine is much increased. It is therefore more slowly and difficultly replaced; and in this confits the chief uneasiness of hemorrhoidal persons. As the internal edge of this ring is necessarily divided by clefts, the whole often puts on the appearance of a number of distinct swellings; and it also frequently happens, that some portions of it are more considerably swelled, become more protuberant, and form those small tumors more strictly called hemorrhoids or piles.

From considering that the pressure of the feces, and other causes interrupting the return of venous blood from the lower extremity of the rectum, may operate a good deal higher up than that extremity, we may understand how tumors may be formed within the anus; and probably it also happens, that some of the tumors formed without the anus may continue when taken within the body, and even be increased by the causes just mentioned. Thus may the production of internal piles be explained, which, on account of their situation and bulk, are not protruded on the person's going to stool, and are therefore more painful.

The production of piles is particularly illustrated by this, that pregnant women are frequently affected with the disease. This is to be accounted for, partly from the pressure of the uterus upon the rectum, and partly from the native habit to which pregnant women are liable. Dr. Cullen has known manyinstances of piles happening for the first time during the state of pregnancy; and there are few women who have born children, that are afterwards entirely free from piles.

Purgatives also, especially those of the more acrid kind, and particularly aloetics, are apt to produce the piles when frequently used; and as they stimulate particularly the larger intestines, they may be justly reckoned among the exciting causes of this disease.

Prognosis. Though the hemorrhoids are commonly, as we have said, to be esteemed a topical disease, they may, by frequent repetition, become habitual and connected with the state of the whole system; and this will more readily happen in persons who have been once affected with the disease, if they be frequently exposed to a renewal of the causes which occasioned it. It happens also to persons much exposed to a congestion in the hemorrhoidal vessels, in consequence of their being often in an erect position of the body, and in an exercise which presses the blood into the depending vessels, while at the same time the effects of these circumstances are much favoured by the abundance and laxity of the cellular texture about the anus. It is to be particularly observed, that when an hemorrhoidal affection has either been originally or has become a disease of the system, it then acquires a particular connection with the stomach; so that certain affections of the stomach excite the hemorrhoidal disease, and certain states of this disease excite the disorders of the stomach.

It has been an almost universally received opinion, that the hemorrhoidal flux is a salutary evacuation, which prevents many diseases that would otherwise have happened; and that it even contributes to give long life; and as this opinion has been strenuously adopted by Dr. Stahl, it has had a very considerable influence on the practice of physic in Germany. But Dr. Cullen maintains that we can never expect to reap much benefit from this flux, which at first is purely topical; and, granting that it should become habitual, it is never, he thinks, proper to be encouraged. It is a disagreeable disease; ready to go to excess, and thereby to prove hurtful and sometimes, even fatal. At best it is liable to accidents, and thus to unhappy consequences. He is therefore of opinion, that even the first approaches of the disease are to be guarded against; and that, though it should have proceeded for some time, it ought always to be moderated, and the necessity of it superceded.

Cure. The general intentions of cure in cases of hemorrhoids are much varied, according to the circumstances of the affection at the time. When hemorrhoids exist in the state of tumor, the principal objects are to counteract inflammation, and to promote a discharge of blood from the part. When it is in the state
state of evacuation, the chief intentions of cure are, to
diminish the impetus of blood at the part affected, and
to increase the resistance to the passage of blood through
the ruptured vessels. And finally, when the disease
exists in the state of suspension, the aims of the prac-
titioner must chiefly be, to obviate the particular af-
fections which are induced in consequence of the sus-
ension; to restore the discharge, as a means of miti-
gating these and preventing others; or when the
discharge cannot with propriety or advantage be re-
stored, to compensate the want of it by vicarious evac-
uations.

With these various intentions in different cases, a
variety of different remedies may be employed with
advantage.

When any evident cause for this disease is perceived,
we ought immediately to attempt a removal of that
disease. One of the most frequent remote causes is an
habitual coliciveness; which must be obviated by a pro-
cer diet, such as the person's own experience will be-
direct; or if the management of diet be not effectual,
the belly must be kept open by medicines, which may
prove gently laxative, without irritating the rectum.
In most cases it will be of advantage to acquire a ha-
bit with regard to the time of discharge, and to ob-
serve it exactly. Another cause of the hemorrhoids to
be especially attended to is the prolapsus ani, which
is apt to happen on a person's having a stool. If this
shall occur to any considerable degree, and be not at
the same time easily and immediately replaced, it may
certainly produce piles, or when the affection occurs as a critical discharge; for if the prolapsus ani, the frequent walking of the anus with cold-water may be useful.

Besides general antiphlogistic regimen, in some cases
where the inflammation runs high, recourse may be
had with great advantage both to general blood-let-
ing and to leeches applied at the anus. Relief is also
often obtained from the external application of emol-
lients, either alone or combined with different articles
of the sedative kind, as acedated Ceruife or opium, by
which it is well known that pain in general, particu-
larly when depending on increased sensibility, or aug-
mented action of the vessels, is powerfully allayed.

When the flux has actually come on, we are to mo-
derate it as much as possible, by causing the patient
to lie in a horizontal posture on a hard bed; by avoiding
exercise in an erect posture, using a cool diet, and
avoiding external heat. But with respect to the fur-
ther cure of this disease, we must observe, that there
are only two cases in which it is common for hemor-
rhoidal persons to call for medical attendance. The one
is, when the affection is accompanied with much pain;
and the other, when the piles are accompanied with
excessive bleeding. In the first, we must consider
whether the piles be external or internal. The pain
of the external piles happens especially when a con-
 siderable protrusion of the rectum has taken place;
and while it remains unreduced, it is strangled by the
contraction of the sphincter; and at the same time no
bleeding happens to take off the swelling of the pro-
truded portion of the intestine; and sometimes an in-
flammation supervesens, which greatly aggravates the
pain. In this case, emollient fomentations and pou-
lincs are sometimes of service, but the application of
leeches is generally to be preferred.

In case of excessive bleeding, we are on all occa-
sions to endeavour to moderate the flux, even where
the disease has occurred as a critical discharge; for if
the primary disease shall be entirely and radically cur-
ed, the preventing any return of the hemorrhoids seems
perfectly safe and proper. It is only when the disease
arises from a plethoric habit, and from a stagnation of
blood in the hypochondriac region, or when, though
originally topical, it has by frequent repetition be-
come habitual and has thereby acquired a connection
with the fympron, that any doubt can arise about curing
it entirely. In any of these cases, however, Dr Cul-
len is of opinion that it will be proper to moderate the
bleeding, left, by its continuance or repetition, the
plethoric state of the body, and the particular deter-
mination of the blood into the hemorrhoidal vessels, be
increased, and the return of the disease be too much
favoured. Dr Stahl is of opinion, that the hemorrh-
rhoidal flux is never to be accounted excessive except-
ing when it occasions great debility or leukophlegma-
tia: but Dr Cullen thinks, that the smallest approach
towards producing either of those effects should be
considered as an excess which ought to be prevent-
ited from going farther; and even in the cases of con-
gleion and plethora, if the plethoric habit and ten-
dency can be obviated and removed, the hemorrhoi-
dal bux may then with safety be entirely suppressed.
In all cases therefore of excessive bleeding, or any ap-
perceived.

Description. The quantity of the menstrual flux is different in different women, and likewise in the same woman at different times. An unusual quantity therefore is not always to be considered as morbid; but when a large flow of the menstrual flux is preceded by headache, giddiness or dyspnea; has been ushered in by a cold stage, and is attended with much pain of the back and loins, with a frequent pulse, heat and thirst; it may then be considered as preternaturally morbid. On the other hand, when the face becomes pale, the pulse weak, an usual debility is felt in exercise, and the breathing is hurried by little labour; when the back becomes pained from any continuance in an erect posture, when the extremities become frequently cold, and when at night the feet appear affected with edematous swelling; from all these symptoms we may conclude, that the flow of the menstrual flux has been immoderate, and has already induced a dangerous state of debility. The debility, induced in this case, often appears also by affections of the stomach, an anorexia, and other symptoms of dyspepsia; by a palpitation of the heart, and frequent faintings; by a weakness of mind, liable to strange emotions from flight causes, especially those preferred by surprize. A large flow of the menstrual flux is attended with barrenness in married women, may generally be considered as preternaturally morbid. Generally, also, that flow of the menstrual flux may be considered as immoderate, which is preceded and followed by a leucorrhrea.

Causes, &c. The proximate cause of the menorrhagia is either the effort of the uterine vessels preternaturally increased, or a preternatural laxity of the extremities of the uterine arteries. — The remote causes may be, 1. Those which increase the plethoric state of the uterine vessels; as a full and nourishing diet, much strong liquor, and frequent intoxications. 2. Those which determine the blood more copiously and forcibly into the uterine vessels; as violent strainings of the whole body; violent shocks from falls; strokes or contusions on the lower belly; violent exercise, particularly in dancing; and violent pallions of the mind. 3. Those which particularly irritate the vessels of the uterus; as excess in venery; the exercise of venery in the time of menstruation; a collute habit, giving occasion to violent strainings at stool; and cold applied to the feet. 4. Those which have forcibly overstrained the extremities of the uterine vessels; as frequent abotions, frequent child-bearing without nursing, and difficult or tedious labours. Or, lastly, those which induce a general laxity; as living much in warm chambers, and drinking much of warm evaporating liquors, such as tea, coffee, &c.

Cure. The treatment and cure of the menorrhagia, must be different according to the different causes of the disease. The practices employed, however, are chiefly used with one or two intentions; either with the view of refraining; the discharge when present, or of preventing the return of an excessive discharge at the succeeding period. The first is chiefly to be accomplished by employing such practices as diminish the force occasioning the discharge of blood, or as augment the resistance to its passage through the vessels by which it is to be discharged. The last is in some degree to be obtained by avoiding causes which either increase the general impetus of the blood, or the impetus at the uterus in particular; but principally by giving additional vigour to the uterine vessels.

In all cases, the first attention ought to be given to avoiding the remote causes, whenever that can be done; and by such attention the disease may be often entirely cured. When the remote causes cannot be avoided, or when the avoiding them has been neglected, and a copious menstruation has come on, it should be moderated as much as possible, by abating from all exercise at the coming on or during the continuance of the menstruation; by avoiding even an erect posture as much as possible; by fumming external heat, and of course warm chambers and beds; by taking a light and cool diet; by abating a light and cool drink, at least as far as former habits will allow; by abating venery; by obviating colitiveness, or removing it by laxatives which give little stimulus. The sex are commonly negligent, either in avoiding the remote causes, or in moderating the first beginnings of this disease. It is by such neglect that it so frequently becomes violent and of difficult cure; and the frequent repetition of a copious menstruation may be considered as a cause of great laxity in the extreme vessels of the uterus.

When the coming on of the menstruation has been preceded by some disorder in other parts of the body, and is accompanied with pains of the back, somewhat like parturient pains, with febrile symptoms, and when in the same time the flow seems to be copious, a bleeding at the arm may be proper, but is not often necessary; and it will in most cases be sufficient to employ, with great attention and diligence, those means already mentioned for moderating the discharge.

When the immoderate flow of the menstrual flux shall seem...
to be owing to a laxity of the vessels of the uterus, as
may be concluded from the general debility and laxity
of the person's habit; from the remote causes that
have occasioned the disease; from the absence of the
symptoms which denote increased action in the vessels
of the uterus; from the frequent recurrence of the
disease; and particularly from this, that the female in
the intervals of menstruation is liable to a leucorrhœa:
in such a case, the disease is to be treated, not only by
employing all the means (above-mentioned for moderating
the hemorrhagy, but also by avoiding all irri-
tation, every irritation having a greater effect in propor-
tion as the vessels are more lax and yielding. If,
in such a case of laxity, it shall appear that some degree
of irritation concurs, opiates may be employed to
moderate the discharge; but in using these much caution
is requisite. If, notwithstanding these measures
having been taken, the discharge shall prove very large,
astringents both external and internal may be employ-
ed. In such cases, Dr Cullen asks, May small doses
of emetics be of service?

When the menorrhagia depends on the laxity of the
uterine vessels, it will be proper, in the intervals
of menstruation, to employ tonic remedies; as cold
bathing and chalybeats. The exercises of geftation
also may be very useful, both for strengthening
the whole system, and for taking
the passage
of the blood to the internal parts.

These remedies may be employed in all cases of
menorrhagia, from whatever cause it may have pro-
ceeded, it shall have already induced a considerable
degree of debility in the body.

Description. The fluor albus, female weaknesses, or
whites, as it is commonly called, is a disease of the womb and its contiguous parts; from which a pale
coloured, greenish, or yellow fluid, is discharges, at-
tended with loss of strength, pain in the loins, bad di-
gestion, and a wan, sickly aspect.

Conject. &c. The quantity, colour, and consistence of the
discharge, chiefly depend upon the time of its dur-
ation, the patient's habit of body, and the nature
of the cause by which it was produced. Taking cold,
strong liquor, immoderate heat and moisture, or vi-
olent exercise, are all observed to produce a bad effect,
as to its quantity and quality.

Weakly women of lax solids, who have had many
children, and long laboured undér ill health, are of
all the most subject to this disfigréeable disease; from
which they unfortunately suffer more severe pene-
tration than others, as the nicest sensations are often con-
neeted with such a delicacy of bodily frame as sub-
jects them to it.

In Holland it is very frequent and in a manner pecu-
lar to the place, to the dampness of its situation;
the surrounding air being so overcharged with
moisture as to relax the body, drop peripetition, and
throw it upon the bowels or womb; producing in the
first a diarrhoea or flux, in the last the fluor albus or
female weaknesses.

The discharge often proceeds from the vessels sub-
fervient to menstruation; because, in delicate habits,
where those vessels are weak, and consequently remain
too long uncontrasted, the fluor albus sometimes im-
imediately follows the menœs, and goes off by degrees
as they gradually close. It also comes from the nu-
cous glands of the womb, as is particularly evident
in very young females of eight and ten years old; in
whom, though very rarely, it has been observed, and
where it must then have necessarily escaped from those
parts, as the uterine vessels are not sufficiently en-
larged for its passage at so early a period.

Sometimes, as in women with child, it proceeds
from the passage to the womb, and not from the womb
itself; which, during pregnancy, is closely sealed up,
so that nothing can pass from thence till the time of
labour. The application of those instruments called
poOFairs, from the pain and irritation they occasion,
are also apt to bring on this discharge. Hence we
may conclude, that this disease may happen although
the blood be in a pure state. Here the fault seems to
be placed in the vessels at the parts, by which the
fluids are vitiated and changed from their natural qua-
lities.

The fluor albus has been supposed to supply the
want of the menœs; because where the first prevails,
the last is generally either irregular or totally wanting;
but it might more properly be said, that the preference
of the fluor al bus, which is a preternatural evacuation,
occasions the absence of that which is natural; as is
evident from the return of the menœs after the fluor
albus has been cured. Indeed, when this discharge
appears about the age of 13 or 14, and returns once
a month, with symptoms like those of the menœs,
then it may be deemed finely natural, and therefore
ought not to be stopped.

Prognostic. The fluor albus may be distinguished in
to two kinds. The first arises from a simple weakness,
or the relaxation of the solids; which may either be
general, where the whole bodily system is enervated,
and unfrrung; or partial, where the womb only is thus
affected,
MEDICINE.

Hemorrhagia.

affected in consequence of hard labour, frequent miscarriages, a suppression or immediate quantity of the menses, or a sprain of the back or loins.

In the first case, the discharge being generally mild, may be safely taken away. In the second it may proceed from a vitiated or impure blood, where the body from thence, is loaded with grofs humours, which nature for her own security and relief thus endeavours to carry off. In such cases, the discharge is often of a reddish colour, like that from old ulcerous sores; being sometimes so sharp as to excoriate the contiguous parts, and occasion a smarting and heat of urine.

A deep-seated, darting pain, with a forcing down, attending such a discharge, is a very dangerous and alarming sign, and indicates an ulceration or cancerous state of the womb. This malignant state of the disease, if of long continuance, is extremely difficult of cure; and disposes the patient to barrenness, a bearing down, dropsey, or consumption.

Cure, &c. The causes of those two kinds of this disease being different, so they will require a very different method of cure. For this purpose, in the first case, nothing will be more proper than nourishing simple food; such as veal broths, jellies, fresh eggs, and milk diet. The acid fruits will also be proper; and the patient may take a reforative, or purgative water, or simple fenn-tea sweetened with manna, till those complaints be removed.

In the second sort of the disease, where the discharge is a deep-teated, darting pain, with a forcing down, the patient may go into the cold bath every second day; and also drink a dry milk diet. The acid fruits will also be proper; such as veal broths, jellies, eggs, milk, which will expedite the cure.

In short, as this is a malady of the most disagreeable kind, which by long continuance or neglect becomes difficult of cure and often produces an ulceration of the womb, bearing down, barrenness, a dropsey, or consumption; it was to be wished that women, on such occasions, would be more attentive to their own safety, by using all possible means, in due time, to prevent those disorders.

Dr. Leake says he has attended more patients labouring under the fluor albus in the autumn than at any other season of the year, especially when the weather was uncommonly moist and cold; most of them were cured by change of diet, an increased perspiration, and the proper use of Peruvian bark with aromatics. He observed, that several about this time who escaped the disorder, were visited with bad colds, a delusion on the throat, or a diarrhoea, which were removed by a similar treatment.

As women are sometimes connected with those who do not conscientiously regard their safety, it is a circumstance of the utmost consequence to distinguish a fresh venereal infection from the fluor albus or subites; for if the first be mistaken for the last, and be either neglected or improperly treated, the worst consequences may arise.

The following signs will best inform the patient whether there be occasion for her doubts or not. A fresh infection, called gonorrhoea, is malignant, and inflammatory; the fluor albus most commonly arises from relaxation and bodily weakness; and therefore the remedies proper in the first disorder would render the laft more violent, by locking up and confining the infectious matter.

In the gonorrhoea, the discharge chiefly proceeds from the parts contiguous to the urinary passage, and continues whilst the menses flow but in the fluor albus it is supplied from the cavity of the womb and its passage, and then the menses are seldom regular.

In the gonorrhoea, an itching, inflammation, and heat of urine, are the fore-runners of the discharge; the orifice of the urinary passage is prominent and painful, and the patient is affected with a frequent irritation to make water. In the fluor albus, pains in the loins, and lofts of strength, attend the discharge; and if any inflammation or heat of urine follow, they happen in a less degree, and only after a long continuance.

MEDICINE.

Catarthi.

Whether one country of Europe, without appearing successfully, the fluids, the profusious objections before, seem rested not only more tedious than otherwise it would be, but also more dangerous by the supervening of other diseases. Some degree of the cynthiae tonsillaris often accompanies the catarth; and when this is aggravated by a freth application of cold, the cynthia becomes more violent and dangerous from the cough, which is present at the same time. When a catarth has been occasioned by a violent causethat it has been aggravated by improper management, and especially when it has been rendered more violent by freth and repeated applications of cold, it often passes into a pneumonic inflammation, attended with the utmost danger.

Unluckily, however, such accidents as those happen, a catarth, in found persons not far advanced in life, is always a slight and safe disease; but in persons of a phthisical disposition, a catarth may readily produce a hemoptysis, or perhaps form tubercles in the lungs; and still more readily in persons who have tubercles already formed in the lungs, an accidental catarth may occasion the inflammation of these tubercles, and in consequence produce a phthisis pulmonalis.

In elderly persons, a catarth sometimes proves a dangerous disease. Many persons, as they advance in life, and especially after they have arrived at old age, have the natural mucus of the lungs poured out in greater quantity, and requiring a frequent expectoration. If, therefore, a catarth happen to such persons, and increase the afflux of fluids to the lungs, with some degree of inflammation, it may produce the peripneumonia notha, or more properly chronic catarrh, a disease continuing often for many years, or at least regularly every winter; which in such cases is very often fatal.

Carnies, &c. The proximate cause of catarth seems to be an increased afflux of fluids to the mucous membrane of the nose, fauces, and bronchee, along with some degree of inflammation affecting the same. The latter circumstance is confirmed by this, that, in the case of catarth, the blood drawn from a vein commonly exhibits the same inflammatory crust which appears in the case of phlegmatiae. The remote cause of catarth is most commonly cold applied to the body. This application of cold producing catarth is generally evident and observed; and Dr. Cullen is of opinion that it would always be so, were men acquainted with and attentive to the circumstances which determine cold to act upon the body.

The application of cold which occasions a catarth, probably operates by stopping the perspiration usually made by the skin, and which is therefore determined to the mucous membrane of the parts abovementioned. As a part of the weight which the body daily loses by innumerable evaporation, is owing to an exhalation from the lungs, there is probably a connexion between this exhalation and the cutaneous perspiration, so that the one may be increased according as the other is diminished; and therefore we may understand how the diminution of cutaneous perspiration, by the application of cold, may increase the afflux of fluids to the lungs, and thereby produce a catarth.

Dr. Cullen observes that there are some observations of Dr. James Keil which may render this matter doubtful; but says there is a fallacy in those observations. The evident effects of cold in producing coryza, leave the matter, in general, without doubt; and there are several other observations which show a connexion between the lungs and the surface of the body.

Whether from the suppression of perspiration, a catarth be produced merely by an increased afflux of fluids, or whether in addition to this the matter of perspiration be at the same time determined to the mucous glands, and there excites a particular irritation, may be uncertain; but Dr. Cullen thinks the latter supposition is most probable.

Although in the case of a common catarth, which is in many instances sporadic, it may be doubtful whether any morbid matter be applied to the mucous glands; we are, however, certain that the symptoms of a catarth do frequently depend upon such a matter being applied to these glands, as appears from the case of measles, chincough, and especially from the frequent occurrence of contagious and epidemic catarrh.

The phenomena of contagious catarrhas have been much the same with those of the others; and the disease has always been particularly remarkable for this, that it has been the most widely and generally spreading epidemic known. It has seldom appeared in any one country of Europe, without appearing successively in almost every different part of it; and, in some instances, it has been also transferred to America, and has been spread there in like manner, so far as we have had opportunities of being informed.

The catarth from contagion appears with nearly the same symptoms as those abovementioned. It seems often to come on in consequence of the application of cold. And indeed catarth from cold and contagion are in every respect so similar, that when this epidemic rages, it is impossible to determine with a person having symptoms of catarth after exposure to cold, whether the disease proceeds from the one cause or the other. In most instances, however, catarth from contagion comes on with more cold shivering than the catarth arising from cold alone; and the former does also not only sooner show febrile symptoms, but to a more considerable degree. Accordingly, it more speedily runs its course, which is commonly finished in a few days. It sometimes ends by a spontaneous sweat; and this, in some persons, produces a military eruption. It is, however, the febrile state of this disease especially that is finished in a few days; for the cough and other catarthial symptoms do frequently continue longer, and often when they appear to be going off they are renewed by any fresh application of cold.

Prognosis. Possessing the number of persons who are afflicted with catarrh of either the one species or the other, and escape from it quickly without any hurt, it may be allowed to be a disease commonly free from danger; but it is not always to be treated as such,
MEDICINE

for in some persons it is accompanied with pneumatic inflammation. In the phthisically disposed, it often accelerates the coming on of phthisis; and in elderly persons it often proves fatal in the manner we have explained above, viz. by degenerating into its chronic state. But though chronic catarrh be often the termination of that species which arises from cold, we have not, in any case, observed it to arise as a consequence of a catarrh from contagion. This species of catarrh, however, is not unfrequently followed by phthisis; or rather where a phthisical tendency before existed, the affection has been begun and its progress accelerated from this cause.

Cure. The cure of catarrh is nearly the same, whether it proceeds from cold or contagion; only in the latter case remedies are commonly more necessary than in the former. In the cases of a moderate disease, it is commonly sufficient to avoid cold, or to abstain from animal-food for some days. In some cases, where the febrile symptoms are considerable, it is proper for that length of time to lie a-bed, and, by taking frequently some mild and diluent drink, a little warmed, to promote a very gentle sweat; and after this to take care to return very gradually only to the use of fluids to the surface of the body, and at the same time for expediting the secretion of mucus in the lungs, which may take off the inflammation of its membrane, vomiting is the most effectual means. For the last-mentioned purpose, it has been supposed that fquills, gum-ammoniac, the volatile alkali, and some other medicines, might be useful; but their efficacy has never been found considerable: and if squills have ever been very useful, it seems to have been rather by their emetic than by their expectorant powers. When the inflammatory affections of the lungs seem to be considerable, it is proper, besides blood-letting, to apply blisters to the back or sides.

As a cough is often the most troublesome circumstance of this disease, so demulcents may be employed to alleviate it. But after the inflammatory symptoms are much abated, if the cough still remains, opiates afford the most effectual means of relieving it; and, in the circumstances just now mentioned, they may be very safely employed. Very considerable advantage is often derived from employing opium in such a manner as to act more immediately on the head of the wind-pipe. For this purpose, opium may often be advantageously conjoined with demulcents, melting slowly in the mouth. And perhaps no form is more convenient, or answers the purpose better, than the trochice glycyrrhiza cum opio of the Edingburgh Pharmacopœia, where purified opium is combined with extract of liquorice, gum Arabic, and other demulcents, to the extent of about a grain in a dram of the composition. After the inflammatory and febrile states of this disease are very much gone, the most effectual means of discharging all remains of the catarrhal affection is by some exercise of generation diligently employed.

Besides the remedies abovementioned, Mr Mudge, in a treatise on this disease, recommends the steam of warm water as a most efficacious and safe remedy for a catarrh, and which indeed he seems to consider as little less than infallible. The method of breathing in these steams is described under the word Inhaler; but he gives a caution to people in health, who may accidentally see his machine, not to make the experiment of breathing through cold water with it, for they will be almost certain of catching a severe cold. His directions for those troubled with the catarrh are as follows:

"In the evening, a little before bed-time, the patient, if of adult age, is to take three drachms, or as many tea-spoonfuls, of elixir pargaricum, in a glass of water: if the subject be younger, for instance under five years old, one tea-spoonful; or within that and ten years, two. About three quarters of an hour after, the patient should go to bed, and, being covered warm the inhaler three parts filled with water nearly boiling (which, from the coldness of the metal, and the time it ordinarily takes before it is to be used by the patient, will be of a proper degree of warmth), and being wrapped up in a napkin, but so that the valve in the cover is not obstructed by it, is to be placed at the arm-pit, and the bed-clothes being drawn up and over it close to the throat, the tube is to be applied to the mouth, and the patient should inspire and expire through it for about twenty minutes or half an hour.

"It is very evident, as the whole act of respiration is performed through the machine, that in inspiration the lungs will be filled with air which will be hot, and loaded with vapour, by passing through the body of water; and in expiration, all that was contained in the lungs will, by mixing with the steam on the surface of the water, be forced thro' the valve in the cover, and settle on the surface of the body under the bed-cloaths.

"The great use of this particular construction of the inhaler is this. First, as there is no necessity, at the end of every inspiration, to remove the tube from the mouth, in order to expir from the lungs the vapour which had been received into them, this machine may therefore be used with as much ease by children as older people. And, secondly, as a feverish habit frequently accompanies the disorder, the valve in that respect allo is of the utmost importance; for a sweat, or at least a free perspiration, not only relieves the patient from the relief's anxiety of a hot, dry, and sometimes parched skin, but is also, of all evacuations, the most eligible for removing the fever; and it will be generally found, that, after the inhaler so constructed has been used a few minutes, the warm vapour under the cloaths will, by settling upon the trunk, produce a sweat, which will gradually extend itself to the legs and feet.

"In a catarrhal fever, or any feverish habit attending this cough, it would be proper to take a draught of warm thin whey a few minutes before the inhaler be used; and after the process is over, the sweat which it has produced may be continued by occasional small
small druggs of weak warm whey or barley-water. The sweating is by no means so necessary to the cure of the catarrhous cough, as that the success of the inhaler against that complaint at all depends upon it; yet I cannot help once more remarking, that when this disorder happens to be accompanied with a feverish habit, the advantages of this particular confection will be very important.

"After this respiratory process is over, the patient usually passes the night without the least interruption from the cough, and feels no farther molestation from it than once or twice in the morning to throw off the trifling leakage which, unperceived, had dripped into the bronchie and vesicles during the night; the thinner parts of which being evaporated, what remains is soon got rid of with a very gentle effort.

"I cannot, however, take leave of this part of my subject, without pointedly observing, that if the patient means not to be disappointed by my assurances or his own expectations, it is essentially necessary that the following remarks, with regard to the time and manner of using this process, should be strictly attended to.

"First, That as tender valetudinary people are but too well acquainted with the first notices of the disorder, the remedy must, or ought to be, used the same evening; which will, in an ordinary feiture, be attended with an immediate cure: but if the forense of the respiritory organs, or the petulance of the cough, throw the cold which has been contracted to have been very severe, the inhaler, without the opiate, should be again repeated for the same time the next morning.

"Secondly, if the use of the inhaler, &c. be delayed till the second night, it will be always right to repeat it again the next morning without the opiate, but with it if the fever is not violent.

"And, lastly, if the cough be of some days standing, it will be always necessary to employ both parts of the process at night and the succeeding morning; as the first simple inflammatory mischief is now most probably aggravated by an additional one of a chronic tendency.

"But if, through the want of a timely application or a total neglect of this or any other remedy, the cough should continue to harass the patient, it is, particularly in delicate and tender constitutions, of the utmost consequence to attempt the removal of it as soon as possible, before any floating injury in the constitution (from the perpetual irritation) receives an habitual determination to an organ so essential to life as the lungs.

"If the patient expectorate with ease and freedom a thick and well-digested inoffensive phlegm, there is generally but little doubt of his spitting off the disorder, with common care, in a few days; and till that be accomplished, a proper dose of elixir paregoricum for a few successive nights will be found very useful in suppreffing the fatigue of irritation and ineffectual cough, occasioned by a matter which, dripping in the early state of the disease into the bronchio during the night, is commonly at that time too thin to be discharged by those convulsive efforts.

"If, however, notwithstanding these other means, the cough continuing dry or unattended with a proper expectoration, should persevere in harassing the patient; if, at last, it should produce, together with a forense, flueting pains through the breast and between the shoulders, attended also with shortness of the breath; and if, added to this, flushes of the cheeks after meals, falding in the hands and feet, and other symptoms of a hectic, should accompany the disorder; there is certainly no time to be lost, as there is the greatest reason to apprehend that some acrimony in the habit is determined to the tender substance of the lungs, and that consequently tubercular suppurations will follow. In this critical and dangerous situation, I think I can venture to say from long experience, that, accompanied with change of air and occasional bleedings, the patient will find his greatest fe-
GENUS XLI. DYSENTERIA.  
THE DYSENTERY.  

DYSENTERIA.  

DESCRIPTION.  

The dysentery is a disease in which the patient has frequent stools, accompanied with much griping, and followed by a tenesmus. The stools, though frequent, are generally in small quantity; and the matter voided is chiefly mucus, sometimes mixed with blood. At the same time, the natural faces seldom appear; and when they do, it is generallv in a compact and hardened form, often under the form of small hard substances known by the name of phylodes. This disease occurs especially in summer and autumn, at the same time with autumnal intermittent and remittent fevers; and with these it is often complicated. It comes on sometimes with cold flushings, and other symptoms of pyrexia; but more commonly the symptoms of the topical affection appear first. The belly is colicky, with an unusual flatulence in the bowels. Sometimes, though more rarely, some degree of diarrhoea is the first appearance. In most cases, the disease begins with griping, and a frequent inclination to go to stool. In indulging this, little is voided, but some tenesmus attends it. By degrees the stools become more frequent, the griping more severe, and the tenesmus more considerable. — With these symptoms there is a loss of appetite, and frequently sickness, nausea, and vomiting, also affecting the patient. At the same time there is always more or less of pyrexia present. It is sometimes of the remittent kind, and observed a tertian period. — Sometimes the pyrexia is manifelty inflammatory, and very often of a putrid kind. These febrile states continue to accompany the disease during its whole course, especially when it terminates soon in a fatal manner. In other cases, the febrile state almost entirely disappears, while the proper dysenteric symptoms remain for a long time after. In the course of the disease, whether for a shorter or a longer time, the matter voided by stool is very various. Sometimes it is merely a mucous matter, without any blood, exhibiting that disease which is named by some the morbus mucus, and by others the dysenteria alta. For the moat part, however, the mucus discharged is more or less mixed with blood. This sometimes appears only in streaks among the mucus; but at other times is more copious, giving a tint to the whole; and upon some occasions a pure and unmixed blood is voided in considerable quantity. In other respects, the matter voided is variously changed in colour and consistence, and is commonly of a strong and unctuous and fetid odour. It is probable, that sometimes a genuine pus is voided, and frequently a putrid faeces, proceeding from gangrenous parts. There are very often mixed with the liquid matter some films of a membraneous appearance, and frequently some small masses of a seemingly seaceous matter. While the stools voiding these various matters are, in many instances, exceedingly frequent, it is seldom that natural faces appear in them; and when they do appear, it is, as we have said, in the form of phylodes, that is, in somewhat hardened, fe-
the common opinion has been, that the disease depends upon an acrid matter thrown upon or somehow generated in the intestines, exciting their peristaltic motion, and thereby producing the frequent foleys which occur in this disease. But this supposition cannot be adopted; for, in all the instances known, of acrid substances applied to the intestines, and producing frequent foleys, they at the same time produce copious foleys, as might be expected from acrid sub-
stances applied to any length of the intestines. This, however, is not the case in a defertility, in which the foleys, however frequent, are generally in very small quantity, and such as may be supposed to proceed from the lower parts of the rectum only. With respect to the superior portions of the intestines, and particularly those of the colon, it is probable they are under a preternatural and considerable degree of con-
triction; for, as we have said above, the natural foleys are seldom voided; and when they are, it is in a form which gives reason to suppose they have been long retained in the cells of the colon, and con-
sequently that the colon had been affected with a preternatural contraction. This is confirmed by almost all the affections which have been noted of the bodies of dyfenteric patients; in which, when gangrene had not entirely destroyed the texture and form of the parts, large portions of the great guts have been found af-
fected with a very considerable contraction.

The proximate cause of dyfenteria, or at least the chief part of the proximate cause, seems to consist in a preternatural contraction of the colon, occasioning at the same time, those spasmodic effects which are felt in severe gripings, and which effects propagated downwards to the rectum, occasion there the frequent mucous foleys and tenesmus. But whether this explanation shall be admitted or not, it will still remain certain, that hardened foleys, retained in the colon, are the cause of the griping, frequent foleys, and tenesmus; for the evacuation of these foleys, whether by nature or by art, gives relief from the symptoms mentioned; and it will be more fully and usefully confirmed by this, that the most immediate and successful cure of dyfenteria is obtained by an early and conftant at-
evacuation of the visceral femeicupium, or by fomentation of the alimentary canal. In the more advanced periods of the disease, the principal objects are, the giving a proper defence to the intestines against irritating caufes; the diminution of morbid fensibility of the intestinal canal; and the reparation of due vigour to the system in general, but to the intestines in par-
cular.

The most eminent of our late practitioners, and of greatest experience in this disease, seem to be of opinion, that it is to be cured most effectual-
ly by purging, affiduously employed. The means may be various; but the most gentle laxatives are usuallly sufficient; and, as the medicine must be fre-
quently repeated, these are the most safe, more es-
pecially as an inflammatory state so frequently ac-
companies the disease. Whatever laxatives produce an evacuation of natural foleys, and a conftant re-
mission of the symptoms, will be sufficient to effectuate the cure. But if the gentle laxatives shall not pro-
duce the evacuation now mentioned, somewhat more powerful must be employed; and Dr. Colten has found nothing more proper or convenient than tartar emetic, given in small doses, and at fuch intervals as may determine its operation to be chiefly by ffool.

To the antimonial tartar, however, employed as a purgative, the great fickfness which it is apt to occa-
fion, and the tendency which it has, notwithstanding every precaution, to operate as an emetic, are certain-
ly objections. Another antimonial, at one time con-
 sidered as an almost infallible remedy for this dis-
ease, the vittrum antimonii ceratum, is no lefs excep-
tionable, from the uncertainty and violence of its op-
eration; and perhaps the safest and belt purgatives are the different neutral falts, particularly thole containing fodic and tartaric, or a mixture of the bodies of Rhubarb and Saltpetre. If they be more frequently employed, it is, he thinks, in feveral repects, amongst the moft unfit purgatives; and indeed from its astringent quality, it is exceptionable at the commencement of the affection, unlefs it be joined with something to render its operation more brisk, such as mild muriated mercury, or caolame as it is commonly called.

Vomiting has been held a principal remedy in this disease; and may be usefully employed in the be-

ing, with a view to both the state of the ftemach and of the fever; but it is not necessary to repeat it often; and, unless the emetics employed, operate alfo by ffool, they are of little service. Speciaauha is by no means a specific; and it proves only useful when fo managed as to operate chiefly by ffool.

For relieving the conftitution of the colon, and evacuating the retained foleys, glyfers may sometimes be useful; but they are seldom fo effectual as laxatives given by the mouth; and acrid glylers, if they be not effectual in evacuating the colon, may prove hurt-
ful by stimulatig the rectum too much.

The frequent and severe griping attending this disease, leads almost neceffary to the ufe of opiates; and they are very effectual for the purpose of relieving from the gripes; but, by occasioning an interuption of the action of the small intestines, they favour the conftitution of the colon, and thereby aggravate the disease; and if, at the fame time, the ufe of them supercede in any measure the employing purgatives, it is doing much mischief; and the neglect of purging seems to be the only thing which renders the ufe of opiates very neceffary.

When the gripes are both frequent and severe, they may sometimes be relieved by the employment of the fecicupim, or by fomentation of the ab-
domen continued for some time. In the fame cafe, the pains may be relieved, and the conftitution of the colon may be taken off, by blitters applied to the lower belly.

At the beginning of this disease, when the fever is any way considerable, blood-letting, in patients of tolerable
and tolerable vigour, may be proper and necessary; and, when the pulse is full and hard, with other symptoms of an inflammatory disposition, blood-letting ought to be repeated. But, as the fever attending dysentery is often of the typhoid kind, or does, in the course of the disease, become a symptom of that nature, blood-letting must be cautiously employed.

From our account of the nature of this disease, it will be sufficiently obvious, that the use of astringents in the beginning of it must be very pernicious. But although astringents may be hurtful at early periods of this affection, yet it cannot be denied that where frequent loose stools remain after the febrile symptoms have subsided, they are often of great service and the intestinal canal. Accordingly, on this ground a variety of articles have been highly extolled in cases of dysentery by some of the Swedish physicians; for diminishing morbid sensibility, and the stagnation of fluids, which attend the dysentery, may be uncertain; but, from the indigestion and the sthenic kind, as the mucus, hordei, potios saccharae, &c. are often employed with advantage. And perhaps also, on the same principles, we are to account for the benefit which has been sometimes derived from the nux vomica, a remedy highly valuable, been but very precarious to allow of its entire state, is of doubtful quality in many cases; but even some portion of the cream is often allowed, often proves very powerful as an evacuant. Its effects, however, whatever its mode of operation may be, are too precarious to allow its ever being introduced into common practice; and in Britain, it has, we believe, been but very rarely employed. Whether an acid matter be the original cause of the dysentery, may be uncertain; but, from the indigestion, and the stagnation of fluids, which attend the disease, we may suppose that some acid matters are constantly present in the stomach and intestines; and therefore that demulcents may be always usefully employed. At the same time, from the consideration that mild oily matters thrown into the intestines in considerable quantity always prove laxative, Dr Cullen is of opinion, that the oleaginous demulcents are the most useful. Where, however, these are not acceptable to the patient's taste, theose of the mucilaginous and farinaceous kind, as the decoctum hordei, potio creatceae, &c. are often employed with advantage.

As this disease is so often of an inflammatory or of a putrid nature, it is evident that the diet employed in it should be vegetable and acidulent. Milk, in its entire state, is of doubtful quality in many cases; but even some portion of the cream is often allowed, and whey is always proper. In the first stages of the disease, the sweet and subacid fruits are allowable, and even proper. It is in the more advanced stages only that any morbid acidity seems to prevail in the stomach, and to require some reserve in the use of astringents. At the beginning of the disease, astringents seem to be superfluous; and by their astringent and septic powers, they may be hurtful; but in other periods they are often of advantage.

When this disease is complicated with an intermitment, and is prostrated from the circumstance chiefly, it is to be treated as an intermitent, by administering the Peruvian bark, which in the earlier periods of the disease is hardly to be admitted.
MEDICINE.

Prognosis. This species is equally fatal with the Apoplexy of the other; and what had been said of the prognosis of the fanguineous, may also be said of that of the serous, apoplexy.

Cure. In this species venefication can fearlessly be admitted: acrid purgatives, emetics, and stimulating clysters, are recommended to carry off the superabundant serum; but in bodies already debilitated, they may perhaps be liable to the same exceptions with venefication itself. Volatile salts, cephalic elixirs, and cordials, are also prescribed; and in case of hemiplegia supervening, the cure is to be attempted by aperient pills, cathartics, and sudorifics; gentle exercise, as riding in a carriage; with blisters and such stimulating medicines as are in general had recourse to in ailments originally of the paralytic kind.

Sp. III. Hydrocephal Apoplexy, or Dropisy of the Brain.

Althenia a hydrocephalo, Sauv. sp. 3.

History and description. This disease has been accurately treated within these few years by several eminent physicians, particularly the late Dr Whytt, Dr Fothergill, and Dr Watton, who concur in opinion with respect to the seat of the complaint, the mode of its symptoms, and its general fatality. Out of twenty patients that had fallen under Dr Whytt's observation, he candidly owns that he had been so unfortunate as to cure only one who laboured under the characteristic symptoms of the hydrocephalus; and he supposes that those who imagine they have been more successful, had mistaken another disposition for this. It is by all supposed to consist in a dropy of the ventricles of the brain; and this opinion is fully established by observations, it is supposed to happen more commonly to healthy, active, lively children, than to those of a different disposition.

Dr Whytt supposes that the commencement of this disease is obscure; that it is generally some months in forming; and that, after some obvious urgent symptoms rendering assistance necessary, it continues some weeks before its fatal termination. This, in general, differs from what has hitherto been observed by Dr Fothergill, the latter informing us, that he has seen children, who, from all appearances, were healthy and active, seized with this distemper, and carried off in about 14 days. He has seldom been able to trace the commencement of it above three weeks.

Though the hydrocephalus be most incident to children, it has been sometimes observed in adults; as appears from a case related by Dr Hack, and from some others.

When the disease appears under its most common form, the symptoms at different periods are so various as to lead Dr Whytt to divide the disease into three stages, which are chiefly marked by changes occurring in the condition of the pulse. At the beginning it is quicker
quicker than natural; afterwards it becomes uncommonly slow, and towards the conclusion of the disease it becomes again quicker than natural, but at the same time very irregular.

Those who are feized with this distemper usually complain first of a pain in some part below the head, most commonly about the nape of the neck and shoulders; often in the legs; and sometimes, but more rarely, in the arms. The pain is not uniformly acute, nor always fixed to one place; and sometimes does not affect the limbs. In the latter case, the head and stomach have been found to be most disordered; so that when the pain occupied the limbs, the sickness or head-ach was less considerable; and when the head likewise with the shoulders; often in the legs; and sometimes, but more feverishly, the pain in the limbs procured. These are generally of a very dark greenish colour with an oiliness or a glairy bile, rather than the slime which accompanies worms; and they are, for the most part extremely offensive. No positive conclusion can be drawn from the appearance of the urine; it being various, in different subjects, both in its colour and contents, according to the quantity of liquor they drink, and the time between the discharges of the urine. From their unwillingness to be moved, they often retain their water 12 or 15 hours, and sometimes longer. In complaints arising from worms, and in dentition, convulsions are more frequent than in this disorder. Children subject to fits are sometimes feized with them a few days before they die. Sometimes these continue 24 hours incessantly, and till they expire.

Causes. The causes of internal hydrocephalus are very much unknown. Some suppose it to proceed from a rupture of some of the lymphatic vessels of the brain. But this supposition is so far from being confirmed by any anatomical observation, that even the existence of such vessels in the brain is not clearly demonstrated. That lymphatics, however, do exist in the brain, cannot be doubted; and one of the most probable causes giving rise to an accumulation of water in the brain is a diminished action of these. Here, however, as well as in other places, accumulation may also be the consequence of augmented effusion; and in this way, an inflammatory disposition, as some have supposed, may give rise to the affection. But from whatever cause an accumulation of water in the ventricles of the brain may be produced, there can be no doubt that from this the principal symptoms of the disease arise, and that a cure is to be accomplished only by the removal of it.

In the first stage of the disease there seems to be a peculiar sensibility of the eyes, as appears from the intolerance of light. But in the progress of the disease a very opposite state occurs: The pupil is remarkably dilated, and cannot be made to contract by the action of strong light; such, for example as by bringing a candle very near to it. In many cases there is reason to believe that total blindness occurs: Often also the pupil of one eye is more dilated than that of another, and the power of moving the eyes is also morbidly affected. Those children, who were never observed to squint before, often become affected with a very great degree of strabismus. The patients are unwilling to be disturbed for any purpose, and can bear no posture but that of lying horizontally. One or both hands are most commonly about their heads. The urine and stools come away insensibly. At length the eyelids become paralytic, great heat accompanied with sweat overpowers the whole body, respiration is rendered totally fulfurus, the pulse becomes in its trembling indubitions beyond the possibility of count. Apoplexy.

Many of the symptoms above enumerated are so common to worm-cafes, teething, and other irritating causes, that it is difficult to fix upon any which particularly characterize this disease. The most peculiar symptom is the pain in the limbs, with sickness and incessant head-ach; which, though frequent in other diseases of children, are neither so uniformly nor so constantly attendant as in this. Another circumstance observed to be familiar, if not peculiar to this distemper, is, that the patients are not only colitive, but it is likewise with the greatest difficulty that ffools can be procured. These are generally of a very dark greenish colour with an oiliness or a glairy bile, rather than the slime which accompanies worms; and they are, for the most part extremely offensive. No positive conclusion can be drawn from the appearance of the urine; it being various, in different subjects, both in its colour and contents, according to the quantity of liquor they drink, and the time between the discharges of the urine. From their unwillingness to be moved, they often retain their water 12 or 15 hours, and sometimes longer. In complaints arising from worms, and in dentition, convulsions are more frequent than in this disorder. Children subject to fits are sometimes seized with them a few days before they die. Sometimes these continue 24 hours incessantly, and till they expire.

Causes. The causes of internal hydrocephalus are very much unknown. Some suppose it to proceed from a rupture of some of the lymphatic vessels of the brain. But this supposition is so far from being confirmed by any anatomical observation, that even the existence of such vessels in the brain is not clearly demonstrated. That lymphatics, however, do exist in the brain, cannot be doubted; and one of the most probable causes giving rise to an accumulation of water in the brain is a diminished action of these. Here, however, as well as in other places, accumulation may also be the consequence of augmented effusion; and in this way, an inflammatory disposition, as some have supposed, may give rise to the affection. But from whatever cause an accumulation of water in the ventricles of the brain may be produced, there can be no doubt that from this the principal symptoms of the disease arise, and that a cure is to be accomplished only by the removal of it. It is, however, probable, that the symptoms are somewhat varied by the position of the water, and that the affection of vision in particular is often the consequence of some morbid state about the thalami nervorum opticorum; at least, in many cafes, large collections of water in the ventricles have occurred, without either strabismus, intolerance of light, or dilatation of the pupil. And in cafes where these symptoms have taken place to a remarkable degree, while upon dissection after death but a very small collection of water was found in the ventricles, it has been observed that a peculiar tumid appearance was discovered about the optic nerves, which upon examination was found to arise from water in the cellular texture. This may have given compreッション producing a state of insensibility; but it may have been preceded, or it may even have originated from, some inflammatory affec-
Comata

**Prognosis and Cure.** Till very lately this disorder was reckoned totally incurable; but of late it has been alleged, that mercury if applied in time, will remove every symptom. This remedy was first thought of by Dr Dobson of Liverpool, and afterwards employed apparently with success by Dr Percival and others. The method of exhibiting this medicine in order to effect a cure, as well as the inutility of other medicines, will fully appear from the following cases.

**Case I. By Dr Percival.**

"September 4, 1777. Master H. a child at the breast, aged seven months, has laboured about a fortnight under a febrile irregular fever. His eyes have been half open and then a little distorted; he has been affected with some degree of flux; his gums have been inflamed and tender; and his mouth uncommonly dry. No tooth has yet made its appearance. An emetic has been administered; a blister applied to his back; and his belly has been kept hot; repeated small doses of magnesia. During the action of the blister, he was thought to be much better, but he soon relapsed into his former state.

"About three o'clock this morning he was convulsed; at nine I saw him; and from his countenance instantly suspected a dropopy of the brain. The symptoms confirmed my apprehensions. His skin was hot; yet his pulse beat only 78 strokes in a minute, which were irregular. The pupils of his eyes were considerably, but unequally, dilated; nor did they contract much when a lighted candle was suddenly held before them. He often squeezed, especially with the right eye, and seemed to take no notice of any objects around him. He refused the bread, and seldom swallowed till the lips and tongue had been fumulated with a feather. During several days past, he had been frequently observed to rub the end of his nose when his hand was at liberty; and notwithstanding his stupor, he was at liberty; and notwithstanding his stupor, he was thought to be much better, but he soon relapsed into his former state.

"On September 5, nine o'clock. The child has had frequent convulsions in the night; his right eye is much distorted; and it has been remarked, that he seldom moves the right hand. The pulse beat 120 strokes in a minute. Two scrupules of the mercurial ointment have been used, and he has taken five grains of mufk. A large discharge of foam has been produced by the blisters. Five o'clock, P.M. the tumor of the head is sensibly diminished; the child's mouth is now moist, and often filled with saliva; and his tongue appears to be swollen. His pulse beat 146 strokes in a minute, I directed another blister to be applied to the head.

"September 6. His convulsions have been much lighter; his eyes are frequently distorted; and the pupils of each are more contracted. The flux is considerably abated; the child seems to take some notice, distinguishes taste, and swallows freely. The mufk has been continued; and half a dram more of the mercurial ointment has been consumed. A clyster was injected last night. Yet, although the flux is considerably abated, the pulse has had a short sleep, and is now composed. His pulse beats 140 strokes in a minute, his heat is moderate; and his skin soft and perspirable. The mercurial ointment has been again used; but, though his gums and tongue are gone and very moist, his breath is not offensive. I directed a grain of calomel to be immediately given, to procure a stool; and a blister to be applied to the occiput.

"September 7. The child has passed the night more comfortably, but not free from convulsions. His head has sweated profusely, and the blisters have run much. The tumor of the bregma is considerably reduced. The jalap operated gently last night, and the mercurial unction has been twice repeated. There is an evident mitigation of all the symptoms.

"September 8. About eleven o'clock last night the child was attacked with severe convulsions, which recurred frequently till one o'clock this morning. He had a short sleep, and is now composed. His pulse beats 140 strokes in a minute, his heat is moderate; and his skin soft and perspirable. The mercurial ointment has again been used; but, though his gums and tongue are sore and very moist, his breath is not offensive. I directed a grain of calomel to be immediately given, to procure a stool; and a blister to be applied to the occiput.

"September 9. He has passed two nights almost entirely free from convulsions. Ten grains of the mercurial ointment have been again rubbed into his thighs. The dose of calomel occasioned three very offensive fumes; and directions are given to repeat it, as he is again coltive. The blister applied to the occiput, like all the others, has produced a very copious discharge. The tumor of the head is now scarcely perceptible. Pulsæ 120.

"September 10. At 12, o'clock last night, the convulsions recurred with greater violence than ever, and still continue. Two teeth have almost protruded through the upper, and the same number through the lower gum. Pulsæ 160, tremulous, and irregular. I directed that the child should be immediately put into a warm bath, and that the following remedies should be administered.

"Small blisters were applied on each side of the head, just below the bregma; and a folded rag, frequently moistened with brandy, was laid upon the tumor to promote absorption. An emetic had been given early in the morning, by which a large quantity of bile was discharged; and a vesicator had also been applied to his leg.

"September 11. Nine o'clock. The child has had frequent convulsions in the night; his right eye is much distorted; and it has been remarked, that he seldom moves the right hand. The pulse beat 120 strokes in a minute. Two scrupules of the mercurial ointment have been used, and he has taken five grains of mufk. A large discharge of foam has been produced by the blisters. Five o'clock, P.M. the tumor of the head is sensibly diminished; the child's mouth is now moist, and often filled with saliva; and his tongue appears to be swollen. His pulse beat 146 strokes in a minute, I directed another blister to be applied to the head.

"September 6. His convulsions have been much lighter; his eyes are frequently distorted; and the pupils of each are more contracted. The flux is considerably abated; the child seems to take some notice, distinguishes taste, and swallows freely. The mufk has been continued; and half a dram more of the mercurial ointment has been consumed. A clyster was injected last night. Yet, although the flux is considerably abated, the pulse has had a short sleep, and is now composed. His pulse beats 140 strokes in a minute, his heat is moderate; and his skin soft and perspirable. The mercurial ointment has again been used; but, though his gums and tongue are sore and very moist, his breath is not offensive. I directed a grain of calomel to be immediately given, to procure a stool; and a blister to be applied to the occiput.

"September 7. The child has passed the night more comfortably, but not free from convulsions. His head has sweated profusely, and the blisters have run much. The tumor of the bregma is considerably reduced. The jalap operated gently last night, and the mercurial unction has been twice repeated. There is an evident mitigation of all the symptoms.

"September 8. About eleven o'clock last night the child was attacked with severe convulsions, which recurred frequently till one o'clock this morning. He had a short sleep, and is now composed. His pulse beats 140 strokes in a minute, his heat is moderate; and his skin soft and perspirable. The mercurial ointment has again been used; but, though his gums and tongue are sore and very moist, his breath is not offensive. I directed a grain of calomel to be immediately given, to procure a stool; and a blister to be applied to the occiput.

"September 9. He has passed two nights almost entirely free from convulsions. Ten grains of the mercurial ointment have been again rubbed into his thighs. The dose of calomel occasioned three very offensive fumes; and directions are given to repeat it, as he is again coltive. The blister applied to the occiput, like all the others, has produced a very copious discharge. The tumor of the head is now scarcely perceptible. Pulsæ 120.

"September 12. At 12, o'clock last night, the convulsions recurred with greater violence than ever, and still continue. Two teeth have almost protruded through the upper, and the same number through the lower gum. Pulsæ 160, tremulous, and irregular. I directed that the child should be immediately put into a warm bath, and that the following remedies should be administered.

The convulsions continued but with less violence; and the child expired about one o'clock in the afternoon.

On this case the Doctor makes the following observations.

"The deplorable case which I have related appears..."
Comat'le, by the powerful expired were more formidable or alarming, even to the parents of the and fully approved of the trial of this new method of into; the course of circulation; to which may be added, mitius, part of the two grains of the calomel administered treating violent; and the half of this quantity might be absorbed, and carried was consumed in the usual way of fluid discharge were probably increased in the ventricles of the brain. That these discharges were diminished, and that the extravasated water was absorbed, by the powerful action of the mercury, may be presumed from the mitigation of all the symptoms which succeeded the salivation. And I am inclined to believe, that the convulsions under which the child expired were more owing to the irritation of his gums by the protrusion of four teeth, than to any remaining water in the brain; for the tumor of the head had entirely disappeared, and after death there was a manifest depression of the bregma. During the space of a week, 110 grains of the unguentum mercuriale nitrius, which contains about 22 grains of mercury, was confumed in the usual way of friction. Perhaps half of this quantity might be absorbed, and were deceit into the course of circulation; to which may be added, part of the two grains of the calomel administered internally. The symptoms of the salivation were not violent; and the effects of the mercury did not appear formidable or alarming, even to the parents of the child, who were apprized of the nature of the disorder, and fully approved of the trial of this new method of treating it.

CASE II. By Dr Dobson

"On the 15th of February 1775, I was called to the only son of Mr C. a gentleman of this place: the child was between three and four years of age; had been indisposed about eight days; and had frequently complained of pain in his head and earis, and pains in his limbs: had been sick by fits, and sometimes vomited; was feverish, and could not bear the light.

"I was much alarmed on hearing this account, as the hydrocephalus internus had already proved fatal to three children of this family, who had all been under my care. And that this had been the disease was evident, both from the symptoms and the appearances on dissection. But my alarm was much farther increased on examining the little patient. The pulse I found very frequent and irregular. The head hot, the cheeks flushed; the pupils dilated, and a great degree of strabismus. There remained no doubt with respect to the nature of the disease.

"An emetic, some calomel powders, and a purgative, had been administered, without affording any relief. I directed the pediluvium, and emetic tartar, to be given in such doses as to excite nausea.

"February 14th. The symptoms the same, with frequent startings, disturbed sleep, and toiling from side to side on the pillow. A blister was applied between the shoulders, the pediluvium repeated, and the emetic tartar continued.

"15th. Comatose, reliefs, and shrieking by fits. The pulse quicker than in health, and the eyes infensible even to the impressions of strong light.

"As I had no hope of doing any thing effectual for the recovery of my patient, I paid my visits, prescribed, and gave directions with a foreboding and heavy heart. Anxiously, however, considering the case in different points of view, and fully convinced that it Apoplexy, was vain to pursue the usual line of practice, it occurred to me, that mercurials, so far urged as to enter the course of circulation, and affect the salivary glands, might possibly reach the sytem of absorbents in the ventricles of the brain, and thus remove the extravasated fluid.

"The short continuance of the disease, and the apparent strength of my patient, were favourable to the trial of this method. No time, however, was to be lost. The parents were consulted, and readily gave their sanction to the proposal; for they were convinced, that, unless some powerful steps were taken, this their only son must be numbered with those of their children who had already fallen a sacrifice to the disease.

"The mercurial course, therefore, was commenced, and urged on with caution and expedition. In 48 hours the breath began to be offensive; the gums were reddish and swelled; and the symptoms of the disease, so far as could be distinguished, were somewhat abated. In 48 hours more the ptyalism came on, and the disease was evidently declining. Between the 15th and 22d he took 20 grains of calomel, and one drachm of the strongest mercurial ointment was likewise rubbed in on the legs and thighs. The dofe of calomel was one grain, mixed with a little sugar, and repeated at such intervals as the circumstances of the case pointed out.

"After the 22d no more mercurials were administered: a moderate ptyalism continued for five or six days, then gradually ceased, and the disease was entirely removed. The bark was then given, as the best tonic remedy after the mercurial course, and as the best preservative against a relapse. The strabismus, I observed, was the last symptom which disappeared.

"From the 15th, no other medicines were used except mercurials. The three sisters of the above patient, who all died of this disease, were treated with blisters; and to one of them they were applied in suffusion to the head, behind the ears, and between the shoulders."

CASE III. By Dr Percival.

"One of my own children, a girl, aged three years and three months, has lately been a severe sufferer under this alarming malady. As soon as the characteristic symptoms of the disease clearly manifested themselves, I laid aside all other remedies, convinced, by repeated observation, of their insufficiency; and trusted solely, though with much solicitude, to the internal and external use of mercury. In 48 hours, signs of amendment appeared, and her recovery was perfected in six days. During this space of time, thirteen grains of calomel were administered, and seven frcuples of unguentum mercuriale fortis carefully rubbed into her legs."

CASE IV. By Mr John Mackie, Surgeon in Huntington.

John Algoood, aged 27, of a thin habit of body, accustomed for four or five years past to work in a tan-yard in a very flopping posture, was attacked in the beginning of May with an irregular intermittent fever, accompanied with much pain in his joints. These
These complaints continued till about the middle of June, when he was seized with a violent and confluent pain in the back-part of his head, attended with giddiness, noise in his head and ears, dimness of lights, &c., and his fever became more continued. He lay in this state upwards of a month, without receiving any benefit from some medicines which he took during this period.

Mr. Mackie was called to him in the middle of July, and found him labouring under the following symptoms: A fixed pain on the right side and back part of his head, which was frequently so acute as to make him quite outrageous, crying out, tearing his hair, beating himself on the head, &c. He had such a giddiness that, unless strongly held, he could not support himself a moment in an upright posture. He could not bear the light; and, when he did venture to open his eyes, could not see objects distinctly. His pupils were uncommonly dilated; and his right eye seemed drawn outward, and rather contracted in its volume. He complained of a strange palpatiting noise in his head and ears; and said, he felt at times as if there was a weight of water falling from one side of his head to the other. He was, in general, sensible; but, on asking him two or three questions together, he became confused, and, like a person with an oppressed brain, answered with hesitation, quite wide of the question, and often opposite to what he meant. Along with these, he had a hot skin, small quick pulse, third, a foul tongue, urine in small quantity and high-coloured; he was emaciated, sick, collyvit, and sweated much; bad often a kind of foppur, but very little fever. Once in the 24 hours he had generally a remission (of three or four hours continuance) of the febrile symptoms, but of none of the other complaints.

July 16th. Ordered three or four leeches to be applied to each temple immediately; an emetic to be taken in the evening, and a cooling purge to-morrow, but all his other complaints better. Pain in his head was well; and the medicines to be continued as on the 23d.

July 19th. The blisters have discharged much, and he has taken the medicines punctually; but the fever and other complaints remain as before. Pulse very irregular; pain in the head and reflexion extreme.

1st. Dressed the blisters with the unguent, &c. He took the calomel, and ordered a double quantity of the mercurial ointment to be rubbed into his thighs every night.

26th. He had a calmer night than any for these two months past. For the first time, he said the pain of his head was abated; he looked more composed; his skin felt cooler; his pulse more full, and not so quick. He complained of his mouth being sore, and his tongue swollen; and had discharged a good deal of saliva in the night. Only one dram of the ointment to be rubbed in, for the two next nights.

30th. He spit about three quarts during the last 48 hours, and complains of much heat in his mouth; but all his other complaints better. Pain in his head almost gone, excepting now and then a swoon. Giddiness much abated. He said he often felt a trickling kind of motion, as of water running along the inside of his temples; but this sensation was without pain. He could sit up in bed, and feed himself; was sensible, and in spirits. Pulse regular, and not above 70 in a minute. He has had a remission of upwards of six hours to-day; ordered the ointment to be left off.

Aug. 1st. Continues to spit freely. Had yesterday a smart return of the fever; which, however, only held him about 12 hours. To-day there is a perfect remission, and he is in every respect much mended.—Has had some hours good sleep. Complains very little of pain. Got out of bed for the first time; sat up three hours; and could even bear the light without being disturbed by it. Complained of being hungry. Allowed plenty of milk-porridge and small broth.

3d. The spitting keeps up about a quart in the 24 hours. Found him out of bed to-day, and almost without complaints. He said his head was well; and that he only wanted strength and to get rid of his fever and low mood. The remissions were now almost as long as the paroxysms, being about 12 hours each. Has taken no medicine internally since he left off the calomel.
Praactic MED

Complied calomel, and was coltive. Ordered a dose of rhubarb; and after its operation a dram of the bark every four hours during the remissions.

6th. The spitting begins to decline. He has had no fever for the last 24 hours. He sleeps well; and has an appetite, if the foreheads of his mouth would let him eat. Headach and giddines gone; but his pupils still continue much dilated. Ordered him another rhubarb-purge, and the bark to be continued every six hours.

6th. Has had no fever, or other complaints. Spitting inconsiderable; mouth better; aspect more natural; is able to walk about, and mends daily. Allowed him a more generous and substantial diet, and continued the bark twice a-day for another week.

From this time, he continued toget strength apace; had good nights, good appetite, a perfect freedom from head-ach and fever; and, on the 23d, went to work, being in every respect quite well, and has continued to do every place.

This patient did not seem to receive the smallest benefit from the blisters, or any thing else, till he took the mercury, which acted like a specific; and the fever seemed to be altogether symptomatic, as it easily yielded after the other complaints were removed.

Although it must be allowed, that the affection here described was in many respects an anomalous one, yet many of the circumstances render it in some degree probable that it depended on water in the head; and there are strong reasons for inferring that the mercury pulsed so far as to excite salivation, was the means by which the cure was accomplished.

It is not wonderful that the publication of these cafes should have led to the frequent employment of mercury in hydrocephalic affections. We are however, sorry to add, that extensive employment of this remedy in such cases has by no means confirmed the favourable opinion which some were disposed to entertain of it. It has been found, that in many cases where mercury with hydrocephalic patients had been employed both internally and externally to a very great extent, no salivation was produced. Some, therefore, have even gone so far as to conclude, that salivation cannot be induced in this disease; and there is little reason to doubt, that, in the advanced periods of the disease, there occurs both an insensibility and diminished action of the absorbtents, by which alone mercury can be introduced into the system; and likewise of the salivaary organs, on which it must act before any obvious salivation can be induced. But, besides that mercury is often given in this disease even to the greatest extent without producing any obvious effect, we must also mention with regret, that in not a few cases of hydrocephalus, where mercury copiously exhibited at an early period produced salivation, the disease nevertheless has had a fatal termination, and it must be confessed, that an effectual remedy in this complaint still remains to be discovered.

At the same time; besides the cafes already mentioned, mercury has also succeeded in several others which had every appearance of hydrocephalus; and as we are yet unacquainted with any remedy, not even excepting blisters, of which some are disposed to think very favourably, on which more dependence is to be put, the careful and regular employment of it should not be neglected in any instance of this affection, unless some circumstance occur strongly contraindicating its use.

Sp. IV. Apoplexy from Atarabils. 219

Apoplexia atarabiliaria, Saw. sp. 12. Prefinger, sp. 6.

This takes place in the last stage of the diffusion of bile through the system, i.e. of the black jaundice, and in some cases the brain hath been found quite tinged brown. It cannot be thought to admit of any cure.

Sp. V. Apoplexy from External Violence.

Apoplexia traumatica, Saw. sp. 2. Carus-traumaticus, Saw. sp. 5.

The treatment of this disease, as it arises from some external injury, properly falls under the article Surgery.

Sp. VI. Apoplexy from Poisons.

The poisons which bring on an apoplexy when taken internally may be either of the Limulant or sedative kind, as spirituous liquors, opium, and the more virulent kinds of vegetable poisons. The vapours of mercury or of lead, in great quantity, will sometimes produce a similar effect; though commonly they produce rather a paralytic, and operate slowly. The vapours of charcoal, or fixed air, in any form, breathed in great quantity, also produce an apoplexy, or a state very similar to it; and even cold itself produces a fatal sleep, though without the apoplectic snorting.—To enumerate all the different symptoms which affect the unhappy persons who have swallowed opium, or any of the stronger vegetable poisons, is impossible, as they are scarce to be found the same in any two patients. The state induced by them seems to differ somewhat from that of a true apoplexy; as it is commonly attended with convulsions, but has the particular distinguishing sign of apoplexy, namely, a very difficult breathing or snorting, more or less violent according to the quantity of poisonous matter swallowed.

Of the poisonous effects fixed of air, Dr Percival gives the following account. “All those notious vapours, whether arising from burning charcoal, the fermenting grape, the Grotti di Cani, or the cavern of Pyrmont, operate nearly in the same manner. When accumulated and confined, their effects are often instantaneous. [omitted]
Comata: they immediately destroy the action of the brain and nerves, and in a moment arrest the vital motions. When more diffused, their effects are flow-
er, but still evidently mark out a direct affection of the nervous system.

"Those who are exposed to the vapours of the fermenting grape, are as instantly destroyed as they would be by the strongest electrical shock. A state of insensibility is the immediate effect upon those animals which are thrust into the Grotti di Cani, or the cavern of Pyrmont: the animal is deprived of motion, lies as if dead; and if not quickly returned into the fresh air, is irrecoverable. And if we attend to the histories of those who have suffered from the vapours of burning charcoal, we shall in like manner find, that the brain and moving powers are the parts primarily affected.

"A cook who had been accustomed to make use of lighted charcoal more than his business required, and to stand with his head over these fires, complained for a year of very acute pain in the head; and after this, till after the vapours of burning charcoal more than his business required, and was, immediately,...

"The vapours of burning charcoal, and other poisonous effluvia, frequently produce their prejudicial, and even fatal effects, without being either offensive to the smell or oppressive to the lungs. It is a matter of importance, therefore, that the common opinion should be more agreeable to truth; for where suffocation is supposed to be the effect, there will be little apprehension of danger, so long as the breath keeps free from pain or oppression.

"It may be well to remember, that the poison itself is distinct from that gross matter which is offensive to the smell, and that this is frequently in its most active state when undistinguished by the fumes. Were the following cautions generally attended to, they might in some instances be the happy means of preferring life. Never to be confined with burning charcoal in a small room, or where there is not a free draught of air by a chimney or some other way. Never to venture into any place in which air has been long pent up, or which from other circumstances ought to be suffocated; unless such suffocated place be either previously well ventilated, or put to the use of the lighted candle. For it is a singular and well-known fact, that the life of flame is in some circumstances destroyed more expeditiously extinguished by noxious vapours than animal-life. A proof of which I remember to have received from a very intelligent clergyman, who was present at a musical entertainment in the theatre at Oxford. The theatre was crowded; and during the entertainment, the candles were observed to burn dim, and some of them went out. The audience complained only of faintness and languor; but had the animal effluvia been still further accumulated or longer confined, they would have been extinguished as well as the candles.

"The most obvious, effective and expeditious means of relief to those who have unhappily suffered from this cause, are such as will dislodge and wash away the poison, restore the energy of the brain and nerves, and renew the vital motions. Let the patient therefore be immediately carried into the open air, and let the air be fanned backwards and forwards to affit its action; let cold water be thrown on the face; let the face, mouth, and nostrils, be repeatedly washed; and as soon..."
MEDICINE.

Practise.

as practicable, get the patient to drink some cold water. But if the case be too far gone to be thus relieved, let a healthy person breathe into the mouth of the patient; and gently force air into the mouth, throat, and nostrils. Frictions, cupping, bleeding, and blisters, are likewise indicated. And if, after the infant danger is removed, a fever be excited, the method of cure must be adapted to the nature and prevailing symptoms of the fever.

With regard to the poison of opium, Dr. Mead recommends the following method of cure. Before evacuations by vomiting, bleeding, and blistering, acid medicines and lixivial fires are proper. These contract the relaxed fibres, and by their diuretic force make a depletion of the vessels. Dr. Mead says he hath given repeated doses of a mixture of salt of wormwood and juice of lemons, with extraordinary success. But nothing is of greater consequence, than to use proper means for the prevention of sleep, by resting the patient, and by forcing him to walk about; for if he be once permitted to fall into a found sleep, it will be found altogether impossible to awake him.

Of a kind somewhat akin to the poison of opium seems to be that of laurel-water, a simple water distilled from the leaves of the lauro-cerasus or common laurel. The bad effects of this were first observed in Ireland, where it had been customary to mix it with brandy for the sake of the flavour; and thus two women were suddenly killed by it. This gave occasion to some experiments upon dogs, in order to ascertain the malignant qualities of the water in question; and the event was as follows: All the dogs fell immediately into torpor and convulsions of the limbs, which were soon followed by a total paralysis; so that no motion could be excited even by prickings or cutting them. No inflammation was found upon dissection, in any of the internal membranes. The most remarkable thing was a great fulness and dilation of the veins, in which the blood was so fluid, that even the lymph in its vessels was generally found tinged with red. The same effects were produced by the water injected into the intestines by way of clyster.

To make the experiment more fully, Dr. Nichols prepared some of this water so strong, that about a dram of strong essentil oil remained at the bottom of three pints of it, which by frequent shaking was again quite incorporated with it. So virulent was this water, that two ounces of it killed a middle-sized dog in less than half a minute, even while it was passing down his throat. The poison appeared to reside entirely in the above-mentioned essentil oil, which comes over by distillation, not only from the leaves of laurel, but from other vegetables; for ten drops of a red oil distilled from bitter almonds, when mixed with half an ounce of water, and given to a dog, killed him in less than half an hour.

Volatile alkalies are found to be an antidote to this poison; of which Dr. Mead gives the following instance. About an ounce of strong laurel-water was given to a small dog. He fell immediately into the most violent convulsions, which were soon followed by a total loss of his limbs. When he seemed to be expiring, a vial of good spirit of sal ammoniac was held to his nose, and a small quantity of the same forced down his throat: he instantly felt its virtue; Apoplexia. and by continuing the use of it for some time, he by degrees recovered the motion of his legs; and in two hours walked about with tolerable strength, and was afterwards quite well.

With regard to the pernicious effects of cold, there is no other way of counteracting them but by the application of external heat. We are apt to imagine, that the swallowing considerable quantities of ardent spirits may be a means of making us refit the cold, and preventing the bad effects of it arising to such an height as to destroy life; but these do not appear to be in the least possessed of any such virtue in those countries liable to great excesses of cold. The Peruvian bark, by strengthening the solids, as well is increasing the motion of the fluids, is found to answer better than any other thing as a preservative: but when the pernicious effects have already begun to discover themselves, nothing but increasing by some means or other the heat of the body can possibly be depended upon: and even this must be attempted with great care; for as in such cases, there is generally a tendency to mortification in some of the extremities, the sudden application of heat will certainly increase this tendency to such a degree as to destroy the parts. But for the external treatment of such morbid situations, see the article Surgery.
This is the kind of apoplexy which takes place in those who are hanged or drowned. For the treatment of those persons, see the articles DROWNING and HANGING.

Besides the species abovementioned, the apoplexy is a symptom in many other distempers, such as fevers both continued and interrupting, exanthemata, hysteria, epilepsy, goat, worms, fichuria, and scurvy.

Description. The palsy under all the various forms here mentioned as particular species, shows itself by a sudden loss of tone and vital power in a certain part of the body. In the lighter degrees of the disease, it only affects a particular muscle, as the sphincter of the anus or bladder, thus occasioning an involuntary discharge of excrements or of urine; of the muscles of the tongue, which occasions a trembling, or loss of speech; of the muscles of the larynx, by which the patient becomes unable to swallow food, and sometimes even liquids also. In the higher degrees of the disease, the paralytic affection is diffused over a whole limb, as the foot, leg, hand, or arm; and sometimes it affects a whole side of the body, in which case it is called hemiplegia; and sometimes, which is the most violent case, it affects all the parts below the waist, or even below the head, though this last be exceedingly rare. In these violent cases, the speech is either very much impaired, or totally lost. Convulsions often take place in the found side, with the cynical spasm or involuntary laughter, and other distortions of the face. Sometimes the whole paralytic part of the body becomes livid, or even mortifies before the patient's death; and sometimes the paralytic parts gradually decay and thrlve up, so as to become much less than before. Whether the disease be more or less extended, many different varieties may be observed in its form. Sometimes there occurs a total loss of sense while motion is entire; in others a total loss of motion with very slight or even no affection of sense; and in some cases, while a total loss of motion takes place in one side, a total loss of sense has been observed on the other. This depends entirely on the particular nerves or branches of nerves in which the affection is situated; loss of sense depending on an affection of the subcutaneous nerves; and loss of motion on an affection of those leading to the muscles.

Cauæ, &c. Palsies most commonly supervene upon the different species of coma, especially the apoplexy. They are also occasioned by any debilitating power applied to the body, especially excites in venery. Sometimes they are a kind of crisis to other distempers, as the colic of Poisonion, and the apoplexy. The hemiplegia especially often follows the last mentioned disease. Aged people, and those who are by any other means debilitated, are subject to palsy; which will sometimes also affect even infants, from the repulsion of exanthemata of various kinds. Palsies are also the invariable consequences of injuries of the large nerves.

