ENCYCLOPÆDIA; OR, A DICTIONARY OF ARTS, SCIENCES, AND MISCELLANEOUS LITERATURE; Constructed on a Plan, by which THE DIFFERENT SCIENCES AND ARTS Are digested into the Form of Distinct TREATISES OR SYSTEMS, COMPREHENDING THE HISTORY, THEORY, and PRACTICE, of each, According to the Latest Discoveries and Improvements; AND FULL EXPLANATIONS GIVEN OF THE VARIOUS DETACHED PARTS OF KNOWLEDGE, WHETHER RELATING TO NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL, CIVIL, MILITARY, COMMERCIAL, &c. Including ELUCIDATIONS of the most important Topics relative to RELIGION, MORALS, MANNERS, and the OECOeMISTRY OF LIFE: TOGETHER WITH A Description of all the Countries, Cities, principal Mountains, Seas, Rivers, &c. throughout the WORLD; A General History, Ancient and Modern, of the different Empires, Kingdoms, and States; AND An Account of the LIVES of the most Eminent Persons in every Nation, from the earliest ages down to the present times.

Compiled from the writings of the best Authors, in several languages; the most approved Dictionaries, as well of general science as of its particular branches; the Transactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. XII.  MIE—NEG

PHILADELPHIA: PRINTED BY THOMAS DOBSON, AT THE STONE HOUSE, NO 41, SOUTH SECOND STREET. M.DCC.XCVIII.
[Copy-Right secured according to law.]
MIEL (Jan), called Giovanni della Vite, a most eminent painter, was born in Flanders in 1599. He was at first a disciple of Gerard Seghers, in whose school he made a distinguished figure; but he quitted that artiff, and went to Italy, to improve himself in design, and to obtain a more extensive knowledge of the several branches of his art. At Rome he particularly studied and copied the works of the Caracci and Corregio; and was admitted into the academy of Andrea Sacchi, where he gave such evident proofs of extraordinary merit and genius, that he was invited by Andrea to assist him in a grand design which he had already begun. But Miel, through some difficulties, rejected those elevated subjects which at first had engaged his attention, refused the friendly proposal of Sacchi, and chose to imitate the style of Bamboccio, as having more of that nature which pleased his own imagination. His general subjects were hunting-scenes, carnivals, gypsies, beggars, pastoral scenes, and conversations; of those he composed his easel-pictures, which are the finest of his performances. But he also painted history in a large size in fresco, and in oil; which, though they seem to want elevation of design, and a greater degree of grace in the heads, yet appear superior to what might be expected from a painter of such low subjects as he generally was fond of representing. His pictures of hunting-scenes are particularly admired: the figures and animals of every species being designed with uncommon spirit, nature, and truth. The transparency of his colouring, and the clear tints of his skies, enliven his compositions; nor are his paintings in any degree inferior to those of Bamboccio either in their force or like. His large works are not so much to be commended for the goodness of the design as for the expression and colouring; but it is in his small pieces that the pencil of Miel appears in its greatest delicacy and beauty. The singular merit of this master recommended him to the favour of Charles Emmanuel duke of Savoy, who invited him to his court, where he appointed Miel his principal painter, and afterwards honoured him with the order of St Mauritius, and made him a present of a crotchet with diamonds of a great value, as a particular mark of his affection. He died in 1664.

Mieris (Francis), the Old, a justly celebrated painter, was born at Leyden in 1635; and was at first placed under the direction of Abraham Toume Vilet, one of the best designers of the Low Countries, and afterwards entered himself as a disciple with Gerard Douw. In a short time he far surpassed all his companions, and was by his master called the prince of his disciples. His manner of painting figures, velvets, stuffs, or carpets, was so singular, that the different kinds and fabric of any of them might easily be distinguished. His pictures are rarely to be seen, and as rarely to be sold; and when they are, the purchase is extremely high, their intrinsic value being so incomparably great. Beside portraits, his general subjects were conversations, persons performing on musical instruments, patients attended by the apothecary or doctor, physicians at work, mechanics and tradesmen, and such like; and the usual valuation he set on his pictures was estimated at the rate of a ducat an hour. The finest portrait of this master's hand is that which he painted for the wife of Cornelius Plaats, which is said to be still preserved in the family, although very great sums have been offered for it. In the possession of the same gentleman was another picture of Mieris, representing a lady painting, and a physician applying the remedies to relieve her. For that performance he was paid (at his usual rate of a ducat an hour) so much money as amounted to fifteen hundred florins when the picture was finished. The grand duke of Tuscany wished to purchase it, and offered three thousand florins for it, but the offer was not accepted. However, that prince procured several of his pictures, and they are at this day an ornament to the Florentine collection. One of the most curious of them is a girl holding a candle in her hand, and it is accounted infallible. This painter died in 1681.

Mieris (John), son of the former, was born at Leyden in 1660, and learned the art of painting from his father. The young artist unhappily was severely afflicted with the gravel and stone, and by those complaints was much hindered in the progress of his studies. But, after the death of his father, he travelled to Germany, and from thence to Florence, where the fame of his father's merit procured him a most honourable reception from the grand duke, who, when he saw some of his paintings, endeavoured to retain him in his service. But Mieris politely declined it, and proceeded to Rome, where his great abilities were well known before his arrival, and his works were exceedingly coveted. In that city his malady increased; yet at the intervals of ease he continued to work with his usual application, till the violence of his distemper ended his days in 1690, when he was only thirty years old. He was allowed to have been as eminent for painting in a large size as his father had been for his works in small.

Mieris (William), called the Young Mieris, was brother to the former, and born at Leyden in 1662. During the life of his father, he made a remarkable progress; but, by being deprived of his director when he was only arrived at the age of nineteen, he had recourse to nature, as the most instructive guide; and by studying with diligence and judgement to imitate her, he approached near to the merit of his father. At
first he took his subjects from private life, in the manner of Francis; such as tradesmen in their shops, or a peasant selling vegetables and fruit, and sometimes a woman looking out at a window; all which he copied minutely after nature, nor did he paint a single object without his model. As Mieris had observed the compositions of Gerrard Lairesse, and other great historical painters, with singular delight, he attempted to design subjects in that style; and began with the story of Rinaldo sleeping on the lap of Armida, surrounded with the loves and graces, the fore-ground being enriched with plants and flowers; a work which added greatly to his fame, and was sold for a very high price. This master also painted landscapes and animals with equal truth and neatness; and modelled in clay and wax, in so sharp and accurate a manner, that he might justly be ranked among the most eminent sculptors. In the delicate finishing of his works, he imitated his father; as he likewise did in the luire, harmony, and truth, of his paintings, which makes them to be almost as highly prized; but they are not equal in respect of design, or of the striking effect, nor is his touch so very exquisite as that of the father. The works of the elder Mieris are better composed, the figures are better grouped, and they have less confusion; yet the younger Mieris is acknowledged to be an artist of extraordinary merit, although inferior to him, who had fearlessly his equal. He died in 1747.

Mieris (Francis), called the Young Francis, was the son of William, and the grandson of the celebrated Francis Mieris; and was born at Leyden in 1689. He learned the art of painting from his father, whose manner and style he always imitated; he chose the same subjects, and endeavoured to render him in his colouring and pencil. But with all his industry he proved far inferior to him; and most of these pictures which at the public sale are said to be of the Young Mieris, and many in private collections ascribed to the elder Francis, or William, are perhaps originally painted by this master, who was far inferior to both; or are only copies after the works of those excellent painters, as he spent abundance of his time in copying their performances.

Mieza, (anc. geog.), a town of Macedonia which was ancietly called Strymonium, situated near Stagira. Here, Plutarch informs us, the flute-stands and shady walks of Arilotie were shown. Of this place was Peuceltes, one of Alexander's generals, and therefore surnamed Miezaux, (Arrian.)

Migdol, or Madoth, (anc. geog.), a place in the Lower Egypt, on this side Pihahiroth, or between it and the Red Sea, towards its extremity. The term denotes a tower or fortress. It is probably the Magdolon of Herodotus, seeing the Septuagint render it by the same name.

Ignard (Nicholas), a very ingenious French painter, born at Troyes in 1628; but, settling at Avignon, is generally distinguished from his brother Peter by the appellation of Mignon of Avignon. He was afterwards employed at court and at Paris, where he became rector of the royal academy of painting. There are a great number of his historical pieces and portraits in the palace of the Tuillery. He died in 1702.

Mignon (Peter), the brother of Nicholas, was born at Troyes in 1610; and acquired so much of the taste of the Italian school, as to be known by the name of the Roman. He was generally allowed to have a superior genius to his brother Nicholas; and had the honour of painting the popes Alexander VII. and Urban VIII. besides many of the nobility at Rome, and several of the Italian princes: His patron, Louis, was ten times to him for his portrait, and respected his talents so much as to enable him, make him his principal painter after the death of Le Brun, and appoint him director of the manufacture. He died in 1695, and many of his pieces are to be seen at St Cloud.

Mignon, or Mignon, (Abraham), a celebrated painter of flowers and still life, was born at Frankfort in 1639; and his father having been deprived of the greatest part of his subsistence by a series of losses in trade, left him in very necessitous circumstances when he was only seven years of age. From that melancholy situation he was rescued by the friendship of James Murel, a flower-painter in that city; who took Mignon into his own house, and instructed him in the art, till he was 17 years old. Murel had often observed an uncommon genius in Mignon: he therefore took him along with him to Holland, where he placed him as a disciple with David de Heem; and while he was under the direction of that master he laboured with incessant application to imitate the manner of de Heem, and ever afterwards adhered to it; only adding daily to his improvement, by studying nature with a most exact and curious observation.—

"When we consider the paintings of Mignon, one is at a loss (Mr Pilkington observes) whether most to admire the freshness and beauty of his colouring, the truth in every part, the bloom on his objects, or the perfect resemblance of nature visible in all his performances. He always shows a beautiful choice in those flowers and fruits from which his subjects are composed; and he groups them with uncommon elegance. His touch is exquisitely neat, though apparently easy and unlaboured; and he was fond of introducing insects among the fruits and flowers, wonderfully finished, so that even the drops of dew appear as round and as translucent as nature itself." He had the good fortune to be highly paid for his works in his lifetime; and he certainly would have been accounted the best in his profession even to this day, if John Van Huylen had not appeared. Weyerman, who had seen many admired pictures of Mignon, mentions one of a most capital kind. The subject of it is a cat, which had thrown down a pot of flowers, and they lie scattered on a marble table. That picture is in every respect so wonderfully natural, that the spectator can scarce persuade himself that the water which is spilled from the vessel is not really running down from the marble. This picture is distinguished by the title of Mignon's Cat. This painter died in 1679, aged only 40.

Migration, the passage or removal of a thing out of one place into another.

Migration of Birds.—It has been generally believed, that many different kinds of birds annually pass from one country to another, and spend the summer or the winter where it is most agreeable to them; and that even the birds of Britain will seek the most distant southern regions of Africa, when directed by a peculiar instinct to leave their own country. It has long
Migration. long been an opinion pretty generally received, that swallows reside during the winter-season in the warm southern regions; and Mr Adamson particularly writes his having seen them at Senegal when they were obliged to leave this country. But besides the swallow, Mr Pennant enumerates many other birds which migrate from Britain at different times of the year, and are then to be found in other countries; after which they again leave these countries, and return to Britain. The reason of these migrations he supposes to be a defect of food at certain seasons of the year, or the want of a secure asylum from the persecution of man during the time of courtship, incubation, and nutrition. The following is his list of the migrating species.

1. Gronis. Of this genus, the hooded crow migrates regularly with the woodcock. It inhabits North Britain the whole year; a few are said annually to breed on Dartmoor, in Devonshire. It breeds also in Sweden and Austria: in some of the Swedish provinces it only shifts its quarters, in others it refides throughout the year. Our author is at a loss for the summer retreat of these which visit us in such numbers in winter, and quit our country in the spring; and for the reason why a bird, whose food is fish, that it may be found at all seasons in this country, should leave us.

2. Cuckoo. Disappears early in autumn; the retreat of this and the following bird is quite unknown to us.

3. Wryneck. Is a bird that leaves us in the winter. If its diet be ants alone, as several affirm, the cause of its migration is very evident. This bird disappears before winter, and revisits us in the spring a little earlier than the cuckoo.

4. Hoopoe. Comes to England but by accident; Mr Pennant once indeed heard of a pair that attempted to make their nest in a meadow at Selborne, Hampshire, but were frightened away by the curiosity of people. It breeds in Germany.

5. Grouse. The whole tribe, except the quail, lives here all the year round: that bird either leaves us, or else retires towards the sea-coasts.

6. Pigeon. Some few of the ring-doves breed here; but the multitude that appears in the winter is so disproportionate to what continue here the whole year, as to make it certain that the greatest part quit the country in the spring. It is most probable they go to Sweden to breed, and return from thence in autumn; as Mr Ekmark informs us: they entirely quit that country before winter. Multitudes of the common wild pigeons also make the northern retreat, and visit us in winter; but not numbers breed in the high cliffs in all parts of this island. The turtle also probably leaves us in the winter, at least changes its place, removing to the southern counties.

7. Star. Breeds here. Possibly several remove to other countries for that purpose, since the produce of those that continue here seems unequal to the clouds of them that appear in winter. It is not unlikely that many migrate into Sweden, where Mr Berger observes they return in spring.

8. Thrushes. The fieldfare and the redwing breed and pass their summers in Norway and other cold countries; their food is berries, which abounding in our kingdoms, tempts them here in the winter. These two and the Roviton crow are the only land-birds that regularly and constantly migrate into England, and do not breed here. The hawkinch and orpithil come here at such uncertain times as not to deserve the name of birds of passage.

9. Chatterer. The chatterer appears annually about Edinburgh in flocks during winter; and feeds on the berries of the mountain-ash. In South Britain it is an accidental visitant.

10. Greybeaks. The greybeak and crofull come here but seldom; they breed in Austria. The pine greybeck probably breeds in the forests of the Highlands of Scotland.

11. Buntings. All the genus inhabits England throughout the year; except the greater Brambling, which is forced here from the north in very severe ffeasons.

12. Finches. All continue in some parts of these kingdoms, except the finch, which is an irregular visitor, said to come from Ruffia. The linnet shifts their quarters, breeding in one part of this island, and remove with their young to others. All finches feed on the seeds of plants.

13. Larks, fly-catchers, swallows, and warblers. All of these feed on insects and worms; yet only part of them quit these kingdoms; though the reason of migration is the same to all. The nightingale, blackcap, fly-catcher, willow-wren, wheat-eater, and white-throat, leave us before winter, while the small and delicate golden-crested wren braves our severest frosts. The migrants of this genus continue longest in Great Britain in the southern counties, the winter in those parts being later than in those of the north; Mr Stillingfleet having observed several wheatshears in the Isle of Purbeck on the 18th of November. As these birds are incapable of very distant flights, Spain, or the south of France, is probably their winter-asylum.

14. Swallows and goat-fishers. Every species disappears at the approach of winter.

Water-Fowl.

Of the vast variety of water-fowl that frequent Great Britain, it is amazing to reflect how few are known to breed here: the cause that principally urges them to leave this country, seems to be not merely the want of food, but the desire of a secure retreat. Our country is too populous for birds so shy and timid as the bulk of these are: when great part of our island was a mere waste, a tract of woods and fen, doubtless many species of birds (which at this time migrate) remained in security throughout the year. Egrets, a species of heron now scarce known in this island, were in former times in prodigious plenty; and the crane, that has totally forsaken this country, bred familiarly in our marshes: their place of incubation, as well as of all other cloven-footed water-fowl (the heron excepted), being on the ground, exposed to every one. As rural economy increased in this country, these animals were more and more disturbed; at length, by a series of alarms, they were necessitated to seek, during the summer, some lonely safe habitation.

On the contrary, those that build or lay in the almost inaccesible rocks that imped over the British seas, breed there still in vast numbers, having little to fear from the approach of mankind; the only disturb-
from the rate attempts of some few to get their eggs.

Cloven-footed Water-Fowl.

15. Heron. The white heron is an uncommon bird, and visits us at uncertain seasons; the common kind and the bittern never leave us.

16. Curlews. The curlew breeds sometimes on our mountains; but, considering the vast flights that appear in winter, it is probable that the greater part retire to other countries; the whimbrel breeds on the Grampian hills, in the neighbourhood of Invercauld.

17. Snipes. The woodcock breeds in the moist woods of Sweden, and other cold countries. Some snipes breed here, but the greatest part retire elsewhere; as do every other species of this genus.

18. Sandpipers. The following continues here the whole year; the ruff breeds here, but retires in winter; the redshank and sandpiper breed in this country, and reside here. All the others abscond themselves during summer.

19. Plovers and oyster-catcher. The long-legged plover and sanderling visit us only in winter; the dotterel appears in spring and in autumn; yet, what is very singular, we do not find it breeds in south Britain. The oyster-catcher lives with us the whole year. The Norfolk plover and sea-lark breed in England. The green plover breeds on the mountains of the north of England, and on the Grampian hills.

We must here remark, that every species of the genera of curlews, woodcocks, sandpipers, and plovers, that forsake us in the spring, retire to Sweden, Poland, Prussia, Norway, and Lapland, to breed: as soon as the young can fly, they return to us again, because the frogs which live in early in those countries totally deprive them of the means of subsisting; as the dryness and hardiness of the ground, in general, during our summer, prevent them from penetrating the earth with their bills, in search of worms, which are the natural food of those birds. Mr Ekmark speaks thus of the retreat of the whole tribe of cloven-footed water fowl out of his country (Sweden) at the approach of winter; and Mr Klein gives much the same account of those of Poland and Prussia.

20. Rails and gallinules. Every species of these two genera continue with us the whole year; the land rail excepted, which is not seen here in winter. It likewise continues in Ireland only during the summer months, when they are very numerous, as Mr Smith tells us in the History of Waterfowl, p. 326. Great numbers appear in Anglesea the latter end of May; it is supposed that they pass over from Ireland, the passage between the two islands being but small. As we have instances of these birds lighting on ships in the channel and the Bay of Biscay, we may conjecture their winter quarters to be in Spain.

Finned-footed Water-Birds.

21. Phalaropes. Visit us but seldom; their breeding place is Lapland, and other arctic regions.

22. Grebes. The great-crested grebe, the black and white grebe, and little grebe, breed with us, and never migrate; the others visit us accidentally, and breed in Lapland.

Web-footed Birds.

23. Avocet. Breed near Fosdike in Lincolnshire; but quit their quarters in winter. They are then not found in different parts of the kingdom, which they visit, not regularly, but accidentally.