Prognosis. Except in the lighter cases of palsy, we have little room to hope for a cure; however, death does not immediately follow even the most severe paralytic affections. In an hemiplegia it is not uncommon to see the patients live several years; and even in the paraplegia, if death do not ensue within two or three weeks, it may not take place for a considerable time. It is a promising sign when the patient feels a slight degree of painful itching in the affected parts; and if a fever should arise, it bids fair to cure the palsy. When the sense of feeling remains there is much more room to hope for a cure than where it is gone, as well as the power of motion. But when we observe the flesh to wither, and the skin to appear withered and dry, we may look upon the disease to be incurable. Convulsions supervening on a palsy are a fatal sign.

Cure. Many remedies have been recommended in palies: but it must be confessed, that, except in the lighter cases, medicines seldom prove effectual; and before any scheme of cure can be laid down, every circumstance relative to the patient's habit of body and previous state of health should be carefully weighed. If an hemiplegia or paraplegia should come on after an apoplexy, attended with those circumstances which physicians have supposed to denote a vitious state of the blood, a course of the attenuant gomps, with fixed alkaline salts, and chalybeate waters, may do service; to which it will be proper to add frictions with the volatile liniment all down the spine: but in habits where the blood is rather inclined to the watery state, it will be necessary to give emetics from time to time; to apply blisters, and cut blisters.

The natural hot baths are often found useful in paralytic cases; and where the patients cannot avail themselves of these, an artificial bath may be tried by dissolving...
Practice.

**M E D I C I N E.**

Comata. — dissolving salt of steel in water, and impregnating the water with fixed air. Frictions of the parts, and scouring them with nettles, have also been recommended, and may do service, as well as volatile and stimulating medicines taken inwardly. And it is probably by operating in this manner, that the use of camphor, or a mercurial dilution falfate of this length of time to such a degree as gently to affect the mouth, have been found productive of a cure in obilinate cafe of this affection. Of late years, an infusion of the arnica montana or German leopard's bane, has been highly extolled in the cure of this disease by some foreign writers: but the trials made with it in Britain, particularly at Edinburgh, have been by no means equally successful with those related by Dr Collins, who has strongly recommended this medicine to the attention of the public.

Sp. IV. The Palsy from Paixs.

Paralyxias mettallariorum, Sauv. fp. 22.

This kind of palsy arises most frequently from lead taken into the body, and is a consequence of the colica piétonum, under which it is more particularly treated.

TREMOR, or TREMBLING.

This by Dr Cullen is reckoned to be always symptomatic either of palsy, at hernia, or convulsions; and therefore need not be treated of by itself.

Description. It is by no means easy to define exactly the distemper called dyspepsia, when considered as an original disease, as there are very few maladies which some way or other do not throw themselves by an affection of the stomach; and much more difficult must it be to enumerate all its symptoms. The most remarkable, however, and the most common, are the following: Want of appetite; dilution of the stomach when no food has been taken for some time before; flight dejection of spirits; a gradual decay of the muscular strength; languor, and aversion from motion; the food which is taken without appetite is not well digested; the stomach and intestines are much disturbed with flatus, whence the patients are tormented with flatulences, gripes, and fickness; frequently a limpid water, having an acid or putrid taste, is brought up; sometimes the food itself is thrown up by mouthfuls; and sometimes, though rarely, the same is swallowed again, after the manner of ruminating animals. While matters are in this situation, the heart sometimes palpitates, and the breath is quick, and drawn with difficulty; the head aches and is giddy; and sometimes both these symptoms are continual, and very violent, insomuch that the patient is not only tormented with pain, but staggerers as if he was drunk. From the too great acieency or putrefaction of the aliment, a cardialgia or heartburn comes on; and in this situation a spontaneous diarrhoea sometimes carries off the disease; but in other cases there is an obilinate colicvines, attended with colic-pains. Frequently the pulle is quick, sometimes flow, but always weak; the circulation is so languid, that the blood can scarce reach the extreme vessels, or at least stagnates.
MEDICINE.

Practice. 

A dysepsia flagnates in them, so that the face becomes livid, swelled, and has an unusual appearance: and at the same time that the circulation and nervous power are in this languid state, the perspiration becomes less copious, the skin becomes dry and corrugated; the natural heat, especially of the extremities, is much diminished; the tongue is white; and an universal laxity takes place, insomuch that the uvula and velum pendumulum palati are sometimes enlarged to such a degree as to become extremely troublesome. The patient is either deprived of rest or wakes suddenly out of his sleep, and is disturbed by frightful dreams; at the same time that the mind seems to be affected as well as the body, and he becomes peevish, fretful, and incapable of paying attention to anything as usual. At last hecific symptoms come on, and the whole frame becomes so irritable, that the slightest cause excites an universal tremor, and sometimes violent vomiting and diarrhea. Sometimes the salivary glands are so relaxed, that a salivation comes on as if excited by mercury; the serum is poured out into the cavity of the abdomen and cellular substance of the whole body, and the patient becomes affected with anaesthesia or acrides.

Causes &c. The causes of dysepsia may be any thing which debilitates the system in general, but in a particular manner affects the stomach. Such are opium taken in immoderate quantities, which hurts by its sedative and relaxing powers; spirituous liquors drunk to excess; tobacco, tea, coffee, or any warm relaxing liquor, taken in too great quantity; acid, unripe fruits; vomits or purges too frequently taken; an indolent sedentary life, &c. &c. All these chiefly upon people of a weak and delicate habit; for the robust and hardy seldom labour under a dysepsia, or at most a very slight one.

Prognostic. When a dysepsia first occurs, it is frequently removed without great difficulty; when it is symptomatic, we must endeavour to cure the primary disease; and without this we cannot expect a complete removal of the affection: but when it frequently returns with symptoms of great debility, hectic fever, or dropy, we have great reason to dread the event.

Cure. A radical cure of dysepsia is only to be expected by removing from the stomach and system that debility on which the disease depends. On this ground, the objects chiefly to be aimed at is the cure are, 1st, The avoiding whatever will tend to diminish the vigour of the stomach; 2d, The employing such remedies as have influence in increasing that vigour; and, in the third place, The obviating urgent symptoms, particularly those which tend to increase and support the affection. Of the avoiding causes, which tend to diminish the vigour of the stomach, after what has already been said of the causes inducing the disease, it is unnecessary to make any particular observations; and indeed every dyspeptic patient will be taught by experience what is to be done with this intention. The medicines chiefly employed with the view of increasing vigour are those of the tonic kind: but, previous to their use, it will be necessary to evacuate the contents of the alimentary canal by emetics or purgatives. If there be a tendency to putrefaction, antiseptics must then be exhibited; but more frequently there is a prevailing acidity, which Dysepsia creates an intolerable heart-burn. To palliate this symptom, magnesia alba may be given; which is much preferable to the common tannaceous powders, as being purgative while dissolved in an acid, when the others are rather astringent. In the third volume of the Medical Observations, we have an account of two cases of dysepsia attended with a very uncommon degree of cardialgia, in which magnesia was so successful, that we can scarce doubt of its efficacy in lighter degrees of the disorder. They were communicated by Dr. Watson.

A woman, aged 34, the mother of several children, was taken, in the fourth month of her pregnancy, with violent vomittings; which growing daily worse, notwithstanding the endeavours of her apothecary to restrain them, brought on at the end of a month such severe pains in the stomach, and ipasms in her abdomen, as to occasion abortion. The vomitings were not lessened by this event, but grew worse and frequently brought on general convulsions to such a degree, that she was many times supposed to be at the point of death.

Scarce any medicine fluid with her; she brought up almost instantly whatever was given her as nourishment, either in a solid or a liquid form. She was exceedingly pale, and very much emaciated; her flesh was cold to the touch; and, though her urine was little in quantity, it was perfectly hlimpid. She had a continual thirst, and was, in a considerable degree, colicive. Her pulse was low and quick, and she was frequently tormented with the hicough. The pain in her stomach was severe and constant; and whatever she brought up was sharp to such a degree as to make her mouth and throat very sore. The parts upon examination appeared high-coloured, and in many places excoriated; and the pain she felt in her stomach upon swallowing any liquor that had the least degree of acrimony, or was more than Luke-warm, made it probable the stomach itself, in its internal surface, was affected in the same manner.

In this wretched state I was consulted; and must confess that I was much at a loss how to relieve a patient so debilitated, and whose stomach was in so dilated a state, that it seemed incapable of retaining any appropriated remedies long enough to correct the acrimony of the juices, and restore the secretions to a more mild and natural state. Anti-emetics of various kinds had been tried without effect, particularly saturated solutions of alkaline salt in juice of lemons. Stomachic medicines of the warm and aromatic kind she could not bear, on account of their piquancy; and, though nothing could so speedily correct the almost caustic acid of the gastric juice as solutions of alkaline salts, neither the tinctures nor gulett could bear their acrimony.

My expectations of relieving this patient, small as they were, depended upon my being able to neutralize, and thereby lessen, the stimulus of the acid of the stomach. To accomplish this was not very easy, as no medicine in small doses could in any considerable degree correct so intense an acid; and, in the present situation, it was difficult to get any medicine to stay long enough to exert its effects. To discharge however what acid matter might be already accumulated in
in the stomach, I directed that the patient should drink plentifully of small, warm, unaltered mutton-broth, and vomit with it so long that it should be discharged with no other taste than that of broth. This was complied with, and a large quantity drank. The pain in her stomach ceased upon this for more than two hours, and was after that time apparently coming on with the same violence as before. Upon which I ordered a draught of magnesia to be given in two ounces of veal-broth. This kept down, and eased her; I therefore directed the same dose to be repeated as often as the pain returned, without any regard to the quantity that the whole might amount to, supposing that the pain continued severe. This was done; and in three days she took three ounces of magnesia, of which very few doses were vomited up, and she was purged considerably.

"This medicine was continued in a somewhat less quantity for three days longer, in which she took two ounces more of magnesia; by this time the vomitings ceased, the convulsions left her, she had no pains in the stomach, and her mouth and fauces lost their intensely red colour and forefhe; nor did even her eructations longer indicate any acidity.

"Besides veal-broth she was allowed boiled rice, and now and then some rice gruel with a small quantity of brandy; and after a few days more she could retain boiled chicken, and other light, solid, animal food.

"When her stomach was in this state, she took literally of decoct corn. Peruvian, with a small portion of French brandy; by which and her nourishment she recovered her strength surprizingly. To this medicine, as she was during the latter part of her illness considerably anaferacous, were added some preparations of steel; and in about a month she perfectly recovered.

"When this patient's stomach was relieved, the thirst, the general and partial pains, and other complaints, which were merely symptomatic, soon ceased; and what remained of her cure was by no means difficult.

"Since the above-recited case, I was consulted in another almost in every respect similar, except that the former began in pregnancy. The vomitings attended with acidity had continued more than a month; the patient's stomach rejected every kind of food and medicine; she was debilitated to a great degree, and universally anaferacous.

"Upon being sent for, I directed for her magnesia, much in the same manner as for the former patient; and in a very few days her vomitings ceased, her stomach became stronger, and in less than a fortnight the anaesthesia disappeared. But it was a considerable time, as this person was more advanced in years than the former, before she recovered her strength, notwithstanding my best endeavours for that purpose. She at length, however, perfectly recovered."

"But although acidity may often be successfully obviated in this manner, yet the best way of counteracting this symptom, as well as of obviating colicines, flatulence, and a variety of others, is by regaining the tone of the stomach in particular, and indeed of the system in general. With this intention, recourse is had to a variety of tonics both from the mineral and vegetable kingdom; particularly chalybeates in different forms, gentian, colombo, and the like; but of all the tonics which can be employed in this affection, none are attended with greater benefit than exercise and cold bathing; and the proper and prudent employment of these is no less effectual in removing the disease, than in preventing the return of it after it is once removed."

**Genus XLVI. HYPOCHONDRIASIS.**

**HYPOCHONDRIAC AFFECTION.**

Morbus hypochondriacus, Borbh. 1098.

Malum hypochondriacum, Hoff. III. 65. Funck. 36.

Although some of the nofological writers, particularly Sauvages, have considered this genus as confiting of different species, Dr Cullen is of opinion, that there is only one idiopathic species, the hypochondriasis melancholica. He considers not only the hypochondriasis hysteric, phthisica, and athmatica, but also the biliosa, fanguinea, and pittuitosa, as being only symptomatic; but he views the true melancholic hypochondriasis as being a proper idiopathic disease, perfectly distinct from hysteric, with which it has often been confounded.

**Description.** The symptoms of hypochondriasis are, stretching, preffing, griping, and tormenting pains, under the ribs, and chiefly in the left side; which sometimes are exasperated, and become pungent, burning, or lancinating. Frequently there is an inflation of the left hypochondrium, which sometimes becomes flatonymous, and by Hippocrates was taken for a symptom of an enlarged spleen. When these symptoms take place in the right hypochondrium, they are commonly attended with colic-pains, uncertain flying heats, especially in the head, with a transient redness of the face, and very frequently an oedematus swelling of the feet succeeds. To these are superadded almost all the affections of the stomach occurring in dyspepsia, besides a variety of other symptoms, such as palpitations, sleepless nights, and the like. But besides these, there occurs also a particular depression of spirit and apprehenion of danger which may be considered as one of the great characterizing symptoms of the disease.

**Causes, &c.** The general causes of the hypochondriac affection are said to be a plethora, and preternatural thickness of the blood; suppressions of customary evacuations; high and full diet, together with a sparing quantity of drink; an hereditary disposition; indolence; atony of the intestines; violent passions of the mind, &c.

**Prognosis.** The hypochondriac affection, when left to itself, is more troublesome than dangerous; but, if improperly treated, it may bring on various diseases of a more fatal tendency, such as the melancholy, bloody urine and nephritis; jaundice, vertigo, palpity, apoplexy, &c.

**Cure.** This is to be attempted by such medicines as counteract occasional causes, and obviate urgent symptoms,

Order III. SPASMI.

SPASMI, SAW. Clas. IV. VOG. Clas. V. SAG. Clas. VIII.

Motorii, LIN. Clas. VII.

Morbi spasmolici et convulsivi, Hoffm. III. 9.

Spasmi et convulsiones, Junck. 45, 54.

Epilepsia, Boerh. 1071, 1088.

GENUS XLVII. CHLOROSIS.

Green Sickness.

Junck. 86.

Of this genus also Dr Cullen thinks there is but one idiopathic species: viz. what some distinguish by the title of chlorosis virginis, others of chlorosis ama
toria.

Description. This disease usually attacks girls a little after the time of puberty, and first shows itself by symptoms of dyspepsia. But a distinguishing symptom is, that the appetite is entirely vitiated, and afterwards turbid; while the same time there is not only a total inappetence to proper food, but it will even excite nausea and vomiting. In the beginning of the disease, the urine is pale, and afterwards turbid; the face becomes pale, and then assumes a greenish colour; sometimes it becomes livid or yellow: the eyes are sunken, and have a livid circle round them; the lips lose their fine red colour; the pulse is quick, weak, and low, though the heat is little altered; and the veins are scarcely felt; the feet are frequently cold, swelI at night, and the whole body seems covered with a soft swelling; the breathing is difficult: nor is the mind free from affections as well as the body; it becomes irritated by the slightest causes; and sometimes the patients love solitude, become sad and thoughtful. There is a retention of the menses throughout the whole course of the disorder; and at last all the bad symptoms increasing, a leucophaematia, ana
fatica, atrophy, and death, succeed.

Causes. The cause of chlorosis is thought to be an atony of the muscular fibres of the alimentary canal, especially of the stomatch, joined with a similar atony of the periphrastic vessels over the whole surface of the body, and the whole depending on an atony of those small arteries which pour out the menstrual blood. This atony may be occasioned by the same causes which bring on dyspepsia and hypochondriasis, but very frequently arises from love and other passions of the mind.

Prognosis. The chlorosis in all cases is tedious, though it does not generally prove fatal; but we can never promise a certain cure unless the menes make their appearance.

Cure. The remedies here in general are the same as in the dyspepsia and hypochondriasis; only in the chlorosis stronger purgatives may be made use of: those which dilate the rectum are useful by dilating also the vessels of the uterus; and for this reason indiglute, an venery has sometimes been said to produce a cure, particularly with love-dick maids. The cold bath is also extremely proper.
Spasm repeats them in another place; but the few symptoms he recounts do not show themselves with us. Galen, Cedius Aurelianus, Aretaeus, &c. seem only to have copied Hippocrates, with the addition of some sopphisticous symptoms, which really do not appear; and the little that Bontius says of it is very faulty.

Among the numerous clasps of spasmodic diseases, there are three which distinguish themselves in a very particular manner, on which the names of emphysematos, opthalmotonos, and tetanus, have been justly enough bestowed, as being expressive of the posture into which they throw and confine the patient. When therefore these muscles which bend the head, neck, and body forwards, suffer such involuntary, violent, and continued contractions, as to fix the chin to the breast, incurvate the spine and body, and retain the neck in this painful and prone posture, the disease is called emphysematous. When the posterior muscles are similarly affected, so that the head is drawn towards the spine, and the spine itself is recurvated, it has then the name of opthalmotonos: although in fact, in this, all those muscles which act in deglutition, bend the head forwards, or turn it to either side, are equally contracted with those which raise the head and spine. The tetanus differs from, or rather is compounded of, both the others; for in this the patient is found rigid and inflexible, being as it were braced between the opposite contractions of the anterior and posterior muscles; yet even here the head is much retracted.

I never saw the emphysematous; and shall only speak of the opthalmotonos and tetanus, the first being by far the most common, and in the last fngale of which the tetanus frequently supervenes. And let it be observed, that the following description by no means respects such symptomatic contractions as often happen immediately before death, both in acute and chronic diseases; neither will it agree with that furious opthalmotonos or tetanus which appear sometimes in the first and second stages of quotidienne intermittence in this country; however, they may emulate the true diseases in some of their symptoms.

Stad. I. The opthalmotonos, contrary to what Bontius afferts, often comes on gradually and by flight approaches, the patient complaining rather of an uneasy stifliness in the back-part of the neck, and about the shoulders, than of any acute pain, with some degree of a general altitude. They increase, and become so troublesome when he attempts to turn his head, or to bend it forward, as to oblige him to walk very erect; for he can by no means look downward nor to either side, without turning his whole body. He cannot open his jaws without pain; and has some difficulty in swallowing, which discourages him from attempting to eat. At times he feels a sudden and painful traction under the cartilago enformis, which strikes thro' to the back and instantly increases the rigidity about the neck and shoulders, draws the head backwards a little, and fluts the jaws closer. The pain under the sternum returns more frequently and with greater violence; and the other contractions become so strong, that the head from this time continues much retracted, and he now refuses nourishment, as swallowing is attended with great pain, and occasions a return of the spasm; which extends along the spine quite to the lower extremities, so that they will no longer support him, and he is under the necessity of going to bed.

In this manner passes over the first stage of the ophthalmotonos, which sometimes takes up three or four days; the patient, as well as those about him, mistaking the first appearances of it for that rheumatic complaint, which is commonly called a crick in the neck; but it sometimes forms itself much quicker and invades the unfortunate person with the whole train of its mildevous symptoms in a few hours: in which case, the danger may truly be estimated from the violence of the first attack; for such generally die in 24, 36, or 48 hours, and very rarely survive the third day. But when it is less acute, few are lost after the ninth or eleventh; which number of days it would not be possible for them to complete, unlefs the violence of the disease was in a good measure subdued; although I had one who recovered, after having been subject to its tyrannical attacks daily for six weeks. In this stage the pulse is slow, and very hard, and the belly is bound; blood taken away seems not to be altered from the natural state, fo that no indication can be deduced therefrom, and it only varies with regard to laxity or compaction, according to the age of the person and feaon of the year.

Stad. II. The spasm under the sternum (which is the pathognonomic symptom of this disease) becomes more violent, returning every 10 or 15 minutes; and never fails to be instantly succeeded by a stronger retraction of the head, with great rigidity and pain all round the neck, and along the spine to the lower extremities which are suddenly put to the stretch. The countenance is very pale and contracted; the jaws are that moment snapped together, and cannot afterwards be opened so wide as to receive the end of one's little finger; an attempt to do which, by way of experiment, surely hurries on the spasm. The malar, cheek, and sternohyoid muscles, as well as all the others concerned in deglutition, and the deltoid and pectoral muscles, are most violently contracted, so that the shoulders are strongly raised forward, and the arms are stretched out or drawn across the body; but the wrists and fingers seem not to be affected.

Such is the condition of the patient in the time of the spasm, which ceases in a few seconds: after which the shoulders and arms recline, and the inferior extremities relax; yet not so entirely, but that such a degree of rigidity for the most part remains as will not permit them to bend when this is attempted by another person, for as to the sick himself, he cannot at all move them. The muscles on the sides and forepart of the neck continue still contracted, although not so strongly; but their action is overcome by the number and strength of the posterior ones; so that the retraction of the head constantly remains. He breathes quick for some minutes, as if he had been excessively exercised; and the pulse is small, fluttering, and irregular, but both become more calm and slow. The face is sometimes pale in the intervals, but oftener flushed; and the whole countenance expresses strong appearances of the most melancholy diftress, as well because of the dread he has of a return of the spasm, which he is sure will soon happen, as from the pain he suffers by the present contractions, and the more general
in the stomach, even in the smallest quantity; and if the spasm should seize him at that time, which an attempt to swallow for the most part occasions, the liquor returns through the nose with some force. The patients desire to lie still as much as possible; and avoid drinking, speaking, or being moved, either of which are apt to occasion a return of the spasm.

"Stad. III. In this last stage, the patient is reduced to the most calamitous and distressful circumstances; for he is on a continual rack, according to the most literal meaning of that word; the spasm returning oftener than once in a minute, is much more violent, and holds him longer, so that he has scarcely any remission. The anterior muscles of the whole body now suffer equal contractions with the posterior; but the last overcome the force of the others, so that the spine is strongly recurvated, and forms a hollow arch with the bed, and he refts on the back part of the head and the heels. The belly is flat, and is drawn inward; and the muscles are so rigidly contracted, that they will not give way to pressure, and do not seem in the least to yield to the defect of the diaphragm in inspiration; the several muscles about the neck, sides, and abdomen, being plainly dilatible from each other. Although the lower extremities are always rigid in this state, yet are they so suddenly and violently dilated in the time of the spasms, that were it not for the flanders-by, he would be projected feet foremost off the bed; while others again are as if they were pushed upward with such a spring, that the head is struck with great force against whatever happens to be in the way, the thighs and legs being in this case no less rigid than the other parts. The tongue is spasmodically darted out, and is often miserably torn, as the teeth are that for most part locked fast, so that it is impossible to give drink or nourishment, nor could he swallow if anything was put into his mouth. In this state they are commonly delirious: and as they cannot subsist many hours under so great a fatiguing of the vital and natural functions, a mortal anxiety ensues and releases them; oftener a continued and severe spasm finishes the tragedy, when it was before almost at an end: but most frequently a general convolution puts a period to their sufferings; and whichever way this happens, they for the most part relax just before death.

"In the tetanus, the general symptoms are nearly the same as in the opillhotonos, except that from the first attack, the lateral, abdominal, and other anterior muscles, are equally contracted with the posterior ones; and the arms become rigid as well as the lower extremities. The abdomen is always flat and rigid as in the last stage of the opillhotonos, and its contents seem to be thrust up into the thorax, which at the same time appears to be much dilated. There are here also some intervals between the spasms, in the time of which the cheeks are drawn towards the ears, so that all the teeth may be seen as in the spasmus cynicus. Deglutition is more free in this than in the other disease; yet so far is the sick from being equally balanced between the contradictions of the opposite muscles, that the head is retracted and the spine is recurvated, although not quite so much as in the opillhotonos. And this spasm, which commences under the sternum, is likewise common to the tetanus, which terminates as the other, and on the same fatal days. But whoever recovers from either, labours long under a general atonia; and they cannot for some months raise themselves from a supine or recumbent posture without pain, nor without help for some time."

Prognosis and Cure. There has never been any thing like a crisis observed in these frightful cafes, or favourable termination from the mere efforts of nature; and therefore all the physician's dependence must be upon art. As in cases of tetanic affections, the disease often arises from some particular irritation, the removal of this must necessarily be an important object in the cure.; But where it cannot be removed, benefit may often be obtained by the prevention of its influence being communicated to the brain. When, however, that influence is communicated to the brain, a cure is to be expected only by diminishing and obviating it. This is principally brought about by the use either of those means which have a general tendency to diminish action, or of those which induce a different state of action. On these grounds the operation of those remedies which are employed with greatest success in this affension, may, we apprehend, be explained. Fortunately it has been found, that opium is capable of giving some relief, if administered in proper time, and if the disease happens not to be in the most violent degree; the warm bath must also be brought in aid; and the patients should lie horizontally in the bath, and while in it have the whole body extremely well rubbed; when taken out, they are not to be dried, but immediately put to bed wrapt in the softest blankets; and while they remain there, the belly ought either to be flaped, or two or three bladders filled with warm water kept constantly lying on it. The bowels at the same time must, if possible, be kept open, by solutions of manna and salt polycryst, or some other purging salt, mixed with deum ricini; or if that should not be at hand, with oil of sweet almonds and a little tincture of iena. The opiates are to be given in large and frequently repeated doses; such as a grain of the extatrum thebaicum, or 20 drops of the tincture, every second or third hour; and it will be safest not to truss to the thebaic tincture which is kept ready prepared in the shops, but order the necessary dose of solid opium, and either give it in pills or dissolve it in some other vehicle.
some convenient liquid. If swallowing should be difficult, or the jaws closed up, the opium must be given in clysters; for during the whole course of the disease it will be of service to order emollient clysters to be injected from time to time, since these will answer not only as a relaxing fomentation, but also contribute to keep the intestinal canal perfectly free.

When the patients recover, they continue for a long time very relaxed and weak; and no wonder, since it is the nature of all spasmodic affections to leave behind them extreme weaknesses and relaxation of the muscular fibres. In order to perfect the recovery, a course of the Peruvian bark, and the Peruvian balsam is to be tried; and the spine may be rubbed with spirituous fomentations, either internally or externally, during the violence of the spasms, mufli, in the opinion of some practitioners, be omitted, since all of them as well as blisters have been allledged to exasperate the disease.

This, in general, is the plan of treatment recommended by Dr Chalmers.

The same dreadful disorders frequently attack young children in the warm climates. Dr Hillary tells us, that they will there arise from the same causes which usually produce convulsions with children in Britain, viz. from a retention of the meconium or first excrement after birth; or from a glutinous matter which is too often found in the intestines of young children soon after the other is discharged; or from a cheesy matter from the coagulation of the milk by an acid in the stomach; or from hard excrements; or from something taken in by the mouth which is over acid, or too hard to digest, which irritates their tender bowels, and so produces startings and convulsive spasms, with all the other symptoms which precede and accompany convulsions in young children in Britain. And this shows how much more readily and easily the nerves are affected and irritated in that warm climate, and the tetanus produced from a much less cause there, than it is in Britain, where it is but seldom seen. But these causes not being timely removed, their acrimony is increased partly by the heat of the climate, and partly by the fever which they produce, which still renders them more acid, and so increases the irritation of their bowels, that it first brings on startings, then convulsive spasms, and regular convolution fits; which, if not soon removed, usually end in a perfect tetanus there, and the disease is but seldom cured in such young children when it arrives at that state: for when the child lies in this miserable, rigid, impossible condition, upon moving its hands or feet in the most gentle manner, or softly touching any part of its body, or giving it the least motion, even feeling its pulse in the most gentle tender manner, or the least noise, or even touching its clothes, will bring on the convulsive spasms, and cause it to be strongly convulsed backwards, or drawn into a rigid straight line, strongly extended and immovable like a statue, and will so remain immovable out of either of those postures for a considerable time, a minute or two; and when the disease is arrived at this degree, Dr Hillary thinks it is never cured. But if the physicians be called in time, before the tetanus has come on (which is too seldom the case there), though he finds strong convulsive spasms have seized the child, or that it has had a convulsive fit or two, it may most commonly be relieved, the coming of the tetanus be prevented, and the life of the babe saved, as Dr Hillary has more than once seen, by removing and carrying off the irritating cause which stimulates their tender bowels, by such gentle evacuations as are suitable to their age; and then quieting and composing the irritation of their nerves with proper anodynes, and correcting the remaining acrimony of the nutritious juices in the prime visa.

To answer these intentions, the following method, with variations pro re nata et pro ratione sitatis, as the cause is different, has been found to answer the desired effect the best: R. Sert. latiss. 3ij. Sapon. Venti. 3j. Manne Calab. 3ij. vel iiiij. Ol. amygd. dol. 3ij. Ol. farenici dul. gut. ij. Balf Peruv. gut. v. Mifia, si enema quem primum inijicendum.

And if the symptoms of the approaching tetanus will permit, he gives something of the following nature to all. This, Dr Hillary says, more than once exhibited to the eye, and to carry off the acrimony the sooner: R. Aq. fem. farenici 3ij. Magnes. alba 3s. Ocul. canum, præp. 3j. Syr. echior. cum rho, Ref. fan. flatus, et 3ij. Mifia. Or. R. Aq. fem. farenici 3ij. Sapem. amygdal. 3ij. Magnes. alba 3s. Syr. echior. cum rho, Manne op. et 3ij. Ol. amygd. dol. 3ij. Mifia : Exs. coch. paro. vel duo pro ratione sitatis omni falsa hora, donec respondat abusus. Two or three stools being obtained by these, the following is exhibited in order to abate the convulsive twitchings, and prevent the tetanus from coming on: R. Aq. fem. farenici 3ij. Magnes. alba 3s. Ocul. canum, præp. 3j. Mofchi orient. gr. iij. Spir. C. C. gut. xv. Syr. et mēcon 3s. Mifia : Exs. coch. paro. (a child's spoonful) ter quatero de die, vel susp. urgent. convuls. vel fpasmi.

But if the symptoms show that the tetanus is more immediately coming on, so that we have no time to wait till the operation of the clyster and opening the laxative be over, something of the following nature must be immediately given; or the tetanus will come on, and most probably prove fatal to such tender babes. R. Aq. farenici 3ij. Mofchi orient. gr. j. Tincl. Thēbaicis. gut. iij. Syr. et mēcon 3j. Mifia pro duobus def. de quiibus exhibe omnem quam primam, et alteram si convuls. spoym. reddant.

This, Dr Hillary observes, may be thought a bold attempt, to give tinct. thebaicis to such a tender young infant: but it is to be considered that the little patient will certainly die if the tetanus seize it, and that it will come on if this do not prevent it; and he has known a bold ignorant old midwife give four or five drops of that tincture to a very young infant without any prejudice more than its doing three or four hours, though not in this case, but in one much less violent.

The clyster may be given at the same time, and the opening laxative not long after it; though it may retard the operation of that for some time, yet it operates soon after, and gives relief; after which the other medicines, and fomenting the body and anointing it as before, may be used, if the physician finds it necessary; also a little of the laxative mixture may be given once or twice a day, if the above julep does not answer
Practice.

MEDICINE.

answer that intention of keeping the child's body open for a few days afterwards, which in this case is generally found necessary to be observed.

These methods and medicines may be varied according to circumstances. For neither the same method nor the same medicines will answer in all cases, though the disease be the same; but they must be changed as the causes differ, or the constitution of the sick, or the time of the disease, or as some other circumstances may require: which is a thing of great importance, not only in this, but in the cure of most other diseases; wherefore it is mentioned here chiefly to caution the practitioners in the West Indies.

When proper medicines are thus timely and judiciously given in this case, they seldom fail to carry off the irritant cause, quiet and ease the nerves, remove the convulsions and spasms; and consequently prevent the tetanus from coming on, and the death of the patient. But if calling in the physician be deferred till the tetanus has already strongly seized the child, as is too often the case here, neither warm bathing, fomenting, nor any other methods or medicines whatever, will remove it or its causes, nor save the life of the little tender patient.

Dr Chalmers gives an account of his having cured one child seized with a tetanus, by purging with an infusion of rhubarb; to which a few grains of mith, and a little d. tartar. per diem, were added, together with the warm bath, and the frequent injection of gyniers made with an infusion of camomile flowers, to each of which was added a small portion of Caffie soap. It is much to be regretted, however, that in those cases where the attendance of the medical art is most wanted, it most generally fails. We have been assured by a gentleman who practised for some time in the warm parts of America, that out of 50 cases of the tetanus he had seen, not one of the patients recovered, though he had given opium to the quantity of 20 grains thrice a-day; and others, he was assured, had taken 30 grains thrice a-day. In the beginning of the disease, the medicine produced a violent head-ach; but towards the end, it had no manner of effect whatever.

In two patients, the disease came on from the slightest cause imagined. The one accidentally fell in attempting to avoid a loaded cart, and put the heel of his foot upon one of his thumbs in rising; the other, in avoiding the same cart, lightly ruffled the skin of his nose. Both were seized with the tetanus; and both died, notwithstanding all possible assistance was given. The former had his thumb amputated without effect.

In the Edinburgh Physical and Literary Essays, Vol. III. Dr Donald Monro describes a new method of cure, communicated to him by a gentleman who was formerly a practitioner in Jamaica. While this gentleman practised in that island, he had under his care a great number of cases of tetanus attended with the locked-jaw. At first, he used to give very freely of opium, mith, and other medicines of this class; to bleed, and make other evacuations; while he used baths, fomentations, embrocations, and other external applications, but all without the least success; and, as he had lost a great many patients without being so lucky as to make one cure, he began to believe that this disorder always proved fatal, and was not to be cured by medicine, notwithstanding what some practitioners had alleged. However, having received an unexpected hint concerning the good effects of the mercurial ointment in such cases, he resolved to try it; and ordered the first patient that offered to be put into a warm room, and to be rubbed two or three times a-day with the ointment, till such time as a salivation was raised; when he with pleasure observed, that as soon as the mercury began to affect the mouth, the convulsions of the muscles of the jaws, as well as all the other spasms and convulsions, ceased, and the patient was freed of all his complaints. After this, he treated every case of this kind which came under his care in the same manner, and cured twelve, which were all who applied to him for advice so early in the disorder that there was time to bring the mercury to the mouth before the fatal period was expected. A few died, in whom the disease was so far advanced before he saw them that there was not time to raise a salivation. None of the cases which were under this gentleman's care in the West Indies were the consequences of wounds or capital operations; nor has he had any opportunity of trying it in cases of the locked-jaw, which sometimes follows capital operations, owing to his having given over his practice:

In the second volume of the Medical Transactions, we have an account of a cure performed by Dr William Carter of Canterbury, by means very different from any of those above related.—On the 17th of May 1757, the doctor was called to a strong healthy man, in the 21st year of his age, and who had been confined to his bed for three weeks. What gave rise to this present disorder was a wound on the inner ankle of his right leg, which he had receive six weeks before from a joiner's chisel. At that time his mouth was so far closed, as to admit only the most liquid nourishment, which he constantly sucked through his teeth: but his legs and jaw, and the whole length of the spine dorsal, were quite immovable, being as stiff and rigid as those of a person long dead; his head was drawn backward, and he was frequently strongly convulsed. The motion indeed of both his arms was but a little impaired. From the beginning to the end, his sight, hearing, and memory, continued perfect; his appetite was good; and his senses, in the day-time, entire, though sometimes wandering in the night. As to his pulse, that was regular; if it deviated at all from the pulse of a person in health, it was rather slow than quick, and somewhat fuller than natural. Such was the situation of his patient: a detail of which had been given before the doctor set out on his journey, which he undertook with a determined resolution to make use of the method recommended by Dr Silvester, in the first vol. of Medical Observations and Inquiries, published in the year 1757, (and which has been related from Dr Chalmers and Dr Hillary.) But, on his arrival at the house, he found great quantities of the extraflum tobaianum dissolved in K k had
had been already given him; and that, for the first 33 last days, he had taken no less than 28 grains of that medicine, with 50 grains of mulk, in the space of 24 hours, without any sensible effect, except the bringing on of a confused sleep, out of which he frequently awoke in great hurry, attended with a violent pain in the head, which almost deprived him of his senses. The doctor was afraid to extend the dose; and soon determined to take some other method, though at a loss what method to pursue, as, during a course of almost 30 years practice, nothing of the kind had ever fallen under his cognizance before. Reflecting, however, that this disorder had always been deemed of the spasmodic kind, and that the good effects produced by the extractum thebaicum must probably be owing to the relaxing and resolving faculty of that medicine, he directed a blister to be applied between the shoulders, the whole length of the spine; the jaw to be anointed with the oleum lateritium; and a purge consisting of the tinctura sarsa, tinctura jalepelli, and the forpus de rharno cathartico, to be given him. This was repeated three several times afterwards, at the distance of three or four days between each dose. On the intermediate days, he was ordered the oleum faccin, the ficdum gum, and the oleum amygadalum. Of the first he took 30 drops, of the gum 20 grains, and of the last four ounces, in 24 hours. By these means, and those only, the convulsions soon ceased; and he grew daily better and better, till at the end of a fortnight he was able to walk about his room, and in less than three weeks became in all respects well, some small weaknesses in the parts only excepted. The jaw was relieved first, after that the spine, and last of all the legs. A pain and uneasiness in the places affected, neither of which he had felt before, were the forerunners of his approaching amendment.

From all this it seems reasonable to conclude, either that there is no certain remedy for tetanus in all cases, or that the medicines which prove effectual in one constitution will fail in another. Thus, it is possible, that in cases where opium proves effectual, mercury may be a remedy; and on the contrary, where mercury fails, opium may be effectual; and even where both are ineffectual, the antimonial remedies recommended by Dr Cochrane may be of use. It is therefore necessary for physicians to be extremely careful to observe the effects of the first doses of their remedies: for if the symptoms show not the least appearance of remission after a large dose of opium, it is improbable that it can be cured by a repetition of the medicine; and as no time can be lost with safety, it will then be proper to apply mercurial ointment, or whatever else may be judged proper.—In the Edinburgh Medical Commentaries we have an account of the cold bath being used as a remedy, by Dr Thomas Cochrane, at that time physician at Nevis, now at Edinburgh. The patient was an Eal Indian boy, who had been shored by a cow, and afterwards exposed to a rainy damp air for some hours. Dr Cochrane ascribes his cure to the cold bath, which was applied by dashing the water upon his body; but as the patient at the same time got laudanum, at first in the quantity of 200 drops a day, and afterwards in still larger doses, and had besides his throat and shoulders anointed with warm oil of turpentine, was bled, and had lenient glyters and laxatives; it is by no means easy to say what share the cold bath had in his cure. Dr Cochrane, however, says he has heard of many cases being treated successfully by cold water and other remedies. The Prussian barking in St. Eustatia and St Kitt's, and in another letter mentions his having used the cold bath in other cases of tetanus with success. But since Dr Cochrane's publication, a more full and satisfactory account of the benefit of this practice has been communicated in a paper published by Dr Wright, in the sixth volume of the London Medical Observations. Dr Wright gives a particular account of six cases, in which the effects were obtained from dashing cold water upon the patient; and he observes, that since he first used this method of cure he has not failed in one instance to obtain a recovery, and that in a shorter time than by any other method hitherto proposed. This practice has on some occasions been adopted by practitioners in Britain, although here the disease is a much less frequent occurrence. It has particularly been employed with success by Dr Currie of Liverpool; and we hope that still more extensive practice will confirm the benefit to be derived from it, although not in every instance, yet in many cases of this affection.

Very lately a different mode of cure in this affection has been recommended by Dr Ruth, professor of medicine at Philadelphia, in a paper intitled Observations on the Cause and Cure of Tetanus, published in the second volume of the Transactions of the American Philosophical Society. Dr Ruth, viewing tetanus as being a disease occasioned by relaxation, thinks the medicines indicated to cure it are such only as are calculated to remove this relaxation, and to restore tone to the system. On this ground he recommends the liberal use of wine and the Peruvian bark; and tells us, that he has employed them with success in actual practice. When the disease arises from a wound of any particular part, he recommends stimulants to the part affected; such as dilatation of the wound, and filling it with oil of turpentine. How far this practice will be confirmed by more extensive experience, we cannot take upon us to determine. We may only observe, that a very contrary practice has been recommended as highly successful by some practitioners in Spain, where tetanic affections are a very frequent occurrence in consequence of slight accidents. There gentle emollients are strongly recommended, particularly immersing the wounded part in tepid oil for the space of an hour or so at a time, and repeating this application at short intervals. By this mode many cases, after very alarming appearances had taken place, are said to have been completely and speedily removed. While the practice is very simple, it appears at the same time in many respects very rational, and may perhaps be considered as well deserving a trial in the first instance.

GENUS XLIX. TRISMUS.

The Locked Jaw.

Sp. 1. TRISMUS NASCENTIUM.

Locked Jaw in children under two months old.

**MEDICINE.**

Pract. This distemper is so closely connected with the tetanus, that it ought rather to be accounted a symptom of the tetanus than a primary disease. We have accordingly discussed it under **tetanus**.

Sp. II. The **Trismus from Sounds or Cold.**

Convulso a nervi punctura, Saw. sp. 2.

The internal remedies proper in all cases of the locked jaw, from whatever cause it may proceed, have been already mentioned under **tetanus**: the external treatment of wounded parts which may give occasion to it belongs to the article Surgery. But of this also we have offered some observations under the head of tetanus; and, indeed, Trismus may be considered as being merely an incipient tetanus, or rather a slight degree of that disease.

**Genus L. Convulsio.**

Convulso universalis, saw. sp. 11.

Hierarhios, Lin. 144. Vog. 190.

Convulso habituales, Saw. sp. 12.

Convulso intermittens, Saw. sp. 16.

Convulso hemitomos, Saw. sp. 15.

Convulso abdominalis, Saw. sp. 10.

Convulso ab inani lib, Saw. sp. 11.

Convulso ab onanismo, Saw. sp. 13.

Sclotyrybe feffimans, Saw. sp. 2.

Description. When convulsions attack only particular parts of the body; they are generally attended with some kind of paralysis at the same time, by which means the affected parts are alternately convulsed and relaxed: a permanent convulsion, or unnatural contraction of particular muscles, is called a spasm or cramp. These partial convulsions may attack almost any part of the body; and are not unfrequently symptomatic, in fevers, the cholera morbus, &c.

The involuntary flutterings of the tendons, the picking of the bed-clothes, &c. in acute diseases, &c. are all of them convulsive disorders. Convulsions, even when most generally extended, differ from epilepsy in not being attended with any mental affection or abolition of sense, and not followed by the same torpid state.

Causes. Convulsions, not only of particular parts, but also over the whole body, often take place from causes not very evident. Sometimes they seem to depend on a certain delicacy or irritability of the nervous system, which is framed with such exquisite sensibility as to be strongly affected by the slightest causes. Delicate women are often subject to hysterical convulsions, and also hypochondriac people. Convulsions, however, often take their rise from wounds, irritations of the stomach and intestines by worms, poisons, violent cathartics and emetics, &c.; and very often they are symptomatic, as in dition, the small-pox, and many kinds of fevers.

Prognosis. Except in some few cases, convulsive disorders are always to be dreaded; but left in young people than in such as are advanced in life. Those which attack girls under the age of puberty, will generally cease on the appearance of the menses; and boys have likewise a chance of being relieved as they advance in life: but in grown up people, unless the cause be very evident, a cure is hardly to be expected, especially after the disease has been of long continuance.

Cure. The treatment is very much the same with that of epilepsy, afterwards to be considered: but a recovery is most frequently obtained by the removal of the existing cause.

**Genus LII. Chorea.**

St Vitus's Dance.

Chorea, Lin. 139.

Sclotyrybe chorea Viti, Saw. sp. 1.

Chorea St Viti, Sydenh. Sched. Monit.

Description. This disease shows itself first by a kind of lameness or inelasticity of one of the legs, which the patients draw after them in a ridiculous manner; nor can they hold the arm of the same side still for a moment; for if they lay it on their breast, or any other part of their body, it is immediately forced away by a convulsive motion. If they be delectious of drinking, they use a number of odd gymnastic before they can bring the cup to their mouths, because their arms are drawn this way and that by the convulsions which affect them.

Causes, &c. The general cause of St Vitus's dance is a debility of the system; and hence we find it attacks only weakly boys, and more especially girls, when under the age of puberty. But the particular causes determining the muscles to be affected in such and such a manner are entirely unknown.

Prognosis. As this disorder scarce ever attacks any persons but such as are under the age of puberty, there is almost a certain prospect of its being then cured, though generally the disorder is easily removed before that time.

Cure. See epilepsy.

**Genus LIII. Raphania.**

Convulso raphania, Saw. sp. 7.

Description. According to Sauvages, this distemper begins with a latitude of the limbs, transient colds and shiverings, pain of the head, and anxieties of the precordia. Then come spasmodic flutterings of the fingers and feet; also of the tendons and muscles, con-
Epilepsia a taburra, Sauv. sp. 5.
Epilepsia a pathemate, Sauv. sp. 7.
Epilepsia ab inanitio, Sauv. sp. 8.
Epilepsia neophytorum, Sauv. sp. 15.

Description. The epilepsy often attacks suddenly and without giving any warning; but more frequently is preceded by a pain in the head, loudness, some disturbance of the senses, unquiet sleep, unusual dread, dreams of flight, a noise in the ears, palpitation of the heart, coldness of the joints, and in some there is a sensation of formication, or a cold-air, &c. ascending from the lower extremities towards the head. In the fit, the persons fall suddenly to the ground (whence the name of the falling-fits), frequently with a violent cry. The thumbs are first up close in the palms of the hands, and are with difficulty taken out; the eyes are dilated, so that nothing but the whites are to be seen; all sensation is suspended, in such a manner, that by no smell, noise, or otherwise, nor even by pinching the body, can they be brought to themselves; they froth at the mouth, with a hissing kind of noise; the tongue is frequently lacerated by the teeth, and there is a violent convulsive motion of the arms and legs. Sometimes, however, the limbs, instead of being agitated by convulsive motions, are all stiff, and the patients are as immovable as a statue. In children the penis is erected; and in young men there is an emission of the semen, and the urine is often thrown out to a considerable distance. At length there is a remission of the symptoms, and the patients recover after a longer or shorter interval; when they complain of a pain, torpor, or heaviness of the head, with a latitude of all the joints.

Causes, &c. The dissection of the epileptic subjects has shown a variety of morbid appearances, which may be supposed to have contributed to the disease; such as indurations in the brain or meninges; carries of the internal surface of the cranium; projections of the bony substance of the same, pressing upon the brain; collections of ferum or purulent matter, and earthy concretions within the skull; besides many others which are registered by Bonet, Morgia, and Lietaud. But often the causes are imperceptible to be discovered; for even in those who have died of the disease, the brain and all other parts of the nervous system have been apparently found. The disease will attack strong as well as weak people; and in those who are subject to it, any considerable excess in drinking, a fever, violent passion, or venery, &c. will certainly be on a fit. Some have epileptic paroxysms returning periodically after considerable intervals; and the disease has been thought to have some dependence on the phases of the moon.

Prognosis. If the epilepsy comes on before the time of puberty, there are some hopes of its going off at that time. But it is a bad sign when it attacks about the 21st year, and will worsen if the fits grow more frequent; for then the animal-functions are often destroyed, as well as those of the mind, and the patient becomes stupid and foolish. Sometimes it will terminate in melancholy or madness, and sometimes in a mortal apoplexy or palsy. It has sometimes however, been observed, that epilepsies have been removed by the appearance of cutaneous diseases, as the itch, smallpox, measles,
measles, &c. While the disease is recent, therefore, we are not to despair of a cure; but if it be of long standing, or hereditary, there is very little reason to be expect that it can be removed.

Cure. From the symptoms occurring in epilepsy, which consist of involuntary convulsive motions, and an affection of the mental powers, there is reason to conclude, that the fit immediately depends on the induction of some peculiar action of the brain; but that convulsions may ensue from this cause, it would seem necessary that there should also occur a peculiar disposition to action in the moving fibres. On this ground then, we may suppose the cure to be chiefly expected on one of two principles; either by our being able to prevent the peculiar action of the brain, or to remove the disposition to action in the moving fibres. The first is chiefly to be accomplished by the removal of irritating causes, by preventing their influence from being propagated to the brain, when they are applied to remote parts; or by counteracting their influence from inducing in the brain a state of action different from that to which they give rise. The second is chiefly to be obtained by diminishing the mobility of the nervous energy, and by strengthening the tone of the moving fibres. It must, however, be allowed, that in all convulsive disorders, except those which are cured by nature about the time of puberty, the cure by artificial means is very difficult. Numberless specifics have been recommended, but all of them have failed of answering the expectation. When the cause can be discovered, that must be removed. In other cases, the cold bath, waterian root, cæter, musk, opium, the various gums, and antispasmodic medicines, have been recommended; but none of these, or indeed any combination of them, have been found generally useful; though the slighter, or symptomatic cases, may often be removed by them.

Of late the calx, improperly called the flowers, of zinc, have obtained such reputation in convulsive disorders as to be received into the Edinburgh Pharmacopoeia under the title of zinca umvum. They were proposed by Dr Gaubius as an antispasmodic, in his Adversaria, and their efficacy has since been confirmed by various observations. In an inaugural dissertation published by Dr Hart at Leyden, the medical virtues of the flowers of zinc are considered. He observes, that they have long been used externally, chiefly for inflammations of the eyes from acute lycph. Glauber first proposed the internal use of them; and Gaubius discovered them to be the remedy of a celebrated empiric Luddemannus, who styled his luna fixata. After this he exhibited them with success in convulsive and spasmodic diseases. Dr Hart supposes, that they act either as absorbents, or as posseffing a specific virtue; but is a strong advocate for their efficacy, on whatever principles they may operate; and, in favour of his opinion, relates several cases in which they proved successful. A girl of 17 years of age, was seized with a slight aura from a fright; and when the disease had continued six days, she began to take the flowers of zinc, by which her disorder was removed in less than three weeks. Her cure required only 16 grains of the calx. In a few months the complaints returned, from the same causes, and were removed by four grains of the medicine divided into ten doses.—A boy of about four years old, labouring under a real epilepsy, suspected to be hereditary, was cured by a grain of the flowers of zinc taken every day for some time.—A man 50 years old, thrown into convulsions from a violent passion, was cured by a grain of the calx taken every two hours. The disease had gone off under vision of the use of some other remedies; but returned again in two weeks, when it was finally removed by the zinc. The two last cases are related by Dr Gaubius, who affirms that he has used the flowers of zinc in cases of the chinchough, and the other spasmodic diseases; that they frequently did more than other medicines, but were by no means successful in every case. The other cases mentioned by Dr Hart are similar to those abovementioned. But it does not appear that he ever saw a confirmed epilepsy cured by this medicine.

In the first volume of Edinburgh Medical Commentaries, we have an account by Mr Benjamin Bell, of a man afflicted with a confirmed epilepsy, who was considerably relieved by the flowers of zinc. He was about 35 years of age, and had been subject to the disease for 10 years. At first the paroxysms did not return oftener than once a month; but becoming gradually more frequent, they came at last to be in a manner continual, inasmuch that he would have ten, eleven, or twelve attacks in a day, and very seldom had an interval of 24 hours. His memory and judgment were so much impaired, that he could scarce answer a question distinctly. He had used a great variety of medicines without any benefit. About three years before applying to Mr Bell, he had violent rheumatic pains in his limbs, which left such an extreme debility that he was never afterwards able to get out of bed without the assistance of two or three people.

On the 22d of October 1752, Mr Bell found him in the abovementioned condition, and prescribed as follows:

R. Flor. Zin. gr. xxiv. Ext. Gent. 5 gr. m. mat. et divid. in pill. xxiv. cap. 1. m. & v.

He continued to take two pills a-day till the first of November, without any sensible benefit. The dose was then doubled, and continued till the 12th; when the fits, though equally violent, became less frequent. The medicine was gradually augmented to ten pills thrice a-day; and the consequence was, that his memory and understanding returned, the fits became much lighter and less frequently repeated, though the disease could not be radically subdued.

In a young man labouring under the epilepsy, in whom the fits were preceded by an aura epileptica, or sensation like air arising from the inside of the knee-joint, the disease was also relieved, but not cured.

Dr Percival relates some cases of epilepsy which seem to have been cured by the flowers of zinc; and in other cases, where the disease was not entirely removed, the spasms were nevertheless much mitigated.

He did not observe that it promoted any evacuation; excepting that in some, upon being first taken, it occasioned a little sickness, which went off with a stool. He adds, that those apothecaries who do not prepare this,
The good effects of calcined zinc as an antispasmodic are also attested by Dr Haygarth of Chelter and Dr Wiltie of York. The former gives a tefl of their good efts which may be of use to those who do not prepare them; namely, that the true flowers of zinc, when strongly heated, become yellow, but reaffume their white colour on being allowed to cool. The latter gives a cafe of heintanosis, or крайне convulsions of almost all the muscles of the body, cured by zinc, after a number of other remedies had failed. The patient, however, had been formerly much relieved by Ward's antimonial pill.

In Dr Home's clinical experiments and histories, also calcined zinc is mentioned as having been found serviceable upon trial in the Royal Infirmary of Edinburgh. Of the other principal remedies which have been recommended for the epilepsy and other convulsive disorders allied to it, we have the following account by the same author.

1. The cold-bath was tried in one who had a convulsive disorder of one side, but the symptoms were rendered much worse by it.
2. Vomiflion. Not to be depended on in convulsions.
3. Electricity. In two convulsive cafes was of no service.
4. Epiftasicles. Do not seem to be powerful antispasmodics.
5. Valerian. In nine convulsive cafes, for which this remedy hath been reckoned almost a specific, it not only made no cure, but could scarcely be reckoned to do any good. Dr Home supposes that it acts as a bitter tonic, something like the herpentaria Virginiana. Though much used at present, he tells us it has always appeared to him a weak, oftentimes a hurtful, medicine.
6. Myrt. Six convulsive patients treated with large doses of this remedy, were neither cured nor in the least relieved.
7. Caffir seems to be unworthy of the confidence formerly put in it. It is indeed possessed of a sedative power, and therefore may be useful in spasmodic feverish cafes.
8. Afiatifrida has considerable antispasmodic powers, but is not always successful. It heats and quickens the pulse; and is therefore improper in cafes attended with inflammation. It disagrees with some from a peculiarity of constitution; exciting pain in the foftomach, and vomiting; but this can be known only after the exhibition of the medicine.
9. Cortex Peruviana. Of seven spasmodic cafes, six were either cured or mitigated. An epilepsy of eight years standing was very much relieved by taking the bark for a month, and one of two years standing by taking it for ten days. But the medicine is of a heating nature, and therefore is not to be employed in cafes attended with inflammatory symptoms.
10. Penny root was given to two epileptic patients without the least success.
11. Vifus quercinus, or mistletoe, was given in the quantity of two scruples five times a-day to an epileptic patient, without success.
12. Extradita bryceadi was given to an epileptic patient, to one afflicted with the hemitqnotos, and to one who laboured under the hysteric affection, without the least good effect.

Folia aurantiorum were exhibited with the like bad success. Five drachms of the powdered leaves were taken at once without any sensible effect.

14. Cardamimo pratensis, in three epileptic cafes, was not attended with any success.
15. Opium did no good.
16. Cuprum ammoniacale made no cure in four cafes of epilepsy in which it was tried.

That in many cafes all these remedies have been employed without success, is not to be denied; and indeed it may with confidence be affirmed, that a great majority of cafes of epilepsy are incurable by any remedy that has yet been discovered. At the same time, as there is incontrovertible evidence that some of them have succeeded at least in certain cafes, the more powerful may always be considered as deserving a fair trial. The cuprum ammoniacum, in particular, seems well intituled to the attention of practitioners; for though it be a medicine of great activity, yet under prudent administration it may be employed even with very young subjects without any hazard; and in several invertebrate cafes, which had obstinately resisted other medicines, it has brought about a complete recovery.

Palpitation of the Heart.

The palpitation of the heart is sometimes so violent, that it may be heard at a considerable distance. It may proceed from a bad constitution of the heart itself, or from the large vessels. It may also be occasioned by wounds or abscesses of that viscus, or from plethora, fear, or spasmodic affections of the nervous system. When it proceeds from diseases of the heart or large vessels, it is absolutely incurable. In spasmodic cafes, the remedies above related may be used. If the patient be phthisic, bleeding will probably remove the disorder, at least for the present.

in the asthma, from the

made after the publication of his book upon that dif-
cafe. Dr Percival says he has frequently directed coffee in the asthma with great success.

In the intervals of the fits, persons subject to the asthma, especially the humid species, should take emetics from time to time. An infusion of tobacco is an emetic that has been said to be very serviceable in some asthmatic cafes; but its operation is both so distressing and so dangerous, that it will never probably be introduced into common use as an emetic; and smoking or chewing the same has been known to prevent the frequency and severity of the paroxysms. Asthmatic patients may also use the lac ammoniaci with a due proportion of oxynel faltilllicum and sinua cu-
tioniales, with a view to promote expectoration; or the gum ammoniaci, and others of similar virtues, may be formed into pills and combined with soap as mentioned for the dyspnea pyrithostis; or a maas may be composed of afafeetica and balsam of Tolu, with syrup of garlic; and these pills may be washed down by a medicated wine, impregnated with squills, hoars-radish root, and mustard seed; or a strong bitter infusion, with a little antimonial wine.

In some cafes crude mercury will be found serviceable; in others flowers of sulphur, made into an emetic, with honey or syrup of garlic; and if, notwithstanding the use of these things, a colitive habit should prevail, it will be necessary, from time to time, to give a few grains of pills of aloes and myrrh, soap and aloes, or a mafs of equal parts of rhubarb, scammony, and soap.

The dry or spasmodic asthma, during the extreme violence of the fit, is best relieved by opiates; and sometimes very large doses are required. But in order to obtain permanent relief, nothing is found to answer better than ipescaquinaba in small doses. Three, five, eight, or ten grains, according to the strength and constitution of the patient, given every other day, have been productive of the happiest effects; acting sometimes as an evacuant, pumping up the vitious phlegm; at others, as an antispasmodic or sedative. Iffues are generally recommended in both species, and will often be found useful.

Changes of weather are usually felt very sensibly by asthmatic people, who in general cannot live with tolerable ease in the atmosphere of large cities; though we shall sometimes meet with patients who agree better with this air, which is so replete with gross effluvia of various kinds, than with the purest that can be found in country situations. And some are found who breathe with the most ease in a crowded room, with a fire and candles.

A light diet of meats that are easy of digestion, and not flatulent, is requisite for asthmatic people; and the exercise of riding is indispenfibly necessary.

When the asthma is found to depend on some other disease, whether it be the gout or an intermittent fever, or when it proceeds from the flickering in of some cutaneous eruption, regard must always be had to the primary disease: thus, in the asthma arthusium, inflammation to the foot, or burning, will be absolutely necessary, in order, if it possible, to bring on a fit of the gout. And when the edges of an agar give rise to an asthma, which is termed febrikulosis, and invades at regular intervals, we must have recourse to the Pen-
MEDICINE.

292.  GENUS LVI. DYSPEPSIA.

Habitual DIFFICULTY of Breathing.

Sp. 251. Juech. 32.

Sp. I. The Catarhhal Dyspepsia.

Asthma catarhal, Sauv. sp. 16.
Asthma pneumaticum, Willis. Pharm. rat. P. II.
feel. i. cap. 12.
Asthma pituitofum, Hoffm. III. feel. ii. cap. 2. § 3.
Asthma pneumodes, Sauv. sp. 17.

This is readily known by the symptoms of pneumonia and catarh attending it, and to the removal of these symptoms the care of the physician must be principally directed.

Sp. II. The Dry Dyspepsia.

Dyspepsia a tuberculis, a hydatibus, &c. Sauv. sp. 2.
4. § 20.
Orthopnea a lipomate, Sauv. sp. 18.

This is generally accompanied with a phthisis pulmonary; but Sauvages mentions one species of phthisis to which the dry dyspepsia seems more particularly to belong. The patients fall away by degrees, and have a great difficulty of breathing, continual thirst, and little or no spitting. When opened after death their lungs are found not to be ulcerated, but shrivelled and contracted as if they had been smoke-dried. Goldsmiths and chemists are said to be made in the vapours they draw in with their breath. Sauvages do not mention any particular remedy. Shortness of breath arising from tubercles, as they are termed, or a fibrinous enlargement of the lymphatic glands which are dispersed through the lungs, is commonly found in scrofulous habits, and may be distinguished by the comitancy of those external swellings and appearances which particularly mark the scrofula. This species of dyspepsia generally ends in a phthisis. Courtes of goat's whey, and of tea-water, have been known to do service; but it must be confessed, that a perfect cure is seldom obtained. Issues are of use in these cases, as they appear to prevent the ill effects of an over-fullness, if it should happen at any time to supervene.

Sp. III. Dyspepsia from Changes in the Weather. (Sauv. sp. 12.)

This seems to be a disease entirely spasmodic, and the antispasmodics already related are accordingly indicated.

Sp. IV. The Dyspepsia from Earthy Substances. formed in the Lungs.

Sauvages mentions this disease as much more common in brutes than in the human race; but Dr Cullen mentions his having seen some instances of it; and we have several accounts by different authors of calculous matters being coughed up by people labouring under a dyspepsia, and threatened with consumption. In three cases of this kind which fell under Dr Cullen's inspection, there was no appearance of earthy or vitious concretions in any other part of the body. The calcareous matter was coughed up frequently with a little blood, sometimes with mucus only, and sometimes with pus. In one of these cases, an exquisite phthisis came on, and proved mortal: in the other two the symptoms of phthisis were never fully formed; and after some time, merely by a milk diet and avoiding irritation, the patients entirely recovered.

Sauvages also greatly recommends milk in these cases, and soap for dissolving the concretions. The reason why brutes are more subject to these pulmonary calculus than mankind, is, that they very seldom cough, and thus the flagrating mucus of lymph concretes into a kind of gypseous matter.

Sp. V. The Watery Dyspepsia.

Dyspepsia pituitofa, Sauv. sp. 1.
Orthopnea ab hydropneumonia, Sauv. sp. 12.

This may arise from too great a defluxion of mucus on the lungs, or from an effusion of serum, as is mentioned under the pneumonia. The treatment of the disease may be gathered from what has been already said under the heads of pneumonia, catarh, empyema, &c.

Sp. VI. The Dyspepsia from Corpulency.

Orthopnea a pinguedine, Sauv. sp. 6.

There have been many inferences of suffocation and death occasioned by too great corpulency. These fatal effects, however, may be almost always avoided if the persons have resolution to perform in an active and very temperate course of life; avoiding animal-food, much sleep, and using a great deal of exercise. In the third volume of the Medical observations, however, there is an extraordinary instance of internal obesity which neither flowed itself externally, nor could be removed by any medicines.

Other species of dyspepsia have been considered under Phthisis. It is frequently symptomatic of diseases of the heart and large vessels, or swellings of the abdomen, &c.

GENUS LVII. PERTUSSIS.

Chincough.

Huxham, de acre, ad. ann. 1732.
Tuliss convulxis, live ferina, Hoffm. III. 111.

Tuliss convulxis, Sauv. sp. 11. Sec. sp. 11.
Amphixerina tuculolis, Sauv. sp. 13.

Description. This disease comes on at first like a common cold; but is from the beginning attended with a greater degree of dyspepsia than is common in catarh; and there is a remarkable affectation of the eyes, as if they were swelled, and a little puffed out of their sockets. By degrees the fits of coughing become longer and more violent, till at last they are plainly convulsive, so that for a considerable time the patient cannot expire, and when at last he recovers his breath, inspiration is performed with a thrill kind of noise like the
MEDICINE.

Practice.

the crowing of a cock. This kind of inspiration serves only as an introduction to another convulsive fit of coughing, which is in like manner followed by another inspiration of the same kind; and thus it continues for many hours, very often till the patient vomits, which puts an end to the paroxysm at that time. These paroxysms are attended with a violent determination of the blood towards the head, so that the vessels become extremely turgid, and blood not frequently flows from the mouth and nose. The disease is tedious, and often continues for many months. It is not commonly attended with fever.

Canker, &c. The chinchough is an infectious disorder, and very often epidemic: but the nature of the contagion is not understood; at least it is not farther understood than that of small-pox, measles, or similar epidemics. We well know that it is from a peculiar and specific contagion alone that this disease, as well as the others abovementioned, can arise. But with regard to the nature of any of them, we are totally in the dark. It generally attacks children, or adults of a lax habit, making its attack frequently in the spring or autumn; at the same time, when this contagion is introduced into any town, village, or neighbourhood, it will rage epidemically at any season. Those alone are affected with this disease who have never before been subjected to it. For in this affection, as well as in small-pox, having had the disease once, gives defence against future contagion. Every individual, however, does not seem to be equally readily affected with this contagion; like other contagious diseases occurring only once in a lifetime, it may naturally be expected to be more frequent among children than at any other period of life. But many, though frequently exposed to contagion, are yet not affected with the disease; and those children who live upon unwholesome watery food, or breathe unwholesome air, are most liable to its attacks, and suffer most from them. In general it has been concluded, that whatever weakens the solids, or tends to bring on a dissolution of the fluids, predisposes to this disease.

Progress. The chinchough is not very often fatal. During one epidemic, however, it is often observed to be much more dangerous and more severe than during another. This is also remarked with regard even to particular periods of the same epidemic; and it is also observed, that on certain families this disease is much more feverish than on others. Its danger, however, is still more connected with the period of life at which it occurs. In children under two years of age it is most dangerous; and kills them by producing convulsions, suffocation, inflammation and suppuration of the brain or in the lungs, ruptures, and incurvation of the spine. In pregnant women it will produce abortion; and in adults inflammations of the lungs, and all the consequences of pneumonia, more frequently than in children. From a long continuance of the disease patients will become asthmatic, ricketty, and scrofulous. It is generally reckoned a good sign when a fit terminates by vomiting; for in this disease there seems to be a great increafe of the secretion of mucus, and the vomiting affords great relief.

Cure. Pertussis is one of those diseases which after the contagion has exerted its influence can be terminated only by running a certain course: but it is much less limited in its course than small-pox and measles, and often it runs on to a very great length, or at least it be very difficult to decide with certainty the sequel of this disease from the disease itself. And when it exists in the former of these states, it admits of an artificial termination. In the treatment of this affection, therefore, the objects at which a practitioner chiefly aims, are in the first place, the obviating urgent symptoms, and forwarding the natural termination of the disease; and secondly, the inducing an artificial termination. With these intentions various practices are employed on different occasions. The most approved remedies are vomits, purges, bleeding, and the attenuating pectorals; for the other kinds generally do hurt; but large evacuations of any kind are pernicious. In the Medical Observations, Vol. III. Dr Morris recommends cali fer and the bark; but in cases attended with any degree of inflammation, the latter must certainly do hurt, and the former will generally be insignificant. Dr Butter, in a dissertation expressly on the subject, relates 20 cases of this disease cured by the extract of hemlock. He directs half a grain a day for a child under six months old; one grain for a child from six months to two years; afterwards allowing half a grain for every year of the patient's age till he be 20: beyond that period, he directs ten grains to be given for the first day's consumption, gradually increasing the dose according to the effect. If the patient have not two stools a day, he advises magnesia or the rhinian citriatae pulvere to be added to the hemlock mixture. By this method he says the peculiar symptoms of the disease are removed in the space of a week; nothing but a slight cough remaining. The use of hemlock, however, has by no means become universal in consequence of this publication, nor indeed has this remedy been found equally successful with others who have given it a fair trial. The remedy must to be depended upon in this disease is change of air. The patient, as soon as the disease is fully formed, ought to be removed to some other part of the country; but there is no occasion for going to a distant place; a mile or two, or frequently a smaller distance, will be sufficient; and in this new habituation, the frequency of the cough is almost instantly diminished to a most surprising degree. After remaining there for some time, however, the cough will often be observed to become again more frequent, and the other symptoms increafed. In this stage, another change of air, or even a return to the former habitation, becomes necessary. Manifest benefit has even been derived by changing a patient from one room of a house to another. But although change of air has thus been advantageous, it must also be remarked, that when it has been had recourse to at very early periods it has often done mischief, particularly by aggravating the febrile and inflammatory symptoms. If the disease be attended with fever, bleeding and other antiphlogistic remedies are proper. Dr Buchan recommends an ointment made of equal parts of garlic and hog's lard applied to the soles of the feet; but if it have any effect, it is probably merely as an euphorium calidum. It ought to be put on a rag and applied like a plaster. Opiums may sometimes
be useful, but in general are to be avoided. They are chiefly serviceable where the cough is very frequent, with little expectoration. In these cases benefit has sometimes also been derived from vitriolic ether, and sometimes from the tincture of cantharides. An almost infalliable termination has on some occasions been put to this disease by exciting a high degree of fear, or by inducing another febrile contagion: But the effects of both are too uncertain and too dangerous to be employed in practice.

Colica flatulenta, pituita, &c. Sauv. sp. 1. 2. 5. 6. 7. Ileus phylodes, volvulus, inflammatorius, &c. Ejus. sp. 1. 3. 5. 7. 8. 9.

Description. The colic is chiefly known by a violent pain in the abdomen, commonly about the umbilical region. The pain resembles various kinds of sensations, as of burning, twifling, boring, a ligature drawn very tight, &c. The belly is generally coltive, though sometimes there is a violent evacuation of bilious matters upwards and downwards. In these cases the disease is sometimes accompanied from the beginning with a weak and intermitting pulse, cold sweats, and fainting. In some the disease comes on gradually, beginning with an habitual coltiness; and if purgatives be taken, they do not operate. The pain comes on generally after a meal, and soon occasions nausea and vomiting. Sometimes the disease is attended with pyrexia, violent thirst, and a full pulse; the vomiting becomes more violent, and excrementitious matters are thrown up with most exquisite pain and tension of the abdomen; an hickup comes on, which continues obstinately; till at last a cessation of pain and feverish breath indicate a mortification of the intestines and approaching death. Sometimes the peristaltic motion of the intestines is so totally inverted, that all their contents are evacuated by the mouth, and even clysters will be vomited; which constituting that disease commonly called the iliac passion.
Practise.  

Spasm.

Medicine.  

Splanchnics. inches above the caecum. This cord formed a circle with the mesentery, large enough to admit a hen's egg to pass through it. The chord had formed a node in a manner difficult to be explained, which included a doubling of about two inches of the lower end of the ileum; and was drawn so tight, that it not only put a stop to the passage of every thing through the bowels and brought on a gangrene of the strangulated part, but it had even cut through all the coats of the intestine on the opposite side to the mesentery, and made an aperture about an inch long. In the Memoirs of the Academy of Surgery are mentioned several similar cases.

Prognostic. The colic is never to be reckoned void of danger, as it may unexpectedly terminate in an inflammation and gangrene of the intestines. Those species of it which are attended with purging must be considered as much less dangerous than those in which the vomiting is very violent. The lillac passion, or that attended with the vomiting of feces, is always to be accounted highly dangerous; but if the passage through the intestines be free, even though their peristaltic motion should be inverted, and clysters evacuated by the mouth, there is much more hope of a cure, than when the belly is obstinately colicky, and there is some fixed obstruction which seems to bid defiance to all remedies.

Cure. In the cure of the spasmotic colic, the recovery must ultimately depend on producing a resolution of the spasmotic affection. In order to accomplish this, it is in general necessary to evacuate the contents of the intestines, and to remove morbid irritability existing in that part of the system. But in order to preserve the life of the patient from the most imminent hazard, it is still more necessary to prevent and remove those inflammatory affections which often occur in this dilatation. As the chief danger in colics arises from an inflammation and consequent mortification of the intestines, it is essentially necessary, in the first place, to diminish the tendency to a pyrexia, if there should happen to be any. This is accomplished by bleeding, emollient injections, warm bathing, and cooling medicines taken inwardly. Dr Porter, in his essay abovementioned, strongly recommends the warm bath in those colics attended with violent evacuations of bile. He supposes it to do service by relaxing the contraction of the intestines, and thus preventing or removing the intestinal spasm. In the mean time opiates may be given to ease the pain, while every method is tried, by cathartics and glysters of various kinds, to procure a stool. In obstinate cases, where stimulating cathartics have proved ineffectual, the milder kinds, such as manna, senna, oleum ricini, &c. will succeed; but where every thing of this kind fails, recourse must be had to some of the more extraordinary methods. Some have recommended the swallowing of leaden bullets, on a supposition that by their weight they would force through the obstruction into the gut; but these seem much more likely to create than to remove an obstruction. It is impossible they can act by their gravity, because the intestines do not lie in a straight line from the pylorus to the anus; and though this was actually the case, we cannot suppose that the weight of a leaden bullet could prove very efficacious in removing either a spasmotic contraction or an obstruction from any other cause. But when we consider, not only that the intestines consist of a great multitude of folds but that their peristaltic motion (by which only the contents are forced through them) is inverted, the facility of this remedy must be evident. It might rather be supposed to aggravate the dilatation as the lead, by its preßure would tend to fix the intumescence more firmly, or perhaps push it still further on. The same thing may be said of quicksilver: not to mention the perilous consequences to be apprehended from swallowing large quantities of this mineral, even if it should prove efficacious in relieving the patient for the present. There are, however, some late cases on record, particularly one by Mr William Perry, published in the sixteenth volume of the Edinburgh Medical Commentaries, in which the hydrargyrum, swallowed in great quantities, was attended with the happiest effects after every other remedy had been tried in vain. Another method has been proposed, in the Medical Essays, for relieving the miserable patients in this disorder, which in many cases has been known to do service. The patient is to be taken out of bed, and made to walk about on the cold floor of a damp apartment. At the same time, purringers of cold water are to be dashed on his feet, legs, and thighs; and this must be continued for an hour or longer, if a stool be not procured before that time, though this will generally be the case much sooner. The exercise does not at all impair the patient's strength, but rather adds to it; and some very remarkable instances are adduced in the 6th volume of the Medical Essays, where this proved effectual after all other medicines had failed. In one person the dilatation had come on with an habitual colicivenes, and he had been for a week tormented with the most violent pain and vomiting, which could be stopped neither by anodynes nor any other medicines, the harpest glysters being returned unaltered, and all kinds of purgatives thrown up soon after they were swallowed; but by the abovementioned method, a stool was procured in 45 minutes, and the patient recovered. In some others the colicivenes had continued for a much longer time. Other remedies are, the blowing air into the intestines by means of a bellows, and the injecting glysters of the smoke of tobacco. But neither of these seems very capable of removing the dilatation. They can affect only the parts below the obstruction; while, to cure the dilatation, it is necessary that the obstructed parts themselves should be reached by the medicine, and therefore we have not many well-attested instances of their success. In some obstinate cases, however, benefit has certainly been derived from tobacco-smoke injections, and likewise from injections of tepid water to the extent of several pounds. For putting in practice these modes of cure a particular apparatus have been contrived; and in cases even apparently desperate, neither should be neglected. The cold water gives a general and very considerable shock to the system, checks the perspiration, and thus drives the humors inward upon the intestines, by which they receive a much more effectual stimulus than can be supposed to arise from any kind of glyster. But when all methods have failed, the only chance the patient can have for life is by a manual operation.