24. Auk and guillemots. The great auk or penguin sometimes breeds in St Kilda. The auk, the guillemot, and puffin, inhabit most of the maritime cliffs of Great Britain, in amazing numbers, during summer. The black guillemot breeds in the Bass Isle, and in St Kilda, and sometimes in Llandinno rocks. We are at a loss for the breeding place of the other species; neither can we be very certain of the winter residence of any of them, excepting of the latter guillemot and black-billed auk, which, during winter, visit in vast flocks the Frith of Forth.

25. Divers. These chiefly breed in the lakes of Sweden and Lapland, and in some countries near the pole; but some of the red-throated divers, the northern and the imber, may breed in the north of Scotland and its isles.

26. Terns. Every species breeds here; but leaves us in the winter.

27. Petrels. The fulmar breeds in the Isle of St Kilda, and continues there the whole year except September and part of October; the shearwater visits the Isle of Man in April; breeds there; and, leaving it in August or the beginning of September, disperses over all parts of the Atlantic ocean. The stormfitch is seen at all distances from land on the same vast watery tract; nor is ever found near the shore except by some very rare accident, unless in the breeding season. Mr Pennant found it on some little rocky isles, off the north of Skye. It also breeds in St Kilda. He also supposes that it nests on the Blafquot Isles off Kerry, and that it is the gourder of Mr Smith.

28. Manx shearwaters. This whole genus is mentioned among the birds that fill the Lapland lakes during summer. Mr Pennant has seen the young of the red-breasted in the north of Scotland: a few of these, and perhaps of the goosanders, may breed there.

29. Ducks. Of the numerous species that form this genus, we know of few that breed here: The swan and goose, the shelduck, the eider duck, a few shovellers, garganey, and teal, and a very small portion of the wild ducks.

The rest contribute to form that amazing multitude of water fowl that annually repair from most parts of Europe to the woods and lakes of Lapland and other arctic regions, there to perform the functions of incubation and nutrition in full security. They and their young quit their retreat in September, and disperse themselves over Europe. With us they make their appearance the beginning of October; circulate first round our shores; and, when compelled by severe frost, betake themselves to our lakes and rivers. Of the web-footed fowl there are some of harder constitutions than others: these endure the ordinary winters of the more northern countries; but when the cold reigns there with more than common rigour, they repair for shelter to these kingdoms: this regulates the appearance of some of the diver kind, as also of the wild swans, the swallow-tailed shelduck, and the different sorts of goosanders which then visit our coasts. Barents found the barnacles with their nests in great numbers in Nova Zembla. (Collect. Voy. Dutch East India Company, 8vo. 1703, p. 19.) Clubius, in his Excurs. 368, also
also observes, that the Dutch discovered them on
the rocks of that country and in Waygate Straits. They,
as well as the other species of wild-geese, go very far
north to breed, as appears from the histories of Green-
land and Spitzbergen, by Egede and Cautz. These
birds seem to make Iceland a resting place, as Horre-
bow observes: few continue there to breed, but only
visit that island in the spring, and after a short stay re-
tire full farther north.

30. Corvus. The corvanton and flag breed on
most of our high rocks: the gannet in some of the
Scotch isles, and on the coast of Kerry: the two first
continue on our shores the whole year. The gannet
differs it'self all round the seas of Great Britain, in
pursuit of the herring and pilchard, and even as far as
the Tagus to prey on the fardina.

But of the numerous species of fowl here enumerat-
ed, it may be observed how very few intru'ce them-
selves to us in the breeding season, and what a distant
flight they make to perform the first great dictate of
nature.

There seems to be scarcely any but what we have
traced to Lapland, a country of lakes, rivers, swamps,
and alps, covered with thick and gloomy woods, that
afford shelter during summer to these fowls, which in
winter diffuse over the greatest part of Europe. In
those Arctic regions, by reason of the thickness of
the woods, the ground remains moist and penetrable to
the woodcocks, and other tender-billed fowl: and for the
web-footed birds the waters afford larva innumerable
of the tormenting knot. The days there are long;
and the beautiful meteoric nights indulge them with
every-opportunity of collecting to minute a food: whilst
mankind is very sparingly scattered over that vast nor-
thern waste.

Why then should Linneus, the great explorer of
these rude deserts, be amazed at the myriads of water-
fowl that migrated with him out of Lapland? which
exceeded in multitude the army of Xerxes; covering,
for eight whole days and nights, the surface of the river
Calis! His partial observation as a botanist, would
confine their food to the vegetable kingdom, almost
denied to the Lapland waters; inattentive to a more
plenteous table of insect food, which the all-bountiful
Creator had spread for them in the wilderness. It may
be remarked, that the lakes of mountainous rocky
countries in general are delirir of plants: few or
none are seen on those of Switzerland; and Linneus
makes the same observation in respect to those of Lap-
land; having, during his whole tour, discovered only
a single specimen of a lemma lyrifulta, or 'ivy-leaved
duck's meat,’ Flora Lap. n° 470; a few of the quen
laxiflora, or ‘bullrush,’ n° 18, the alepuchura
geniculata, or ‘fite foxtail grass,’ n° 58; and the
ramunculus aquatilis, n° 234; which are all he enu-
erates in his Prolegomena to that excellent perform-
ance.

Under the article Swallow will be found the prin-
cipal arguments for and against the migration of swal-
lows. Here we shall give a short abstract of the ar-
guments used by the Hon. Daines Barrington against
the migration of birds in general, from a paper pub-
lished by him in the 62d volume of the Philosophical
Transactions. This gentleman denies that any well-
attested instances can be produced of this supposed mi-
gration; which, he thinks, if there were any such perio-
dical flight, could not possibly have escaped the frequent
observation of seamen. It has indeed been asserted
that birds of passage become invisible in their flight,
because they rise too high in the air to be perceived,
and because they choose the night for their passage.
The author, however, expresses his doubts "whether
any bird was ever seen to rise to a greater height
than perhaps twice that of St. Paul's crofs;' and he
further endeavours to show, that the extent of some
of these supposed migrations (from the northern parts
of Europe, for instance, to the line) is too great to be
accounted for, by having recourse to the argument
founded on a nocturnal passage.

The author next recites, in a chronological order,
all the instances that he has been able to collect, of
birds having been actually seen by mariners when they
were crossing a large extent of sea; and he endeavours
to show that no signs can be laid on the few casual
observations of this kind that have been produced in
support of the doctrine of a regular and periodical mi-
gration.

Mr Barrington afterwards proceeds to invalidate
M. Adanson's celebrated observation with respect to
the migration of the swallow in particular, and which
has been considered by many as perfectly decisive of the
present question. He endeavours to show that the
four swallows which that naturalist caught, on their
settling upon his ship, on the 6th of October at about
the distance of 50 leagues from the coast of Senegal,
and which he supposed to have been then proceeding
from Europe to pass the winter in Africa, could not be
true European swallows; or, if they were, could not
have been on their return from Europe to Africa.

His objections are founded principally on some proofs
which he produces of M. Adanson's want of accuracy
on this subject, which has led him in the present in-
stance, to mistake two African species of the swallow-
tribe, described and engraved by Brisson, for Euro-
pean swallows, to which they bear a general resemble-
ance; or granting even that they were European
swallows, he contends, that they were sitting from the
Cape de Verd Islands to the coast of Africa; "to
which short flight, however, they were unequal, and
accordingly fell into the failer's hands." See the ar-
icle Swallow.—We shall here only add, in oppo-
sition to the remarks of Mr Barrington, the following
observations of the Rev. Mr White * in a letter to
Mr Pennant on this subject.

* Natural

ian Bosporus from Asia to Europe. Besides the abovementioned, he remarks, that the procession is swelled by whole troops of eagles and vultures.

"Now it is no wonder that birds residing in Africa should retreat before the sun as it advances, and retire to milder regions, and especially birds of prey, whose blood being heated with hot animal food, are more impatient of a sultry climate: but then I cannot help wondering why kites and hawks, and such hardy birds as are known to defy all the severity of England, and even of Sweden and all north Europe, should want to migrate from the south of Europe, and be dissatisfied with the winters of Andalucia.

"It does not appear to me that much stress may be laid on the difficulty and hazard that birds must run in their migrations, by reason of vast oceans, cross winds, &c.; because, if we reflect, a bird may travel from England to the equator without launching out and exposing itself to boundless seas, and that by crossing the water at Dover and again at Gibraltar. And I with the more confidence advance this obvious remark, because my brother has always found that some of his birds, and particularly the swallow kind, are very sparing of their pains on crossing the Mediterranean: for when arrived at Gibraltar, they do not

Milton.

but scout and hurry along in little detached parties of six or seven in a company; and sweeping low, just over the surface of the land and water, direct their course to the opposite continent at the narrowest passage they can find. They usually slope across the bay to the south-west, and fly over opposite to Tangier, which it seems is the narrowest space.

"In former letters we have considered whether it was probable that woodcocks in moon-light nights cross the German ocean from Scandinavia. As a proof that birds of less speed may pass that sea, considerable as it is, I shall relate the following incident, which, though mentioned to have happened so many years ago, was hardly matter of fact:--As some people were shooting in the parish of Trotton, in the county of Sussex, they killed a cuck in that dreadful winter 1708-9, with a silver collar about its neck (I have read a like anecdote of a swan), on which were engraved the arms of the king of Denmark. This anecdote the rector of Trotton at that time has often told to a near relation of mine; and, to the best of my remembrance, the collar was in the possession of the rector.

"At present I do not know any body near the sea-side that will take the trouble to remark at what time of the moon woodcocks first come. One thing I used to observe when I was a sportsman, that there were times in which woodcocks were so flagrantly and fleetly that they would drop again when flushed just before the fpariels, nay just at the muzzle of a gun that had been fired at them; whether this strange laziness was the effect of a recent fatiguing journey, I shall not presume to say.

"Nightingales not only never reach Northumber-

land and Scotland, but also, as I have been always told, St. Miguel, Devonshire and Cornwall. In those two last counties we cannot attribute the failure of them to the want of warmth: the defect in the west is rather a presumptive argument that these birds come over to us from the continent at the narrowest passage, and do not stroll so far westward."

Migration of Fishes. See Clupea.

St. Miguel, one of the Azore islands, situated in W. Long. 22 45. N. Lat. 38 10. This island appears to be entirely volcanic. The best account we have of it hath been published in the 6th volume of the Philosophical Transactions by Mr Francis Mason. According to him the productions differ greatly from those of Madeira, inasmuch that none of the trees of the latter are found here, except the faya: it has a nearer affinity to Europe than Africa. The mountains are covered with the erica vulgaris, and an elegant ever-green shrub very like a philyrea, which gives them a most beautiful appearance.

"It is one of the principal and most fertile of the Azorian islands, lying nearly east and west. Its length is about 18 or 20 leagues; its breadth unequal, not exceeding five leagues; and in some places not more than two. It contains about 80,000 inhabitants.

Its capital, the city of Ponta del Guda, which contains about 12,000 inhabitants, is situated on the south side of the island, on a fine fertile plain country, pretty regularly built; the streets straight, and of a good breadth. It is supplied with good water, which is brought about the distance of three leagues from the neighbouring mountains. The churches and other religious edifices are elegant and well built for such an island. There is a large convent of Franciscan friars and one of the order of St. Agustin, four convents for professed nuns, and three Recolhimentos for young women and widows who are not professed. The vesels anchor in an open road; but it is not dangerous, as no wind can prevent their going to sea in calm stormy weather.

The country round the city is plain for several miles, well cultivated, and laid out with good tafe into spacious fields, which are fown with wheat, barley, Indian corn, pulse, &c. and commonly produce annually two crops; for as soon as one is taken off, another is immediately sown in its place. The soil is remarkably gentle and easy to work, being for the most part composed of pulverized pumice-flone. There are in the plains a number of pleasant country-feats, with orchards of orange-trees, which are esteemed the best in Europe.

The second town is Ribeira Grande, situated on the north side of the island, containing about as many inhabitants as the city; a large convent of Franciscan friars, and one of nuns. It gives title to a convent, called the Conde Ribeira Grande, who first instituted linen and woolen manufactories in the island.

The third town is Villa Franca, on the south side of the island, about six leagues east of Ponta del Guda. It has a convent of Franciscan friars, and one of nuns, which contains about 300. Here, about half a mile from the shore, lies a small island (Ilhao), which is hollow in the middle, and contains a fine baion with only one entrance into it, fit to hold 50 sail of vessels secure from all weather; at present it wants cleaning out,
The water boils up so hot, that there was no one able to approach it; in a short time it discharged itself into the sea.

This wonderful place had been taken little notice of until very lately: so little curiosity had the gentlemen of the island, that scarcely any of them had seen it, until of late some persons, afflicted with very virulent disorders, were persuaded to try its waters, and found immediate relief from them. Since that time it has become more and more frequented; several persons who had lost the use of their limbs by the dead palpitation, have been cured; and also others who were troubled with eruptions on their bodies.

A clergyman who was greatly afflicted with the gout, tried the said waters, and was in a short time perfectly cured, and has had no return of it since. When Mr Mason was there, several old gentlemen, who were quite worn out with the said disorder, were using the waters, and had received incredible benefit from them; in particular, an old gentleman about 60 years of age, who had been tormented with that disorder more than 20 years, and often confined to his bed for six months together: he had used these waters about three weeks, had quite recovered the use of his limbs, and walked about in the greatest spirits imaginable. A friar also who had been troubled with the said disorder about 12 years, and reduced to a cripple, by using them a short time was quite well, and went about every day.

There are several other hot springs in the island, particularly at Ribeira Grande; but they do not possess the same virtues, at least not in so great a degree.

The east and west part of the island rises into high mountains; but the middle is low, interpenetrated with round conic hills, all of which have very recent marks of fire; all the parts below the surface consisting of melted lava lying very hollow.

Most of the mountains to the westward have their tops hollowed out like a punch-bowl, and contain water. Near the west end is an immense deep valley like the Furnas called the Sete Cidades. This valley is surrounded with very abrupt mountains, about seven or eight leagues round; in the bottom is a deep lake of water, about three leagues in circuit, furnished with great numbers of water-fowls. This water has no mineral quality; neither are there any hot springs in the valley. All these mountains are composed of a white, three bathing-houses, which are most commonly used. St Miguel.
MIL [8] MIL

white crumely pumice-stone, which is so loose, that
if a man thrust a fllick into the banks, whole wag-
gons of it will tumble down. The inhabitants of the island relate a story, that he who first discovered
it Osborne an extraordinary high peak near the well end; but the second time he visited it, no such
peak was to be seen, which he supposed must have
certainly sunk; but, however improbable this story
may be, at some period or another it must have cer-
tainly been the case.

MILAN, or the duchy of the Milanesi, a country
of Italy, bounded on the west by Savoy, Piedmont,
and Montferrat; by Switzerland on the north; by the
territories of Venice, the duchies of Mantua, Parma,
and Placentia, on the east; and by the territories of
Genoa on the south.

Anciently this duchy, containing the north part
of the old Liguria, was called Infabria, from its
inhabitants the Infabres; who were conquered by
the Romans, as there were by the Goths; who in
their turn were subdued by the Lombards. Di-
dier, the last king of the Lombards, was taken prisoner
by Charlemagne, who put an end to the Longobardic
empire, and appointed governors of Milan. These go-
 vernors, being at a distance from their masters, soon
began to assume an independency, which brought a
dreadful calamity on the country; for, in 153, the
capital itself was levelled with the ground by the em-
peror Frederic Barbaroffa, who committed great de-
vastations otherwise throughout the duchy. Under
this emperor lived one Galvian, a nobleman who was
defended from Otho a Milanesi. Galvian, along
with William prince of Montferrat, served in the
crusade, when Godfrey of Boulogne took Jerusalem:
he killed in single combat the Saracen general, whom
he stripped of his helmet, which was adorned with
the image of a serpent swallowing a youth; and this ever
afterwards was the badge of that family. His grand-
fon Galvian, having opposed the emperor, was taken
prisoner, and carried in irons into Germany, from
whence he made his escape and returned to Milan,
died in the service of his country. From him defend-
ed another Otho, at the time that Otho IV. was em-
peror of Germany, and who soon distinguished him-
sely by the accomplishments both of his mind and
body. When he grew up, he was received into the
family of cardinal Ubaldini at Rome. This prelate,
who was himself aspiring at the popedom, was in a short time greatly taken with the address and
accomplishments of young Otho, and predicted his
future greatness. In the mean time, one Torriess, or
Torrian, a Milanesi nobleman of unbounded ambi-
tion, was attempting to make himself master of Mi-
lan. The popular faction had some time before been
caballing against the nobility; and at last, Torrian,
putting himself at their head, expelled the bishop, and
put to death or banished, all the nobility: by which
means the popular government was fully established;
and Torriess, under this pretence, ruled every thing
as he pleased. He was, however, soon opposed by
one Francisco Sepri, who formed a great party, pre-
tending to deliver the city from Torrian's haughti-
ness and cruelty. But while the two parties were
collecting their forces against each other, cardinal
Ubaldini was projecting the destruction of both, by
means of his favourite Otho. This prelate had for
some time borne an implacable hatred to Torriano,
because he had been by him prevented from carrying
out of the treasury of St Ambrose's church at Mil-
an, a carbuncle or jewel of great value, which he
pretended to refer to for adorning the papal tiara; for
which reason he now determined to oppose his ambition.

Ubaldini began with naming Otho archbishop of
Milan; which, as the pope's legate, he had a right to
do. This nomination was confirmed by Pope Ur-
ban IV.; and the party of the nobility having now
got a head from the pope himself, began to gather
strength. Otho in the mean time employed himself in
collecting troops; and had no sooner procured a show
of an army, than, he advanced towards Lago Mag-
gione, and took possession of Arona, a strong poUt
near that lake; but Torriano, marching immediately
against him with all his troops, obliged him to aban-
don the place, and leave his party to make the best
terms they could with the conqueror. This was fol-
low by the destruction of the castles of Arona, An-
ghiari, and Brebbia: soon after which Torriano
died, and was succeeded by his brother Philip, who
had sufficient interest to get himself elected pope,
and prefect of Milan, for ten years. During his lifetime,
his party, however, the party of the nobility increafed conde-
rably under Otho, notwithstanding the check they had
received. Philip died: in 1265, having left ground con-
derably in the affections of the people, though he ob-
tained a great reputation for his courage and con-
duct. His successor Napi rendered himself terrible to
nobility, whom he proscribed, and put to death as of-
ten as he could get them into his power. He pro-
ceeded fuch lengths, and acted with fuch fury against
that unfortunate party, that pope Clement IV. who
had succeeded Urban, at laft interceded Milan, and
excommunicated Napi and all his party. By this
Napi began to lose his popularity, and the public dif-
affection towards him was much heightened by the
natural cruelty of his temper. But in the mean time,
the party of the nobility was in the utmost difter-
se. Otho himself and his friends, having spent all their
fubitance, wandered about from place to place; the
pope not being in a capacity of giving them any af-
fittance. Otho, however, was not discouraged by his
bad successe, but found means still to keep up the spi-
rits of his party, who now chose for their general Squar-
cini Burri, a man of great eminence and courage,
whole daughter was married to Matthew Visconti, af-
terwards called Matthew the great. At the same
time they renewed their confederacy with the marquis
of Montferrat, who was fon-in-law to the king of
Spain. The marquis agreed to this confederacy chiefly
with a view to become master of the Milanesi.

The nobility now again began to make head; and
having collected an army, which was joined by 600
Spanish cavalry and a body of foot, gained some ad-
vaniges. But in the mean time Napi, having gather-
ed together a superior army, suddenly attacked Otho
and Burri, and defeated them. After this disaf-
ter Otho applied to the pope; from whom, however,
he did not obtain the afittance he defired; and in the
mean time Napi invited the emperor Rodolph into
Italy, with the promise of being crowned at Milan.
This invitation was accepted of with great readiness
by
by Rodolph; who constituted Napi his governor and vicar-general in Lombardy, sending to him at the same time a fine body of German horse, the command of which was given to Caftioni, Napi's nephew. On this Otho again applied to the pope (Gregory X.) but he was so far from granting him any assistance, that he is said to have entered into a scheme of aff٬inating him privately; but Otho escaped the danger, and in 1276 began to recover his affairs. The reason of pope Gregory's enmity to him was, that he and his party were thought to be Ghibelines, and were opposed by great numbers of the nobility themselves; but after that pope's death, the Milanesi exiles being united under one head, soon became formidable. They now chose for their general Godfrey count of Langue, a noble Pavan, and an inveterate enemy of the Torriano family. This nobleman being rich and powerful, enlisted many German and other mercenaries, at whom head he marched towards the Laghi Maggiore. All the towns in that country opened their gates to him, through the interest of the Visconti family, who retired in these parts. But this success soon met with a severe check in an unfortunate engagement, wherein Godfrey was defeated and taken prisoner; after which he and 34 nobles had their heads cut off, and sent from the field of battle piled up in a common waggon.

This defeat greatly affected Otho; but having in a short time recovered himself, he again attacked his enemies, and defeated them; but, suffering his troops to grow remiss after their victory, the fugitives rallied, and entirely defeated him. The next year, however, Otho had better success, and totally defeated and took prisoner Napi himself. After this victory Caftioni was obliged to abandon Milan to his competitor, who kept possession of it till his death, which happened in 1295, in the 87th year of his reign.

Otho was succeeded by Matthew Visconti above-mentioned; and Milan continued in subjection to that family without any visible occurrence till the year 1378, when, by the death of Galeazzo II. his brother Barnabo became sovereign of Milan. He was of a brave and active disposition; but excessively partial in his favours, as his brother Galeazzo had also been; and to procure money to supply his extravagancies, was obliged to oppress his subjects. Galeazzo had engaged in an enterprise against Bologna, and the siege of it was continued by Barnabo. It lasted for nine years; and during this time he is said to have cost 300 millions of gold, a prodigious sum in those days, near 40 millions sterling; being in value somewhat more than half-a-crown English. Both the brothers were exceedingly fond of building. Barnabo erected a bridge over the Adda, confining three stories; the lowest for chariots and heavy Carriages, the middle for horses, and the uppermost for foot-passengers. He built also another bridge, which was carried over houses without touching them. To accomplish these, and many other expensive schemes, he became one of the greatest tyrants imaginable, and every day produced fresh instances of his rapacity and cruelty. He instituted a chamber of inquiry, for punishing all those who had for five years before been guilty of killing bears, or even of eating them at the table of another. They who could not redeem themselves by money were hanged, and above 100 wretches perished in that manner. Those who had any thing to lose were obliged of all their substance, and obliged to labour at the fortifications and other public works. He obliged his subjects to maintain a great many hunting-dogs, and each district was taxed a certain number. The owners of his dogs were at the same time the first and last of his capacity. When the dogs were poor and slender, the owners were always fined; but when the dogs were fat, the owners were also fined for suffering them to live without exercise.

The extravagant behaviour of Barnabo soon rendered public affairs ready for a revolution, which was at last accomplished by his nephew John Galeazzo. He affected a solitary life, void of ambition, and even inclining to devotion; but at the same time took care that his nephew John Galeazzo had soldiers advancing from other quarters; so that Barnabo and his sons were immediately seized, and the houses of those who had fined with them given up to be plundered. The booty in plate, money, and all kinds of rich furniture, was immense. The ministers of the late government were dragged from their hiding-places, and put to death; and at last the citadel itself fell into the hands of Galeazzo, who found in it an immense sum of money. Barnabo was carried prisoner to Trissio, a castle of his own building, where he had the happiness to find one person still faithful to him. This was his mistress, named Dominia Pozza; who, when he was abandoned by all the world, shut herself up a voluntary prisoner in his chamber, and remained with him as long as he lived, which was only seven months after his degradation.

John Galeazzo was the first who took upon him the title of the duke of Milan, and was a prince of great policy and no less ambition. He made war with the Florentines, became master of Pisa and Bologna, and entirely defeated the emperor in 1402, so that he entertained hopes of becoming master of all Lombardy, and cutting off all possibility of invading it either from France or Germany; but his designs were frustrated by death, which happened in 1403, in the 55th year of his age. After his decease the Milanesi government fell into the most violent dissensions, so that it ...
could not be supported, even in time of peace, without an army of 20,000 foot and as many horses. In the year 1421, however, Philip duke of Milan became master of Genoa; but though he gained great advantages in all parts of Italy, the different states still found means to counterbalance his successes, and prevent him from enslaving them; so that Milan never became the capital of any extensive empire; and in 1437 Genoa revolted, and was never afterwards reduced.

Philip died in 1448, and by his death the male line of the Visconti family was at an end. The next lawful heir was Valentina his sister, who had married the duke of Orleans son to Charles V. of France. By the contract of that marriage, the lawful progeny of it was to succeed to the duchy of Milan in failure of the heirs-male of the Visconti family; but this succession was disputed by Sforza, who had married Philip's natural daughter. It is certain, however, that the right of succession was vested in the house of Orleans and the kings of France; and therefore though the Sforza family got possession of the duchy for the present, Louis XII. afterwards put in his claim, as being grand-son to John Galeazzo. For some time he was successful, but at length in such an important manner, that they were driven out of the Milanese by the Swis and Maximilian Sforza. The Swis and Milanese were in their turn expelled by Francis I, who obliged the Sforza family to relinquish the government for a pension of 50,000 ducats a-year. Francis Sforza, the son of Maximilian, however, being allied to the emperor and the pope, regained the possession of the Milanese about the year 1521; and, eight years after, the French king, by the treaty of Cambrai, gave up his claim on the duchy.

But, in fact, the emperors of Germany seem to have had the fairest title to the Milanese in right of their being for a long time sovereigns of Italy. On the death of Francis Sforza, therefore, in the year 1536, the emperor Charles V. declared the Milanese to be an imperial fief, and granted the investiture of it to his son Philip II. king of Spain. In his family it continued till the year 1706, when the French and Spaniards were driven out by the Imperialists, and the emperor again took possession of it as a fief. It was confirmed to his house by the treaty of Baden in 1714, by the quadruple alliance in 1718, and by the treaty of Aix-la-Chapelle in 1748.

The duchy of Milan is one of the finest provinces in Italy. It is bounded on the south by the Appenine mountains, and the territory of Genoa; on the north by Switzerland; on the east by the Venetian territories, and the duchies of Mantua, Parma, and Placentia; and on the west by Savoy, Piedmont, and Montferrat; extending from north to south about 100 miles, and from east to west about 70 miles. It is well watered by the Tiffino, the Sile, the Adda, the Po, the Oglio, the Lombr, Serio, &c. and also by several canals and lakes. Of the latter the Lago Maggiore is between 30 and 40 miles in length, and in some places six or seven miles broad. In it lie the Boromenian islands, as they are called, viz. Isola Bella and Isola Madre, the beauty of which almost exceeds imagination; art and nature seem to have vied with one another in embellishing them. In each of them is a palace with delicious gardens, belonging to the Boromean family. The water of the lake is clear and of a greenish colour, and abounds with fish. The hills which it is surrounded presents a most charming landscape, being planted with vines and chestnut-trees, intersected with summer-houses. There is a canal running from it towards Switzerland, with which the city of Milan has a communication. It was anciently called Lacus Verbanus. The Lago de Como, which was called by the Latin poets Lacus Larius, but had its modern name from the city, near which it lies, extends itself about 30 miles northward from Como, but its greatest breadth is not above five miles. From the Lago Maggiore issues the Tessino; and from that of Como the Adda. Of the other lakes, that of Lago and Guarda are the chief; that of Guarda was anciently called Benacus.

The trade and manufactures of this duchy consist principally in silks, stuffs, stockings, gloves, and handkerchiefs, linen and woollen cloth, hardware, curious works of crystal, agate, hyacinths, and other gems; but their exports are usually far short of their imports. As to the revenue of the duchy, it must without doubt be very considerable. It is said to have amounted to 2,000,000 dollars while the duchy was in the hands of Spaniards.

In the year 1767, the Austrian government of Milan published a law, by which all the rights which the pope or the bishops had till then exercised over ecclesiastics, either with regard to their effects or persons, is transferred to a council established for that purpose at Milan. By the same edict, all ecclesiastics were obliged to sell the estates which they had become possessed of since the year 1722; and no subject, whether ecclesiastic or secular, was to go to Rome to solicit any favour, except letters of indulgence, without the consent of the said council.

MILAN, the capital of the duchy of that name, in Latin Mediolanum, is a very large city, and has a wall and rampart round it, with a citadel; yet is thought to be incapable of making any great resistance. The gardens within the city take up a great deal of ground. In the citadel is a foundry for cannon, and an arsenal furnished with arms for 12,000 men. The governor of it is quite independent of the governor-general of the Milanese, who resides in the city, in a large but old and ill-contrived palace. The yearly income of the governor of Milan is said to be 200,000 guilders. The council belonging to the city is composed of a prefrident and 60 doctors of law, who are all nobles, and independent of the governor-general. Milan hath experienced a great variety of fortune, having been subject sometimes to the French, sometimes to the Spaniards, and sometimes to the Germans. A great number of persons of rank and fortune live in it, especially during the winter. The ladies in France are not allowed more liberty than those of this city; even the aulterities of the monastic life are so far mitigated here, that gentlemen have not only the liberty of talking with the nuns, and of railing and laughing at the grate, but of joining with them in concerts of music, and of spending whole afternoons in their company. The place where the bauc monde take the air, either in their coaches or on foot, is the rampart betwixt the Porta Orientale and the Porta Tofa, where it is straight and broad, and extremely pleasant.
Milan, pleasant, being planted between the ramparts and the city. Milan, have been built by the hospitals, and though something has been doing for near 600 years towards the outward or inward ornament thereof, it is not yet finished. Of the great number of statues about it, that of St Bartholomew, just dead alive, with his skin hanging over his shoulders; and of Adam and Eve, over the main portal, are the finest. The pillars supporting the roof of the church are all of marble, and the windows finely painted. This church contains a treasure of great value, particularly a shrine of rock-crystal, in which the body of St Charles Borromeo is deposited. The other churches most worthy of a stranger's notice are those of St Alexander, St Jerome, St Giovanni de Cafarotti della Paffione, that of the Jesuits, and of St Ambrose, in which lie the bodies of the saints and of the kings Pepin and Bernard. In the Ambroian college, founded by Frederic Borromeo, 16 professors teach gratis. In the same college is also an academy of painting, with a museum, and a library containing a vast number of printed books and manuscripts; among the last of which is a translation of Josephus's History of the Jews, done by Rufinus about 1250 years ago, and written on the bark of a tree. St Ambrose's works on vellum, finely illuminated; the orations of Gregory Nazianzen, and the works of Virgil, in folio, with Petrarch's notes. In the museum are Leonardo da Vinci's mathematical and mechanical drawings, in 12 large volumes. The seminary for sciences, the college of the nobles, the Helvetian college, and the mathematical academy, are noble foundations and stately buildings. Of the hospitals, the most remarkable are the Lazaretto, and that called the great hospitals, the latter of which receives sick persons, foundlings, and lunatics, and has six smaller hospitals depending on it, with a revenue of 100,000 rixdollars.

The number of the inhabitants of this city is said to be about 200,000. It has been 40 times besieged, taken 20 times, and four times almost entirely demolished; yet it has always recovered itself. It is said that gunpowder is sold here only by one person, and in one place. The court of inquisition is held in the Dominican convent, near the church of Madonna della Grazia. The houses of entertainment, and the ordinaries here, are represented as very indifferent. Mr. Keyfer says, it is not usual for young travellers, when they go to any of the taverns in Milan, to be asked, “whether they choose a letto fornito, or female bed-fellow,” who continues maid till the enters the bed-chamber. Milan is described as inferior to Turin both in beauty and conveniency: many of the streets being crooked and narrow, and paper-windows much more frequent than in that city; even in grand palaces, the windows are often composed promiscuously of glass and paper. Two large canals extend from hence, the one to the Telfino, and the other to the Adda; the Telfino having a communication with the Lago Maggiore, and, by a canal, with the S. S., and the Adda rising from the Lago di Como, and having a communication by canal with the Lambro and S. Siro. In a void space in one of the fronts of Milan, where stood the house of a barber who had confpired with the comminity of health to poison his fellow-citizens, is ered a pillar called Colonna Infausta, with an inscription to perpetuate the memory of the execrable design. The environs of this city are very pleasant, being adorned with beautiful fountains, gardens, orchards, &c. About two Italian miles from it, at the seat of the Simonetti family, is a building, that would have been a masterpiece of its kind had the architect designed it for an artificial echo. It will return or repeat the report of a pistol above 60 times; and any tingle musical instrument, well touched, will have the same effect as a great number of instruments, and produce a most surprising and delightful concourse.

According to Dr Moore, “there is no place in Italy, perhaps in Europe, where strangers are received in such an easy hospitable manner as at Milan. Formerly the Milanese nobility displayed a degree of splendor and magnificence, not only in their entertainments, but in their usual style of living, unknown in any other country in Europe. They are under a necessity at present of living at less expense, but they still show the same obliging and hospitable disposition. This country having, not very long since, been possessed by the French, from whom it devolved to the Spaniards, and from them to the Germans, the troops of those nations have, at different periods, had their residence here, and, in the course of these vicissitudes, produced a style of manners, and stamped a character on the inhabitants of this duchy, different from what prevails in any other part of Italy; and nice observers imagine they perceive in Milanese manners the politeness, formality, and honesty imputed to those three nations, blended with the ingenuity natural to Italians. The great theatre having been burnt to the ground last year, there are no dramatic entertainments, except at a small temporary play-house, which is little frequented; but the company assemble every evening in their carriages on the ramparts, and drive about, in the same manner as at Naples, till it is pretty late. In Italy, the ladies have no notion of quitting their carriages at the public walks, and using their own legs, as in England and France. On seeing the number of servants, and the splendor of the equipages which appear every evening at the Corso on the ramparts, one would not suspect that degree of depopulation, and diminution of wealth, which we are assured has taken place within these few years all over the Milanese; and which proceeds from the burdensome nature of some late taxes, and the inolent and oppressive manner in which they are gathered.” E. Long. 15. 35. N. Lat. 38. 32.

MILBORN-roxt, a town of Somersetshire in England, seated on a branch of the river Parret, 115 miles from London. Though it is represented in parliament, it is no market-town nor corporation; but it appears in Domesday-book to have had a market once, and 56 burgesses. It is in a manner surrounded by Dorsetshire. Here are nine capital burgesses, who
MIL [12] MIL

Milbrook yearly choose two bailiffs, that have the government of the borough under them, and jointly return the members of parliament with the two stewards, who are chosen yearly out of nine commonalty stewards, and have the custody of the corporation-seal. These two stewards also distribute the profits of the lands given to the poor here, of which the said commonalty stewards are trustees. The inhabitants are about 1,100, the houses not much above 200. There are two fairs, June 6th and October 28th.

Milbrook, a town of Cornwall, on the west side of Plymouth-Haven. It has a good fishing-trade, and has formerly furnished the British fleet with many able hands.

Mildenhall, a town of Suffolk, seven miles from Newmarket, 12 from Bury, and 70 from London. It is a large populous town on the river Lark, a branch of the Ouse, with a harbour for boats. It has a well-frequented market on Friday, especially for fish. "It has been recommended to send two men into the drawing this along the field through the ears, the disorder attacks the milletus. It was founded by a Cretan colony under Miletus, the companion of Bacchus; or (according to others) by Neleus the son of Codrus; or by Sarpedon, Minos's brother, (Ephorus, quoted by Strabo). Milos, the people, (Ovid).

Miletus (anc. geog.), a celebrated town of Asia Minor, on the confines of Ionia and Caria. It was the capital city of all Ionia, and famous both for the arts of war and peace. It was situated about 10 miles south of the mouth of the river Meander, near the sea-coast. It was founded by a Cretan colony under Miletus, the companion of Bacchus; or (according to others) by Neleus the son of Codrus; or by Sarpedon, a son of Jupiter. It has successively been called Leipues, Pityius, and Anadone. The inhabitants, called Milici, were very powerful, and long maintained an obstinate war against the kings of Lydia. They early applied themselves to navigation; and planted no less than 80 colonies, or (according to Seneca) 380, in different parts of the world. It was the only town that made head against Alexander, and was with much difficulty taken. It gave birth to Thales, one of the seven wise men, and the first who applied himself to the study of nature. It was also the country of Anaximander, the scholar and successor of Thales, the inventor of sun-dials and the gnomon, and the first that published a geographical map; of Anaximenes, scholar and successor to the foregoing; and of other great men. It was noted for its excellent wool, according to Virgil; and was also celebrated for a temple and oracle of Apollo Dylmenus. This famous people, from being powerful,
MILFORD, of Sulis-County in the Delaware flate, is situated at the source of a small river, 15 miles from Delaware bay, and 150 southward of Philadelphia. This town, which contains about 100 houses, has been built, except one house, since the revolution. It is laid out with much taste, and is by present it is called by the Turks becoming afterwards opulent and abandoned to pleasures, lost both their riches and their power.—At present it is called by the Turks Melas, and not far distant from it runs the river Meander. St. Paul going from Corinth to Jerusalem passed by Miletus, and as he went by sea, and could not take Ephesus in his way, he caused the bisho.p and priests of the church of Ephesus to come to Miletus (Acts xx. 15, &c.), which was about 12 leagues from them.