Another caufe to which violent colics are frequently
ly to be afcribed, and which often gives occasion to
them where it is very little fufpected, is lead, or fome
folution or fume of it, received into the body. To
this caufe is evidently owing the colics to which plumbers, lead-miners, and smelters of lead, are
infu:ient. To the fame caufe, though not fo apparent at
first fight, are we to afcribe the Devonshire colic,
where lead is received into the body diffolved in
cyder, the common drink of the inhabitants of that
country. This has been proved by experiment; for
lead has been extracted from cyder in quantity suffi-
cient to produce pernicious effets on the human body.
The colic of Poitou and what is called the dry
holy-ache in the Well Indies, are of the fame nature;
for which reafon we give the following general
description of the fymptoms of all these difeafes.

The patient is generally first feized with an acute
pain at the pit of the fjomach, which extends itself
down with griping pains to the bowels. Soon af:ter
there is a diflention, as with wind; and frequent reach-
tings to vomit, without bringing up any thing but
small quantities of bile and phlegm. An obfinate
colitiveves follows, yet fometimes attended with a
tenfious, and the bowels ftem to the patient as if
they were drawn up towards the back; at other times
they are drawn into hard lumps, or hard rolls,
which are plainly perceptible to the hand on the belly,
by ftrong convulflve fpafts. Sometimes the coat of
the intestines seem to be drawn up from the anus and
down from the pylorus towards the navel. When a
fiool is procured by artificial means, as clyflers, &c.
the feces appear in little hard knots like thief's dung,
called jyphalus, and are in small quantity. There is,
however, usually an obfinate colitiveves; the urine
is difcharged in small quantity, frequently with pain
and much difticulty. The pulse is generally low,
though fometimes a little quickened by the violence
of the pain; but inflammatory fymptoms very feldom
occur. The extremities are often cold, and fometimes
the violence of the pain caufes cold clammy fweats and
ftainting. The mind is generally much affected,
and the fpirits are funk. The difeafe is often tedious
especially if improperly treated, infomuch that the
patient will continue in this miserable state for twenty
or thirty days infeffively; nay, infances have been
known of its conitining for fix months. In this cafe
the pains at laft become almost intolerable: the pa-
tient's breath acquires a ftrong fetid fmen like excre-
ments, from a retention of the feces, and an abforp-
tion of the putrid effluvia from them by the laftmeal.
At laft, when the pain in the bowels begins to abate,
a pain comes on in the shoulder-joints and adjoining
muscles, with an unusual fenfation and tingling along
the spinal marrow. This foon extends itfelf from
thence to the nerves of the arms and legs, which
become weak; and that weakness increases till the
extreme parts become paralytic, with a total loss of
motion, though a benumbed fenfation oft en remains.
Sometimes, by a fudden metalafis, the brain becomes
affected, a fpuror and delirium come on, and the
nervous fystem is irritated to fuch a degree as to pro-
duce general convulfions, which are frequently followed
by death. At other times, the perifhalic motion of
the intestines is inverted, and a true iliac paflion is
produced, which also proves fatal in a fhort time.
Sometimes the paralytic affection of the extremities
goes off, and the pain of the bowels returns with its
former violence; and on the ceflation of the pain in
the intestines, the extremities again become paralytic
and thus the pain and paraly will alternate for a ver-
Y long time.

Cure. Various methods have been attempted for
removing this terribie difeafe. The obfinate colitive-
ves which attends it, made physicians at firft exhibit
very ftrong purgatives and stimulating clyflers. But
these medicines, by increafing the convufive fpafms of
the intestines, were found to be pernicious. Balm
of Peru, by its warm aromatic power, was found to
fucceff much better; and Dr Sydenham accordingly
precribed it in the quantity of 40 drops twice or
three a day taken on fugar. This, with gentle pur-
gatives, opiates, and fome drops of the h etter effential
oils, continued to be the medicine commonly em-
ployed in this difeafe, till a specific was publifhed by
Dr Lionel Chalmers of South Carolina. This recipi
t was purchafed by Dr Chalmers from a family where
it had long been kept a fecret. The only unusual
medicine in this receipt, and on which the efficacy of
it chiefly if not wholly depends, is vitriliated copper.
This must be difolved in water, in the quantity of
one grain to an ounce, and the dofe of the folution
is a wine-glaflful given falling for nine fucceffive
infpiffions. For the firft four or five days this me-
dicine difcharges much eruguous bile both ways;
but the excretions of this humour leffen by degrees
and before the course be ended, it has little other ef-
fect than to caufe fome degree of fquamifhes, or
promote a few bilious foools, or perhaps may not
move the patient at all. At the time of using this
medicine the patients fhould live upon broth made of
lean meat, gruel, or panada; but about the feventh
or eighth day, they may be allowed bread and boiled
chicken. Here the copper seems to do fervice by its
tonic power; and for the fame reafon, alum, recom-
mended by Dr Pereival, moft probably cures the
difeafe. He fays he has found this very efficacious
in obfinate affections of the bowels, and that it gene-
really proves a cure in the lighter cafes of the colica
pictonum. It was given to the quantity of fifteen
grains every fourth, fifth, or fixth hour; and the
third dofe feldom failed to mitigate the pain, and
sometimes entirely removed it. Among purgative
medicines, the eleum Rivini is found to be the moft
efficacious.

Colica Japonica, accidentalis, lachentium, a venen, Sauv. fp. 10, 14, 18, 20.
Cholora ficca auriginosa a fungis venenatis, gyfyl. fp. 2.

When cholics arise from acid poisonous matter taken into the stomach, the only cure is either to evacuate the poison itself by vomiting, or to swallow some other substance which may decompose it, and thus render it inactive. The most common and dangerous substances of this kind are corrosive mercury and arsenic. The former is easily decomposed by alkaline salts; and therefore a solution of lixivial salt, if swallowed before the poison has time to induce a mortification of the bowels, will prove a certain cure. Much more dangerous of this kind are corrosive mercury and arsenic. Milk has been considered as efficacious; and lately a solution of this medicine are so weak, that its qualities more obtunded by that than by any other known substance. Some of the fungi, when swallowed, are apt to produce colics attended with vomiting, or to be vomited, or to be expelled. But when once it has taken place, it cannot be removed till either a vomiting be induced, or the whole system is thrown into the utmost astonishment.

Sp. V. Colic of New-born Infants from a Retention of the Meconium. (Sauv. fp. 19.)

This disorder would be prevented were children allowed immediately to suck their mothers' milk at first; but as this is not commonly done, the child is frequently troubled with colics. These, however, may be removed by a few grains of specu-cuanha, or a drop or two of antimonial wine. By these means the stomach is cleansed by vomiting, and the belly is generally loosened; but if this last effect does not happen, some gentle purge will be necessary.

Sp. VI. Colic from a Callosity of the Colon.

It is in a manner impossible to discover this distemper before the patient's death; and though it should, it does not admit of a cure.

Sp. VII. The Colic from Intestinal Calculi (Sauv. fp. 10, 15.)

When certain indigestible bodies, such as cherry stones, plum-stones, small pieces of bones, &c. are swallowed, they frequently prove the basis of calculi, formed by an accretion of some kind of earthy matter; and being detained in some of the flexures of the intestines, often occasion very violent colics. These calculi do not discover themselves by any peculiar symptoms, nor do they admit of any particular method of cure. In the Medical Essays we have an instance of colics for six years, occasioned by calculi of this kind. The concretions were at last passed by stool; and their passage was procured by caufing the patient drink a large quantity of warm water, with a view to promote the evacuation of bile, a redundancy of which was supposed to be the cause of her disorder.

Genus I. Cholera, the Cholera Morbus.

Diarrhoea choleric, Junc. 112.

Sp. I. The Spontaneous Cholera, coming on without any manifest cause.

Cholora Indica, Sauv. fp. 7.

Sp. II. The Accidental Cholora, from acrid matters taken inwardly.

Cholora crapulosa, Sauv. fp. 11.
Cholora a venenis, Sauv. fp. 4. 5.

The cholera shows itself by excessive vomiting and purging of bilious matters, with violent pain, inflation and dilatation of the belly. Sometimes the patients fall into universal convulsions; and sometimes they are affected with violent spasms in particular parts of the body. There is a great thirst, a small and unequal pulse, cold sweats, fainting, coldness of the extremities, and hicouche; and death frequently ensues in 24 hours.

In this distemper, as the quantity of bile is deposited in the alimentary canal, particularly in the stomach, the first object is to counteract its influence, and to promote an easy discharge of it. It is next necessary to restrain that increased secretion of bile, by which a fresh deposition in the alimentary canal would otherwise be soon produced. And, in the last place, measures must often be employed to restore a found condition to the alimentary canal, which is frequently much weakened by the violence of the disease.

On these grounds, the cure of this distemper is effected by giving the patient a large quantity of warm water, or very weak broth, in order to cleanse the stomach of the irritating matter which occasions the disease, and injecting the same by way of syringe, till the pains begin to abate a little. After this, a large dose of laudanum is to be given in some convenient vehicle,
vehicle, and repeated as there is occasion. But if the vomiting and purging have continued for a long time before the physician be called, immediate recourse must be had to the laudanum, because the patient will be too much exhausted to bear any further evacuations. Sometimes the propensity to vomit is so strong, that nothing will be retained, and the laudanum itself thrown up as soon as swallowed. To settle the stomach in these cases, Dr. Douglas, in the Medical Essays, recommends a decoction of oat-bread toasting as brown as coffee; and the decoction itself ought to be of the colour of weak coffee. He says he does not remember that this decoction was ever vomited by any of his patients. An infusion of mint-leaves or good simple mint-water is also said to be very efficacious in the same case.

The tincture of opium is sometimes retained when given in conjunction with a portion of the vitriolic acid properly diluted. But when it cannot be retained in a fluid form by the aid of any addition, it will sometimes fit upon the stomach when taken in a solid state.

After the violence of the disease is overcome, the alimentary canal, and the stomach in particular, requires to be braced and strengthened. With this view recourse is often had with advantage to different vegetable bitters, particularly to the uce of the colocombo root; which, while it strengthens the stomach, is also observed to have a remarkable tendency in laying a disposition to vomiting, which often remains for a considerable time after the cholera may be said to be overcome.

Sp. I. The Fusculent Diarrhoea.

Diarrhoea fuscurosa & vulgaris, Saw. sp. 1. 2.

This is occasioned by the too great quantity of matter thrown into the alimentary canal; and what is discharged has not the appearance of excrements, but is much whiter, and of a thinner consistence. Voracious people who do not sufficiently chew their food, gourmandizers, and even those who bammer in their speech, are said to be liable to this disease. In lighter cases it is removed without any medicine, or by a dose of rhubarb; but where the matters have acquired a putrid taint, the disorder may be exceedingly protracted and become dangerous. In this case leucint and antisepctic purgatives are to be made use of, after which the cure is to be completed by astringents.

Sp. II. The Bilious Diarrhoea.

(Saw. sp. 8.)

This distemper shows itself by copious floods of a very yellow colour, attended with gripes and heat of the bowels, thirst, bitterness, and dryness of the mouth. Diarrhoea, yellowness of the tongue, and frequently follows an intermitting or bilious fever. When the fever is gone, the diarrhoea is to be removed by acidulated and cooling drinks, with small doses of nitre.

This kind of diarrhoea, besides the matters usually excreted, is attended with a copious dejection of the mucus of the intestines with great pain; while the patient daily pines away, but without any fever. Persons of all ages are liable to it, and it comes on usually in the winter-time; but is so obstinate, that it will sometimes continue for years. In obstinate loosenesses of this kind, vomits frequently repeated are of the greatest service. It is also very beneficial to keep the body warm, and rub the belly with stimulative ointments; at the same time that astringent elyters, rhubarb, and stomachic medicines, are to be exhibited. Starch elyters are very often efficacious. Some kinds of looefees are contagious; and Sir John Pringle mentions a soldier who laboured under an oblitinate diarrhoea, who infected all those that used the same privy with himself. In the looefees which frequently followed a dyfenter, the same author tells us that he began the cure with giving a vomit of pecanahna, after which he put the patients on a course of astringents. He used a mixture of three drachms of extract of logwood, diluted in an ounce and a half of spirit of cinnamon, to which was added seven ounces of common water, and two drachms of tincture of catechu. Of this the patient took two spoonsfuls once in four or five hours, and sometimes also an opiate at bed-time. He recommends the same medicine in oblitinate diarrhoeas of all kinds. A decoction of fimaruba bark was also found effectual, when the dysenteric symptoms had gone off. Dr. Hux, who used this article in North-America, also recommends it in diarrhoeas. Two or three ounces of the fimaruba are to be boiled in a pound and a half of water to a pound, and the whole quantity taken throughout the day. He began with the weakest decoction; and, when the stomach of the patient could easily bear it, he then ordered the strongest; but at the same time he acknowledges, that, unless the sick found themselves sensibly better within three days from the time they began the medicine, they seldom afterwards received any benefit from it. But when all astringents have failed, Sir John Pringle informs us, he hath known a cure effected by a milk and farinaceous diet; and he thinks in all cases the disorder would be much more easily removed, if the patients could be prevailed on to abstain entirely from spirituous liquors and animal-food. If the milk by itself should turn
Practise.

Sp. IV. The COELICAL PASSION.

Coeliac chylodes, Sauv. sp. 1.
Coeliac ladeus, Sauv. sp. 4.

There are very great differences among physicians concerning the nature of this disease. Sauvages says, from Aretæus, it is a chronic flux, in which the aliment is discharged half digested. It is attended with great pains of the loins, reeling the prickings of pins; rumbling and flatulency in the intestines; white fots because deprived of bile, while the patient becomes weak and lean. The disease is tedious, periodical, and difficult to be cured. Sauvages adds, that none of the moderns seem to have observed the disease properly; that the excrements indeed are white, on account of a deficiency of the bile, but the belly is bound as in the jaundice. Dr Cullen says there is a defecion of a milky liquid of the nature of chyle; but this is treated by Vogel as a vulgar error. He accuses the moderns of copying from Aretæus, who mentions white fots as a symptom of the distemper; from whence authors have readily fallen into the notion that they never appeared of any other colour in any person labouring under the coeliac passion. This error quickly produced another, which has been very generally received; namely, that the chyle was thrown out of the ladeals by reason of some obstruction there, and thus paffed along with the excrements; of which he says there is not the least proof, and agrees with Aretæus that the whiteness is only occasioned by the want of bile. He endeavours to prove at length, that the coeliac passion can neither be occasioned by an obstruc- tion of the ladeals, nor of the mesenteric glands; though he owns that such as have died of this disease and were diffected, had obstructions in the mesenteric glands; but he denies that all those in whom such obstruc- tions occur, are subject to the coeliac passion. He considers the diæmeter as arising from a cachexy of the stomachic and intestinal juices; and directs the cure to be attempted by emetics, purgatives, antiseptics and tonics, as in other species of diætaient.

Sp. V. The LIENTERY.

Lienetera spontanea, Sauv. sp. 2.

The lientery, according to Sauvages, differs from the coeliac passion only in being a lighter species of the disease. The aliment passes very quickly through the intestines, with scarce any alteration. The patients do not complain of pain, but are sometimes affected with an intolerable hunger. The cure is to be attempted by stomachics and tonics, especially the Peruvian bark. This disease is most common at the earlier periods of life; and then rhubarb in small quantities, particularly when combined with magnesia, is often productive of the best effects.

Sp. VI. The Hepatic FLUX.

Hepatica adventitia, Sauv. sp. 2.

The hepatic diætement is by Sauvages described as a flux of bloody serous matter like the washings of fish, which percolates through the coats of the intestines by means of the anatomomating vesicles. It is the coeliac passion of Trallianus; and which, according to Sauvages, rarely, if ever, occurs as a primary disease. It has, however, been observed to follow an inflammation of the liver, and then almost always proves fatal.

GENUS LXII. DIABETES.

A profuse discharge of Urine.

Diabetes, Sauv. gen. 263. Lit. 197. Fazg. 115.

Diurese, Fazg. 114.

Sp. I. The Diabetes with sweet Urine.

Description. The diabetes first shows itself by a dryness of the mouth and thirst, white frothy pittle, and the urine in somewhat larger quantity than usual. A heat begins to be perceived in the bowels, which at first is a little pungent, and gradually increases. The thirst continues to augment by degrees, and the patient gradually loses the power of retaining his urine for any length of time. It is remarkable, that though the patients drink much, the quantity of urine always exceeds what is drank. In Dr Home's Clinical Experiments we have an account of two patients labouring under this disease; one of them drank between 12 and 15 pints of urine in the day: the latter, 11 or 12; so that his urine always exceeded his drink by eight, or at least seven pints. When the urine is retained a little while, there is a swelling of the loins, illia, and tellæ; in this disease the strength gradually decays; the skin is dry and shrivelled; edematous swellings arise in various parts of the body, but afterwards subsides without relieving the diætem in the leafl; and the patient is frequently carried off by con- vulsions.

The most singular phenomenon in this disease is, that the urine seems, to be entirely or very much di-
MEDICINE.

Spasms veiled of an animal-nature, and to be largely impregnated with a saccharine salt scarce distinguishable from that obtained from the sugar-cane. This discovery was first made by Dr Dobson of Liverpool, who made some experiments on the urine of a person labouring under a diabetes, who dischargeth 28 pints of urine every day, taking during the same time from 12 to 14 pounds of solid and liquid food. Some of this urine being set a-fide, fell into a spontaneous effervescence, changed first into a vinous liquor, and afterwards into an acetoxy one, before it became putrid and offensive.

Eight ounces of blood taken from the same patient, separated into crassalementum and serum; the latter being sweet to the taste, but less so than the urine.

Two quarts of the urine, evaporated to dryness, left a white cake weighing four ounces two drachms and two scruples. This cake was granulated, and broke easily between the fingers; it smelled sweet like brown sugar; neither could it by the taste be distinguished from sugar, except that it left a slight tinge of coolness on the tongue. The experiment was repeated after the patient was recovered to such a degree as to pass only 14 pints of urine a-day. There was now a strong urinous smell during the evaporation; and the residuum could not be procured in a solid form, but was blackish, and much resembled very thick treacle.

In Dr Home's patients, the serum of the blood had no pterunal sweetness; in one of them the crassalementum was covered with a thick inflammatory crust. In one of these patients the urine yielded an ounce and a half, and in the other an ounce, of saccharine matter from each pound. It had, however, an urinous smell during the evaporation; and the residuum could not be procured in a solid form, but was blackish, and much resembled very thick treacle.

In Dr Home's patients, the serum of the blood had no preternatural sweetness; in one of them the crassalementum was covered with a thick inflammatory crust. In one of these patients the urine yielded an ounce and a half, and in the other an ounce, of saccharine matter from each pound. It had, however, an urinous smell during the evaporation; and the residuum could not be procured in a solid form, but was blackish, and much resembled very thick treacle.

These are exceedingly obscure and uncertain; spasms of the nervous system, debility, and everything inducing it, but especially strong diuretions and immediate venery, have been accused as producing on the diabetes. It has, however, occurred in persons where none of these causes could be suspected; nor have the best physicians been able to determine it.

Diuretions have only shown that the kidneys were in an enlarged and lax state. In one of Dr Home's patients, who died, they smelled sour, and the urine of one fermented with yeast, we are told, into a tolerable small-beer. Both these patients had a voracious appetite, and perpetual gnawing sense of hunger; as had also Dr Dobson's patient. The incontinent urine of those affected with diabetes has not been examined by physicians with sufficient accuracy to enable us to speak with confidence of its contents.

Causes. These are exceedingly obscure and uncertain; spasms of the nervous system, debility, and everything inducing it, but especially strong diuretions and immediate venery, have been accused as producing on the diabetes. It has, however, occurred in persons where none of these causes could be suspected; nor have the best physicians been able to determine it.

Diuretions have only shown that the kidneys were in an enlarged and lax state. In one of Dr Home's patients, who died, they smelled sour, and the urine of one fermented with yeast, we are told, into a tolerable small-beer. Both these patients had a voracious appetite, and perpetual gnawing sense of hunger; as had also Dr Dobson's patient. The incontinent urine of those affected with diabetes has not been examined by physicians with sufficient accuracy to enable us to speak with confidence of its contents.

Prognosis. The diabetes is rarely cured, unless when taken at the very beginning, which is seldom done; and in a confirmed diabetes the prognoses must therefore be unfavourable.

Cure. As there is reason to believe that in this affection the morbid secretion of urine, which is both preternatural in point of quantity and of quality, arises from a morbid diminution of tone in the kidney, the great object in the cure must be the restoration of due tone to the secreting vesicles of the kidney. But as even this diminished tone would not give rise to the peculiar vitiated secretion without a morbid sensibility of that organ, it is necessarily a second object to remove this morbid sensibility. But besides this, the morbid secretion of urine may also be counteracted both by a diminution of the determination of fluids to the kidney, and by preventing the occurrence of superfluous water in the general mass of blood.

On these grounds the principal hopes of a cure in this distemper are from altrient and strengthening medicines. Dr Dobson's patient was relieved by the following remedies; which, however, were frequently varied, as none of them produced their good effects for any length of time: The bark in substanence, with small doses of rhubarb; decoction of the bark, with the acid elixir of vitriol; the cold infusion of the bark, of which he drank from a quart to two quarts daily; Dover's powder; alum-whey; lime-water; antimonials combined with tinture Thebaica. The warm bath was used occasionally when the skin was remarkably hot and dry, and the patient complained of restlessness and anxiety. The tinture of cantharides was likewise tried; but he could never take more than 25 drops for a dose, without exciting great uneasinesses in his bowels. The body was kept constantly open, either with rhubarb or the infusion of fenna joined with rhubarb. His common drinks were rice-water, barley-water, lime-water, and milk; lime-water alone; fage, balm, or mint-tea; small-beer, simple water, and water acidulated with the vitriolic acid. In seven months, these remedies, in whatever manner varied, made no further progress in removing the disease. In Dr Home's patients, all these medicines, and many others, were tried without the least good effect; infomuch that he uses this remarkable expression: "Thus, these two patients have exhausted all that experience had ever recommended, and almost all that theory could suggest; yet, in both cases, the disease has refisted all the means of cure used." It is remarkable, that though septicism were given to both, in such quantity as evidently to produce a putrefaction in the praema, vie, the urine remained unaltered both in quantity and quality.

But although this disease be frequently in its nature so obstant as to reftit every mode of cure, yet there can be no doubt that particular remedies have succeeded in different cases. Dr Bribiane relates several cases cured by the use of tinture of cantharides; and Dr McCormck has related some in the 9th volume of the Edinburgh Medical Commentaries, which yielded to Dover's powder after a variety of other remedies had been tried in vain.

GENUS LXIII. HYSTERIA.

Malum hyystericum, Loff. III. 50. Fau. 36.

Affectio hysterica, Villis de Morb. Convulsiv. cap. 5.

Description. The hysteria is a convulsive disease, which comes on at uncertain intervals, sometimes longer and sometimes shorter, but at no flated time. The paroxysms commonly begin with a languor and debility
than at any other. It also more frequently affects young women and young widows than such as are bearing children.

Progress. Though the appearance of this disease be so very terrible, it seldom proves mortal unless by wrong treatment; but notwithstanding this it is extremely difficult of cure, and rarely admits of any thing efficacious, than being palliated; for though it should seem to be conquered by medicine for a time, it very quickly returns, and that from the slightest causes.

Cure. The ends principally to be aimed at in the cure of this disease are, in the first place, the removal of particular convulsive or spasmodic affections immediately producing various appearances in the disease, whether under the form of proper phlegmatic fits, or merely of what may be called hysterical symptoms; and in the second place, the prevention of the return of symptoms after they have been removed, by the employment of proper remedies during those intervals from complaints which patients often have when labouring under this affection.

The most powerful remedy hitherto discovered in hysterical cases is opium, or the mixture of it called laudanum. By this commonly the most violent paroxysms are stopt, though it is insufficient to accomplish a radical cure. In Dr Home's Clinical Experiments we find an instance of a cure performed by venefection, though this remedy has been generally condemned in hysterical cases. Afaetida seems to stand next in virtue to opium; though with some it disagrees, and occasions pains in the loins and vomiting. Ether will also frequently remove an hysterical fit; but its effects are of short duration; and if it do not effect a cure soon after its exhibition, no service is to be expected either by perseverance in the use of it or by increasing the doses; and with some constitutions it disagrees to such a degree as to occasion convulsions. If the patient be seized with a violent fit, so that he can swallow nothing, which is frequently the case, he will be proper to apply some strong volatile alkali to her nose; or if that be not at hand, the vapour of burning feathers is sometimes very efficacious. In some instances benefit is derived from the sudden application of cold water to the face or hands; but still more frequently the application of water in a tepid state, particularly the warm pediluvium, is found to be of very great service in bringing about a favourable termination of different violent hysterical symptoms. A plaster of galbanum and afaetida will also prove serviceable; but it must be remembered, that none of these things will prevent the return of the disease; and therefore a radical cure is to be attempted by exercise, the Peruvian bark, chalybeates, mineral waters, and other tonics; but particularly where the state of the patient is such as to be able to bear it, by the use of the cold bath, which, where it does not disagree with the constitution, is often of the greatest service in preventing returns of this affection.

GENUS LXIV. HYDROPHOBIA. 323

The Dread of Water.
MEDICINE.

Hydrophobia.

Practise.

Sp. I. Hydrophobia Rabiea, or Hydrophobia consequent on the Bite of a Mad Animal.

Hydrophobia vulgaris, Sauv. 1st. p. 1.

It is the opinion of some, that Dr Cullen has done wrong in employing the term hydrophobia as a generic name, under which canine madness is included: and it must be allowed, that the dread of water, while it is not universal, is also a symptom occurring only late in the disease, at least in the greater part of cases. Perhaps his arrangement would have been less objectionable, if, following Linnaeus, he had adopted rabies as a generic term, and had distinguished this particular species by the epithet of canina, contagiosa, or the like. Disputes, however, about names are in general not very important; and it is sufficient to observe, that the affection now to be treated of is canine madness, or that disease which arises from the bite of a mad animal.

Description. This disease commonly does not make its attack till a considerable time after the bite. In some few instances it has commenced in from five or six days from the accident; but generally the patient continues in health for 20, 30, or 40 days, or even much longer. The bite, if not prevented; will in general be healed long before that time; frequently with the greatest ease; though sometimes it refists all kinds of healing applications, and forms a running ulcer which discharges a quantity of matter run for many days. It has been said that the nearer the wounded place is to the salivary glands, the sooner the symptoms of hydrophobia appear. The approach of the disease is known by the eczema of the wound becoming hard, hard, and elevated, and by a peculiar sense of prickling at the part; pains shoot from it towards the throat; sometimes it is surrounded with livid or red streaks, and seems to be in a state of inflammation; though frequently there is nothing remarkable to be observed about it. The patient becomes melancholy, loves solitude, and has tickness at the throat. Sometimes the peculiar symptom of the disease, the dread of water, comes on all at once. We have an instance of one who having vomited a vomit of speeacanths for the tickness he felt at his stomach, was seized with the hydrophobia in the time he was drinking the warm water. Sometimes the disease begins like a common sore throat; and the forenes daily increasing, the hydrophobic symptoms show themselves like a convulsive spasm of the muscles of the fauces. In others, the mind seems to be primarily affected, and they have a real dread of water or any liquid before they try whether they can swallow it or not. Dr James, in his Treatise on Canine Madnefs, mentions a boy sent out to fill two bottles with water, who was so terrified by the noise of the liquid running into them, that he fled into the house crying out that he was bewitched. He mentions also the case of a farmer, who, going to draw some ale from a cask, was terrified to such a degree at its running into the vessel, that he ran out in a great haste with the spigot in his hand. But in whatever manner this symptom comes on, it is certain that the most painful sensations accompany every attempt to swallow liquids. Nay, the bare sight of water, of a looking-glass, of any thing clear or pellucid, will give the utmost uneasiness, or even throws the patient into convulsions.

With regard to the affection of the mind itself in this disease, it does not appear that the patients are deprived of reason. Some have, merely by the dint of resolution, conquered the dread of water, though they never could conquer the convulsive motions which the contact of liquids occasioned: while this resolution has been of no avail; for the convulsions and other symptoms increasing, have almost always destroyed the unhappy patients.

In this disease there seems to be an extreme sensibility and irritability of the nervous system. The eyes cannot bear the light, or the sight of anything white; the least touch or motion offends them; and they want to be kept as quiet and in as dark a place as possible. Some complain of the coldness of the air, frequently when it is really warm. Others complain of violent heat; and have a great desire for cold air, which yet never fails to increase the symptoms. In all there is a constant inclination to drink, which do not like the hollow barking of a dog, and which he conjectures might have given rise to the common notion that hydrophobous patients bark like dogs. They are in general unable to take any drink, except with the utmost difficulty, though sometimes they can swallow bread soaked in liquids, slices of oranges, or other fruits. There is a pain under the hyobrillus cordis, as in the tetanus; and the patients mournfully point to that place as the seat of the disease. Dr Vaughan is of opinion that it is this pain, rather than any difficulty in swallowing, which dismounts the patient on every attempt to drink. The voice is commonly plaintive and mournful; but Dr Vaughan tells us there is a mixture of peliacenfs and timidity in the countenance which he cannot describe, but by which he could know a hydrophobous person without asking any questions.

In this distemper, indeed, the symptoms are so various, that they cannot be enumerated; for we will seldom read two cases of hydrophobia which do not differ very remarkably in this respect. Some seem to have at times a furious delirium, and an inclination to spit at or bite the bystanders; while others show no such inclinations, but will even suffer people to wipe the inside of their mouths with the corner of a handkerchief in order to clear away the viscid saliva which is ready to suffocate them. In some male patients there is an involuntary erection of the penis, and emission of
Spasm is the frequent return of the spasms. In a letter from Dr Wolf of Warsaw to Henry Baker, F. R. S. dated Warsaw Sept. 26th, 1767, we have the following melancholy account of the cases of five persons who died of the hydrophobia: "None of them quite lost their right senses; but they were all talking without intermission, praying, lamenting, despairing, crying, listening, spitting a trothful saliva, screaming, sometimes belching, retching, but rarely vomiting. Every member is convulsed by fits, but most violently from the navel upwards to the breath and oesophagus. The fit comes on every quarter of an hour; the waves are not red, nor the tongue dry. The pulse is not at all feverish; and when the fit is over nearly like a found pulse. The face grows pale, then brown, and during the fit almost black; the lips livid; the head is drowsy, and the ears tingling; the urine limpid. At last they grow weary; the fits are less violent, and cease towards the end; the pulse becomes weak, intermittent, and not very quick; they sweat, and at last the whole body becomes cold. They compose themselves quietly as if to get sleep, and so they expire. The blood drawn a few hours before death appears good in every respect. A general observation was, that the hnt and dressings of the wounds, even when dry, were always black, and that when the pus was very good in colour and appearance." In one of Dr Wolf's patients who recovered, the blood spunk intolerably as it was drawn from a vein; and one of Mr Vaughan's patients complained of an intolerable fetid smell proceeding from the wounded part, though nobody but himself could perceive it. In general, the violent convulsions cease a short time before death; and even the hydrophobia goes off, so that the patients can drink freely. But this does not always happen; for Mr Vaughan mentions the cafe of a patient, in whom, "when he had in appearance ceased to breathe, the spasmus cynicus was observable, with an odd convulsive motion in the muscles of the face; and the strange contrariety which took place in the action of these produced the most horrid appearance of features that can well be conceived. Of this patient also it was remarkable, that in the last hours of his life he ceased to call for drink, which had been his constant request; but was perpetually asking for something to eat."

The hydrophobia seems to be a symptom peculiar to the human race; for the mad animals which communicate the infection, do not seem to have any dread of water. Dr Wolf, in the letter above quoted, says in general, that cattle bit at the same time and by the same animal (a mad wolf) which bit the persons whose cafes he related, died nearly with the same frightful raging as the men; but says nothing of their having any hydrophobia: nay, Dr James and some others assert, that the hydrophobia is not always an attendant on rabies canina in the human race; and indeed it is certain that the disease has proved mortal after this terrible symptom has been removed. With regard to the symptoms of madness in dogs, they are veryequivocal; and those particularly enumerated by some authors, are only such as might be expected in dogs much heated or agitated by being violently pursued and struck. One symptom indeed, if it could be depended upon, would determine the matter; namely, that all other dogs avoid and run away from one that is mad; and even large dogs will not attack one of the smallest size who is infected with this disease. Upon this supposition they point out a method of discovering whether a dog who has been killed was really mad or not; namely, by rubbing a piece of meat along the inside of his mouth, and then offering it to a found dog. If the latter eats it, it is a sign the dog was not mad; but if the other rejects it with a kind of howling noise, it is certain that he was. Dr James tells us, that among dogs the disease is infectious by staying in the same place; and that after a kennel has been once infected, the dogs put into it will be for a considerable time afterwards in danger of going mad also. A remedy for this, he says, is, to keep geese for some time in the kennel. He rejects as fallacious the opinion that dogs when going mad will not bark; though he owns that there is a very considerable change in their bark, which becomes hoarse and hollow.

a. In no disease whatever are we more at a loss to discover the causes than in the hydrophobia. In dogs, foxes, and wolves, it seems to come on spontaneously; though this is contested by some authors. It is said, that the causes commonly aaligned, viz. heat, feeding upon putrid flesh, want of water, &c. are not sufficient for producing the distemper. It does not appear that madness is more frequent among dogs in the warm than in the cold climates; may, in the island of Antigua, where the climate is very hot, and the water very scarce, this distemper has never, it is said, been observed. As to putrid aliment, it seems natural for dogs to prefer this to any other, and they have been known to subsist upon it for a long time without any detriment. For these reasons, they think the disease arises from a specific contagion, like the small-pox and measles among the human race, which, being once produced by cassets unknown, continues to be propagated by the intercourse which dogs have with each other, as the diseases just mentioned continue to be propagated among the human race by means of the intercourse which they have with one another.

With regard to the immediate cause among mankind, there is not the least doubt that the hydrophobia is occasioned by the saliva of the mad animal being mixed with the blood. It does not appear that this can operate through the cuticula; but, when that is rubbed off, the smallest quantity is sufficient to communicate the disease, and a slight scratch with the teeth of a mad animal has been found as pernicious as a large wound. It is certain also, that the infection has been communicated by the bites of dogs, cats, wolves, foxes, weasels, fwiens, and even cocks and hens, when in a state of madness. But it does not appear that the distemper is communicable from one hydrophobous person to another, by means of the bite, or any other way. Dr Vaughan inoculated a dog with the saliva of a hydrophobous child, but the animal continued free from disease for two months; and though the doctor promised to inform the public if it should happen to occur afterwards, nothing has hitherto appeared on that subject. A nurse also frequently killed the child during this time of his disorder, but no bad consequences ensued.

When we attempt to investigate the nature of the
case
cause of the hydrophobia by diffusion, our inquiries are commonly disappointed. In two bodies opened by Dr Vaughan, there was not the leaft morbid appearance; in the very fauces, where we might have expe- cted that the difease would have fhown itself moft evidently, there was not the leaft appearance even of inflammation. The stomach, intestines, diaphragm, oesophagus, &c. were all in a natural state: neither do we find in authors of credit any certain accounts of morbid appearances in the bodies of hydrophobous persons after death. Dr Vaughan therefore concludes, that the poison acts upon the nervous fystem; and is fo wholly confined to it, that it may be doubted whether the qualities of the blood are altered by it or not; and that it acts upon the nerves by impairing and disturbing their functions to a fuch a degree as speedily to end in a total extirpation of the vital principle. As to the difficulty in swallowing generally believed to accompany dread of the water, he treats it as a misre- preffentation, as well as that the oesophagus with the muscles subfervient to deglutition are especially concerned in this difeafe. The principal foundation of the evil, he thinks, refts on a morbid fensibility both of the external and internal fauces. For the fource of a liquid, or the application of any fubftance to the in- ternal fauces, but more especially of a fluid, infantly excites the moft painful feelings. Nay, the fame symptoms are produced by touching the external fauces with a fluid, or by the contact of cold air with thefe parts; and nearly in as great a degree. But a solid or a fluid fubftance being conveyed into the oesophagus, the transit into the stomach is accomplished with little or no impediment; fo that in fact the difficulty is furmouted before the patient be engaged in the action of swallowing. Nor is the excruciating pain, which never fails to be the companion of every attempt to drink, felt in the fauces and throat: it is, he fays, at the ferubculaii cordis; to which the fufferer applies his hand. From this laft circumftance, therefore, from the prefence of the rixos farciomites, from the muscles of the abdomen being forcibly con- tracted, and from the fenfe of suffocation which feems to threaten the patient with immediate death, Dr Vaughan has been led to think that in the hydrophobia a new sympathy was eftablifhed between the fauces, the diaphragm, and the abdominal muscles.

Prognofis. When a perfon is bit, the prognojis with regard to the ensuing hydrophobia is very uncertain. All thofe who are bit do not fall into the difeafe; nay, Dr Vaughan relates that out of go bit by a mad dog, only one was feized with the hydrophobia. During the interval betwixt the bite and the time the difeafe comes on, there are no symptoms by which we can judge whether it will appear or not. When once it hath made its appearance, the prognojis is exceedingly fatal.

Prevention and Cure. It has been generally allowed by practitioners, that though the hydrophobia may be prevented, yet it can feldom if ever be cured after it has made its appearance. The moft effential part of the treatment therefore depends on the proper use of means of prevention. The great objects to be aimed at in prevention, are, in the firft place, the complete removal of the contagious matter as foon as po- fible; or, secondly, means of destroying it at the part, where there is even the lighteft reafon to believe that it has not been completely removed. Of all the means of removal, the complete cutting out the part to which the tooth has been applied, is unquestionably the moft to be depended upon. This practice, therefore, should be had recourse to as fon as poifible. The sooner it can be accomplished, the better. But as it has been obferved, that a peculiar fenfation at the part aff- fected always precedes the accession of the difeafe, even when it takes place at a late period after the bite, there is good ground for believing that removal of the part may be of advantage even after a coniderable interval. But besides removal of the contagious matter, by cutting away the part to which it is attached, this fhould alfo be done by careful and long continued washing. This may be done, in moft infances, be- fore a proper opportunity can be had of having recourse to the knife. Cold water should particularly be poured upon the wound from a coniderable height, that the matter may be washed away with fome force. Even after removal by the knife, careful washing is still a neceffary and proper precaution. And after both thofe, to prevent as far as can be, the poifibility of any contagious matter lurking about the wounded part, it fhould not be allowed to heal, but a fufficient amount of matter fhould be supported for the fpace of feveral weeks, by ointment with cantharides, or fimilar applications. By thofe means there is at leaft the beft chance of removing the matter at a sufficiently early period. And this mode of prevention feems to be of more confequence than all others put together which have hitherto been difcovered. But besides removal, prevention may alfo be obtained by the deftitution of the contagious matter at the part; and where there is the leaft reafon to think that a complete removal has not been obtained, thofe fhould always be had recourse to. With this intention the actual cauterity and burning with gun-powder have been employed. And the action of fire is probably one of the moft powerful agents that can be ufed for this purpofe. But recourse has alfo been had to washing both with acids and with alkalies. Of the former kind, vinegar has been chiefiy ufed, but more may probably be expected from the latter; and particularly from the caufic alkali, fo far diluted that it can be applied with safety: for from its influence as a folvent of animal mucus, it gives a better chance of a complete removal of the matter, independent of any influence in changing its nature. It has been thought alfo, that oil applied to the part may be of fervice. But if recourse be had to it, more adive meafures fhould at leaft be previously employed; and even then, fome are of opinion that it is of ad- vantage to increafe the activity of the unctuous matter by combining it with mercury.

On thofe grounds, and by thofe means, we are in- clined to think that the action of this contagion on the fystem, after it has been applied by the bite of a rabid animal, may be moft effeclually prevented. But after this action has once taken place, no remedy has yet been difcovered on which much dependence can be put. A very great variety of articles indeed have at different periods been held forth as infallible, both in the prevention and cure of this affecfion; but their reputation has, perhaps, universally been founded on their being given to people, who, though really...
Practice.

MEDICINE. 277

bit by a mad dog, were yet not infected with the contagion. And this happily, either from the tooth being cleaned in making the bite, or not being covered with contagious matter, is by no means an unfrequent occurrence. Mankind, however, even from the earliest ages, have never been without some bailed specific, which has been held forth as an infallible remedy for this affection till fatal experience demonstrated the contrary. Dr Boerhaave has given a pretty full catalogue of those specifics from the days of Galen to his own time; and concludes, that no dependence is to be put in any of them. It is now, therefore, altogether unnecessary to take notice of burnt crabs, the hyana's skin, morihdrate with tin, liver of the rabid animal, or a variety of other pretended remedies for this disease, proved by experience to be totally inefficacious. But although no greater confidence is perhaps to be put on specifics of modern date, it will be proper that these should be mentioned in the annals of the art.

Bathing in cold water, especially in the sea, and drinking sea-water for a certain time, have been prescribed, and by some accounted a certain preventive. It should be put in any of them. It was prescribed, and by some accounted a certain preventive. It should be put in any of them. It was prescribed, and by some accounted a certain preventive. It should be put in any of them.

When this was known to fail, a long course of antiphlogistic regimen, violent submersion in water, even to danger of drowning, and keeping the wounded place open with cauteries, were recommended. To this regimen, violent submersion in water, even to danger of drowning, and keeping the wounded place open with cauteries, were recommended. To this regimen, violent submersion in water, even to danger of drowning, and keeping the wounded place open with cauteries, were recommended.

Another celebrated remedy is Palmarius's powder, composed of the leaves of rue, vervain, farge, polygypdy, wormwood, mint, mugwort, balm, betony, St John's-wort, and fefter centuary. These herbs must be gathered in their prime, dried separately in the shade, and then powdered. The dose is a drachm, or a drachm and an half, taken every day.

A remedy which might promise to be more efficacious than any of those hitherto mentioned is mercury. This hath been recommended in frictions, and to be taken inwardly in the form of calomel and turpentine, in order if possible to raise a flight faliation, on which the efficacy was thought to depend. Besides this, veneficton, opium, the bark, and camphor, have been tried in very large quantities; the warm bath; and, in short, every thing which human invention could suggest; but with what success, can best be judged from the following well authenticated Hydrophobia cases.

In the beginning of December 1728, a young gentleman, aged 17, was bit by a dog in the middle-finger of the right-hand about the middle of the nail. In the beginning of January 1729, he complained of pain in that finger reaching along the back of the hand to the elbow. In the night between the sixth and seventh days of that month he became hot and restless: emollient and anodyne fomentations were applied; but the pain became very sharp, and the hydrophobia came on in the night-time. He was blooded; but became worse every hour, and at last quite furious and outrageous. The bandage was thrown off from his arm, and he loosit about 20 ounces of blood besides what had formerly been taken from him. This, however, made no abatement of the symptoms, and he died the same night.

In 1733, a woman, feizd with the hydrophobia in consequence of the bite of a dog supposed to be mad, was treated in the following manner by Dr Nugent. First she was blooded to about 15 ounces; she took 16 grains of muk in powder, and alonit with it a pill of two grains of pure opium, every three hours. A platter of galbanum, with half an ounce of pure opium, was laid to her neck and throat. She began to take these medicines on a Saturday morning, an hour or two after the dread of water had commenced. In the evening she was a little easier at intervals. The muk and opium pill were continued as before, and the hand that was bit was ordered to be chased with warm salad oil several times a day. Only two papers of powder and two pills were taken in the night; for the laft made her feel and vomit. She had little or no sleep, but lay pretty quiet. On Sunday, 20 ounces of blood were taken away, and a clyster with antimonial wine injected: the pills and powders were continued as before. On Sunday morning she could swallow liquids a little better, and the lay quiet all night. On Monday her swallowing was greatly better. The muk and opium were continued, and twelve ounces more of blood were taken from her; the platter was renewed with only two drachms of opium, and the oil was used as before. At night she was better; her hand eafy; and by a continuance of these remedies she recovered.—This was the cafe which chiefly brought opium into reputation.

The following cases published by M. Deffault, a Frenchman, first brought mercury into reputation.—Four men were bitten by the same wolf, on the same day, at the same hour. They were dipped in salt-water, and came back persuaded that they had nothing to fear. Some days after, one of them felt a numbed pain about his fears, while the fears themselves grew hard and rofe like an embroidery: he was soon after feized with the usual symptoms, as was also another. The father of the former likewise began to feel a pain about the cicatrices, and a swelling with hardnes, as did also the fourth. They were ordered to rub a drachm and a half of the mercurial or blue ointment upon the cicatrices and about the whole arm. This was repeated three days successively, and then every other day: after the fifth friction, he allowed an interval of two days.

Besides this, they took every day: a drachm and a half of Palmarius's powder. After the third friction the cicatrices grew flat and soft, the pain
went off, their courage returned, and their mind resumed its former tranquillity.

But how far mercury, or indeed any thing else, is from being a specific in the hydrophobia, will appear from the following account of Dr Wolf's patients.

In the middle of April 1767, seventeen people, and a great number of cattle were bitten in the neighbourhood of Warsaw by a mad wolf. One of these, an officer, was brought into the city that same day, and had the best advice of the surgeons and physicians in that place; besides which, he took the barks very copiously with camphor. He continued well till the seventh week, when he became hydrophobous, and died.

Eleven of the others applied to Dr Wolf on the ninth day. Their wounds were all deeply scarified; diligently washed and fomented with vinegar, salt, and theriac; and kept open till the 80th day, in those who lived so long. Every two weeks they were blooded largely, and were purged every week with fauls and jalap. Their diet was mostly vegetable, and their drink whey and water. They all eat as much as could be got of the herbs materfiosus and anagallis flora funice; and they all took often the pulvis Palmari. The muticus cineusus terrestris could not be got, or it would also have been prescribed. Besides the general treatment, two were rubbed daily with a drachm of mercurial ointment, and had their purges with calomel. Two took every day four ounces of vinegar, three drachms mixture of poppies, and half an ounce of rob sambuci every night. One took every day 16 grains of camphor, with four scruples of salt-petre, and at night half an ounce of rob sambuci.

Two took 24 grains of musk, with 50 grains of cinchabar. Other two took from 40 to 60 drops of spirit of sal ammoniac, prepared with quicklime, and the milk took a scruple of crystallized salt of tartar made by the mixture of a little spirit of sal ammoniac with a solution of that salt.

One of the first who used the mercurial ointment was feized with the hydrophobia on the 23rd day, immediately after being well purged with calomel. He was blooded copiously, plunged abundantly in cold water, and had several clisters administered, without effect. Two pounds of oil, and as much of drink, were poured down by force; also a drachm of salt of tartar and half a drachm of musk were given in three doses. He then began to drink freely, but died the third day. His companion then left off the use of mercury, and took 80 drops a day of Dippel's animal oil, till he had taken six drachms of it; after which he went on with 100 drops daily of spirit of sal ammoniac made with alkali.

One of those who took the vinegar fell sick the 3rd day. He was immediately blooded, and vomited with speciaevanha. This man was too strong to make experiments on by force; he refused every thing, and died the third day. His companion, on old man, began to be feized in the same manner: he was purged with fauls, took the morulae balami Percuviani, and drank lemonade. He recovered, and used afterwards 100 drops of spirit of sal ammoniac daily. This was the patient formerly mentioned, whose blood had the fetid smell.

The man who used the camphor fell sick the 33rd day. He was thrice copiously blooded, was plunged forcibly into the coldest water for the space of two hours, and was nearly drowned. He was elythered with effect. He himself forced down with incredible aversion and labour, a great quantity of drink; by which he vomited more than 50 times abundance of frothy flume. He took several ounces of oil, and several boluses of salt and opium, of each four grains, without effect; and died the fourth day.

A girl who used the musk with cinchabar, fell ill the 62d day, and died the third day after. No further attempt was made to save her life, the being then at a distance. Her companion, a pregnant woman, then left off the musk, and took in its stead spirit of sal ammoniac.

A woman who had taken nothing fell ill on the 40th day. She suffered terribly in the night, but left in the day time. Besides the usual symptoms, she had great pain and swelling in her belly. In the space of two days she drank about two bottles of brandy, but would taste no other liquor. The Doctor ordered her to mix an equal quantity of oil with her brandy, and to take every day two boluses of salt and opium.—She recovered: and at half took two doses of turbish-mineral, by which she was vomited and purged.

After the 80th day, all the surviving people took thrice the turbish-mineral, except the pregnant woman; and they afterwards continued their alkaline medicines to the 100th day.

On these cases Dr Wolf makes the following observations.—"Thus we see, that the bark, the mercury, the acids, the musk, the feeding on the most famous herbs, the sweating, the cura antiphlogistica, are no specifics. I don't know what to say to the alkalies: the danger is not yet over; and there are still four people who used nothing, in as good health as my patients."

The following case by Dr Raymond of Marseille: shows the inefficacy of mercury even as a preventive.

—On the 10th of July 1765, Mr Boyer, aged 25, of a bloated cachectic habit, was bit by a mad dog in the inferior part of the leg: the wound extended half way round, bled freely, and was like a great frcatch. The patient's legs had been swelled for a considerable time before the accident; and there were also two ulcers in the other leg. Some hours after the accident, the actual cautery was applied to the wound. The Doctor was not present at this operation; but the part around the bite was rubbed with mercurial ointment immediately after, and the echar was drenched with the same ointment. The echar was separated on the first day, but the dressing was continued till the wound was cicatrized. The second day a bolus of four grains of turbish and eight grains of camphor was exhibited. This procured a considerable evacuation both by vomit and stool, and a spitting also came on. The third day the bitten leg was rubbed with mercurial ointment: in the space of a month the frictions were repeated five times on both legs, three drachms of mercurial ointment being used in each friction. During the same time the bolus was five times repeated; and this treatment kept up a slight salivation to the 40th day. The evening of the third day he took the Tanquin medicus; called also Sir George Cobb's powder, in a bolus; which vomited him briskly. This powder was repeated seven or eight times in the month, generally with the same effect. During the first seven or eight days he got four times,
ME D I C I N E.

Practice.

In the morning, a drachm of the angallia flore punico, freshly gathered and powdered. The 41st day, the turbith bolus was prescribed for the seventeenth time; he was bathed in the sea, and continued the bathing for two days more. On the 74th he was feized with the diarrhœa; and died on the 76th seemingly suffocated. About the middle of April the temperature of his body was still high. About the middle of the month he was bit by a mad dog, with mercurial f İstanbul; applying them as in the case of Mrs. Vaughan, he began to complain of a pain in the liver, which ascended the arm, and affected the temple on the same side. He was put into the warm bath for three hours, and had a feverish return. This was healed by the use of the same medicine. It was put in several times during the night; he had a feverish return, and took medicines every five minutes. He was then taken out again, and the same medicine was put in. He had a feverish return, and this was healed by the use of the same medicine.

Another instance is mentioned by the same author, of a pregnant woman bit by the same dog, and on the same day with Mr. Boyer, who was never seized with feverish return. About the middle of April, drops of laudanum, HC1, were put in, two pills of a grain of salt each, during which time he was feverish. About the middle of the day before Dr. Vaughan saw him, he began to complain of a pain in the part bitten, which ascended the arm, and affected the temple on the same side. He was put into the warm bath for three hours; and during which time he was feverish; he had a feverish return, and this was healed by the use of the same medicine.

In the following case all the foregoing remedies were tried. — In the afternoon of the 29th of Aug. 1778, Mr. Bellamy of Holborn, aged 40, was bit by a cat, which was killed by a cat, and from an apothecary. A servant maid who was bitten in the leg before her master was bitten, likewise took the same remedy. About the middle of April Mr. Bellamy complained of a pain in his right knee, which he supposed to be rheumatic, and which continued and increased till the 7th of June, when he got some pills of colchicum, ipecacuanha, and pil. sapon. from an apothecary, which hussam's time of the bark in small doses. In six days more he had a termination in the urethra, a contraction of the ferotum and penis to a degree of pain, and an emfion of semen after making water, to which he had frequent calls. The medicines were discontinued; and on the 10th of that month the hydrophobia came on, and Dr. Fothergill was called. Six ounces of blood were taken from his arm, and a bolus of a ferrule of native cinchona and half a ferrule of musk was given every four hours. The temperature increased through the day. In the evening a clyster was injected, and several times repeated during the night; he had been put into the warm bath, and two drachms of strong mercurial ointment rubbed into his legs and thighs by himself.
himself. He was greatly relieved by the warm bath while he continued in it, but the symptoms returned with increased violence in the night. The next day, being greatly worse, he was bled to as great a quantity as he could bear, had the warm bath and Clysters repeated, and half an ounce of mercurial ointment rubbed into his thighs and legs. Pills of opium were prescribed, but he did not take them. He died the same night, at half an hour after 12. This patient was a man of great resolution, and could in part conquer his aversion at water. He seemed to have totally forgot the accident of the bite; and cautiously said, that he thought this disorder resembled the hydrophobia, without supposing that he was afflicted with that distemper at the time. The bite on the girl’s leg refused to heal, buffled the art of a young surgeon who attempted to cure it, and continued a running ulcure for a long time. She did not fall into the hydrophobia. Hence Dr Fothergill thinks it probable, that plaster of Paris was kept for a long time. In the course of a month, without any further trouble, the wound was healed, excepting a small portion, which operated, when he first felt a pain in that hand and arm; for which he bathed in a river that evening, supposing that it had been a rheumatic complaint. The next day he was sick; and in the evening was seized with a violent vomiting, which continued all that night and till the middle of the next day, when it was succeeded by the hydrophobia. He was treated with the warm bath; had a purgative Clyster injected; and as far as it had operated, a second was given, consisting of four ounces of oil, and half an ounce of laudanum: half an ounce of strong mercurial ointment was rubbed upon the fauces, and the part was afterwards covered with the cataplasma & cymino, to which was added an ounce of opium. An embrocation was applied to the region of the stomach with continued friction, consisting of half an ounce of spirit of sal ammoniac, ten drachms olive oil, six drachms of oil of amber, and ten drachms of laudanum. Two ounces of strong mercurial ointment were rubbed upon the shoulders and back; and as a further means of kindling a pykæmia speedily, he received the smoke of cinnabar into the mouth by throwing a drachm of that substance now and then upon a hot iron; he was also directed to take every four hours a bolus of 15 grains of muk, three grains of turbit, and four grains of opium. He was easier while in the warm bath, and during the application of the ointment; but died the same night about two o’clock.

Many other instances might be adduced of the inefficacy of this pretended specific: the danger of acquiescing in which, will, it is hoped, create a due degree of caution in those to whom they are so unfortunate as to be bit by a mad animal may commit themselves. Another remedy may also be mentioned as having had the reputation of being sometimes successful in this disease; which is chiefly employed in different parts of India, particularly in the territory of Tanjore. The medicine to which we now allude contains indeed several articles which are altogether unknown in our materia medica: but it contains at least once very powerful substanee well known to us, viz. arfencic. This medicine, known by the name of the Snake Pills, as being principally employed against the bite of the most venomous snakes, is directed to be prepared in the following manner:

Take white arfencic, of the roots of neili navi, of nevi vilham, of the kernels of the ner valum, of pepper, of quicksilver, each an equal quantity. The quicksilver is to be rubbed with the juice of the wild cotton till the globules are perfectly extinguished. The
The atonic being first levigated, the other ingredients, reduced to a powder, are then to be added, and the whole beat together with the juice of the wild cotton to a consistence fit to be divided into pills.

Though these pills are principally used against the bite of the cobra de capello, yet they are said also to be successful in the cure of other venomous bites; and, for the prevention of rabies canina, one is taken every morning for some length of time. Of this remedy European practitioners have, we believe, as yet no experience; and if, in the accounts transmitted by Earl India practitioners, it cannot be said that we have: authentic evidence of its want of success, it can as little be pretended that there is indubitable evidence of its efficacy in any instances; and it is by no means improbable, that it will be found equally inefficient with others at one time considered as infallible.

Of the great variety of remedies which have had their day of reputation, there is not one which has not poached the credit, some time or other, of preventing the noxious effects arising from the bite of a mad dog. A more adequate experience has with all of them disconcerted the deception. It was above observed, that the hydrophobia is by no means the infallible consequence of being bit by a mad animal; and that of between 20 and 30 persons who were bit by the dog which gave the fatal wound to one of Dr. Vaughan's patients, not one felt the least ill effect but himself. In the above number (says the Doctor) were some who took the Ormus Kirk Medicine; others went to the salt-water; and a part of them used no remedy, who yet fared equally well with the most attentive to their injury. The same thing has often happened before; and much merit, I doubt not, has been attributed to the medicine taken, from that celebrated one of Sir George Cobb down to the infallible one which my good Lady Bountiful's receipt book furnishes.

From all that has been said, the reader will judge how far the hydrophobia is capable of being subdued by any of the medicinal powers which have yet been tried. Some eminent physicians assert, that it is totally incurable; and allege that the instances recorded by different authors of its cure have not been the genuine kind, but that which comes on spontaneously, and which is by no means so dangerous. Indeed two of Dr. Wolf's patients recovered, where the disease seems to have been perfectly genuine; but in these the poison seemed to vent itself partly on some other place besides the nervous system. In one the blood was evidently infected, as it had an abominable fetor, and the other had a violent pain and swelling in the belly. In all the others, it seemed to have attacked only the nervous system; which perhaps has not the same ability to throw off any offending matter as the vascular system.

There is, however, a possibility that the prodigious affections of the nerves may arise only from a vitiated state of the galenic juices; for it is well known, that the most terrible convulsions, nay the hydrophobia itself, will arise from an affection of the stomach, without any bite of a mad animal. This seems to be somewhat confirmed from one of Dr. Wolf's patients, who, though he vomited more than 50 times, yet still threw up a frothy matter, which therefore was evidently secreted into the stomach, just as a continual vomiting, of bilious matter flows a continual and extraordinary secretion of bile. Dr. Wolf himself adopts this hypothesis so far as to say, that perhaps the februm may become frothy; but in blood drawn from a vein not the least fault appears either in the fever or emunctum. He affirms, however, that the dogmum appears to be one of the parts first and principally affected; and as it is not informed, it would seem that the affection it sustains must arise from the vitiated state of its juices.

Be this as it will, however, in the hydrophobia, the stomach seems totally, or in a great measure, to lose the power which at other times it possessed. Two grains of *cuprum ammoniacatum* were repeatedly given to a child of eight years of age without effect; but this dose would occasion violent vomiting in a strong healthy man. Something or other therefore must have prevented this substance from acting on the nervous coat of the stomach; and this we can only suppose to have been the exceedingly disordered state of the galenic juice, which occasioned such violent irritation through the whole body that the weaker stimulus of the medicine was entirely lost. It would seem proper therefore to consider the stomach in hydrophobic cases as really containing a poisonous matter, which could not be expelled by vomiting, because it is renewed as fast as evacuated. The indication therefore must be, to change its nature by such medicines as are certainly more powerful than the poison; and this indication will naturally lead us to think of large doses of alkaline反思. These, it is certain, will destroy any animal-substance with which they come in contact, and render even the poison of serpents inactive. By exhibiting a few doses of them, larger no doubt than what could be safely done on other occasions, we would be certain to change the state of the stomachic juices; and thus might free the patient from those intolerable spasm which always occasion death in such a short time. Dr. Wolf seems inclined to think that volatile alkalies were of service; but the above hypothesis would incline us to use rather the fixed kind. At any rate, it seems vain for physicians to trust much to the power of opium, mercury, musk, or cinnabar, either singly or combined in any possible way. The bark has also failed, and the most celebrated specifics have been found inefficient. Alkalies are the next most powerful remedies which the materia medica affords and they cannot be more unsuccessful than the others have generally been.

Another remedy which seems adapted to change the nature of the galenic juices is ardent spirits. In one of Dr. Wolf's patients two bottles of brandy seem to have effected a cure. The oil mixed with it was of no efficacy in other cases, and the opium and turpith seem not to have been exhibited till the worst was past. In this case the disease seems to have attacked the vascular as well as the nervous system.

In all the patients the warm bath seems to have been a palliative, and a very powerful one, and as such it ought never to be omitted, though we can by no means trust it to it as a radical cure; and the above histories abundantly show, that though the warm bath and opium may palliate for a short time, the caufe
MEDICINE.

The symptoms depend on and increasing, till at last the symptoms become too strong to be palliated even for a moment by any medicine however powerful. At any rate, the abovementioned hypothesis suggests a new indication, which, if attended to, may perhaps lead to useful discoveries. In cases where putrefactive bile is abundantly secreted, colocynth root and vegetable acids are recommended to change the nature of the poison which the body is perpetually producing in itself. Where corrosive mercury has been swallowed, alkaline salt is recommended to destroy the poison which nature cannot expel by vomiting; and why should not something be attempted to destroy the poison which the stomach seems to fecrete in the hydrophobia, and which nature attempts to expel, though in vain, by violent efforts to vomit? But whatever plan may be pursued in the hopes of curing this dreadful malady after any of the symptoms have made their appearance, we ought in every instance of the accident that gives rise to it, to direct our immediate care to prevention, as being perhaps the only real ground of hope. And the most certain and efficacious way of preventing the ill consequences, is instantly (if it may be done) to cut out the piece in the place that happens to be bitten. Dr James, indeed, says, that he would have little opinion of cutting or cauterizing, if ten minutes were suffered to elapse from the receiving of the bite before the operation was performed. But in an inaugural dissertation lately published at Edinburgh by Dr Parry, the author is of opinion that excision will be of use a considerable time after the bite is received. He adopts this opinion from what happens in the small-pox, where the blood does not seem to receive the infection till some days after inoculation has been performed. A second inflammation, he tells us, then takes place, and the days after inoculation has been performed. A second inflammation which does all the mischief. Excision, or the cautery, will therefore be of service, especially as it readily yielded to venefaction, 30 drops of laudanum, and pills of a grain and a half of opium given every three hours, some bolus of musk and cinnabar, &c. while in some of the former cases as much opium was given to a boy as would have deprived of life the ilighest healthy man had he swallowed it; and yet this amazing quantity produced no effect. This patient also dreaded the sight of a dog.

Amentia, Lin. 67.
Delirium maniacum, Hoffm. III. 251.

Although these distempers may be considered as difficult genera, yet they are so nearly allied, and so readily change into each other, that it sufficiently justifies the treating all of them together.

The distinguishing characteristic of madness, according to Dr Battie, is a false perception; and under this general character may be comprehended all kinds of what is called madness, from the most silly stupidity and idiocy to the most furious lunacy. Frequently the different kinds of madness are changed into each other by the casual excitement of some passion; thus, an idiot may become furiously mad, by being put in a violent passion; though this does not so often happen as the change of melancholy into the raving madness, and vice versa.

It is a very surprising circumstance, that mad people are not only less liable to be seized with infectious disease than those who are in perfect health; but even when labouring under other diseases, if the patient chance to be seized with madness, they are sometimes freed from their former complaints. Of this kind Dr Mead relates two very remarkable instances.

On the other hand, it has been known, that an intermitting fever, supervening madness of long standing, has proved a cure for the madness; the fries having returned when the fever terminated. Dr Monro saw two instances of this himself; and mentions it as an observation of his predecessor in the care of Bethlem hospital.

Another remarkable circumstance is, that immoderate joy, long continued, as effectually disorders the mind as anxiety and grief. For it was observable in the famous South-Sea year, when so many immense fortunes were suddenly gained, and as suddenly lost, that more people had their heads turned, from the prodigious flow of unexpected riches, than from the entire loss of their whole subsistence.

Mad people, especially of the melancholic kind, sometimes obliquely pervert in doing things which must excite great pleasure; wherein it should seem as if their minds were troubled with some disturbing notions, which make them patiently bear the present distresses, lest more severe tortures should follow; or possibly they may think, that, by thus tormenting the body, they render themselves more acceptable to the divine Being, and expiate the heinous sins of which they may imagine themselves to have been guilty.

It is, however, also highly probable, that their feelings differ exceedingly from what they are in a natural state; at least they are every day observed to endure apparently without the smallest uneasiness, watching, hunger, and cold, to an extent which in a state of health would not only be highly distressing, but to the greater part of individuals would even prove fatal. And this resistance of hunger, cold, and sleep, affords perhaps the best test for distinguishing cases of real insanity, from cases where the disease is only feigned, and appearances of it put on, to answer particular purposes; at least where this power of resistance is present, we have good reason to conclude that the affection is not feigned.

Cure. Although we are well acquainted with many of the remote causes of this disease, some of the principal of which have already been mentioned, yet we are still ignorant of the influence of these upon the system, as giving a derangement of the mental faculties, that no general principles on which the cure may be conducted, can with any confidence be pointed out.

It may, however, be observed, that while some remedies seem to operate by producing an artificial termination of this complaint, many others have effect only by aiding a natural termination. And where a recovery from this disease does take place, it most frequently happens in consequence of a natural convalescence. All the species and degrees of madness which are hereditary, or that grow up with people from their early youth, are out of the power of physic; and so, for the most part, are all maniacal cases of more than one year's standing, let them arise from what source soever. Very often mere debility, the dregs of some particular disease, such as an ague, the small-pox, or a nervous fever, shall occasion different degrees of foolishness or madness. In these cases, the cure must not be attempted by evacuations; but, on the contrary, by nourishing diet, clear air, moderate exercise, and the use of wine; whereas, in almost all the other maniacal cases, which arise from different causes, and which come on in consequence of intertemporal living, violent passions, or intense thinking, it is generally held, that evacuations of every kind are necessary, unless the constitution of the patient be such as absolutely forbids them.

Blood is most conveniently drawn either from the arm or jugulars; and if the weaknes be such as renders it improper to take away much blood, we may apply cupping-glasses to the occiput.

Vomiting, in weakly people, must be excited by the vinous ipecacuanha; but in the more robust by emetic tartar or antimonial wine: the most efficacious cathartics are the infusion or tincture of black hellebore, or infusion of fena quickened with tincture of jalap; but if there be suppression of the menses, or hemorrhoidal discharge, then aloe purges will be more proper; and in some instances cooling saline purgatives, such as liquified tartar, are of great service. In general, mad people require very large doses, both of the emetics and cathartics, before any considerable operation ensues.

Dr Monro affirms us, that the evacuation by vomiting is infinitely preferable to any other: the prodigious quantity of phlegm with which the patients in this disease abound, he says, is not to be got the better of but by repeated emetics; and he observes, that the purges have not their right effect, or do not operate to so good purpose, until the phlegm be broken
and attenuated by frequent emetics. He mentions the
case of a gentleman who had laboured under a melan-
choly for three years, from which he was relieved en-
tirely by the use of vomits and a proper regimen.
Increasing the discharge by urine, is also of the greatest
moment, especially when any degree of fever is pre-
sent. The cutaneous discharges are also to be pro-
moted; for which purpose the hot bath is of the highest
service in maniacal cases. Hoffman afferts, that he
has seen numerous instances, both of inveterate melan-
choly and raging madness, happily cured by means of
warm bathing; bleeding and nitrous medicines having
been premised. Camphor has also been highly com-
mended; but, if we can believe Dr Locker of Vienna,
not very defervedly. Having found very good effects
from a solution of this medicine in vinegar, he took it
for granted that all the success was owing to the
camphor; therefore, in order to give it a fair trial, he
collected seven patients, and gave it in large doses of half
a drachm twice a day. This was continued for two
months, and the doctor was surprized to find that
only one of his patients received any benefit. He then
returned the other six back to the camphorated julep
made with vinegar, and in a few weeks four of them
recovered the use of their reafon. This inclined him
to think that the virtue depended solely on the vine-
gar, and accordingly he began to make the trial.
Common vinegar was first given; but after a little while
he fixed on that which had been distilled, and gave
about an ounce and half of it every day; the patients
having been previously prepared by bleeding and pur-
ging, which was repeated according as it was found
necessary. He gives a lift of eight patients who were
cured by this method; some in six weeks, others in
two months, and none of them took up more than
three months in perfecting the cure. He does not in-
deed give the ages of the patients, nor mention the cir-
cumstances of the case; he only mentions the day on
which the use of the vinegar was begun and the day
on which they were discharged; and he adds, that
they all continued well at the time of his writing.

Dr Locker informs us, that this medicine acts
chiefly as a sudorific; and he observed, that the more
the patients sweated, the sooner they were cured: it
has by many been found to prove a cure,
the patients sweated, the sooner they were cured: it
has by many been found to prove a cure,
having been previously prepared by bleeding and
purging, which was repeated according as it was found
necessary. He gives a list of eight patients who were
cured by this method; some in six weeks, others in
two months, and none of them took up more than
three months in perfecting the cure. He does not in-
deed give the ages of the patients, nor mention the cir-
cumstances of the case; he only mentions the day on
which the use of the vinegar was begun and the day
on which they were discharged; and he adds, that
they all continued well at the time of his writing.

His operation consists of tying the sleeve-strings round the waist, he has no
use of his hands. A broad strap of girdle-web is then
carried across the breast, and fastened to the bedhead,
by which means the patient is confined on his back;
and if he should be so outrageous as to require further
refrain, the legs are secured by ligatures to the foot
of the bed; or they may be secured by being both
put into one bag not very wide, which may be more
easily fixed than the feet themselves, at least without
giving pain.

It is of great ufe in practice to bear in mind, that
all mad people are cowardly, and can be awed even by
the menacing look of a very expressive countenance;
and when those who have charge of them once impre
t them with the notion of fear, they easily submit to any
thing that is required. The physician, however,
should never deceive them in any thing, but more ef-
sically with regard to their dilhomer; for as they are
more particularly conscious of it themselves, they acquire a
kind of reverence for those who know it; and by
letting them fee that he is thoroughly acquainted with
their complaint, he may very often gain such an ad-
cendant over them that they will readily follow his di-
rections.

It is a more difficult matter to manage those whole
madness is accompanied either with excessive joy or
with great dejection and despondency, than those
who are agitated with rage: and all that can be done
is to endeavour to excite contrary ideas, by repressing
the immoderate fits of laughter in the one kind by chi-
ding or threatening (taking care, however, not
absolutely to terrify them, which can never be done without
danger, and has often added to the misery of the un-
happy sufferer); and dispelling the gloomy thoughts in
the other, by introducing pleasing concerts of muffic,
or any other species of entertainment which the pa-
tients have been known to delight in while they had the
use of their reason.

Though blistering the head has generally been
directed, Dr Mead says he has oftener found it to do
harm than service: but he recommends jiftus in the
back; and advises to keep the head always close
flaved, and to wash it from time to time with warm
vaguer. Opium has by many been forbidden in ma-
iacal cases, as supposing that it always increafes the
disturbance; but there are instances where large doses
of this medicine have been found to prove a cure,
and perhaps if they were tried oftener we should find
powerful effects from it: there certainly cannot much
harm enite from a few doses, which may be immedia-
tely diluted if they should be found to exasperate
the disease.

The diet of maniacal patients ought to be perfectly
light and thin: their meals should be moderate; but
they should never be suffered to live too low, especially
while they are under a course of phyfick: they should
be obliged to observe great regularity in their hours:
even their amusements should be such as are belt suited
to their disposition; and after the disease appears to
be subdued, chalybeate waters and the cold bath will
be highly proper to strengthen their whole frame and
secure them again a relapse.

The greatest uneasiness which people feel in sleep is that commonly called the incubus or night-mare. Those seized with it seem to have a weight on their breasts and about their preordial region. Sometimes they imagine they see spectres of various kinds which oppress or threaten them with suffocation. Neither does this uneasiness continue only while they are asleep; for it is some time after they awake before they can turn themselves in their beds or speak; nay, sometimes, though rarely, the incubus has proved mortal.—The incubus rarely seizes people except when the stomach is oppressed with aliment of hard digestion, and the patient lies on his back. It is to be cured by eating light suppers, and raising the head high; or, if it become very troublesome, anti-epileptic medicines are to be administered, and the body strengthened by chalybeates. The same method is to be followed by those who are subject to walking in their sleep; a practice which must necessarily be attended with the greatest danger; and somnambulism may justly be considered as merely a different modification of this disease. Accordingly Dr Cullen has distinguished the one by the title of oneirodynia activa, and the other by that of oneirodynia gravans.

**Genus LXIX. Tabes.**
Wasting of the Body.

This disorder is occasioned by the absorption of pus from some ulcer external or internal, which produces an hectic fever. The primary indication therefore must be to heal the ulcer, and thus take away the cause of the disease. If the ulcer cannot be healed, the patient will certainly die in an emaciated state. But the proper treatment of the tabes proceeding from this cause, falls to be considered under the head of *Ulcer in Surgery,* and likewise under the genera *Siphylis,* *Scrofula,* *Scorbustics,* &c. diseases in which ulcers are lead, a very common symptom.
constituent parts; or there is an uncommon tendency to the formation of oily matter. In these cases it is apt to accumulate in such quantities, that we may suppose it to burst those vessels which were originally designed to hinder it from spreading too far; or almost every cell of the membra adiposa, many of which are in ordinary cases altogether empty, may be completely filled with fat.

The increase of the omentum particularly, and the accumulation of fat about the kidneys and mesentery, swell the abdomen, and obstruct the motions of the diaphragm; whence one reason of the difficulty of breathing which is peculiar to corpulent people; while the heart, and the large vessels connected therewith, are in like manner so encumbered, that neither the systaltic nor sub systaltic motion can be performed with sufficient freedom, whence weakness and fowness of the pulse: but when the whole habit is in a manner overwhelmed with an oily fluid, the enlargement of the cellular interstices will necessarily interrupt the general distribution and circulation throughout the nervous and vascular systems; impeding the action of the muscular fibres, and producing insensibility, fomnolency, and death.

These cases are the more deplorable, as there is but little prospect of a cure. For the animal oil is of too gross a nature to be easily taken up by absorption; and we know, that when fluids are accumulated in the cellular system, there are only two ways in which they can be carried off or escape; namely, by the absorbents, which take their rise from the cellular interstices, and through the pores of the skin by transudation.

Another misfortune is, that the disease steals on so imperceptibly, that it becomes inextirpate before people begin to think of pursuing the proper means of relief.

In this disease the cure must turn upon two points: First, on preventing the farther deposition of fat, by avoiding the introduction of superfluous aliment, particularly of fatty matters, into the system; and, secondly, on promoting and forwarding the absorption of fat. On these grounds, besides what may be done by proper regimen, a variety of articles have been recommended in the way of medicine.

Soap has been proposed as a remedy to melt down and facilitate the absorption of the fat in corpulent people; and Dr Fleming some years ago published a little treatise, wherein he recommends this medicine, and relates the case of a gentleman who is said to have received considerable benefit from it. But perhaps the soap-leys would be more powerful, and might be more easily taken, heached, as directed when recommended as a diluent of the flone.

Lieutaud advises to take acutm fettiticum in small doses, with frequent purging and brisk exercise. But it will seldom happen that the patients will be found sufficiently steady to persif in any of these courses, it being the nature of the disorder to render them irrefolutive and inattentive to their condition. Therefore the principal use of rules must be with a view to prevention; and persons who are disposed to corpulency should take care in time to prevent it from becoming an absolute disease, by using a great deal of exercise, not indulging in sleep, and abridging their meals, especially that of supper. Salted meats are less fattening than Poultry, such as are fresh; and drinking freely of coffee is recommended to corpulent people.