MILFOIL, or Yarrow. See Achillea.

MILFORD, a town of Sussex-county in the Delaware flate, is situated at the source of a small river, 15 miles from Delaware bay, and 150 southward of Philadelphia. The inhabitants are Episcopalians, Quakers, and Methodists.

MILFORD-Haven, one of the finest harbours in Europe, and indispensably the best in Britain, is situated in Pembroke-shire in South-Wales, and lies on the north side of the Bristol Channel. It is very large,large, and deep; there is no danger of going in or out with the tide, or almost with any wind. If a ship comes in without a cable or anchor, she may run ashore on the ooze, and there lie safe till she is rehitched; and in an hour's time she may get out of the harbour into the open sea. It lies extremely convenient for ships bound from the English or Bristol Channels to Ireland, or farther west, and from thence to the Channel. It is said, that 1000 fall of any ship may ride secure in this haven. It has 16 deep and safe creeks, five bays, and 13 roads, all distinguished by their several names. The spring tide rises 36 feet; so that ships may at any time be laid ashore. Dale harbour is a ready outlet for small vessels, where they may ride in two or three fathoms at low-water.—In the reign of Queen Elizabeth, before the Spanish invasion, two forts were begun at the entrance of Milford-Haven; one on each side, called Nangle and Dale blockhouses; but they were not then finished.—The Stuck-rock rises here above water, lying near the middle of the entrance between Nangle and Dale. Penrithmouth is the opening of that branch of the haven on which the town of Pembroke is seated, and where the custom-house of Milford is kept. The breadth of the entrance between rock and rock is but 200 yards at high-water, and 112 at low-water. There is a ridge of rocky ground that has the name of Carrs, which runs almost across Milford-Haven, from Peter church towards Llanladwell, where it renders the landing place difficult to strangers, from its not appearing at low-water. The great convenience of this harbour is, that in an hour's time a ship may be in or out of it, and in the way between the land's end and Ireland. As it lies near the mouth of the Severn, a ship in eight or ten hours may be over on the coast of Ireland, or off the Land's-End in the English Channel; and a vessel may get out hence to the west much sooner than from either Plymouth or Falmouth. This harbour has been greatly improved by new works, at the expense of the government. The parliament, on April 14, 1759, granted 10,000l. for fortifying the harbour of Milford, all of which was expended on the fort at Neyland, which, however, still remains unshaken.

MILIARY, in general, something resembling millet-feed.

MILITARY-FARM. See MEDICINE, n° 229.

MILITANT, or CHURCH-MILITANT, denotes the body of Christians while here on earth.

MILITARY, something belonging to the soldiery or militia.

MILITARY-Discipline, the training of soldiers, and the due enforcement of the laws and regulations instituted by authority for their conduct.

Next to the forming of troops, military discipline is the first object that presents itself to our notice: it is the soul of all armies; and unless it is established amongst them with great prudence, and supported with unshaken resolution, they are no better than so many contemptible heaps of rabble, which are more dangerous to the very state that maintains them than even its declared enemies.

MILITARY-Execution, the ravaging or destroying of a country or town that refuses to pay the contribution inflicted upon them.

MILITARY-Exercife. See EXERCISE and WORDS of Command.

MILITARY-State, in British polity, one of the three divisions of the laity. See LEIT.

This state includes the whole of the soldiery, or such persons as are peculiarly appointed among the rest of the people for the safeguard and defence of the realm.

In a land of liberty, it is extremely dangerous to make a distinct order of the profession of arms. In absolute monarchies, this is necessary for the safety of the prince; and arises from the main principle of their constitution, which is that of governing by fear: but, in free states, the profession of a soldier taken singly and merely as a profession, is justly an object of jealousy. In these no man should take up arms but with a view to defend his country and its laws: he puts not off the citizen when he enters the camp; but it is because he is a citizen, and would with to continue so, that he makes himself for a while a soldier. The laws, therefore, and constitution of these kingdoms, know no such state as that of a perpetual standing soldier, bred up to no other profession than that of war; and it was not till the reign of Henry VII. that the kings of England had so much a guard about their persons.

In the time of the Anglo-Saxons, as appears from Edward the Conqueror's laws, the military force of England was in the hands of the dukes or earls, who were constituted through every province and county in the kingdom; being taken out of the principal nobility, and such as were most remarkable for being sapientes, fidels, et animos. Their duty was to lead and regulate the English armies, with a very unlimited power; prout eis vidum fuerit, ad honorem corone et militem regni. And because of this great power they were elected by the people in their full assembly, or folk-mote, in the same manner as sheriffs were elected: following still that old fundamental maxim of the Saxon constitution, that where any officer was entrusted with such power, as if abused, might tend...
Military

to the oppression of the people, that power was delegated to him by the vote of the people themselves. So too, among the ancient Germans, the ancestors of our Saxon forefathers, they had their dukes, as well as kings, with an independent power over the military, as the kings had over the civil state. The dukes were elective, the kings hereditary: for so only can be sufficiently understood that passage of Tacitus, Reges ex nobilitate, duces ex virtute fumunt. In constituting their kings, the family or blood-royal was regarded: in choosing their dukes or leaders, warlike merit: just as Cæsar relates of their ancestors in his time, that whenever they went to war, by way either of attack or defence, they elected leaders to command them. This large share of power, thus conferred by the people, though intended to preserve the liberty of the subject, was perhaps unreasonably detrimental to the prerogative of the crown: and accordingly we find a very ill use made of it by Edric duke of Mercia, in the reign of king Edmond Ironside; who, by his office of duke or herethoch, was intituled to a large command in the king’s army, and by his repeated treacheries at last transferred the crown to Canute the Dane.

It seems universally agreed by all historians, that king Alfred first settled a national militia in this kingdom, and by his prudent discipline made all the subjects of his dominions soldiers: but we are unfortunately left in the dark as to the particulars of this his celebrated regulation; though, from what was last observed, the dukes seem to have been left in possession of too large and independent a power: which enabled duke Harold, on the death of Edward the Confessor, though a stranger to the royal blood, to mount for a short space the throne of this kingdom, in prejudice of Edgar Etheling the rightful heir.

Upon the Norman conquest, the feudal law was introduced here in all its rigour, the whole of which is built on a military plan. In consequence thereof, all the lands in the kingdom were divided into what were called knight’s fees, in number above 60,000; and for every knight’s fee a knight or follower, miles, was bound to attend the king in his wars, for 40 days in a year; in which space of time, before war was reduced to a science, the campaign was generally finished, and the king either conquered or victorious. By this means the king had, without any expense, an army of 60,000 men always ready at his command. And accordingly we find one, among the laws of William the conqueror, which in the king’s name commands and firmly enjoins the personal attendance of all knights and others; qual habebant et teneant se semper in armis et equis, ut decet et opportet: et quod jiperum fuit promptum et forati ad servitium fuum integrum nobis eisdem mandubi, cum opus adfererit, facendum quod dentent de foedibus et to-nementis suis de jure nobis facere. This personal service in process of time degenerated into pecuniary commutations or aids; and at last the military part of the feudal system was abolished at the Restoration, by statute 12 Car. II. c. 24. See Feodat-Sytem.

In the meantime, we are not to imagine that the kingdom was left wholly without defence in case of domestic insurrections, or the prospect of foreign invasions. Besides those who by their military tenures, were bound to perform 40 days service in the field, first the office of arms, enacted 27 Hen. II. and afterwards the statute of Winchester, under Edward I. obliged every man, according to his estate and degree, to provide a determinate quantity of such arms as were then in use, in order to keep the peace; and confibles were appointed in all hundreds by the latter statute, to see that such arms were provided. These weapons were changed, by the statute 4 & 5 Ph. & M. c. 2. into others of more modern service; but both this and the former provisions were repealed in the reign of James I. While these continued in force, it was usual from time to time for our princes to issue commissions of array, and send into every county officers in whom they could confide, to muster and array (or in military order) the inhabitants of every district; and the form of the commission of array was settled in parliament in the 5 Hen. IV. But at the same time it was provided, that no man should be compelled to go out of the kingdom at any rate, nor out of his shire, but in cases of urgent necessity; nor should provide soldiers unless by consent of parliament. About the reign of king Henry VIII. and his children, lord-lieutenants began to be introduced, as flanding representatives of the crown, to keep the counties in military order; for we find them mentioned as known officers in the statute 4 & 5 Ph. & M. c. 3, though they had not been then long in use; for Camden speaks of them in the time of Queen Elizabeth as extraordinary magistrates, constituted only in times of difficulty and danger.

In this statute things continued till the repeal of the statutes of armour in the reign of king James 1.; after which, when king Charles I. had, during his northern expeditions, lifted commissions of lieutenancy, and exerted some military powers which, having been long exercised, were thought to belong to the crown, it became a question in the long-parliament, how far the power of the militia did inherently reside in the king; being now unsupported by any statute, and founded only upon immemorial usage. This question, long agitated with great heat and resentment on both sides, became at length the immediate cause of the fatal rupture between the king and his parliament: the two houses not only denying this prerogative of the crown, the legality of which claim perhaps might be some what doubtful; but also feizing into their hands the entire power of the militia, the illegality of which step could never be any doubt at all.

Soon after the restoration of king Charles II. when the military tenures were abolished, it was thought proper to ascertain the powers of the militia, to recognize the sole right of the crown to govern and command them, and to put the whole into a more regular method of military subordination: and the order in which the militia now stands by law, is principally built upon the statutes which were then enacted. It is true, the two last of them are apparently repealed; but many of their provisions are re-enacted, with the addition of some new regulations, by the present militia-laws; the general scheme of which is to discipline a certain number of the inhabitants of every county, chosen by lot for three years, and officered by the lord-lieutenant, the deputy lieutenants, and other principal landholders, under a commission from the crown. They are not compellable to march out of their counties, unless
Military

forces should be kept on foot in Ireland, though paid at the charge of that kingdom: which permission is extended by flat. 8. Geo. III. c. 13. to 16,235 men in time of peace.

To prevent the executive power from being able to oppress, says baron Montesquieu, it is requisite that the armies with which it is intrusted should confit of the people, and have the same spirit with the people; as was the case at Rome, till Marius new-modelled the legions by enlisting the rabble of Italy, and laid the foundation of all the military tyranny that ensued.

Nothing then, according to these principles, ought to be more guarded against in a free state, than making the military power, when such a one is necessary to be kept on foot, a body too distinct from the people. Like this, therefore, it should wholly be composed of natural subjects; it ought only to be enlisted for a short and limited time; the soldiers also should live intermixed with the people; no separate camp, no barracks, no inland fortresses, should be allowed. And it perhaps might be still better, if, by enlisting a flated number, and enlisting others at every renewal of their term, a circulation could be kept up between the army and the people, and the citizen and the soldier be more intimately connected together.

To keep this body of troops in order, an annual act of parliament likewise passed, "to punish mutiny and desertion, and for the better payment of the army and their quarters." This regulates the manner in which they are to be differeed among the several inn-keepers and victuallers throughout the kingdom; and establishes a law-martial for their government. By this, among other things, it is enacted, that if any officer or soldier shall excite, or join any mutiny, or, knowing of it, shall not give notice to the commanding officer, or shall desert, or lie in any other regiment, or leap upon his post, or leave it before he is relieved, or hold correspondence with a rebel or enemy, or strike or use violence to his superior officer, or shall disobey his lawful commands; such officer shall suffer such punishment as a court-martial shall inflict, though it extend to death itself.

However expedient the most strict regulations may be in time of actual war, yet in times of profound peace, a little relaxation of military rigour would not, one should hope, be productive of much inconvenience. And, upon this principle, though by the standing laws (still remaining in force, though not attended to) desertion in time of war is made felony without benefit of clergy, and the offence is triable by a jury, and before the judges of the common law; yet, by the militia laws beforementioned, a much lighter punishment is inflicted for desertion in time of peace. So, by the Roman law also, desertion in time of war was punished with death, but more mildly in time of tranquility. But the mutiny-act makes no such distinction: for any of the faults abovementioned are, equally at all times, punishable with death itself, if a court-martial shall think proper. This discretionary power of the court-martial is indeed to be guided by the direction of the crown; which, with regard to military offences, has almost an absolute legislative power. "His Majesty (says the act) may form articles of war, and constitute courts-martial, with power to try any crime by such articles, and inflict such penalties as the articles direct."
MIL [16] MIL

Military. direct.” A vast and most important truth! an unlimited power to create crimes, and annex to them any punishments not extending to life or limb! These are indeed forbidden to be inflicted, except for crimes declared to be so punishable by this act; which crimes we have just enumerated, and among which, we may observe, that any disobedience to lawful commands is one. Perhaps in some future revision of this act, which is in many respects hastily penned, it may be thought worthy the wisdom of parliament to ascertain the limits of military subjection, and to enact express articles of war for the government of the army, as is done for the government of the navy; especially as, by the present constitution, the nobility and gentry of the kingdom, who serve their country as militia officers, are annually subjected to the same arbitrary rule during their time of exercise.

One of the greatest advantages of the law is, that not only the crimes themselves which it punishes, but also the penalties which it inflicts, are ascertained and notorious: nothing is left to arbitrary discretion; the king by his judges infenches what the law has previously ordained, but is not himself the legislator. How much, therefore, is it to be regretted, that a set of men, whose bravery has so often preferred the liberties of their country, should be reduced to a state of servitude in the midst of a nation of freemen; for Sir Edward Coke will inform us, that it is one of the genuine marks of servitude, to have the law, which is our rule of action, either concealed or precarious; ubi jus, ubi remedium. Nor is this state of servitude quite conformable with the maxims of sound policy observed by other free nations. For the greater the general liberty is which any state enjoys, the more cautious has it usually been in introducing slavery in any particular order or profession. These men, as baron Montesquieu observes, seeing the liberty which others possess, and which they themselves are excluded from, are apt (like enuchs in the eastern seraglions) to live in a state of perpetual envy and hatred towards the rest of the community, and indulge a malignant pleasure in contributing to destroy those privileges to which they can never be admitted. Hence have many free states, by departing from this rule, been endangered by the revolt of their slaves; while, in absolute and despotic governments, where no real liberty exists, and consequently no invidious comparisons can be formed, such incidents are extremely rare.

Two precautions are therefore advised to be observed in all prudent and free governments: 1. To prevent the introduction of slavery at all; or, 2. If it be already introduced, not to intrust those slaves with arms, who will then find themselves an overmatch for the freemen. Much less ought the soldiery to be an exception to the people in general, and the only state of servitude in the nation.

But as soldiery, by this annual a5, are thus put in a worse condition than any other subjects; so, by the humanity of the founding laws, they are in some cases put in a much better. By statute 43 Eliz. c. 3, a weekly allowance is to be raised in every county for the relief of soldiery that are sick, hurt, and maimed: not forgetting the royal hospital of Chelsea for such as are worn out in their duty. Officers and soldiery, that have been in the king’s service, are by several statutes, enabled at the close of several wars, at liberty to use any trade or occupation they are fit for, in any town in the kingdom (except the two universities), notwithstanding any statute, custom, or charter to the contrary. And soldiery in actual military service may make uncaptive wills, and dispose of their goods, wages, and other personal chattels, without these forms, solemnities, and expenses, which the law requires in other cases. Our law does not indeed extend this privilege so far as the civil law; which carried it to an extreme that borders upon the ridiculous; for if a soldier, in the article of death, wrote any thing in bloody letters on his shield, or in the dust of the field with his sword, it was a very good military testament.

Military Court. See Chivalry (Court of).

Military Ways (see military), are the large Roman roads which Agrippa procured to be made through the empire, in the time of Augustus, for the more convenient marching of troops and conveyance of carriages. N. Bergier has written the history of the origin, progress, and amazing extent, of these military roads, which were paved from the gates of Rome to the extreme parts of the empire. See Way.

Militia, in general, denotes the body of soldiery, or those who make profession of arms.

In a more refined sense, militia denotes the trained bands of a town or country, who arm themselves, upon a short warning, for their own defence. So that, in this sense, militia is opposed to regular or flated troops. See Military State, and Feudal System.

Miliun, millet, in botany; a genus of the diagnosta order, belonging to the triandria clafs of plants; and in the natural method ranking under the 4th order, Gramina. The calyx is bivalved, and uniflorous; the corolla is very short: the stigmata pencil like.—There are five species; of which the most remarkable is the panicum, or common millet. This is a native of India, but is now commonly cultivated in many parts of Europe as an eculent grain. It rises, with a reed-like stalk, three or four feet high, and channelled: at every joint there is one reed-like leaf, which is joined on the top of the sheath, and embraces and covers that joint of the stalk below the leaf; this sheath is closely covered with soft hairs, but the leaf which is expanded has none. The top of the stalk is terminated by a large loose panicel, which hangs on one side, having a chaffy flower, which is succeeded by a small round feed. There are two varieties; one with white, and the other with black seeds; but they do not differ in any other particular. This plant is greatly cultivated in the oriental countries, and from whence we are annually furnished with it. It is seldom cultivated in Britain but in small gardens, for feeding of poultry, where the seeds generally ripen very well. It is used as an ingredient in puddings, and is by some people greatly esteemed. The seeds must be sown in the beginning of April, upon a warm dry soil, but not too thick because the plants divide into several branches, and should have much room. When they come up they should be cleaned from weeds; after which they
MIL [17] MIL

Milk. will in a short time get the better of them, and prevent the future growth. In August the seeds will ripen, when the plant must be cut down, and the seeds beaten out, as is practised for other grain; but if it is not protected from birds, they will devour it as soon as it begins to ripen.

MILK, a well-known fluid, prepared by nature in the breasts of women, and the udders of other animals, for the nourishment of their young.—According to Dr Cullen, milk is a connecting and intermediate substance between animals and vegetables. It seems immediately to be secreted from the chyle, both being a white liquor of the same fluid. Such a fluid nature has perfectly assimilatory food, as the albumen of the oviparous, and in the viviparous animals, and somewhat of the same kind, as it was necessary the vessels should be filled with such a fluid as would make way for an after-assimilation. When the infant has attained a considerable degree of firmness, as when it is separated from the mother, yet such a degree of weakness still remains as makes somewhat of the same indication necessary, it believes the infant to have an alkalescent food ready prepared, and at the same time its noxious tendency to be avoided. Milk then is given, which is alkalescent, and at the same time, has a sufficient quantity of acidity to correct that alkalescence. As the body advances in growth, and the alkalescent tendency is greater, the animal, to obviate that tendency, is led to take vegetable food, as more suited to its strength of assimilation.

Dr Cullen observes, that milk is almost suited to all temperaments; and it is even so to stomachs disposed to acidity, more than those substances which have undergone the vinous fermentation; nay, it even cures the heart-burn, checks vinous fermentation, and precipitates the lees, when, by renewal of fermentation, the wine happens to be fouled. It, therefore very properly accompanies a great deal of vegetable aliment; although sometimes its acidity is troublesome, either from a large proportion taken in, or from the degree of it; for, according to certain unaccountable circumstances, different acids are formed in the stomach in different states of the body; in a healthy body, e.g. a mild one; in the hypochondriac diseased, one sometimes as corrosive as the foallic acid. When the acidity of milk is carried to a great degree, it may prove remarkably refrigerant, and occasion cold crudities, and the recurrence of intermittent fevers. To take the common notion of its passing unchanged into the blood, it can suffer no solution. But if we admit its coagulum in the stomach, then it may be reckoned among soluble or insoluble foods, according as that coagulum is more or less tenacious. Formerly rennet, which is employed to coagulate milk, was thought an acid; but, from late observations, it appears, that, if it be an acid it is very different from other acids, and that its coagulum is stronger than that produced by acids. It has been imagined, than a rennet is to be found in the stomachs of all animals, which causes coagulation of milk; but to Dr Cullen the coagulation of milk seems to be owing to a weak acid in the stomach, the relics of our vegetable food, inducing, in healthy persons, a weak and soluble coagulum: but in different stomachs this may be very different, in those becoming heavy and less soluble food, and sometimes even evaporated in a coagulated undisolved state both by stomach and food.

As milk is acidulent, it may be rendered sometimes purgative by mixing with the bile; and some examples...
Milk. of this I have been remarked. More commonly, however, it is reckoned among those foods which occasion colicivenes.

Hoffman, in his experiments on milk, found that all kinds of it contained much water; and when this was diluted, found the residue very different in their solubility. But we must not thence conclude, that the same insolubility takes place in the stomach; for extracts made from vegetables with water are often very insoluble substances, and hardly diffusible through water itself: therefore, in Hoffman's extracts, if we may so call them, of milk, somewhat of the same kind might have appeared; and these substances, which in their natural state were not so, might appear very insoluble. However, we may allow that milk is always somehow insoluble in the intestines, as it is of a drying nature, and as chest, &c. is very colitive. And this effect shows that milk is always coagulated in the stomach: for if it remained fluid, no cases would be produced, whereas sometimes very hard ones are observed. In the blood-vessels, from its animal nature, it may be considered as nutritious; but when we consider its vegetable contents, and acceitancy in the prime size, we find that, like animal-food, it does not excite that degree of fever in the time of digestion, and that from its acceitancy it will resist putrefaction. Hence its use in hectic fevers, which, whatever be their cause, appear only to be exacerbations of natural febrile paroxysms, which occur twice every day, commonly after meals, and at night. To obviate these, therefore, we give such an aliment as produces the least exacerbation of these fevers: and of this nature is milk, on account of its acecent vegetable nature.

There appears all somewhat peculiar to milk, which requires only a small exertion of the animal-powers in order to its assimilation; and besides, in hemic complaints there is wanted an oily, bland food, approaching to the animal-nature; so that on all these accounts milk is a diet peculiarly adopted to them, and, in general, to most convalescents, and to those of inflammatory temperaments. So far of milk in general. We shall now speak of the particular kinds which are in common use.

The milk of women, mares, and asses, agree very much in their qualities, being very dilute, having little solid contents, and, when evaporated to dryness, having these very soluble, containing much saccharine matter, of a very ready acceitancy, and, when coagulated, their coagulum being tender and easily broke down. From this view they have left oil, and seem to have left coagulable matter than the rest.

The milk of cows, sheep, and goats, agree in opposite qualities to the three just mentioned; but here there is somewhat more of gradation. Cows' milk comes nearest to the former kind: goats' milk is less fluid, left sweot, less flatulent, has the largest proportion of insoluble part after coagulation, and indeed the largest proportion of coagulable part; its oily and coagulable parts are not spontaneously separable, never throwing out a cream, or allowing butter to be readily extracted from it. Hence the virtues of these milks are obvious, being more nourishing, though at the same time left easily soluble in weak stomachs, than the three first, lefts acceitant than these, and so more rarely laxative, and peculiarly fitted for the diet of convalescents without fever. The three first again are left nourishing, more soluble, more laxative, as more acceitant, and adapted to the convalescents with fever.

These qualities, in particular milks, are considerably diversified by different circumstances. First, different animals, living on the same diet, give a considerably different milk; for there seems to be something in the constitution, abstracting from the aliment, which constitutes a considerable diversity of milk, not only in the same species of animals, but also in the same animal, at different ages, and at different distances after delivery: this applies to the choice of nurses. Secondly, Milk follows the nature of the aliment more than any other juice in the human body, being more or less fluid and dilute, more or less solid and nourishing, in proportion as these qualities are more or less in the aliment. The nature of the aliment differs according to its time of growth, e.g. old griefs being always found more nourishing than young. Aliment, too, is always varied according to the season, as that is warm or dry, moist or cloudy.

The milk of each particular kind of animal is fitter for particular purposes, when fed on proper food—Thus the cow delights in the succulent herbage of the vale: if the sheep be fed there he certainly rots, but on the higher and more dry side of the mountain he feeds pleasantly and healthily; while the goat never stops near the bottom, but ascends to the craggly summit: and certainly the milks of these animals are always best on their proper soil, and that of goats is best on a mountainous country. From a dissertation of Linnaeus, we have many observations concerning the variety of plants on which each animal chooses to feed. All the Swedish plants which could be collected together, were preferred alternately to domestic animals, and then it appeared that the goat lived on the greatest variety, and even on many which were poisonous to the rest; that the cow chose the first succulent shoots of the plant, and neglected the frutification; which last was preferred by the goat. Hence may be deduced rules, concerning the sustenance of different animals; e.g. Farmers find, that in a pasture which was only fit to feed a certain number of sheep, an equal number of goats may be introduced, while the sheep are no less nourished than before.

It is not easy to assign the difference between milk fresh-drawn and that contained in the open air for some time: but certainly there is some material one, otherwise nature universally would not have directed infants to sucking; and indeed it seems, better than the other, fitted for digestion and nourishment. Physicians have supposed that this depended on the evaporation of some of the milk, which, just after, returns, but our author cannot conceive any such, except common water here; and besides, the volatile parts can hardly be nutritious. A more plausible account seems deducible from mixture: milk newly-drawn has been but lately mixed, and is exposed to spontaneous separation, a circumstance hurtful to digestion, none of the parts being, by themselves, so easily assimilated as when they are all taken together. Hence, then, milk new drawn is more intimately blended, and therefore then is more proper to the weakly and infants.

Another difference in the use of milk exposed for some time to the air, is taking it boiled or unboiled. Physicians...
Physicians have generally recommended the former; but the reason is not easily assigned. Perhaps it is this: Milk kept for some time exposed to the air has gone so far to a spontaneous separation; whereas the heat thoroughly blends the whole, and hence its resolution is not so easy in the stomach; and thus boiled milk is more agreeable than raw, and gives more ease.

Again, when milk is boiled, a considerable quantity of air is detached, as appears from the froth on the surface; and air is the chief instrument of fermentation in bodies; so that after this process it is not liable to aecency: for these reasons it is proper for the robust and vigorous.

Another difference of milk is, according as it is fluid or coagulated. The coagulated is of two kinds, as induced by rennet, or the natural aecency of the milk. The former preparation makes the firmer and less easily soluble coagulum; though, when taken with the whey unseparated, it is less difficult of solution, though more so than any other coagulum in the same cafe. Many nations use the latter form, which is easier soluble, but very much aecent, and therefore, in point of solution, should be confined to the vigorous, in point of aecency, to those who live on alkali salts food; and in the last cafe, the Laplanders use it as their chief aecent condiment. From the same considerations it is more cooling, and in its other effects like all other aecent vegetables.

Milk by evaporation yields a sweet saline matter, of which Dr Lewis gives the following proportions:

<table>
<thead>
<tr>
<th>Twelve ounces of</th>
<th>Left of dry matter</th>
<th>From which water extracted a sweet saline substance amounting to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cows milk</td>
<td>13 drams.</td>
<td>1½ drams.</td>
</tr>
<tr>
<td>Goats milk</td>
<td>12½</td>
<td>1½</td>
</tr>
<tr>
<td>Human milk</td>
<td>8</td>
<td>6</td>
</tr>
<tr>
<td>Aifes milk</td>
<td>8</td>
<td>6</td>
</tr>
</tbody>
</table>

The saline substance extracted from aifes milk was white, and sweet as sugar; those of the others brown or yellow, and considerably less sweet; that from cows milk had the least sweetness of any.

On distilling 12 quarts of milk in balneo maris, at least nine quarts of pure phlegm were obtained: the liquor which afterwards arose was acridulous, and by degrees grew sensibly more and more acid as the distillation was continued. After this came over a little spirit, and at last an empyreumatic oil. The remaining solid matter adhered to the bottom of the retort, in the form of elegant shining black flowers, which being calcined and elixated yielded a portion of fixed alkaline salt.

Milk, set in a warm place, throws up to the surface an unctuous cream, from which, by agitation, the butter is easily separated. The addition of alkaline salts prevents this separation, not (as some have supposed) by absorbing an acid from the milk, but by virtue of their property of intimately uniting oily bodies with watery liquors. Sugar, another grand intermediate between oils and water, has this effect in a greater degree, though that concrete is by no means alkaline, or an absorbent of acids.

The sweet saccharine part of the milk remains dissolved in the whey after the separation of the curd or cheesy matter, and may be collected from it in a white crystalline form, by boiling the whey till all remains of the curdled substance have fallen to the bottom; then filtering, evaporating it to a due consistence, festing it to shoot, and purifying the crystals by solution in water and a second crystallization. Much has been said of the medicinal virtues of this sugar of milk, but it does not seem to have any considerable ones: it is from cows milk that it has been generally prepared; and the crystals obtained from this kind of milk have but little sweetness.

When milk is suffered to coagulate spontaneously, the whey proveth acid, and on standing grows more and more so until the putrefactive state commences. Sour whey is used as an acid, preferably to the directly vegetable or the mineral acids, in some of the chemical arts; as for dissolving iron in order to the bluing of linen and leather. This acid was commonly made use of in the bleaching of linen, for dissolving and extracting the earthy particles left in the cloth by the alkaline salts and lime employed for cleaning and whitening it. Butter-milk is preferred to plain four-milk or four whey: this last is supposed to give the cloth a yellow colour. Dr Home, in his ingenious treatise on this subject, recommends water acidulated with spirit of vitriol (in the proportion of about half an ounce, or at most three quarters of an ounce, to a gallon), as preferable in many respects to the acid of milk, or of the more directly vegetable substances. He observes, that the latter are often difficultly procurable, abound with oleaginous particles, and hsten to corruption; whilst the vitriolic acid is cheap, and pure, and indispensible for putrefying: That milk takes five days to perform its office, whilst the vitriolic acid does it in as many hours, perhaps in as many minutes: That this acid contributes also to whiten the cloth, and does not make it weaker though the cloth be kept in it for months. He finds, that acids as well as alkalis, extract an oily matter from the cloth, and lose their acidity and alkaliity. Since this treatise appeared, the use of four-milk is very generally superseded by oil of vitriol.

It is observable, that aifes milk is greatly disposed, on standing for a little time, to become thick and ropy. In the Breulau collection for the year 1720, there is a remarkable account of milk (which probably was that of the aifes) grown so thick and tenacious as to be drawn out into long strings, which, when dried, were quite brittle.

New cows milk, suffered to stand for some days on the leaves of butterwort or sun-devil, becomes uniformly thick, slippery, and coherent, and of an agreeable sweet taste, without any separation of its parts. Fresh milk, added to this, is thickened in the same manner, and this successively. In some parts of Sweden, as we are informed in the Swedish Memoirs, milk is thus prepared for food.

New milk has a degree of glutinous quality, so as to be used for joining broken stone ware. There is a far greater tenacity in cheese properly prepared.

Milk, when examined by a microscope, appears composed of numerous globules swimming in a transparent fluid. It boils in nearly the same degree of heat with common water; some forts rather sooner, and some a little later: after boiling, it is less diff
Milk.

posed to grow four than in its natural state. It is coagulated by acids both mineral and vegetable, and by alkalies both fixed and volatile. The coagulum made by acids falls to the bottom of the serum; that made by alkalies swins on the surface, commonly forming (especially with volatile alkalies) a thick corkaceous skin. The serum, with alkalies, proves green or dirty; with acids, it differs little in appearance from the whey that separates spontaneously. The coagulum formed by acids is dissolved by alkalies, and that formed by alkalies is redissolved by acids; but the milk does not in either case resume its original properties. It is coagulated by most of the middle salts, whose basis is an earth or a metallic body; as solution of alum, fixed salt ammonia, sugar of lead, green and blue vitriol; but not by the chalybeate or purging mineral waters, nor by the bitter salt extracted from the purging waters. Among the neutral salts that have been tried, there is not one that produces any coagulation. They all dilute the milk, and make it less disposed to coagulate with acids or alkalies: Nitre seems to have this effect in a greater degree than the other neutral salts. It is instantly coagulated by highly-rectified spirit of wine, but scarcely by a phlegmatic spirit. It does not mingle with expressed oils. All the coagula are dissolved by gall.

It has generally been supposed by medical authors, that the milk of animals is of the same nature with mineral waters, nor by the bitter salt vomited by infants of a few days old are yellow, of the cream thrown by the stomach, or labours under any disease. We may presume, that the cream of woman's milk, by its inferior specific gravity, will swim on the surface of the contents of the stomach; and being of an oily nature, that it will be of more difficult digestion than any other constituent part of milk. When an infant then frets very plentifully, fo as to over-dilute the stomach, or labours under any weakness in the powers of digestion, it cannot appear unreasonable to suppose, that the cream shall be first rejected by vomiting. Analogous to this, we know that adults affected with dysepsia often bring up greasy fluids from the stomach by eructation, and this especially after eating fat meat. We have, in some instances, known this to blaze when thrown into the fire like spirit of wine or oil.” Our author derives a confirmation of his opinion from the following observation, viz. that curds vomited by infants of a few days old are yellow, while they become white in a fortnight or three weeks. This he accounts for from the yellow colour of the cream thrown up by the milk of women during the first four or five days after delivery.

Mr Clarke likewise controverts that common opinion of the human milk being so prone to acidity; that a great number of the diseasfs of children are to be accounted for from that principle. “Whoever (says he) takes the trouble of attentively comparing human milk with that of ruminant animals, will soon find it to be much less prone to run into the acid or acid procfs. I have very often exposed equal quantities of human and cows milk in degrees of temperature, varying from the common summer heat, or 65° to 100°; and
and I haveconfantly found that cows' milk acquires a greater degree of acidity in 36 hours than the human milk did in many days: cows' milk becomes offensively putrid in four or five days; a change which healthy human milk, exposed in the same manner, will not undergo in many weeks, nay sometimes in many months. I once kept a few ounces of a nurse's milk, delivered about six or seven days, for more than two years in a bottle moderately corked. It stood on the chimney-piece, and was frequently opened to be examined. At the end of this period it showed evident marks of moderate acidity, whether examined by the taste, smell, or paper stained by vegetable blues or purples; the latter it changed to a florid red colour, whereas cows' milk kept a few days changed the colour of the same paper to a green, thereby clearly showing its putrefient tendency.

Our author next goes on to consider of the probability there is of milk becoming so frequently and strongly acid as to occasion most of the diseasés of infants. He begins with an attempt to show, that the phenomena commonly looked upon to be indications of acidity are by no means certain. Curdled milk has already been shown to be no sign of acidity; and the other appearance, which has commonly been thought to be fo certain, viz. green faces, is, in the opinion of Mr Clarke, equally fallacious. In support of this he quotes a letter from Dr Sydenham to Dr Cole; in which he says that the green matter vomited by hysterical women is not any proof of acid humors being the cause of that disease, for sea-fleec people do the same. The opinion of green faces being an effect of acidity, proceeds on the supposition that a mixture of bile with an acid produces a green colour; but it is found, that the vegetable acid, which only can exist in the human body, is unable to produce this change of colour, though it can be effected by the strong mineral acids. As nothing equivalent to any of these acids can be supposèd to exist in the bowels of infants, we must therefore take some other method of accounting for the green faces frequently evacuated by them. "Why should four milk, granting its existence, give rise to them in infants and not in adults? Have butter milk, summer-fruits of the most acceefcent kind, leemon or orange juice, always this effect in adults by their admixture with bile? This is a question which, I believe, cannot be anwsered in the affirmative."

On the whole, Dr Clarke considers the disease of acidity in the bowels, though so frequently mentioned, to be by no means common. He owns, indeed, that it may sometimes occur in infancy as well as in adults, from weakness of the stomach, colic, or improper food; and an indubitable evidence is affordèd by faces which stain the blue or purple colour of vegetables to a red, though nothing can be inferred with certainty from the colour or smell.

The Doctor next proceeds to state several reasons for his opinion, that the greater number of infantile diseases are not owing to acidity: 1. Woman's milk in an healthy state contains little or no coagulable matter or curd. 2. It shows a less tendency out of the body to become accefeent than many other kinds of milk. 3. The appearances which have been generally supposèd to characterize its acidity do not afford satisfactory evidence of such a morbid cause. 4. Granting this to be the case, we have plenty of mild absorbents, capable of destroying all the acid which can be supposèd to be generated in the bowels of an infant; yet many children are observed to die in consequence of these diseasés supposèd to arise from acidity. 5. The milk of all ruminant animals is of a much more accefeent nature than that of the human species, yet the young of these animals never suffer anything like the disèasés attributed to acidity in infants. 6. History informs us, that whole nations live four curdled milk as a considerable part of their food without feeling any inconvenience; which, however, must have been the case, if acidity in the stomach was productive of such deleterious effects as has been supposèd.

The reasoning of Dr Clarke seems here to be very plausible, and nothing has as yet been offered to contradict it. The reviewers in taking notice of the treatise only observe, that the Doctor's posìtions are supported by great probability; yet "they have seen them, or think they have seen them, contradicted by the appearance of diseases and the effects of medicines" so that they must leave the subject to farther examination.