But Dr Fothergill observes, that a strict adherence to vegetable diet reduces exuberant fat more certainly than any other means that he knows; and gives two cases wherein this regimen succeeded remarkably well. The famous Dr Cheyne brought himself down in this way, from a most unwholesome bulk to a reasonable degree of weight; as he himself informs us. It deferves, however, to be remarked, that every practice for the removal or prevention of fatness must be used with great caution and prudence: for not a few, anxious to prevent this affection, have had recourse to a regimen and to medicine which have proved fatal. This has particularly arisen from the excessive use of acids, probably operating by entirely destroying the action of the cholypoietic visera.

**Genus LXXII. Pneumatosis.**

**Empyema, or Windy Swelling.**

The emphysema sometimes comes on spontaneously; but more frequently is occasioned by wounds of the lungs, which giving vent to the air, that fluid inflates itself into the cellular texture, and often blows it up to a surprising degree. It must be observed, however, that it is only in cases of laceration of the lungs where this disease can take place; for in a simple wound, the effusion of blood always prevents the air from getting out. The cure is to be accomplished by scarifications and compresses; but in some cases only by the paracentesis of the thorax. When air introduced from the lungs is collected in a considerable quantity in the cavity of the thorax, the operation of the paracentesis is perhaps the only means of cure. Upon an opening being thus made, the air sometimes rushes out with incredible violence; and the patient receives at least immediate relief from circumstances the most distressing imaginable. In some instances it is followed even by a complete cure.

**Genus LXXIII. Tympanites.**

**Tympany.**

This is an inflation of the abdomen, and is of two kinds: 1. That in which the statys is contained in the intestines, in which the patient has frequent expulsions of wind, with a swelling of the belly frequently unequal. 2. When the statys is contained in the cavity of the abdomen; in which case the swelling is more equal, and the belly sounds when struck, without any considerable emission of statys. Of these two, however, the former disease is by much the most common; infomuch, that many, even extensively engaged in practice, have never met with an instance of true abdominal tympanites. In both cases the rest of the body falls away.
The typhany sometimes takes place in those who have been long troubled with flatulencies in the stomach and intestines. It happens frequently to women after abortion; to both sexes after the suppression of the haemorrhoids; and sometimes from tedious febrile disorders injudiciously treated.

Prognosis. This disease is generally very obstinate, and for the most part proves fatal by degenerating into an anæsthesia. Sometimes, if the patient be healthy and strong, the disease may terminate favourably, and that the more readily if it has followed from some disorder. A hectic consumption, dry cough, and emaciated countenance in a typhany, with a swelling of the feet, denote approaching death in a very short time.

Cura. With a view to the prevention of this affection, it is necessary, in the first place, to avoid, as far as can be done, causes giving rise to an uncommon extrication of air, by preserving the proper tone of the alimentary canal. After this affection has taken place, the indications are, first, to expel the air already extricated and confined in different cavities; and, secondly, to prevent further accumulation. On these grounds different remedies are employed. The cure, however, is principally attempted by carminative, reflexion, and stomachic medicines, gentle laxatives, and at lat tonics, especially chalybeates. In the Edinburgh Medical Essays, Vol. I. we have a very remarkable history of a typhany by Dr Monro senior. The patient was a young woman of 22 years of age, who fell into the diluter after having a tertian ague, in which she was badly treated. She became a patient in the Edinburgh Infirmary the 24th of March 1730; took several purgatives; and some doses of calomel; used the warm bath; and had an antiphyloric plaster applied over the whole belly, but with very little effect. She was monstrously distended, insomuch that the skin seemed to be in danger of bursting; her breathing was much strained; but the swelling sometimes gradually decreased without any evacuation. The returns and degree of this swelling were very uncertain; and when the belly was most distended, several unequal and protuberant balls could be felt over the whole abdomen, but especially at its sides. Her stomach was good, she had no thirst, and her urine was in proportion to the quantity she drank. She was very colicky, had her menses at irregular periods, but no edematous swellings appeared in the feet or any where else. In this situation she continued from the time of her admission till the 21st of June, during which interval she had only her menses twice. Throughout this space of time, the following circumstances were observed. 1. Several times, upon the falling of the swelling, she complained of a headache; once of pains throughout all her body, once of a giddiness, twice of a nausea and vomiting, and the last time threw up green bile; and once her stomach swelled greatly, whilst the rect of the abdomen subsided. 2. During the flowing of the menses she did not swell, but became very big upon their stopping. 3. Blood-letting and emetics, which were made use of for some accidental urgent symptoms, had no very sensible effect in making the typhany either better or worse. 4. She never had passage of wind either way except a little belching some days before the first monthly evacuation.

Some time before the last eruption of the menses, the purgatives were given more sparingly; and antiphylories of the strongest kinds, such as afafetida, oleum corn. cerv. &c. mixed with soap, were given in large doses, accompanied with the hotter anticorbutics as they are called, as horde-radishes and ginger-root infused in strong ale with steel. The patient was ordered to use frequent and strong frictionst to all the trunk of her body and extremities, and to use moderate exercise. Immediately before the menstruation began to flow, clysters of the same kind of medicines were injected. The menses were in sufficient quantity; but as soon as they ceased, her belly increased in its circumference four inches and a half, but soon subsided. She then complained of pains, which a gentle sweat carried off. Borborygmi were for the first time observed on the same day, June 25th; and having taken some tintura jaca at night, she passed a small quantity of blood by stool. This was the first appearance of the return of the haemorrhoids, to which she had been formerly subject.

The two following days her faponaceous, antiphyloric, and anticorbutic medicines being still continued, she had such explosions of wind upwards and downwards, that none of the other patients would remain in the same room, nay fear to come in with her. Her belly became lefs and softer than it had been from the first attack of the disease; her medicines, with a dose of syrup of buckthorn at proper intervals, still continued; only the proportion of steel was increased; her flatulent discharge went on successfully, and she gradually recovered her former health.

Physometra, Sauv. gen. 290. Sag. 119.
Hydraphyse, Vtg. 317.

The treatment of this is not different from that of the typhany. It is however, upon the whole, a very rare disease; and when it takes place, very seldom if ever admits of a cure.

Genus LXXV. Anasarca.

Waterny Swelling over the whole Body.

In this disease the feet first begin to swell, especially in the evening, after exercise, and when the patient has stood or lain long; which swelling-rises frequency to the thighs. By lying in bed, the swelling becomes less, or even almost disappears. In the progress of the disease, the swelling often rises to the hips, loins, and belly, and at last covers the whole body. This disease, besides the other symptoms afterwards mentioned under Ascites, is attended with a remarkable
Medicine.

In the cure of this, as well as other species of dropsy, the general intentions are, first, the evacuation of the water already effused either by natural or artificial outlets; and, secondly, the prevention of it from accumulation, which is chiefly to be expected from supporting a durance of the absorbents, and from keeping up a proper discharge by the secretory excretions.

The remedies employed with these intentions are much the same with what are employed against the more important genus of affections. Only it may be here noticed, that in anaemia it is usual to scatify the feet and legs. By this means the water is often discharged; but the operator must be cautious not to make the incision too deep; they ought barely to penetrate through the skin; and especial care must be taken, by spirituous fomentations and proper digestives to prevent a gangrene. Dr Fothergill observes, that the safest and most efficacious way of making these drains is by the instrument used for copping, called a cannifer; and he always orders it to be applied as to make the little wounds transversely; as they not only discharge better, but are also longer in healing, than when made longitudinally.

Notwithstanding every precaution, however, gangrene will often ensue; and it is upon the whole a much safer practice to evacuate the water by the natural outlets, the valvular lymphatic absorbents; and with this intention emetics and cathartics, but particularly diuretics, are often employed with success.

Genus LXXVII. HYDRORACHITIS. Spina bifida.

Spinola, Lin. 289.

Spina bifida, Vog. 386.

This disease, which consists in a soft tumor on the lumbar vertebrae, attended with a separation of the vertebrae themselves, though generally considered as approaching to the nature of rachitis, is commonly referred to the article Surgery, which may be consulted with regard to this affection.

Genus LXXVIII. HYDROTORAX. Dropsy of the breast.

This affection, particularly with respect to its causes, is in many circumstances similar to other kinds of dropsy, particularly to affections. But from the situation of the water which is here deposited in the cavity of the thorax, it may naturally be supposed that some peculiar symptoms will occur. Besides the common symptoms of dropsy, paleness of the countenance, icarity of urine, and the like, this disease is, in some instances, attended with a fluctuation of water within the breast, and when it does occur may be considered as a certain distinguishing mark of this affection. But besides this, it is also distinguished by the remarkable affections of circulation and respiration with which it is attended.

The breathing is peculiarly difficult, especially in a recumbent posture; and in many instances patients cannot breathe, with tolerable ease, unless when sitting erect, or even flopping somewhat forwards. The pulse is very irregular, and has often remarkable intermissions. But the disease has been thought to be principally characterized by a sudden starting from sleep, in consequence of an almost inexpressible uneasy sensation referred
referred to the breast, and attended with strong palpitation, which may probably arise from an affection either of circulation or of respiration.

That these symptoms are common attendants of this disease is undeniable; and they are certainly the best characteristics of this affection which we are yet acquainted: but it must be allowed that they are present in some cases where there is no water in the breast; and that in other instances where the disease exists, they are either altogether wanting, or occur only to a very slight degree. Certain diagnostics, therefore, of this disease full remain to be discovered.

When hydrothorax is present from the affection of the vital functions with which it is attended, it may readily be concluded that it is a dangerous disease, and in many instances it proves fatal. The cure, as far as it can be accomplished, is obtained very much on the same principle as in other dropies. Here, however, probably from the uncertainty of the diagnostics, the artificial abstraction of water, by paracentesis of the thorax, is less frequently had recourse to than in ascites; though in some instances, after other means have failed, it has been paid not only to give relief of symptoms highly urgent, particularly dyspnea, but even to produce a complete cure. Benefit is often obtained from an artificial discharge of water by the application of blisters to the breast; but in this, as well as other dropies, a discharge is chiefly effected by the natural outlets, particularly from the use of cathartics and diuretics. In this species of dropy, more perhaps than in any other, recourse has been had to the use of the digitalis purpurea, or fox-glove, so strongly recommended as a diuretic by Dr Withering in his "Treatise respecting the use of it. There can be no doubt that this article the sometimes producive of inconvenience from the disfrefling sickness and severe vomiting which it not unfrequently excites though used even in small doses, often operates as a powerful diuretic, and produces a complete evacuation of water, after other articles have failed. From the effects mentioned above, however, as well as from its influence on the pulse, which it renders much flower, it is necessary that it should be employed with great caution and in small doses. A dram of the dried leaves of the digitalis, macerated for hours in half a pint of warm water, forms an infusion which may be given in doses of an ounce, and the dried powder of the leaves in doses of one or two grains: these doses may be gradually increased, and repeated twice or oftener in the day: but this requires to be done with great caution, lest severe vomiting, or other disfrefling symptoms, should take place.

Genus LXXIX. ASCITES.

DROPSY OF THE ABDOMEN.

Description. This disease assumes three different forms: 1. When the water immediately washes the intestines. 2. When it is interposed between the abdominal muscles and peritoneum; or, 3. When it is contained in sacs and hollow vessels, in which case it is called the engorged dropsy. Some physicians of great reputation have asserted, that the water was often placed within the duplicature of the peritoneum: but this is alleged by Dr Milman to be a mistake, as that membrane is looked upon by the best anatomists to be sable; and he thinks that the abovementioned physi­cians have been led into this error from observing the water collected in the cellular substance of the peritoneum.

In the beginning of an ascites the patient becomes languid, breathless, and has an aversion at motion: his belly swells; and when bruised, the sound of fluctuating water is perceptible; there is a difficulty of breathing when the belly is pressed. There is an almost continual thirst, which in the progress of the disease becomes very urgent; the urine is thick, in small quantity, and red. The pulse is small and frequent; and as the body swells, the other parts whistle away. A fever at last arises, which, constantly increasing, in the end carries off the patient. These symptoms are most urgent where the waters are in immediate contact with the intestines; in the other kinds the rest of the body is left wasted; nor is there there for great thirst or difficulty of breathing.

Causes, &c. The immediate cause of dropsy is a greater effusion of serum by the exhalant arteries than the absorbents take up. This may be occasioned either by too great a quantity of liquid thrown out by the former, or by an inability of the latter to perform their office. This commonly happens in people whole bodies are of a weak and lax texture, and hence women are more subject to this malady than men; chlorotic girls especially are very apt to become dropical.

Sometimes, however, this disease is occasioned by a debility of the vital powers, by great evacuations of blood, or by acute diseases accidentally protracted beyond their usual period; and although this cause seems very different from a laxity of fibres, yet the dropsy seems to be produced in a similar manner by both. For the vital powers being debilitated by either of these causes, naturally bring on a certain debility and laxity of the solids; and on the other hand a debility of the solids always brings on a debility of the vital powers; and from this debility of the vital powers in both cases it happens, that those humours which ought to be expelled from the body are not, but accumulate by degrees in its cavities. There is, however, this difference between the two kinds of dropsy arising from these two different causes, That in the one which arises from laxity the solid parts are more injured than in that which arises from a debility of the vital powers. In the former, therefore, the water seems to flow out from every quarter, and the body swells all over. But when the disease is occasioned by a debility of the vital powers, though the solids be left damaged, yet the power of the heart being much diminished, and the humours scarce propelled through the extreme vessels, the thin liquids, by which in a healthy state the body is daily recruited, are carried by their own weight either into the cavities or into the cellular texture. Hence those aqueous effusions which follow great evacuations of blood, or vio...
MEDICINE.

This page contains a discussion on the production of dropsy, its causes, and various methods of treatment. The text mentions that dropsy can be caused by an obstruction of the circulation, and it discusses the effects of drinking large quantities of water, which can lead to a drop in blood pressure and the formation of ascites or fluid accumulation in the abdomen. The page also describes the symptoms of dropsy, such as a swelling in the abdomen, and the methods used to treat it, including the injection of water or other substances. The text references several medical practices and observations from the time, such as Fothergill's experiment on a dog to demonstrate the effects of drinking large quantities of water on the body, and the use of digitalis to treat heart conditions. The page concludes with a discussion on the prognosis of dropsy and the importance of early treatment.
that in a short time; those, however, are very frequently cured who fall into this disease without any preceding hemorrhagy.

Cure. In the cure of this disease authors chiefly mention two indications. 1. To expel the superfluous quantity of water; and, 2. To prevent its being again collected. But before we proceed to speak of the remedies, it is necessary to take notice, that by the animal economy, if a great evacuation of a fluid takes place in any part of the body, all the other fluids in the body are directed towards that part, and those which lie as it were lurking in different parts will be immediately absorbed, and thrown out by the same passage. Hence the humours which in hydroptic persons are extravasated into the different cavities of the body will be thrown into the interstines, and evacuated by purgatives; or by diuretics will be thrown upon the kidneys, and evacuated by urine. It is, however, not only necessary to excite these evacuations in order to remove this malady, but they must be ad libitum promoted and kept up till the abundant humour is totally expelled. For this reason Sydenham has advised purgatives to be administered every day, unless, either through the too great weakness of the body, or the violent operation of the purgative, it shall be necessary to interpose a day or two now and then; because if any considerable intervals be allowed to take place between the exhibition of the purgatives, an opportunity is given to the waters of collecting again. In this method, however, there is the following inconvenience, that, when the waters are totally evacuated, the strength is at the same time so much exhausted, that the diuretic commonly returns in a very short time. Hence almost our only hopes of curing a dropsy consist in gently evacuating the waters by means of diuretics. But the efficacy of these is generally very doubtful. Dr Friend hath long ago observed, that this part of medicine is of all others the most lame and imperfect; but a French physician, Mr Bacher, lately discovered, as he alleges, a method of making the diuretics much more successful. His reputation became at first so great, that the French king thought proper to procure his secret for a great sum of money. The basis of his medicine was hellebore-root, the malignant qualities of which he pretended to correct in the following manner. A quantity of the dried roots of black hellebore were pounded, and then put into a glass earthen vessel, and afterwards sprinkled with spirit of wine. They were suffered to stand for twelve hours, stirring them about twice or thrice during that space of time. They were then sprinkled again, and at last good Rhénish wine was poured on till it stood fix fingers above the roots. The mixture was frequently agitated with a wooden spatula; and as the wine was imbibed by the roots, more was poured on, so as to keep it always at the same height for 48 hours. The whole was then put on the fire and boiled for half an hour, after which the decoction was violently pressed out; the same quantity of wine was added as at first, and the mixture boiled as before. After the second expersion the woody relictum was thrown away as useless. Both the strained liquors are then mixed together with two parts of boiling water to one of the decoction. The whole is afterwards evaporated in a silver vessel to the confidence of a syrup. One part of the extract is again added with two parts of boiling water, and the whole infipidified as before.—By this means, says he, the volatile nauseous acid particles are separated by evaporation, and the fixed ones remain corrected and prepared for medicinal uses; adding, towards the end, a pinch of old brandy, and evaporating to the confidence of turpentine. Mr Bacher reasons a good deal on the way in which this process corrects the medicine; but tells us, that notwithstanding the improvement, his pills will not have the desired effect unless properly made up. For forming them, they ought to be mixed with matters both of an invicifying and indurating nature; yet so prepared that it will be readily soluble in the stomach, even of a person already debilitated. For answering these purposes, he chose myrrh and carduus beneditus, and then gives the following receipt for the formation of his pills.

"Take of the extract of hellebore prepared as above directed, and of solution of myrrh, each one ounce; of powdered carduus beneditus three drachms and a scruple. Mix them together, and form into a mass, dividing it into pills of a grain and an half each." To these pills Mr Bacher gives the name of the pilula tinctae, from an idea, that while they evacuate the water, they at the same time act as tonics; and thus from augmenting the action of the lymphatics, prevent the return of the disease. And if both these intentions could be effectually answered by the use of the same remedy, it would unquestionably be of great importance in practice.

The effects of these pills were, we are told, very surprising. Dr Daigman relates, that he gave them to 18 hydroptic patients at once; and these he divided into three classes, according to the degree of the disease with which they were affected. The first class contained those who laboured under an anasarca following intermittent fevers. The second class contained those who had an anasarca, together with some degree of aficites, arising from tedious febrile disorders. All these were cured; but these two classes consisted of such cases as are most easily removed. But the third contained those who were seized with a most violent anasarca and aficites, after being much weakened by tedious disorders, and of consequence in whom the disease was very difficult to be cured. Even of these, however, four were cured, and the other two died. The body of one of these being diffected, both sides of the cavity of the thorax were found to be full of a blackish-red water. The lungs were unfound; there was a polyposus concretion in the right ventricle of the heart; the liver and spleen were hard, and of a prettarnentium bulk; and the glands of the mesentery were oblitered and infalted. In the other, the liver and pancreas were febrishous, and the spleen very hard.

The same medicines were given by Dr lomme to eight persons, six of whom had both an anasarca and aficites, but the other two only an aficites. Four of these recovered; three died without being freed from the dropsy; one is whom the dropsy was cured died in a short time after, having for some time before his death become speechless.

By these patients 10 of the pills were taken at once;
and the same dose repeated to the third time, with an interval of an hour betwixt each dose. At first they proved purgative, and then diuretic; by which lait evacuation they finally cured the difeafed. But though Mr Bacher was firmly of opinion that his pills cured the dropfy by reason of the above-related correction; yet it is certain, that, in the hands of other practitioners, these very pills have failed, unlefs they made use of the fame regimen recommended by that physician; while, on the other hand, it is also certain, that different medicines will prove equally efficacious made ufe of.

As Infible ease was 'added that to dropfical patients to derive benefit from drink, and thus to the torments of their difeafe, that he fwallowed his thirft as much as poöible from drink, and thus to the torments of their diseafe. For a great number of ages it has been recommendedit to dropfical patients to abtain as much as poösible from drink, and thus to the torments of their disease was added that of an intolerable thirft; and how great this torment was, we may understand from an example of a friend of king Antigonus, who, having been closly watched both by order of the physicians and alio of the king, was fo unable to bear the raging thirft occasioned by his difeafe, that he swallowed his own excrements and urine, and thus speedily put an end to his life. Dr Milman fows at great length the perrnicious tendency of this practice. He maintains that it is quite contrary to the sentiments of Hippocrates and the beat ancient physicans. He afferts, that unlefs plenty of diluting drink be given, the blood diuretics can have no effect. He condemns alio the strongest terms of giving dropfical patients only dry, hard, and indigedible aliments. Thse would oppress the stomac even of the moö health; and how much more mušt they do fo to those who are already debilitated by labouring under a tedious disorder? By what means alio are thse aliments to be dilufed in the stomac when drink is with-held? By what means alio are these aliments to be dilufed in the stomac when drink is with-held? If the patient be not very much debilitated, he is now the common drink of hydropic patients in the hospital abovementioned, of which they drink at pleasure along with their medicines.

Among purgative medicines Dr Milman recommends the radix seneka; but says the decoction of it, according to the Edinburgh Pharmacopoeia, is too strong, as he always found it excite vomiting when prepared as there directed, and thus greatly to disturb the patient: but when only half an ounce or fix drachmas of the root are used to a pound of decoction, instead of a whole ounce as directed by the Edinburgh college, he finds it an excellent remedy: and though it may sometimes induce a little vomiting, and frequently a nauseas, yet it feldom fails to produce a plentiful flow of urine. This liquor is now the common drink of hydropic patients in the hospital abovementioned, of which they drink at pleasure along with their medicines.
be observed to succeed, after another, though commonly much more powerful, has been tried in vain. Accordingly various articles of this kind are often used in succession. Recourse is particularly often had to the roots of taraxacum, of colchicum, and of squills; the latter, especially when combined with calomel, is often found to be a very powerful diuretic. And according to various authors mercury in different forms probably from acting as a deobstruent, is often of very great use in drophical complaints. Among other diuretics, the laudanum, tinctura has of late been highly extolled by Dr Collins of Vienna, and the nicotine tabaccum by Dr Fowler of York: but neither has been extensively introduced into practice, although we have known some instances in which the latter has been used with great advantage.

The water having been drawn off, we are to put the patient on a course of strengtheners; such as the Peruvian bark, with some of the warm aromatics, and a due proportion of rhubarb infused in wine and chaly beates. Gentle exercise, and frictions on the belly, with such a course of diet as shall be light and nourishing, are also to be enjoined: and it may be observed, that the use of tonic medicines is by no means to be dispensed with. For the treatment of these two diseases, we chiefly, as before, till it

**Description.** This is one of the diseases peculiar to infancy. It seldom attacks children till they are nine months, nor after they are two years old; but it frequently happens in the intermediate space between these two periods. The disease shows itself by a flaccid tumor of the head and face, a loose flabby skin, a swelling of the abdomen, and falling away of the other parts, especially of the muscles. There are protuberances of the epiphyses of the joints; the jugular veins swell, while the rest decrease; and the legs grow crooked. If the child has begun to walk before he be seized with this disease, there is a flowery, debility, and tottering in his motion, which soon brings up sharp, while the extremities of the ribs are knotty. The abdomen is protubereat, and the teeth black and carious. In such patients as have died of this disease, all the solids appear foist and flaccid, and the fluids dissolved and mucous.

**Cauies.** The rickets may proceed from scrofulous or venereal taints in the parents, and may be increased by those of the nurse. It is likewise promoted by feeding the child with aqueous and mucous substances, crude summer-fruits, fish, unleavened farinaceous aliment, and too great a quantity of sweet things. Sometimes it follows intermittent fevers and chronic disorders; and in short is caused by any thing which tends to debilitate the body, and induce a vivid and unhealthy state of the juices.

**Prognostics.** The rickets do not usually prove fatal by themselves, but if not cured in time, they make the person throughout life deformed in various ways; and often produce very pernicious disorders, such as carious bones in different parts of the body.

**Cure.** This is to be affected by mild cathartics, alteratives, and tonics, such as are used in other diseases attended with a debility of the sytem and a vitiated state of the blood and juices. In the Western islands of Scotland, the medicine used for the cure of the rickets is an oil extracted from the liver of the skate-fish. The method of application is as follows: First, the wrists and ankles are rubbed with the oil in the evening: this immediately raises a fever of several hours duration. When the fever from the first rubbing subsides, the same parts are rubbed again the night following; and repeated as long as the rubbing of these parts continues to excite the fever.

When no fever can be excited by rubbing the wrists and ankles alone, they are rubbed again along with the knees and elbows. This increased union brings on the fever again; and is practised as before, till it no longer has that effect. Then the vertebrae and sides are rubbed, along with the former parts; and this.

this ulceration, which again brings on the fever, is repeated as the former. When no fever can be any longer excited by this ulceration, a flannel shirt dipped in the oil is put upon the body of the patient: this brings on a more violent and sensible fever than any of the former ulcerations; and is continued till the cure be completed, which it commonly is in a short time.

A German physician, Dr. Strack, has lately published a paper, in which he recommends the filings of iron as a certain remedy in the rickets. This disease, he observes, in general begins with children when they are about 16 months old. It is seldom observed with children before they be one year old, and seldom attacks them after they pass two; and it is very generally worse where it begins early than where it begins late.

For effecting a cure, it is, he affirms, a matter of the utmost consequence to be able to distinguish, very early, whether a child will be afficted with rickets or not. And this he assures us may be determined by the following symptoms: pallor and swelling of the countenance; and in that part of the cheeks which the following symptoms, paleness and swelling of the face.

When that is the case, he directs that a medicine should be immediately had recourse to which will retard the further progress of the disease and remove what has already taken place. For this purpose, he advises that five grains of the filings of iron, and as much rhubarb, should be rubbed up with ten grains of sugar, and given for a dose every morning fasting, and every evening an hour before supper. But if considerable looseness should be produced, it will be necessary, at first, to perforce in the use of one dose only every day.

After a month's continuance in this course, according to Dr. Strack, there in general enforces a keen appetite for food, quick digestion, and a copious flow of urine; by means of which the fulness of the face and yellowness of the complexion are gradually removed, while the natural colour of the countenance and firmness of the body in general are gradually restored. This practice, he assures us, has never failed of success in any one instance; not even in those children born of parents greatly afflicted with the rickets.

In addition to the use of字符beheas, great benefit is often also obtained in this disease from the use of the cold bath; which, under prudent administration, is perhaps one of the most effectual remedies for this complaint with which we are yet acquainted. When the bones of rickety children begin to bend, they may sometimes be restored to their natural shape by compresses, boiler, and proper supports. See the article Surgery.

**Genus LXXXIV. Scrofula.**

**King's Evil.**

**Description.** This disease shows itself by hard, fir-
In indolent swellings of the glands from sickly humours, sea-water also has been strongly recommended by Dr. Rafæl.

Dr. Fothergill also acquaints us, that the cicuta even by itself is not without a considerable share of efficacy in removing sferoulous disorders. He mentions the case of a gentlewoman, about 28 years of age, afflicted from her infancy with sferulous complaints, fevere ophthalmies, glandular swellings, &c. cured by the extrædatum cicuta taken constantly for the space of a year. He observes, however, that when given to children even in very small doses, it is apt to produce spasmodic affections; for which reason he rarely exhibits it to them when very young, or even to adults of very irritable habits.

Dr. Fothergill gives several other instances of the success of cicuta in sferulous cases, and even in one which seemed to be not far removed from a confirmed phthisis; but owns that it seldom had such good effects afterwards; yet he is of opinion, that where there are symptoms of tubercles forming, a framous habit, and a tendency to phthisis, the cicuta will often be serviceable. It is aodyne, corrects acrimony, and promotes the formation of good matter. With regard to the quality of the medicine, he observes, that the extract prepared from hemlock before the plant arrives at maturity, is much inferior to that which is made when the hemlock has acquired its full vigour, and is rather on the verge of decline; whilst when the flowers fade, the rudiments of the seeds become observable, and the habit of the plant inclines to yellow. This, he thinks, is the proper time to collect the hemlock. It has then had the full benefit of the summer heat; and the plants that grow in exposed places will generally be found more active than those that grow in the shade. The leaf heat it undergoes during the preparation, the better. Therefore, if a considerable quantity of the dry powder of the plant gathered at a proper season be added, leaf boiling will be necessary, and the medicine will be the more efficacious.

But let the extract be prepared in what manner soever it may, provided it be made from the genuine plant, at a proper season, and be not destroyed by boiling, the chief difference observable in using it is, that a larger quantity of one kind is required to produce a certain effect than of another. Twenty grains of one sort of extract have been found equal in point of efficacy to thirty, nay near forty, of another; yet both of them made from the genuine plant, and most probably prepared with equal fidelity. To prevent the inconveniences arising from this uncertainty, it seems always expedient to begin with small doses, and proceed step by step till the extract produces certain effects, which seldom fail to arise from a full dose. These effects are different in different constitutions. But, for the most part, a giddiness affecting the head, and motions of the eyes as if something pulled them outwards, are first felt; a slight sickness, and trembling agitation of the body; a laxative flood or two. One or all these symptoms are the marks of a full dose, let the quantity in weight be what it will. Here we must stop till none of these effects be felt; and in three or four days advance a few grains more. For it has been supposed by most of those who have used this medicine to any good purpose, that the cicuta seldom procures

any
any benefit, though given for a long time, unless in as large a dose as the patient can bear without suffering any of the inconveniences above-mentioned. There is, however, reason to believe, that its effects as a difficulty are in no degree dependent on its narcotic powers: and we are inclined to think, that recourse is often had to larger doses than are necessary; or at least that the same benefit might be derived from smaller ones continued for an equal length of time.

Patients commonly bear a greater quantity of the extract at night than at noon, and at noon than in the morning. Two drachms may be divided into thirty grains, and three or four at night, with directions to increase each dose, by the addition of a pill to each, as they can bear it.

But after all, the best form under which the cicuta can, we think, be exhibited, is that of powder from the leaves. This, either in a flake of powder or made into pills, may be given at first to the extent of four or five grains, and the dose gradually rising till it amount to 15 or 20 grains twice or thrice a day. Given to this extent, particularly when conjugated with the Peruvian bark, it has often been found of great service in fcrifulous cases. At the same time it must be allowed, that such patients, after submitting every mode of cure, will have in some infames a spontaneous recovery in the progress of life, probably from the system acquiring additional vigour.

**GENUS LXXV. SYPHILIS.**

**LUES VENEREA, or French Pox.**

Dr. Arture, who writes a very accurate history of the lues veneraea, is fully convinced that it is a new disease, which never appeared in Europe till some time between the years 1494 and 1496, having been imported from America by the companions of Christopher Columbus; though this opinion is not without its opponents. Dr. Sanchis in particular has contended with much learning and ability, that it appeared in Europe at an earlier period: But it is at least certain, that it was altogether unknown to the medical practitioners of Greece and Rome, and that it was a very common disease in America when the Europeans first visited that country. But at whatever period it may have been introduced into Europe, or from whatever source it may have been obtained, there can be no doubt that, as well as small-pox or measles, syphilis depends on a peculiar specific contagion; or a matter sui generis which is alone capable of inducing this disease.

The venereal infection, however, cannot, like the contagious miasma of the small-pox and some other diseases, be carried through the air, and thus spread from place to place: for unless it is transmitted from the parents to the children, there is no other way of contracting the disease but from actual contact with the infectious matter. Thus, when a nurse happens to labour under the disease, the infant that the suckles will receive the infection; as on the other hand, when the child is infected, the nurse is liable to receive it:

and there have even been instances known of lying-in women being infected very violently, from having employed a person to draw their breasts who happened to have venereal ulcers in the throat. It may be caught by touching venereal sores if the cuticle be abraded or torn; and in this way accoucheurs and midwives have sometimes been infected severely. Dr. Macbride says, the most inveterate pox be ever faw was caught by a midwife, who happened to have a whitelow on one of her fingers when she delivered a woman ill of the lues venerea.

But by far the most ready way of contracting this disease is by coition, the genital parts being much more bibulous than the rest of the body. When the disorder is communicated, the places where the morbid matter enters are generally those where it first makes its appearance; and as coition is the most usual way of contracting it, so the first symptoms commonly appear on or near the pudenda.

The patient's own account will, for the most part, help us to distinguish the disease: but there are sometimes cases wherein we cannot avail ourselves of this information, and where instead of confessing, the parties shall conceal all circumstances; while, on the other hand, there are now and then people to be met with, who perfide themselves that symptoms are venereal, which in reality are owing to some other cause; and therefore it is of the utmost importance to inform ourselves thoroughly of the nature of those symptoms and appearances which may be considered as pathognomic signs of lues venerea.

In the first place, when we find that the local symptoms, such as chancres, buboes, ptyomas, and the like, do not give way to the usual methods; or when these complaints, after having been cured, break out again without a fresh infection; we may justly suspect that the virus has entered the whole mass of fluids; but if at the same time ulcers break out in the throat, and the face is deformed by callous tubercles, covered with a brown or yellow scab, we may be assured that the caufe is now become a confirmed lues, which will require a mercurial course.

When eruptions of the furfuraceous and superficial kind are venereal, they are not attended with itching; and the scale being picked off, the skin appears of a reddish brown or rather copper-colour, underneath; whereas leprous eruptions are itchy, throw off a greater quantity of scales, and rife in greater blotches, especially about the joints of the knees and elbows. Venereal tubercles or pultules are easily distinguished from carbuncles of the face, by not occupying the cheeks or the nose, nor as having a purulent apex, but are covered at top, either with a dry branny crust like the superficial eruptions just now mentioned, or else with a hard dry scab of a tawney yellow hue; they particularly break out among the hair or near to it, on the forehead or on the temples.

Venereal ulcers affecting the mouth are distinguishable from those which are scorbatic in the following manner: 1. Venereal ulcers first affect the tonsils, fauces, and uvula; then the gums but these very rarely: on the contrary, scorbatic ulcers affect the gums first of all; then the fauces, tonsil, and uvula. 2. Venereal ulcers frequently spread to the nose: scorbatic ones almost never. 3. Venereal ulcers are carious in the
Practice.

MEDICINE.

Impetignes the edges; scorbutic ones are not so. 4. Venereal ulcers are circumscribed, and, for the most part, are circular, at least they are confined to certain places; scorbutic ones are of more irregular form, spread wider, and frequently affect the whole mouth. 5. Venereal ulcers are for the most part hollow, and generally covered at bottom with a white or yellow scurf; but scorbutic ones are more apt to grow up into loose fungi. 6. Venereal ulcers are red in their circumference, but scorbutic ones are always livid. 7. Venereal ulcers frequently rot the subjacent bones, the scorbutic ones seldom.

Another sure sign of the confirmed lues is often afforded from certain deep-seated nocturnal pains, particularly of the thins, arms, and head. As for any superficial wandering pains that have no fixed seat, and which affect the membranes of the muscles and ligaments of the joints, they, for they most part, will be found to belong to the gout or rheumatism, and can never be considered as venereal unless accompanied with some other evident signs; but with regard to the pains that are deeply seat, and always fixed to the same place, and which affect the middle and more solid part of the ulna, tibia, and bones of the cranium, and rage chiefly and with greatest violence in the forepart of the night, so that the patient can get no rest till morning approaches, these may serve to convince us that the disease has spread itself throughout the whole habit, whether they be accompanied with other symptoms of the lues or not. Gummatæ in the flabby parts, nodæ in the periosteum, ganglia upon the tendons, tophi upon the ligaments, excoriæ upon the bones, and faciæ at the verge of the anus, are all of them signs of the confirmed lues: these are hard indolent swellings; but as they sometimes arise independently of any venereal infection, and perhaps may proceed from a scrofulous taint, unless they be accompanied or have been preceded by some of the more certain and evident symptoms of the lues, we must be cautious about pronouncing them venereal. When these swellings are not owing to the syphilitic virus, they are very seldom painful, or tend to inflame and suppurate; whereas those that are venereal usually do, and if they lie upon a bone generally bring on a caries.

These curious ulcers are most commonly met with upon the ulna, tibia, and bones of the cranium; and when accompanied with nocturnal pains, we can never hesitate about declaring their genuine nature. Frequent abortions, or the exclusion of scabby, ulcerated, filmant, and dead fetuses, happening without any manifest cause to disturb the fetus before its time, or to destroy it in the womb, may be reckoned as a sure sign that at least one of the parents is infected.

These then are the principal and most evident signs of the confirmed lues. There are others which are more equivocal, and which unless we can fairly trace them back to some that are more certain, cannot be held as signs of the venereal disease: Such are, 1. Obdurate inflammations of the eyes, frequently returning with great heat, itching, and ulceration of the eye-lids. 2. A snoring and hissing noise in the ears, with ulcers or caries in the bones of the meatus auditorius. 3. Obdurate head-aches. 4. Obdurate cutaneous eruptions, of the itchy or leprous appearance, not yielding to the milder methods of treatment. 5. Swellings of the bones; and, 6. Wandering and obdurate pains. None of these symptoms, however, can be known to be venereal, except they happen to coincide with some one or other of the more certain signs.

It may, perhaps, be considered as a singularity in this disease, that the diagnosis is often more difficult in the advanced than in the early periods of the affection. That is, with those who have been certainly subjected to syphilis, it is often very difficult to say whether certain symptoms, remaining after the ordinary modes of cure have been employed, be syphilitic or not. Very frequently, as appears from the sequel, nocturnal pains, ulcerations, and the like, remaining after a long course of mercury has been employed, are in no degree of a venereal nature, but are in reality to be considered as consequences rather of the remedy than of the disease; and are accordingly best removed by nourishing diet, gentle exercise, and tonics. But as long as any symptoms of any kind remain, it is often impossible to convince some patients that they are cured; and it is often impossible for a physician with certainty to affirm that the disease is altogether overcome.

Upon the whole, we are first to distinguish and consider the several symptoms apart; and then, by comparing them with each other, a clear judgment may be formed upon the general review.

Prognosis. Being thoroughly convinced that the case is venereal, we are to consider, first of all, whether it be of a longer or shorter date; for the more recent it is, it will, ceteris paribus, be less difficult to remove. But there are other circumstances which will assist us in forming a prognosis as to the event. As,

1. The age of the patient. This disorder is more dangerous to infants and old people than to such as are in the flower and vigour of life, in whom some part of the virus may be expelled by exercise, or may be subdued in some degree by the strength of the constitution.

2. The sex. Though women are for the most part weaker than men, and therefore should seem less able to resist the force of any disease, yet experience shows that this is easier borne by them than by men; perhaps owing to the menstrual and other uterine discharges, by which a good share of the virus may be carried off immediately from the parts where it was first applied; for it is observable, that whenever these discharges are obstreperous, or cease by the ordinary course of nature, all the symptoms of this disease grow worse.

3. The habit of body. Persons who have acrid juices will be liable to suffer more from the venereal poison than such as have their blood in a milder state; hence, when people of a scorbutic or scrofulous habit contract venereal disorders, the symptoms are always remarkably violent, and difficult to cure. And for the same reasons, the confirmed lues is much more to be dreaded in a person already inclined to an althma, phthisis, droopy, gout, or any other chronic differen-
inflammation of the uvula, or of the soft palate, and the patient seems suddenly to be in an apoplectic fit or sink under a consumption.

Cure. View this disease as depending on a peculiar contagious matter introduced into the syphilitic system, and multiplied there, it is possible to conceive that a cure may be obtained on one of three principles; either by the evacuation of the matter from the system; by the destruction of its activity, or by counteracting its influence in the system. It is not impossible that articles exist in nature capable of removing this complaint on each of these grounds: but we may venture at least to assert, that few such are yet discovered. Notwithstanding numbers of pretended infallible remedies, for syphilis, mercury is perhaps the only article on which dependence is placed among European practitioners; and with regard to its mode of operation, all the three different opinions pointed out have been adopted and supported by different theorists.

But although many ingenious arguments have been employed in support of each, we, upon the whole, inclined to think it more probable that mercury operates by destroying the activity of the venereal virus, than that it has effect either by evacuating it, or by exciting a state of action, by which its influence is counteracted. Some practitioners have affirmed, that the disease may be totally extirpated without the use of mercury: but, excepting in flight cases, it appears from the most accurate observations, that this grand specific is indispensable; whether it be introduced through the pores of the skin, in the form of ointments, plasters, washes, &c.; or given by the mouth, disguised in the different shapes of pills, troches, powders or solutions.

Formerly it was held as a rule, that a salivation ought to be raised, and a great discharge excited. But this is now found to be unnecessary: for as mercury probably acts by some specific power in subduing and correcting the venereal virus, all that is required is to throw in a sufficient quantity of the medicine for this purpose; and if it can be diverted from the salivary glands, or in the secretion, the inconvenience attending a spitting are such as we should always with to avoid.

Mercury, when combined with any saline substance, has its activity prodigiously increased; hence the great variety of chemical preparations which have been contrived to unite it with different acids.

Corroive sublimate is one of the most active of all the mercurial preparations, infomuch as to become a poison even in very small doses. It therefore cannot safely be given in sublimate; but must be dissolved in order to render it capable of a more minute division.

We may see, by looking into Widemann, that this is an old medicine, though seldom given by regular practitioners. How it came to be introduced into a remote part of the world as Siberia, is not easily found out; but Dr Clerc, author of the Histoire Naturelle de l'Homme Malade, affiures us, that the sublimated solution has been of late time out of mind.

It appears to have been totally forgotten in other places, until of late years, when the Baron Van Swieten brought it into vogue for that afoine period, if we credit Dr Locher, they used no other mercurial preparation at Vienna. The number of patients cured by this remedy alone in the hospital of St Mark, is under the care of this gentleman, from 1754 to 1771 inclusive, being 4880.

The way to prepare the solution is, to dissolve as much sublimate in any kind of ardent spirit (at Vienna they use only corn-brandy) as will give half a grain to an ounce of solution. The dose to a grown person is one spoonful mixed with a pint of any light pittan or barley-water, and this to be taken morning and evening; the patient should keep mostly in a warm chamber, and lie in bed to fast after taking the medicine: their diet should be light; and they ought to drink plentifully throughout the day, of whey, pittan, or barley-water. If the solution does not keep the belly open; a mild purge must be given from time to time; for Locher observes, that those whom it purges two or three times a-day, get well sooner than those whom it does not purge; he also says, that it very seldom affects the mouth, but that it promotes the urinary and cutaneous discharges. This course is not only to be continued till all the symptoms disappear, but for some weeks longer. The shortest time in which Locher used to let the patients out was six weeks; and they were continued on a course of decocation of the woods for some weeks after they left off the solution.

This method has been introduced both in Britain and Ireland, though by no means to the exclusion of others; but it appears, that the solution does not turn out to be the remedy for syphilis, either in these kingdoms, or in France, as they say it has been done in Germany. It was seldom if ever found to perform a radical cure, and the frequent use of it proved in many cases highly prejudicial. It has therefore been succeeded in practice, even at Vienna, by mercury exhibited in other forms; and, among these, by a remedy first recommended by Dr Plenck, and since improved by Dr Saunders; consisting of mercury united with mucilage of gum arabic, which is said to render its exhibition perfectly mild and safe. For particulars, we refer to Dr Saunders's treatise.

But a late French writer, supposed to be Dr Petit, in a small book, intitled A Parallel of the different methods of treating the venereal disease, infiuits, that there is neither certainty nor safety in any other method than the repeated frictions with mercurial ointment.

If therefore it is determined to have recourse to the mercurial frictions, the patient may with advantage be prepared by going into the warm bath some days successively; having been previously bledded if of a plethoric habit, and taking a dose or two of some proper cathartic.

The patient being fitted with the necessary apparatus of flannels, is then to enter on the course.
If the person be of a robust habit, and in the prime of life, we may begin with two dractions of the *u nagentum hydrargyrus fortunis* (Ph. Lond.) which is to be rubbed in about the ankles by an affilant whose hands are covered with bladders: then having intermitted a day, we may expend two dractions more of the ointment, and rest for two days: after which, if no symptoms of the mouth come on, use only one draction: and at every subsequent friction ascend till the ointment shall reach the trunk of the body; after which the rublings are to be begun at the wrists, and from thence gradually extended to the shoulders. In order to prevent the mercury from laying too much hold of the hands, the mercury should tend to raise a feeling, then, from time to time, we are either to give some gentle cathartic, or order the patient into a vapour or warm bath: and thus we are to go on, rubbing in a draction of the ointment every second, third, or fourth night, according as it may be found to operate; and on the intermediate days either purging or bathing, unless we should choose to let the fermentation come on, which, however it is much better to avoid, as we shall thus be able to throw in a larger quantity of mercury.

It is impossible to ascertain the quantity of mercury that may be necessary to be rubbed in, as this will vary according to circumstances; but we are always to continue the frictions for a fortnight at least, after all symptoms of the disease shall have totally disappeared; and when we have done with the mercury, warm bathing and sudorific decoctions of the woods, are to be continued for some time longer.

This is a general sketch of the methods of treatment for the confirmed cases; but for a complete history of the disease, and for ample directions in every situation, we refer to Altru, and his abridger Dr Chapman. — We have to add, however, that a method of curing this disease by fomentation has been lately recommended in France; but it is seems not to meet with general encouragement. One of the most recent proposals for the cure of the venereal disease is that of Mr Clare, and consists in rubbing a small quantity of mercury under the form of mercurialis muriatus niturus, or colonel as it is commonly called, on the inside of the cheek; by which means it has been suppos'd that we will not only avoid the inconveniences of union, but also the purgative effects that are often produced by this medicine when taken into the stomach. But after all, the introduction of mercury under the form of union, as recommended by the late and best writers in Britain on the venereal disease, Dr Sednam, Mr John Hunter, and others, is still very generally preferred in Britain to any mode that has yet been proposed.

Where, after a long trial of mercury, disfiguring symptoms still remain, particularly obliturate ulcerations and severe pains, benefit has often been derived from the use of opium: but there is little reason to believe, as has been held by some, that of itself it affords an infallible cure of this disease; at least we are inclined to think, that all the facts hitherto brought in support of the cure of syphilis by opium are at the utmost very doubtful.

In oblinitate ulcerations, remaining probably after the venereal virus has been overcome, and fulfilling the use of mercury, a complete cure has in many instances been obtained from the use of the root of the mezerone, the haphne mezerium of Linnaeus. This article has been chiefly employed under the form of decoction; and it now appears that it is the basis of an article at one time highly celebrated in venereal complaints, under the title of *Lepon d'isdrin*. But, upon the whole, the specific of this disease are perhaps more readily overcome by country air, gentle exercise and nourishing diet, particularly a milk diet, than by the use of any medicine whatever. It must indeed be allowed, that for combating different feaqueiras, various practices accommodated to the nature of these will on particular occasions be requisite. But into the consideration of these we cannot here proceed to enter.

Genus LXXXVI. SCORBUTUS.

Description. The first indication of the scorbutic distemper is generally a change of colour in the face, from the natural and healthy look to a pale and bloated complexion, with a little faintness, and aversion from every kind of exercise; the gums soon after become itchy, swell, and are apt to bleed on the slightest touch; the breath grows offensive; and the gums, dwelling daily more and more, turn livid, and at length become extremely fungous and putrid, as being continually in contact with the external air; which in every case favours the putrefaction of substances disposed to run into that state, and indeed is absolutely requisite for the production of actual rottenness.

The symptoms of the scorbuty, like those of every other disease, are somewhat different in different subjects, according to the various circumstances of constitution; and they do not always proceed in the same regular course in every patient. But what is very remarkable in this disease, notwithstanding the various and immense load of difeases under which the patients labour, there is no sicknees at the stomach, the appetite keeps up, and the faeces remain entirely moist, and at the very last, when lying at rest, they make no complaints, and feel little difeases or pain; but the moment they attempt to rise or sit themselves, the breathing becomes difficult, with a kind of headainesis or catching, and great oppression, and sometimes they have been known to fall into a syncope. This catching of the breath upon motion, with the loss of strength, dejection of spirit, and rotten gums, are held the essential or distinguishing symptoms of the disease. The skin is generally dry, except in the very last stage, when the patients become exceedingly subject to faintings, and then it grows clammy and moist: in some it has an anemic appearance; but much oftener it is smooth and thinning; and when examined, is found to be spread over with spots not rising above the surface, of a redish, bluish, livid, or purple colour, with...
Medicine.

Impetigo are spots for the most part small, but in time they increase to large blotches. The legs and thighs are the places where they are principally seen: more rarely on the head and face. Many have a swelling of the legs, which is harder, and retains the impression of the finger longer than the common drophial or truly oedematous swellings. The slightest wounds and bruises, in scurvy habits, degenerate into foul and unto-ward ulcers. And the appearance of these ulcers is so singular and uniform, that they are easily dis-tinguished from all others. Scurvy ulcers afford no good digestion, but give out a thin and fetid ichor mixed with blood, which at length has the appear-ance of coagulated gore lying caked on the surface of the fole, not to be separated or wiped off without some difficulty. The flesh underneath these ulcers feels to the probe soft and spongy, and is very putrid. Neither detergents nor escharotics are here of any service; for though such flows be with great length taken away, they are found again at the next dressing, where the fame fungidous putrid appearance always prelents itself. Their edges are generally of a livid colour, and pulsed up with excrescences of proud flesh arising from below the skin. As the violence of the diseafé increases, the ulcers shoot out a soft bloody fungus, which often rises in a night's time to a monstrous size; and although destroyed by cauteries, actual or potential, or cut away with the knife, is found at next dressing as large as ever. It is a con siderable time, however, before these ulcers, bad as they are, come to affect the bones with rottenness—These appearances will always serve to affire us that an ulcer is scurvy; and should put us on our guard with re spect to the giving mercurials, which are the most pernicious things that can be administered in these cases.

Scurvy people, as the diseafé advances are seldom free from pains; though they have not the fame feet in all, and often in the same person shift their place. Some complain of universal pain in all their bones; but most in the limbs, and especially the joints. The most frequent pain of their pain, however, is some part of the breast. The pains of this diseafé seem to arise from the dilatation of the fensible fibres by the extrava- sated blood being forced into the interelfes of the perifoleum and of the tendinous and ligamentous parts; whose texture being so firm, the fibres are liable to higher degrees of tension, and consequently of pain.

The states of the bowels are various: in some there is an obstinate colliciveness; in others a tendency to a flux, with extremely fetid ffools: the urine is also rank and fetid, generally high-coloured; and, when it has flood for some hours, throws up an oily film on the surface. The pulse is variable; but most commonly flower and more feeble than in the time of perfect health. A fifeft is in the tendons, and weakness in the joints of the knees, appear early in the diseafé: but as it grows more inveterate, the patients generally lose the use of their limbs altogether; having a contraction of the flexor-tendons in the hand, with a swelling and pain in the joint of the knee. Some have their legs monftrously swelled, and covered over with livid spots or ecchymofes; others have had tumors there; some, though without swelling, have the calves of the legs and the flesh of the thighs quite indurated. As per- fons far gone in the feurvy are apt to faint, and even expire, on being moved and brought out into the fresh air, the utmost care and circumfeption are requisite when it is neceffary to flir or remove them.

Scurvy patients are at all times, but more espe- cially as the diseafé advances, extremely subject to profuse bleedings from different parts of the body; as from the nofe, gums, intemines, lungs, &c. and likewise from their ulcers, which generally bleed plentifully if the fungus be cut away. It is not easy to conceive a more difmal and diversified scene of misery than what is beheld in the third and laft stage of this diftemper: it being then that the anomalous and more extraordinary symptoms appear, such as the boiling out of old wounds, and the dißolution of old fractures that have been long united.

Causes. The term feurvy has been indiscriminate-ly applied, even by physicians, to almost all the dif- ferent kinds of cutaneous feaftness; owing to some writers of the laft century, who comprehended such a variety of symptoms under this denomination, that there are few chronic diftempers which may not be so called, according to their scheme: but the diseafé here meant is the true putrid feurvy, to often fatal to feamen, and to people pent up in garrifons with out sufficient supplies of found animal-food and fresh vegetables; or which is commonly known to be endemic in certain countries, where the nature of the soil, the general state of the atmosphere, and the common course of diet, all combine in producing that singular species of corruption in the mafs of blood which constitutes this diseafé; for the appearances, on difsecting scurvy subjects, sufficiently shew that the feurvy may, with great propriety, be termed a diseafé of the blood.

Dr Lind has, in a postscript to the third edition of his traiíte on the feurvy, given the refult of his obervations drawn from the difsection of a confiderable number of victims to this fatal malady, from which it appears that the true feurvy state, in an advanced figure of the diftemper, confifts in a numerous effusion of blood into the cellular interllices of moft parts of the body, superficial as well as internal; particularly the gums and the legs; the texture of the former being almost entirely cellular, and the generally de-pendent state of the latter rendering thefe parts, of all others in the whole body, the moft apt to receive, and retain the fagnant blood, when its crafts comes to be decompy, and it lofes that glutinous quality which, during health, binds it from escaping thro' the pores in the coats of the blood-veffels or through exhalant extremities.

A drophical indisposition, especially in the legs and back, was frequently, but not always, observed in the subjects that were opened, and the pericardium was sometimes found dif tended with water: the water thus collected was often fo sharp as to fhrivel the hands of the difector; and in fome instances, where the skin happened to be broken, it irritated and fellered the wound.

The fleshy fibres were found so extremely lax and tender, and the bellies of the muscles in the legs and thighs fo tubbled with the effufed fagnating blood, that it was always difficult, and sometimes impossible,
The experiment of Dr. Hales, as well as many others made since his time, show that an aerial principle is greatly connected with, and remarkably abundant in, the gelatinous parts of animal bodies, and in the mucilage or farina of vegetables. But these are the parts of our food which are most particularly nutritive; and Dr. Cullen, whose opinion on this as on every other medical subject must be allowed of the greatest weight, affirms, in his Lectures on the Materia Medica, that the substances on which we feed are nutritious only in proportion to the quantities of oil and sugar which they respectively contain. This oil and sugar are blended together in the gelatinous part of our animal-food, and in the mucilaginous and farinaceous part of succulent vegetables; and, while thus intimately combined are not perceivable by our taste, though very capable of being developed and rendered distinct by the power of the digestive organs; for in consequence of the changes produced during digestion, the oily and the saccharine matter become manifest to our senses, as we may see and taste in the milk of animals, which is chiefly chyle a little advanced in its progress toward sanguification; the oil is observed to separate spontaneously, and from which a quantity of actual sugar may be obtained by a very simple process.

Thus much being premised, we can now readily comprehend how the blood may come to lose those qualities of smoothness, mildness, and tenacity, which are natural to it. For if, in the first place, the fluids, and organs subervient to digestion should be so far detempered or debilitated that the nutritious parts of the food, cannot be properly developed, the blood must be deprived of its due supplies; which will also be the case if the aliment should not originally contain enough of oily and saccharine matter, or should be so circumstanced, from being dried or salted, as to hinder the ready extrication of the nutritious parts; or lastly, if the natural discharges should be interrupted or suspended, so that the superfluous, acrid, and effete fluids are retained in the general mass; in all these instances the blood must of necessity run into proportionate degrees of depravation.

And hence we may understand how it may possibly happen, that the instances of the scurvy are so frequently connected with the consumption of salted meat; since, in the presence of salt, the necessity of increasing the amount of the nutritive principles absorbed is increased, and this, in its turn, is a cause of depravation, and therefore of the scurvy.
The phenomena of the disease than any conjecture can.

A close attention to these matters will, in general, prevent the scurvy from making its appearance at all, and will always hinder it from spreading its influence far. But when these precautions have been neglected, or the circumstances such that they cannot be put in practice, and the disease hath actually taken place, our whole endeavours must be to restore the blood to its original state of soundness: and happily, such is the nature of this disease, that if a sufficiency of new matter, of the truly mild nutritious sort, and particularly such as abounds with vital air, such as recent vegetables, or different acid fruits, can be thrown into the circulation while the fibrous fibres retain any tolerable degree of firmness, the patient will recover; and that in a surprisingly short space of time, provided a pure, comfortable lodging, sufficient clothing, cleanliness, and exercise lend, their necessary aid.

This being the case, the plan of treatment is to be conducted almost entirely in the dietetic way; as the change in the mafs of blood, which it is necessary to produce, must be brought about by things that can be received into the stomach by pints or pounds, and not by those which are administered in drops or grains, draughts or ounces. For here, as there is no disorder of the nervous system, we have no need of those active drugs which are indispensably necessary in febrile or nervous diseases; the scurvy diathesis being quite opposite to that which tends to produce a fever or any species of spasmodic disorders; nay, Dr. Lind says, he has repeatedly found, that even the infection of an hospital fever is long resisted by a scurvy habit.

It will now naturally occur to the reader, what those alimentary substances must be which bill the fairest to restore the blood to its healthy state; and he needs scarcely to be told, that they are of those kinds which the stomach can bear with pleasure though taken in large quantities, which abound in jelly or mulligano, and which allow those nutritive parts to be easily developed; for though the visera in scurvy patients may be all perfectly found, yet we cannot expect that either the digestive fluids or organs should possess the same degrees of power, which enable them, during health, to convert the crude dry farinaces, and the hard salted flesh of animals, into nourishment. We must therefore search for the antiscorbutic virtue in the tender sweet flesh of herbivorous animals; in new milk; and in the mucilaginous acid juices of recent vegetables, whether they be fruits, leaves, or roots.

The four juices of lemons, oranges, and limes, have been generally held as antiscorbutics in an eminent degree, and their power ascribed to their acid; from an idea that acids of all kinds are the only correctors of putrefaction. But the general current of practical observations...
observations show, and our experiments confirm it, that the virtue of these juices depends on their aerial principle; accordingly, while perfectly recent and in the unacclimated state, and especially if mixed with wine and sugar, the juices of any one of these fruits will be found a most grateful and powerful antiscorbutic.

Dr. Lind observing, "that the lemon-juice, when given by itself undiluted, was apt, especially if over-dosed, to have too violent an operation, by occasioning pain and sickness at the stomach, and sometimes a vomiting; therefore found it necessary to add wine and sugar. A pint of Madeira wine, and two ounces of sugar, were put to four ounces and a half of juice; and this quantity was found sufficient for weak patients to use in 24 hours; such as were very weak, a little of this frequently according as their strength would permit; others who were stronger took about two ounces of it every two hours; and when the patients grew still stronger, they were allowed eight ounces of lemon-juice in 24 hours."

While this very pleasant mixture, which is both a cordial and an antiscorbutic, may be had, it would be needless to think of prescribing any other; but when the fresh juice cannot be procured, we must have recourse to such other things as may be obtained. But the various modes of combining and administering these, so as to render them perfectly agreeable to the stomach, must always be regulated by circumstances, and therefore it will be in vain to lay down particular directions; since all that we have to do is, to fix on such fruits and other fresh vegetables as can be most conveniently had and taken, and contrive to give them in those forms, either alone or boiled up with flesh-meat into soups, that will allow the patients to consume the greatest quantities.

The first promising alteration from such a course is usually a gentle diarrhoea; and if, in a few days, the skin becomes soft and moist, it is an infallible sign of recovery; especially if the patient gain strength, and can bear being fuddled or carried into the open air without fainting.

But if the belly should not be loosed, by the use of the fresh vegetables, nor the skin become soft and moist, then they must be assisted by stewed prunes, or a decoction of tamarinds with cream of tartar; in order to abate the coltivenees; and by drinking a light decoction of the woods, and warm bathing, in order to relax the pores of the skin; for nothing contributes more to the recovery of scorbutic patients than moderate sweating.

With regard to particular symptoms, antiscorbutic mouth-waters composed of a decoction of the Peruvian bark and infusion of roves, with a solution of myrrh, must be used occasionally, in order to cleanse the mouth, and give firmness to the spongy gums. Swelled and indurated limbs, and stiffened joints, must be bathed with warm vinegar, and relaxed by the steam of warm water, repeatedly conveyed to them, and confined to the parts by means of close blankets; ulcers on the legs must never be treated with unfruitful applications nor sharp ecchymotises; but the dressing should consist of lint or soft rags, kept in a strong decoction of Peruvian bark.

This diæase, at no time requires, or indeed bears, large evacuations, either by bleeding or purging; and as has been already mention'd, the belly must only be kept open by the fresh vegetables or the mildest laxatives. But we are always to be careful that scorbutic persons, after a long abstinence from greens and fruits, be not permitted to eat voraciously at first, but they fall into a fatal dysentery.

All, however, that has now been laid down as necessary towards the cure, supposes the patients to be in situations where they can be plentifully furnished with all the requisites; but unhappily these things are not to be procured at sea, and often deficient in situations; therefore, in order that a remedy for the scurvy may never be wanting, Dr. Macbride, in the year 1762, first conceived the notion, that the infusion of mahl, commonly called Court, might be substituted for the common antiscorbutics; and it was accordingly tried.

More than three years elapsed before any account arrived of the experiments being made; at length ten histories of cafes were received, wherein the work had been tried, with very remarkable success; and this being judged a matter of great importance to the seafaring part of mankind, these were immediately communicated to the public in a pamphlet under the title of An historical account of a new method of treating the scurvy at sea.

This was in 1767; but after that time a considerable number of letters and medical journals, sufficient to make up a small volume, were transmitted to the author, particularly by the zealous efforts of his Britannic Majesty's ships who had been employed of late years for making discoveries in the southern hemisphere. Certain it is, that in many instances it has succeeded beyond expectation. In others it has fallen short; but whether this was owing to the untoward situation of the patients, or inattention on the part of the persons who were charged with the administration of the work, not preparing it properly, or not giving it in sufficient quantity, or to its own want of power, must be collected from the cafes and journals themselves.

During Captain Cook's third voyage, the most remarkable, in respect of the health of the crew, that ever was performed, the work is acknowledged to have been of singular use.

In a letter which this very celebrated and successful circumnavigator wrote to Sir John Pringle, he gives an account of the methods pursued for preserving the health of his people, and which were productive of such happy effects, that he performed "a voyage of three years and 18 days, through all the climates from 52° north to 71° south, with the loss of one man only by diæase, and who died of a complicated and lingering illness, without any mixture of scurvy. Two others were unfortunately drowned, and one killed by a fall; so that out of the whole number 118 with which he set out from England, he left only four."

He says, that much was owing to the extraordinary attention of the admiral, in causing such articles to be put on board as either by experience of conjecture were judged to tend most to preserve the health of men; and with respect to the work, he expresses himself as follows:

"We had on board a large quantity of mahl, of which
MEDICINE.

Cook had also a liberal supply of portable soup; of which the men had generally an ounce, three days in the week, boiled up with their peas; and sometimes it was served to them oftener; and when they could get fresh greens, it was boiled up with them, and made such an agreeable mefs, that it was the means of making the people eat a greater quantity of greens than they would otherwise have done. And what was still of further advantage, they were furnished with sugar in lieu of butter or oil, which is seldom of the sweetest sort; so that the crew were undoubtedly great gainers by the exchange.

In addition to all these advantages of being so well provided with every necessary, either in the way of diet or medicine, Captain Cook was remarkably attentive to all the circumstances respecting cleanliness, exercise, sufficient clothing, provision of pure water, and purification of the air in the closer parts of the ship.

From the effect of these different means, as employed by Captain Cook, there can be little doubt that they will with due attention be sufficient for the prevention and cure of the disease, at least in most situations: but besides these, there are also some other articles which may be employed with great advantage.

Newly brewed spruce-beer, made from a decoction of the tops of the spruce-fir and melafies, is an excellent antiscorbutic; it acts in the same way that the wort does, and will be found of equal efficacy, and therefore may be substituted. Where the tops of the spruce-fir are not to be had, this beer may be prepared from the essence of spruce as it has been called, an article which keeps easily for a great length of time. But in situations where neither the one nor the other can be had, a most salutary mefs may be prepared from oatmeal, by infusing it in water, in a wooden vessel, till it ferments, and begins to turn fourth; which generally happens, in moderately warm weather, in the space of two days.—The liquor is then strained off from the grounds, and boiled down to the confidence of a jelly, which is to be eat with wine and sugar, or with butter and sugar.

Nothing is more commonly talked of than a land-scurvy, as a distinct species of disease from that which has been now described; but no writer has yet given a description so clear as to enable us to distinguish it from the various kinds of cutaneous sores and eruptions, which indeed are vulgarly termed scorbutic, but which are akin to the itch or leprosy, and for the most part require mercurials. These, however, are very different diseases from the true scorbutus, which, it is well known, may prevail in certain situations on land as well as at sea, and is in no degree to be attributed to sea air.

Genus LXXXVII. ELEPHANTIASIS.

Elephantia Arabum, Vog. 332.

The best account of this disease is that by Dr. Heberden, published in the first volume of the Medical Transactions. According to him, frequently the first symptom is a sudden eruption of tubercles, or bumbs of different sizes, of a red colour, more or less intense (attended
Practice. M E D I C I N E.

attended with great heat and itching), on the body, legs, arms, and face; sometimes in the face and neck alone, at other times occupying the limbs only; the patient is feverish; the fever ceasing, the tubercles remain indolent, and in some degree firrhous, of a livid or copper colour, but sometimes of the natural colour of the skin, or at least very little altered; and sometimes they after some months ulcerate, discharging a fetid ichorous humor in small quantity, but never laudable pus.

The features of the face swell and enlarge greatly; the part above the eye-brows seems inflamed; the hair of the eye-brows falls off, as does the hair of the beard; but Dr Heberden has never seen any one whose hair has not remained on his head. The alna nasi are swollen and scarrous; the nostrils patulous, and sometimes affected with ulcers, which, corroding the cartilage and fpatium nasi, occasion the nose to fall off. The lips are tumid; the voice is hoarse; which symptom has been observed when no ulcers have appeared in the throat, although sometimes both the throat and gums are ulcerated. The ears, particularly the lobes, are thickened, and occupied by tubercles. The nails grow scabrous and rugosely, appearing something like the rough bark of a tree; and the surface of a tree; and the superfcies of thefe is remarkable for its shining appearance, as if it was varnished.

The breath is very offensive; the bowels in general weak and sluggish; the pulse in general weak and slow. The febile often attacks the patient in a different manner from that above described, beginning almost insensibly; a few indolent tubercles appearing on various parts of the body or limbs, generally on the legs or arms, sometimes on the face, neck, or breast, and sometimes in the lobes of the ears, increasing by very slow degrees, without any disorder, previous or concomitant, in respect of pain or uneasiness.

To distinguish the differen in its manner of attacking the patient. Dr Heberden styles the first by fluxion and the other by congestion. That by fluxion is often the attendant of a carapula, or furfeit from gross foods; whereby, perhaps, the latent seeds of the disease yet dormant in the mass of blood are excited, and probably from frequent observations of this kind (the last meal always having the blame laid on it), it is, that, according to the received opinion, either fif, (the tunny, mackerel, and shell-fish, in particular), melons, cucumbers, young garden-beans, or mulberries, eaten at the same meal with butter, cheese, or any preparation with milk, are supposed to produce the distemper, and are accordingly religiously avoided.

Violent commotions of the mind, as anger, fear, and grief, have more than once been observed to have given rise to the disorder; and more frequently, in the female sex, a sudden suppression of an accustomed evacuation, by bathing the legs and feet in cold water at an improper season.

The disorder by fluxion is what is the oftener endeavored to be remedied by timely application; that by congestion, not being so conspicuous, is generally either neglected or attempted to be concealed, unless perhaps it be too late to be cured, at least unless the patients would submit to a longer course of medicine and stricter regimen of diet than they are commonly inclined to do.

Several incipient disorders by fluxion have been known to yield to an antiphlogistic method, as bleeding, refrigerant salts, in the saline draughts, and a solution of crysftals of tartar in water, for common drink, (by this means endeavouring to precipitate part of the peecant matter, perhaps too gross to pass the pores by the kidneys); and when once the fever is overcome, the Peruvian bark combined with faithias is the remedy principally to be relied on. The only topical medicine prescribed by Dr Heberden, was an attenuating embrocation of brandy and alkaline spirit. By the same method some confirmed cases have been palliated. But, excepting in one patient he never saw or heard of a confirmed elephantiasis radically cured. He adds however, that he never met with another patient possessed of prudence and perseverance enough to prosecute the cure as he ought.

GENUS LXXXVIII. LEPRA.

This disease is but little known to physicians in the western parts of Europe. Wallis tells us, that it first begins with red pimples, or pustules, breaking out in various parts of the body. Sometimes they appear single; sometimes a great number arise together; especially on the arms and legs; as the disease increases, fresh pimples appear, which, joining the former, make a sort of chulters; all which enlarge their borders, and spread in an orbicular form. The superficies of these pustules are rough, whitish, and scaly; when they are scratched the scales fall off, upon which a thin ichor oozes out, which soon dries and hardens into a scaly crust. These chulters of pustules are at first small and few; perhaps only three or four in an arm or leg, and of the size of a silver penny. But if the disease be suffered to increase, they become more numerous, and the chulters increase to the size of a crown-piece, but not exactly round. Afterwards it increases to such a degree, that the whole body is covered with a leprous leuc. The cure of this distemper is very much the...
MEDICINE.

Impregnated with that of the ELEPHANTIASIS. Here, however, recourse is frequently had to antimonial and mercurial medicines, continued for a considerable length of time. In conjunction with these, warm bathing, particularly the vapour bath, has often been employed with advantage.

Although what can strictly be called leprosy is now at least, a very rare disease in this country, yet to this general head may be referred a variety of cutaneous affections which are there very common, and which in many instances prove very obstinate. These appear under a variety of different forms; sometimes under that of red pustules; sometimes of white scurf; sometimes of ulcerations; and not unfrequently a transition takes place from one form to another, so that they cannot be divided into different genera from the external appearance. These affections will often yield to the remedies already mentioned; but where antimonials and mercurials either fail, or from different circumstances are considered as unadvisable, a cure may sometimes be effected by others. In particular caules, purging mineral waters, the decoction of elm bark, the infusion of the ananthe crocata, and various external applications also have been employed with success. Different external applications also have sometimes been employed with advantage. An article used in this way, known under the name of Gowland's lotion, with the composition of which we are unacquainted, has been much celebrated, and has been said to be used with great success, particularly against eruptions on the face and nose.

GENUS LXXXIX. FRAMBOESIA.
The Yaws.

Frambezia, Saw. gen. 125. Sig. 125.

Definition. The description which is given of this disease by the anonymous author of a paper in the sixth volume of the Edinburgh Medical Essays (art. 76.) differs, in some circumstances, from that of Sauvages, received from M. Virgile, an adjutant surgeon of Montpelier, who practiced 12 years in the island of St. Domingo; and therefore he distinguishes the frambeia into two species, Guineensis and Americana.

The frambeia Guineensis is said by the first mentioned writer to be so common on the coast of Guinea and other parts of Africa, that it seldom fails to attack each individual of both sexes, one time or other in the course of their lives; but most commonly during childhood or youth. "It makes its appearance in little spots on the cuticle, level with the skin, at first no larger than a pin's head which increase daily, and become protuberant like pimples; soon after the cuticle frets off, and then, instead of finding pus or scurf, in this small tumor, only white floughs or fordes appear, under which is a small red fungus growing out of the cutis, increasing gradually to very different magnitudes, some less than the smallest wood strawberry, some as big as a raphberry, and others exceeding in size even the largest mulberries; which berries they very much resemble, being knobbled as they are." These protuberances, which gave the name to the disease, appear on all parts of the body; but the greatest numbers, and the largest fixed, are generally found in the groins, and about the pudenda or anus, in the arm-pits, and on the face, when the yaws are very large, they are few in number; and when remarkably numerous, they are less in size. The patients, in all other respects, enjoy good health, do not lose their appetite, and seem to have little other uneasiness than what the disease occasion.

M. Virgile describes the species of yaws that is common among the negroes of St. Domingo, and which Sauvages has termed frambeia Americana, as beginning from an ulcer that breaks out indeterminately in different parts of the body, though most commonly on the legs; at first superficial, and not different from a common ulcer in any other circumstances save in healing by the usual applications; sooner or later, numerous fungous excrescences break out on the surface of the body, as before described, like little berries, with a reddish mucous. Besides these, the soles of the feet and palms of the hands became raw, the skin fretting off, so as to leave the muscles bare; these excoriations are sometimes moist with ichor and sometimes dry, but always painful and consequently very distressful. They are mentioned also by the author of the article in the Medical Essays; and both he and M. Virgile observe, that there is always one excrescence, or yaw, of an uncommon size, which is longer in falling off than the others, and which is considered as the naffiver yaw, and so termed. An ingenious inguinal dissection on the subject of the yaws was lately published at Edinburgh by Dr. Jonathan Anderson Ludford, now physician in Jamaica. The author of that dissection considers Dr. Cullen as improperly referring frambeia to the class of cachexia. He thinks that this disease ought rather to be referred to the exanthemata; for, like the small-pox, he tells us it has its accession, height, and decline. It begins with some degree of fever, either more or less violent; it may be propagated by inoculation; and it attacks the same individual only once in the course of a lifetime, those who once recover from the disease being never afterwards affected with it. These particulars respecting frambeia are refted not merely on the authority of Dr. Ludford, but are supported also by the testimony of Dr. William Wright, a physician of distinguished eminence, who, while he resided in Jamaica, had, in the course of extensive practice, many opportunities of observing this disease, and to whom Dr. Ludford acknowledges great obligations for having communicated to him many important facts respecting it.

Dr. Ludford considers the yaws as being in every instance the consequence of contagion, and as depending on a matter sui generis. He considers no peculiar predisposition from diet, colours, or other circumstances, as being in any degree necessary. He views the disease as chiefly arising from contact with the matter, in consequence of sleeping in the same bed, washing in the same vessel with the infected, or the like. In short, the yaws may be communicated by any kind of contact; nay, it is even believed that flies often convey the infection, when, after having gorged themselves with the virulent matter by sucking the effusions of those who are diseased, they make punctures in the skin of such as are found, and thus inoculate them; in consequence of which the disorder will soon appear, provided the morbid disposition of body be present.

Prognosi. The yaws are not dangerous, if the cure
The cure of this disease, the four following indications are chiefly to be held in view:

1. To support the strength of the patient.
2. To promote excretion by the skin.
3. To correct the vitiated fluids.
4. To remove and counteract the injuries done either to the constitution in general, or to particular parts by the disease.

With the first of these intentions, a liberal diet, consisting of a considerable quantity of animal food, with a considerable proportion of wine, and gentle exercise, are to be employed: but the cure is principally to be effected by mercurial salivation, after the virulent matter has been completely thrown out to the surface of the body by sudorifics. The following are the particular directions given on this head by the author of the article in the Medical Essays. The yaws being an infectious disease, as soon as they begin to appear on a negro, he must be removed to a house by himself; or if it is not certain whether the eruption be the yaws or not, let him up seven days, and look on him again, as the Jews were commanded to do with their lepers, and in that time you may be commonly certain.

As soon as you are convinced that it is the yaws, give a bolus of flowers of sulphur, with camphor and theriaque. Repeat this bolus every night for a fortnight or three weeks, or till the yaws come to the height; that is, when they neither increase in size or number: then throw your patient into a gentle salivation with calomel given in small doses, without further preparation; five grains repeated once, twice, or thrice a-day, is sufficient, as the patient can bear it. If he spits a quart in 24 hours, it is enough. Generally, when the salivation is at this height, all the yaws are covered with a dry scaly crust or scab; which, if numerous, look terrible. These fall off daily in small white scales; and in ten or twelve days leave the skin smooth and clean. Then the calomel may be omitted, and the salivation permitted to go off of itself. A dram of corrosive sublimate dissolved in an ounce of rum or brandy, and the solution doused on the yaws, will, if it is laid, keep the yaws from coming back. The yaws will be cured in two days.