In a memoir by Miss Parmentier and Deyeux, members of the royal college of pharmacy, &c. in Paris, we have a great number of experiments on the milk of asses, cows, goats, sheep, and mares, as well as women. The experiments on cows milk were made with a view to determine whether any change was made in the milk by the different kinds of food eaten by the animal. For this purpose some were fed with the leaves of "mais" or Turkey wheat; some with cabbage; others with small potatoes; and others with common grasses. The milk of those fed with the "mais" or Turkey wheat was extremely sweet; that from the potatoes and common grasses much more acrimonious and in¬fipid; and that from the cabbages the most disagreeable of all. By distillation only eight ounces of a colourless fluid were obtained from as many pounds of each of these milks; which from those who fed upon grass had an aromatic flavour; a disagreeable one from cabbage; and none at all from the potatoes and Turkey wheat. This liquid became fetid in the space of a month whatever the animal had been fed with, acquiring at the same time a viscidity and becoming turbid; that from cabbage generally, but not always, becoming first putrid. All of them separated a filamentous matter, and became clear on being exposed to the heat of 25° of Reaumur's thermometer. In the residua of the distillations no difference whatever could be perceived. As the only difference therefore existing in cow's milk lies in the volatile part, our authors conclude, that it is improper to boil milk either for common or medicinal purposes. They observed also, that any sudden change of food, even from a worse to a better kind, was attended by a very remarkable diminution in the quantity of milk. All the residuums of the distillations yielded, in a strong fire, a yellow oil, an acid, a thick and black empyreumatic oil, a volatile alkali, and towards the end a quantity of inflammable air, and at last a coal remained containing some fixed alkali with muriatic acid.

On agitating, in long bottles, the creams from the milk of cows fed with different substances, all of them
were formed into a kind of half-made butter; of which that formed from the milk from mais was white, firm, and infpid; that from potatoes was softer and more pinguedinous; but that from common grafs was the best of all. Cabbage, as in other cafes, gave a strong taint.

In the course of their experiments, it was endeavoured to determine whether butter is actually contained in the cream, or whether it be a chemical production of the operation of churning. They could not find any reafon absolutely satisfactory on either side, but incline to the latter opinion; because when cream is allowed to remain among the milk, and the whole curdled promiscuously, only fat cheef, without any butter, is produced. The oily parts cannot be separated into butter either by acids or any other means than churning: even the artificial mixture of oil with the cream is insufficient for the purpose.

The ferum of milk was reduced by filtration to a clear and pellucid liquor; and, by mixture with fixed acid, was confirmed by experiments made upon the milk of 20 nurfees. Its coagulability was not increafed by heat. The cream, by agitation, formed a vilcid unctuous matter, but could not be changed into perfect butter: but they found that it was extremely difficult to determine the proportions of the various component parts in human milk, as it differs remarkably, not only in different subjéfts, but in the fame subjéct at different times. In a nurfe aged about 32 years, who was extremely subjéct to nervous affections, the milk was one day found almost quite colourles and transparent. In two hours after, a second quantity drawn from the breafh was vilcid like the white of an egg. It became whiter in a short time, but did not recover its natural colour before the evening. It was afterwards found that these changes were occasioned by her having some violent hystericfits in the mean time.

Sugar of Milk. Under the article Chemistry an account has been given of the fugar of milk, with fome of the different methods of making it: but of late we have an account of a method used by fome of the Tartar nations of preferring their milk by means of froft; in which operation great quantities of the fugar of milk are accidentally formed. The account was given by Mr Fahrig of Peterburgh, who undertook a journey, by order of the academy of Peterburgh, among the Mogul tribes who inhabit the country beyond the lake Baikal, on the Banks of the river Salenga. These people allow their milk to freeze in large quantity in iron kettles; and, when it is perfectly congealed, they place them over a gentle fire to soften the edges of the cake, after which it may be taken out with a wooden spatula. They commence these operations at the beginning of the cold, when they have milk in the greatest abundance; after which it may be preferred with great celerity throughout the whole winter. Mr Fahrig having frequent opportunities of seeing these cakes, soon observed, that the surface of them was covered to a confiderable depth with a farinaceous powder; and having eftablifhed a daily upon the fame plan with thofe of the Moguls, he found the fame thing take place with himself. This powder was extremely sweet, and he received platefuls of it from the natives, who used it in their food, and sweetened their other viuals with it. Having caufed a number of cakes of frozen milk to be conveyed to the top of his house, where they were directly exposed to the violent cold, he found that the separation of the farinaceous powder was greatly promoted by this means. He scraped the cakes every week to the depth...
is given to substances very different from milk, properly so called, and which resemble milk only in colour. Such is water in which quicklime has been flaked, which acquires a whiteness from the small particles of the lime being suspended in it, and has hence been called the milk of lime. Such also is the solution of liver of sulphur, when an acid is mixed with it, by which white particles of sulphur are made to float in the liquor.

Mix of Vegetables. For the same reason that milk of animals may be considered as a true animal emulsion, the emulifiable liquors of vegetables may be called vegetable milks. Accordingly emulsions made with almonds are commonly called milk of almonds. But besides this vegetable milk, which is in some measure artificial, many plants and trees contain naturally a large quantity of emulifiable or milky juices. Such are lettuce, spurge, fig-tree, and the tree which furnishes the classic American resin. The milky juices obtained from all these vegetables derive their whiteness from an oily matter, mixed and undissolved in a watery or mucilaginous liquor. Most resinous gums were originally such milky juices, which afterwards become solid by the evaporation of their moist fluid and volatile parts.

These natural milky juices have not been examined by any chemist. Such an examination would, however, procure much essential knowledge concerning vegetable economy. We should probably find examples of all kinds of oils reduced into milky juices; and this knowledge cannot fail of throwing much light on the nature of refined and gum-refins.

Mix of Pear, See Mowifery, p. 806.

Mix of Hedges, the English name of a shrub growing on the coast of Coromandel, where it is used for hedging. The whole shrub grows very bushy with numerous erect branches, which are composed of cylindrical joints as thick as a tobacco-pipe, of a green colour, and from three to six inches long; the joints are thicker than the other parts, but always give way at the thinnest place of the plant. When broken it yields a milk of an exceedingly caustic quality, which blistered any part of the skin it touched. When the joints are broken off at each end, the tube then contains but very little milk. In this state Mr. Ives ventured to touch it with his tongue, and found it a little sweet. In the hedges it is seldom very woody; but when the wood is pretty solid, and the bark grey and cracked. This plant, he informs us, has acquired a great reputation in curing the venereal disease, on the following account. A poor Portuguese woman, the eldest female of her family, had wrought surprising cures in the most intractable venereal disorders, even such as the European physicians had pronounced incurable. These facts became so notorious, that the servants of the company, and especially their surgeons, were induced to offer her a very considerable premium for a discovery of the medicine; but she always refused to comply, giving for a reason, that while it remained a secret, it was certain provision for the maintenance of the family in the present as well as in future generations. On account of this denial the English surgeons were sometimes at the pains to have her motions without doors carefully watched; and as they were not able to discover that she ever gathered of any other plant or tree but this, they conjecture...
Mr. Ives inquired at the black druggist concerning the virtues of this plant; who all agreed, that it would cure the lues venera, but differed as to the manner of administering it; some saying that a joint of it should be eaten every morning; others that the milk only should be dropped upon sugar; and then put into milk, oil, &c. and given daily to the patient.

**MILK-WAY.** See Astronomy-Index.

**MILL,** a machine for grinding corn, &c. of which there are various kinds, according to the different methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c. See *Mechanics,* Sept. V.

The first obvious method of reducing corn into flour for bread would be, by the simple expedient of pounding. And that was for ages the only one which was practised by the various descendants of Adam, and actually continued in use among the Romans below the reign of Valpallian. But the process was very early improved by the application of a grinding power, and the introduction of mill-stones. This, like most of the common refinements in domestic life, was probably the invention of the antediluvian world, and certainly practised in some of the earliest ages after it. And, like most of them, it was equally known in the east and west. Hence the Gauls and Britons appear familiarly acquainted with the use of hand-mills before the time of their submission to the Romans; the Britons particularly distinguing them, as the Highlanders and we distinguis/h them at present, by the simple appellations of *querns,* *carnes,* or *flones.* And to the Romans the added the very useful invention of water-mills. For this discovery the world is pretty certainly indebted to the genius of Italy; and the machine was not uncommon in the country at the conquest of Lancashire. This, therefore, the Romans would necessarily introduce with their many other refinements among us. And that they actually did, the British appellation of a *water-mill* fully suggests of itself; the *menas* of the Welsh and Cornish, the *mull,* *mesil,* and *menial* of the Armoricans, and the Irish *mills* and *moldon,* being all evidently derived from the Roman *molae* and *molendinum.* The subject Britons universally adopted the Roman name, but applied it, as we and our successors do, only to the Roman *mill,* and one of these was probably erected at every stationary city in the kingdom. One plainly was at Manchesten, serving equally the purposes of the town and the accommodation of the garrison. And one alone would be sufficient, as the use of handmills remained very common in both, many having been found about the site of the station particularly; and the general practice having continued among us nearly to the present period. Such it would be peculiarly necessary to have in the camp, that the garrison might be provided against a siege. And the water-mill at Manchester was fixed immediately below the Cattlefield and the town, and on the channel of the Medlock. There, a little above the ancient ford, the sluice of it was accidentally discovered about 30 years ago. On the margin of Dyer's-croft, and opposite to some new constructions, the current of the river, accidentally swelled with the rains, and, obstructed by a dam, broke down the northern bank, swept away a largeock upon the edge of it, and disclosed a long tunnel in the rock below. This has been since laid open in part with a spade. It appeared entirely uncovered at the top, was about a yard in width, and another in depth, but gradually narrowed to the bottom. The sides showed everywhere the marks of the tool on the rock, and the course of it was parallel with the channel. It was bared by the flood about 25 yards only in length, but was evidently continued for several further; having originally begun, as the nature of the ground evinces, just above the large curve in the channel of the Medlock.

For the first five or six centuries of the Roman state, there were no public bread-bakers in the city of Rome. They were first introduced into it from the east, at the conclusion of the war with Perseus, and about the year 167 before Christ. And, towards the close of the first century, the Roman families were supplied by them every morning with fresh loaves for breakfast. But the same custom, which prevailed originally among the Romans and many other nations, has continued nearly to the present time among the Mancunians. The providing of bread for every family was left entirely to the attention of the women in it. And it was baked upon loaves, which the Welsh denominate *gri-dials* and we *gredds.* It appears, however, from the kiln-burnt pottery which has been discovered in the British sepulchres, and from the British appellation of an *odyn* or *oven* remaining among us at present, that furnaces for baking were generally known among the original Britons. An *odyn* would, therefore, be erected at the mansion of each British baron, for the use of himself and his retainers. And, when he and they removed into the vicinity of a Roman station, the oven would be rebuilt with the mansion, and the public bakehouses of our towns commence at the first foundation of them. One bakehouse would be constructed, as we have previously shown, one mill to have been set up, for the public service of all the Mancunian families. One oven and one mill appear to have been equally established in the town. And the inhabitants of it appear immemorially accustomed to bake at the one and grind at the other. But the therefore, were in all probability constructed at the first introduction of water-mills and ovens into the country. The great similarity of the appointments refers the consideration directly to one and the same origin for them. And the general nature of all such institutions points immediately to the first and actual introduction of both. And, as the same establishments prevailed equally in other parts of the north, and pretty certainly obtained over all the extent of Roman Britain, the same creeds were as certainly made at every stationary town in the kingdom.

**MILL (John),** a very learned divine, was born at Shap in Westmoreland, about the year 1645; and became a servitor of Queen's college Oxford. On his entering into orders he became an eminent preacher, and was made prebendary of Exeter. In 1681, he was created doctor of divinity; about the same time he was made chaplain in ordinary to King Charles II. and in 1685 he was elected principal of St Edmund's Hall in Oxford. His edition of the Greek Testament, which will ever render his name memorable, was published about a fortnight before his death, which happened...
Before Littleton’s time, however, a somewhat nicer characteristic than seems compatible with his notion appears to have belonged to them; for Shakespeare, in his Henry IV, makes Hotspur, when complaining of the daintiness of a courtier, say, “I was perfumed like a millener.”

The fact seems to be, that there were milleners of several kinds: as barke-milleners, (for so those persons were called who made ornaments of coloured wood for horses); haberdashers of small wares, the milleners of Littleton; and milleners such as these now peculiarly known by that name, whether male or female, and to whom Shakspeare’s allusion seems most appropriate.

Laflly, Dr Johnson, in his Dictionary, derives the word from milner, an inhabitant of Milan, from whence people of this profession first came, as a Lombard is a banker.

MILLE PASSUS, or Milia Paffium; a very common expression among the ancient Romans for a measure of distance, commonly called a mile. Millarium, rarely used. Which Hefychius made to consist of seven stadia; Plutarch, little short of eight; but many others, as Strabo and Polybius, make it just eight stadia. The reason of this difference seems to be, that the former had a regard to the Grecian foot, which is greater than the Roman or Italic. This distance is oftentimes called lapsis, which fce. Each paffus consisted of five feet, (Collumella).”

MILLENIUM, “a thousand years” generally employed to denote the thousand years, during which, according to an ancient tradition in the church, grounded on fome texts in the Apocalypse and other scriptures, our bleffed Saviour fhall reign with the faithful upon earth after the firft refurrection, before the final completion of beatitude.

Though there has been no age of the church in which the millennium was not admitted by individual divines of the firft eminence, it is yet evident from the writings of Eufebius, Irenreus, Origen, and others, among the ancients, as well as from the histories of Dupin, Motheim, and all the moderns, that it was never adopted by the whole church, or made an article of the established creed in any nation.

About the middle of the fourth century the millenians held the following tenets: 1. That the city of Jerufalem fhould be rebuilt; and that the land of Judea fhould be the habitation of thofe who were to reign on earth 1000 years. 2. That the firft refurrection was not to be confined to the martyrs; but that after the fall of Antichrift all the just were to rife, and all that were on the earth were to continue for that space of time. 3. That Christ fhall then come down from heaven, and be fecn on earth, and reign there with his fervants. 4. That the fants during this period fhall enjoy all the delights of a te rrificial paradise.

These opinions were founded upon several passages of scripture, which the millenarians among the fathers understood in no other than a literal fense, but which the moderns, who hold that opinion, confider as partly literal and partly metaphorical. Of these passages, that upon which the greateft stress has been laid, we believe to be the following:—“And I faw an angel come down from heaven, having the key..."
MILL

by the reign of Christ and the saints. For a thousand years upon earth, nothing more is meant, than that before the general judgment the Jews shall be converted, genuine Christianity be diffused through all nations, and mankind enjoy that peace and happiness which the faith and precepts of the gospel are calculated to confer on all by whom they are sincerely embraced.

Our Saviour's own account of his religion, that from a small beginning it will increase to the full harvest. The millennium therefore is to be considered as the full effect of the Christian principles in the hearts of men, and over the whole world; and the divines who have treated of this subject endeavour to prove, that this is to be expected from the facts which have already existed, and from the importance of the Christian doctrine.

1. The gradual progress of Christianity is no objection to this fact. This is similar to the progress and advancement from left to greater perfection in every thing which possesses vegetable or animal life. The same thing is observed in the arts, in civilization, in societies, and in individuals—and why should it not be admitted to have place in religion? There is indeed a general principle on which a gradual progression, both in the natural and moral world, is founded. The Almighty never employs supernatural means where the thing can be accomplished by those which are natural. This idea is of the most general extent through the whole of the present system of nature. The possibility of another plan could easily be admitted; but in this case there would be a total alteration of every part of the works of God or of man that we are acquainted with. In the same manner, if the religion of Christ had been irresistible, it would have totally altered its natural consequences. It was necessary, therefore, from the present condition of man as an active, intelligent, and accountable being, that means should be employed; and wherever means are employed, the effects produced must be gradual, and not instantaneous.

2. Though the progress of a divine revelation be gradual yet it is to be expected, from the wisdom and compation of God, that it will still be advancing in the hearts of men, and over the world. In the first age of the church, the word of God, supported by miracles, and by the animated zeal of men, who spake what they saw and heard, grew and prevailed. In this case supernatural means were necessary, because the prejudices of the world could not be subdued without them. It was the first watering of a plant which you afterwards leave to the dew of heaven. Miracles at the same time were employed only as the means of conviction; and they were not continued, because in this case they would have become a constant and irresistible principle, incompatible with the condition of man as a responsible agent. After this power was withdrawn, there were many ages of ignorance and superstition in the Christian church. But what is necessary to be established on this subject is, not that the progress of Christianity has never been interrupted, but that on the whole it has been advancing. The effects of this religion on mankind, in proportion as it was received, were immediate and visible.
to the accumulation of this world's property, if they
lawed from bread to bread, and operated with equal
force on all men, would be productive of equal good
and happiness to all. We are scarcely able to
perceive the force of this at first view, because the deceit
and imposition which yet exist in the world, prevent
the operation of the beet principles even in the beet hearts.
But in proportion to the improvement of mankind,
what is their real interest, and what are the real ob-
jects of happiness, will gradually unfold. The con-
tempt of vice will be greater in proportion to the fear-
city of it: for one villain gives countenance and sup-
port to another, just as iron sharpeneth iron. This
opens to our view another fact connected with the
practice of Christianity, namely, that the nearer it
arrives to its perfect state, it will be the more rapid
in its progress. The beauty of holiness will be more
visible; and, in the strong language of the prophet,
"the earth shall bring forth in one day, and a nation
shall be born at once." This fact is perfectly
true, for the gospel is consistent with its nature and importance.—8.

We can scarcely believe that means so admirably adapt-
ted to the reformation of mankind should be without
their effect; and if the most difficult part be already
accomplished, we have no reason to apprehend that
the scheme will not be completed. This fact is also clear-
ly the subject of ancient prophecy. For "thus faith
the Lord," I will extend peace to her like a river,+ Ver. 12,
and the glory of the Gentiles like a flowing stream. 23.
And it shall come to pass, from one sabbath to an-
other, and from one new moon to another, shall all
flesh come to worship before me, faith the Lord."—
"Violence shall be no more heard in thy land, waiting
nor defraction within thy border; but thou shalt call
thy walls salvation, and thy gates praise." (If. lx. 18.)