After the salivation, sweet the patient twice or thrice in a frame or chair with spirits of wine; and give an alterative electuary, of aniseed and gum guaiac. He may likewise use the decoction of guaiacum and saffranis fermented with melafles, for his constant drink while the electuary is taking, and a week or a fortnight after the electuary is finished.

The matter-yaw must be confumed an eighth or a tenth of an inch below the skin, with Mercur. corros. rub. & alum. aq. an. part. equal. and digested with Ung. bals. flav. 3l. and mercur. corros. rub. 3l. and cistisized with lint prepur'd out of spirits of wine, and with the vitriol of copper.

After the yaws are cured, some patients are afflicted with carbuncles in their feet; which sometimes render them incapable of walking, unless with pain. The method of cure is, by bathing and purging, to destroy the cuticle, and then proceed as in the matter-yaw. The gentle sudorifics are to be preferred, especially here; and all imaginable care is to be taken to avoid the tendons and periosteum.

To children under six or seven years old, at the proper time of salivating, when the yaws are come to their full growth, give a grain or two of calomel in white sugar, once a-day, once in two days, or once in three days, to keep their mouths a little open till the yaws dry, and, falling off in white scales, leave the skin clean. This succeeds always, but requires a longer time than in adults.

In St Domingo they salivated byunction: but it does not appear that success always followed this practice. It is also usual in that island to give the solution of corrosive sublimate along with a decoction of farapallita. Twelve ounces of this root, and 12 pounds of the coarsest sugar, macerated for 15 days in 12 quarts of water, is mentioned as a specific, and said to be the prescription of an English physician; the dose is four ounces every fifth hour.

Genus XC. TRICHOMA.

The Plica Polonica, or Platted Hair.

Trichoma, Sauv. gen. 311. Sag. 137.
Plica, Lin. 313.
Plica five Rhopolasia, Veg. 323.

This disorder is only met with in Poland and Lithuania, and consists of several blood-vessels running from the head into the ends of the hairs; which cleave together, and hang from the head in broad flat pieces, generally about an ell in length, but sometimes they are five or six yards long; one patient hath more or less of these, up to 20, and sometimes 50. They are painful to the wearer, and odious to every spectator. At the approach of winter an eruptive fever happens to many in these countries: the eruptions principally infect the head, and when at the height an ichorous humour flows from them. In this state they are too tender to admit of being touched, and the matter running down the hairs matt them together; the skin by degrees breaking, the ramifications of the capillary vessels following the course of the hair, or prolonged out of the skin are increased to a vast length.

No method of relief is yet known; for if the discharge be checked, or the vesseles cut off, the consequence is an increase of more miserable symptoms, and in the end death. Sensers says, when all the morbid matter is thrown out of the body the plica fall off spontaneously. He further observes, that the only safe practice in this case is, to solicit the pecent matter to the hairs, to which it naturally tends; and that this is best answered by lotions of bear's breech. Some say that a decoction of the herb club-moss, and its roots, with which the head is to be washed, is a specific.

Genus XCL ICTerus.

The Jaundice.

Cachexia Icterica, Hoffw. Ill. 301.

Q 2

Description.
MEDICINE.

The jaundice first shows itself by a lightening and want of appetite, the patient becomes dull, oppressed, and generally cold. These symptoms have continued but a very short time, when a yellow colour begins to diffuse itself over the tunic aterculina or white part of the eye, and the nails of the fingers; the urine becomes high coloured, with a yellowish sediment capable of giving a yellow tint to linen; the stools are whitish or grey. In some there is a most violent pain in the epigastric region, which is considered as being a paroxysm incapable of giving a yellow colour to the urine; and which can be cured by no means till the concretion is either passed entirely through the ductus communis or returned into the gall-bladder. Sometimes, in the opinion of many celebrated physicians, the jaundice is occasioned by spasmodic contractions of the ducts; but this is denied by others, and it is not yet ascertained whether these ducts are capable of being affected by spasm or not, as the existence of muscular fibres in them has not with certainty been discovered. It cannot, however, be denied, that violent fits of passion have often produced jaundice, sometimes temporarily, but frequently permanent. This has been by some deemed a sufficient proof of the spasmodic contraction of the ducts; but their opponents suppose, that the agitation occasioned by the passion might push forward some biliary concretion into a narrow part of the duct, by which means a jaundice would certainly be produced, till the concretion was either driven backward or forward into the duodenum altogether. But even supposing the ducts themselves to be incapable of spasm, yet there can be no doubt that by a spasm of the intestines biliary concretions may be retained in the ducts; and indeed it is principally where the duct entering obliquely into the intestines forms as it were a species of valve that these concretions are retained.

In a very relaxed state of the body there is also an absorption of the bile, as in the yellow fever; and in all putrid disorders there is a kind of yellowish tint over the skin, though much less than in the true jaundice. The reason of this is, that in these disorders there is usually some degenerated secretion of bile, commonly of a thinner consistence than in the healthy state, while the orifices of the lymphatics are probably enlarged, and thus ready to absorb a fluid somewhat thicker than what they ought to take up in a healthy state; but these diseases are of short duration in comparison with the real jaundice, which sometimes lasts for many years. These affections, however, cannot with propriety in any case be considered as real instances of jaundice; for to constitute that disease, bile must not only be present in the blood, but wanting in the alimentary canal.

It is observable, that women are more subject to jaundice than men, which probably arises from their more sedentary life; for this, together with some of the depressing passions of the mind, are found to promote the accidet of the disease, if not absolutely to produce it. Pregnant women are also frequently attacked by the jaundice, which goes off after their delivery.

Prognosis. As jaundice may arise from many different causes, some of which cannot be discovered during the patient's life, the prognosis must on this account be very uncertain. The only cases which admit of...
of a cure are those depending upon biliary concretions, or obstructions of the biliary ducts by viscid bile; for the concretions are seldom of such a size that the ducts will not let them pass through, though frequently not without extreme pain. Indeed this pain, though so violent, and almost intolerable to the sick person, affords the best prognostic; as the physician may readily assure his patient that there is great hope of his being relieved from it. The coming on of a gentle diarrhoea, attended with bilious stools, together with the effusion of pain, are signs of the disease being cured. We are not however, always to conclude, because the disease is not attended with acute pain, that it is therefore incurable; for frequently the passage of a concretion through the biliary ducts is accompanied only with a fenation of flight uneasiness.

Cures. The great object to be aimed at in the cure of jaundice is unquestionably the removal of the cause which obstructs the passage of bile into the intestine: But before this can be accomplished, practices are often necessary for alleviating urgent symptoms; which may be done sometimes by supplying the want of bile in the alimentary canal, sometimes by affording an exit for bilious matter from the general mass of blood, but most frequently by obviating the effects of distention and obstruction to the circulation in the system of the liver.

The measures to be employed for the removal of the obstruction must depend very much on the nature of the obstructing cause. When the jaundice arises from indurated swellings or fistula of the vifera, it is absolutely incurable; nevertheless, as these cannot always be discovered, the physician ought to proceed in every case of jaundice as if it arose from calculi. The indications here are, 1. To dissolve the concretions; and 2. To prevent their formation a second time. But unhappily the medical art has not yet afforded a solvent for biliary concretions when dried straw is involved; for the juice of common grass has indeed been tried out with no success; and in the same manner with vomits, which are often made use of in the jaundice, the patient is by no means equal to the common evacuation by food; nor can all the attempts to supply the want of bile in the intestines by bitters and other remedics restore the patient to his wonted appetite and vigour. If the pain be very violent, we must on all occasions have recourse to opiates; or if the blood has acquired a tendancy to distillation, it must be counteracted by proper antifeptics.

If the disease goes off, its return must be prevented by a course of tonic medicines, particularly the Peruvian bark and antifeptics: but we can by no means be certain that the jaundice will not return, and that at any interval; for there may be a number of concretions in the gall-bladder, and though one hath paffed, another may very quickly follow, and produce a new fit of jaundice; and thus some people have continued to be afflicted with the distemper, at short intervals, during life.

In the East-Indies, mercury has been lately recommended as exceedingly efficacious in disorders of the liver, especially those which follow intermitting and remitting fevers. Dr. Monroe, in his observations on the means of preserving the health of soldiers, acquaints us, that he has seen some sick cases which, he thought,
MEDICINE.

Practice.

It is received benefit from taking a few grains of mercurius dulcis at night and a purge next morning; and this repeated two or three times a week.

Infants are subject to a temporary jaundice, commonly called the gum, soon after birth, the cause of which is not well understood. It differs remarkably from the common jaundice; as, in the latter, the disease is first discoverable in the white of the eyes; but though the skin of infants in the gum is all over yellow, their eyes always remain clear. The disorder goes off spontaneously, or by the use of a gentle purgative or two.

ORDER I. DYSÆSTHESIÆ.

Dysœsthesia, Sav. Cl. VI. Ord. I. Seg. Cl. IX. Ord. I.

GENUS XII. CALIGO.

The Catarract.

Catarrha, Lin. 169.

A catarrh is an obstruction of the pupil, by the interposition of some opaque substance which either diminishes or totally extinguishes the sight. It is generally an opacity in the crystalline humour. In a recent or beginning catarrh, the same medicines are to be used as in the gutta serena; and they will sometimes succeed. But when this does not happen, and the catarrh becomes firm, it must be coughed, or rather extruded; for which operation, see SURGERY.—Dr Buchan says he has resolved a recent catarrh by giving the patient some purges with calomel, keeping a poultice of fresh hemlock constantly upon the eye, and a perpetual blister on the neck.

There is, however, but little reason to suppose that these practices will frequently succeed. A resolution can only be effected here by an aborption of the opaque matter; and where this is possible, there is perhaps a better chance of its being effected by the agency of the electric fluid than by any other means. For this purpose electricity is chiefly applied under the form of the electric cure, as it has been called; but even this is very rarely successful.

GENUS XCIII. AMAUROSIS.

The Gutta Serena.

Amblyopia, Lin. 108. Veg. 236.

A gutta serena is an abolition of the sight without any apparent cause or fault in the eyes. In every case it depends on an affection of some part of the optic nerve. But the affections which may produce this disease are of different kinds. When it is owing to a decay or wasting of the optic nerve, it does not admit of a cure; but when it proceeds from a compression of the nerves by redundant humours, there may be in some measure drained off, and the patient relieved. For this purpose, the body must be kept open with the laxative mercurial pills. If the patient be young, and of a fanguine habit, he may be bled. Cupping with scarifications on the back part of the head will likewise be of use. A running at the nose may be promoted by volatile salts, stimulating powders, &c. But the most likely means of relieving the patient, are blisters or blisters kept open for a long time on the back part of the head, behind the ears, or on the neck; which have been known to restore sight even after it had been for a considerable time lost. Should these fail, recourse must be had to a mercurial fulivation; or, what will perhaps answer the purpose better, 13 grains of the corrosive sublimate mercury may be dissolved in an English pint and a half of brandy, and a table-spoonful of it taken twice a-day, drinking half a pint of the decoction of farfaparilla after it.—Oil of iodine has been much celebrated as efficacious, when no other thing could do service, and here it has in some degree the fame chance of success as in other cases of insensibility, depending on an affection of the nerves, in some of which it has certainly in particular cases been of use.

In the amaurosis, Dr Porterfield observes, that it is of the utmost consequence to know of how long standing the disease has been; which is not always easily done if one eye only be affected. This is a very essential point; because an amaurosis of long standing is altogether incurable. Mr Boyle mentions the case of a man who had a catarrh for several years without knowing it himself, though others did. He discovered it at last by happening to rub his sound eye, and was surprised to find himself in the dark. When a person therefore has a gutta serena only in one of the eyes, he may think that the eye has but lately lost the power of sight; though this perhaps has been the case for several years. On the other hand, he may imagine that a recent disease of this kind is really of long standing. But by inquiring at what time he first became subject to mistakes in all actions that require the distance to be exactly distinguished, as in pouring liquor into a glass, snuffing a candle, threading a needle, we may discover the age of the disease, and thence be assisted to form a more just prognostic with respect to its cure. Dr Porterfield gives an instance of his conjecturing in this manner concerning the case of a young lady who had discovered a loss of sight in one of her eyes only the day before. The disease was thought to be of long standing; but as the Doctor found that she had only been subject to mistakes of the kind abovementioned for about a month, he drew a favourable prognostic, and the disease was cured.

GENUS XCIV. DYSPHIA.

Diminished Vision.

Amblyopia, Sav. gen. 154. Seg. 258.

There are several species referred to this genus by Dr Cullen, viz.

1. Dysopia Tenebrarum; 2. Dysopia Luminalis.—The former of these is properly the nyctalopia, or night-blindness,
The functions of the ear may be injured by wounds, ulcers, or any thing that hurts its fabric. The hearing may likewise be hurt by excessive noise; violent colds in the head; fevers; hard wax, or other substances sticking in the cavity of the ear; too great a degree of moisture or dryness of the ear. Deafness is very often the effect of old age, and is incident to most people in the decline of life. Sometimes it is owing to an original fault in the structure or formation of the ear itself. When this is the case it admits of no cure; and the unhappy perfon not only continues deaf, but generally becomes dumb, for life.

When deafness is the effect of wounds or ulcers of the ears, or of old age, it is not easily removed. When it proceeds from cold applied to the head, the patient must be careful to keep his head warm, especially in the night; he should likewise take some gentle purges, and keep his feet warm, and bathe them frequently in lukewarm water at bed-time. When deafness is the effect of a fever, it generally goes off after the patient recovers. If it proceeds from dry wax sticking in the ears, it may be softened by dropping oil into them; afterwards they must be syringed with warm milk and water.

If deafness proceeds from dryness of the ears, which may be known by looking into them, half an ounce of the oil of sweet almonds, and the same quantity of camphorated spirit of wine, or tincture of aaffetida, may be mixed together, and a few drops of it put into the ear every night at bed-time, dropping them afterwards with a little wool or cotton. Some, instead of oil, put a small slice of the fat of bacon into each ear which is said to answer the purpose very well. When the ears abound with moisture, it may be drained by an infusion of aconite, which should be made as near the affected parts as possible.

Some, for the cure of deafness, recommend the gall of an eel mixed with spirit of wine, to be dropped into the ear; others, equal parts of Hungary-water and spirit of lavender. Etneller extols amber and musk; and Brookes says, he has often known hardness of hearing cured by putting a grain or two of musk into the ear with cotton-wool. Where, however, an application with considerate stimulant power is necessary, camphorated oil with the addition of a few drops of volatile alkaline spirit, may be considered as the best. It is proper however, to begin with a small quantity of the alkali, increasing it as the ear is found to bear it. In some infirmities, where deafness depends on a state of insensibility in the nerves, electricity, particularly under the form either of sparks or of the electric aura, has been employed with great success. But these and other applications must be varied according to the cause of the disorder.

Though such applications may sometimes be of service, yet they much oftener fail, and frequently they do hurt. Neither the eyes nor ears ought to be tampered with; they are tender organs, and require a very delicate touch. For this reason, what we would chiefly recommend in deafness, is to keep the head warm. From whatever cause this disorder proceeds, this is always proper; and more benefit has often been derived from it alone, in the most obdurate cases of deafness, than from any medicines whatever.
Anosnia, Sauv. gen. 156. **Genus C. ANESTHESIA.**

Defect of the Sense of Feeling.

Caus. &c. This sense may be hurt by any thing that obstructs the nervous influence, or prevents its being regularly conveyed to the organs of touching, as pressure, extreme cold, &c. It may likewise be hurt by too great a degree of sensibility, when the nerve is not sufficiently covered by the cuticle or scurf-skin, or where there is too great a tension of it, or it is too delicate. Whatever disorders the functions of the brain and nerves, hurts the sense of touching. Hence it appears to proceed from the same general causes as palsy and apoplexy, and requires nearly the same method of treatment.

In a fluxor, or defect of touching, which arises from an obstruction of the cutaneous nerves, the patient must first be purged; afterwards such medicines as excite the action of the nerves, or stimulate the system, may be used. For this purpose, the spirit of turpentine, either by itself or combined with essential oils, horse-radish, &c. may be taken inwardly; the disordered parts, at the same time, may be frequently rubbed with fresh nettles or spirits of salt ammoniac. Blisters and finapisms applied to the parts will likewise be of use; and also warm bathing, especially in the natural hot-baths.

**Genera**

**DEFECT OF SMELLING.**

**Anosmia.** Sauv. gen. 156. *Genus XCVIII. ANOSMIA.**

Defect of smelling.

S. 262.

Caus. Morbid affections in the sense of smelling, may be considered with respect to their causes, as arising from one of two sources; either from some organic affection of the parts here principally concerned, or from a mere atonic state of the parts without any obvious affection. The sense of smelling may be diminished or destroyed by various diseases of the parts; as, the moisture, dryness, inflammation or suppuration of that membrane which lines the inside of the nose commonly called the olfactory membrane; the compression of the nerves which supply this membrane, or some fault in the brain itself at their origin. A defect, or too great a degree of solidity of the small spongy bones of the upper jaw, the cavities of the forehead, &c. may likewise impair the sense of smelling. It may also be injured by a collection of fetid matter in those caverns, which keeps constantly exhalming from them. Few things are more hurtful to the sense of smelling than taking great quantities of off-flavours.

Cure. When the nose abounds with moisture, after gentle evacuations, such things as tend to take off irritation and coagulate the thin sharp serum may be applied; as the oil of anise mixed with fine flour, camphire dissolved in oil of almonds, &c. The vapours of amber, frankincense, gum-mastic, and benjamin, may likewise be received into the nose and mouth. For moistening the mucus when it is too dry, some recommend snuff made of the leaves of marjoram, mixed with oil of amber, and aniseed; or a fermentatory of calcined white vitriol, 12 grains of which may be mixed with two ounces of marjoram-water and filtrated. The steam or vapour of vinegar thrown upon hot iron received up the nostrils is likewise of use for softening the mucus, opening obstructions, &c.

If there be an ulcer in the nose, it ought to be dressed with some emollient ointment, to which, if the pain be very great, a little laudanum may be added. If it be a veneral ulcer, it is not to be cured without mercury. In that cafe, the solution of the corrosive sublimate in brandy may be taken, as directed in the gutta perena. The ulcer ought likewise to be washed with it; and the fumes of cinnamon may be received up the nostrils.

If there be reason to suspect that the nerves which supply the organs of smelling are inert or want stimulating, volatile fats, strong snuff, and other things which occasion freezing, may be applied to the nose. The forehead may likewise be anointed with balsam of Peru, to which may be added a little of the oil of amber.

**DEFECT OF TASTE.**

**Ageustia.** Sauv. gen. 157. *Genus XCIX. AGEUSTIA.**

Defect of tasting.

Apogeustia, *Vog. 449.*

Caus. This defect also may arise either from an organic affection, or an atomic state of the parts. The taste may be diminished by crafts, filth, mucus, ageutia, aphthae, pellicles, warts, &c. covering the tongue; it may be depraved by a fault of the salivary, which being discharged into the mouth, gives the same sensation as if the food which the person takes had really a bad taste; or it may be entirely destroyed by injuries done to the nerves of the tongue and palate. Few things prove more hurtful either to the sense of tasting or smelling than obstinate colds, especially those which affect the head.

Cure. When the taste is diminished by filth, mucus, &c. the tongue ought to be scraped, and frequently washed with a mixture of water, vinegar, and honey, or some other detergent. When the salivary is vitiated, which seldom happens unless in fevers or other diseases, the curing of the disorder is the cure of this symptom. To relieve it, however in the mean time, the following practices may be of use: if there be a bitter taste, it may be taken away by vomits, purges, and other things which evacuate bile; what is called a nidorous taste, rising from putrid humours, is corrected by the juice of citrons, oranges, and other acids; a salt taste is cured by plentiful dilution with watery liquors: an acid taste is destroyed by absorbents and alkaline salts, as powder of oyster-shells, salt of wormwood, &c.

When the sensibility of the nerves which supply the organs of taste is diminished, the chewing of horseradish, or other stimulating substances, will help to recover it.

**DEFECT OF HEARING.**

**Deafness.** Sauv. gen. 156. *Genus XC. DEAFNESS.*

Defect of hearing.

S. 262.

Caus. This defect may arise from the soft hinder parts of the head, or from some disordered parts of the middle ear, or from some affection of the nerves which supply the sense of hearing. This feeling of hearing is produced by the waves of the air, which are refracted or diffracted by a sound, and then converted into a sense of hearing.

Cure. When the sense of hearing is hurt by the noise of hunting, or a certain noise of machines, the following medicines may be used. To relieve the hearer, when the sense of hearing is most hurt, the patient may apply the following medicines: as a violent headache, or other things that affect the sense of hearing, is one of the causes that provoke the sense of hearing.

**OF THE SENSES.**

**APPETITUS ERRONEI.**

Sect. I. *APPETITUS ERRONEI.*

Morostates, Sauv. Clas. VIII. Order II. *Sag. Clas. XIII. Order II.*

Pathetici,
This disease is commonly owing to some fault in the stomach, by which the aliments are thrown out too soon; and unless the person be indulged in his desire for eating, he frequently falls into fainting fits. Sometimes it is attended with such a flate of the stomach, that the aliment is rejected by vomit almost immediately after being swallowed; after which the appetite for food returns as violent as ever. But there are many circumstances which seem to render it probable that it more frequently arises from a morbid condition of the secreted fluid poured into the stomach, by means of which the aliment is diffused. When the activity of this fluid is morbidly increased, it will both produce too sudden a solution of the solid aliment, and likewise operate as a powerful and peculiar stimulus to the stomach, giving an uneasy sensation, similar to that which takes place in natural hunger. Such things are proper for the cure as may enable the stomach to perform its office: chalybeates and other tonics will generally be proper. In some, brandy drunk in a morning has been useful; and frequent smoking tobacco has relieved others. Oil, fat meat, pork, opiates, and in short every thing which, in a found person would be most apt to pall the appetite, may also be used as temporary expedients, but cannot be expected to perform a cure. In some, the pylorus has been found too large; in which case the disease must have been incurable.

Genus CIV. NYMPHOMANIA.

Furor Uterinus.

Satyria is a violent desire of venery in men, even so that reason is deprived by it. The pulse is quick, and the breathing short; the patient is sleepless, thirsty, and loathes his food; the urine is evacuated with difficulty, and a fever soon comes on. These symptoms, however, are probably not so much the consequence of satyria, as merely concomitant effects resulting from the same cause. And indeed this affection is most frequently the concomitant of a certain modification, of infancy. The nature and cause of this affection are in most instances very little ascertained; but as far as we are acquainted with the treatment, it agrees very much with the affection next to be mentioned, which, of the two, is the most common occurrence.

Order III. DYSCINESIÆ.

Genus CX. APHONIA.

Loo of Voice.

The loss of voice may proceed from various caufes. If one of the recurrent nerves, which are formed by the par vagum and the nervus accessorius, and reach the larynx, be cut the person is capable of only as it were a half-pronunciation; but if both be cut, the speech and voice are both loft. The loss of speech happening in hysteric patients is also called aphonia; but more properly that loss of speech is thus named which depends on some fault of the tongue.

Seeing that the motion of any part is destroyed, or leffened at leaft, by the interception of the nervous fluid in its passage thither, and that the nerves defigned for the motion of the tongue arife principally from the fifth pair, it appears that the feat of this disorder is in the faid fifth pair of nerves, and that the immediate caufe is a diminution or total deftruction of the nervous power in them. Hence a pally of the tongue, which is either antecedent or fubfequent to hemiplenic or apoplectic disorders, demand our utmost attention.

If an aphonia appears alone, it generally befits an approaching hemiplegia or apoplexy; but if it succeed these disorders, and is complicated with a weak memory and a sluggishness of the mental powers, it threatens their return. That aphonia usually terminates the fett which proceeds from a diaphragmation of the feroous humours comprifing the branches of the fifth pair of nerves, which run to the tongue; but it is no lefs afflactive to the patient, and is very obdurate of cure.

Other caufes of this disorder are, the striking in of eruptions on the skin, a congefion of blood in the fauces and tongue, obftructed periodical evacuations in plethoric habits, fpaftic affections, worms, a crum of bread falling into the larynx, fear, too free an ufe of spiritual liquor; aften whatever deftrays the ligaments which go from the artenuroid to the thyroid cartilages, will deftray the voice.

The prognofis vary according to the caufe or caufes. That species which is owing immediately to fpafts,foon gives way on the removal of them. If a pally of the tongue be the caufe, it is very apt to return, tho' relieved, but often continues incurable.

In order to the cure, we muft endanger first to remove whatsoever obftructs the influx of the nervous fluid into the tongue, and secondly to strengthen the weak parts. Thefe general intentions, in all cafses, being regarded, the particular caufes muft be removed as follows:

If worms be the caufe, anti-fpaftic medicines may give pre-"
MEDICINE.

Genus CXI. Mutitas, Dumbness.

Dumb people are generally born deaf; in which case the dilatation is incurable by medicae; though even such people may be taught not only to read and write, but also to speak and to understand what others say to them. For some observations on the method in which this has been accomplished, we may refer the reader to the article Dumbness in the alphabetical order. But in such cases, admitting of cure in the manner above alluded to, the dumbness proceeds principally, if not solely, from the deafness. For when it proceeds from a defect of any of the organs necessary for speech, the tongue for instance, it is always incurable; but if it arise from a palsy, the medicines applicable in that case will sometimes restore the speech.

Genus CXII. Paraphonia. Change in the Sound of the Voice.

Paraphonia. Sauv. gen. 168.
Cacophonía. Sag. 274.
Raucedo. Lin. 145.
Rancitás. Vog. 252.
Aphasia. &c. Sig. 250, 251, 254, 255, 256.

The voice may be changed from various causes. In males it becomes much more hard about the time of puberty; but this can by no means be reckoned a disease. In others it proceeds from a catarrh, or what we call a cold; it arises also from affections of the nose and palate, as polypi, ulcers, &c. in which case the cure belongs properly to surgery. In some it arises from a laxity of the velum pendulum palatii and glottis, which makes a kind of snoring noise during inspiration. The cure of this last case is to be attempted by tonics and such other medicines as are of service in diseases attended with laxity.

Genus CXIII. Pfellismus. Defect in Pronunciation.

Of this disease (if such it may be called), there are many different kinds. Some cannot pronounce the letter S; others labour under the same difficulty with R, L, M, K, &c.; while some can with sufficient ease pronounce all the letters, yet repeat their words, or the first syllables of them, in such a strange manner, that they can scarce be understood. Very frequently these defects arise entirely from habit, and may then be got the better of by those who have the resolution to attempt it; as we are told that Demosthenes the celebrated orator got the better of a habit of stammering by declaiming with pebbles in his mouth. Sometimes, however, pronunciation may be impeded by a wrong conformation of the tongue or organs of speech; and then it cannot by any pains whatever be totally removed.

Genus CXIV. Strabismus. Squinting.

Sag. 222.

Description. This disease flows itself by an uncommon contraction of the muscles of the eye; whereby the axis of the pupil is drawn towards the nose, temples, forehead, or cheeks, so that the person cannot behold an object directly.

Causes, Prognostic, &c. 1. This disease may proceed from custom and habit; while in the eye itself, or in its muscles, nothing is preternatural or defective.

Thus children by imitating those that squint, and infants by having many agreeable objects presented to them at once, which invite them to turn one eye to one and the other eye to another, do frequently contract a habit of moving their eyes differently, which afterwards they cannot so easily correct. Infants likewise get a custom of squinting by being placed obliquely towards a candle, window, or any other agreeable object capable of attracting their sight; for though, to see the object, they may at first turn both eyes towards it; yet because such an oblique situation is painful and laborious, especially to the most distant eye, they soon relax one of the eyes, and content themselves with examining it with the eye that is next it; whence arises a diversity of situation and a habit of moving the eyes differently.

In this case, which may admit of a cure if not too much confirmed, it is evident, that objects will be seen in the same place by both eyes, and therefore must appear single to other men; but because, in the eye that squints, the image of the object to which the other eye is directed falls not on the most sensible and delicate part of the retina, which is naturally in the axis of the eye, it is easy to see that it must be but faintly perceived by this eye. Hence it is, that while they are attentive in viewing any object, if the hand be brought before the other eye, this object will be but obscurely seen, till the eye change its situation, and have its axis directed to it; which change of situation is indeed very easy for them, because it depends on the muscles of the eyes, whose functions are entire; but, by reason of the habit they have contracted of moving their eyes differently, the other eye is at the same time frequently turned aside, so that only one at a time is directed to the object.

That all this may be the better perceived; for an object, cause them to look at the image of the upper part of your nose in a plain mirror, while you stand directly behind them, to observe the direction of their eyes.

II. The strabismus may proceed from a fault in the first conformation, by which the most delicate and sensible part of the retina is removed from its natural situation, which is directly opposite to the pupil, and is placed a little to a side of the axis of the eye; which obliges them to turn away the eye from the object.
When the eye has this conformation, no object to which it is directed can be clearly seen, because its image falls not on the retina at the axis of the eye; and therefore the eye turns aside from the object it would view, that its image may fall on the most sensible part of the retina.

When the strabismus proceeds from this cause, the prognostic and the phenomena that attend it will be much the same as in the case immediately preceding; from which nevertheless it may be distinguished by the obliquity of the cornea, which is manifest to the senses; and if the cornea be also more arched and prominent than what it is naturally, which is commonly the case, the eye will also be short-sighted.

V. This want of uniformity in the motions of our eyes, may arise from a defect, or any great weakness or imperfection, in the sight of both or either of the eyes; and this, according to Dr. Porterfield, is the most common cause of this disease. The prognostic in this case is the same with that of the disease from which it proceeds.

VI. Another cause from which the strabismus may proceed, lies in the muscles that move the eye. When any of those muscles are too short or too long, too tense or too lax, or are seized with a spasm or paralysis their equilibrium will be destroyed, and the eye will be turned towards or from that side where the muscles are faulty.

In this case, the disease frequently yields to medicine, and therefore admits of favourable prognostic; excepting only when, by a fault in the first conformation, any of the muscles are longer or shorter than their antagonists; in which case, if ever it should happen, no medicine can be of any use.

As to what concerns the optical phenomena, they are the same here as in the case first: only when the disease commences not till, by custom and habit, the uniform motion of the eyes has been rendered necessary, all objects do for some time appear double; but in time they appear single.

Lastly. This want of uniformity in the motions of our eyes may proceed from a preternatural adhesion or attachment to the eye-lids; of this we have an instance in Langius. And that the same thing may also be occasioned by a tumor of any kind within the orbit, pressing the eye aside, and restraining it from following the motions of the other, is so evident, that instances need not be brought to prove it. Here also the cafe may admit of a favourable prognostic; and as for what concerns the optical phenomena they must be the same as in the case immediately preceding.

The cure in confirmed cases, is to be effected by mechanical contrivances, by which the person may be obliged to look straight upon objects, or not see them at all; or at least that he may see with uneasiness and confusedly when he squints. In the 68th volume of the Philosophical Transactions we have an account of a confirmed case of squinting of a very uncommon kind. The patient was a boy of five years old, and viewed every object which was presented to him with but one eye at a time. If the object was presented on his right side, he viewed it with his left eye; and if it was presented on his left side, he viewed it with his right eye. He turned the pupil of that eye
Practice.

Medicine.

Dyschiasia eye which was on the same side with the object in such a direction that the image of the object might fall on that part of the bottom of the eye where the optic nerve enters it. When an object was held directly before him, he turned his head a little to one side, and observed it with but one eye, viz. that most distant from the object, turning away the other in the manner above described; and when he became tired of observing it with that eye, he turned his head the contrary way, and observed it with the other eye alone, with equal facility; but never turned the axis of both eyes on it at the same time. He saw letters which were written on bits of paper, so as to name them with equal ease, and at equal distances, with one eye as with the other. There was no perceptible difference in the diameters of the irises, nor in the contrariety of them after having covered his eyes from the light. These observations were carefully made by writing single letters on shreds of paper, and laying wagers with the child that he could not read them when they were presented at certain distances and in certain directions.

As from these circumstances it appeared that there was no defect in either eye, which is frequently the case with persons who squint, and hence that the disease was simply a depraved habit of moving his eyes, the disease seemed capable of a cure. A paper gnomon was made for this purpose, and fixed to a cap; and when this artificial nose was placed over his real nose, so as to project an inch between his eyes, the child, rather than turn his head so far to look at oblique objects, immediately began to view them with that eye which was next to them. But having the misfortune to lose his father soon after this method was begun to be followed, the child was neglected for six years, during which time the habit was confirmed in such a manner as seemed to leave little room to hope for a cure. The same physician, however, being again called, attempted a second time to remove the deformity by a similar contrivance. A gnomon of thin brass was made to stand over his nose, with a half circle of the same metal to go round his temples; these were covered with black silk, and by means of a buckle behind his head, and a cross-piece over the crown of his head, this gnomon was worn without any inconvenience, and projected before his nose about two inches and an half. By the use of this machine he soon found it less inconvenient to view all oblique objects with the eye next to them instead of the eye opposite to them.

After this habit was weakened by a week's use of the gnomon, two bits of wood, about the size of a goose-quill, were blackened all but a quarter of an inch at their summits; these were frequently presented to him to look at, one being held on one side the extremity of his black gnomon, and the other on the other side of it. As he viewed these, they were gradually brought forwards beyond the gnomon, and then one was concealed behind the other: by these means, in another week, he could bend both his eyes on the same object for half a minute together, and by continuing the use of the gnomon, he was in a very fair way of being cured when the paper was written.

Dr. Darwin, who writes the history of the above case, adds, that all the other squinting people he had occasion to attend, had one eye much less perfect than the other these patients, says he, are certainly curable by covering the best eye many hours in a day, as by a more frequent use of the weak eye it not only acquires a habit of turning to the objects which the patient wishes to see, but gains at the same time a more distinct vision; and the better eye at the same time seems to lose somewhat in both these respects, which also facilitates the cure.

Genus CXV. Contractura.
Contractions of the Limbs.

Obliptitas, Sauv. gen. 11.
Caput obliptum, Vog. 513.
Digitum, Vog. 221.

The contraction of various muscles of the body is generally the consequence of some other disease, as the rheumatism, gout, scurvy, or palsy, especially that species of the latter which follows the colica Pidi­num. It is exceedingly difficult of cure; though the warm medicinal waters are much recommended, and have sometimes done great service. Of late electricity has been found to perform surprising cures in this way.

Order IV. Apocenososes.

Apocenoles, Vog. Clas II. Ord. II.
Fluxus, Sauv. Clas IX. Sag. Clas V.
Morbi evacuatorii, Lin. Clas IX.

Genus CXVI. Profusio.
Flux of Blood.

Profusio, Lin. 239.

The disease commonly known by the name of bloody-flux, is the putrid or contagious dysentery, a disease which has already been treated of. But independent of the discharge of blood which then takes place, haemorrhagy may take place from the alimentary canal as well as from other parts of the system. In such instances, however, if we except the place from which the discharge occurs, the phenomena are very much the same as in menorrhagia, hæmoptysis, and other hæmorrhages already treated of; while the disease is to be combated on the same principles and by the same remedies.

Genus CXVII. Ephidrosis.
Excessive Sweating.

Ephidrosis, Sauv. gen. 258. Sag. gen. 194.
Sudor, Lin. 208.
Hydropeides, Vog. 121.

This is generally symptomatic; and occurs in almost all fevers, but especially in the latter stages of the hectic. Sometimes it is a primary disease, arising merely from weakness; and then early admits of a cure by the use of the Peruvian bark, the cold bath, and other tonics.

Genus CXVIII. Epiphora.
Flux of the Lachrymal Humour.

This by Sauvages is described as an involuntary effusion.
effusion of tears without any remarkable itching, heat, or pain. It follows long-continued ophthalmiae; or it may be occasioned by immoderate study, or any thing that weakens the eyes: hence it comes on about the age of 50 years, when the eyesight naturally becomes weak. It in general grows worse in the winter-time, and is very hard to cure. Some authors recommend purgatives, and blisters on the nape of the neck, in order to draw off the abundant humours; but as the disease evidently proceeds from weakness, it would rather seem proper to pursue a contrary method. Sauvages recommends to the patients to abstain from study, wine, and falted meats; and also to avoid smoke or wind, and at night to foment the eyes with an infusion of four cloves in two ounces of Hungary water, rose water with white vitriol dissolved in it; &c. have also been recommended.

**GENUS CXIX. PTYALISMUS.**

**Salivation.**

A salivation is often symptomatic, but rarely a primary disease. Dr Cullen is of opinion, that when the latter happens to be the case, it arises from laxity; and then it is to be cured by astringents and tonics. In the Medical Transactions we have the following account of a salivation brought on by a foreign substance irritating one of the parotid glands.

In the month of April 1751, a young lady about the age of 16 years, of a delicate habit, but subject to no particular complaints, perceived the beginning of a disease which afterwards proved most obstinate and loathsome, viz. an incessant spitting. The quantity of this discharge was different at different times, varying from one pint to two pints and an half in 24 hours. As to its quality, it seemed to be no other than the ordinary secretion of the salival glands. By so large and constant an evacuation, her strength became extremely impaired, and the most efficacious medicines had proved ufeless. She had taken large quantities of the Peruvian bark, both alone and combined with preparations of iron; and afterwards the fetid gum, opium, amber, alum, and the Neville-Holt-water, had in succession been given her. In the mean time an exact regimen had been prescribed: she had been ordered to ride constantly; and to confine herself into a mucilaginous diet, such as veal, calves' feet, &c. Likewise a gently opening medicine had now and then been interposed. The disease still continued unaltered, the had afterwards tried the *indura fatoria*; and had, at the same time, been encouraged to chew the Peruvian bark, and to swallow the saliva. But all these attempts had been vain; and after they had taken some or other of the medicines abovementioned until the end of September 1753, namely, above two years, it appeared to her physician, Sir George Baker, unreasonable to expect relief in such a cafe from any internal medicines whatever.

He now conceived a suspicion, that some extraneous body having accidentally found its way into the *necrus auditivus*, might possibly be the cause of this extraordinary secretion, by keeping up a continued irritation in the parotid glands. With this view he examined her ears, and extracted from them a quantity of fetid wool. How, or when, it came thicker, no account could be given.

To this salivation he attributed the beginning of the salivation, notwithstanding that the disease did not immediately abate on the removal of the wool; as it appeared to be no improbable supposition that the discharge might be continued by the force of habit, though the original cause no longer remained.

It seemed, therefore expedient to introduce some other habit, in the place of the increased secretion of saliva; which habit might afterwards be gradually left off. With this intention, he prevailed on the patient to chew perpetually a little dry bread, and to swallow it with her spittle. In a few weeks, it became necessary for her to chew the bread only at certain hours in the day; and thus, after two months, she became entirely free from a most disagreeable and tedious disorder.

It is worthy of observation, that, at first, the swallowing of so much saliva frequently occasioned a nausea; and that then, for a few hours, she was obliged to spit it out as usual; and that, during the greater part of the time, when she chewed the bread, she had a tooth or two every day more than common.

**GENUS CXX. ENURESIS.**

**An Involuntary Flux of Urine.**

This is a distemper which frequently affects children, other-wise healthy, when asleep; and is extremely disagreeable. Often it is merely the effect of laziness, and may be driven off by proper correction; but sometimes it proceeds from an atony or weakness of the sphinter of the bladder. Many ridiculous cures have been prescribed for it, and among the rest field-mice dried and powdered. Tonics are frequently of use; but sometimes the distemper proves obstinate, in spite of every thing we can use. In the London Medical Observations we find blisters much recommended in this disease, when applied to the region of the os facrum. A girl of 13 years of age had been subject to an enuresis for four years. She could retain her water but a very little time in the day-time, but it flowed continually in the night. She had taken Peruvian bark and elixir of vitriol in considerable quantities; also Valerian and the volatile julep, without effect. She was severely threatened, as the physician suspected it might arise from a bad habit; but this producing no effect, a blister was applied to the os facrum, which in 24 hours totally removed the disease. A managed 32, having been feized with an incontinence of urine and palsy of the lower extremities in consequence of taking a quack medicine, was cured of the incontinence of urine in 24 hours by one blister and of the palsy itself by another. A woman of 50 having been feized with an enuresis and paralytic affection of the right thigh and leg in consequence of a strain, was cured of both by a single blister. Several other cafes are there mentioned, by which the power of blisters in removing this distemper seems to exceed that of every other medicine whatever.
Practise.

GENUS CXXI. GONORRHoea.

The gonorrhoea is a flux of scititious matter of various colours, from the urethra in men and the vagina in women. It commonly proceeds from coition with a person infected with the venereal disease, and is one of the most common forms under which that disease shows itself.

Description. The first symptoms of the disease in men are commonly a sensation at the end of the penis not unlike a flea-bite, together with a fullness in the lips of the urethra, and some degree of tension in the penis, the urinary canal feeling as if tightened, and the urine flowing in a small and unequal stream: a little whitish mucus is to be seen about the orifice of the urethra, and oozing from it when slightly pressed, especially if the prepuce be made on the spot where the foreskin is most felt. The discharge soon increases in quantity, and varies in its colour according to the degree of inflammation. The patient feels a sensation of heat and pain in evacuating his urine, particularly at certain spots of the urethra, and above all towards its orifice; and the involuntary erections to which he is subjected from the stimulus, particularly when warm in bed, occasion a distortion or curvature of the penis, attended with exquisite pain. When the inflammation is violent, the glans appears tumid and transparent, and cannot be drawn back, occasioning what is called a phymosis; at other times, as in the paraphymosis, it remains in an inflamed state below the glans, so that it cannot be drawn forwards; and, if the stricture and inflammation be violent, may terminate in gangrene. Now and then, especially when there is a phymosis, we may perceive a hard chord extending along the back of the penis. This is an inflamed lymphatic, and may be considered as a prelude to a bubo. When, however, a bubo does appear, almost universally some ulceration is previously to be discovered about the praeputium, or glans penis; which gives ground to presume that some other contagious matter besides that of gonorrhoea may have been applied to the urethra. For it is certain that matter capable of communicating the contagion of gonorrhoea to a female, is often copiously applied to the whole glans penis of a male for several days together without giving either ulceration or bubo.

In many cases, the seat of the disease is in the urethra, not far from its orifice; but it frequently happens that the virus infinuates itself much higher up, so as to affect Cowper's glands, the prostrate, and parts very near to the neck of the bladder.

In the generality of cases, the inflammation goes on increasing for several days, commonly for a week or a fortnight; after which the symptoms begin to subside; and the running, when left to itself, gradually lessens in quantity, and becomes whiter and thicker, till at length it totally stops. The colour of the mucus, however, is by no means a certain guide in these cases; for in many patients it is of a yellowish, and sometimes of a greenish hue to the very last; but in general it becomes more confluent towards the close of the disease.

In women, the external parts of generation being fewer and more simple, the disease is less complicated than in men. Sometimes the vagina only is affected; and when this happens, the symptoms are very trifling; but in general it comes on with an itching and sensation of heat in the other sex; and is attended with inflammation of the nympha, inside of the labia, clitoris, cornuqué nortiformis, the orifice and sometimes the whole of the meatus urinarius. Very often the deep-seated glands of the vagina are affected, and it is sometimes difficult to distinguish the discharge of a gonorrhoea from that of the fluo albus.

Caujé, &c. Many ingenious arguments have of late been advanced to prove, that the gonorrhoea and the lues venerea are different affections, originating from two distinct species of virus; and this controversy still, perhaps, remains to be decided by future facts. Certain it is, that in 19 or 20 cases of gonorrhoea, no symptom whatever of syphilis appears; and that the disease readily admits of cure without having recourse to those remedies which are universally requisite for combating the contagion of syphilis. It is by no means wonderful, that in some cases both contiguities, supposing them different, should be communicated at the same time. Nay, cases are by no means rare, where the contagion of itch, though essentially different from both, has been communicated with either. But as undeniable proof that the contagion in both cases is precisely the same, it has been alleged by some, that the matter of a chancre introduced into the urethra will generate a gonorrhoea, and that the discharge from a gonorrhoea will produce chancres, bubo, and every other symptom of syphilis. On the other hand, however, it is contended, that when experiments of this nature are conducted with the greatest accuracy, the matter of syphilis uniformly produces syphilis, and that of gonorrhoea, gonorrhoea only. Without pretending to decide on which of these experiments the greatest dependence is to be put, we may only observe, that while an almost inconceivably small portion of syphilitic matter applied to the glans penis, from connection with an infected female, infallibly produces syphilis, if it be not speedily removed, the matter of gonorrhoea, in every instance of that disease, is applied to the whole surface of the glans penis for many days together without producing almost any bad effect whatever. From this, therefore, there is ground for inferring, either that it is not capable of being absorbed, or that if absorbed it is innocent.

But while there have been disputes with regard to the peculiar nature of the matter in gonorrhoea, there have also been controversies with respect to the source from whence it is derived. While some suppose it to be principally purulent matter arising from ulcerations, others affirm that no such ulceration is ever produced in the urethra by gonorrhoea. They contend that the increased secretion in these cases is exactly similar to what happens in the catarrh. But the comparison, will be by no means hold good in every particular; in the latter the whole membrane of the nose is equally irritated; whereas in the gonorrhoea, only particular parts of
...of the urethra seem to be affected. The disease, in the generality of cases, seldom extends more than an inch and a half along that canal, and in many is confined (at least in the beginning) to a small spot about an inch from the extremity of the glans. The discharge is produced from that part of the urethra where the pain is felt; and the patient, when he voids his urine, feels no smarting till it reaches the inflamed spot; but, as the disorder increases, the inflammation affects a greater number of points, just in the same manner as chancre affects different parts of the glans. It might be supposed that defecation would at once clear up this matter, and put an end to the dispute; but this is far from being the case. Dr. Simmons has seen several urethras opened in persons who had a gonorrhoea at the time of their death: in three of them the surface of the urethra, as in the cases related by Morgagni, appeared for some way down of a light red colour, and in all of them was covered with mucus; but without any appearance of ulceration, except in two dissections at Paris, in which most of the gentlemen present were convinced that they saw evident marks of it: but Dr. Simmons says that the appearances were to him not sufficiently satisfactory to enable him to decide with certainty on the subject. On the other hand, when we consider that the discharge in a gonorrhoea is sometimes tinged with blood, and that when this happens a little blood-vesel is no doubt ruptured, we can have no reason to doubt that an ulceration may, and sometimes does, happen in these cases; especially as we often observe an excoration near the orifice of the urethra. It is certain, that wherever there is considerable inflammation, there will be danger of ulceration. Besides, from a neglected or badly-treated gonorrhoea, we often see fistulas in perineum, and other ulcers of the urethra, penetrating through its substance, and affording a passage to the urine. And perhaps some of those fistulas are not sufficiently well known, and that from hence it is propagated upwards, particularly where the excretories of mucus are most numerous; and that on the parts to which it is applied, it operates as a peculiar irritating caufe. The consequences of this irritation will be inflammation and an increased secretion of mucus; and so far the complaint will be local. In ninety-nine cases of an hundred a local affection of this kind constitutes the whole of the disease; and of this inflammation, ulcerations within the urethra, fistulas, and other local affections, may be the consequence. But whether a disease of the habit ever takes place, unless when the contagion of syphilis is communicated with that of gonorrhoea, still remains to be determined by future observations and experiments.

Nothing can be more variable than the period at which the disease makes its appearance after infection. Perhaps, at a medium, we may place it between the 4th and 14th day; but in some cases it happens within 24 hours; and in others, not before the end of five or even six weeks: neither of these extremes, however, are common.

From what has been said of the manner in which the contagious matter in gonorrhoea acts, and of the influence it exerts on those parts with which it comes in contact, it follows, that the prevention of gonorrhoea must depend on the removal of the contagious matter as soon as it can be done; and where this is either altogether neglected or not properly accomplished, that the cure must depend on counteracting the inflammation which this contagious matter excites, and the consequences which result from it.

The first of these intentions may be most certainly and most easily accomplished by careful lotion of all the parts to which the contagious matter has any chance of being applied. These parts, at least on the first application of the matter, are readily accessible: for even in men there is no reason to believe that it at first penetrates to any extent in the urethra. This washing of the parts should be performed as soon as possible; because then the matter is both most accessible and least involved with mucus; but although washing cannot be accomplished at an early period, it should not be neglected afterwards; for from the disease uniformly commencing, even when it does not appear till a considerable time after the application of the contagious matter, with a peculiar sneeze of irritation at the external parts, particularly in men at the extremity of the urethra, there is reason to believe that the contagious matter attached to the mucus may remain latent there for a very considerable time. For the purpose of washing, with a view to the prevention of this disease, recours may be had to almost any watery fluid, provided it be not so stimulant as to produce bad effects from injuring the parts. Pure water, properly applied, is perhaps one of the best lotions; but there can be no doubt that its power in removing the contagious matter may be somewhat increased by such additions as render it a more powerful solvent of mucus. With this intention, one of the most powerful additions is the vegetable alkali, either in its mild or caustic state. In the latter state it is the most active, but in the former it is most safe; and the liquida purificata of the Edinburgh pharmacopoeia, to the extent of half a drachm, dissolved in fix or eight ounces of water, is one of the best lotions that can be employed. The purpose of removing the contagion may often also be effectually answered from washing with water impregnated with soap; for there the alkali, though in a caustic state, is prevented from exerting any disagreeable effects, in consequence of its being combined with oily matters.

With the view of preventing gonorrhoea, some have advised, that the alkali, either in its mild or caustic state, properly diluted with water, should be injected into the urethra; and there can be no doubt, that by this...
Practice.

MEDICINE.

Apericenofe this means the contagious matter, when it has entered the uretha may be removed. A removal may also be effected by the injection of a weak solution of corrosive sublimate, which seems to act not by dissolving the mucus but by producing an augmented secretion. But at a very early period of the disease, injections are probably unnecessary; and if it has made any considerable progress, they are dangerous: for from the augmented sensibility of the part, even very gentle ones are apt to excite a high degree of inflammation.

There are practitioners who, supposing that the body possesses powers to expel the virus, and that the disease has a certain period to run through its several fages of progress, acme, and decline, are for leaving the cure to nature; or at least content themselves with adlitng her by an antiphlogistic regimen, gentle evacuations, and the like.

That in many cases the disorder admits of a natural cure, there can be no doubt; the increased secretion of mucus carrying off the virus faster than it is formed, till at length the infection is wholly removed: But it is equally certain, that it every cafe, by the application of suitable remedies to the inflamed part, we may shorten the duration of the complaint, and abridge the sufferings of the patient, with the same certainty and safety as we are enabled to remove the effects of an ophthalmia or any other local inflammation, by proper topical applications. General remedies, such as occasional blood-letting, a cooling diet, the liberal use of diluting liquors, and mild purges, are by all allowed to be useful, and even necessary. All are was of opinion that in these cases blood-letting ought to be repeated five or six times; and there are still many practitioners who depend much on repeated evacuations of this sort for a removal of the inflammation. But there is, perhaps, not one cafe in ten in which it is at all requisite; and this small number of cases will consit of only fireng and plethoric in such, when the chordee is frequent and painful, and the pulse hard and full, the loss of from eight to twelve ounces of blood will be beneficial, but it will be seldom necessary to repeat the operation the inflammation in these cases is kept up by the local stimulus of the virus and the urine; and all that we can expect from veneration is to moderate the pain and the frequency of erition. In persons of a delicate habit, and of an irritable fibre, the evacuation will do no good; but if repeated will certainly be liable to do harm, by increasing irritability, and of course rendering the patient more susceptible of filthum.

The utility, and even the necessity, of a cooling regimen, are sufficiently obvious; wine and spirituous liquors, spiceries, a fish-diet, much animal-food, and failed and high seasoned dishes of every sort, will constantly add to the complaint. The patient should eat meat only once a day, and that sparingly. He should abstain from hot-supperers. Milk, mild vegetables, and fruit, should constitute the principal part of his diet while the inflammatory symptoms continue. Every thing that tends to excite the venereal imagination should be judiciously avoided; for whatever promotes erection of the penis will increase the inflammation, and of course add fuel to the disease. For the same reasons much walking or riding on horseback will be hurtful, from the irritation kept up in the perineum by such means. Violent exercise of any kind, or any thing that is liable to increase the heat and the momentum of the blood, will of course be improper.

The drinking freely of mild, cooling, mucilaginous liquors, such as linseed-tea, orceate, whey, milk and water, almond emulsion, and the like, will be extremely useful, by diluting the urine, and preventing its falls from stimulating the urethra. When the heat and pain in making water are very considerable, mucilaginous substances are found to have the best effect, particularly the gum tragacanth. It is a common practice to give equal doses of this gum or gum arabic and nitre, and to dissolve nitre in the patient's drink, with a view to lefus the inflammation. But in these cases nitre is always improper: it is known to be a powerful diuretic, its chieft action being upon the urinary passages; so that the stimulus it occasions will only serve to increase the evil it is intended to alleviate. Cream of tartar, on account of its diuretic quality, will be equally improper. Our view here is not to promote a preternatural flow of urine; for the virus, being insoluble in water, cannot easily be washed away by such means; but our object ought to be, to render the urine that is secreted as mild and as little stimulating as possible.

Mild purges, which constitute another material part of the general remedies, are no doubt extremely useful when exhibited with prudence; but it is well known that the abuse of purgative medicines in this disease has been productive of numerous evils. Formerly it was a pretty general practice to give a large dose of calomel at bed-time, three or four times a-week; and to work it off the next morning with a strong dose of the pilule cocceor, or some other drastic purge. This method was perfurred in for several weeks; in consequence of which the patient often found himself troubled with an obfolute gleet, and perhaps his constitution materially injured; the effect of such a method being (especially in irritable habits) to weaken the stomach and bowels, and lay the foundation of hypochondrical complaints. Violent purging likewise often occasioned stranguary, hernia humorals, and other troublesome symptoms.

The purges employed in these cases should be gentle; such as Rochelle salt, manna, tartarified alkali, and the like. They should be given only in a dose sufficient to procure two or three stools, and to be repeated only every two or three days. The daily use of the purgative electuaries that are full given by some practitioners, serves only to keep up a continual irritation on the bladder, and of course to prolong the inflammation.

The topical remedies that are used confilt chiefly of different sorts of injections, the ingredients of which are extremely various; but their modes of operation may in general be referred to their mucilaginous and sedative, or to their detergent, stimulating, and abrin gent qualities. In the hands of skilful practitioners, great advantages may doubtless be derived from the use of these remedies; but, on the other hand, the improper and unfeafonable administration of them may prove a source of irreparable mischief to the patient.

We know that mucilaginous and oily injections will tend to allay the local inflammation; and that a seda-
A deterrent injection, such as a solution of opium, will lessen the irritability of the parts, and of course produce a similar effect; the utility of such applications is therefore sufficiently obvious.

A deterrent injection, or one that will act upon the mucus of the urethra, increase the discharge of it, wash it away, and with it the venereal virus that is blended with it, can only be used as a prophylactic before the symptoms of infection have made their appearance. But great circumdiction is necessary in the use of this kind of injection. It it be too weak, it can be of no efficacy; and if it be too strong, it may prove dangerous to the patient. A supposition of urine has once made their appearance, the stimulus of this kind of mucus of the urethra, increases the discharge of it, washes it away, and an injection, containing it, can of no efficacy; and if it be too strong, it may prove dangerous to the patient. But every thing that stimulates it must be hurtful. The injection excites a painful sensation in the urethra, as irritation and astringent effects; and, in some it degenerated into a gleet, the running be checked and the inflammation abates, he may add some of the medicinal compounds, as calomel., and thereby the bowels, and so the discharge be properly checked before the virus that excited the discharge be properly subdued, the patient will be exposed to fresh dangers; and perhaps to a variety of local complaints, such as obstructions in the urethra, and ulcers of the pelvic organs, which are well known to be sometimes owing to applications of this sort improperly managed.

When the inflammation has subsided, gently stimulating and astringent injections may be used with safety, and with considerable advantage: for as the inflammation is at first excited by the stimulus of the venereal virus, so when the former begins to lessen, we may be assured that the activity of the latter has abated in proportion; and, in general, when the inflammatory symptoms are entirely removed, it will be found that the mucus is no longer of an infectious nature but is merely the effect of an increased secretion and of relaxation. Mild astringents will therefore serve to brace and strengthen the vessels secreting mucus, and in this way will lessen the discharge, and greatly promote the cure. It is certain, that in the greater number of cases, a gonorrhoea, which is treated by internal remedies alone, would continue for five or six weeks, or longer, may, when judiciously treated with injections, be cured in a fortnight, and very often in less time. The great aim, therefore, of the practitioner ought to be at first to make use of such injections only as will tend to lubricate the surface of the urethra, and to counteract and destroy the stimulus of the virus: as the inflammation abates, he may add some gently astringent preparation to a mucilaginous and sedative injection; taking care that its astringency be united to the state of the digestive, and to the irritability of the patient. Amongst a great variety of substances, mercury in different forms is one of those that is the most frequently employed in injections. All these mercury injections have more or less of astringency: and according to Dr. Simmons, is solely to this property that we are to ascribe their effects; for the idea of correcting the venereal virus was originally introduced, and has, he thinks, been continued upon mistaken principles.

Calomel, mixed with the mucus discharged in a gonorrhoea, has no more power in destroying the infectious properties of that mucus than cerule or any other preparation would have. A diluted solution of sublimate injected into the urethra, will like a solution of verdigris, or blue vitriol, or any other astringent, render the mouths of the lumen; but this is all that it will do, for it will never lessen the infectious nature of the virus. The same thing may be observed of crude mercury extinguished by means of mule, or of mercurial mucus, blended with the yolk of an egg, and which, when thrown up into the urethra, will act nearly in the same manner as balsam of copaiva, or any other stimulating injection. The stimulus of calomel, however, has often been found of considerable efficiency; and in women, when the vagina, only was affected, after washing the parts well, the cure has been accomplished by rubbing them repeatedly with mercurial ointment.

As the gonorrhoea is only a local affection, it may be inferred, that the internal use of mercury is unnecessary towards the cure. Very often indeed the complaint may be removed without having recourse to mercurials. Sometimes patients have been met with whose general health has been greatly impaired by a long continued use of mercury in such cases, while the original disease, the gonorrhoea, was rendered much worse by it. In some it degenerated into a gleet, that was cured with extreme difficulty; in others it brought on a variety of distressing symptoms. In cases of gonorrhoea, therefore, whenever mercury is administered, it ought to be, not with a view to expedite the cure, but merely to obviate the dangers of syphilis. When the infection is apparently flight, and the inflammation and the symptoms trifling, we may proceed without the assistance of mercury, especially if the patient be of a weak relaxed, and irritable habit, likely to be injured by mercurial medicines. On the other hand, when the discharge is violent, the inflammation considerable, or the lesion of the disease high up in the urethra, it is perhaps the most prudent plan to give mercurials in small doses, and in such forms as seem the best adapted to the constitution of the patient.

The pilula hydrargyri, as prepared according to the receipts in the last edition of the London or Edinburgh pharmacopoeias, in both of which the mercury is rendered active merely by trituration, may perhaps be considered as one of the mildest and most efficacious forms under which mercury can be exhibited by the mouth. Its efficacy will depend on its not irritating the bowels, and so passing off by stool; care must likewise be taken to prevent its affecting the mouth. Of the chemical preparations of mercury, the mildest and least irritating is calomel. It may be given from gr. i. to gr. iii. at bed-time, occasionally proposing a mild purgative to prevent it from exciting; but in general the mercurial pill just mentioned is to be preferred.

When there is no chancre or bubo, no appearance in short of syphilitic infection, it would be improper to
Practice.

To administer corrosive sublimate, the mercurius calcinatus, or any other of the more acrid preparations of mercury.

After a gonorrhoea proceeding from venereal causes has been removed, another kind of running without pain, called the gonorrhoea mucosa, or gleet, sometimes remains. Sometimes it arises from a conflation and excoriatio of the urethra, and frequently it is the effect of an enlargement and diseased state of the prostate. In each of these cases, as the gleet is the effect of irritation, the cure will depend on the removal of the local disease that occasions it. But there is another species of gleet that seems to depend chiefly on relaxation. It is in general free from infection, and is most common in those who have had long and frequent gonorrhoeas. It is likewise often the effect of a debilitated habit, from severe purging, or a long continued use of mercurials. A discharge of this kind is more frequent in women than in men; or, at least, the fluent albus, after a gonorrhoea, will often be mistaken for a gleet.

When there is no reason to suspect remaining contagion, altringent injections will be of the greatest service. It will be necessary, at the same time, to attend to the health of the patient, by employing the Peruvian bark, chalybeate waters, cold bathing, and such other remedies as will tend to strengthen the phlegm: and indeed by the use of these, particularly by the Peruvian bark, such runnings are often successfully combated in those who from apprehension of dangerous consequences cannot be prevailed upon to employ injections. When there is no tendency to inflammation, the balm of copaiba may be prescribed with advantage in large doses. Dr. Simmons says he once saw a complaint of this sort removed by applying a blister to the perineum, after it had resisted a variety of other remedies. In the Medical Observations also we have an account of a gleet and incontinence of urine removed at once by a blister to the os facrum. In general, however, the other methods abovementioned will be sufficient to remove it, though sometimes it will continue for a long time in spite of all our endeavours to check it. — Other kinds of gonorrhoea, in which the femen itself is ejected, especially during sleep, may be cured by tonics and a mild cooling regimen.

Order V. Epischeeses.

Genus CXXII. Obstipatio. Costiveness.

Obstitution, Lin. 166. Vag. 128. Sag. 221.

Costiveness is sometimes occasioned by debility in dyspeptic persons, sometimes it is the effect of rigidity, and sometimes it is symptomatic of the colic. It may proceed from an excessive heat of the liver; drinking rough red wines, or other altringent liquors; too much exercise, especially on horseback: it may likewise proceed from a long use of cold infipid food, which does not sufficiently stimulate the intestines. Sometimes it is owing to the bile not depending to the intestines, as in the jaundice; and at other times it proceeds from diseases of the intestines themselves, as a palsy, spams, tumors, a cold dry state of the intestines, &c.

Excessive costiveness is apt to occasion pains of the head, vomiting, colics, and other complaints of the bowels. It is peculiarly hurtful to hypochondriac and hysterical persons, as it generates wind and other distressing symptoms.

Persons who are generally costive should live upon a moistening and laxative diet; as roasted or boiled apples, pears, flewed prunes, raisins, greuels with curants, butter, honey, sugar, and such like. Broths with spinach, leeks, and other soft pot-herbs, are likewise proper. Rye-bread, or that which is made of a mixture of wheat and rye together, ought to be eaten. No person troubled with costiveness should eat white bread alone, especially that which is made of fine flour. The best bread for keeping the belly soluble is what in some parts of England they call moliin. It is made of a mixture of wheat and rye, and is very agreeable to those who are accustomed to it.

Costiveness is increased by keeping the body too warm, and by every thing that promotes the perpiration; as wearing flannel, lying too long a-bed, &c. Intense thought and a sedentary life, are likewise hurtful. All the secretions and excretions are promoted by moderate exercise without doors, and by a gay, cheerful, sprightly temper of mind.

The drink should be of an opening quality. All ardent spirits, balsamic and altringent wines, as port, claret, &c. ought to be avoided. Malt liquor that is fine and of a moderate strength is very proper. Buttermilk, whey, and other watery liquors, are likewise proper, and may be drank in turns, as the patient’s inclination directs.

Those who are troubled with costiveness ought, if possible, to remedy it by diet, as the constant use of medicines for that purpose is attended with many inconveniences, and often with bad consequences. In time the custom becomes necessary, and generally ends in a total relaxation of the bowels, indigestion, loss of appetite, watling of the strength, and death.

The learned Dr. Arbuthnot advises those who are troubled with costiveness to use animal-oils, as fresh butter, cream, marrow, fat broths, &c. He likewise recommends the expressed oils of mild vegetables, as olive, almonds, pistaches, and the fruits themselves; all oily and mild fruits, as figs; decoctions of mealy vegetables; their lubricate the intestines; some sapoaceous substances which stimulate gently, as honey, hydromel, or boiled honey and water, unrefined sugar, &c.

The doctor observes, that such sapoaceous substances are proper for persons of dry astrabiliarian constitutions, who are subject to airdation of the belly and the piles, and will operate when stronger medicinal substances are sometimes ineffectual: but that such sapoaceous diet hurts those whose bowels are weak and lax. He likewise observes, that all watery substances are sapoaceous: that even common water, whey, four milk, and butter milk, have that effect. — That new milk, especially after milk, stimulates still more when it forms on the stomach: and that whey, turned four, will purge strongly. — That most part of fruits are likewise sapoaceous: and that some of them, as grapes, will throw such
MEDICINE.

Practice.

Epilepsies, such as take them immediately, into a cholera morbus, or incurable diarrhoea.

When the body cannot be kept open without medicine, gentle doses of rhubarb may be taken twice or thrice a week. This is not near so injurious to the stomach as aloe, jalap, or other drastic purges so much in use. Infusions of fenas and mana may likewise be taken, or half an ounce of tartarized alkali dissolved in water-gruel. About the size of a nutmeg of laudanum was taken twice or thrice a day, generally answers the purpose very well.

GENUS CXXIII. ISCHURIA.

Suppression of Urine.

This distemper is distinguished into various species, according as the seat of it is in the kidneys, the ureters, the bladder, or the urethra; and hence these species are named renales, ureterica, vesicalis, and urethralis.

Ischuria renales, or a suppression of urine from an affection of the kidneys, happens but rarely; however, Dr. Home in his clinical experiments describes such a case. In the end of December 1774, a man of a full habit, aged 35, was feized with shivering, coldness, and feverish cough. Three days after, his urine appeared high-coloured, was passed with pain, and in small quantity. About the 8th of January 1775, he was attacked with violent pains in the small of his back, over the whole abdomen, and in the ankles, with pain in the region of the liver when pressed. A general swelling was afterwards observed all over the body, but mostly in the ankles and abdomen, which lasted ten and a half months. These were attended with vomiting, bad appetite, and considerable thirst. When he entered the clinical ward (January 21st), the cough, sickness, and vomiting, had gone off, but the suppression of urine remained. The urine, which he had made, was passed with his ffools, so that Dr. Home saw it but once; and then it was pale, and had a white powder at bottom. The pains and swellings, which retained the impression of the finger, continued; he had a head-ache, and a very low pulse, beating only 48 strokes in a minute. He had taken a great many diuretic medicines before he came in. The day after his reception, he was feized with a spontaneous diarrhoea, which continued during the remainder of his life. Crystals of tartar were exhibited in doses of half an ounce each morning; at bed-time he took 20 drops of tincture of opium with a fperule of nitre, and continued this course for eight days without any increase of urine. The stronger and heating diuretics were then tried, as an infusion of juniper berries and pills of garlic; but they were attended with no sensible advantage. Whenever the pulse became so strong that he could bear bleeding, eight ounces of blood were taken away, which was easy. This was thrice repeated; he appeared eafier after each bleeding, his pulse bore it well, and the swellings and other symptoms abated. The heating diuretics, in this state, were given up; and a mixture of vinegar and nitre was substituted in their place, in each dose of which, taken every two hours, there was a copious of nitre. Measurements were applied to the region of the kidneys, and camphorated oil was afterwards rubbed on the part. He was ordered the semicium, which from a deficiency of water in the hospital at that time he got only once; and which then seemed to have a good effect, as he passed a full of urine when he was in it. Notwithstanding this, however, the diuretic continually gained ground; he became comatose, delirious, and died ten days after his admission. On diuresis, the kidneys were found of an irregular form; some watery vesicles appeared on their surface, containing black gritty particles like fine sand; and the lower part of the right kidney was considerably inflamed. The pylorus, part of the duodenum, and a considerable part of the small intestines, were much inflamed. In the abdomen were found about five pounds of fluid, and in the cavities of the thorax about half a pound. The lungs were a little inflamed, and full of small tubercles on their surface and in their substance; the heart was large, and a polypus in each ventricle. About six ounces of fluid were found in the pericardium: in the brain nothing preternatural appeared, except about an ounce of water in each ventricle.

Dr. Home seems to have been at a loss for the remote cause of this suppression of urine, which manifestly had its immediate origin from the kidneys having lost the power of performing their functions. He thinks the inflammation which appeared in the right kidney was scarce sufficient to have occasioned the diuretespersion, as the other would have supplied its place: for which reason also he thinks that the ischuria was owing to a general affection of the system; and that it was of an arthritic nature, the patient having been troubled with complaints of that kind for a long time before.

The indications of cure are, to exclude the stone as easily as possible, and prevent the breeding of others. If the patient be of a sanguineous temperament, Sydenham recommends to take away ten ounces of blood from
Medicine.

Practice.

325

Epistaxis from the affected side; and then to give the patient a gallon of poult-drink in which two ounces of marshmallow roots have been boiled, injecting at the same time an emollient glycerin. After the poult-drink has been vomited up, and the clyster returned, give a pretty large dose of an opiate. But if the patient be old or weak, or subject to nervous affections, bleeding may be omitted, especially if his urine at the beginning of the fit be coffee-coloured, and mixed with gravel; but as to other things, the cure is the same. — Huxham greatly recommends an emollient bath prepared of a decoction of marshmallow root, linseed, fennugreek seed, and flowers of chamomile, to which may be added a few white-poppy seeds.

By the use of this bath he says he has seen the most cruel fit of the gravel suddenly ended, when neither copious bleeding nor opiates had the least effect. Mild diuretics are also of service. Hoffman recommends dulcized spirit of nitre as proper to relax the spasm.

It is to be taken with suitable distilled waters and syrup of poppies; or in broth, with a few spoonfuls of oil of sweet almonds. Turpentine glyniers are also accounted very serviceable; and may be prepared by mixing with sufficient quantity of honey. The fand diuretics, or acetated alkalii, is much esteemed by some, when taken along with an opiate. But when the stone is too big to pass, Arbuthnot recommends a cool and diluent diet to hinder the further growth of it. Whey, infusio of linseed, decoction of marshmallows, and gently resolving diuretics, are also proper. To put a stop to the vomiting, balsamum traumaticum may be used with success when almost every other means have failed.

3. The ichuria vesicul is may arise from a stone in the bladder; and this indeed is the most common cause of it; but there are certain cases in which, though the usual quantity of urine, or perhaps more, be passed, the patient dies from the retention of a still greater quantity in the bladder. Of this Dr Home gives the following instances. A man of 58 years of age, of a strong spare habit, and never subject to the gravel, had, during the winter of 1777, a cough with expectoration, which went off in the beginning of 1778. About the 17th of February 1778 he felt some difficulty in passing his urine, and much pain about the region of the bladder. He continued in this way for ten days, after which he became easier on application of some medicines. The abdomen then swelled, and he had pains in his loins and thighs.

On the 3d of March he was admitted into the clinical ward: his abdomen was then swelled and tense; and an evident fluctuation was felt, which some that touched him thought was honorious and produced by wind. A tumor was discovered between the navel and spine of the os ilium on the left side, which gave him much pain, especially when pressed. This tumor became more easily felt after the swelling of the abdomen decreased, seemed round, and very near as large as the head of a child. It appeared very much on the left side; and when the patient lay on the right, and the tumor then became dependent. He passed urine frequently, and rather more in health, as it was computed at four pints a-day. It was always clear, and of a light colour. His body had a strong disagreeable smell; his skin was dry, belly bound, and his appetite entirely gone, so that he had hardly taken any food for 12 days. His legs swelled slightly for some days in the evening. His pulse was generally regular, sometimes lower than natural, and sometimes a little quicker; being once felt at 64, and another time at 52. He was often feized, especially after eating or drinking, with hicough; which increased and lasted till his death. On the 20th day of his disease, after some doses of squills, the general swelling of his abdomen fell; became much softer; and more distinctly discovered the swelling of the left side. The next day a vomiting came on; he became delirious, and died the day following. The body being opened, it appeared that the tumor which was so distinctly felt on the left side of the abdomen, was owing to a dilatation of the bladder with urine. Its fundus reached to about the division of the aorta into the iliacs; it entirely filled the pelvis, and contained between five and six pounds of urine of a pale colour. On examining the external surface, its neck, and the beginning of the urethra, were found to be surrounded with a chrosoity, which impeded the evacuation of the urine. The bladder itself was much thickened, but not more in one part than another. The ureters entered naturally; but were much thickened in their upper half near the kidney. The kidneys were somewhat enlarged; particularly the left, which had several watery vehicles on its external surface. These organs were not in their usual situation; but lay close on each side of the spine, and very near the aorta; so that the renal vessels were very short. What was very singular, the lower end of each rose over the spine, and they were united together by their membranes and sublimices, the aorta passing beneath the union.

The bladder had professed considerably on this part; and the peritoneum covering them was considerably thicker than natural. The lungs adhered every where to the pleura, and in some places very firmly; they were of a loose texture and black colour; and the veins of the lower extremities were turgid with blood. It does not appear that this patient got any medicines further than a few dried squills, which diminished the swellings and brought off much wind. He also got a mixture of musk, and afterwards of opium, for his hicough; but without success. His disease was mistaken for an ascites; and the catheter was not tried; but in another case the use of this instrument was apparently of more service than any internal medicines.

This last patient was about 90 years of age, and laboured under symptoms very similar to those already mentioned. When admitted into the clinical ward, he had the hypogastric region swelled, and difficulty of passing his water; but without pain, vomiting, or hicough. He had lost all appetite; was thirsty, and colitive. His pulse was 110, and weak. In the evening about three English pints of pale clear urine were drawn off by means of the catheter: the next day all the symptoms were gone off or abated. After this he continued to pass some urine, sometimes voluntarily, sometimes involuntarily and inefhible; but so much always remained behind, that his bladder was constantly full, unless when the urine was drawn off,
M E D I C I N E.

Episcopes

off, which was done twice every day. The urine was
sometimes pale, sometimes of a deep red colour; and
once there was some blood mixed with it, which
perhaps might have been occasioned by the catheter.
About the sixth day the urine was very putrid, with
much purulent matter at the bottom, and was
passed with more pain. About the 11th, the putrid
smell went off. The next day all the urine passed in-
sensibly except what was drawn off; and an hiccough,
though not very severe, had come on. In this way he
continued without fever, though frequently troubled
with the hiccough, especially during those nights in
which the urine had not been drawn off. A month
after admittance, the bladder, with the assistance of
the catheter, was almost entirely, though insufficiently
evacuated, and the hiccough had left him; he had no
other complaint but that of voiding his urine in-
sensibly, the natural effect of a cicatrized bladder, and
which was probably incurable. With this patient:
the hot bath and mercurials were tried, in order to
soften the cicatrix of the bladder, but without effect.

4. The icterus uræthralis arises from some tumour
stopping up the passage of the urethra, and thus
hindering the flow of urine. It is an uncommon dis-
temper, and generally follows a gonorrhœa. Dr Home
gives us an example of this also.—The patient was a
man of 60 years of age, who had laboured under a
gonorrhœa six months before, and which was stopped
by some medicines in two or three days. He felt
soon afterwards, a difficulty in passing his urine, which
gradually increased. About 10 days before his ad-
mittance into the clinical ward, it was attended with
pains in the glans, and arder urine; he had passed
only about eight ounces the day before his admission,
and that with very great difficulty; and the hypo-
gastric region was swelled and pained. On introduc-
ing the catheter, three pounds of urine were drawn
off, by which the pain and swelling were removed.
The instrument required force to make it pass the
neck of the bladder, and blood followed the opera-
tion; and the finger, introduced into the anus, felt a
hard tumour about its neck. He was treated with
mercurial pills and ointment, by which the swelling
about the neck of the bladder soon began to decrease;
but at the same time a swelling of the right testicle
appeared. He was vomited with four grains of
turbith-mineral, which operated gently; and here Dr
Home observes, that though these vomits are little

Since, from a mistaken notion of their severity, he
never saw them operate with more violence than other
vomits, or than he could have wished. The swelling
diminished in consequence of the vomits and some ex-
ternal applications; and the cure was completed by
bleeding and a decoction of meconem-root.

Genus CXXIV. Dysuria.

Dysurias, Sag. gen. 265. Lin. 57. Vsl. 164
Stranguria autorum.

A difficulty of making water may arise from many
different causes; as from some acid matter in the
blood, cantharides, for instance; and hence a stran-
gury very often succeeds the application of blisters.

In many cases it arises from a compression of some
of the neighbouring parts; of the uterus, for instance,
in a state of pregnancy. Or it may arise from a par-
modic affection of the bladder, or rather its sphincter;
or from an inflammation of these parts, or others near
them. Hence the disease is distinguished into so many
species, the cure of which depends upon the remedies
indicated by their different causes.

But the most common, as well as the most dangerous
species is that arising from a calculous concretion, or

Stone in the Bladder.

Dysuria calculosa, Sauv. fp. 12.

The signs of a stone in the bladder are, pain, espe-
cially about the sphincter; and bloody urine, in con-
sequence of riding or being jolted in a carriage; a ten-
fé of weight in the perineum; an itchiness of the glans
genis; slimy sediment in the urine; and frequent flop-
pages in making water; a tenesmus also comes on
while the urine is discharged: but the most certain
sign is, when the stone is felt by the finger intro-
duced into the anus, or by the catheter.

Causes, &c. It is not easy to say what the part-
cicular causes are that occasion the apparently earthly
particles of the fluids to run together, and form those
calculous concretions which are found in different parts
of the body, and especially in the organs for straining
off and discharging the urine.

The gout and stone are generally supposed to have
some affinity, because gouty people are for the most
part afflicted with the gravel. But perhaps this is
in part owing to their long confinement, and to the
lying on the back, which people who labour under
the gout are often obliged to submit to; since the
want of exercise, and this posture, will naturally fa-
avour the flagration of gross matters in the kidneys;
besides, there are many instances of people severely
afflicted with the stone for the greatest part of a long
life, who have never had the least attack of the
gout.

There is, however, good reason for believing, that
some farther connexion takes place between the two
diseases; and when treating of the gout we have al-
ready given some account of the opinion of an inge-
nious anonymous author, who has endeavoured to
prove, that both the one and the other depend on a
peculiar acid, the concreting or lithic acid, which is
always present in blood; and which may be precipi-
tated from thence by various causes, such as the intro-
duction of other acids, or the like. When thus precipi-
tated, he supposes it to produce the whole pheno-
mena of both diseases. The objections we formerly fta-
ted to his theory of gout, do not equally militate against
that of calculus; and it is at least certain, from the
best chemical analysis, that what are commonly called
urinary calculi, and have been considered as entirely
an earthly matter, consist principally of acid in a solid
state united only with a small proportion of earth or
mucus. We may, therefore, whether this hypothe-
sis be altogether well founded or not, justly view lithi-
fis as depending on the separation of an acid from
the blood.

Whatever may be the particular cause of the dis-
position
Practice.

position to lithiasis, the kidneys appear to be the most likely places for particles to concret or run together, because of the great quantity of blood which passes through the renal arteries, and which comes immediately from the heart, fraught with various newly-received matters, that have not undergone much of the action of the vesicles, and therefore cannot as yet be supposed to be thoroughly assimilated.

Anatomists who have carefully examined the kidneys in the human subject, particularly M. Bertin, inform us, that there are two sets of tubuli uriniferi; the one continued directly from the extremities of the renal artery, and the other springing from that vesicular texture which is conjunctive in the kidneys.

It is in this vesicular part of the kidney that we presume the particles of the concreting matter first agitate and coalesce: for it is hardly to be supposed, that such solid matters could be allowed to stop in the extremities of the renal arteries, since the blood, and the urine separated from it, must flow through these vesicles with great degrees of force and velocity; but in the intermediate vesicles the particles may lie, and then attracting each other, soon come to acquire sensible degrees of magnitude, and thus become sand or gravel. As long as this sand or gravel formed in the vesicular part of the kidney lies quiet, there will be no pain or uneasiness, until the concretions become large enough to press either on the adjoining tubuli, or on the blood-vesicles; then a sense of weight, and a kind of obscure pain in the loins, will be felt. But when the small pieces of concreting matter shall be dislodged and washed off by the force of the circulating fluids, or loosened by some sfammodic action of the moving fluids in these parts, they will in their passage create pain, raise different degrees of inflammation, or perhaps lacerate some blood-vesseils, and cause bloody urine. When these little concretions happen to be detained in the pelvis of the kidney, or any other place where a flow of urine continually passes, they soon increase in size, and become calculus, from the concretion of particles, which are attracted by the original bit of sand, which thus become the nucleus of a stone.

It is an opinion which Hippocrates first advanced, and which has been almost universally adopted by his followers, and has remained till lately uncontroverted, that the stone and gravel are generated by the use of hard water. And from this quality, which the waters of certain springs possess, of depositing a large earthy sediment, either in the aqueducts thro' which they are conveyed, or in the vesicles in which they are boiled or preferred, it was conjectured, that in passing through the kidneys, and especially whilst retained in the bladder, they would let fall their rougher particles, which by the continued apposition of fresh matter, connected by the animal gluten, and compactered by the muscular action of that organ, would in time form a calculus sufficiently large to produce a train of the most excruciating symptoms. And this reasoning a priori has been supposed to be confirmed by facts and experience; for not to mention the authority of Hippocrates, Dr Lister has observed, that the inhabitants of Paris are peculiarly subject to the stone in the bladder. Nicholas de Blegny has related the history of one who was dissected at Paris, in whom the pylorus, a great part of the duodenum, and the stomach itself, were found incrusted with a fomy matter, to the thickness of a finger's breadth. And it is well known, that the water of the river Seine, with which that city is supplied, is so impregnated with calcareous matter, as to incrustulate, and in a short time to choke up, the pipes through which it runs. But on the other hand it is objected, that the human calculus is of animal origin, and by chemical analysis appears to bear very little analogy to the fomy concretions of water; and though it be allowed, that more perceive are cut for the stone in the hospitals at Paris than in most other places; yet upon inquiry it is found, that many of those patients come from different provinces, and from towns and villages far distant from the Seine.

Dr Percival conjectures, that though this disease may chiefly depend upon a peculiar disposition to concret in the animal fluids, which in many instances is hereditary, and in no instances can with certainty be impu­ted to any particular cause; yet hard water is at least negatively favourable to this diathesis, by having no tendency to diminish it. The urine of the most healthy person is generally loaded with an apparently terrestrial matter, capable in favourable circumstances of forming a calculus; as is evident from the thick crust which it deposits on the sides of the vessels in which it is contained. And it seems as if nature intended by this exertion to discharge all the superfluous salts of the blood, together with those earthy particles, which are either derived from our aliment, and fine enough to pass thro' the ladtteals, though inappreciable by the powers of circulation, or which arise from the abrasion of the solids, or from the dissolution of the red globular part of our fluids. Now water, whether used as nature presents us with it, or mixed with wine, or taken under the form of beer or ale, is the great diluter, vehicle, and menstruum, both of our food, and of the saline, earthy, and excrementitious parts of the animal juices. And it is more or less adapted to the performance of these offices, in proportion to its degree of purity. For it must appear evident to the most ordinary understanding, that a menstruum already loaded, and perhaps saturated with different contents, cannot act so powerfully as one which is free from all sensible impregnation. Nor is this reasoning founded upon theory alone; for it is observed, that Malvern water, which lies from a spring in Worcestershire remarkable for its uncommon purity, has the property of dissolving the little fabulous stones which are often voided in nephritic complaints. And the solution too, which is a proof of its being complete, is perfectly colourless. Hence this water is drunk with great advantage in disorders of the urinary passages. And during the use of it the patient's urine is generally limpid, and seldom deposits any sandy sediment. Yet notwithstanding this appearance of transparency, it is certainly at such times loaded with impurities, which are so diluted and dissolved as not to be visible. For it is attended with a strong and fetid smell, exactly resembling that of asparagus. Hoffman mentions a pure, light, simple water in the principality of Henneberg, in Germany, which is remarkable for its efficacy in the stone and gravel; and a water of similar virtues was discovered not many years ago.
MEDICINE

Practi ce.

In nephritic cases, distilled water would be an excellent substitute for Malvern water, as the following experiment evinces.

Two fragments of the fame calculus nearly of equal weight, wereimmerfed, the one in three ounces of distilled water, the other in three ounces of hard pump-water. The phials were hung up close together in a kitchen-chimney, at a convenient distance from the fire. After 14 days maceration, the calculi were taken out, and carefully dried by a very gentle heat. The former, viz. that which had been immerfed in distilled water, was diminished in its weight a grain and a half; the latter had lost only half a grain.

It is the passage of these calculi from the kidneys down into the bladder, which occasions the pain, vomiting, and other symptoms, that constitute what is usually termed a fit of the gravel or stone.

When an inflammation is actually raised, the disease is known by the name of nephritis, and has been already treated of.

As soon as the stone passes through the ureter, and falls into the bladder, the pain and other nephritic symptoms ceases; and every thing will remain quiet, either till the stone be carried into the urethra, or until it has remained long enough in the bladder to acquire weight sufficient to create new difficulties.

If a stone happens to be smooth and of a roundish form, it may lie in the bladder and acquire considerable bulk before it can be perceived by the patient; but when it is angular, or has a rugged surface, even though it may be small in size, yet it seldom fails to raise pain, and occasion bloody urine, or the discharge of a slimy fluid, with tenesmus, and difficulty in making water.

There have been various attempts made to dissolve the stone; and there are certainly some articles which have this effect when applied to them out of the body; but the almost total impossibility of getting these conveyed to the kidneys, renders it extremely doubtful whether a solvent ever will be discovered. Of all the articles employed for this purpose, no one perhaps has had greater reputation than fixed alkaline salt in its medicinal state, particularly under the form of the aqua liti-ervica; but this being of a very acrid nature, it requires to be well heathed by means of some gelatious or mucilaginous vehicle. Veal broth is as convenient as any for this purpose; and accordingly it is used by those who make a secret of the caustic alkali as a solvent of calculus.

Mr Blackkie, who has taken much pains in this inquiry, has proved very satisfactorily, that Chitrick's nostrum is no other than soap-lees given in veal-broth, which the patients fend every day to the doctor, who returns it mixed up with the medicine, in a close vessel secured by a lock.

It is not every case, however, that either requires or will bear a course of the caustic alkali. Some calculi are of that soft and friable nature, that they will disolve even in common water; and there are cases wherein it appears that the confluent use of some very simple decoction or infusion of an insignificant vegetable, has brought away large quantities of earthy matter, in flakes which apparently have been united together in layers to form a stone. Dr Macbride assures us, that a decoction of raw coffee, only 30 berries in a quart of water, boiled till it acquired a deep greenish colour, taken morning and evening to the quantity of eight or ten ounces, with ten drops of sweet spirit of nitre, had the powerful effect of bringing away, in the course of about two months, as much earthy matter in flakes as filled a large tea-cup. The patient was far advanced in years; and, before he began this decoction, had been reduced to great extremities by the continuance of pain and other distressing symptoms: he was purged occasionally with oleum ricini.

Very lately the alkali in a mild state, and in a different form, has been much used by many calculous patients and with great advantage, under the form of what is called alkaline aerated water. For the introduction of this medicine, or at least for its extensive use, we are chiefly indebted to that ingenious physician Dr William Falconer of Bath. He has lately published an account of the Aqua Mephitica Alkalis, or Solution of fixed alkaline falt, faturated with fixable air, in calculous disorders; which contains a number of cases strongly supporting the benefit to be derived from it. But whether the good effects obtained in these instances are to be explained from its operating as a solvent of calculus, seems to be extremely doubtful.

There are indeed cases in Dr Falconer's treatise of patients in whom, after using it for a considerable time, no stone could be detected by sounding, although it had been discovered in that way before they began the employment of it. But in many instances, the relief has been so sudden, that it may be concluded, that, notwithstanding the cafe obtained, the calculus still remained. In such cases, it probably removed from the urine that quality by which it gives to the calculus fresh accretions, producing that roughness of its surface by which it is chiefly capable of acting as a Himulus. For the distrefling symptoms resulting from stone, are more immediately to be attributed to the inflammatory and spasmotic affections which it induces; and when its surface is least capable of operating as a Himulus, these of course will be least considerable. It is therefore not improbable, that this remedy produces relief, by preventing fresh additions, being made to the calculus.

An infusion of the seeds of daucus fylvestris sweetened with honey, is another simple and much celebrated remedy;
remedy: it has been found to give considerable ease in cases where the stomach could not bear any thing of an acrid nature: the leaves of the *wu urf* were strongly recommended by the late very celebrated De Haen; and, whatever its way of operating may be, seems to have been productive of good effects in some instances. There is no reason to believe that it has any influence in dissolving calculus; and indeed it seems to be chiefly useful in these instances where ulcerations take place in the urinary passages.

In the *Edinburgh Medical Commentaries*, vol. 3, we have an account of a method used by the inhabitants of Arabia Petraea for curing the stone, to which they are very much subject, and which the author (an English gentleman of experience and candour) affirms he has frequently performed with never-failing success. By means of a catheter they inject into the bladder a weak ley of alkali with the purified fat of a sheep's tail, and a proper quantity of opium all put together. Their catheters are made of gold; and in performing the operation they introduce them quite into the bladder; so that the composition is safely conveyed to the stone without hurting any other part. But when a stone is situated in the kidney, they have no method of cure.

If this method of curing by injection could be safely practiced, it would no doubt greatly have the advantage over that of taking alkalis by the mouth, where the medicine is not only much weakened, but the constitution of the patient runs the risk of being greatly injured. But from some experiments mentioned in the second volume of the *Medical Transactions*, it appears that the human calculi are very different from one another in their natures. Some, for instance, will easily yield to an alkaline menstruum, and very little to an acid; while others are found to resist the alkali, and yield to the acid; and some are of such a compact nature, that they yield neither to acids nor alkalis. An attention, however, to the fragments, stones, or films, which the stone may cast off, and also to the contents and sediment of the urine, may lead to the discovery of what solvent is proper, or whether the stone can be dissolved by any. To use either alkalis or acids improperly may be hurtful; though there may be such kinds of calculi as demand the alternate use of acids and alkalis: may, there may be found calculi of opposite kinds in the same subject.

In such cases as will not allow us to think of dissolving the flinty concretions, and where the only scheme is to palliate and procure ease from time to time, little more can be done than to keep the bowels open occasionally by some gentle cathartic, and wash off as much of the loose gravelly matter and stone as can be removed by such mild diuretic infusions and decoctions as shall be found to pass freely and fit well on the stomach. Persons afflicted with the stone should be careful in respect of their diet, and studiously avoid all heavy and flatulent food, as well as high sauces that are apt to turn rancid. For the same reason, butter and acids are to be shunned; for these often create heart-burning, and every thing that offends the stomach rouses the nephritic pain: such is the sympathy that obtains between the digestive and the uropoietic organs.

Vol. XI.

There have been surgeons bold enough to entertain an idea of cutting even into the kidney, in order to extract a stone: this, however, except in cases where an abscess has been formed, and nature points out the way is merely chimerical. But cutting into the bladder for the same purpose, is an ancient and well-known operation, and often crowned with successes. A description, however, of this operation belongs to the article *Surgery*, to which we refer; and here shall only make this remark, that a surgeon should never begin his operation, until he and his assistants are perfectly satisfied, from actually feeling the stone, that there is one in the bladder; because it has sometimes happened, that when the incision has been made, no stone could be found: and the patient having died in consequence of the operation, and the body being opened, it has appeared that the symptoms which occasioned the belief of a stone in the bladder arose from some other cause.

When a dysuria proceeds from any acrimonious matter thrown into the blood, it may be readily cured by biching, emollient cyphets, cooling and diluting drinks with gum, arabic or gum tragacanth, linseed tea, or the warm bath. When it arises from inflammations of the bladder or parts adjoining to it, we are to regard it only as a symptomatic affection; and the remedies used to remove the primary disease will also remove the dysuria. Sometimes it may arise from an ulcer of the bladder; in which case it is generally incurable; a mild nutritious diet will, however, protract the patient's life.

**Agenesis, Vog. 283.**

This impediment proceeds generally from obstructions in the urethra, either by tumors in itself, or in the cavernous bodies of the penis; in which case the treatment is the same as in the itchuris urethralis; sometimes it is owing to a kind of epileptic fit which seizes the man in the venereal act; and sometimes the semen, when excited from the proper receptacles, is again absorbed by them, or flows into the bladder and is expelled along with the urine. The last case is very difficult, or indeed impossible to cure; as proceeding from scirrhous, or other indissoluble tumors of the vesicoumamentum, or the neighbouring parts. In some it proceeds merely from too violent an eredion: in which case emollient and relaxing medicines will be of service; and we have an example of a cure performed by means of these in the first volume of the *Edinburgh Medical Essays*.

MEDICINE.

APPENDIX.

ANGINA PECTORIS.

Dr Heberden was the first who described this disease, though it is extremely dangerous, and, by his account not very rare. It occurs those who are subject to it when they are walking, and particularly when they walk soon after eating, with a most disagreeable and painful sensation in the breast, which seems to threaten immediate death; but the moment they stand still, all the uneasiness vanishes. In all other respects the patients at the beginning of this disorder are well, and have no shortness of breath; from which the angina pectoris is totally different. After it has continued some months, the fits will not cease instantaneously on standing still; and it will come on not only when the patients are walking, but when they are lying down, and obliges them to rise up out of their beds every night for many months together. In one or two very invasive cases, it has been brought on by the motion of a horse or carriage, and even by swallowing, coughing, going to sleep, speaking, or by any disturbance of mind. The persons affected were all men, almost all of whom were above 50 years of age, and most of them with a short neck and inclining to be fat. Something like it however, was observed in one woman, who was paralytic; and one or two young men complained of it in a flight degree. Other practitioners have observed it in very young persons.

When a fit of this sort comes on by walking, its duration is very short, as it goes off almost immediately upon stopping. If it comes on at night, it will last an hour or two. Dr Heberden met with one in whom it once continued for several days; during all which time the patient seemed to be in imminent danger of death. Most of those attacked with the delirium died suddenly; though this rule was not without exceptions; and Dr Heberden observed one who sunk under a lingering illness of a different nature.

The azileni is usually pointed to as the seat of this malady; but it seems as if it was under the lower part of that bone, and at other times under the middle or upper part, but always inclining more to the left side; and in many cases there is joined with it a pain about the middle of the left arm, which appears to be seated in the biceps muscle.

The appearance of Dr Heberden's paper in the Medical Transactions very soon raised the attention of the faculty, and produced other observations from physicians of eminence; namely, Dr Fothergill, Dr Wall of Worcester, Dr Haygarth of Chester, and Dr Percival of Manchester. It also induced an unknown sufferer under the disease to write Dr Heberden a very sensible letter, describing his feelings in the most natural manner; which, unfortunately, in three weeks after the date of this anonymous epistle, terminated in a sudden death, as the writer himself had apprehended.

The youngest subject that Dr Fothergill ever saw was afflicted with...
Appendix.

MEDICINE.

Angina Pectoris.

afflicted with this disorder was about 30 years of age; and this person was cured. The method that succeeded with him was a course of pills, composed of the mias of gum pill, soap, and native cinnauber; with a light chalybetic bitter: this was continued for some months, after which he went to Bath several successive feasons, and acquired his usual health: he was ordered to be very sparing in his diet; to keep the bowels open; and to use moderate exercise on horseback, but not to take long or fatiguing walks.

The only symptom in this patient that is mentioned, was a frieure about the chest, which came on if he was walking up hill or a little faster than ordinary, or if he was riding a very brisk trot; for moderate exercise of any kind did not affect him: and this uneasy sensation always obliged him to stop, as he felt himself threatened with immediate death if he had been obliged to go forward.

It is the sharp constrictive pain across the chest, that (according to Dr Fothergill's observation) particularly marks this singular disease; and which is apt to supervene upon a certain degree of muscular motion, or whatever agitates the nervous system.

In such cases as fell under the inspection of Dr Fothergill, he very seldom met with one that was free from pain and at rest; but Dr Heberden observes, that the pulse is, at least sometimes, not with the only morbid change, that the pulse appears white, not unlike a ligament; as it should seem, in both cases, from the vessels and force of the spasms squeezing the blood out from the cavities.

If this hypothesis be allowed, we must conclude that the spasm can only take place in an inferior degree, as long as the patient continues to survive the paroxysm; and accordingly, as far as could be traced, the persons who have been known to labour under this disease have in general died suddenly.

The differences also show, that whatever may be the true seat of the spasm, it is not necessary for the bringing of it on, that the heart, or its immediate appendages, should be in a morbid state; for in three out of the six that have as yet been made public, these parts were found in a found state.

On opening the body of the poor gentleman who wrote the letter to Dr Heberden, "upon the most careful examination, no manifest cause of his death could be discovered; the heart, in particular, with its vessels and valves, were all found in a natural condition."

In the case communicated by Dr Percival to the publishers of the Edinburgh Medical Commentaries, "the heart and aorta descended were found in a found state."

And in Dr Haygarth's patient, "on opening the thorax, the lungs, pericardium, and heart, appeared perfectly found." Not to mention Dr Fothergill's patient (R. M.), in whose body the only morbid appearance about the heart was a small white spot near the apex. So that the cause, whatever its nature might have been, was at too great a distance, or of too subtle a nature, to come under the inspection of the anatomist. But there was a circumstance in two of the subjects that is worthy of remembrance; and which shows that the crafts of the blood, while they were living, must have been greatly injured, namely, its not coagulating, but remaining of a cream-like nature; but though it should be admitted, that the whole difference in these cases arise from spasm, it may not be so easy to ascertain the particular muscles which are thus affected.

The voluntary sense of strangling or choking, which flows the circulation through the lungs to be interrupted during the height of the paroxysm; and the peculiar constrictive pain under the sternum, always inclining (according to Dr Heberden's observation) to the left side; together with that most disturbing and alarming sensation, which, if it were to increase or continue, threatens an immediate extinction of life; might authorize us to conclude that the heart itself is the muscle affected: the only objection to this idea, and, if it had been constantly observed, it would be insurmountable, is, that the pulse is not always interrupted during the paroxysm. The appearances in two of the differences, favour the opinion that the spasm affects the heart; as in one subject the left ventricle (and, though it be not mentioned, we may presume the right one also) was found as empty of blood as if it had been washed; and in another, the substance of the heart appeared whitish, not unlike a ligament; as it should seem, in both cases, from the vessels and force of the spasms squeezing the blood out from the cavities.
does not appear: that any considerable advances have been made towards the actual cure of this anomalous

The very judicious and attentive Dr Heberden (to whom the public are highly indebted for first making the disorder known) confesses, that bleeding, vomits, and other evacuations, have not appeared to do any good: wine and cordials, taken at bed-time, will sometimes prevent or weaken the fits; but nothing does this so effectually as opiates: in short, the medicines usually called nervos or cordial, such as relieve and quiet convulsive motions, and invigorate the languishing principle of life, are what he recommends.

Dr Wall mentions one patient, out of the 12 or 13 that he had seen, who applied to him early in the disease, and was relieved considerably by the use of antimonial medicines joined with the fiddle gums: he was still living at the time the Doctor wrote his paper, (November 1772), and going about with tolerable ease. Two were carried off by other disorders; all the rest died suddenly.

Dr Fothergill's directions are chiefly calculated with the view to prevent the disorder from gaining ground, and to alleviate present distress. Accordingly he enjoins such a kind of diet as may be most likely to prevent irritability: in particular, not to eat voraciously: to guard against irritability: in particular, not to eat voraciously: to guard against

Dr Fothergill's directions are chiefly calculated with the view to prevent the disorder from gaining ground, and to alleviate present distress. Accordingly he enjoins such a kind of diet as may be most likely to prevent irritability: in particular, not to eat voraciously: to guard against irritability: in particular, not to eat voraciously:

_"A. B. a tall, well made man: rather large than otherwise; of healthy parents, except that there had been a little gout in the family; temperate; being very attentive to the business of his trade (that of a watch-maker), led a life uncommonly sedentary; had, from his boyhood upwards, been remarkably subject to alarming inflammations of this throat, which pleased him, at least, once in course of the year; in all other respects well.

In 1767, (then 48 years of age), he was taken, without any evident cause, with a sudden and very distressing throbbing under the sternum. It soon afterwards increased, and returned upon him every third or fourth week, accompanied with great anxiety, very laborious breathing, choking, a sensation of fulness and distension in the head, a bloated and flushed countenance, turgid and watery eyes, and a very irregular and unequal pulse. The paroxysm invaded, almost constantly, while he was sitting after dinner; now and then he was seized with it in the morning, when walking a little faster than usual; and was then obliged to stop, and rest on any object at hand. Once or twice it came on in bed; but did not oblige him to fit up, as it was then attended with no great difficulty in breathing. In the afternoon fits his greatest ease was from a supine posture; in which he used to continue motionless for some hours, until, quite spent and worn out with anguish, he dropped into a slumber. In the intervals between these attacks, which at length grew so frequent as to return every fourth or fifth day, he was, to appearance, in perfect health.

"Thus matters continued for more than two years; and various anti-paesthesiaes were ineffectually tried for his relief. In 1769, there supervened a very sharp constrictory pain at the upper part of the sternum, stretching equally on each side, attended with the former symptoms of anxiety, dysphoria, choking, &c. and with an exciting cramp, as he called it, that could be covered with a crown-piece, in each of his arms, between the elbow and the wrist, exactly at the infection of the prominent teres; the rest of the limbs was quite free. The fits were sometimes brought on, and always exacerbated, by any agitation of mind or body. He once attempted to ride on horseback during the paroxysm; but the experiment was not approving fatal to him. The difference of season or weather made no impression upon him. Still, in the intervals, his health was perfectly good; except that his eyes, which before his illness were remarkably strong and clear, were now grown extremely tender; and that his sight was much impaired. He had no flatulence of stomach, and his bowels were regular.

"In this situation, February 22, 1770, he applied to me for assistance. I had seen, I believe, eight or ten of these frightful cases before. Two of the patients dropped dead suddenly. They were men between 40 and 50 years of age, and of a make somewhat flabby. The fate of the others I was not informed of; or, at least, cannot now recollect.

"Having found the total inefficacy of blisters and the whole class of nervous medicines in the treatment of this anomalous fits, I thought it right to attempt the correcting or draining off of the irritating fluid in the cafe now before us. To this purpose, I ordered a mixture of lime-water with a little of the compound juniper-water, and an alternative proportion of Huxham's antimonial wine: I put the patient on a plain, light, imperishable diet; and restrained him from all vile, flatulent, and acrimonious articles. By purusing this course, he was soon apparently mended; but after he had persifled regularly in it for at least two months, he kept for some time at a stand. I then ordered a large infus to be opened on each of his thighs. Only one was made. However, as soon as it began to discharge, his amendment manifestly increased. The frequency and severity of the fits abated considerably; and he continued improving gradually, until, at the end of 18 months he was restored to perfect health; which he has enjoyed, without the least interruption, till now, except when he has been tempted (perhaps once in a twelvemonth) to transgress rules, by making a large meal on salted meat, or indulging himself in ale or rum-punch, each of which never failed to dis-order
order him from the beginning of his illness: and even on these occasions he has felt no more than the lightest motion of his former sufferings; insomuch that he would despise the attack, if it did not appear to be of the same flocks with his old complaint. No other cause has had the least ill effect on him.

"Though rum was constantly hurtful, yet punch made with a maceration of black currants in our vulgar corn-spirit, is a liquor that agrees remarkably well with him.

"He never took any medicine after the issue began to discharge; and I have directed that it shall be kept open as long as he lives. The inflammations of his throat have disappeared for five years past: he has recovered the strength and clearness of his sight; and his health seems now to be entirely restored.

Dr Macbride, in a letter to Dr Duncan, published in the Edinburgh Medical Commentaries, gives the following additional observations on this disease.

"Within these few weeks I have, at the desire of Dr Smyth, visited, three or four times, a very ingenious man who keeps an academy in this city, of about 34 years of age, who applied to the Doctor for his advice in January last.

"I shall give you his symptoms as I had them from his own mouth, which appear to me to mark his case to be an anginapectoris, and as deplorable as any that I have read of. It was strongly distinguished by the exquisite constrictive pain of the sternum, extending to each of his arms as far as the insertion of the deltoid muscle, extreme anxiety, laborious breathing, strangling, and violent palpitation of the heart, with a most irregular pulse. The paroxysms were so frequent, that he scarcely ever escaped a day, for six or seven years, without one. They were usually excited by any agitation of mind or body, though flight. He had clear intervals of health between the fits. The dieterper seems hereditary in him, as he says his father was affected in the same manner some years previous to his death. He has a strong, guilty taint, which never showed itself in his limbs; and he has led a life of uncommon sedentaries, from intense application to the mental and mechanical work of mind, and passion, even from his boyish years. These circumstances may, perhaps, account for his having been taken with this disease at so early an age as 17.

"A large issue was immediately opened in each of his thighs. In a month afterwards he began to mend, and has gone on improving gradually. He has now been totally free from them for six years past."

The PUERPERAL, or CHILD-BED FEVER.

This species of fever, as its name imports, is peculiar to women in child-bed; and is usually the most fatal of all the disorders to which the sex is liable. But, notwithstanding the prevalence of it in all ages, its real nature has remained, to the present time, a subject of much dispute and uncertainty. The critical period of its invasion, when febrile commotions are apt to be excited by various accidents, and equivocal symptoms which accompany it, have even afforded room for questioning whether it be a primary or a secondary disease. Some writers have considered it as proceeding entirely from an inflammation of the uterus; others have imagined it to be the consequence of an obstruction to the secretion of the milk; while the greater number has been inclined, for reasons equally if not more plausible, to impute it to a supposition of the lochia. If we examine this fever attentively, however according to its natural course, and independently of all the accidental concomitant symptoms with which it is not essentially connected, we may safely pronounce it to be a primary disease of a particular character, and perhaps not the necessary consequence of any of the causes abovementioned.

This fever is most generally incident to women within 48 hours after delivery, though it may supervene on the fourth or fifth day, and sometimes considerably later. It is preceded, like other fevers, by a rigor, which is commonly violent; and, when happening during the time of labour, may be confounded with the pains of parturiency. In its earlier stage it is attended with the signs of inflammation. A great pain is felt in the back, hips, and the region of the uterus; which, in the part last mentioned, is accompanied with the sense of heat and throbbing. A sudden change in the quality or quantity of the lochia now also takes place; the patient is frequently troubled with a tenesmus; and the urine, which is very high coloured, is discharged in small quantity and with pain. At the first attack of the fever, the woman is generally feized with vomiting of porridge matter, as in the cholea morbus, to which disfaste it then bears a strong resemblance. But instead of this symptom, there is sometimes only
PUERPERAL FEVER.

A nausea, or loathing at the stomach, with a disagreeable taste in the mouth. The belly swells to a considerable bulk, and becomes susceptible of painful sensations from the slightest impression. The tongue is generally dry, though sometimes moist, and covered with a thick brownish fur. When the fever has continued a few days, the symptoms of inflammation usually subside, and the disease acquires a more putrid form. At this period, if not at the very beginning of the disorder, a bilious or putrid diarrhoea, of a dangerous and obnoxious nature, supervenes, and accompanies it through all its future progress; each motion to stool being preceded by a temporary increase, and followed by an alleviation of pain. The patient usually nauseates all kind of food and drink, except what is cold and acidulated. A brown or blackish froth, the consequence of putrid exhalations, adheres to the edges of the teeth; a troublesome hicough is at length produced, which greatly exacerbates the pains of the abdomen; petechiae or vibices also appear, with sometimes a miliary eruption, but which produces no mitigation of the disease. Through the whole course of the fever the patient is affected with great anxiety and dejection of spirits.

Such in general is the course of the puerperal fever; the symptoms of which, however, may be often varied according to the constitution of the patient, the degree of the disease, and its earlier or later invasion. When the woman is naturally weak, or her strength has been greatly reduced by longcontinued evacuations after delivery; when the disease is violent, and immediately follows that period; its progress and termination are proportionably rapid and fatal. In such unfortunate circumstances, many have been known to expire within 24 hours from the first attack of the disease; nay, there are some instances where the rigor has concluded the scene. The catastrophe, however, is most generally suspended for some days; and the number of these is variable, though the 11th from commencement of the fever may justly be fixed as the period which is usually decisive. In whatever stage of the disease an unfavourable termination may happen, it would seem as if the commencement of the puerperal fever was not marked by any critical renovation of the fever, as depending on an alteration of the humors; but that the cure is gradually effected, either by a spontaneous vomiting, or a long-continued discharge by stool of that putrid matter, the existence of which in the stomach is usually evinced at the first attack of the disease. The most unfavourable prognostic, therefore, arises from such a weakness of the patient as renders her unable to support so tedious an evacuation as that by which the fever is overcome. When the lochia return to their former state, when the swelling and tenderness of the abdomen abate, and there is a moisture on the skin, we have reason to hope for a happy termination of the disease.

Though the puerperal fever may generally be ascertained from the description which has been given, and chiefly by that remarkable tenderness of the abdomen; which particularly distinguishes it; yet, as some of its symptoms may be confounded with those arising from other diseases, and which require a different method of cure, it will be proper to mention here the circumstances whereby it may be known with greater certainty.

The pains of the abdomen, attending the child-bed fever, may be distinguished from those called after-pains, by their uninterrupted continuance through the course of the disease, though sometimes they suffer exacerbations; whereas, in the latter, they often totally intermit. They are also distinguishable by the absence of fever with concomitant symptoms in the one, and their evident existence in the other.

Many circumstances evince a dissimilarity between the puerperal and miliary fevers, notwithstanding the symptoms of anxiety and oppression are common to both; infomuch that the nature of the approaching disease may be ascertained at the very commencement of its attack. In the puerperal fever the rigor is more violent, of longer duration, and not interrupted, as in the other. The pulse is fuller and stronger; the skin is more hot; and the tongue, whether moist or dry, though generally the latter, is not of a white, but brownish appearance; and the urine is also of a more coloured. Eruptions, which are critical in miliary fevers, procure no mitigation of the puerperal fever, and cordials generally increase it.

When the original attack of the puerperal fever happens to coincide with the febrile commotion which is excited in child-bed women by the milk, the nature of it may at first be misapprehended; but the concomitant symptoms, and greater violence of the disease, must in a short time dissipate such an error.

From all the most accurate accounts of this disease, and from the period at which it generally commences, there seems reason to conclude, that it owes its rise more immediately to accidents after delivery. For it is allowed that it may follow a labour under the best and most favourable circumstances, though endeavours to dilate the os internum are supposed frequently to produce it. The more immediate causes generally assigned by authors are a stoppage of perspiration, the too free use of spices, and the neglect of procuring floths after delivery; sudden frights, too hasty a separation of the placenta, and binding the abdomen too tight. The putrid appearance, however, which this disease so soon assumes, affords ground to suspect that the predisposing cause of it is a vitiated state of the humors; for it is generally observed to be most prevalent in an unhealthy season, and among women of a weak and febrotic constitution.

Within these few years this fever has been treated of by several writers, most of whom have differed from each other in their sentiments of the nature of the disease. The first in the order of publication is Dr Dennman, who seems to be of opinion, that it may derive its origin either from a redundancy or too great acrimony of the bile, the secretion of which appears to be much interrupted in the time of gestation. In Dr Manning's treatise on this fever, he mentions it as being highly probable that such a cause contributes greatly to produce the disease, especially where the putrid tendency of the humors is increased by unwholesome air and diet.

It has likewise been the fate of the puerperal fever, that no disease has more divided the sentiments of physicians in regard to the method of cure. The apparent
rent indications and contra-indications of bleeding, and other remedies, arising from the complication of inflammatory and putrid symptoms; the equivocal appearance of the vomiting and purging, as whether they be critical or symptomatical; and the different causes whence symptoms similar to each other may arise in pregnant women; all these circumstances concur to involve the subject in great obscurity and illusion. If we carefully attend to the several characteristics of the disease, however, so as to be able to distinguish it from every other puerperal complaint, and observe at the same time the usual manner of its declension, our judgment may be guided in the method of cure by the salutary efforts of nature. But, in order to obtain a clearer view of the genuine indications, it will be proper to consider them under the several lights in which they have been generally agitated by authors.

One of the most essential points to be ascertained in the course of the child-bed fever, respects the propriety of bleeding. A free use of the lancet has been generally regarded as the most successful expedient in practice; and there are some instances of critical haemorrhagies which would seem to confirm its utility. But Dr Denman thinks we may safely affirm from experience, that for one who will be benefited by large bleedings, a much greater number will be injured, and that even almost irretrievably. Nor can this seem surprising, when we consider the situation of child-bed women. In most, the evacuations consequent upon delivery are sufficient to diminish any undue superabundance of the fluids; and if, as frequently happens, the disease be produced by too haughty a separation of the placenta, the consequence of which is generally a very copious discharge of blood, we cannot suppose that nature will be affiicted in overcoming the febrile commotion, by the farther evacuation of the vital fluid, through the defect of which she is now rendered unequal even to the ordinary support of the animal economy. We may appeal to every practical physician, how much he has known the pulse to sink, and what a train of nervous symptoms he has observed to succeed an excess of the discharge abovementioned.

Besides, it is an axiom in phitie, that a remedy which cures any disorder, will always prove sufficient to prevent it; and therefore, if bleeding were the proper cure in the child-bed fever, the disease ought to have been prevented by a large evacuation of blood, when that happened previous to its seizure. Experience, however, in this, as in all other diseases, is the only unerring guide we can follow; and whoever regulates his practice by fact and observation, will be convinced that bleeding, especially in a larger quantity, is, in general, very far from being attended with success. Bleeding is seldom proper, except in women of plethoric constitutions, and in whom the signs of inflammation rise high. Nor even in such patients ought it to be repeated without great caution, and the existence of strong indications. Bleeding, when used in proper circumstances, may unquestionably palliate the fever; but that it often shortens the duration of it, appears to be a matter of much doubt. On this account the practice becomes still more inquisitive and exceptionable, when we consider that by venefaction improperly used the person's strength may be so far reduced as not to support the tedious loofeness by which the disease is generally carried off. Though bleeding, however, ought in general to be used with great caution, there are certainly many cases in which it is both necessary and advantageous.

The genuine nature and effects of the looseness in this disease, is another controverted point of the highest importance, and which merits the most attentive inquiry. Physicians, observing that women who die of the puerperal fever are generally molested with that evacuation, have been induced to consider this symptom as of the most dangerous and fatal tendency; and what, therefore, we should endeavour by every means to restrain. In this opinion, however, they would seem to have been governed by too partial an observation of facts. For experience certainly authorizes the assertion, that more women appear to have recovered of the child-bed fever, through the intervention of a diarrhoea, than have been destroyed by that cause. It is also considered, that purging is usually almost the only sensible evacuation of the more advanced state of the disease, and that which accompanies it to its latest period, we shall have the strongest reason to think that it is critical rather than symptomatical, and ought therefore to be moderately supported, instead of being unwarily restrained. Nay, the advantage which is found to attend vomiting as well as purging, in the earlier stage of the disease, would seem to evince that the matter discharged by these evacuations is what chiefly foments the disease. Emetics and purgatives, therefore, in the opinion of Dr Manning, are the only medicines on which any rational dependence is to be placed in the fever; at least, they are certainly such as are found the most successful. It is an established rule in practice, to prescribe a vomit at the beginning of every fever attended with any nausea or loathing of the stomach, and where there is not any reason to apprehend an inflammation of that organ. Nor does the state of child-bed women afford the smallest ground for prohibiting our recourse to the same expedient in answering a similar indication.

It is so seldom a physician is called during the rigor preceding the puerperal fever, that he has few opportunities of trying the effects of remedies in that early stage of the disease. When such occur, however, we should endeavour as much as possible to abate and shorten that period, as the succeeding fever is generally found to bear a proportion to the violence and duration of it. For this purpose, warm diluting drinks should be plentifully used, with a small quantity of volatile spirits or brandy. When Dr Manning apprehended such an accident, he sometimes ordered the nurse to give immediately a diph or two of warm vinegar, taking care that it was not too strong, which is a caution that ought always to be remembered; for though a freer use of the more cordial and spiritual kinds of liquors might perhaps soon abate the rigor, there is danger to be feared from their influence on the approaching fever, especially in women of a strong and healthy constitution. In all cases, warm applications to the extremities, such as heated bricks, towels, or toasted grains in a linen bag, may be used with perfect safety, and some advantage.

When the hot fit is advanced, the first thing Dr Manning orders is some emollient injection, as chicken-

Puerperal Fever.

water, or water and milk, which ought to be frequently repeated through the course of the diseased. These prove beneficial, not only by promoting the discharges from the intestines, which seems in fact to be the solution of the disease; but also by acting as a kind of fomentation to the uterus and adjacent parts. With this intention they are particularly serviceable when the lochia are suppressed. Great care, however, is requisite in administering them, on account of the tenderer and inflammatory disposition, which at that time renders the parts in the pelvis extremely susceptible of pain.

The next step in the method of cure ought to be to promote the discharge of the morbid matter both by the stomach and intestines. This intention is best answered by the remedy prescribed by Dr. Denman, of which the following is the receipt.

R. Tartar, emetic, gr. ii.

Of a powder thus prepared, Dr. Denman gives from two to six grains, and repeats it as circumstances require. If the first dose do not procure any sensible operation, he repeats it in an increased quantity at the end of two hours, and proceeds in that manner; not expelling any benefit but from its sensible evacuation.

Should the disease be abated, but not removed, (which sometimes happens), by the effect of the first dose, the same medicine must be repeated, but in a less quantity, till all danger be over. But if any alarming symptoms remain, he does not hesitate one moment to repeat the powder, in the same quantity as first given; though this be seldom necessary, if the first dose operates properly.

It is to be observed, says Dr. Denman, that as the certainty of cure depends upon the proper repetition of the medicine, the method of giving it at stated hours does not appear eligible. If the first dose produce any considerable effect by vomiting, procuring stools, or plentifully sweating, a repetition of the medicine in a less quantity will seldom fail to answer our expectations; but great judgment is required in adapting the quantity first given to the strength of the patient and other circumstances. We are not to expect that a disease which from the first formation carries so evident marks of danger, should infinitely cease, even though a great part of the case be removed.

Frequent doses of the saline draughts ought also to be given, which not only promote the evacuation by the intestines, but likewise increase the salutary discharges of urine and perspiration. These medicines are particularly serviceable in subsisting the remains of the fever, after its violence has been broken by the more efficacious remedies abovementioned; but when they are used even in the decline of the disease, gentle laxatives of rhubarb and magnesia, as advised by Dr. Denman, ought to be frequently interposed, since, as he justly observes, without stools we can do little service.

Notwithstanding the discharge by the intestines appears to have the most salutary effect in this disease, yet when the stomach has not been properly unloaded of offensive matter, though a great nausea and sickness had indicated the expediency of such an evacuation at the beginning of the fever, the continuance of the looseness is sometimes so long protracted as in the end to prove fatal. In this alarming state of the disease, when the stools are very frequent and involuntary, and all appearances threaten danger, Dr. Denman says, that a glass of chicken-water injected every one, two or three hours, or as often as possible without fatiguing the patient too much, with the following draught taken every fix hours, has produced better effects than could be expected.

While these medicines are using, we should endeavour to mitigate the pains of the belly by relaxing applications. During the course of the disease, the patient ought to drink freely of diluting liquors, and abstain from every thing of a heating quality, unless great faintness should indicate the use of a small quantity of some cordial medicine.

Such is the practice recommended in this disease by Dr. Denman. We shall now take a cursory view of the sentiments of succeeding writers on this subject.

According to Dr. Hulme, the proximate cause of the puerperal fever is an inflammation of the intestines and omentum; for the confirmation of which opinion he appeals to observations. He supposes the chief predisposing cause of the disease to be the pressure of the gravid uterus against the parts abovementioned. The omentum, says he, in the latter stage of pregnancy, must either be flat, which is its natural situation, or be rumpled or carried up by the gravid uterus in folds or doublings. When the latter is the case, which he observes is probably not seldom, the danger of a strangulated circulation will be greater.

Mr. White, who has also written on this disease, judiciously remarks, that were Dr. Hulme's hypothesis well founded, the disorder ought rather to take place before delivery, and be immediately removed at that period: That it would likewise most generally happen to women at their first labour, when the abdominal muscles are less yielding, and the pains more violent; the contrary of which is most frequently experienced to be the case.

It also deserves to be remarked, that upon Dr. Hulme's supposition, we cannot account for the disease being more common and fatal in large towns and in hospitals, than in the country and private practice, while other inflammatory disorders are more endemic among those who live in the latter than the former situation. Even admitting the friction of the intestines and omentum against the uterus to be as violent as Dr. Hulme supposes, is it not highly improbable, that any inflammation could be occasioned by the pressure of such soft substances upon each other? Or, were this effect really produced, ought not the puerperal fever to be more common and fatal after the most laborious deliveries? But this observation is not supported by experience.

Dr. Hulme, in favour of his own hypothesis, alleges that it gives a satisfactory answer to the question, "Why all lying-in women have been, and ever will be, subject to this disease?" In this proposition, however, the Doctor supposes such an uniformity of the disease as is not confirmed by observation. It is affirmed
Appendix.

MEDICINE.

Puerperal Fever. formed upon undoubted authority, that in many parts of Britain the puerperal fever is hardly known; whereas, were it really produced by the causes he assigns, it would be equally general and unavoidable.

But how peculiar ever this author's sentiments are in respect of the proximate cause of this disease, they have not led him to any method of cure different from the established practice. On this subject Dr Hulme divides his observations into two parts, comprehending under the former the more simple method of treatment, and under the latter the more complex. He set out with remarking, that the patient being generally colitive at the beginning of the disease, an emollient opening clyster will often give immediate relief; but if this should not prove effectual, recourse must be had to cathartics. Those which he found answ'er his purpose best, were the sal carbonate of ammonia, the oleum ricini, emetic tartar, and antimonial wine. When the bowels have been sufficiently cleared and the pain abated, he advises encouraging a gentle diaphoresis by medicines which neither bind the body nor are heating; such as a small dose of ipecacuan, emetic tartar, and antimonial wine, combined in a moderate dose, and given once or twice in the course of 24 hours; administering the saline draughts in the intermediate spaces. If, preceding or during this course, a faintness at throat or vomiting attend, he advises affisting the efforts of nature, by drinking plentifully of camomile tea, warm water, or any other diluting liquor. He concludes with recommending a cooling regimen, rest of body, and tranquillity of mind; prohibiting all kinds of bandages upon the abdomen, and enjoining particular attention to the state of the bowels, which ought to be kept gently open for some time, even after the disorder seems to be gone off, till the patient be quite out of danger.

So much for this simple treatment; we now proceed to the second part, where he describes the method of practice when the disease is in its more irregular and complicated state.

When a diarrhoea accompanies the disease, he observes that it ought by no means to be checked, but supported, by ordering the patient to drink plentifully of mild aperient liquors. If the pain of the hypo-gastric region be attended with stitches in the sides or on the pit of the stomach, and a pulse that resists the finger pretty strongly, he remarks that bleeding would then be highly necessary: declaring, however, his opinion, that in the puerperal fever, bleeding is to be considered only as a secondary means of relief, though the first in point of time; that it ought to be advised with great caution; and that the greatest dependence is always to be placed upon evacuations by stool.

Mr White, abovementioned, imputes the puerperal fever to a putrid disposition of the humours, contracted during pregnancy, and fomented by the hot regimen commonly used by women in child-bed. In conformity to this opinion, the chief means which he recommends for preventing the disease is a cool regimen and free circulation of air, which he evisces to be of the greatest importance. In respect of bleeding, he informs us, that, upon the strictest inquiry, he cannot find that those who have bled the most copiously have had the greatest success, either in private or hospital practice. He even seems to question the propriety of this evacuation in any case; but approves of emetics, cathartics, and clysters, for clearing the prime vis, and likewise of such medicines and diet as will correct the putrid humours; adding, that an upright posture and free ventilation are at all times useful, and absolutely necessary, both for the prevention and cure of the disease.

Another writer who treats of the child-bed fever is Dr Leake, who has published the result of his observations on this disease from April 1768 to the autumn of the year 1770; but chiefly from December 1769 to May 1770, during which period the child-bed fever prevailed much about London.

Dr Leake tells us that this fever generally commenced the evening of the second or morning of the third day after delivery, with a rigor or shivering fit. Sometimes it invaded soon after delivery; and at other times, though rarely, it has lasted so late as the fifth or sixth day. Now and then it seemed to be occasioned by catching cold, or by errors in diet; but oftener by anxiety of mind. Sometimes the thirst was great; tho' the tongue had, in general, a better appearance at the beginning than is common in fever. The lochia, from its more irregular and putrefcent disposition, is changed into a putrid nature; and no longer can be prevented by that mechanical draughts of the midwife, which he found answer his purpose best; the patient being restrained by those who attend. When the disease proved mortal, the patient generally died on the 1st or 11th day from the first attack. In those who died of the fever, the omentum was found suppurated; an inflammation of which part, or of the intestines, Dr Leake concludes to be the proximate cause of the disease.

In consequence of this idea of the cause of the disease, Dr Leake affirms that venesection is the only remedy which can give the patient a chance for life. But, though it be the principal resource to be depended upon at the beginning of the fever, he observes that it will seldom prove of service after the second or third day; and, if directed yet later, will only weaken and exhaust the patient; when, matter having begun to form in the omentum, the progress of the disease can no longer be prevented by that exhaustion. At this period the blood begins to be tainted by the absorption of the purulent fluid; and the fever, from being inflammatory, is changed into a putrid nature.

After bleeding in such a quantity as the symptoms require, he advises that the corrupted bile be evacuated and corrected as soon as possible; that the diarrhoea
MEDICINE.

Appendix.

Of this disease also, as it appeared in Derbyshire and some of the adjacent provinces, an account has been published by Dr. Butter. Concerning the causes and nature of the disease, he observes, that pregnancy seems to add much to the natural susceptibility of the female constitution; because at this period women are often subject to a train of nervous symptoms, which never molest them at other times. During gestation likewise, the appetite is for the most part keen, while the digestion appears to be impaired; and this weakness is increased not only by improper food, of which the woman is frequently debauched, but also by the inactivity attending her situation. To these circumstances, it is added, that the intestinal passage being interrupted by the uterine formation, constipation generally prevails. From the several observations here enumerated, Dr. Butter concludes, that the proximate cause of the puerperal fever is a spasm either of the first passages, with a morbid accumulation in their vicinity; and upon this supposition he endeavours to account for the various symptoms of the disease.

In treating of the method of cure, he lays down two indications; the former of which is to promote two, three, or four stool daily, in manner suited to the strength of the patient, till such time as they resume a natural appearance. The second indication is to relieve all uneasy symptoms, such as heat, thirst, head-ache, &c.

With respect to the opinion entertained by Dr. Butter of the cause of the puerperal fever, it nearly coincides with that of Mr White. But however plausible it may appear, we are not entirely satisfied that a disease attended with so peculiar symptoms as the puerperal fever can depend principally upon an irritability, which is not restrained either to the pregnant or puerperal state.

The late Dr Thomas Young professor of midwifery in the university of Edinburgh, although he published nothing on the subject of the puerperal fever, wrote a very ingenious dissertation refpecting it, which was read in the Philosophical Society of Edinburgh. In that dissertation, after giving a very accurate account of the symptoms of the disease, which coincides very nearly with the account given by others, he endeavours to show, that the puerperal fever, firstly so called, is in every instance the consequence of contagion; but he contends, that the contagious matter of this disease is capable only of producing its effect, in consequence of a peculiar predisposition given by delivery and its consequences. In support of this doctrine, he remarks, that for many years the disease was altogether unknown in the lying-in ward of the Royal Infirmary at Edinburgh; but that after it was once accidentally introduced into the hospital, almost every woman was in a short time after delivery attacked with it; although prior to her delivery, the may have lain even for weeks together, not only in the same ward with the infected, but even in the very next bed. He remarks, that it was only eradicated from the hospital in consequence of the wards being entirely emptied, thoroughly ventilated, and new painted. After these procedures, puerperal females in the hospital remained as free from this disease as formerly. The puerperal fever, according to Dr Young, has very generally a strong tendency to the typhoid type; although he allows, that in
in the beginning it is not unfrequently attended with inflammatory symptoms, and even with topical inflammation, particularly in the intestinal canal. On this idea, he considers the puerperal fever as admitting of the same variety of treatment with other affections depending on contagion, in which sometimes an inflammatory, sometimes a putrefactive tendency, prevails; such, for example, as small-pox or erysipelas. But from the prevailing putrefactive tendency in this affection, he considers the free access of cool air, with the liberal use of antifeptics, as being very generally requisite.

It deserves to be remarked, that though the several writers who treat of this subject have conducted their method of cure conformably to their particular idea of the cause of the disease, respecting which their sentiment are very different, they seem to have been equally successful in the treatment of their patients. Indeed, the several writers differ less from each other in their method of cure than might be expected, where so great an opposition of theoretical sentiments prevails. For after endeavouring to establish indications correspondent to their particular systems, those who contend for the expediency of promoting the intestinal discharge, diffuse not from a recourse to phlebotomy when the disease is attended with inflammatory symptoms; while, on the other hand, the most strenuous advocates for bleeding admit the utility of the former evacuation. It appears, therefore, that a due regulation of the alvinate discharge is necessary through the whole course of the fever, but venefaction only sometimes.

CEPHALALGIA.

Head-Ach

The head-ach is symptomatologic of very many distempers, but is rarely an original disease itself. Dr Home acquaints us, that his report-books only furnish four instances of it; and of these four, three were women. The disease proved fatal to the man; and after death, a considerable effusion of blood was found on the brain, together with some hydatids, and water in the ventricles.

Head-achs appear frequently to be occasioned by effusions of blood or serous; as well as by ulcers, and abscesses of the brain, dura and pia mater. Accretions and obliterations of different parts of the dura mater, falx, and brain, are also frequently discovered. An obliteration of the falx, however, does not always produce head-ach; for Dr Home mentions a patient who had the falx obliterated without head-ach; but he had been observed to be very furious when drunk. Congestions of blood in the vesicles of the brain are also discovered from obliteractions to be a frequent cause of the head-ach; and nervous irritation alone will frequently produce it, as we see in the clausus hystericus.

In the cure of this disease we have little or no power over obliteractions, effusions, or ulcerations; and hence the head-ach is frequently incurable. In congections, and nervous affections, medicines may indeed be of some service. Congestion may be relieved by an evacuation of blood, either general or topical; as venefaction, cupping, or leeches: by erthines; which, however, Dr Home thinks are little to be depended upon: by topical evacuations near the head by blisters, infusions, or foment; by purgatives; or by determining the fluids to other parts, by rubefaciens applied to the temples, pedulivus, &c.

Nervous irritation may be diminished. 1. By a great quantity of cold water drunk every morning. This is recommended by Hoffman; and will wash off all acrid particles from the stomach, while the cold strengthens and diminishes the sensibility of the part. This remedy was tried for a considerable time in one of Dr Home’s patients without any effect. 2. Nervous and tonic medicines; as the bark, valerian, &c. These were tried in two of Dr Home’s patients, but also without success. In a third the valerian succeeded. 3. By cold water applied to the head, immersion, or the shower-bath. 4. Cephalics; as lavender, rosemary, &c. In flight cases, the smell of cam de toc, or any strong volatile alkali, will generally prove a cure.

A Dangerous Affection of the Oesophagus.

This distemper has only been treated of by Dr Muncley, who reckons it one of the most deplorable diseases of the human body. Its beginning is in general so flight as to be scarce worth notice, the patients perceiving only a small impediment to the swallowing of solid food: they usually continue in this state for many months; during which, all liquid foods, and even solids themselves, when cut small and swallowed leisurely, are got down without much difficulty: by degrees the evil increases, and the passage through the esophagus becomes so narrow, that not the smallest solid whatever can pass through it; but, after having been detained for some time at the part where the obstacle is formed, is returned again with a hollow noise of a very peculiar kind, and with the appearance of convulsion.

The seat of this malady is sometimes near the top of the oesophagus, and at other times farther down, nearer the inferior orifice of the stomach. In this last case, the part of the alimentary tube which is above the obstruction is frequently fo dilated by the food which is detained in it as to be capable of containing a large quantity; and the kind of vomiting, by which it is again returned through the mouth, comes on sooner or later after the attempt to swallow, in proportion to the nearness or remoteness of the part affected. In the last stage of this disease, not even liquids themselves can be swallowed so as to pass into the stomach, and the patient dies literally starved to death.

On the obstitutions of such as have died in this manner, the esophagus is found to be considerably thickened; and in some so contracted within at the diseased part, as scarcely to admit the passing of a common probe; in others, to adhere together in such a manner as entirely to close up the passage, and not to be separated without great difficulty.

He comes next to show what he has found to be the most efficacious method of treating this disease, which, though not uncommon, yet in general has been considered as incurable.

He claims not the merit of having discovered the method of cure, but hopes that some service may arise from publishing what his experience has confirmed to him; having first received the hint from another eminent physician.
The only medicine, then, from the use of which he has ever found any service, is mercury; and in cases which are recent, and where the symptoms have not risen to any great height, small doses of mercury given every right, and prevented, by purgative medicines, from affecting the mouth, have accomplished the cure.

But where the complaint has been of long standing, and the symptom has come on of the food's being returned through the mouth, a more powerful method of treatment becomes necessary. In this case he has never found anything of the least avail in removing any of the symptoms, but mercury, used in such a manner as to raise a gentle but constant spitting; and this method he has pursued with the happiest success. If this method be commenced before the complaint has gained too much ground upon the constitution, the case is not to be despaired of; and of those who have come under his care in this state, by much the greater part have received considerable benefit from it, and many have been entirely cured.

The complaint itself he observes, is not very uncommon; but there is no instance, to his knowledge, recorded, of success from any other manner of treating it, than that he has recommended.

WORMS.

Those infesting the human body are chiefly of three kinds: the ascarides, or small round and short white worms; the teres, or round and long worm; and the tertia, or tape worm.

The ascarides have usually their seat in the rectum.—The teretes or lumbrici are about a span long, round and smooth: they are feated for the most part in the upper small intestines; but sometimes they are lodged also in the stomach, and in any part of the intestines, even to the rectum.—The tape worms are from two to forty feet long, according to the testimony of Platerus; they generally fill the whole tract of the intestines, but especially the ileum: they very much resemble a tape in their appearance, whence the name of tape-worm: but another species of this genus, from the resemblance of each joint to a gourd seed, has the name of gourd worm.

In the Medical Transact. Vol. I. Dr Heberden gives a very accurate account of the symptoms produced by the ascarides, from an eminent physician who was troubled with them all his life. They brought on an unaesthetic in the rectum, and an almost intolerable itching in the anus; which sensations most usually came on in the evening, and prevented sleep for several hours. They were attended with heat, sometimes so considerable as to produce a swelling in the rectum both internally and externally; and if these symptoms were not soon relieved, a tenesmus was brought on, with a mucous defecation. Sometimes there was a griping pain in the lower part of the abdomen, a little above the os pubis. If this pain was very severe, a bloody mucus followed, in which there was often found ascarides alive. They were also sometimes inspected of occasioning disturbed sleep, and some degree of head-ache.

On this case Dr Heberden observes, that the general health of the patient did not seem to have suffered from the long continuance of the disease, nor the immediate inconvenience of the disorder itself to have increased. "It is (says he) perhaps universally true, that this kind of worms, though as difficult to be cured as any, yet is the least dangerous of all. They have been known to accompany a person through the whole of a long life, without any reason to suspect that they had hastened its end. As in this case there was no remarkable sickness, indigestion, giddiness, pain of the stomach, nor itching of the nose, possibly these symptoms, which have happened to be joined with the ascarides, did not properly belong to them, but arose from some other causes. There is indeed no one sign of these worms, but what in some patients will be wanting."

The abovementioned patient used purging and irritating cathartics with very little success. One drachm and an half of tobacco was infused in six ounces of boiling water; and the strained liquor being given as a clyster, occasioned a violent pain in the lower part of the abdomen, with faintness and a cold sweat; this injection, though retained only one minute, acted as a smart purg, but did little or no good. Lime water was also used as a clyster; which brought on a colic, but had no good effect. Six grains of salt of mercury were dissolved in six ounces of water, and injected. This clyster in a few minutes occasioned an aching in the rectum, gripped a little without purging, and excited a tenesmus. Some few ascarides were brought off with it; but all of them were alive. The uneasy sensation in the rectum did not abate till some warm milk was thrown up. Whenever the tenesmus or mucus stools were thought worth the taking notice of, warm milk and oil generally gave immediate relief. If purging was necessary, the lienient purges, such as manna with oil, were, in this particular case, made use of; rhubarb was found too stimulating.—But, in general, the most useful purge, and which therefore was most usually taken, was cinnabar and rhubarb, of each half a drachm: this powder seldom failed to bring away a mucus as transparent as the white of an egg, and in this many ascarides were moving about. The cinnabar frequently adhered to this mucus, which did not come off in large quantities, when a purge was taken without cinnabar. Calomel did no more than any other purge which operates briskly would have done; that is, it brought away ascarides, with a great deal of mucus. Oil given as a clyster sometimes brought off these animalcules: the oil swam on the surface of the mucus, and the ascarides were alive and moving in the mucus itself, which probably hindered the oil from coming in contact with them and killing them.

The doctor also observes, that mucus or slime is the proper seat of the ascarides, in which they live, and is perhaps the food by which they are nourished; and it is this mucus which preserves them unhurt, though surrounded with many other liquors, the immediate touch of which would be fatal. It is hard to satisfy ourselves by what instinct they find it out in the human body, and by what means they get at it; but it is observable in many other parts of nature, as well as here, that where there is a fit foil for the hatching and growth of animals and vegetables, nature has taken sufficient care that their feeds should find the way thither. Worms are said to have been found in the intestines of infants born dead. Purges, by
Appendix.

MEDICINE.

by lessening this time, never fail to relieve the patient; and it is not unlikely, that the worms which are not forced away by this quickened motion of the intestines, may, for want of a proper quantity of it, languish, and at last die; for if the aercariaes are taken out of their mucus, and exposed to the open air, they become motionless, and apparently die in a very short time.

Dr Heberden supposes that the kind of purge made use of is of some consequence in the cure of all other worms as well as aercariaes; the animals being always defended by the mucus from the immediate action of medicines: and that therefore those purges are the belt which act briskly, and of which a repetition can be most easily borne. Purging waters are of this sort, and jalap especially for children; two or more grains of which, mixed with sugar, are most easily taken, and may be repeated daily.

From the case above-mentioned, and from Dr Heberden's observations, we may easily see why it is so difficult to destroy these animals; and why anthelmintics, greatly celebrated for some cures, are yet so far from being specific in the disease. As the worms which reside in the cavities of the human body are never exposed to the air, by which all living creatures are invigorated, it is evident, that in themselves they must be the most tender and easily destructible creatures imaginable, and much less will be requisite to kill them than of any of our common infincts. The most pernicious substances to any of the common infincts are oil, caustic fixed alkali, lime, and lime-water. The oil operates upon them by flattening up the pores of their bodies; the lime-water, lime, and caustic alkali, by dissolving their very substanee. In the case of intestinal worms, however, the oil can have very little effect upon them, as they are defended from it by the moisture and mucus of the intestines; the like happens with lime-water; and therefore it is necessary that the medicine should be of such a nature as to destroy both mucus and infincts together: for which purpose the caustic fixed alkali is at once safe and efficacious; nor is it probable that any caie of worms whatever could refist the proper use of this medicine.

A very large dose of any salt indeed will also destroy the mucus and destroy the worms; but it is apt to inflame and excoriate the stomach and intestines, and thus to produce worse dillempers than that which it was intended to cure. Dr Heberden gives the following remarkable case of a patient cured of worms by enormous doses of common salt, after trying many other remedies in vain. In February 1757, the patient was seized with uncommon pains in his stomach, attended with nausea, vomiting, and copulation of bowels, and an almost total loss of sleep and appetite. He soon became much emaciated, and could neither stand nor walk upright; his belly grew small and hard, and closely retracted, insomuch that the sternum covered the navel, and the latter could scarce be discovered or felt by the finger: his urine was always milky, and soon deposited a thick white sediment; his excrements were very hard and lumpy, resembling those of sheep, only of a brown colour; nor had he ever a fcool without some medicine or other to procure it. In this situation he continued four years; during which time he had been in an infirmary, attended by eminent physicians, but was diffirmed as incurable. At last he was advised by a neighbour to drink salt and water, as he said he knew one cured by it who had for many years been afflicted with the same kind of pains in the belly and stomach. As his diflemper was now almoft infupportable, he willingly tried the experiment. Two pounds of common salt were dissolved in as little water as possible, all which he drank in less than an hour. Soon afterwards he found himself greatly oppressed at the stomach, grew extremely sick, and vomited violently; on the fourth fasting he brought up about half a pint of small worms, part aercariaes, and the rest rehmming those worms which are called the bots, and frequently mixt with in the stomach of horses, but much smaller, and about the size of a grain of wheat. The salt soon began to operate downwards, and he had five or fix very copious fetid flobes, tinged with blood; and in them discharged near an equal quantity of the fame kind of worms he had vomited. Being greatly fatigued with the violence of the operations, he fell into a calm sleep, which lasted two hours, during which, he sweated profusely, and awoke much refreshed. Instead of his usual pains, he now only complained of a rawness and foreness of his gullet, stomach, and bowels, with an almost unquenchable thirst; to allay which, he drank large quantities of cold water, whey, butter-milk, or whatever he could get. The urine he now passed was small in quantity, and rendered with very great difficulty, being highly saturated with the salt, from whence arose a molt troublesome dysuria and irregulaty. However, these symptoms gradually abated by a free use of the liquors abovementioned; and on the third morning he was so well recovered, that he took two pounds more of salt, dissolved in the like quantity of water. The effects were nearly similar to the former; only that most of the worms were now burst, and came away with a considerable quantity of flime and mucus. The drought, irregulaty, ceased, returned with their former violence, but soon yielded to the old treatment. He sweated very copiously for three days, slept easily, and by that time could extend his body freely; on the fifth day he left his bed, and, though very weak, could walk upright; his strength and appetite soon returned, and he became robust and well.

The anthelmintic medicines which have been recommended by one person or other, are in a manner immemorable; but the principal are,

1. Quickfiver. This is very efficacious against all kinds of worms, either taken in the form of calomel or corrosive sublimate. Even the crude metal boiled in water and the water drunk, has been recommended as an almost certain cure. But this, it is evident, can receive no impregnation from the mercury. If, therefore, it have any effect, it must be from some foreign and accidental impregnation. In most instances there can be no objection to mercury, but only that it is not endowed with any attenuating quality whereby the mucus in which these infincts reside can be dissolved. It therefore fails in many cases, though it will most certainly destroy worms where it can get at them.

2. Powder of tin. This was for some time celebrated as a specific; and indeed we may reasonably expect good effects from it; as by its weight and grittiness
grittiness it rubs off the mucus and worms it contains from the coats of the intestinal canal, in which case they are easily evacuated by purgatives. In order to produce any considerable effects, it must be given in a large dose.

3. 

Geoffrsea-inermis, or cabbage bark. This remedy is used by the inhabitants of Jamaica. The first account of it which appeared in Britain was published in the Physical and Literary Essays, vol. ii. by Mr Duguid surgeon in that island. He acquaints us, that the inhabitants of Jamaica, young and old, white and black, are much infested with worms, especially the long round sort; the reason of which, he thinks, is the quantity of sweet viscid vegetables which they eat. On dissecting a child of seven months old, who died of vomiting and convulsions, twelve large worms were found; one of them filled the appendix vermiformis, and three of them were intertwined in such a manner as to block up the valva tulpis, so that nothing could pass from the small to the great guts.—The cabbage-bark, however, he tells us, is a safe and effectual remedy, and the most powerful vermifuge known; and that it frequently brings away as many worms by stool as would fill a large hat. He owns that it has sometimes violent effects; but this he ascribes to the negroes who make the decoction (in which form the bark is used), and not to the remedy itself.

Mr Anderson, surgeon in Edinburgh, has also given an account of this bark and its operation, in a letter to Dr Duncan, published in the Edinburgh Medical Commentaries, volume iv. p. 04. From this account it appears, that there are two different kinds of bark; the one much paler than the other; the pale kind operates much more violently than the other. It often occasions loofe stools, great nausea, and such like symptoms, attended with great uneasiness in the belly; in one or two instances it was suspected of inducing fyncope. The darker coloured kind resembles the caffia lignea, though it is of a much coarser texture. This kind, Mr Anderson thinks, may be exhibited in any case where an anthelmintic is necessary; the dangerous symptoms might have followed either from the use of the first kind, or from an over-dose of the second. The usual method of preparing the medicine is by boiling two ounces and a half of the bark in two quarts of water to a pint and a half. Of this a tea-spoonful may be given at first in the morning, gradually increasing the quantity till we come to four or five table spoonfuls in a day. When exhibited in this manner, Mr Anderson informs us, that he never saw it produce any violent symptoms, and has experienced the best effects from it as an anthelmintic.

After the use of this decoction for eight or nine mornings successively, a dose of jalap with calomel must be given, which seldom fails to bring away the worms, some dead, some alive. If at any time the decoction produces more than one or two loose stools, a few drops of liquid laudanum may be given; and, in general, Mr Anderson gave 15 or 20 drops of the spirit of lavender with each dose.

In a letter from Dr Ruth, professor of chemistry at Philadelphia, to Dr Duncan of Edinburgh, the following account is given of another preparation of this medicine. "It has long (says he) been a complaint among physicians, that we have no vermifuge medicine which can be depended upon. Even calomel fails in many cases where there are the most pathognomonic signs of worms in the bowels. But this complaint, it is hoped, is now at an end. The physicians of Jamaica have lately found, that the cabbage-bark, as it is called in the West Indies, made into a syrup with brown sugar, is an infallible antidote to them. I have used above 30 pounds of it, and have never found it fail in one instance. The syrup is pleasant; it sometimes pukes, and always purges, the first or second time it is given."

Notwithstanding these encomiums, however, the cabbage-bark (A) hath not come into general use in Britain. But diseases from the teretes, or lumbrici as they are often called, the species of worm against which this bark is employed, much less frequently occur than in some other countries. When they do occur, in almost every instance they readily yield to more gentle and safe anthelmintics; and the worms may not only be expelled by calomel, but by the vegetable bitters; as the powder of the femen fantonicum, or the like.

4. 

Cowslip, or cow-itch. This is the Dolichos urceus or purpureus of Linnaeus; and the principles on which it acts have been already explained under the article Dolichos. It is somewhat similar to the powder of tin, but bids fair for being more efficacious. It might at first appear to occur as objections to this medicine, that by the hairs of it entangling themselves with one another, calculi might be formed in the intestines, or obstructions equally bad; or if the sharp points and hooks with which it abounds were to adhere to the nervous coats of the intestines themselves, they might occasion a fatal irritation, which could not be removed by any means whatever. But from the experience of those who have employed it extensively in practice, it would appear, that these objections are entirely theoretical; and that it may be employed with perfect safety. The spicules, gently scraped off from a single pod, and mixed with syrup or molasses, are taken for a dose in the morning fasting. It is repeated in this manner for two or three days without any sensible operation; but even a very slight purgative taken afterwards has been found to discharge an almost incredible quantity of worms. And according to Dr Bancroft, who has given a very particular account of its use in his Natural History of Guiana, it is one of the safest and most certain anthelmintics yet discovered; but, as well as the bark of the Geoffrsea, it has hitherto been very little used in Britain, probably from its not being necessary.

5. 

Indian pink. The plant, which in the Spigelia marilandica

(a) The most accurate account of this vegetable, and its effects, has been given by Dr Wright in the Philosophical Transactions, of which the reader will find a short view under the article Geoffrsea, in the order of the alphabet.
after which the excreta followed. The next day she was extremely low; her pulse could scarcely be felt; the extremities were cold; and there was a considerable discharge from the wound, which had already begun to mortify. She got a decoction of the bark with wine, which alleviated the symptoms; but in removing the mortified parts a worm was found among them nine inches long, and as thick as an eagle's quill. By proper applications, the discharge of excrements ceased, and the recovered perfect health. She was sensible of no accident giving rise to the inflammation; so that in all probability it arose entirely from the worm itself.

The _tenia_, or tape-worm, as it is called, is one of those most difficult to be removed from the human body. It is of two kinds, _tenia folum_ and _tenia lata_; for a description of which see the article _Tenia_.

The reason of its being so difficult to cure, is, that though portions of it are apt to break off and be dischargin, it is endowed with a power of reproduction, so that the patient is little or nothing better. The symptoms occasioned by it are not different from those above described. A specific against the _tenia lata_ hath been lately so much celebrated in France, that the king thought proper to purchase it from the proprietor (Madam Noufer), and the account of it has been translated into English by Dr. Simmons. The patients are required to observe no particular regimen till the day before they take the specific. That day they are to take nothing after dinner till about 7 o'clock; after which, they are to take the following soup: "Take a pint and an half of water, two or three ounces of good fresh-butter, and two ounces of bread cut into thin slices; add to this salt enough to season it, and then boil it to the consistence of panada." About a quarter of an hour after this, they take a diffick and a glass of white-wine, either pure or mixed with water; or even water alone, if they have not been accustomed to wine. If the patient has not been at stool that day, (which, however, is not usual with patients in this way), the following clyster is to be injected. "Take a small quantity of the leaves of mallows, and boil them in a sufficient quantity of water, mixing with it a little salt, and when drained off add two ounces of oil olive." Next morning, about eight or nine hours after the supper abovementioned, the specific is to be taken. This is no other than two or three drachms of the root of male fern, _polypodium filix mas_ of Linnaeus, gathered in autumn, and reduced to fine powder. It is to be taken in any distilled water, or in common water. This medicine is apt to occasion a nausea: to avoid which, Madam Noufer allows her patients to chew any thing that is agreeable, but forbids any thing to be swallowed; or they may smell to vinegar, to check the sicknese: but if, notwithstanding this, the specific be thrown up, a fresh dose must be swallowed as soon as the sicknese is gone off, and then they must try to sleep. About two hours after this the following bolus is to be taken. "Take of the panacea of mercury 14 times sublimed, and elect reflex of lammony, each ten grains; of freth and good gamboge, fix or seven grains; reduce each of these subfluences separately into powder, and then mix them with some conifere into a bolus." This composition is to be swallowed at two different times, washing it down with
Worms.

MEDICINE.

Appendix.