Without entering more minutely on the prophecy
already quoted from chap. xx. of the book of the Rele-
vation, it is sufficient to observe, that Dr Whitby, in
his treatise on the millennium at the end of his com-
mentary endeavours to prove, from the spirit of the
passage and the similarity of the expressions with
those of other prophets, that it refers to a state of
the church for a thousand years, which shall be like life
from the dead. The commencement of this period
is connected with two events; the fall of antichrift,
and the conversion of the Jews. The latter of these
events he considers as a key to all the prophecies
concerning the millennium. As the Jews were the
ancient people of God, and as their conversion is to
be the previous step to the general knowledge of Chris-
tianity, the prophecies of the millennium have a chief
relation to this important event. We have already ob-
erved, that God never interposes with miraculous
power to produce what can be effected by natural
means; and from what we know of human nature, we
cannot but perceive that the conversion of the Jews
will powerfully operate to the general conversion of
mankind. Freed from those prejudices which now
make them the objects of hatred in all nations, and
fired with that zeal by which new converts are always
actuated, they will preach the gospel with a fervour
of which we, who have long been blessed with its rays,
can hardly form a conception; and, by their present
dispersion over the whole earth, they will be enabled
to adapt their instructions to every individual of the
human
MILLEPS, or WOOD-LOUSE, in zoology; a species of Oniscus. These insects are found in cellars, under fences, and in cold moist places; in the warmer countries they are rarely met with. Millepedes have a faint disagreeable smell, and a somewhat pungent, sweetish, nauseous taste. They have been highly celebrated in suppers of urine, in all kinds of obstructions of the bowels, in the jaundice, weakness of sight, and variety of disorders. Whether they have any just title to these virtues is greatly to be doubted; thus much is certain, that their real effects come far short of the character usually given them.

MILLEPORA, in natural history, a name by which Linnaeus distinguishes that genus of lithophytes, of a hard structure and full of holes, which are not flat or radiated, and whose animal is the hydra, in which it differs from the madrepore, and comprehending 14 different species.

In the millepora, the animal which forms and inhabits it occupies the substance; and it is observed that the millepora grow upon one another; their little animals produce their spawn; which attaching itself either to the extremity of the body already formed, or underneath it, gives a different form to this production. Hence the various shapes of the millepora, which is composed of an infinite number of the cells of those little insects, which all together exhibit different figures, though each particular cellula has its essential form, and the same dimensions, according to its own species.

MILLET, in botany. See MILLIUM.

MILLIARE, or MILLIARIUM, a Roman mile, which consisted of 1000 paces, mille passus, whence the name.

MILLIARIUM Aureum, was a gilded pillar in the forum of Rome, at which all the highways of Italy met, as one common centre. From this pillar the miles were counted, and at the end of every mile a stone was put down. The military column was erected by Augustus Cæsar, and, as we are informed by travellers, it still be seen.

MILLING of CLOTH. See FULLING.

MILLION, in arithmetic, the sum of ten hundred thousand, or a thousand times a thousand. See ARITHMETIC.

MILLO, a part of mount Zion at its extremity; and therefore called Millo of the city of David (2 Chron. xxxii.), taken in with the wall that encompassed mount Zion. Uncertain whether Beth-Millo, (Judges ix. 20.) denotes a place; if it did, it lay near Sechem.

MILLOT (Claude Francis Xavier), of the French academy, was born at Besançon March 1726, and was for some time Jesuit. He was consecrated for the pulpit, and continued to preach after he left the society: But the weakness of his voice, his timidity, and the awkwardness of his manner, not permitting him to continue in this profession, he relinquished it, although he had preached Advent sermons at Verfailles, and Lent sermons at Luneville. The Marquis de Felino, minister of Parma, instituted an historical clas for the benefit of the young nobility; and, at the desire of M. le Duc de Nivernois, he gave the charge of it to the Abbé Millot. The minister having occasioned a kind of rebellion among the people by some innovations which he had made in the flate, the Abbé continued attached to the interest of his patron, and would not desert him till the storm was blown over.

When he was told that he would lose his place by this conduct, he replied, "My place is with a virtuous perfected man who has been my benefactor; and that I shall never lose." At length, having filled the historical chair with great approbation, he returned to France, and was appointed preceptor to M. le Duc d'Enghien. In this situation he died, A. D. 1785, aged 59. The Abbé Millot did not shine in company; he was cold and reserved in his manner; but every thing he said was judicious, and exactly in point.

D'Alembert said, that of all his acquaintance the Abbé Millet had the fewest prejudices and the least pretension. He composed several works, which are digested with great care, and written in a pure, simple, and natural style. The principal are, 1. Éléments de l'Histoire de France, depuis Clovis jusqu'à Louis XIV. 3 vols. In 12mo. The author, feeling the most curious and important facts, has suppressed every thing foreign to the subject; and has not only arranged the materials in their proper order, but chosen them with the greatest judgment. Querlon thought this the best abridgment which we have of the history of France, and preferred it to that of the President Renaut. 2. Éléments de l'Histoire d'Angleterre, depuis son origine jusque à Louis X. 3 vols. In 12mo. In this valuable abridgment, the author satisfies, without tiring, his readers. It is all that is necessary for those who wish to gain a general knowledge of the English history, without entering minutely into its particular parts.

A certain critic maintains, that this work is merely a counterfeit of Voltaire's general history. But this censure is altogether unjust. The ancient history in this work is wholly composed by the Abbé Millet; and, no less than the modern part, discovers his abilities in the choice of facts, in divesting them of useless circumstances, in relating them without prejudice, and in adorning them with judicious reflections.
attended by his wife and a numerous retinue of gladiators and servants, he met on the Appian road his enemy Clodius, who was returning to Rome with three of his friends and some domestics completely armed.— A quarrel arose between the servants. Milo supported his attendants, and the dispute became general. Clodius received many severe wounds, and was obliged to retire to a neighbouring cottage. Milo pursued his enemy in his retreat, and ordered his servants to dispatch him. The body of the murdered tribune was carried to Rome, and exposed to public view. The enemies of Milo inveighed bitterly against the violence and barbarity with which the faced peron of a tribune had been treated. Cicero undertook the defence of Milo; but the continual clamours of the friends of Clodius, and the flight of an armed soldiery, which surrounded the seat of judgment, so terrified the orator, that he forgot the greatest part of his arguments, and the defence he made was weak and indiscriminate.— Milo was condemned, and banished to Mafilia. Cicero soon after sent his exiled friend a copy of the oration which he had prepared for his defence, in the form in which we have it now; and Milo, after he had read it, exclaimed, O Cicero, how I wish spoken before my accusers in these terms, Milo could not be now eating figs at Marsilles. The friendship and cordiality of Cicero and Milo were the fruits of long intimacy and familiar intercourse. It was to the successful labours of Milo that the orator was recalled from banishment, and restored to his friends.

MILIO, (anciently Melos), an island in the Archipelago, about 50 miles in circumference, with a harbour, which is one of the largest in the Mediterranean. The principal town is of the same name as the island, and was prettily built, but abominably nasty: the houses are two stories high, with flat roofs; and are built with a fort of pumic-Rome, which is hard, blackish, and yet very light.

This island was formerly rich and populous. From the earliest times of antiquity it enjoyed pure liberty. The Athenians, not being able to purchase the Melians to declare in their favour in the Peloponnesian war, made a descent upon the island, and attacked them vigorously. In two different expeditions they failed of their purpose; but returning with more numerous forces, they laid siege to Melos; and, obliging the besieged to surrender at discretion, put to the sword all the men who were able to bear arms. They spared only the women and children, and these they carried into captivity. This act of cruelty put humanity to the blush, and disgraced the Athenian name. But war was then carried on with a degree of wild rage, unexampled in the present times. That republic knew not how to pardon, and always carried its vengeance to an extravagant height. When Lyander, the Lacedemonian general, came to give law to the Athenians, he expelled the colony which they had lent to Melos, and re-established the unfortunate remains of its original inhabitants.

This island left its liberty when Rome, aspiring to the empire of the world, conquered all the isles of the Archipelago. In the partition of the empire, it fell to the share of the eastern emperors, was governed by particular dukes, and was at last conquered by Solomon II. Since that period, it has groaned under the
yoke of Turkish depotisim, and has left its opulence and splendor. At the commencement of the present century, it boasted of 17 churches, and 11 chapels, and contained more than 20,000 inhabitants. It was very fertile in corn, wine and fruits; and the whole space from the town to the harbour, which is nearly two miles, was laid out in beautiful gardens. M. Tournafort, who visited it in the year 1700, gives a fine description of it. The earth, being constantly warmed by subterraneous fires, produced almost without interruption plenteous crops of corn, barley, cotton, exquisite wines, and delicious melons. St Elias, the finest monastery in the island, and situated on the most elevated spot, is encircled with orange, citron, cedar, and fig trees. Its gardens are watered by a copious spring. Olive trees, of which there are but few in the other parts of the island, grow in great numbers around this monastery. The adjacent vineyards afford excellent wine. In a word, all the productions of the island are the very best of their kinds; its patridges, quails, kids, and lambs, are highly valued, and may yet be bought at a very cheap price.”

Were M. Tournefort to return to Milo, M. Savary assures us, he would no longer see the fine island which he has described. “He might still see alum, in the form of feathers, and fringed with silver thread, hanging from the arches of the caverns; pieces of pure sulphur filling the cliffs of the rocks; a variety of mineral springs; hot baths, (though these are now only a few of small dirty caves); the same subterraneous fires which in his days warmed the bottom of the earth, and were the cause of its extraordinary fertility: but instead of 5000 Greeks, all paying the capitation tax (5), he would now find no more than about 700 inhabitants on an island 18 leagues in circumference. He would fight to behold the finest lands lying uncultivated, and the most fertile valleys converted into morasses; of the gardens scarcely a vestige left; three-fourths of the town in ruins, and the inhabitants daily decreasing. In short, during the last 50 years, Milos has assumed a quite different appearance. The plague, which the Turks propagate everywhere, has cut off one part of its inhabitants; the injudicious administration of the Porte, and the oppressive extortions of the Captain Pacha, have destroyed the rest. At present, for want of hands, they cannot cut out a free channel for their waters, which flagrate in the valleys, corrupt, and infect the air with their putrid exhalations. The salt marishes, of which there are numbers in the island, being equally neglected, produce the same effect. Add to these inconveniences, those sulphurous exhalations which abound all over the island, and by which the inhabitants of Milos are afflicted with dangerous fevers during three-fourths of the year. Perhaps they may be obliged to forsake their country. Every countenance is yellow, paler, and livid; and none bears any mark of good health. The prudent traveller will be careful to spend but a very short time in this unwholesome country, unless he chooses to expose himself to the danger of catching a fever.

To sleep over-night, or to spend but one day in the island, is often enough to occasion his being attacked with that distemper.

“Yet (continues our author) a judicious and enlightened government might expel those evils which ravage Milos. Its first care would be to establish a lazaretto, and to prohibit vessels whose crews or cargoes are infected with the plague from landing. Canals might next be cut, to drain the marishes, whose exhalations are so pernicious. The island would then be re-peopled. The sulphurous vapours are not the most noxious. These prevailed equally in ancient times, yet the island was then very populous. M. Tournafort, who travelled through it at a time less distant from the period when it was conquered by the Turks, and when they had not yet had time to lay it waste, reckons the number of its inhabitants (as we have said) at about 20,000. The depopulation of Milos is therefore to be ascribed to the depopulation of the Porte, and its detestable police.”

The women of Milo once so celebrated for their beauty, are now fallow, unhealthful, and disgracefully ugly; and render themselves still more hideous by their drees, which is a kind of loose jacket, with a white coat and petticoat, that scarcely covers two-thirds of their thighs, barely meeting the stocking above the knee. Their hind hair hangs down the back in a number of plaits; that on the fore part of the head is combed down each side of the face, and terminated by a small stuff curl, which is even with the lower part of the cheek. All the inhabitants are Greeks, for the Turks are not fond of trusting themselves in the small islands; but every summer the captain bahaw goes round with a squadron to keep them in subjection, and to collect the revenue. When the Russians made themselves masters of the Archipelago during the late war, many of the islands declared in their favour; but being abandoned by the peace, they were so fearfully mulcted by the Grand Signior, that they have professed a determination to remain perfectly quiet in future. As the Turks, however do not think them worth a garrison, and will not trust them with arms and ammunition, all those which the Russians may choose to invade will be obliged to submit. The two points which form the entrance of the harbour, crouching each other, render it imperceptible until you are close to it. Thus, while you are perfectly secure within it, you find great difficulty in getting out, particularly in a northerly wind; and as no trade is carried on except a little in corn and salt, Milos would fearfully ever be visited, were it not that, being the first island which one makes in the Archipelago, the pilots have chosen it for their residence. They live in a little town on the top of a high rock, which, from its situation and appearance, is called the castle. Patridges still abound in this island; and are so cheap, that you may buy one for a charge of powder only. The peasants get them by standing behind a portable screen, with a small aperture in the centre, in which they place the muzzle of their piece, and then draw the

(a) Grown up men are the only persons who pay the capitation tax. Therefore, by adding to the number of 5000 who paid the tax, the women, boys, and girls, we find that Milos, in the days of Tournefort, contained at least 20,000 souls.
the partridges by a call. When a sufficient number are collected, they fire among them, and generally kill from four to seven at a shot: but even this method of getting them is so expensive, from the scarcity of ammunition, that the people can never afford to shoot them, except when they are gentlemen in the island, from whom they can beg a little powder and shot.

Milo is 60 miles north of Candia; and the town is situated in E. Long. 25. 15. N. Lat. 36. 27.

MILSTONE. See MILL-STONE.

MILT; in anatomy, a popular name for the SPLEEN.

Milt, or Mel, in natural history, the soft ree in fishes; thus called from its yielding, by expression, a whitish juice resembling milk. See Roe.

The milt is properly the seed or spermatic part of the male fish. The milt of a carp is reckoned a choice bit. It consists of two long whitish irregular bodies, each included in a very thin fine membrane. M. Petit considers them as the testicles of the fish wherein the seed is preserved; the lower part, next the anus, he takes for the vesicula seminalis.

MILTHORPE, a port-town of Westmoreland, at the mouth of the Can, five miles from Kendal. It is the only sea-port in the county; and goods are brought thither in small vessels from Grange in Lancashire. Here are two paper-mills. It has a market on Friday, and a fair on Old May-day; and there is a good stone-bridge over the river Betha, which runs through the town.

MILTIADES, an Athenian captain, son of Cypselus. He obtained a victory in a chariot race at the Olympic games. He led a colony of Athenians to the Cheroneus. The causes of this appointment are striking and singular. The Thracian Dolonci, harassed by a long war with the Abshynians, were directed by the oracle of Delphi to take for their king the first man they met in their return home, who invited them to come under his roof and partake his entertainments. This was Miltiades, whom the appearance of the Dolonci, with their strange arms and garments, had struck. He invited them to his house, and was made acquainted with the commands of the oracle. He obeyed; and when the oracle of Delphi had approved a second time the choice of the Dolonci, he departed for the Cheroneus, and was invited by the inhabitants with sovereign power. The first measures he took was to stop the further incursions of the Abshynians, by building a strong wall across the Ithmus. When he had established himself at home, and fortified his dominions against foreign invasion, he turned his arms against Lamppacus. His expedition was unsuccessful; he was taken in an ambush, and made prisoner. His Friend Cretus king of Lydia was informed of his captivity, and procured his release. He lived few years after he had recovered his liberty. As he had no issue, he left his kingdom and possessions to Stefagoras the son of Cimon, who was his brother by the same mother. The memory of Miltiades was greatly honoured by the Dolonci, and they regularly celebrated festivities and exhibited shows in commemoration of a man to whom they owed their greatness and preservation.

MILTIADES, the son of Cimon, and brother of Stefagoras mentioned in the preceding article, was some time after the death of the latter, who died without issue, sent by the Athenians with one ship to take possession of the Cheroneus. At his arrival Miltiades appeared mournful, as if lamenting the recent death of his brother. The principal inhabitants of the country visited the new governor to console with him; but their confidence in his sincerity proved fatal to them. Miltiades seized their persons, and made himself absolute in Cheroneus. To strengthen himself, he married Hgegypyla, the daughter of Olorus the king of the Thracians. His triumph was short. In the third year of his government, his dominions were threatened by an invasion of the Scythian Nomades, whom Darius had some time before irritated by entering their country. He fled before them; but as their hostilities were of short duration, he was soon restored to his kingdom. Three years after, he left Cheroneus; and set sail for Athens, where he was received with great applause. He was present at the celebrated battle of MARATHON; in which all the chief officers ceded their power to him, and left the event of the battle to depend upon his superior abilities. He obtained an important victory over the more numerous forces of his adversaries. Some time after, Miltiades was intrusted with a fleet of 70 ships, and ordered to punish those islands which had revolted to the Persians. He was successful at first; but a sudden report that the Persian fleet was coming to attack him, changed his operations as he was besieging Paros. He raised the siege, and returned to Athens.

He was accused of treason, and particularly of holding correspondence with the enemy. The falsity of these accusations might have appeared, if Miltiades had been able to come into the assembly. But a wound which he had received before Paros detained him at home, and his enemies, taking advantage of his absence, became more eager in their accusations, and louder in their clamours. He was condemned to death; but the rigor of his sentence was softened on the recollection of his great services to the Athenians, and he was put into prison till he had paid a fine of 50 talents to the state. His inability to discharge so great a sum detained him in confinement; and his wounds becoming incurable, he died a prisoner about 489 years before the Christian era. His body was interred by his son Cimon, who was obliged to borrow and pay the 50 talents, to give his father a decent burial.—The accusations against Miltiades were probably the more readily believed by his countrymen, when they remembered how he made himself absolute in Cheroneus; and in condemning the barbarity of the Athenians towards a general, who was the source of their military prosperity, we must remember the jealousy which ever reigns among a free and independent people, and how watchful they are in defence of the natural rights which they fear wrested from others by violence. Cornelius Nepos has written the life of Miltiades the son of Cimon; but his history is incongruous and unintelligible, from his confounding the actions of the son of Cimon with those of the son of Cypselus. Greater reliance is to be placed on the narration of Herodotus, whose veracity is confirmed, and who was indisputably better informed and more capable of giving an account of
Milton.

THE LIFE AND EXPLOITS OF MEN WHO FLOURISHED IN THEIR AGE, AND OF WHICH THEY LEFT THE LIVING MONUMENTS.

Hegesippus was born about six years after the famous battle of Marathon; and C. Nepos, as a writer of the Augustan age, flourished about 450 years after the age of the father of history.

MILTON (John,) the most illustrious of the English poets, was descended of a genteel family, seated at a place of their own name, viz. Milton, in Oxfordshire. He was born December 9, 1608, and received his first rudiments of education under the care of his parents, assisted by a private tutor. He afterwards professed some time at St Paul's School, London; in which city his father had settled, being engaged in the business of a scrivener. At the age of 17, he was sent to Chirill's college, Cambridge, where he made a great progress in all parts of academical learning; but his chief delight was in poetry. In 1628, he proceeded to St. John's College, Cambridge, both of which performances spread his fame over all Europe. He now dwelt in a pleasant house, with a garden, in Petty France, Westminster, opening into St James's Park. In 1632, he buried his wife, who died not long after the delivery of her fourth child; and about the same time he also lost his eye-sight, by a gouty fever, which had been growing upon him many years.