Worms.

with one or two dillies of weak green-tea, after which the patient must walk about his chamber. When the bolus begins to operate, he is to take a dill of the same tea occasionally, until the worm be expelled; then, and not before, Madame Noufier gives him broth or boug, and he is directed to dine as is usual after taking physic. After dinner he may either lie down or walk out, taking care to conduct himself discreetly, to eat but little supper, and to avoid every thing that is not of easy digestion.

The cure then is complete; but it is not always effected with the same quickness in every subject. He who has not kept down the whole bolus, or who is not sufficiently purged by it, ought to take, four hours after it, from two to eight drachms of Epfom salt dissolved in boiling water. The dose of this salt may be varied according to the temperament and other circumstances of the patient.

If the worm should not come away in a bundle, but in the form of a thread (which particularly happens when the worm is involved in much tenacious mucus), the patient must continue to sit upon the close floor without attempting to draw it away, drinking at the same time warm weak tea: sometimes this alone is not sufficient, and the patient is obliged to take another dose of purging salt, but without varying his position till the worm be wholly expelled.

It is unusual for patients who have kept down both the specific and purging dofe, not to discharge the worm before dinner-time. This, however, sometimes happens when the dead worm remains in large bundles in the intestines, so that the feces become more limpid towards the end of the purging, pass by it without drawing it with them. The patient may in this case eat his dinner; and it has been observed, that the food, joined to the ufe of a clyster, has brought about the expulsion of the worm.

Sometimes the worm is brought away by the action of the specific alone, before the patient has taken the purging bolus: when this happens, Madame Noufier gives only two-thirds of it, or substitutes the salt in its stead.

Patients must not be alarmed by any fenfation of heat or uneasiness they may feel during the action of the remedy, either before or after a copious evacuation, or just as they are about to void the worm. These fenfations are transitory, and go off of their own accord, or by the alliament of the vapour of vinegar drawn in at the nofe.

They who have vomited both the specific and bolus, or who have kept down only a part of them, sometimes do not vomit the worm that day. Madame Noufier therefore directs them to take again that night the sopp, the wine and bifeuit; and if circumstances require it, the clyster. If the worm do not come away during the night; he gives them early the next morning another dose of the specific, and, two hours afterwards, fix drachms or an ounce of purging salt, repeating the whole process of the preceding day; excepting the bolus, which she supprefles.

She observes, that very hot weather diminishes in some degree the action of her remedy; she therefore prefers the month of September for administering it; but as she has not been always able to choose the feafon, and has been sometimes obliged to undertake the cure of patients in the hottest days of summer, she then gave her specific very early in the morning; and with this precaution the flaw no difference in its effects.

On the day appointed for the trial of this medicine before the commissioners nominated by the king of France, it was exhibited to five different persons; but only one of them was certainly known to have the tenia lutea by having discharged parts of it before. That person was cured; the second voided a portion of the tenia folium; the third some ascarides, with a part of the tenia folium; the fourth and fifth voided no worms; but the last confidered much of the vivid flime he voided to be worms in a disolved flate.

This trial was thought sufficient to ascertain the efficacy of the medicine, and further trials were made by thofe to whom the fecret was communicated. The fift voided two tenia, after much vomiting and 18 or 20 foofs; the fefond had no vomiting, but was as violently purged, and discharged two worms; the third had 20 copious foools during the night, and discharged the worm in the morning; and the fifth was effected in much the fame manner. Some others who were not relieved, were suppofed not to have a tenia.

This specific, however, is not to be confused as a new discovery; the efficacy of fern in cafes of tenia having been known long ago. Theophratus prefcribes its root, in doses of four drams, given in water sweetened with honey, as ufeful in expelling flat worms.

Diocorides orders it in the fame dofe, and adds, that its effects are more certain when it is mixed with four oboli (40 grains) of scammony or black hellebore; he particularly requires that garlic should be taken before hand. Pliny, Galen, Oribafius, and Aëlius, afcribe this fame virtue to fern; and are followed in this by Avicenna, and the other Arabians, physicians. Dorothenius, Valerius Cordus, Dodonæus, Mathiæus, Dallechampius, who commented on Diocorides, or copied him in many things, all mention the fern-root as a specific against the tenia. Sennertus, and Burnet after him, recommended in fimilar cafes an infamce of this plant, or a dram of its powder for young persons, and three drams for adults. Simon Paulus, quoted by Ray and Geoffroy, coniders it as the moft efficacious of all poifons againft the flat worm, and as being the baft of all the secret remedies extolled by emperors in that difafe. Andry (général des Vers, p. 246, 249) prefers distilled fern-water to the root in powder, or he employs it only in the form of an opiate, or mixed with other substances.

These are not the only authors who have mentioned the tenia; many others have described this worm, the symptoms it excites, and the treatment proper to expel it. Almost all of them mention the fern-root, but at the fame time they point out other remedies as poiffling equal efficacy. Amongf these we find the bark of the root of the mulberry tree, the juice of the auricula murus, the roots of chamæleon niger, ginger, zedoary; decoctions of mugwort, footherwood, wormwood, penny-royal, origanum, hyssop, and in general of all bitter and aromatic plants, &c. Some of them direct the specific to be fimply mixed and taken in wine or honey and water; others join to it the ufe of some purgative remedy, which they say adds to its efficacy. Oribafius, Silvius, &c. distinguish the specific
M E D I C I N E.

Practice.

Worms.

Worms.

cific that kills the worm, from the purgative that evacuates it, and direct them to be given at different times. Semnertus gives a very satisfactory reason for adopting this method. If we give, says he, the purgative medicine and the specific at the same time, the latter will be hastily carried off before it can have exerted its powers on the worm: whereas, if we give the specific first, and then weaken the worm, it will collect itself into a bundle, and being brought away by means of the purge, the patient will be cured. The cure will be more speedy if the prima via have been previously lubricated. These precautions are all of them essential to the success of the remedy, nor are they neglected by Madame Nouffer in her method of treatment. The purgative and injection she prefers the night before, to lubricate the intestines, and prepare the prime via. The fen-root, taken in the morning, kills and detaches the worm: of this the patients are sensible by the cessation of the pain in the stomach, and by the weight that is felt in the lower belly. The purgative bolus administered two hours after this, procures a complete evacuation: it is composed of substances that are at once purgative and vermifuge, and which, even when administered alone, by different physicians, sometimes succeeded in expelling the worm. If this purgative appear to be too strong, the reader is desired to recollect, that it produced no ill effects in either of the cases that came under the observation of the physicians appointed to make the trials, and that in one of those cases, by diminishing the dose, they evidently retarded the evaucations.—

Regard however, they observe, is to be had both to the age and the temperament of the patient, and the treatment should always be directed by a prudent and experienced physician, who may know how to vary the proportions of the dose as circumstances may require. If the purgative be not of sufficient strength, the worm, after being detached by the specific, remains too long a time in the intestines, and becoming soon corrupted is brought away only in detached portions: on the other hand, if the purgative be too strong, it occasions too much irritation, and evacuation that cannot fail to be inconvenient.

Madame Nouffer's long experience has taught her to distinguish all these circumstances with singular acuteness. This method of cure is, as we have seen, copied in a great measure from the ancients: it may be possible to produce the same effects by varying the remedies; but the manner of applying them is by no means indifferent: we shall be always more certain of success, if the intestines be previously evacuated, and if the specific be given some time before the purgative bolus. It is to this method that Madame Nouffer's constant success is attributed.

Her remedy has likewise some power over the tertia folium; but as the rings of this worm separate from each other more easily than those of the tenia lata, it is almost impossible for it to be expelled entirely. It will therefore be necessary to repeat the treatment several times, till the patient can't avoid any portions of worms. It must likewise be repeated, if, after the expulsion of one tertia folium, another should be generated in the intestinal canal. This last caution is so rare, that it has been supposed that no person can have more than one of these worms; and for this reason it has been named solitary worm, which, being once removed, could never be renewed or replaced by a second: but experience has proved, that this notion is an ill-founded prejudice, and we know that sometimes these worms succeed each other, and that sometimes many of them exist together. Two living teniae have frequently been expelled from the same patient.

Dr De Haen (Rat. Med. tom. viii. p. 157.) relates an instance of a woman who voided 18 teniae at once. In these cases the symptoms are usually more alarming; and the appetite becomes excessive, because these worms derive all their nourishment from the chyle. If too auteurs ill judged a regiment deprives them of this, they may be expected to attack even the membranes of the intestines themselves. This evil is to be avoided by eating frequently.

Such are the precautions indicated in this disease. The ordinary vermifuge remedies commonly procured only a palliative cure, perhaps because they were too often improperly administered. But the efficacy of the present remedy, in the opinion of the French physicians, seems to be sufficiently confirmed by experience. To the above account, however, it seems proper to subjoin the following observations by Dr Simmons.

"A Swiss physician, of the name of Herrenachwand, more than 20 years ago, acquired no little celebrity by distributing a composition of which he styled himself the inventor, and which was probably of the same nature as Madame Nouffer's. Several very eminent men, as Tronchin, Hovius, Bonnet, Crammer, and others, have written concerning the effects of this remedy. It seems that Dr Herrenachwand used to give a powder by way of preparation, the night before he administered his specific. Nothing could be said with certainty concerning the composition either of one or the other. The treatment was said sometimes to produce most violent effects, and to leave the patients in a valetudinary state. Dr De Haen was dissuaded by his friends from using it, because it disordered the patients too much. It will be readily conceived, now that we are acquainted with Madame Nouffer's method that these effects were occasioned wholly by the purgative bolus. It is not strange, that refins of feammony or jalap, combined with mercurius dulcis and gamboge, all of them strong poisons, should in many subjects occasion the greatest disorders. It seems likely, however, that much of the success of the remedy depends on the use of a drastic purge. Some of the ancients who were acquainted with the virtues of the sen-root, observed that its efficacy was increased by feammony. Refinous purges especially when combined with mercury, have often been given with success in cases of tenia. Dr De Haen saw a worm of this sort five ells long expelled by the resins of jalap alone. Dr Gaulius knew a woman who had taken a variety of anthelmintic remedies without any effect, though he had voided a portion of tenia an ell and an half long previous to the use of these medicines: but at length, after taking a purge of singular strength, he voided the worm entire. Many other instances of the same kind are to be met with in authors. Other remedies have occasionally been given with success. In Sweden, it has been a practice to drink several
Of POISONS.

These have all been treated of already, except the bites and stings of serpents, scorpions, &c. According to Dr Mead, the symptoms which follow the bite of a viper are, an acute pain in the place wounded, with a swelling, at first red, but afterwards livid, which by degrees spreads farther to the neighbouring parts; with great faintness, and a quick, low, and sometimes interrupted pulse; great sickness at stomach, with bilious convulsive vomitings, cold sweats, and sometimes pains about the navel. Frequently a fanious liquor runs from the small wound, and little putrefactions are raised about it: the colour of the whole skin in less than an hour is changed yellow, as if the patient had the jaundice. These symptoms are very frequently followed by death, especially if the climate be hot, and the animal of a large size. This is not, however, the case with all kinds of serpents. Some, we are assured, kill by a fatal sleep; others are said to produce an universal hemorrhagy and dissolution of the blood; and others an unquenchable thirst. But of all the species of serpents hitherto known, there is none whose bite is more expeditiously fatal than that of the rattlesnake. Dr Mead tells us, that the bite of a large serpent of this kind killed a dog in a quarter of a minute; and to the human species they are almost equally fatal. Of this serpent it is said, that the bite makes the person's skin become spotted all over like the skin of the serpent; and that it has such a motion as if there were innumerable living serpents below it. But this is probably nothing more than a dissolution of the blood, by which the skin becomes spotted as in pectinal fevers, at the same time that the muscles may be convulsed as in the distemper called hieranos, which was formerly thought to be the effect of evil spirits: but it is even not improbable that observers have been somewhat aided by fancy and superstitition when they thought that they detected such appearances.

It has juftly appeared surprizing to philosophers, how such an incomprehensible quantity of matter as the poison emitted by a viper at the time of biting should produce such violent effects. But all inquiries into this matter must necessarily be uncertain; neither can they contribute any thing towards the cure. It is certain that the poison produces a gangrenous disposition of the part itself, and likewise seemingly of the rest of the body; and that the original quantity of poison contains some time before it exerts all its power on the patient, as it is known that removing part of the poisonous matter by suction will alleviate the symptoms. The indications of cure then are three, 1. To remove the poisonous matter from the body; Or, 2. If this cannot be done, to change its destructive nature by some powerful and penetrating application to the wound; And, 3. To counteract the effects of that portion already received into the system.

The poisonous matter can only be removed from the body by sucking the wound either by the mouth, or by means of a cupping-glass; but the former is probably the more efficacious, as the saliva will in some measure dilute and perhaps obtund the poison. Mead directs the person who sucks the wound to hold warm oil in his mouth, to prevent inflammation of the lips and tongue: but as bites of this kind are most likely to happen in the fields, and at a distance from houses, the want of oil ought by no means ought to retard the operation, as the delay of a few minutes might prove of the most fatal consequence; and it appears from Dr Mead's experiments, that the taking the poison of a viper into the mouth undiluted, is attended with no worse consequences than that of raising a flight inflammation. A quick excitement of the part might also be of very great service.

The only way of answering the second indication is, by destroying the poisoned part by a red-hot iron, or the application of alkaline fluids, which have the power of immediately altering the texture of all animal-substances to which they are applied, provided they are not covered by the skin; and as long as the poison is not totally absorbed into the system, these must certainly be of use.

To answer the third indication, Dr Mead recommends a vomit of ipecacuanha, encouraged in the working with oil and warm water. The good effects of this, he says, are owing to the shake which it gives to the nerves, whereby the irregular pangs into which their whole system might be drawn are prevented. After this the patient must go to bed, and a sweat must be procured by cordial medicines; by which the remaining effects of the poison will be carried off.

It has been confidently asserted by many, that the American Indians are possessed of some specific remedy by which they can easily cure the bite of a rattlesnake. But Mr Cateby, who must have had many opportunities of knowing this, positively denies that they have any such medicine. They make applications indeed, and sometimes the patient recovers; but these recoveries he ascribes to the strength of nature overcoming the poison, more than to the remedies made use of.

He says, they are very acute in their prognostics whether a person that has bit will die or not; and when they happen to receive a bite in certain parts of the body, when the teeth of the animal enter a large vein, for instance, they quietly resign themselves to their fate, without attempting any thing for their own relief. Indeed, so violent and quick is the operation of this poison, that unless the antidote be instantly applied, the person will die before he can get to a house. It would seem therefore eligible for those who are in danger of such bites, to carry along with them some strong alkaline key, or dry alkaline salt, or both, which could be instantly clapt on the wound, and by its dissolving power would destroy both the poison and the infected parts. Strong cordials also, such as ardent spirits, volatile alkali, &c. might possibly excite the languid powers of nature, and enable her to expel
Appendix.

MEDICINE.

Poisons. expel the enemy, which would otherwise prove too powerful. This seems to be somewhat confirmed from the account we have in the Philosophical Transactions of a gentleman bit by a rattle-snake, who was more relieved by a poultice of vinegar and vine-ailies put to the wound than any thing else. The vine-ailies being of an alkaline nature, must have fatuated the vinegar, so that no part of the cure could be attributed to it: on the other hand, the ailes themselves could not have been fatuated by the small quantity of acid necessary to form them into a poultice; of consequence they must have operated by their alkaline quality.

Soap-leaf, therefore, or very strong salt of tartar, may reasonably be thought to be the best external application, not only for the bites of vipers, but of every venomous creature; and in fact we find dry salt universally recommended both in the bites of serpents and of mad dogs. Dr Mead recommends the fat of vipers prefently rubbed into the wound; but owns that it is not safe to trust this remedy alone.

Some years ago the volatile alkali was strongly recommended by M. Sage of the French academy, as a powerful remedy against the bite of the viper: and, by a letter from a gentleman in Bengal to Dr Wright, it would appear that this article, under the form of the eau de lucis, which is very little if any thing different from the spiritus ammoniaci fuscatus of the London Pharmacopoeia, has been employed with very great success against this affection in the East Indies: but from the trials made with it by the Abbé Fontana, published in his Treatise on the poison of the Viper, it would appear that it by no means answered his expectation: and the efficacy of this, as well as of the snake pills mentioned under the article Hydrophobia, still requires to be confirmed by further experience.

MELENÉ.

This is a distemper not very common, but it has been observed by the ancient physicians, and is described by Hippocrates under the name of morbus niger. It shows itself by a vomiting and purging of black tar-like matter; which Hippocrates, Boerhaave, and Van Swieten, supposed to be occasioned by ater bilis. But Dr Home, in his Clinical Experiments, shows that it is owing to an effusion of blood from the mæteric vessels, which by its inflammation and corruption affumes that strange appearance. The disease, he says, frequently follows hemorrhaps; and those of a febbrific habit are most subject to it. It is an acute disease, and terminates soon; yet is not attended with any great degree of fever. In one of Dr Home's patients the crisis happened on the eighth day by diarrhœa; in another, on the 14th, by sweat and urine; and a third had no evident critical evacuation.

As to the cure, Dr Home observes, that bleeding is always necessary where the pulse can bear it; nor are we to be deterred from it by a little weakness of the pulse, more than in the interitis. Emetics are hurtful, but purgatives are useful. But the most powerful medicine for checking this hemorrhage is the vitriolic acid: and, that this might be given in greater quantity, he mixed it with muscall γ gum arabic; by which means he was enabled to give double the quantity he could otherwise have done. The cold bath was tried in one instance, but he could not determine whether it was of any service or not. The cure was completed by exercise and the bark.

Of the DISEASES of CHILDREN.

Dr Buchan observes, that from the annual registers of the dead it appears, that about one half of the children born in Great Britain die under twelve years of age; and this very great mortality he attributes in a great measure to wrong management. The particulars of this wrong management enumerated by him are,

1. Mothers not suckling their own children. This, he owns, is sometimes impossible for them to do; but where it can be done, he affirms that it ought never to be omitted. This, he says, would prevent the unnatural custom of mothers leaving their own children to suckle those of others; on which he passes a most severe censure, and indeed scarce any censure can be severe enough upon such inhumanity. Dr Buchanan informs us, "He is sure he speaks within bounds, when he says not one in an hundred of these children live who are thus abandoned by their mothers." For this reason he adds, that no mother should be allowed to suckle another's child till her own be fit to be weaned. A regulation of this kind would save many lives among the poorer sort, and would do no harm to the rich; as most women who make good nurses are able to suckle two children in succussion upon the same milk.

2. Another source of the diseases of children is the unhealthiness of parents: and our author infils that no per son who labours under an incurable malady ought to marry.

3. The manner of clothing children tends to produce diseases. All that is necessary here, he says, is to wrap the child in a soft loose covering: and the softness of every part of the infant's body sufficiently shows the injury which must necessarily ensue by pursuing a contrary method.

4. A new-born infant, instead of being treated with syrups, oils, &c. ought to be allowed to suck the mother's milk as soon as it comes into the world. He condemns the practice of giving wines and spirituous liquors along with the food soon after birth; and says, that if the mother or nurse has a sufficient quantity of milk, the child will need little or no other food before the third or fourth month. But to this it may reasonably be objected, not only that the nursing would thus be very severe on the mother; but if the child be left thus long without food, it will not easily relish it for some time, and its stomach is apt to be easily hurt by a slight change of diet after it has been long accustomed to one thing. Neither can it be shown, that the strongest and most healthy infants are those which get no other food but the mother's milk during the first months of their life. In fact, children are evidently of a weak and lax habit of body, so that many of their diseases must arise from that cause; all directions which indiscriminately advise an antiphlogistic regimen for infants as soon as they come into the world, null of necessity be wrong. Many infants in fact might be brought to thrive, that by the preposterous method ofstarving infants, and at the same time treating them with vomits and purges, they are
which afterwards mixing with the mucus of the gullet and stomach, render the milk of a flimsy confidence, by which means it is not so readily absorbed into the intestines; and as in most infants there is too great an acidity in the stomach, the milk is thereby curdled, which adds to the load; hence sickness and spasms, which, being communicated by sympathy to the nerves of the gullet and fauces, produce the convulsive motions above described, which go commonly by the name of inward fits. The air, likewise, which is drawn in during suction, mixing with the milk, &c. in the stomach, perhaps contributes towards increasing the spasms above-mentioned. Dr Armstrong is the more induced to attribute these fits to the causes now assigned, that they always appear immediately after sucking or feeding; especially if the child has been long at the breast, or fed heartily, and has been laid down to sleep without having first broken wind, which ought never to be done. Another reason is, that nothing relieves them so soon as belching or vomiting; and the milk or food they throw up is generally either curdled, or mixed with a large quantity of heavy phlegm. In case they are not relieved by belching or vomiting, the fits sometimes continue a good while, and gradually abate, according as the contents of the stomach are pushed into the intestines; and as soon as the former is pretty well emptied, the child is waked by hunger, cries, and wants the breast; he fixes, and the same process is repeated.

Thus, some children for the first weeks are kept almost always in a daze, or seemingly so; especially if the nurser, either through laxness or want of skill, do not take care to rouse them when they perceive that it is not a right sleep, and keep them awake at proper intervals. This dozing is reckoned a bad sign amongst experienced nurses; who look upon it as a forerunner of the then, as indeed it often is; and therefore, when it happens, we ought to be upon our guard to use the necessary precautions for preventing that disorder.

For these disorders, the only remedy recommended by Dr Armstrong is antimonic wine, given in a few drops, according to the age of the infant. By this means the superabundant mucus will no doubt be evacuated; but at the same time we must remember, that this evacuation can only pass in cases where the disease was not produced by any interruption of the child in the menses, do not cure the disease. This can only be effected by nurses; and a decoction of the Peruvian bark, made into a syrup, will readily be taken by infants, and may be safely exhibited from the very day they come into the world, or as soon as their bowels are emptied of the meconium by the mother's milk or any other means.

Dr Clarke observes, that fractures of the limbs, and compressions of the brain, often happen in difficult labours; and that the latter are often followed by convulsions soon after delivery. In these cases, he says, it will be advisable to let the navel-string bleed two or three spoonfuls before it be tied. Thus the oppression of the brain will be relieved, and the disagreeable consequences just mentioned will be prevented. But if this has been neglected, and fits have actually come on, we must endeavour to make a revolution by all the means in our power; as by opening the jugular vein, procuring an immediate discharge of the urine and meconium, and applying small blisters to the back, legs, or behind the ears. The semicupium, too, would seem to be useful in this case, by driving the oppressive load of fluids from the head and upper parts.
**Appendix.**

**Medicine.**

It sometimes happens after a tedious labour, that the child is so faint and weak as to discover little or no signs of life. In such a case, after the usual cleansing, the body should be immediately wrapped in warm flannel, and briskly towed about in the nurse's arms, in order, if possible, to excite the languid circulation. If this fail, the nurse should rub her back with brandy or other spirits; or the child may be provoked to cry, by whipping, or other stimulating methods, as the application of onion, or salt and spirit of hartshorn, to the mouth and nostrils. But after all these expedients have been tried in vain, and the recovery of the child absolutely defpaired of, it has sometimes been happily revived by introducing a short catheter or blow-pipe into the mouth, and gently blowing into the lungs at different intervals. Such children, however, are apt to remain weak for a considerable time, so that it is often no easy matter to rear them; and therefore particular care and tenderness will be required in their management, that nothing may be omitted which can contribute either to their preservation or their cure. This at least certainly holds with regard to some cathartics; such, for example, as the infusion of fenna, particularly if a very weak infirnbe be employed, and not used to such an extent as to be a purgative to the nurse.

When cathartics are necessary, but the child seems too tender and weak to bear their immediate operation, they should be given to the nurse; in which case they will communicate so much of their virtues to the milk as will be sufficient to purge the infant. This at least is certain, and is often the effect of giving a dose to the mother before she gives the child her breast. When cathartics are not so immediately necessary, but it is known that something is amiss when they begin to be used too much, the nurse is to communicate them to her doctor, and be especially cautious in the circumstances of the case.

There is no complaint more frequent among children than that of worms, the general symptoms of which have been already enumerated; but it must be observed, that all the symptoms commonly attributed to worms alone, may be produced by a foulness of the bowels. Hence practitioners ought never to rest satisfied with administering to their patients such medicines.
inMES.

Diseases of Children.

Cines as are possessed only of an anthelmintic quality, but to join them with those which are particularly ad-
apted for cleansing the prime vix; as it is uncertain
whether a foulness of the bowels may not be the cause
of all the complaints. This practice is still the more
advisable, on account of vivid humors in the inte-
lines affording lodgment to the ova of worms; which,
without the convenience of such a receptacle, would be
more speedily discharged from the body.

The difficulty of curing what is called a "worm-fever,
arises, according to Dr Muirgrave, from its being fre-
quently attributed to worms, when the cause of the
disorder is of a quite different nature. He does not
mean to deny that worms do sometimes abound in the
human body, nor that the irritation caused by them
does sometimes produce a fever; but he apprehends
these cases to be much more uncommon than is gen-
erally imagined, and that great mischief is done by treat-
ing some of the disorders of children as worm-cases,
which really are not so. Dr Hunter, it is ob-
erved, is of the same opinion on this point; and he has,
we are told, dissected great numbers of children who have
been supposed to die of worm-fevers, and whose com-
plaints were of course treated as proceeding from worms,
whom however, there appeared, upon dissection, to be
not only no worms, but evident proofs of the disor-
der's having been of a very different nature.

The "furious worm-fever," as Dr Muirgrave terms it,
has, in all the instances he has seen of it, arisen evi-
dently from the children having been indulged with
too great quantities of fruit; though a poor cold diet
may, he thinks, occasionally give birth to it. Every
fort of fruit eaten in excess will probably produce it;
but an immediate use of cherries seems to be the most
common cause of it. The approach of this disorder has a
different appearance, according as it arises from a ha-
babit of eating fruit in rather too large quantities, or
from an excessive quantity eaten at one time. In the
former case, the patient gradually grows weak and
lagritudinous; his colour becomes pale and livid; his belly
swells and grows hard; his appetite and digestion are
destroyed; his nights grow restless, or at least his sleep
is much disturbed with fluctuations, and then the fever
soon follows; in the progress of which, the patient
grows pale and atrophies, and at times convulses; in which
state, when it takes place to a high degree, he often dies.
The pulse at the wrist, though quick, is never strong or hard;
the carotids, however, beat with great violence, and el-
evate the skin so as to be distinctly seen at a distance. The
heat is at times considerable, especially in the trunk;
though at other times, when the brain is much oppressed,
it is little more than natural. It is sometimes accom-
panied by a violent pain of the epigastric region, though
more commonly the pain is at the back, and terminates in a
coma; some degree of pain, however, seems to be infe-
pammable from it, so as clearly to distinguish this disor-
der: from other comatose affections.

When a large quantity of fruit has been eaten at
once, the attack of the disorder is instantaneous, and its
progress rapid; the patient often pails away in the
space of a few hours, from apparently perfect health,
to a stupid, comatose, and almost dying state. The
symptoms of the fever, when formed, are in both cafes
nearly the same; except that, in this latter fort, a little
purulent matter is sometimes discharged, both by vo-
mit and stool, from the very first day. The stools, in both
cases, exhibit sometimes a kind of curd resembling
curdled milk, at other times a floating substance is ob-
served in them; and sometimes a number of little threads
and pellicles, and now and then a single worm.

Strong purgatives, or purges frequently repeated, in
this disorder, are greatly condemned by Dr Armstrong,
as they in general not only aggravate the symptoms
already present, but are sometimes the origin of con-
volutions. Bloodletting is not to be thought of in any
stage of the disorder.

Although frequent purging, however, be not recom-
manded, yet a single vomit and purge are advised in
the beginning of the disorder, with a view to evacuate
such indigested matter and mucus as happens to remain
in the stomach and bowels. These having operated
properly, there is seldom occasion for repeating them;
and it is sufficient, if the body be colicky, to throw up,
every second or third day, a clyster, composed of one
grains of aloes, dissolved in five ounces of infusion of
chamomile.

The principal part of the cure, however, depends
upon external applications to the bowels and stomach;
and as the cause of the disorder is of a cold nature,
the applications must be warm, cordial, and invigorating;
and their action must be promoted by constant
actual heat.

The following is the form recommended.

"Take of leaves of wormwood and rue, equal
goods: make a saturated decoction in a sufficient quan-
tity of water, with which foment the region of the
stomach; and the bowels to be long persisled in, though
sometimes
"Tome of rue and wormwood, is much re-
dissolved; mixed with an equal quantity of

"Take of spirituous

Strong decoction of rue and worm-wood, is much re-
commended. It is a perfectly safe remedy, and, by
invigorating the bowels, may thereby have some
influence in rendering them capable of expelling such
worms.
wounds as they happen to contain. After the fomentation, it is advised to anoint the belly with a liment composed of one part of essentia! oil of rue, and two parts of a decoction of rue in sweet oil. It is, however, a matter of great doubt whether these external applications, in consequence of the articles with which they are impregnated, exert any influence on the worms themselves.

The diet of children disposed to worms, should be warm and nourishing, consisting in part at least of animal food, which is not the worse of being a little seasoned. Their drink may be any kind of beer that is not so necessary, perhaps, as is generally imagined. Well hopped, with now and then a small draught of porter or negus. The appetite returns, the diet here recommended will, perhaps, be found serviceable. Their drink may be any kind of beer that is not so necessary, perhaps, as is generally imagined. A total abstinence from butter is not so necessary, perhaps, as is generally imagined. Poor cheese must by all means be avoided; but such as is rich and pungent, in a moderate quantity, is particularly serviceable.

The toothache, occasioned by cold, rheumatism, or inflammation, is generally relieved by drawing the electric fluid with a wooden point, immediately from the part, and also externally from the face. But when the body of the tooth is affected, electrization is of no use; for it seldom or never relieves the disorder, and sometimes increases the pain to a prodigious degree.

Swellings in general, which do not contain any matter, are frequently cured by drawing the electric fluid with a wooden point. The operation should be continued for three or four minutes every day. It is very remarkable, that in some cafes of white swellings, quite cured by means of electricity, the bones and cartilages were in some measure disfigured.

Inflammations of every sort are generally relieved by a very gentle electrization.

In inflammations of the eye, the throwing of the electric fluid by means of a wooden point is often attended with great benefit; the pain being quickly abated, and the inflammation being generally dissipated in a few days. In these cases, the eye of the patient must be kept open; and care should be taken not to bring the wooden point very near it, for fear of causing any spark. Sometimes it is sufficient to throw the fluid with a metal point; for in these cases, too great an irritation should be always avoided. It is not necessary to continue this operation for three or four minutes without intermission, but after throwing the fluid for about half a minute, a short time may be allowed to the patient to rest and to wipe his tears, which generally flow very copiously; then the operation may be continued again for another half minute, and so on for four or five times every day.

The gutta pernosa has been sometimes cured by electrization; but at the same time it must be confessed, it has proved ineffectual in many such cases, in which it was administered for a long time and with all possible attention. However, it has never been known that any body was made worse by it. The best method of administering electricity in such cases, is first to draw the electric fluid with a wooden point for a short time, and then to send about half a dozen of shocks of one-twentieth of an inch from the back and lower part of the head to the fore head, very little above the eye.

A remarkable disfigure of the eye was some time ago perfectly cured by electrization; it was an opacity of the vitreous humour of the eye.
All these cases of fibula lacrymalis which Mr. Cavallo
has known to have been electrified by persons of
ability for a sufficient time, have been entirely cured.
The method generally practised has been that of
drawing the fluid with a wooden point, and to take
very small sparks from the part. The operation may
be continued for about three or four minutes every day.
It is remarkable, that in those cases, after curing the
fibula lacrymalis, no other disease was occasioned by it,
as blindness, inflammations, &c. by supposing that
diseases.
Polyps are seldom perfectly cured by means of elec-
tricity, especially when they are of long standing; but
they are generally relieved to a certain degree. The
method of electrifying in those cases, is to draw the
fluid with the wooden point, and to draw sparks thro'
flannel, or through the usual coverings of the part if
they are not too thick. The operation may be con-
tinued for about five minutes per day.
Ulcers, or open sores of every kind, even of a long
standing, are generally disposed to heal by electriza-
tion. The general effects are a diminution of the in-
flammation, and a promotion of the discharge
of properly formed matter; which discharge gradually
lessens, according as the limits of the sore contract,
till it be quite cured. In these cases the gentlest elec-
trization must be used, in order to avoid too great an
irritation, which is generally hurtful. To draw or
throw the fluid with a wooden or even with a metal
point, for three or four minutes per day, is fully
sufficient.
Cutaneous eruptions have been successfully treated
with electrization; but in these cases it must be ob-
erved, that if the wooden point be kept too near the
skin, so as to cause any considerable irritation, the
eruption will be caused to spread more; but if the
point be kept at about six inches distance, or farther
if the electrical machine be very powerful, the erup-
tions will be gradually diminished, till they are quite
cured. In this kind of disease, the immediate and ge-
eral effect of the wooden point is to occasion a
warmth about the electrified part, which is always a
sign that the electrization is rightly administered.
The application of electricity has perfectly cured
various cases of St. Vitus's dance, or of that disease
which is commonly called so; for it is the opinion of
some very learned physicians, that the real disease cal-
ced St. Vitus's dance which formerly was more frequent
than it is at present, is different from that which now
goes under that name. In this disease the shocks of about
one-tenth of an inch may be sent through the body in
many directions, and also sparks may be taken. But
this treatment prove very disagreeable to the patient
then the shocks must be leftened, and even omitted; in-
stead of which some other more gentle applications
must be substituted.
Sarcomata tumors, when they are at first beginning,
are generally cured by drawing the electric fluid with
a wooden or metal point from the part. This is one
of those kinds of diseases in which the action of elec-
tricity requires particularly the aid of other medicines
in order to effect a cure more easily; for sarcomatous
affections commonly accompany a great laxity of the
habit, and a general cachexy, which must be ob-
viated by proper remedies.
In cancers, the pains only are commonly alleviated by
drawing the electric fluid with a wooden or metal point.
Mr. Cavallo, however, mentions one case in which a most
confirmed cancer of very long standing, on the breast
of a woman, had been much reduced in size. It is re-
markable, that this patient was so far relieved by draw-
ing the fluid with a metal point from the part, that
the excruciating pains she had suffered for many years
did almost entirely disappear; and also, that when the
electric fluid was drawn by means of a wooden point,
the pains did rather increase.
Albications, when they are in their beginning, and in
general whenever there is any tendency to form mat-
ter, are dispersed by electrization. Lately, in a case
in which matter was formed upon the hip, called the
lumbar albications, the disease was perfectly cured by
means of electricity. The fistatica has also been often
cured by it. In all such cases, the electric fluid must
be sent through the part by means of two directors
applied to opposite parts, and in immediate contact
either with the skin, or with the coverings, when these
are very thin. It is very remarkable, that the mere
pallage of the electric fluid in this manner is generally
felt by the patients afflicted with those disorders,
neither as much as a small shock is felt by a person in
good health. Sometimes a few shocks have been also
given, but it seems more proper to omit them: be-
cause sometimes, instead of dispersing, they rather ac-
celerate the formation of matter.
In cases of pulmonary inflammations, when they are
in the beginning, electrization has been sometimes be-
neficial; but in confirmed diseases of the lungs, it does
not seem to have ever afforded any unquestionable be-
nefit; however, it seems that in such cases the power
of electricity has been but seldom tried.
Nervous headaches, even of a long standing, are
generally cured by electrization. For this disease, the
electric fluid must be thrown with a wooden, and some-
times even with a metal point, all round the head suc-
cessively. Sometimes exceedingly small shocks have
been administered; but these can seldom be used, be-
cause the nerves of persons subject to this disease are so
very irritable, that the shocks, the sparks, and some-
times even the throwing the electric fluid with a wooden
point kept very near the head, throw them into
convulsions.
The application of electricity has often been found
beneficial in the dropsy when just beginning, or ra-
er in the tendency to a dropsy but it has never
been of any use in advanced dropies. In such cases,
the electric fluid is sent through the part, in various
directions, by means of two directors, and sparks are
also drawn across the flannel or the cloaths; keeping
the metal rod in contact with them, and shifting it con-
tinually from place to place. This operation should
be continued at least ten minutes, and should be re-
peated once or twice a day—Perhaps in these cases, a
simple electrization (viz. to inflate the patient, and
to connect him with the prime conductor whilst the
machine is in action), continued for a considerable time,
as an hour or two, would be more beneficial.
The gout, extraordinary as it may appear, has cer-
tainly been cured by means of electricity, in various
instances. The pain has been generally mitigated, and
sometimes the disease has been removed so well as not
to
to return again. In those cases, the electric fluid has
been thrown by means of a wooden point, although
sometimes, when the pain was too great, a metal point
only has been used.

Attempts have not unfrequently been made by electricity,
so that sometimes one electricity or two have been
sufficient. The most effectual and sure method has been
that of drawing sparks through the Netherlands, or
the cloths, for about ten minutes or a quarter of an
hour. The patients may be electrified either at the
time of the fit, or a short while before the time in
which it is expected.

The suppression of the menses, which is a disease of
the female sex that often occasions the most distressing
and alarming symptoms, is often successfully and
specifically cured by means of electricity, even when
the disease is of long standing, and after the most
powerful medicines used for it have proved ineffectual.
The cases of this sort in which electrization has
proved useful are few, and the successful ones far
numerous, that the application of electricity for this disease
may be justly considered as an efficacious and certain remedy.
Great attention and knowledge is required, in
order to distinguish the arrest of the menses from a
state of pregnancy. In the former, the application of
electricity, as we observed above, is very beneficial;
whereas, in the latter, it may be attended with very
disagreeable effects: it is therefore a matter of great
importance to ascertain the real cause of the disease,
before the electricity be applied in these cases. Pregn­
ant women may be electrified for this disease, but
always using very gentle means, and directing the
electric fluid through other parts of the body distant
from those subverted to generation. In the real sup­
pression of the menses, small shocks, that is, of about
one-twentieth of an inch, may be sent through the pelvis;
sparks may be taken through the cloths from the parts adjacent to the seat of the disease; and also
the electric fluid may be transmitted by applying the
metallic or wooden extremities of two directors to the
hips, in contact with the clothes; part of which may
be removed in cases they be too thick. Those various
applications of electricity should be regulated accord­
ing to the constitution of the patient. The number of
shocks may be about 12 or 14. The other applica­
tions may be continued for two or three minutes;
repeating the operation every day. But either strong
shocks, or a stronger application of electricity than the
patient can conveniently bear, should be carefully
avoided; for by those means, sometimes more than a
sufficient discharge is occasioned, which is not safely
cured. In cases of uterine hemorrhages, it is not
known that the application of electricity was ever ben­
eficial. Perhaps a very gentle electrization, so as to
keep the patient inflamed and connected with the
prime conductor whilst the electrical machine is in ac­
tion, may be of some benefit.

In respect to urinary discharges and fluxes in gen­
eral, it may be observed, that those discharges are
quite uncommon or adventitious, as the filth into which
the discharges were made, and some species of the venereal disease; but oth­
er species are only increased natural discharges, such as the
urinary perversion, &c. Now the power of electricity in general has been found more beneficial for the
first than for the second sort of discharge, which are mostly increased by it.

In the general disease, electrization has been generally
forbidden; having commonly increased the pains, and
other symptoms, rather than diminished them. Indeed,
considering that any sort of stimulus has been found
hurtful to persons afflicted with that disorder, it is no
wonder that electricity has produced some bad effects,
especially in the manner it was administered some time
ago, viz. by giving strong shocks. However, it has
been lately observed, that a very gentle application of
electricity, as drawing the fluid by means of a wooden
or metal point, is peculiarly beneficial in various cases
of this kind, even when the disease has been of long
standing. Having remarked above, that tumors, when
just beginning, are dispersed, and that unnatural dis­
charges are gradually suppressed by a judicious elec­
trization, it is superfluous to describe particularly those
flares of the venereal disease in which electricity may
be applied; it is only necessary to remind the oper­
atore to avoid any considerable stimulus in cases of
this sort.

The application of electricity has been found also
beneficial in other diseases besides those mentioned a­
bove; but as the facts are not sufficiently numerous, so
as to afford the deduction of any general rules, we
have not thought proper to take any particular notice
of them.

We may add, that, in many cases, the help
of other remedies to be prescribed by the medical
practitioner will be required to obtain the action of
electricity, which by itself would perhaps be useless;
and, on the other hand, electrization may often be
applied to assist the action of other remedies, as of
affo­rriage, strengthening medicines, &c.

Of Fixed Air as a Medicine.

The antiseptic qualities of fixed air, or as it is now
more generally called of the aerial or carbolic acid,
have of late introduced it as a medicine in cases of
patri disorder, and various other complaints.—
Dr Percival observes, that though fatal if inspired in
a very large quantity, it may in smaller quantities be
breathed without danger or uneasiness. And it is a
confirmation of this conclusion, that at Bath, where
the waters copiously exhale this mineral spirit, the
bathers inspire it with impunity. At Duxton also, where
the bath is in a close vault, the effects of such effluvia,
if noxious, must certainly be pernicious.

Encouraged by these and some other considerations,
he has administered fixed air in more than 30 cases of
the phthisis pulmonalis, by directing his patients to in­
spire the rooms of an effervescing mixture of chalk and
vinegar through the spout of a coffee-pot. The hec­
tic fever has in several instances been considerably ab­
ated, and the matter expectorated has become less of­
fensive and better digested. He has not, however,
been so fortunate in any one case as to effect a cure;
although the use of mephitic air has been accompanied
with proper internal medicines. But Dr Withering
has been more successful. One phthisical patient un­
der his care, by a similar course, entirely recovered; an­
other was rendered much better; and a third, whose
cafe was truly deplorable, seemed to be kept alive by
it
Fixed Air. It may be proper to observe, that fixed air can only be employed with any prospect of success in the latter stages of the phthisis pulmonalis, when a purulent expecoration takes place. After the rupture and discharge of a vomica allo, such a remedy promises to be a powerful palliative. Antiseptic fumigations and vapours have been long employed, and much extolled, in cases of this kind. The following experiment was made to determine whether their efficacy in any degree depends on the separation of fixed air from their substance.

One end of a bent tube was fixed in a phial full of lime-water; the other end in a bottle of the tincture of myrrh. The junctures were carefully luted; and the phial containing the tincture of myrrh was placed in water, heated almost to the boiling point, by the lamp of a tea-kettle. A number of air-bubbles were separated, but probably not of the mephitic kind; for no precipitation ensued in the lime-water. This experiment was repeated with the tinct. Tobitana Ph. Ed. and with sp. winof. camph. and the result was entirely the same. The medicinal action therefore of the vapours raised from such tinctures, cannot be ascribed to the extraction of fixed air; of which it is probable bodies are deprived by chemical solution as well as by mixture.

If mephitic air be thus capable of corroding purulent matter in the lungs, we may reasonably infer it will be equally useful when applied externally to foul ulcers; and experience confirms the conclusion. Even the fancies of a cancer, when the carrot-poultice failed, has been sweetened by it, the pain mitigated, and much extolled, in cases of this kind. The already mentioned; but those of the softer sex who have already suffered from the uterine scour and the restult was entirely the same. The medicinal action therefore of the vapours raised from such tinctures, cannot be ascribed to the extraction of fixed air; of which it is probable bodies are deprived by chemical solution as well as by mixture.

In the ulcerous sore throat, much advantage has been experienced from the vapours of effervescing mixtures drawn into the fauces. But this remedy should not supercede the use of other antiseptic applications.

In malignant fevers, wines abounding with fixed air may be administered to check the septic ferment, and sweeten the putrid colliquiae in the prime vitæ. If the laxative quality of such liquors be thought an objection to the use of them, wines of a greater age may be given, impregnated with aerial acid.—The patient's common drink might also be medicated in the same way. A putrid diarrhoea frequently occurs in the latter stage of such disorders; and it is a most alarming and dangerous symptom. If the discharge be flopped by asprings, a putrid faeces is retained in the body, which aggravates the delirium, and increases the fever. On the contrary, if it be sufffered to take its course, the strength of the patient must soon be exhausted, and death unavoidably ensue. The injection of mephitic air into the intelines, under these circumstances, bids fair to be highly serviceable. And in some cases of this kind the gas emitted from a mixture of chalk and oil of Fixed Air, vitriol conveyed into the body by the machine employed for tobacco-clysters, quickly retrained the diarrhoea, corrected the heat and fetor of the bowels, and in a short time removed every symptom of danger.

As a solvent of the calculi, its virtues have been already mentioned; but the experiments made on that subject do not determine the matter with sufficient accuracy.

I. Rules for the management of Valetudinarians.

That part of the medical system which lays down rules for the preservation of health, and prevention of diseases, termed Hygiene, is not to be strictly understood as if it respected only those people who enjoy perfect health, and who are under no apprehensions of disease, for such seldom either desire or attend to medical advice; but should rather be considered as relating to valetudinarians or to such as, though not actually sick, may yet have sufficient reason to fear that they will soon become so: hence it is that the rules must be applied to correct morbid dispositions, and to obviate the various things that were shown to be the remote or possible causes of diseases.

From the way in which the several temperaments are usually mentioned by systematic writers, it should seem as if they meant that every particular constitution must be referred to one or other of the four; but this is far from being reducible to practice, since by much the greater number of people have constitutions so indistinctly marked, that it is hard to say to which of the temperaments they belong.

When we actually meet with particular persons who have evidently either, 1. Too much strength and rigidity of fibre, and too much sensibility; 2. Too little strength, and yet too much sensibility; 3. Too much strength, and but little sensibility; or, 4. But little sensibility joined to weakness; we should look on such persons as more or less in the valetudinary state, who require that these morbid dispositions be particularly watched, lest they fall into those diseases which are allied to the different temperaments.

People of the first-mentioned temperament being liable to suffer from continued fevers, especially of the inflammatory species, their scheme of preserving health should consist in temperate living, with respect both to diet and exercise; they should studiously avoid immoderate drinking, and be remarkably cautious lest any of the natural discharges be checked. People of this habit bear evacuations well, especially bleeding; they ought not, however, to lose blood but when they really require to have the quantity lefened; because too much of this evacuation would be apt to reduce the constitution to the second-mentioned temperament, wherein strength is deficient, but sensibility redundant.

Persons of the second temperament are remarkably prone to suffer from painful and spasmodic diseases, and are easily ruffled; and those of the softer sex who have
Appendix.

MEDICINE.

But in opposite circumstances, where the fluids have been exhausted, we are to attempt the prevention of further waste by the use of strengthening tonics, nourishing diet, and indulgence from fatigue of body or mind.

Vitiated fluids are to be considered as affected either with the different kinds of general acrimony, or as betraying signs of some of the species of morbific matter which give rise to particular diseases, such as gout, rheumatism, calculus, fever, &c.

During the state of infancy, we may sometimes observe a remarkable acidity, which not only shows itself in the first passages, but also seems to contaminate the general mass of fluids. As it takes its rise, however, from weak bowels, our views, when we mean to prevent the ill consequences, must be chiefly directed to strengthen the digestive organs, as on their soundness the preparation of good chyle depends; and hence small doses of rhubarb and chalybeats (either the natural chalybeate waters mixed with milk, or the flores mariales in doses of a few grains, according to the age of the child), are to be administered; and the diet is to be so regulated as not to add to this acid tendency: brisk exercise is likewise to be enjoined, with frictions on the stomach, belly, and lower extremities.

Where the fluids tend to the putrescent state, which shows itself by putrid breath, epistaxis, and bleeding of the gums, a light diet and vivifying cafe, the diet then should be chiefly of fresh vegetables and ripe fruits, with wine in moderation, brisk exercise, and strengthening bitters.

Where acrimony shows itself by itching eruptions, uncommon thirst, and flushing heats, nothing will answer better than such sulphureous waters as the Harrowgate and Moffat in Britain, or the Lucan and Swadlinbar in Ireland; at the same time using a course of diet that shall be neither acid nor heating.

So far with respect to those kinds of morbific matter which do not invariably produce a particular species of disease: but there are others of a specific nature, some of which are generated in the body spontaneously, and seem to arise from errors in diet, or other circumstances of ill management with respect to the animal economy; and hence it is sometimes possible, in some degree if not altogether, to prevent the ill consequences. Thus, there are infirmities where returns of the gout have been prevented by adhering fridly to a milk diet.

The rheumatism has also been sometimes warded off by wearing a flannel shirt, or by using the cold bath without interruption.

Calculus may be retarded in its progress, and prevented from creating much distress, by the internal use of soap and lime-water, by soap-lees taken in milk or in veal-broth, or by the use of aerated alkaline water, which may perhaps be considered as being both more safe and more efficacious, and at the same time more pleasant, than any of the other practices.

The acrimony may be prevented by warm clothing and perseverance in brisk exercise, by drinking wine or cyder, and eating freely of such vegetable substances as can be had in those situations where this disease is most apt to show itself.

In constitutions where there is an hereditary disposition...
The infection of a putrid fever or dysentery is best prevented by immediately taking an emetic on the first attack of the sickness or shivering; and if that do not completely answer, let a large blister be applied between the shoulders: by this method the nurses and other attendants on the sick in the naval hospitals have often been preserved. As to other infectious morbid matter, we must refer to what has already been said when treating of hydrophobia, fevers, &c.

The ill effects which may arise from the different species of saffurra, are to be avoided, in general by the prudent administration of emetics, and carefully abstaining from such kinds of food as are known to occasion the accumulation of noxious matters in the first passages.

Crude vegetables, milk, butter, and other oily substances, are to be avoided by persons troubled with a sordes in the stomach; brisk exercise, especially riding, is to be used, and they are to refrain from fermented liquors: the common drink should be pure water; or water with a very little of some ardent spirit, such as rum or brandy. Seltzer and Vahls water are to be drunk medicinally; and aromatic bitters, infusions, or tinctures, with the acid elixir of vitriol, from 10 to 20 drops, will be found serviceable, in order to strengthen the fibres of the stomach, and promote the expulsion of its contents, thereby preventing the too hasty fermentation of the alimentary mixture. In order to procure immediate relief, magnesium alba, or ereta preparata, will seldom fail; the magnesia, as well as the chalk, may be made into lozenges, with a little sugar and mucilage; and in that form may be carried about and taken occasionally by people afflicted with the acid saffurra.

In constitutions where there is an exubrance or flagration of bile, and a troublesome bitterness in the mouth, it is necessary to keep the bowels always free, by taking occasionally small doses of pure aloes, alum victini, cream of tartar, fome of the common purging salts, or the natural purging waters.

When there is a tendency to the empyreumatic and rancid saffurra, people should carefully avoid all the various kinds of those oily and high-seasoned things generally termed made-dishes and eat sparingly of plain meat, without rich sauces or much gravy; and in these cases the most proper drink is pure water.

II. RULES FOR THOSE WHO ENJOY PERFECT HEALTH.

There can be no doubt, that, in general, temperance is the true foundation of health; and yet the ancient physicians, as we may see in the rules laid down by Celsus did not scruple to recommend indulgence now and then, and allowed people to exceed both in eating and drinking; but it is safer to proceed to excess in drink than in meat: and if the debauch should create any extraordinary or distressing degree of pain or sickness, and a temporary fever should ensue, there are two ways of shaking it off, either to lie in bed and encourage perspiration, or to rolling-back and by brisk exercise reduce the body to its natural state. The choice of these two methods must always be determined by the peculiar circumstances of the parties concerned, and from the experience which they may before have had which agrees best with them.

If a person should commiss excess in eating, especially on high-seasoned things, with rich sauces, a draught of cold water, acidulated with vitriolic acid, will take off the sense of weight at the stomach, and afflit digestion, by moderating and keeping within bounds the alimentary fermentation, and thus preventing the generation of too much flatus. The luxury of ices may be here of real service at the tables of the great, as producing similar effects with the cold water acidulated. Persuad in these circumstances ought not to lay themselves down to sleep, but should keep up and exercise until they are sensible that the stomach is unloaded, and that they no longer feel any oppressive weight about the preocular region.

If a man be obliged to fast, he ought, if possible, during that time, to avoid laborious work: after suffering severe hunger, people ought not at once to gorge and fill themselves; nor is it proper, after being overfilled, to enjoy an absolute fast: neither is it due to rely totally immediately after excessive labour, nor suddenly fall hard to work after having been long without motion: in a word, all changes should be made by gentle degrees; for though the constitution of the human body be such that it can bear many alterations and irregularities without much danger, yet, when the transitions are extremely sudden, they cannot fail of producing some kind of degree of disorder.

It is also the advice of Celsus to vary the scenes of life, and not confine ourselves to any settled rules: but as inaction renders the body weak and listless, and exercise gives vigour and strength, people should never long omit riding, walking, or going abroad in a carriage; fencing, playing at tennis, dancing, or other similar engagements, which afford both exercise and amusement, as each shall be found most agreeable or convenient, are to be used in their turns, according to the circumstances and tendency to any particular species of disease. But when the weakness of old age shall have rendered the body incapable of all these, then dry frictions with the flesh-brush will be extremely requisite to preserve health, by accelerating the flow of humours through the smallest orders of vessels, and preventing the fluids from stagnating too long in the cellular interstices of the thirsty parts.

Sleep is the great restorer of strength; for, during this time, the nutritious particles appear to be chiefly applied to repair the waist, and replace those that have been abraded and washed off by the labour and exercise of the day; but too much indulgence in sleep has many inconveniences, both with respect to body and mind, as it blunts the senses, and encourages the fluids to stagnate in the cellular membrane; whence corpulence, and its necessary consequences languor and weakness.

The proper time for sleep is the night season, when
Appendix.

Means of黑暗 and silence naturally bring it on: therefore a day-sleep in general is not so refreshing; and to some people is really distressful, causing an unusual giddiness and languor, especially in persons addicted to literary pursuits. Custom, however, frequently renders sleep in the day necessary; and in those constitutions where it is found to give real refreshment, it ought to be indulged.

INDEX.

M E D I C I N E.

With regard to the general regimen of diet, it has always been held as a rule, that the fatter and milder kinds of aliment are most proper for children and younger subjects; that grown persons should eat what is more substantial; and old people lessen their quantity of solid food, and increasethat of their drink.

MEDICINES, whether simple or compound; the
former being prepared by nature alone; and the latter
owing to the industry of man, by variously mixing
the simples together. See PHARMACY.

MEDICINES are likewise distinguished from the man­
er of using them, into external and internal; and with
regard to their effects, they are said to be emetic, ca­
tonic, aromatic, astringent, &c. See MAXIMA Medica.

Pocket Medicines, in surgery, those which a sur­
geon ought always to carry about with him, in a box
or convenient case.

These, according to Heister, are the common di­
gestive ointment, and some detergent ointment, for
cleaning and digesting foul ulcers; to which must
also be added a tablet or two fitted for defence or
adhesion, since one or other of these is almost
constantly wanted. Neither should there be want­
ing a piece of blue vitriol for the taking down
luxuriant flesh, and to stop hemorrhages: but if
vitriol is wanting, burnt alum, red precipitate, the
infernal bone, or any other corrosive medicine, will
supply its place in corrosive intentions; and the last
will also serve to open abscesses, to make ious, and
perform many other operations of that kind.

With these there should always be kept in readiness
also a quantity of scraped lint, that the surgeon may
give to be able to give immediate assistance to wounded
persons; since, if he is unprepared for this, they may
easily be taken off by an hemorrhage; a circumstance
which ought also to prevail with him to be always
provided with suitable bandages.

MEDICIS (Cosimo de), called the Elder, son of John
de Medicis, was born at Florence Sept. 1389. Altho' in
a private station, he appeared with the splendor of the
molt powerful sovereign; and his fortune, accumu­
lated by successful commerce, was surpassed by the
revenue of few princes. He was partial to the sciences,
and liberal to men of genius. His library consisted
of a vast number of books of his own collecting, and he
enriched it with many scarce and valuable manuscripts.
Banished from his native country by the envy which
his riches inspired, he went to Venice, where he was
received with the honours due to a sovereign prince.
His counsylmen soon perceived their error, and re­
called him from banishment. For 34 years he was
the supreme judge of the republic; and his advice was fo­
licited by the greater part of the cities and sovereig­
ties of Italy. This great man died August 1464, in
the 77th year of his age, full of happiness and glory.
On his tombstone he is styled, "Father of the people,
and deliverer of his country.”

MEDICIS (Laurence de), styled the Great and the
Father of learning, was born A. D. 1448. He was
the son of Peter, the grandson of Cosmo, and the
brother of Julian de Medicis. These two brothers,
who were in possession of absolute power at Florence,
exited the jealousy of Ferdinand of Naples and Pope
Sixtus IV. The first hated them, because they had
ruined his influence in Florence; and the second,
caufe they opposed the advancement of his nephew.
It was at their instigation that the Pazzi conspired
against them. Julian was murdered while he heard
mass April 26th 1478; and Laurence, who was only
wounded, was carried back to his houfe in the midst
of the shouts and acclamations of the people. Heir to
the greater part of his grandfather's virtues, he was,
like him, the Mænas of his age. It was equally a
flonishing (lays an historian of that country) and for­
reign to our manners, to see the same man engaged in
commerce, and supporting the burden of the public
affairs; conversing with factors, and receiving ambas­
adors; giving shews to the people; affording an afy­
llum to the unfortunate; and adorning his country with
many magnificent buildings. He was so much be­
lowed by the Florentines, that they appointed him chief
magistrate of the republic. By his unbounded lib­
erality, he drew to his court a great number of learned
men. He sent John Lascaris into Greece to recover
manuscripts, with which he enriched his library. He
cultivated learning himself, and was the author of the
following works: 1. Des Postes Italianes. Venice, 1554,
12mo. 2. Cammeone à ballo, 1568, 4to. 3. La Com ­
pagnia del Manteluccio Beoni, with the sonnets of
Burchiello.
Medici. Burchiello, 1558 or 1568, 8vo. Laurence de Medicis was so universally admired, that the princes of Europe did him the honour to appeal their differences to his decision. It is even reported, that Bajazet emperor of the Turks, to show him a mark of esteem and regard, caused search, for the murderer of his brother Julian in Constantinople, and fent back one of them who had concealed himself in that city. Pope Sixtus IV. was the lait of his enemies; but he opposed him with so much ability, that he brought him to terms of accommodation. This illustrious man died April 9th 1492, aged 44. His reputation was fullied by his passion for women and by his infidelity. His two sons, Peter who succeeded him and who was expelled from Florence in 1494, and John who went by the name of Pope Leo X. were like their father remarkable for their generosity and their love of learning. Peter died in 1559, leaving Laurence, the last male issue of this branch. Laurence was the father of Catharine de Medicis, who married Henry II. king of France.

Medici (John de), on account of his bravery and knowledge in military affairs was sworn the Iuveinelli. He was the son of John, otherwise called Joue dain, de Medicis. His only son Cofno I. styled the Great, was chosen duke of Florence after the murder of Alexander de Medicis. A. D. 1537. He first carried arms under Laurence de Medicis against the duke of Urbino, afterwards under Pope Leo X. Upon the death of Leo, he entered into the service of Francis I. which he quitted to follow the fortunes of Francis Sforza duke of Milan. When Francis I. formed an alliance with the pope and the Venetians against the emperor, he returned to his service. He was wounded in the battle at Governois, a small town in the Mantuan territory, by a musket-ball; and being carried to Mantua, he died the 29th of November 1528, aged 28. Brantome relates, that when his leg was to be cut off, and when he was informed that he needed some person to support him, "Proceed without fear (said he), I need nobody!" and he held the candle himself during the operation. This anecdote is also mentioned by Varchi. John de Medicis was above the middle stature, strong, and nervous. His fiddlers, to express their affection for him and their concern for his loss, assumed a mourning dress and standards, which gave the name of the black band to the Tuscian troops whom he commanded.

Medici, (Laurence, or Laurenein de), was descended from a brother of Cofino the Great, and affected the name of popular. In 1537, he killed Alexander de Medicis, whom Charles V. had made duke of Florence, and who was believed to be the natural son of Laurence de Medicis duke of Urbino. He was jealous of Alexander’s power, and disguised this jealousy under the specious pretext of love to his country. He loved men of learning, and cultivated literature. His works are, 1. Lamenti, Modena, 12mo. 2. Avicia Commedia, Florence 1557, 12mo. He died without issue.

Medici, (Ippolitus de), natural son of Julian de Medicis and a lady of Urbino, was early remarkable for the brilliancy of his wit and the graces of his person. Pope Clement VII. his cousin, made him cardinal in 1529, and sent him as legate into Germany to the court of Charles V. When that prince went into Italy, Medici, yielding to his warlike disposition, appeared in the dress of an officer, and advanced before the emperor, followed by several respectable gentlemen of the court. Charles, naturally suspicious, and afraid that the legate intended to do him some ill offices with the pope, sent after him and caused him to be apprehended. But when he understood that it was a mere fally of humour in the young cardinal, he set him at liberty in a few days. The character which Medici obtained by the happy success of this appointment, was of essential service to him. He was considered as one of the supports of the Holy See; and a little before Clement’s death, when the colport Barbarossa made a descent into Italy to the great terror of Rome, which was only defended by 200 of the pope’s guards, Medici was dispatched to protect the coasts from the fury of the barbarians. On his arrival at the place of destination, he was fortunate enough to find that Barbarossa had withdrawn himself at that critical moment; which allowed him to claim the honour of the retreat without exposing his person or his army. When he returned to Rome, he was of great service in the election of Paul III., who nevertheless refused to make him legate to Ancona, though that office had been promised to him in the conclave. Enraged also that the pope had belittled the principality of Florence on Alexander de Medicis, supposed to be the natural son of Laurence duke of Urbino, he was promptily by his ambition to believe that he might succeed to that dignity by the destruction of Alexander. He entered into a conspiracy against him, and determined to carry him off by a mine; but the plot was discovered before he had accomplished his purpose. Ottavian Zanga, one of his guards, was arrested as his chief accomplice. Hypolitus de Medicis, apprehensive for his own safety, retired to a castle near Trivoli. On his road to Naples, he fell sick at Irvi in the territory of Fondi, and died August 15th 1535, in his 24th year, not without suspicion of being poisoned. His house was an asylum for the unfortunate, and frequently for those who were guilty of the blackest crimes. It was open to men of all nations; and he was frequently addressed in 20 different languages. He had a natural son named Afdrubal de Medicis, who was a knight of Malta. This anecdote proves that his manners were more military than ecclesiastic. He wore a sword, and never put on the habit of cardinal except on occasions of public ceremony. He was wholly devoted to the theatre, hunting, and poetry.

Medici, (Alexander de), first duke of Florence in 1550, was natural son of Laurence de Medicis and named the Younger, and nephew of pope Clement VII. He owed his elevation to the intrigues of his uncle and to the arms of Charles V. This prince having made himself master of Florence after an obstinate siege, conferred the sovereignty of this city on Alexander, and afterwards gave him in marriage Margaret of Austria his natural daughter. According to the terms of capitulation granted to the Florentines, the new duke was to be only hereditary doge, and his authority was tempered by councils; which left them at least a shadow of their ancient liberty. But Alexander,
Alexander, who felt himself supported by the emperor and the pope, was no sooner in possession of his new dignity, than he began to govern like a tyrant; being guided by no law but his own caprice, indulging the most brutal passions, and making light of dishonouring families, and of violating even the asylum of the cloisters to gratify his lust. Among the confidants of his debauchery was a relation of his own, Laurence de Medici. This young man, who was only 22 years of age, at the instigation of Philip Strozzi, a zealous republican, conceived the design of affalinating Alexander, and thereby of delivering his country from oppression. From the moment when he first became attached to him, he tried to gain his confidence, for no other reason but that he might the better have in his power to take away his life. A considerable time elapsed before he found such an opportunity as he desired. At length, under pretence of procuring the duke a tite à tête with a lady of whom he was deeply enamoured, he brought him alone and unattended into his chamber, and put him under his bed. He went out, under pretence of introducing the object of his passion; and returned along with an affalinator by profession, to whom alone he had entrusted his design, only to stab him. This cruel scene happened on the night between the 5th and 6th of January 1537. Alexander was only 26 years of age. The glory. In 1562 he instituted the military order of

Alfred: in law, signifies a jury, or inquest impanelled, of which the one half are natives of this land and the other foreigners. This jury is never used except when one of the parties in a plea is a stranger and the other a denizen. In petit-treason, murder and felony, foreigners are allowed this privilege; but not in high-treason, because an alien in that case shall be tried according to the rules of the common law, and not by a mediata lingua. A grand jury ought not in any case to be of a mediata lingua; and the person that would have the advantage of a trial in this way, is to pray the same, otherwise it will not be permitted on a challenge of the jurors.

Medimnus, in Grecian antiquity, a measure of Capacity. See Measure.

Medina-Talarni, a famous town of Arabia Petraea, between Arabia Deserta and Arabia the Happy; celebrated for being the burial-place of Mahomet. It stands at a day's journey from the port of Jamb. It is of moderate size, surrounded by wretched walls, and situated in the midst of a sandy plain. It belongs to the Scherif of Mecca, although it had of late times a particular soveraigny of the family of Dacel Barkad. At present, the government is confined by the Scherif to a vizir, who must be taken from the family of the sovereign. Before Mahomet, this city was called Lathreb; but it got the name of Medina Nabi, “the City of the Prophet,” after Mahomet, being driven from Mecca by the Koreichites, had taken refuge there, and paffed in it the rest of his days. The tomb of Mahomet at Medina is respected by Mussulmans, but they are under no obligation to visit it for the purposes of devotion. The caravans of Syria and Egypt alone, which on their return from Mecca pass near Medina, go a little out of their way to see the tomb. It stands in a corner of the great square, whereas the Kaba is situated in the middle of that at Mecca. That the people may not perform some superstitious worship to the relics of the prophet, they are prevented from approaching the tomb by grates, through which they may look at it. It consists of a piece of plain motion-work in the form of a chefc, without any other monument. The tomb is placed between two others, where the ashes of the two first caliphs repose. Although it is not more magnificent than the tombs of the greater part of the founders of mosques, the building that covers it is decorated with a piece of green silk stuff embroidered with gold, which the pacha of Damasius renewes every seven years. It is guarded by 40 eunuchs, who watch the treasure-guarded to be deposited there. It is seated in a plain abounding with palm-trees, in E. Long. 39. 55. N. Lat. 25. See (History of) Arabia.

Medina-Celi, an ancient town of Spain, in Old Castile, and capital of a considerable duchy of the same name; seated near the river Xalon, in W. Long. 2. 9. N. Lat. 41. 15.

Medina-de-la-Torre, a very ancient town of Spain, in Estremadura, with an old castle, and the title of a duchy. It is seated on the confines of Andalusia, at the foot of a mountain near Bajadoz.

Medina-del-Campo, a large rich, and ancient town of Spain, in the kingdom of Leon. The great square is very fine, and adorned with a superb fountain. It
MEDINA (Sir John), a very eminent painter, was son of Medina de L'Auffrias, a Spanish captain who had settled at Brussel, where the son was born in 1660. He was instructed in painting by du Chatel; under whose direction he made good progress; and applying himself to the study of Rubens, that eminent master his principal model. He painted both history and portrait; and was held in extraordinary esteem by most of the princes of Germany, who distinguished his merit by several marks of honour. He married young, and came into England in 1686, where he drew portraits for several years with great reputation; as he painted those subjects with remarkable freedom of touch, a delicate management of iver, and strong resemblance of the persons. The Earl of Lennox encouraged him to go to Scotland, and procured him a subscription of 500 l. worth of buffets. He went, carrying a large number of bodies and pictures, to which he painted heads. He returned to England for a short time; but went back to Scotland, where he died, and was buried in the church-yard of the Greyfriers at Edinburgh in 1711, aged 52. He painted most of the Scotch nobility; but was not rich, having 20 children. The portraits of the professors in the surgery's-hall at Edinburgh were painted by him, and are commended. At Wentworth-castle is a large piece containing the first duke of Argyle and his sons, the two late dukes of Gordon too was drawn by him, with his son the marquis of Huntly, and his daughter Lady Jane, in one piece. Medina was knighted by the duke of Queensberry, lord high commissioner; and was the last knight made in Scotland before the union. The prints in the octavo edition of Milton were designed by him; and he composed another set for Ovid's Metamorphoses, but they were never engraved.

MEDINE, an Egyptian piece of money, of iron silvered over, and about the size of a silver threepence.

MEDILONUM, an ancient city, the capital of the infubres, built by the Gauls on their settlement in that part of Italy. A municipality, and a place of great strength. The seat of the liberal arts; when it had the name of Nova Athenae. Now Milan, capital of the Milanese, situated on the rivers Olana and Lombro, E. Long. 9° 30'. N. Lat. 45° 25'.

MEDILONUM Acebronum (anc. geog.), a town of Gallia Celtica, which afterwards took the name of the Eburovicii Civitas (Antonine), corrupted to Civitas Eburovonum, and this last to Eburovon; whence the modern appellation Evora, a city of Normandy. E. Long. 1° 12'. N. Lat. 49° 21'.

MEDITLANUM Gasterorum (anc. geog.), a town of Mediomatrici, now the village Meyland, not far from Cologne.

MEDITLANUM Ordovicum (anc. geog.), a town of Britain, now Lan Feleni, a market-town in Montgomery in Wales.

MEDITLANUM Santonum (anc. geog.), which afterwards taking the name of the people, was called Sanctia Urbi; allo Sancta; and Sotonum; a town of Aquitaine. Now Saintes, capital of Saintonge in Guienne, on the river Charente.

MEDIOMATRICI, anciently a territory of Belgia. Now the diocese of Metz.

MEDITATION, an act by which we consider anything closely, or wherein the soul is employed in the search or consideration of any truth. In our religion, it is used to signify a consideration of the objects and grand truths of the Christian faith.

Mythic divines make a great difference between meditation and contemplation: the former consists in discursive acts of the soul, considering methodically and with attention the mysteries of faith and the precepts of morality; and is performed by reflections and reasonings, which leave behind them manifest impressions on the brain. The pure contemplative has no need of meditation. He is free from all things in God at a glance, and without any reflection. When a man, therefore, has once quitted meditation, and is arrived at contemplation, he returns no more; and, according to Alvarez, never resumes the oar of meditation, except when the wind of contemplation is too weak to fill his sails.

MEDITERRANEAN, something inclosed within land; or that is remote from the ocean.

MEDITERRANEAN is more particularly used to signify that large sea which flows between the continents of Europe and Africa, entering by the straits of Gibraltar, and reaching into Asia, as far as the Euxine Sea and the Palus Moeotis.

The Mediterranean was anciently called the Grecian Sea and the Great Sea. It is now cantonned into several divisions, which bear several names. To the west of Italy it is called the Liguric or Tuscan Sea; near Venice, the Adriatic; towards Greece, the Ionian and Aegean; between the Hellespont and the Bosphorus, the White Sea, as being very safe; and beyond, the Black Sea, its navigation being dangerous.

The British trade carried on by means of the Mediterranean Sea is of the last consequence to Great Britain; and the permanent preservation therefore depends on the possession of the town and fortification of Gibraltar.

The counterfeiting of Mediterranean pales for ships to the coast of Barbary, &c. or the seal of the admiralty office to fish pales, is felony without benefit of clergy; Stat. 4 Geo. II. c. 18.

MEDITRINALIA, a Roman festival in honour of the goddess Mediitrini, kept on the 30th of September. Both the deity and the festival were so called a medena, because on this day they began to drink new wine mixed with old by way of medicine. The mixture of wines, on this festival, was drunk with much form and solemn ceremony.

MEDITULLUM, is used by anatomists for that spungy
M E D

Medium

Medium

spungy substance between the two plates of the cranium, and in the interlucines of all laminated bones. See Anatomy, n° 1, 11.

MEDIUM, in logic, the mean or middle term of a syllogism, being an argument, reason or consideration, for which we affirm or deny anything; or, it is the cause why the greater extreme is affirmed or denied of the less in the conclusion.

MEDIUM, in arithmetic, or arithmetical medium or mean, called in the schools medium rei; that which is equally distant from each extreme, or which exceeds the lesser extreme as much as it is exceeded by the greater, in respect of quantity, not of proportion; thus 9 is a geometrical medium between 6 and 12.

Geometrical MEDIUM, called in the schools medium perpensa, is that where the same ratio is preferred between the first and second as between the second and third terms; or that which exceeds in the same ratio or quota of itself, as it is exceeded: thus 6 is a geometrical medium between 4 and 9.

MEDIUM, in philosophy, that space or region through which a body in motion passes to any point: thus ether is supposed to be the medium through which the heavenly bodies move; air, the medium wherein bodies move near our earth; water, the medium whereof many species, being an argument, reason or consideration, for which we affirm or deny anything; or, it is the cause why the greater extreme is affirmed or denied of the less in the conclusion.

MEDIUM, in optics, any substance through which light is transmitted.

MEDULAR, in botany. See Mesplius.

MEDULLA OSSIUM, or Marrow of the Bone. See Anatomy, n° 5.

Medulla cerebri and cerebelli, denotes the white soft part of the brain and cerebellum, covered on the outside with the cortical substance, which is of a more dark or airy colour. See Anatomy, n° 131—133.

Medulla oblongata, is the medullary part of the brain and cerebellum, joined in one; the fore-part of it coming from the brain, and the hind-part from the cerebellum. See Anatomy, n° 134.

It lies on the basis of the skull, and is continued through the great prolongation thereof into the hollow of the vertebra of the neck, back, and loins; though only so much of it retains the name oblongata as is included within the skull. After its exit thence, it is dilated by the name of medulla spinalis. Ibid. n° 135.

Medusa (fab. hist.), one of the three Gorgons, daughter of Phorcys and Ceto. She was the only one of the Gorgons who was subject to mortality. She is celebrated for her personal charms and the beauty of her locks. Neptune became enamoured of her, and obtained her favours in the temple of Minerva. This violation of the sanctity of the temple provoked Minerva; and she changed the beautiful locks of Medusa, which had inspired Neptune's love, into serpents, the fight of which turned the beholders into stones: but Perseus, armed with Mercury's axe with which he killed Argus, cut off Medusa's head, from whose blood sprang Pegasis and Chrysaor, together with the innumerable serpents that infest Africa. The conqueror placed Medusa's head on theegis of Minerva, which he had used in his expedition; and the head still retained the same petrifying powers as before.

Medusa, in zoology, a genus of vernes, belonging to the order of molulacea. The body is gelatinous, roundish, and depressed; and the mouth is in the centre of the under part of the body. Many species, being handled, affect with a nettle-like burning, and excite a redness. The ancients, and some of the moderns, add that they have an aphrodisiac property, and in several languages they are called by an obscene name. They were known to the Greek and Romans by the name of Typhoe, or Typhoeus, and Cassius, or Cassius-von. They attributed medicinal virtues to them. Dioscorides informs us, that, if rubbed fresh on the diseased part, they cured the gout in the feet, and kibed heels. Ælian says, that they were depilatory; and, if macerated in vinegar, would take away the beard. Their phoshoric quality is well known; nor was it overlooked by the ancients. Pliny observes, that if rubbed with a stick it will appear to burn, and the wood to shine all over. The same naturalist observes, that when they linking to the bottom of the sea, they portend a continuance of bad weather.

On Plate CCXCIV, are figured several specimens, viz. 1. The aurita, or aurited medusa, which appears, as floating on the water, to be a mere lifeless lump of jelly. It is of a whitish colour, with a cast of bluish grey, and is of an orbiculated figure, elevated into a convexity in the middle on the upper side, flat on the under, and furnished with a fringe of fine and some what rigid filaments round the edge, resembling white hairs: on the under surface there are four cavities near the centre, each of an arcuated figure, and surrounded with an opaque line, formed of about 24 parallel points or dots: from the very centre of the under side there arise four crooked appendages, which have each a row of hairy filaments on the exterior edge; and on the upper surface there is an appearance of fine vesicles of a pale colour. This species is frequent, floating on the surface of the sea, or adhering to rocks about our own coasts; and when the fun-flines on them, they have a very beautiful lucid appearance. It is called by the name of sea nettles, it being one of those animals that when touched occasions a very disagreeable tingling in the hand.

2. The capillata, or capitulated medusa, is a very Hold, singular and odd animal: it seems a mere lump of a whitish semi-pellucid jelly; and is as easily broken and destroyed by a touch as the common jellies brought to our tables; its shape is rounded, rising into a convexity in the middle, where it is therefore thickest, and whence it becomes gradually thinner to the sides; on the under side it is plain, and on this there is visible a rough, or as it were circinate circle, within which
there run eight pairs of rays from the centre toward
the circumference; and from the centre there arise
also a number of curled appendages, which are some-
times reddish, but more usually whitish, and a vast
number of slender filaments: the edge or the circum-
ference of the body is regularly divided into eight por-
tions, and each of them is emarginated, so that on the
whole verge there are 16 fins. This species is to be
met with in vast abundance floating on the surface of
the water about Sheppy island in Kent, England, and el-
sewhere on that coast: great quantities of it are de-
stroyed by being thrown on shore with the waves,
whence it has no power of getting off again; and in
the open seas, many fish skim near the surface, and
prey on them. This is the species called by many
authors *palma marinus*, on the sea lungs. The mar-
ked.

Fig. 3. *n* 3.

*Fupialis, or purbe medufa*, is semi-oval, with four ten-
tacula on the edge. It inhabits the Mediterranean.

Ibid. *n* 4.

4. The waved medufa, has the edges waved, with
the tings on the projecting parts; four filaments beneath,
between which rides a ftem divided into eight large
ragged tentacula.

These animals swim in large companies in search
of food, with their tentacula in continual motion, with
which they seize their prey, and convey it to their
mouths: they vary in size, the largest being generally
about eight inches in diameter. They vary likewise
in the number of their tentacula; some having only
two, others four, six, and some eight, but they rarely
exceed that number. So powerful is their embrace,
that whatever prey comes within their reach never
echapés. They suck in onsets, finall filis, &c.

Mr. Banks, in his passage from Madeira to Rio de
Janeiro, discovered a new species, which, when brought
aboard by the passing net, had the appearance of metal
violently heated, and emitted a white light. With
these animals were taken small crabs of three different
species, altogether new, each of which gave as much
light as the glow-worm, though the creature was not
so large by nine-tenths. These luminous animals are
one of the caufes of that appearance to the sea which
has been mentioned by many navigators, and of which
various reafons have been assigned. It appeared to
emit flashes of light exactly resembling thofe of light-
ing, only not fo confiderable, but fo frequent, that
sometimes eight or ten were visible at the fame mo-
moment.

MEDWAY, a river of England, rises in the Weald
of Sussex, and entering Kent near Ashbury runs by
Tunbridge, and thence continues its course towards
Maidstone. It is navigable for large ships to Rochef-
ter bridge, and thence for vessels and barges to Maid-
stone, the tide flowing up to that town. The diftance
between the mouth of this river, where the fort at
Sheernefs is erected, and Rochester bridge, is between
16 and 18 miles. In this part of the river, the chan-
nel is fo deep, the banks fo foft, and the reaches fo
short, that it is one of the belt and safest harbours in
the world; and ships of 80 guns ride a-float at low-
water, within musket-shot of Rochester-bridge. Nor
is there a fingle infance upon record, that any of the
British navy ever fuffered here by florms, except in the
dreadful tempeft which happened in November 1703,
when the Royal Catharine was driven on fhire, where
the funk and was loft. On the shore of this river are
two cattles, one at Uppor, which guards two reaches
of the river, and is fpoodooed to defend all the ships
which ride above, between that and the bridge; on
the other side of the river is Gillingham cattle, built
for the fame purpofe, and well ruined with cannon
which commands the river. Besides thefe, there is a
platform of guns at a place called the Swam, and an-
other at Cockham-wood. But the principal fortification
on this river is the castle at Sheernefs.

MEEREN, or MEER, (John Vander,) called the
Old, an efteemed painter, was born in 1627; but the
mafter under whom he learned the art of painting, is
not mentioned. His genius directed him to choofe for
his subje&s sea-pieces, landscapes, and views of the sea
and its fleers; which he painted with great truth, as
he had accustomed himself to fketch every fcene after
nature. The fituations of his landscapes, are agreeably
chofen, frequently they are solemn, and generally
pleading. The forms of his trees are easy and natural,
his diftances well observed, and the whole fcenery has
a striking eflect, by a happy pofition of his lights
and shadows. He alfo very often painted battles
in fuch a fìle as, met with approbation; as they
showed good composition, were touched with spirit,
and had a great deal of tranfparenfe in the colouring.
But the fault imputable to Vander Meer is, that in
fome of his pictures the back-gounds are a little too
blue, and fome of his landscapes have a tint which
appears rather too yellifh. He died in 1690.

MEEREN, or MEER, (John Vander,) called De Jonghe,
an eminent landscape-painter, is fuppofed to have been
the fon of the old John Vander Meer, and of whom,
he learned the ftrft rudiments of the art; but being
in his youth deprived of his inftutor before he had
made any great progress, he became a disciple of Ni-
holas Bergham, and was accounted the belt of thofe
who were educated in the fchool of that admired ma-
fier. In the manner of his mafter, he painted land-
scape and cattle; and his ufual fubje&s are cottages,
with peafants at their rural occupations and divereions.
It is obferved of him, that he very rarely introduced
cows, hofes, or any other fpecies of animals, except
goats and fheep; the latter of which are fo highly fi-
nifhed, that one would imagine the wood might be felt
by the defign of its appearance. His touch is fcarce
perceptible, and yet the colours are admirably united.
He died in 1688. The genuine works of this Van-
der Meer bear a very high price, and are fteemed even
in Italy, where they are admitted into the belt collec-
tions; but the scarcity of them has occasioned many
moderate copies after his works to be pafted on the
market for originals.

MEGACLES POLIS, (anc. geog.) dividedly (Ptole-
my, Paufanius) or conjuntly MEGALEPOLIS. (Strabo):
A town of Arcadia, built under the auipices of Epa-
minondas; after the battle of Leuctra; many incon-
siderable towns being joined together in one great city
the better to withfand the Spartans. It was the
greatefl city of Arcadia, according to Strabo.

MAGALESIA, and MEGALENSÆ LUDI, fefts
and games in honour of Cybele or Rhea the mother
of the gods, kept on the 12th of April by the Ro-
mans, and famous for great rejoicings and divereions
of various forts. The Galli carried the image of the
goddes along the city, with found of drums and other
MEGARA

music, in imitation of the noise they made to prevent Saturn from hearing the cries of his infant son Jupiter, when he was doped to devour him.

MEGARA (anc. geog.), a noble city, and the capital of the territory of Megarides, which for many years carried on war with the Corinthians and Athenians. It had for some time a school of philosophers, called the Megarics, successors of Euclid the Socrates, a native of Megara. Their dialect was the Doric; changed from the Attic, which it formerly used; not being durable, may be reckoned among the causes of the desolation at Megara, which is so complete, that one searches in vain for vestiges of the many public edifices, temples, and sepulchres, which once adorned the city.

Megara was engaged in various wars with Athens and Corinth, and experienced many vicissitudes of fortune. It was the only city of the Greek cities which did not re-flourish under their common benefactor Hadrian; and the reason assigned is, that the avenging anger of the gods pursued the people for their impiety in killing Athenocritus a herald, who had been sent to them in the time of Pindar. The Athenian generals were sworn on his account to invade them twice a-year. Hadrian and Atticus were followed by another friend, whose memory is preserved by an inscription on a stone lying near a church in the village. — "This too is the work of the most magnificent count Diogenes son of Archelaus, who, regarding the Greek cities as his own family, had bestowed on that of the Megarensians one hundred pieces of gold toward the building of their town, and also one hundred and fifty more with two thousand two hundred feet of marble towards re-ediifying the bath; deeming nothing more honourable than to do good to the Greeks, and to restore their cities." This person is not quite unnoticed in history. He was one of the generals employed by the emperor Amilcar on a revolution in Iberia. He captured the capital Cadiopolis, and sustained a siege with great bravery, A. D. 494.

Megara retains its original name. It has been much infected by cemeteries; and in 1676 the inhabitants were accustomed, on being in a boat approach in the daytime or hearing their dogs bark at night, immediately to erect their effects and run away. The Vr nullable or Turkish governor, who resided in a forlorn tower above the village, was once carried off. It is no wonder, therefore, that Nilea has been long abandoned. The place was burned by the Venetians in 1687.

MEGARA (anc. geog.), formerly called Hybla, a town towards the east coast of Sicily; extinct in Strabo's time, though the name Hybla remained on account of the excellence of its honey. It was a colony of Megareans from Greece. Rhus Megaricus denotes a heart-ease.

MEGARIS (anc. geog.), the country of the Megareans, is described as a rough region, like Attica; the mountain called Oenian or the Alpheius, now Maresias or "the long Mountain," extending through it toward Boeotia and mount Citharon. It belonged to Ionia or Attica, until it was taken by the Peloponnesians in the reign of Codrus, when a colony of Dorians settled in it. This territory had Attica to the east, Boeotia to the north and west, and the Ilissus of Corinth to the south.

MEGARIS, a small island in the Tidcan sea, joined to Naples by a bridge. Now called Castello dell'Ovo.

MEGASTHENES, a Greek historian in the age of Seleucus Nicanor, about 350 years before Christ. He wrote about the oriental nations, and particularly the Indians. His history is often quoted by the ancients. What now passes as his composition is fictitious.

MEIGDISO (anc. geog.), a town of Galilee, erected (Joshua xvii. 11.) among the cities of Manaeith, in the tribe of Issachar or Aser, on the west side of Jordan. Famous for the defeat of Ahaziah and Jehu, who perished there (2 Kings xxii. 29.): near it was
MEL [366]

MELANTHEMUM, an open plain, fit for drawing up an army in battle array. It was situated to the north, contrary to its position in the common maps. The Canaanites, a name of several learned Germans.—John Henry Melanocn was professor of phyfic at Helmut, where he was born, and at Lubec; he wrote the Life of Method, published at Leyden in 1653, with several other learned works. Henry, his son, was born at Lubec in 1638; became professor of phyfic at Helmmt; and, besides works in his own profession, published Scriptores rerum Germanicarum, 3 vol. folio, 1688; a very useful collection, first begun by his father.—Marcus Melanion, of the same family, published a collection of seven Greek authors who had written upon ancient music, with a Latin version by himself; dedicated to Queen Christina of Sweden. But this edition is added, besides works of his own, by himself; dedicated to Queen Christina of Sweden.

HELLEBORES. Melampsorium, in botany: A genus of the polygamia necessaria order, belonging to the syngefeia class of plants, and in the natural method ranking under the 49th order, Compositae. The receptacle is pericarpos and conical; the pappus is monophyllous and valve-like; the calyx pentaphyllous. Melampus (Iab. hist.), a celebrated tooth-fayer and physician of Argos, son of Amythas and Idomea or Dorippe. He lived at Pylos in Peloponnesus. His servants once killed two large serpents who had made their nests at the bottom of a large oak; and Melampus paid so much regard to their remains, that he raised a burning pile and burned them upon it. He also took particular care of their young ones, and fed them with milk. Some time after this, the young serpents crept to Melampus as he slept on the grass near the oak, and, as if sensible of the favours of their benefactor, they wantonly played around him, and softly licked his ears. This awoke Melampus, who was astonished at the sudden change which his fences had undergone. He found himself acquainted with the chirping of the birds, and with all their rude notes, as they flew around him. He took advantage of this supernatural gift, and soon made himself perfect in the knowledge of futurity, and Apollo also instructed him in the art of medicine. He had soon after the happiness of curing the daughters of Perseus, by giving them hellebore, which from that circumstance has been called melampodium; and as a reward for his troubles, he married the eldest of these princesses. The tyranny of his uncle Neleus, king of Pylos, obliged him to leave his native country; and Perseus, to show himself more sensible of his services, gave him part of his kingdom. About this time the personal charms of Hero, the daughter of Neleus, had gained many admirers; but the father promised his daughter only to him who brought into his hands the oxen of Iphiclus. This condition displeased many; but Bias, who was also one of her admirers,
MELAMYRUM, COW-WHEAT: A genus of the angiopermia order, belonging to the dinandinae class of plants; and in the natural method ranking under the 40th order, Peronata. The calyx is quadripart; the upper lip of the corolla is compressed, with the edges folded back; the capsule is bilocular and oblique, opening at one side; and there are two gibbous seeds. There are four species, all of them natives of Britain, and growing spontaneously among corn-fields. They are excellent food for cattle; and Linnaeus tells us, that where they abound the yellowwell and buttermilk is made. Their seeds, when mixed with bread, give it a dunty colour; and according to some authors, produce a vertigo, and alters the ideas of the head; but this is denied by Mr Withering, though he allows that they give it a bitter taste.

MELANCHOLY, a kind of delirium attended with gloomy thoughts, heaviness, and sorrow. See Medicine, no. 85, 327.

MELANCHTHON (Philip), born at Bretten in 1495, was one of the wisest and most able men of his age among the Reformers, though of a mild temper, and dispense to accommodate rather than to inflame disputes. In his youth he made an admirable progress in learning, and was made Greek professor at Wittenberg in 1509. Here he lectured upon Homer, and the Greek text of St Paul's Epistle to the Titus, drew to him a great number of auditors, and entirely effaced the contempt to which his low stature and mean appearance had exposted him. Melanchthon reduced the sciences to systems; and acquired such reputation, that he had sometimes 2000 auditors. He soon entered into an intimate friendship with Luther, who taught divinity in the fame university; and in 1519 they went together to Leipzic, to dispute with Eriugena. The following years he was continually engaged in various employments; he compos'd several books; he taught divinity; took several journeys, in order to found colleges and visit churches; and in 1530 drew up a confession of faith, whi'ch goes by the name of the Confession of Augsburg, because it was presented to the emperor at the diet held in that city. All Europe was convinced, that he was not, like Luther, backward to accommodate the differences between the various sects of Christians. He hated religious disputes, and was drawn into them only through the necessity of the part he was called to act in the world; and therefore would have facrificed many things to have produced an union among the Protestants. For this reason, Francis I. the French king, wrote to desire him to come and confer with the doctors of the Sorbonne, in order to agree with them about putting an end to all controversies; but though Luther endeavoured to persuade the elector of Saxony to consent to that journey, and though Melanchthon himself desired it, that prince, whether he disliked Melanchthon's moderation, or was afraid of quarrelling with the emperor Charles V., would never grant his permission. The king of England also in vain desired to see him. Melanchthon, in 1529, assisted at the conferences of Spires. In 1541, he was at the famous conference at Ratibon. In 1543, he went to meet the archbishop of Cologne to assist him in introducing the reformation into his diocese; but that project came to nothing; and in 1548, he assisted at seven conferences on the subject of the interim of Charles V., and wrote a cenfure on that interim, and all the writings presented at these conferences. He was extremely affected at the differences raised by Faccius Illiricus. His last conference with those of the Roman communion was at Worms, in 1557. He died at Wittenberg in 1560, and was interred near Luther. Some days before he died, he wrote upon a piece of paper the reasons which made him look upon death as a happiness; and the chief of them was, that it "delivered him from theological persecutions." Nature had given Melanchthon a peaceable temper, which was but ill suited to the time he was to live in. His moderation served only to be his cross. He was like a lamb in the midst of wolves. Nobody liked his mildness; it looked as if he was luke-warm; and even Luther himself was sometimes angry at it.

Melanchthon was a man in whom many good as well as great qualities were wonderfully united. He had great parts, great learning, great sweetness of temper, moderation, contentedness, and the like, which would have made him very happy in any other times but those in which he lived. He never affected dignities, or honours, or riches, but was rather negligent of all these things; too much so in the opinion of some, considering he had a family; and his son-in-law Sarinus, who was of a more ambitious make, was actually at variance with him upon this very article. Learning was infinitely obliged to him on many accounts; on none more than this, that, as already observed, he reduced almost all the sciences which had been taught before in a vague irregular manner, into systems. Considering the distractions of his life, and the infinity of disputes and tumults in which he was engaged, it is astonishing how he could find leisure to write so many books. Their number is prodigious, inasmuch that it was thought necessary to publish a chronological catalogue of them in the year 1582. His works indeed are not correct, and he himself owned it; but as he found them useful, he chose rather to print a great number, than to finish only a few; "which, however (as Bayle says), was polishing his own glory to the advantage of others." His constitution was very weak, and required great tenderness and management; which made Luther, as hot and zealous as he was, blame him for labouring too earnestly in the vineyard.

MELANIPPIDES.
MELANTIPIDES (fab. hist.), a Greek poet about 520 years before Christ. His grandson of the same name flourished about 60 years after at the court of Perdicas the Second, of Macedonia. Some fragments of their poetry are still extant.

MELANTERIA, in natural history, a very beautiful fossil, of a dense, compact, and regular texture, and of an extremely bright pale yellow, resembling nothing so much as the purest gold. It is remarkably heavy and is sometimes found in little irregular masses of the bigness of a pigeon's egg, which are broken with a slight blow: but it is usually met with in the form of a fine gold-coloured efflorescence on vitriolic and pyritic bodies; or in loose, shattery, and friable masses of a more dusty yellow; in which latter state it so much resembles a native sulphur, that it is frequently mistaken for one; however, it is not inflammable; but calcines in the fire to a purple.

Melassae. See Molasses.

MELASTOMA, the American Gooseberry-tree, in botany. A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 17th order, Calycanthene. The calyx is quinquefid and campanulated; the petals are five, inserted into the calyx; the berry is quinquelocular, and wrapped in the calyx. There are a great many species, all of them natives of the warm parts of America, and very beautiful on account of the variegation of their leaves. Most of the leaves are of two different colours on their surfaces; the under side being either white, gold-coloured, or rufset, and their upper parts of different shades of green: so that they make a fine appearance in the hot-house all the year round. There are but few of these plants in the European gardens which may perhaps have been occasioned by the difficulty of bringing out growing plants from the West Indies; and the seeds being small when taken out from the pulp of their fruits, rarely succeed. The best way is to have the entire fruits put up in dry sand as soon as they are ripe, and forwarded by the quickest contrivance to England. They should be immediately taken out when they arrive, and the seeds sown in pots of light earth, and plunged into a moderate hot-bed of tanner's bark. When the plants come up, and are fit to be removed, they must each be planted in a small pot, and plunged into the tan-bed; and afterwards treated as other exotic plants.

MELCHA, a small village of Barbary, situated about 30 miles from the city of Tunis, built on the ruins of Carthage, some of which are still visible.

MELCHITES, in church-history, the name given to the Syriac, Egyptian, and other Christians of the Levant. The Melchites, excepting some few points of little or no importance, which relate only to ceremonies and ecclesiastical discipline, are in every respect professed Greeks; but they are governed by a particular patriarch, who resides at Damas, and assumes the title of patriarch of Antioch. They celebrate mass in the Arabian language. The religious among the Melchites follow the rules of St Basil, the common rule of all the Greek monks. They have four fine convents, distant about a day's journey from Damas, and never go out of the cloister.

MELCHISEDÉC, or Melchizedek, king of Salem, and priest of the Most High. The scripture tells us nothing either of his father, or of his mother, or of his genealogy, or of his birth, or of his death. And in this sense he was a figure of Jesus Christ, as St Paul affirms, who is a priest for ever, according to the order of Melchisedec, and not according to the order of Aaron, whose original, life, and death, are known. When Abraham returned from pursuing the four confederate kings who had defeated the kings of Sodom and Gomorrah, and had taken away Lot Abraham's nephew along with them (Gen. xiv. 17, 18, 19, &c.), Melchisedek came to meet Abraham as far as the valley of Shaveh, which was afterwards named the king's valley, presented him with the refreshment of bread and wine (or he offered bread and wine in sacrifice to the Lord, for he was a priest of the most high God), and blessed him. Abraham being desirous to acknowledge to him the quality of priest of the Lord, offered him the tythes of all he had taken from the enemy. After this time, there is no mention made of the person of Melchisedek; only the Psalmist (ex. 4.) speaking of the Messiah, says, "Thou art a priest for ever after the order of Melchisedec." St Paul, in his epistle to the Hebrews, unfolds the mystery which is concealed in what is said of Melchisedek in the Old Testament. See Heb. v. 6–10. An infinite number of difficulties and scruples have been started upon the subject of Melchisedek.—St Jerome thought that Salem, of which Melchisedek was king, was not Jerusalem, but the city of Salem near Scythopolis, where they full pretended to show the ruins of the palace of this prince. The greatness and extent of these ruins are a sufficient proof of the magnificence of this ancient building. He thinks it was at this city of Salem or Shalem, that Jacob arrived after his passage over Jordan, and his return from Mesopotamia (Gen. xxxviii. 18.) Some believe that Salem, where Melchisedek reigned, is the same as Salim spoken of in the gospel of St John, chap. iii 23. From the time of Epiphanes there were names invented for the father and mother of Melchisedek. To his father was given the name of Heracles or Hercules, and to his mother that of Aftaroth or Aftaria. It is generally agreed on by the learned, that when the apostle says, he was "without father and without mother," no more is meant, than that he is introduced into the history of Abraham without acquainting us who he was, or whence he came, where he lived, or when he died. Nevertheless, some have taken St Paul's words literally, and contended that he was not of human but divine nature. Origen and Didymus took him to be an angel; and the author of the Epitomes upon the Old and New Testament pretended that he was the Holy Ghost, who appeared to Abraham in a human form. The Arabic Catena, upon the ninth chapter of Genesis, makes Melchisedek to be descended from Shem by his father, and from Japheth by his mother.
MELCHIZEDEC.

MELCHIZEDEC.

Melchizedec was the son of Phileg and the son of Heber; and his mother named Salathiel, was daughter of Gomer son of Japheth. Cendresus and others derive Melchizedec from an Egyptian flock. They say his father was called Sidon or Sida, and was the founder of the city of Sidon the capital of Phoenicia. Suidas says he was of the cursed race of Canaan; for which reason the scripture does not mention his genealogy. The Jews and Samaritans believed Melchizedec to be the same with the patriarch Shem; which opinion has been followed by a great number of modern writers. M. Jurieu has undertaken to prove that he is the same as Cham or Ham. It would be endless to set down all the opinions upon this matter; therefore we shall only add, that Peter Cuneus and Peter du Moulin have asserted, that Melchizedec who appeared to Abraham was the Son of God, and that the patriarch worshipped him and acknowledged him for the Messiah.

About the beginning of the third century arose the history of the Melchizedecians, who affirmed that Melchizedec was not a man, but a heavenly power, superior to Jesus Christ: for Melchizedec, they said, was the intercessor and mediator of the angels, but Jesus Christ was so only for men, and his priesthood only a copy of that of Melchizedec, who was the Holy Ghost.

We shall only beg leave to add here one opinion more concerning Melchizedec, which is that of the learned Heidegger, who, as the author of the Historia Patriarcalis, has taken the right method of explaining the accounts of Moses and the apostle Paul relating to this extraordinary person. He supposes a twofold Melchizedec; the one historical, whereof Moses gives an account in the sixth chapter of Genesis; as that he was king as well as high-priest of Jerusalem; the other allegorical, whom St Paul describes, and this allegorical person is Jesus Christ.

As the history of this prince and priest is so little known, it is no wonder, as Selden observes, that many fabulous accounts have been invented of him; of which the following may suffice as a specimen. Eutychus of Alexandria relates, that the body of Adam having been embalmed according to his order, was deposited in a cave under a mountain of the children of Seth; but that Adam before his death had commanded that they should take away his remains from that place, and transport them to the middle of the earth: that Noah, to follow the orders of his ancestors, had preferred the bodies of Adam and all the patriarchs with him in the ark; that finding himself near his death, he ordered his son Shem to take the body of Adam, to furnish himself with bread and wine for his journey, to take with him Melchizedec the son of Phileg, and go to the place in which an angel would show them where to bury the first man; that Noah added this order, "Command Melchizedec to fix his residence in that place, and to live unmarried all his lifetime, because God has chosen him to do service in his presence; command him, that he build no temple, nor shed the blood of birds, nor four-footed beasts, or any other animal; and that he offer no other oblations to God but bread and wine." This is the reason, according to this author, why, Melchizedec, when he met Abraham, brought forth only bread and wine.

A Greek author, under the name of Athanatus, relates, that Melchizedec was the son of an idolatrous king called Melch and of a queen called Salem. Melch, having resolved to offer a sacrifice to the gods, sent his son Melchizedec to fetch him seven calves. In the way the young prince was enlightened by God, and immediately returned to his father, to demonstrate to him the vanity of idols. Melch, in wrath, sent him back to fetch the victims. While he was absent, the king sacrificed his eldest son, and a great many other children to his gods. Melchizedec returning, and perceiving great horror at this butchery, retired to mount Tabor, where he lived seven years, without clothes, and fed only on wild fruits. At the end of seven years, God appeared to Abraham, bid him go up to mount Tabor, where he should find Melchizedec. He ordered him to clothe him, and to ask his blessing; which Abraham having done, Melchizedec anointed him with oil, and they came down together from the mountain.

MELCOMB-BEGIS, a town of Dorsetshire, in England, 150 miles from London, is situated at the mouth of the river Wey, by which it is parted from Weymouth. It appears from the name to have been anciently the king's demesne, and from the records to have paid quit-rent to the crown all along after king Edward I. till it was brought off by the inhabitants before they were united to Weymouth. It lies on the north side of the haven, on a peninsula surrounded by the sea on all sides except on the north. The streets are broad and well paved, and many of the houses large and high. It sent members to parliament in the reign of king Edward I. before Weymouth had that privilege. It was by parliament appointed a staple in the reign of Edward III. In the next reign the French burnt it; and it was thereby rendered so desolate, that the remaining inhabitants prayed and obtained a discharge from customs. On account of its quarrels with Weymouth, in the reign of Henry VI. it lost its privileges as a port were removed to Poole: but in that of queen Elizabeth they were restored to it by act of parliament, which was confirmed in the next reign, on condition that Melcomb and Weymouth should make but one corporation, and enjoy their privileges in common; and so this was owing the flourishing state of both. In the two reigns last mentioned, a wooden bridge with seventeen arches was built from hence to Weymouth; to which, as well as its church, the chief contributors were certain citizens of London; and upon its decay it was rebuilt in 1770. Here is a good market-place and town-hall, to which the members of the corporation of Weymouth come to attend public business, as the inhabitants do to its church for public worship. For several years past the sea has retired from it on the east, the priory, formerly being bounded by the sea, but there is now a street beyond it, from which it is several paces to the high-water-mark. The priory was situated in the east part of the town, in Maiden-street, whose site occupied about an acre, now covered with tenements. On the south side are the remains of an ancient
MELEAGER (fab. hist.) a celebrated hero, son of Oeneus king of Calydonia, by Althaea daughter of Thetis. The parcae were present at the moment of his birth, and predicted his future greatness. Clotho said that he would be brave and courageous; Lachesis foretold his uncommon strength and valor; and Atropos said that he should live as long as the firebrand which was on the fire remained entire and unconfined. Althaea no sooner heard this, than she snatched the flick from the fire, and kept it with the most jealous care, as the life of her son totally depended upon its preservation. The fame of Meleager increased with his years; he signalized himself in the Argo彜cian expedition, and afterwards delivered his country from the neighbouring inhabitants, who made war against his father at the instigation of Diana, whose altars Oeneus had neglected. But Diana punished the negligence of Oeneus by a greater calamity. She sent a huge wild boar, which laid waste all the country, and seemed invincible on account of its immense size. It became soon a public concern: all the neighbouring princes assembled to destroy this terrible animal; and nothing is more famous in mythological history, than the hunting of the Calydonian boar. The princes and chiefs that assembled, and which are mentioned by mythologists, were Meleager son of Oeneus, Idas and Lynceus sons of Aphareus, Dryas son of Mars, Callot and Pollux sons of Jupiter and Leda, Pirithous son of Ixion, Theseus son of Aegus, Aeneus and Cepheus sons of Lycurgus, Admetus son of Phereus, Jason son of Aeson, Peleus and Thessalom sons of Aeacus, Iphicles son of Amphitrion, Eurysthen of Aetes, Atalanta daughter of Sceiron, Iolas the friend of Hercules, the sons of Theseus, Amphitrion son of Oileus, Protus, Cometes, the brothers of Alcmen, Hippothous son of Cercyon, Leucippus, Adractus, Ceenus, Thileus, Echion, Lelex, Phoenix son of Amytides, Panpeus, Hylecta, Hippias, Nessor, Menodorus, the father of Patroclus, Anchises, Laertes the father of Ulysses, and the four sons of Hippocoon. This troop of armed men attacked the boar, and it was at last killed by Meleager.—The conqueror gave the skin and the head to Atalanta, who had first wounded the animal. This irritated the reft, and particularly Toxeus and Plexipus the brothers of Althea, and they endeavoured to rob Atalanta of the honored present. Meleager defended her, and killed his uncles in the attempt. Mean time the news of this celebrated conquest had already reached Calydon, and Althaea went to the temple of the gods to return thanks for the victory which her son had gained: But being informed that her brothers had been killed by Meleager, she in the moment of returnment threw into the fire the fatal flick on which her son’s life depended, and Meleager died as soon as it was consumed. Homer does not mention the firebrand; whence some have imagined that this fable is posterior to that poet’s age. But he says, that the death of Toxeus and Plexipus so irritated Althea, that she uttered the most horrible curses and imprecations upon her son’s head.

MELEAGRIS, in ornithology, the TURKEY; a genus of birds belonging to the order of gallinifers. The head is covered with spongy caruncles; and there is likewise a membranous longitudinal caruncle on the throat.

There is but one (A) species, viz. the gallopavo, or North American turkey of Ray. It has a caruncle both on the head and throat; and the breast of the male is bearded or tufted. He lives upon grain and infests: when the cock struts, he blows up his breast, sprays and erects his feathers, relaxes the caruncle on the forehead, and the naked parts of the face and neck become intensely red. Barbot informs us that very few turkeys are to be met with in Guinea, and those only in the hands of the chiefs of the European forts; the negroes declining to breed any on account of their tenderness; which sufficiently proves them not to be natives of that climate. He also remarks, that neither the common poultry nor ducks are natural to Guinea any more than the turkey. Neither is that bird a native of Asia: the first that were seen in Peru were brought

(A) Two others were formerly enumerated; but in the late edition of the Syll. Nat. by Gmelin, they have been transferred to a new genus. See Perdops.
MELEAGRIS, Meles. They are bred in Ceylon, but not found by them taken by means of dogs, though they run faster for feed on acorns; they are frequently met with by wild-fowl in the northern birds soon grow fatigued, and take to the height. The fowl was first seen in trees, where they will suffer themselves to be shot one bird found in India, which some writers have ed to be the turkey; but Mr Gefner, that it was either the peacock, or some bird grey allured thereto by putting often have from fourteen to seventeen for one brood; as the several hundreds, which are countenances, the inhabitants of which think it well worth cottages about Norfolk, their while to attend carefull

ty was once esteemed as a great rarity, and the breed tured by the end of a

t.uft black. There is also a beautiful variety of a fine deep spots, or rather freckles. She fits well, and is

counties, the inhabitants of which think it well worth

careful during the breeding

season. It is pleasing to see with what facility the driver manages them, by means of a bit of red rag faithed to the end of a flick, which, from their antipathy to it as a colour, acts with the same effect as a fences to a quadruped.

Of the turky there are several varieties, which have arisen from domestication. The most common is dark grey inclining to black, or barred duney white and black. There is also a beautiful variety of a fine deep copper colour, with the greater quills pure white, and the tail of a dirty white; it is often a old a most beautiful bird. A variety with a pure white plumage is also now not uncommon, and appears very beautiful. It was once esteemed as a great rarity, and the breed supposed originally to have arisen in Holland. In the Leverian Museum is also a common turky, with a large set of feathers on its head, much resembling one figured by Albin.

MELEAGRI, in zoology. See UREUS.

MELEAE (anc. geog.), a fine river running by the walls of Smyrna in Ionia, with a cave at its head, where Homer is said to have written his poems. And from it Homer takes his original name Melageone, given by his mother Critheis, as being born on its banks, (Herodotus.)

MELETIANS, in ecclesiastical history, the name of a considerable party who adhered to the cause of Meleitus bishop of Lycopolis, in Upper Egypt, after he was deposed, about the year 306, by Peter bishop of Alexandria, under the charge of his having sacrificed to the gods, and having been guilty of other horrid crimes; though Epiphanius makes his only failing to have been an excessive severity against the lapsed. This dispute, which was at first a personal difference between Meleitus and Peter, became a religious controversy; and the Meleitan party subsisted in the fifth century, but was condemned by the first council of Nice.

MELIA, Azaderach, or the Bael tree, in botany: A genus of the monogynia order, belonging to the decidua class of plants; and in the natural method ranking under the 23rd order Tribulaceae. The calyx is quinquennated: the petals five; the nectarium cylindrical, as long as the corolla, with its mouth ten-toothed: the fruit is a plum with a quinquelocular kernel. There are three species, all of them exotic trees of the Indies, rising near 20 feet high; adorned with large pinnated or winged leaves, and clusters of pentaphalous flowers. They are all propagated by seeds sown on hot-beds.

MELEANTHUS, Honey-flower, in botany: A genus of the angiosperma order, belonging to the dicynnia class of plants; and in the natural method ranking under the 24th order Corydaleaceae. The calyx is pentaephyllous, with the lowermost leaf gibbous: there are four petals, with the nectarium under the lowest one. The capsule is quadrilocular. There are two species.

1. The major hath a thick, ligneous, spreading root; many upright, ligneous, durable stalks, rising fix or eight feet high; garnished with large pinnated, of four or five pair of serrated lobes terminated by an odd one; and, from the fides and tops of the stalks, long spikes of chocolate-coloured flowers. 2. The minor hath a root like the former; upright, ligneous, soft, durable stalks, rising four or five feet high; garnished with smaller pinnated leaves; and from the sides and ends of the branches, long, loose, pendulous bunches of flowers tinged with green, faffron colours, and red.—Both the species flower about, June: but rarely produce seeds in this country. They are very ornamental, both in foliage and flower, and merit admittance in every collection. They are easily propagated by suckers and cuttings. They thrive best in a dry soil, and in a sheltered warm exposure.

MELIBOEIA (anc. geog.), an island of Syria, at the mouth of the Orontes; which, before it falls into the sea, forms a spreading lake round it. This island was famous for its purple dye. Thought to be a colony of the Thessalians; and hence Lucretius's epithet, Thyeddias.

MELICA, Ropegrass: A genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order Gramineae. The calyx is bivalved, biflorous, with an embryo of a flower between the two florets. There are three species; of which the most remarkable is
MELICERES, in surgery, a kind of encysted tumors, so called when their contents are of the consistence of honey.

MELICERTA, MELICERES, or MELICERTUS (fab. hist.), a son of Athamas and Ino. He was saved by his mother from the fury of his father, who prepared to dash him against a wall as he had done his brother Leucrus. The mother was so terrified that she threw herself into the sea with Melicerta in her arms. Neptune had compassion on the misfortunes of Ino and her son. He changed them both into sea deities. Ino was called Leuceolus or Matuta; and Melicerta was known among the Greeks by the name of Palomen, and among the Latins by that of Portunus. Some suppose that the Thibmen games were instituted in honour of Melicerta.

MELILLA, an ancient town of Africa in the kingdom of Fez, and in the province of Garet. It was taken by the Spaniards in 1409, but returned back to the Moors. W. Long. 2°. 9' N. Lat. 35° 20'.

MELILOT. See TRIFOLIUM.

MELINDA, a kingdom on the east coast of Africa, situated, according to some, between the third and fourth degree of south latitude; though there is great disagreement among geographers as to its extent. It is allowed by all, however, that the coasts are very dangerous; being full of rocks and shelves, and the sea at some seasons very liable to tempests. The kingdom of Melinda is for the most part rich and fertile; producing almost all the necessaries of life except wheat and rice, both which are brought thither from Cambaya and other parts; and those who cannot purchase them make use of potatoes in their stead, which are here fine, large, and in great plenty. They likewise abound with great variety of fruit-trees, roots, plants, and other esculents, and with melons of exquisite taste. They have also great plenty of venison, game, oxen, sheep, hens, geese, and other poultry, &c. and one breed of sheep whose tails weigh between 30 and 40 pounds.

The capital city is also called Melinda.

MELINUM, in natural history, the name of an earth famous in the earliest ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the three colours most used in painting. It is frequently found forming a stratum in the earth, lying immediately under the vegetable mould. It is of a very smooth but not glossy surface; is very soft to the touch; adheres firmly to the tongue; is easily broken between the fingers; and flakes the skin in handling. It melts readily in the mouth, and is perfectly fine; leaving not the least grittiness between the teeth: thrown into water, it makes a loud bubbling and hissing noise, and moulders away into a fine powder. It does not ferment with acids; and suffers no change in the fire. These are the characters by which the melinium of the ancients is distinguished from all other white earths. It is still found in the same place from which the painters of old had it, viz. the isle of Milo or Melos, from whence it had its name; and is common in most of the adjacent islands. It has of late been tried here; but is found not to make such a bright paint as the other substances now employed. It is not, however, liable, like them, to turn yellow; hence it would seem to be worth the consideration of painters in the colour-trade; especially as it might be had in any quantities for the carriage.

MELISSA, in natural history, a daughter of Melleus king of Crete, who with her sister Amalthaea fed Jupiter with the milk of goats. She first found out the means of collecting honey; whence it has been said that she was changed into a bee, as her name is the Greek word for that insect.

MELISSA, BAUM: A genus of the gymnospermia order belonging to the didynamia class of plants; and in the natural method ranking under the 42d order Verticillate. The calyx is aird, a little plane above, with the upper lip having its dents nearly of equal height; the upper lip of the corolla is arched and bifid; the under one, with the middle lobe, cordated. There are several species; but the most remarkable are the following. 1. The officinalis, or common baum, has fibrous perennial roots; many upright, square, branchy, annual stalks, rising two or three feet high: garnished with oblong, indented, opposite leaves, by pairs, two or three inches long, and half as broad; and from the upper axillas verticillate clusters of small white flowers upon fingle footstalks. There is also a kind with variegated leaves. 2. The grandiflowa, or Hltrurian calamint, hath fibrous perennial roots and annual stalks, rising about a foot high, garnished with oblong, oval, indented, hairy, opposite leaves; and from the upper axillas verticillate clusters of large purple flowers on forked footstalks. 3. The calamintha, or common calamint of the shops, has fibrous perennial roots; upright, square, branchy hairy footstalks, rising a foot high; roundish, indented, opposite leaves; and verticillate clusters of small bluish flowers, on forked footstalks as long as the flowers. All these species are easily propagated by offsets.

Medicinal use. The first species, when in perfection, has a pleasant smell, somewhat of the lemon kind; and a weak, roughish, aromatic taste. The young shoots have the strongest flavour: the flowers, and the herb itself when old or produced in very rich moist soils or rainy seasons, are much weaker both in smell and taste. Baum is appropriated, by the writers on the materia medica, to the head, stomach, and uterus; and in all disorders of these parts is said to do extraordinary service. So high an opinion have some chemists entertained of this plant, that they have expected to find in it a medicine which should prolong life beyond the usual period. The prentice practice, however, holds it in no great esteem; and ranks it (where it certainly deserves to be) among the weaker corroborants. Infusions of the leaves in water smell agreeably of the herb, but have not much taint, though on being impregnated they leave a considerable quantity of a bitterish astringent extract. Infusions of baum do not, like other aromatics, offend.
offend the head, as is complained of from figs, &c. Cold infusions in water or spirit are far better than the cohabated distilled water, and are the best preparations from the plant. On distilling the fresh herb with water, it impregnates the first running pretty strongly with its grateful flavour. When large quantities are subjected to the operation at once, there separates and rises to the surface of the aqueous fluid a small portion of essential oil, which some call al. Syria, and others al. Germanis. It is of a yellowish colour, and of a very fragrant smell.

MELISSUS of Samos, a Greek philosopher, was the son of Rhaegines and the disciple of Parmenides; and lived about 440 B. C. He pretended that the universe is infinite, immovable, and without a vacuum. The fathers of education among his pupils.

MELITE, an island referred to Africa by Scylax and Ptolemy; but nearer Sicily, and allotted to it by the Romans: commended for its commodious harbours; for a city well built, with artificers of every kind, especially weavers of fine linen; all owing to the Phoenicians the first colonists. Now Malta; remarkable for St Paul's shipwreck. See MALTA.

MELITENSIS TERRA, the Earth of Malta: an earth of which there are two very different kinds; the one of the genus of holes, the other of the marles. The latter is that known by medicinal authors under this name; the former is the Malta earth now in use: but both being brought from the same place, are confusedly called by the same name. The Maltese marle, which is the terra Melitensis of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture; and, when exposed to the weather, soon falls into fine soft powder: but when preferred and dried, it becomes a loose, light mass, of a dirty white colour, with a greyish cast: it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and flains the hands. Thrown into the water, it swells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstrua. Both kinds are found in great abundance on the island of Malta, and the latter has been much esteemed as a remedy against the bites of venomous animals. The other has supplied its place in the German shops; and is used there as a cordial, sudorific, and astringent.

MELITO (canonized), bishop of Sardis in Lydia, in the second century; remarkable for the apology he presented to the emperor Aurelius, in favour of the Christians; on which Eusebius and the other ancient ecclesiastical writers bestowed great praises: but that apology and all Melito's other works are lost.

MELITUS, a Greek orator and poet, the accuser of Socrates. The Athenians, after the death of Socrates discovering the iniquity of the sentence they had passed against that great philosopher, put Melitus to death, 400 B. C.

MELLAN (Claude), an engraver of considerable note, was a native of Abbeville in Picardy, and born in 1601. His father was the receiver of the customs in that town; and he took great care of the education of his son. His genius for drawing discovering itself very early in life, he was sent to Paris, and placed under the direction of Simon Vouet in order to perfect himself in that art, and his studies promised success; but he was diverted from his application to them by the desire he had of learning the management of the graver, which he acquired with much facility. From Paris, at the age of sixteen, he went to Rome; where he engraved a considerable number of plates, many of which are held in great estimation; particularly those for the Juliiian Gallery, the portrait of the Marquis Julian, and that of Pope Urban VIII. Returning to France, he married at Paris and settled there in 1654. The king of France being made acquainted with his merit, assigned him apartments in the Louvre, in the double quality of a painter and an engraver. He acquired a competent fortune, and was greatly esteemed by all who knew him. He died in 1688, aged 87.

Florent le Comte tells us, "That Charles II. was so much pleased with his performances, that he invited him to come into England, making him at the same time very advantageous offers. But the love of his country (continues that author) prevented his accepting of them."

It is remarked, that most of the plates which he engraved at Rome, and before he went thither, are executed in the usual manner; that is, with parallel strokes, crossed with second and third strokes, as the depth of the shadows might require. But afterwards he adopted a new mode of working with single strokes only, without any second strokes laid upon them; and the shadows are expressed by the same strokes being made stronger and brought nearer to each other. The effect which he produced by this method of engraving was soft and clear. In single figures and small subjects he succeeded very happily; but in large compositions, where great depth of shadow was required, he has failed. His neatest plates in this style have an unifiified appearance, by no means suitable to large engravings; but at the same time a lightness exceedingly agreeable when confined to small ones. According to Le Comte, the works of this master amount to 342.

MELLER, a lake of Sweden, 50 miles long, and 50 broad; on which stands the city of Stockholm.

MELLIL, with the country of the Mundingoes, in Africa. The country formerly called Melii, now chiefly inhabited by the Mundingoes, who still retain pretty much of the character ascribed to the people of Melii, lies to the south of the river Gambia; on the west it borders on the kingdom of Kabo; on the south it has Melii, properly so called, and the mountains that part it from Guinea; and on the east it extends to the kingdom of Gago. A great part of this country we are little acquainted with; as is the case with regard to most of the inland territories of Africa, but towards the sea coast this country is a little better known.

The first place of note we meet with is Kannha, a Portuguese colony, situated on the river of St Domingo, which falls into the sea about 25 leagues below
Melmoth, one may trade for about this town. About 26 leagues above Kachao, on the same side of the river, is another trading town called Fariji, where, in the months of October and November, one may trade for about half the quantity of wax and ivory which is traded for at Kachao. Here are also some flaves to be bought. But is a village near the mouth of the river Gelves, where most of the traders buy rice; which is in a great plenty there, and very good. Gelves is a village on a river of the same name, on which the Portuguese have a factory.

At Gelves one may trade yearly for 250 flaves, 80 or 100 quintals of wax, and as many as ivory. Near the mouth of the river Gelves is a village called Karbali, where there is a considerate trade for salt; here are also some flaves and ivory. Rio Grande, or the Great River, runs about 10 or 12 leagues to the south of the river Gelves. About 80 leagues from the mouth of it is a nation of Negroes, who are good traders in ivory, rice, millet, and some flaves. They are called Andrones. Over-against the mouth of Rio Grande is a cluster of islands called Bifago Ilhes; the most considerable of which is Calafagt, being about six leagues long and two broad; its soil is very good, and produces millet, rice, and all kinds of pulse, besides orange and palm-trees, and many others. This island, with those of Carache, Canbac, and La Gallina, are the only ones where the Europeans may trade with some security. They trade, however, sometimes at the other islands, but they must be extremely cautious; and yet after all their precautions, they will be robbed and murdered if they venture to go afloat. The river Nunho runs 16 leagues to the south of Rio Grande; it is very considerable, and comes from a vast distance inland. One may buy here 300 quintals of ivory and 100 flaves a-year. Rice grows here admirably well, and is very cheap. There are everywhere sugar-canes which grow naturally; and plants of indigo, which might turn to good account. The trade is carried on here from March till August. In the river of Sierra Leone, the late Royal African company of England had, in the year 1728, two islands; the one, called Tanfo, a large flat island, near three leagues in circumference, in which the company’s flaves had a good plantation; the rest of the island is covered with wood, amongst which are fillet-cotton trees of an uncommonly fine. The other island is Benfo, whereon stood a regular fort. It was formerly the residence of one of the English chiefs.

MELMOTH (William, Esq.), a learned and worthy bencher of Lincoln’s Inn, was born in 1666. In conjunction with Mr Peere Williams, Mr Melmoth was the publisher of Vernon’s Reports, under an order of the court of chancery. He had once an intention of printing his own Reports; and a short time before his death advertised them at the end of those of his coadjutor Peere Williams, as then actually preparing for the press. They have, however, not yet made their appearance. But the performance for which he justly deserves to be held in perpetual remembrance is, “The Great Importance of a Religious life,” concerning which it may be mentioned, to the credit of the age, that notwithstanding many large editions had before been circulated, 42,000 copies of this useful treatise have been sold in the last 18 years. It is a somewhat singular circumstance, that the real author of this most admirable treatise should never before have been publicly known (it having been commonly attributed to the first earl of Egmont, and particularly by Mr Walpole in his Catalogue); which is the more surprising, as the author is plainly pointed out in the following short character prefixed to the book itself: “It may add weight, perhaps, to the reflections contained in the following pages, to inform the reader, that the author’s life was one uniform exemplar of those precepts which, with so generous a zeal, and such an elegant and affecting simplicity of style, he endeavours to recommend to general practice. He left others to contend for modes of faith, and inflame themselves and the world with endless controversy: it was the wiser purpose of his more ennobled aim, to act up to those clear rules of conduct, which revelation hath graciously prescribed. He poised by temper every moral virtue; by religion every Christian grace. He had a humanity that melted at every diftress; a charity which not only thought no evil, but suspected none. He exercised his profession with a skill and integrity which nothing could equal but the disinterested motive that animat ed his labours, or the amiable modesty which accompanied all his virtues. He employed his industry, not to gratify his own desires; no man indulged himself less: not to accumulate useless wealth; no man more disdainfully unworthy a puririt: it was for the decent advancement of his family, for the generous affistance of his friends, for the ready relief of the indigent. How often did he exert his distinguished abilities, yet refuse the reward of them, in defence of the widow, the fatherless, and him that had none to help him! In a word, few have ever passed a more useful, not one a more blameless life; and his whole time was employed either in doing good or in meditating it. He died on the 6th day of April 1743, and lies buried under the cloister of Lincoln’s Inn Chapel. MEM. PAT. OPT. M. F. L. D. C. The son, by whom this character is drawn, is William Melmoth, Esq; the celebrated translator of Pliny and of Cicero’s Letters; and author of those which pass under the name of Sir Thomas Fitzgibbons. MELOCHIA, JEW’S MALLOW, in botany : A genus of the pantanaria order, belonging to the monadelphia class of plants; and in the natural method ranking under the 37th order, Columniferae. The capsule is quinquilocular and monospermaeous. There are several species; but the only remarkable one is the olitorius, or common Jew’s-mallow, which is a native of the warm parts of Asia and America. It is an annual plant, which rifes about two feet high, dividing into several branches, garnished with leaves of different sizes and forms: some are pear-shaped, others are oval, and some almost heart-shaped: they are of a deep green, and lightly indented on their edges, having near their base two brily reflexed segments. They have very long slender footstalks, especially those which grow on the lower part of the branches. The flower fits close on the opposite side of the branches to the leaves, coming out tingly; they are composed of five small yellow petals, and a great number of filaments surrounding the oblong germen, which is situated in the centre of the flower, and afterwards turns to a rough swelling capsule two inches long, ending in a point, and
and having four cells filled with angular greenish seeds. This species is cultivated about the city of Aleppo in Syria, and in the East Indies, as a pot-herb; the Jews boiling the leaves, and eating them with their meat. It is supposed by Rauwolf to be the *alis tympani* of Avicenna, and the *corchorum of Pliny.*

**MELODUNUM,** (anc. geog.) a town of the Cnones in Gallia Celta above Ludens, now Melun, in the isle of France, on the Seine.

**Melody,** in music, a succession of sounds ranged in such a manner, according to the laws of rhythm and modulation, that it may form a sentiment agreeable to the ear. Vocal melody is called *finging*, and that which is performed upon instruments may be termed *symphonic melody.*

The idea of rhythmus necessarily enters into that of melody. An air is not an air but in proportion as the laws of measure and quantity are observed. The fame succession of sounds is susceptible of as many different characters, as many different kinds of melody, as the various ways by which its emphatic notes and the quantities of those which intervene, may be diversified; and the change of duration of the notes alone, may diffuse that very sensation in such a manner that it cannot be known. Thus, melody in itself is nothing; it is the rhythmus or measure which determines it, and there can be no air without measure. If then we abstract measure from both, we cannot compare melody with harmony; for to the former it is essential, but not at all to the latter.

Melody, according to the manner in which it is considered, has a relation to two different principles. When regarded only as agreeable to the ear according to the laws of modulation, it has its principle in harmony; since it is a harmonic analysis, which exhibits the different gradations of the scale, the chords peculiar to each mode, and the laws of modulation, which are the sole elements that compose an air. According to this principle, the whole power of melody is limited to that of pleasing the ear by agreeable sounds, as the eye may be pleased with an agreeable assemblage of fitable colours. But when considered as an imitative art, by which we may affect the mind with various images, excite different emotions in the heart, inflame or soothe the passions; by which, in a word, we produce different effects upon our moral faculties, which are not to be effectuated by the influence of external sense alone, we must explore another principle for melody: for in our whole internal frame there appears to be no power upon which either harmony alone, or its necessary results, can seize, to affect us in such a manner.

What then is the second principle? It is as much founded on nature as the first; but, in order to discover its foundation in nature, it will require a more accurate though simpler observation, and a more exquisite degree of sensibility in the observer. This principle is the same which varies the tone of the voice, when we speak according as we are interested in what we say, and according to the different emotions which we feel in expressing it. It is the accent of languages which determines the melody of every nation; it is the accent which determines as to employ the emphasis of speaking while we sing, and to speak with more or less energy according as the language whose accents are the most sensible ought to produce a more passionate and more lively melody; that which has little accentuation, or none at all, can only produce a cold and languid melody, without character and without expression. These are the true principles: in proportion as we depart from them, when we speak of the power of music upon the human heart, we shall become unintelligible to ourselves and others, our words will be without meaning.

If music does not impress the soul with images but by melody, if from thence it obtains its whole power, it must follow, that all musical sounds which are not pleasing by themselves alone, however agreeable to harmony they may be, is not an imitative music and being incapable, even with its most beautiful chords, either to present the images of things, or to excite the finer feelings, very soon cloys the ear, and leaves always the heart in cold indifference. It follows likewise, that notwithstanding the parts which harmony has introduced, and which the present taste of music has only abus’d, wherever two different melodies are heard at the same time, they counteract each other, and destroy the effect of both, however beautiful each may be when performed alone; from whence it may be judged with what degree of taste the French composers have introduced in their operas the miserable practice of accompanying one air with another, as well in finging, which is the native expression of passion and sentiment, as in instrumental performances; which is the same thing as if whimsical orators should take it in their heads to recite two orations at the same time, that the elegance of each might derive more force from the other.

So much for Rousseau. The translator, however, has reason to fear, that the canons by which national melody is diversified and characterized, are more profound and permanent than the mere accentuation of language. This indeed may have great influence in determining the nature of the rhythmus and the place of emphatic notes; but very little in regulating the nature of the emphasis and expression themselves. If Rousseau’s principle be true in its full extent, he must of necessity acknowledge, than an air which was never felt or intended for words, however melodious, cannot be imitative: we must likewise confess that what is imitative in one nation cannot be such in another: nor can it be denied upon his hypothesis, that the recitative, which is formed upon the mode of speaking, is the most forcible of all melodies; which is absurd. His other observations are at once judicious and profound. Though it is impossible to exhibit the beauty and variety of harmony by playing the same melody at the same time upon different keys, admitting those keys to form among themselves a perfect chord, we must be uniform in pleasing the ear. We must therefore, of necessity introduce less perfect chords to vary and increase the pleasure, and those chords in any complex system of music must of necessity produce dissonances. It then becomes the business of the composer to be careful that these discord may arise as naturally from, and return as naturally to, perfect har-
MELOE, in zoology; a genus of insects of the order of coleoptera. The antennæ are jointed, the last joint being oval; the breast is roundish; the elytra are soft and flexible; and the head is inflected, and gibbous. The insects of this genus are divided into two families; one without wings, and having the elytra shorter than the abdomen; and the other winged, with elytra shorter than the body and wholly covering the wings.—The most remarkable species are,

1. **The procarabæus**: the colour of which is black, but without brightness, though intermixed with a small degree of purple, especially towards the under part of the body. Its head, which is large, is dotted; as is the thorax, which is narrower, round, and without a margin. The elytra are as soft as leather, flagegreen, and cover but part of the abdomen. They are, as it were, cut off obliquely, from the inner to the outer part, being shorter towards the future, longer on the side. There are no wings under the elytra. The abdomen, is large, especially that of the female, in which it far exceeds the elytra.—This insect makes its abode on the sides of wet roads and in woods. Its food are insects, violet leaves, and delicate herbs. There oozes from its body a fat, viscid, and flexible; and the head is unlike that of mice, beeps their approach; which pass through the skin, they first inflame, and afterwards excoriate the part, raising a more perfect blister than any of the vegetable acids, and occasioning a more plentiful discharge of serum. All the blistering compositions have cantharides for their basis. The external application of cantharides is often followed by a strangury, accompanied with thirst and feverish heat: this inconvenience may be remedied by soft unctuous or mucilaginous liquors liberally drank.

**Cantharides**: taken internally often occasion a discharge of blood by urine, with exquisite pain. If the dose is considerable, they seem to inflame and exacerbate the whole intestinal canal; the fluids become mucuous and purulent; the breath fetid and cadaverous; intense pains are felt in the lower belly; the patient faints, grows giddy, raging mad, and dies. All these terrible consequences have sometimes happened from a few grains. Herman relates, that he has known a quarter of a grain inflame the kidneys, and occasion bloody urine with violent pain. There are nevertheless cafes in which this stimulating fly, given in larger doses, proves not only safe, but of singular efficacy for the cure of diseas that yield little to medicines.-Cantharides, taken in very small doses, may be given with safety also in other cafes. Dr. Mead observes, that the obinate greetings which frequently remain after the cure of venereal maladies, and which rarely yield to balsamic medicines are effectually remedied by cantharides; and that no one remedy is more efficacious in leprous disorders; in which laft, proper purgatives are to be occasionally taken during the use of the cantharides. The current and safe preparation of cantharides for these purposes, is a spirituous tincture; and indeed, in all cafes, the tincture is far preferable, for internal use, to the fly in substance.

The virtues of cantharides are extracted by rectified spirit.
MEL [ 377 ]

Melon.
spirit of wine, proof spirit, and water; but do not
arise in distillation. The watery and spirits of
extracts blister as freely as the fly in substance; whil
the fly remaining after the several menstrua hepat
formed their office, is to the taint insipid, and does
not in the least blister or inflame the skin.

*See Cicu

Melon, in botany, a species of cucumis *, in
the Linnaean system. The female flowers have no fla
mina or stamens, but have a very large oval germin
situated below the flower, which turns to an oval
fruit with several cells, filled with oval, acute-pointed,
compresse seeds, included in a soft pulp. There is
a great variety of this fruit cultivated in different parts
of the world, many of them of no value, few being
regarded too much in the markets. The Cantaloupe
so called from a place in the neighbourhood of
Rome, where this fruit has been long cultivated, and
whether it was brought from Armenia, is the great
seem among the curious in every part of Europe.
Besides this, there are also the roman, the succado, the
Zatte, the small Portuguese or dorner, and the black Galloway
melons, most of which are cultivated for an early crop.
The management and culture of melons in England are
as follows; the seeds should be procured from good
melons, of the fouleest and highest quality, pro
duced, as some have advised, in a distant garden; for
if found on the place where it was raised and ripened,
itis very apt to degenerate. This seed should be kept
three years before it is sown but not more than six
and if it should be sown at two seasons, or at
three it will be still better; the first for the early
crop, to be raised under frames. Should be sown about
the middle of February; the second, to be raised in
the fame manner, is to be sown about the middle of
March; and those which are designed for hand or
bell-glasses, or to be covered with oil-papers, should
not be sown till about a week in April.

For those of the first lea.nn, the seeds may be sown
on the upper side of a cucumber-bed, if there be any;
or, a proper quantity of new loofe dung must be pro
vided, and thrown on a heap to ferment, and turned
over, that it may acquire an equal heat; and the plants
must be raised and managed like cucumbers, until they
are planted where they are to remain. The beds or
ridges, where the plants are to remain, should be placed
in a warm situation, so that they may be decaed
from all cold and strong winds, and enclosed in a good
reed fence. In preparing the earth for these plants,
the Dutch and German gardeners form a mixture of
a third part of loam, a third part of the pouring
of ditches and ponds, and the same quantity of
very rotten dung; which they mix up at least one,
and often two years, before they make use of it, fre
quently turning it over, so that the parts may be well
incorporated; but the compost in which Mr. Miller
has found melon plants to succeed best in England is
two thirds of fresh gentle loam, and one-third of ro
ten near's dung; if these are mixed together one
year before it is wanted, so as to have the benefit
of a winter's fruit and summer's heat, observing to turn
it over often, and never allowing weeds to grow upon
it. Before the plants appear, there should be a quantity
of new dung thrown in a heap, allowing about 15
ears, as it is raised up to each light which must be turned
during two or three times, and in a fortnight it will be
fit for use; when the trench must be dug to receive
the dung where the bed is designed to be made, which
in a dry ground should not be less than a foot or
and a half deep. The frames should then be
placed over the bed to keep out the wet; but no
earth should be laid upon it for three or four days,
till it is found of a proper temperature of heat. When
this is the case, the earth may be laid upon it, about
two inches thick, except in the middle of each light,
where the plants are to be placed, which must be
raised into a hill 1 foot high or more, terminating
in a flat cone; in two or three days after the earth is
put on the bed, it will be a proper temper to receive
the plants; which should be carefully taken up
with a trowel, so as to preserve all the fibres of
their roots; or if the beds cannot be ready for them in
time, soon after the third or rough leaf is put out,
it will be a good method to put each plant into a
small pot while they are young, and these may
be plunged into the hot-bed where they were raised,
or in a cucumber-bed, where there is room; and when
the bed is ready, the plants may be turned out of
the pots with the whole ball of earth to their roots:
and this is the best method for the Cantaloupe melon.

When the plants are placed on the top of the hills,
they should be gently watered once or twice, till they
have taken good root; and when they are well fixed
in the new beds, a greater quantity of earth should
be laid on the beds, prefixed down as close as possible,
and raised at least a foot and a half thick upon the dung
all over the bed; observing also to raise the frames,
that the glasses may not be too near the plants lest
the sun should scorch them. When the plants have
four leaves, the top of the plants should be pinched
off with the finger and thumb, that they may put
out lateral branches for producing the fruit; and when
two or more of these lateral shoots are produced, they
must also be pinched to force out more. The manage
tment of these beds is much the same as that of cucum
bers, except that melons require more air and very
little water. In five or six weeks, the plants will spread
over the bed, and reach to the frames, when the alleys
between the beds should be dug out; or in case of
one bed, a trench should be made on each side about
four feet wide, as low as the bottom of the bed; and the
hot dung wheeled in for a lining, to the same
height as the dung of the bed; this should be trodden
down close, and covered with the same earth that was
Laid on the bed, to the thickness of a foot and a half
or more, treading it down as close as possible. In
this way the bed will be extended to the width of 12
feet, that the roots of the plants may spread quite
through it; and the beds will also require a fresh
warmth, which will be of great service in setting
the fruit. When the vines have extended fo as to fill
the frames, and want more room, the frames should
be raised up with bricks about three inches high, to
admit the shoots of the vines to run out under them.
When the fruit appears, the vines should be carefully
looked over three times a week; and one should be
chopped upon each runner that is situated nearest
the item, having the largest foot-mark, and appearing
to be the strongest fruit; then pinch off all the other
fruits which may appear upon the main runner, and pinch
off the end of the runner at the third joint above the
fruit; and if the runner is gently pinched at the next
joint
There is also another method practised by some gardeners to set this fruit, which is the taking off some of the male flowers, whose farina is just ripe and fit for the purpose, laying them over the female fruit, and gently tying them with the nails the male flowers, to shake the farina into the female flowers; whereby the plants are impregnated, and the fruit will soon after swell, and manifest visible signs of being perfectly set; so that where the plants are under frames, and the wind excluded from them, which is wanted to convey the farina from the male to the female flowers, this practice may be very necessary. The glaishes of the hot-bed should also be raised high to admit a large share of air to the plants, otherwise the fruit will not set; and if the season should prove very warm, the glaishes may be frequently drawn off, especially in an evening, to receive the dew, provided there is little wind firing: but they should not remain off the whole night; the cold should prove too great. When the plants have extended themselves from under the frames, in cold weather their extremities should be covered every night with mats, and the plants should be watered once in a week in dry weather, in the alleys between the beds.

For these melons that are raised under bell or hand-glaishes, the plants should be raised in the manner already directed, and about the latter end of April, in a forward season, the beds may be made. For this purpose, a sufficient quantity of hot-dung should be provided allowing eight or nine good wheel-barrows of dung to each glaish. For one bed extended in length, the trench should be cut out three-one-half feet wide, and of such a length, that the glaishes may not be placed nearer than four feet to each other; in digging the trench, it should be so situated, as to allow for the widening of the bed three or four feet on each side; the depth must depend on the nature of the soil; and when there is no danger of the beds being injured by the wet, the lower it is made the better. When the dung prepared as before is laid on the bed, there should be a hill for each plant, one foot and a half high, and the other part need not be covered more than four inches thick; the glaishes should then be placed over the hills, and in two or three days after the beds are made they will be fit for receiving the plants, which should be removed in the manner already directed. These plants must be watered at first, to settle the earth to their roots, and shaded every day, till they have taken new root; and if the nights prove cold, it will be proper to cover the glaishes with mats, in order to preserve the warmth of the bed. If several beds are made, they should be placed at eight feet distance from each other. When the plants have taken good root, their tops must be pinched off, and the pruning must be the same as for those under frames. In the day-time, when the weather is warm, the glaishes should be raised on the opposite side to the wind, to admit fresh air to the plants; and when they reach the sides of the glaishes, in favourable weather the glaishes must be set up on three bricks, that the vines may have room to run out under them; but when this is done, the beds should be covered all over with earth to the depth of one foot and an half, and trod down as close as possible; and in cold nights, the beds should be covered with mats. And as the vines of the Cantaloupe melons cannot bear wet without injury, it will be necessary to arch the beds over with props to support the mats, that they may be ready for covering at all times when they require it. If the weather should prove cold, hot dung may be laid to these beds in the manner directed for those under frames. Some have lately raised their melons with considerable success under celled paper; but great care must be taken not to keep their coverings too close over the plant. And Mills advises to bring up the plants under hand or bell glaishes, till they begin to extend themselves under the glaishes, and then, instead of the covering of mats, to put over them the paper done over with linseed oil.

The farther management of melons, after their fruit is set, is to keep pulling off all the superfluous fruit, and to pinch off all weak runners; and also to turn the fruit gently twice a week, that each side may have equal benefit of the sun and air. When the fruit is fully grown, care should be taken to cut it at a proper time; for if it is left a few hours upon the vines, it will lose much of its delicacy: therefore the vines should be looked over at least twice in a day; and if the fruit intended for the table is cut early in the morning, before the sun has warmed it, it will be much better flavoured; but if it should be necessary to cut any afterwards, it should be put into cold spring-water or ice to cool it, before it is brought to table; and that cut in the morning should be kept in the coolest place till it is used. The signs of this fruit's maturity is, its beginning to crack near the footstalk, and its beginning to smell, which never fail: but the Cantaloupe melons seldom change their colour till they are too ripe.

Mr. Reynolds has communicated to the Society of Arts the following method of raising melons without earth, dung, or water. About a month before the seeds are sown, he prepares a bed of cut-off tanner's bark, four feet deep, six feet wide, and twelve feet in length; this he covers with four lights, so as not to admit rain or water. March (he says) is a proper season for this purpose. When the bed becomes warm, which generally happens in about 20 days, a few melon seeds are put into warm milk in an earthen vessel, which is prefied down into the bark-bed, where it remains 36 hours, in order to promote the vegetation of the seeds. Then, at equal distances, he directs to open four holes in the bed, each nine inches in diameter, and five inches deep; having in readiness about a peck of pounded bark, like sawdust, some of it to be put at the bottom of the holes, to the thickness of three inches; on this bark some of the seeds are to be placed, and prefied down with the fingers; then the seeds are to be covered with two inches more of the powdered bark, prefiding the whole down with the hand. When the plants are advanced to a proper size, the beet are chosen and the others cast away; those that are received are ordered to be properly pruned, and to have as much warm air as possible during the summer. In this way (he says) he has raised as good melons as can be desired.

When a melon is perfectly fine, it is full without any vacuity; this is known by knocking upon it; and when cut, the flesh must be dry, no water running
Large melons are not to be coveted, but firm and well-flavoured ones. Our gardeners who raise melons for sale, few the seeds of the larger rather than the good kinds, and they increase the size of these by much watering the roots; but this spoils the taste. Some of the French raise at this time particularly fine melons, by a method kept as a secret, but which we find, on a strict enquiry, is no other than the ingenious Mr Quintiny's of that nation, published near 80 years ago in the Philosophical Transactions.

The melons particularly proper to be treated in this manner, are those which have a thin and somewhat embroidered skin, not divided by ribs, and have a red pulp, dry and melting on the tongue, not mealy, and of a high flavour. These are what succeed in the following method, and are greatly improved in size and flavour by it.

When the seeds of this melon are placed in the ground, the first thing that appears is a pair of seminal leaves, or ears, as the gardeners call them. Between these two leaves there shoots, some days after, a leaf called the first leaf or knot; and out of the same place, after some days more, there shoots another leaf, called the second knot. Out of the midst of this leaf of the second knot, there shoots a third knot; this third knot must be cut off at its insertion, without hurting the branch of the second knot from whence it grows. Out of this place there will grow, after this cutting, a branch, which will be what the gardeners call the frut or stem; and this arm will, in the same manner as the first plant, shoot out, first one, then a second, and then a third knot; this third knot must be cut again as before, and thus the third knots are all along to be cut off, and arms or branches will grow up in the places of them all the way in the same manner as the first; and it is at these arms that the melons will be produced, and they will be always good, if the foot or root be well nourished in good earth, and cherished by a good hot-bed and the sun. The foot of the melon must never be suffered to pass into the dung, and the earth must not be watered but moderately, when it is seen to grow too dry; but in this case, it must be moderately moistened in the same, so that the shoot suffer by it. Twice or thrice a week is often enough to water in the driest weather, and this must always be done about sunet; and when the heat of the sun is too violent, the melons must be covered with straw mats from 11 in the morning to about two in the afternoon. When it rains much, the melons must also be covered, lest it harm them by too much moisture. (Philosoph. Tran. n. 45.)—

If the root produce too many branches, the weakest are to be cut off, and only three or four left; and those which are left are to be such as have their knots closed to one another. When the plants are removed from the seed-bed to the places where they are to stand, if they are very strong, they should be planted single; but if otherwise, two are to be set in each hole.

When they are planted single, the two branches, which always grow on each side from the base of the seed-leaves, are to be left on; but when two plants are set together, these branches are to be cut off, otherwise all the branches will be too numerous, and they will entangle and trip one another.

When the melons are kept, two of them only are to be left upon each foot, choosing those which are best placed, and next to the first and principal leaf, that is, to the heart of the foot. None but fair fruits are to be left, and such as have a thick and florid stem; and the foot of the melon must be short, well trusses, and not far distant from the ground. Melons of a long stem, and having the stalk of the leaf too long and slender, are never vigorous. All the superfluous branches must be cut off from time to time, as they shoot out. There sometimes shoots out a branch more than is here mentioned, between the two seed-leaves or ears. If this is strong and vigorous, it is to be kept on, but if weak, it is best to take it off, for it will never bear good fruit.

Water-Melon. See Anguria.

Melos (anc. geog.), an island between Crete and Peloponnesus, about 24 miles from Scyllamus. It is about 60 miles in circumference, and of an oblong figure. It enjoyed its independence for above 700 years before the time of the Peloponnesian war. This island was originally peopled by a Lacedaemonian colony, in 1116 years before the Christian era. For this reason the inhabitants refused to join the rest of the islands and the Athenians against the Peloponnesians. This refusal was severely punished. The Athenians took Melos, and put to the sword all such as were able to bear arms. The women and children were made slaves, and the island left desolate. An Athenian colony repeopled it, till Lyfander reconquered it and re-established the original inhabitants in their possessions.

Melothria, in botany: A genus of the monoga- nia order, belonging to the triandria class of plants; and in the natural method ranking under the 34th order, Cucurbitaceae. The calyx is quinquelobed; the corolla campanulate and monopetalous; the berry tri­locular and monoperymous. There is only one species, viz. the pendula, a native of Carolina, Virginia, and also many of the American islands. The plants strike out roots at every joint, which fallen down and extend into the ground thereby which means their stolons extend to a great distance each way. The flowers are very small, in shape like those of the melon, of a pale sulphur colour. The fruit in the West Indies grows to the size of a pea, is of an oval figure, and changes to black when ripe: these are by the inhabitants sometimes pickled when they are green. In Britain the fruit are much smaller, and are so hidden by the leaves that it is difficult to find them. The plants are too tender to be reared in that country without artificial heat.

Melpomene (Fab. Hist.), one of the muses, daughter of Jupiter and Mnemosyne. She presided over tragedy. Horace has addressed the finest of his odes to her, as to the patroness of lyric poetry. She was generally represented as a young woman with a serious countenance. Her garments were splendid; she wore a bukkin, and held a dagger in one hand and in the other a sceptre and crown.

Melrose, a town of Scotland, in the count ry of Selkirk, and on the confines of Tweeddale.
This abbey was founded by king David I. in 1136. He peopled it with Cillertians brought from Rivale abbey in Yorkshire, and dedicated it to the Virgin Mary. At the reformation James Douglas was appointed commendator, who took down much of the building, in order to furnish materials for a large house to himself, which still remains, and is dated 1590. Nothing is left of the abbey excepting a part of the cloister walls elegantly carved; but the ruins of the church are of most uncommon beauty. Part is at present used for divine service, the rest uncovered; but every part does great honour to the architect.—Alexander II. was buried beneath the great altar, and it is also the place of interment of the Douglases and other potent families.—Its situation is extremely pleasant.

**MELT** or **FISHES.** In the melt of a living cod there are such numbers of thoe animalcules fail to be found in the bodies of all male animals, that in a drop of its juice, no larger than a grain of sand, there are contained more than 10,000 of them; and considering how many such quantities there are in the whole melt of one such fish, it is not incredible, that there are more animals in one melt of it than there are living men at one time upon the face of the earth. However strange and romantic such a conjecture must appear, a serious consideration and calculation will make it appear very plain. An hundred such grains of sand, if those just mentioned will make about an inch in length; therefore in a cubic inch there will be a million of such sands; and if there be 10,000 animals in each of those quantities, there must be in the whole 150,000 millions, which is a number vastly exceeding that of mankind, even supposing the whole as populous as Holland.

**MELTING CONE,** in effaying, an hollow cone of brass or cast iron into which melted metallic substances are thrown, in order to free them from their floe. When a small quantity of matter is melted, it will be sufficient to rub the inside of the cone with grease; but when the quantity is very large, especially if it contains any thing fulaceous, this caution of hollowing the moulds is not sufficient. In this case the effayer has recourse to a tube reduced to thin pap with water, which effectually prevents any injury to the cone.

**MELTON-MOUBRAY,** a town of Leicetershire, 108 miles from London. It is a large built place, in a fertile soil; with a market on Tuesday, the most considerable for cattle of any in this part of the island. It is almost encompassed with a little river called the Eye, over which it has two fine bridges; and has a large handloome church, with a free-school. Here are frequent horse-races, and three fairs in the year.

**MELVIL** (Sir James), descended from an honourable Scots family, being the third son of the laird of Kaeth, was born about the middle of the 16th century. He went to France very young; in the capacity of page to Queen Mary, then married to the dauphin; and on the death of her husband, followed her to Scotland, where he was made gentleman of her chamber, and admitted a privy-councillor. She employed him in her most important concerns, till her unhappy confinement in Lochleven, all which he discharged with the utmost fidelity; and, from his own accounts, there is reason to conclude, that, had she taken his advice, she might have avoided many of her misfortunes. When she was prisoner in England, he recommended him strongly to her son James; with whom he continued in favour and employment until the death of Queen Elizabeth: James would then have taken him to England; but Melvil, now grown old, was desirous of retiring from business, and in his retirement he drew up the memoirs of his past life for the use of his son. These Memoirs were accidentally found in Edinburgh castle in the year 1660, though nobody knew how they came to be deposited there were published in folio in 1683.