Cromwell took the reins of government into his own hands in the year 1653; but Milton still held his office. His leisure-hours he employed in prosecuting his studies; whereof he was so far from being discouraged by the loss of his sight, that he even conceived hopes this misfortune would add new vigour to his genius; which, in fact, seems to have been the case. Thus animated, he again ventured upon matrimony; his second lady was the daughter of Captain Woodlock of Hackney; she died in childbirth about a year after. On the deposition of the protector, Richard Cromwell, and on the return of the long parliament, Milton being still continued secretary, he appeared again in print; pleading for a further reformation of the laws relating to religion; and, during the anarchy that ensued, he drew up several schemes for re-estabishing the commonwealth, exerting all his faculties to prevent the return of Charles II. England's destiny, however, and Charles's good fortune, prevailing, our author chose to consult his safety, and retired to a friend's house in Bartholomew-Closet. A particular prosecution was intended against him; but the just clemency to which his admirable genius and extraordinary accomplishments entitled him, had raised him to so many friends, even among those of the opposite party, that he was included in the general amnesty.

This form over, he married a third wife, Elizabeth, daughter of Mr. Minshull, a Cheshire gentleman; and was now established in the house of a gentleman, who did not wish for his removal, and who lived in the same house. He was now taken into the service of the commonwealth, and made Latin secretary to the council of state, which resolved neither to write to others abroad, nor to receive any answer, except in the Latin tongue, which was common to them all. The famous Bona Dei, coming out about the same time, our author, by command, wrote and published his Les Moeurs de la Fille de France. "A Defence of the People of England, in answer to Salmantius's Defence of the King," which performance spread his fame over all Europe. He now dwelt in a pleasant house, with a garden, in Petty France, Westminster, opening into St James's Park. In 1652, he buried his wife, who died not long after the delivery of her fourth child; and about the same time he also lost his eye-sight, by a gouty fever, which had been growing upon him many years.
MILTON, or Milton, in Dorsetshire, south-west of Blandford, near the road to Dorchester, 114 miles from London. It is chiefly noted for its abbey, built by king Athelstan. The church stands near the south side of the abbey. It is a large and magnificent pile of Gothic architecture, and contains several ancient monuments. Here is an alms-house for six people, who have 12s. a week, and three yards of cloth for a gown, one pair of shoes and stockings, and 10s. each on St Thomas’s day yearly. Here is a free-school, and a market on Tuesdays.

MILTON, in Kent, near Sington and the Isle of Sheppey, 6 miles north-west of Feverham, and 40 from London. It is also called Middle ton from its situation near the middle of the county, i.e. from Deptford to the Downs. The kings of Kent had a palace here, which was cattellated, and stood below the church; but was burnt down in Edward the Confessor’s time by Earl Godwin, &c. Its church stands near a mile off. On approaching the town up the Thames, by the East-Swale, it seems hid among the creeks; yet it is a large town; and has a considerable market on Saturdays, and a fair on July 24. The oyster taken hereabouts are the most famous of any in Kent. This town is governed by a portreeve, chosen yearly on St James’s-day, who supervises the weights and measures all over the hundred of Milton.

MILTON, in Kent, a mile on the east side of Grave ford, was incorporated with it in the reign of Queen Elizabeth by the name of the portreeve, jurats, and Habitants of the towns of Graveford and Milton. King Henry VIII. raised a platform or block-house here, for the defence both of this town and Grave ford, and the command of the river. It has a fair Jan. 25.

MILVIUS MOLVIUS, or MULVIUS, Pont; a bridge on the Tiber, built by Emilius Scaurus the censor, in the time of Sylla, at two miles distance from the city, on the Via Flaminia, and repaired by Augustus. From this bridge the ambassadors of the Allobroges were brought back to Rome, by Cicero’s management, and made a discovery of Catilina’s conspiracy (Sallust). Near it Maxentius was defeated by Constantine (Eutropius). Now called Ponte Molli.

MILVIUS, in ornithology, a species of Falco. MIMES, in the ancient comedy, were buffoons or mimics, who entertained the people by taking off certain characters, using such gestures as suited the persons or subjects they represented. There were on the Roman stage female performers of this kind called mimina. The word is derived from mimes, I imitate. Some of the mimia added their parts to the found of the share they called mimina. MIMES were also a kind of farces or ludicrous comedies, generally performed by one person. They had no acts, nor any exordium. The mimia were introduced upon the Roman stage long after comedy and tragedy had arrived at their full perfection. The actor wore no mask, but smeared his face with foot, was drest in lambkin, wore garlands of ivy, and carried a basket of flowers and herbs, in honour of Bacchus, and diverted the audience with apith tricks and ridiculous dances. This was the flute of the mimia soon after their first introduction; but they underwent many alterations, which it would take up too much room to relate, and which are not of sufficient importance to justify a detailed account. See Pantomimes.

MIMESIS, in rhetoric, the imitating the voice and gestures of another person.

MIMNERMUS, an ancient poet and musician, flourished about the beginning of the 6th century B.C. He was of Smyrna, and contemporary with Solon. Athenaeus gives him the invention of pentameter verse. His elegies, of which only a few fragments are preserved, were so much admired in antiquity, that Horace preferred them to those of Callimachus. He composed a poem of this kind, as we learn from Pausanias, upon the battle fought between the people of Smyrna, and the Lydians, under Gyges. He likewise was author of a poem in elegiac verse, quoted by Strabo, which he entitled Nannus, and in which we may suppose he chiefly celebrated a young and beautiful girl of that name, who, according to Athenaeus, was a player on the flute, with whom he was enamoured in his old age. With respect to love matters, according to Propertius, his verses were more valuable than all the writings of Homer.

Plus in amore vult Mimmermi veris Homero.

Lib. i. Eleg. 9. v. 11.

And Horace bears testimony to his abilities, in describing that seducing passion:

Si Mimmermi uti cenfet, sine amore jouctque

Nil est juicandum, vivas in amore joyctque.

Ep. VI. Lib. i. v. 63.
It, as with Mimnermus said,
Life unbless'd with love and joy
Ranks us with the senseless dead,
Let these gifts each hour employ.

Alluding to some much admired lines of this Greek poet, which have been preferred by Stobæus.

Mimosa, the sensitive plant: A genus of the polygamy order, belonging to the monoecea class of plants; and in the natural method ranking under the 33d order, Leguminosae. The hermaphrodite calyx is quinquedentate; the corolla quinquefid; there are five stamens; the ovary is sessile; the fructification is a pinnate legume, with various kinds of seeds; the leaves are of the shrub and tree kind, and are of warm climates.

The very rapidly affected, and in some sorts the footstalks and all are affected, so as instantly to fall downward as if fastened by hinges, which last are called humble sentitives. They have all winged leaves, each wing consisting of many small pinnae.

In the System Vegetabilium, this genus, including the mimosa properly so called, and the acacias, is divided into several sections, distinguished by the figure, situation, and arrangement, of the leaves; as simple, pinnated, bigeminous and tergeminous, conjugate and pinnated, double pinnated. The following are the most remarkable species, with their properties. 1. The Senfitive, or common sensitive humble plant, rises with an underhairy, declinated, prickly stem; branching two or three feet around, armed with hairy spines; pinnated, digitated leaves, each leaf being of five or more long foliages, attached by their base to a long footstalk, and spread out above like the fingers of a hand; and at the sides and ends of the branches roundish heads of greenish white flowers, succeeded by small jointed prickly pods.—This is truly of the humble sensitive kind: for by the leaf touch the leaves instantly recede, contract, close, and together with the footstalk quickly decline downward, as if ashamed at the approach of the hand.

3. The Pernambucanæ, or Pernambuca fputful mimosa, has unshrubby, procumbent, unarmed stems, branching two or three feet around; bipinnated leaves, of three or four pair of short, winged foliages; and at the axillas drooping spikes of pentandrous flowers, the lower ones calbruated.—This species recedes very slowly from the touch, only contracting its pinna a little when smartly touched; hence the name filoful mimosa.

4. The Ageratæ, or Panama sensitive plant. Of this curious species, which has been well described by Dr Browne (but not figured), there is a good figure in the Raritæ Floræ Americæ published by Sir Joseph Banks. It grows in moist places, and by the sides of rivulets, in the parishes of St. James and Hanover, Jamaica. It seldom rises above three feet in height; but its slender branches extend considerably on the neighbouring bushes. It is armed with crooked, sharp, spines, so thickly set on the trunk, branches, and leaves, that there is no touching it with futility. But the plant has a beautiful appearance; the flowers are yellow and globular, growing at the extremity of the branches. The pods are hairy, brown, and jointed; each containing a small, flat, and brown seed. The leaves are numerous, small, and winged: next to those of the mimosa pudica, they are the most irritable; contracting with the leaf touch, and remaining so for several minutes after. This species would form a good hedge or fence around a garden, and by being trimmed now and then by a gardener's pruners, may be easily kept from spreading.

5. The Punctata, or punctated sensitive mimosa, rises with a shrubby, upright, taper, spotted, unarmed stem, branching erectly five or six feet high; bipinnated leaves, of four or five pair of long winged foliages, having each about 20 pair of pinnae; and at the axillas and termination of the branches oblong spikes of yellowish deciduous flowers, the inferior ones calbruated; succeeded above by oblong feed-pods. This sort, though naturally shrubby and perennial in its native soil, yet in this country it sometimes decays in winter. It is only sensitive in the foliola, but quick in the motion.

6. The Visa, lively mimosa, or small leaf sensitive weed, has many creeping roots, and spreads itself to cover large spots of ground. It rises at most to two inches, has winged leaves, with numerous small pinnae. The flower is globular, of a bluish colour, and grows in clusters from the axilla: these are followed by little short, hairy, pods, containing smooth shining seeds. This is the most sensible of all the mimofas, the pudica not excepted. By running a stick over the plant, a person may write his name, and it will remain visible for ten minutes.

7. The Quadrivalvæ, perennial, or quadrivalve humble mimosa.
11. The *Arborea*, or wild tamarind tree, is common in all the woodlands, and especially near where settlements have been made, in Jamaica. It rises to a considerable height, and is proportionally thick. The timber is excellent, and serves many purposes in rural economy: it is of the colour of cedar, pretty hard and takes a good polish. The leaves are numerous; the flowers globular and white. The pods are about a foot in length, of a fine scarlet colour: when they are ripe they open and become twived. The seeds then appear; they are oblong, smooth, of a shining black, and quite soft. On the whole, from the leaves, flowers, and pods, this tree exhibits a singular and beautiful contrast. With us this plant is raised in hot-houses; but it appears, that with a little pains it may be made to grow in the open air. A good, small tree of this sort grew in the garden of the late Dr William Pictairn, at Hilfington, near London.

12. The *Laifolia*, shag-bark, or white wild tamarind. This excellent timber tree is very common in Jamaica, and rises to a moderate height and good thickness. The trunk is rough and scaly: the leaves are numerous, of a rhomboid figure, and yellowish and green colour. The flower-spikes are from the axille; their colour is yellow. The seed-vessels are flat, jointed, and twived. The seeds are of the bigness of a vetch, white, and finely streaked with blue.

13. The *Lebœus* or ebony tree. This is a native of the East Indies but raised from seeds in Jamaica and St Vincent's. It is figured, though not accurately, by Plukenet, Tab. 331. fig. 1. To what height this tree grows, we cannot yet say: but it must be of a considerable thickness if it be the ebony we have in ufe here. Time will soon determine this, as the few plants in the islands are reared with great care by Dr Dancer in Jamaica and Mr Alexander Anderson in St Vincent's.

14. 15. The *Cinerea a*; & *Pinnata* Caliaw bushes. These species are common about Kingston and Spa-fig. 4, in both Jamaica and rife by blender trunks to about 20 feet. Dr Roxburgh of Madras, amongst a number of useful discoveries, has found the lac in Torn on this subject. 

16. The *Scardens*, caconos, or maroooyh witch (Gigalosium fandens, Brown's Jam. p. 362. Paphosus maximus perennis, Sloane's Cat. 68. Perin Kaku-valli, H. M. vii. 3. & see 3. 4.) This species of mimosa is frequent in all the upland valleys and woodlands on the north side of Jamaica. It climbs up the tallest trees, and spreeds itself in every direction by means of its cirris or claspers, so as to form a complete arbour, and to cover the space of an English acre from one root. This circumstance has a bad effect on the trees or bushes to shed. Light, air, and rain (so necessary for all plants), being shut out, the leaves drop off, the tree gradually rots, and the limbs fall down by the weight of this parasite.

Several authors have mentioned the cacon; but their descriptions of the plant, and particularly the figures, are erroneous. On that account we have given a figure from the herbarium of a gentleman long resident in Jamaica: and the following are the characters, fig. 3, transcribed from his field notes.

The roots of this plant run superficially under the ground or herbage. The trunk is seldom thicker than a man's thumb, and sends off many branches, with numerous shining green leaves, each of which terminates in a tendril or clawer, that serves to fasten it to trees or bushes. The flower-spikes are from the axil: they are slender, and the florets on them small and numerous. The pod is perhaps the largest and longest of any other in the world; being sometimes eight or nine feet in length, five inches broad, jointed, and containing 10 or 15 seeds. These seeds are brown, shining, flattened, and very hard, and called cardoon. They are the same mentioned in the Philosophical Transactions, No. 222, page 296, by Sir Hans Sloane, as being thrown ashore on the Hebrides and Orkneys. This happens in the following manner: The seeds or beans fall into the eastward till they fall into the gulf stream, which forces them northward along the coast of America and the Bahama islands. As the winds blow frequent and strong from America, these seeds are driven to the eastward, till at length they are thrown ashore and left with the tide as aforesaid.

This bean, after being long soaked in water, is boiled and eaten by some negroes; but, in general, there seems to be no other use made of it than as a sort of snuff-box.

17. The Catechu, according to Mr Ker, grows only to 12 feet in height, and to one foot in diameter; it is covered with a thick rough brown bark, and towards the top divides into many close branches: the leaves are bipinnated, or doubly winged, and are placed alternately upon the younger branches: the partial pinnae are nearly two inches long, and are commonly from 15 to 30 pairs; having small glands inserted between the pinnae: each wing is usually furnished with about 40 pairs of pinnule or linear lobes, beft with short hairs: the spines are short, recurved, and placed in pairs at the bases of each leaf: the flowers are hermaphrodite and male, and stand in clove spikes, which arise from the axil of the leaves, and are about four or five inches long: the calyx is tubular, hairy, and divides at the limb into five ovate pointed segments: the corolla is monopetalous, white, and of the same form as the calyx, but twice its length: the filaments are numerous, capillary, double the length of the corolla, adhering at the base of the germ, and crowned with roundish anthers: the germ is ovate, and supports a slender style, which is of the length of the filaments, and terminated by a simple stigma: the fruit, or pod, is lance-shaped, brown, smooth, compressed, with an undulated thin margin; it contains six or eight roundish flattened seeds which produce a nauseous odour when chewed. From this tree, which grows plentifully on the mountains in India, where it flowers in June, is produced the official drug long known in Europe by the name of terra japonica; for the history and preparation of which, see the article Terra japonica.

18. The Niloticus, or true Egyptian acacia, rises to a greater height than the preceding: the bark of the trunk is smooth, and of a grey colour; that of the branches has commonly a purplish tinge: the leaves are bipinnated, and placed alternately: the partial pinnae are opposite, furnished with a small gland between the outermost pair, and beft with numerous pairs of narrow elliptical pinnule, or leaflets: the spines are long, white, spreading, and proceed from each side of the base of the leaves: the flowers are hermaphrodite and male: they assume a globular shape, and stand four or five together upon slender peduncles, which arise from the axil of the leaves: the calyx is small, bell-shaped, and divided at the mouth into five minute teeth: the corolla consists of five narrow yellowish segments: the filaments are numerous, capillary, and furnished with roundish yellow antherae: the germ is conical, and supports a slender style, crowned with a simple stigma: the fruit is a long pod, resembling that of the lupin, and contains many flatish, brown seeds. It is a native of Arabia and Egypt, and flowers in the rivers, and by the sea.

Although the mimosa nilotica grows in great abundance over the vast extent of Africa, yet gum arabic is produced chiefly by those trees, which are situated near the equatorial regions; and we are told, that in Lower Egypt the solar heat is never sufficiently intense for this purpose. The gum exudes in a liquid from the bark of the trunk and branches of the tree, in a similar manner to the gum which is often produced upon the cherry-trees &c. in this country; and by exposure to the air it soon acquires solidity and hardness. In Senegal the gum begins to flow when the tree first opens its flowers; and continues during the rainy season till the month of December, when it is collected for the first time. Another collection of the gum is made in the month of March, from incisions in the bark, which the extreme dryness of the air at that time is said to render necessary. Gum arabic is now usually imported into England from Barbary; not packed up in skins, which was the practice in Egypt and Arabia, but in large casks or hogheads. The common appearance of this gum is well known; and the various figures which it assumes seem to depend upon a variety of accidental circumstances attending its transudation and concretion. Gum Arabic of a pale yellowish colour is most esteemed; on the contrary, those pieces which are large, rough, of a roundish figure, and of a brownish or reddish hue, are found to be less pure, and are said to be produced from a different species of mimosa (M. Senegal); but the Arabian and Egyptian gum is commonly intermixed with pieces of this kind, similar to that which comes from the coast of Africa near the river Senegal.

Gum-arabic does not admit of solution by spirit or oil, but in twice its quantity of water it dissolves into a mucilaginous fluid, of the complexion of a thick syrup; and in this state answers many useful pharmaceutical purposes; by rendering oily, refractive, and pungent substances, miscible with water. The glutinous quality of gum-arabic is preferred to most other gums and mucilaginous substances; as a demulcent in coughs, hoarseness, and other catarrhal affections, in order to obtund irritating acrimonious humours, and to supply the loss of abraded mucus. It has been very generally employed in decoctions of ardent urine and stranguary;

R. Scott & S. Wardice
MINAGNHINIM, a pulifilable instrument of music, among the Hebrews, which was a square table of wood, fitted with a handle; over this table was stretched an iron chain, or hempen cord, passing thro’ balls of wood or brass, which struck against the table when the instrument was struck, and occasioned a clear sound, which might be heard at a great distance. See Kircher’s figure of it in Plate CCCXIV.

MINCHA, in the Jewish customs, offerings of meal, cakes, or biscuits, made in the temple of the Lord. The Seventy have sometimes preferred this word in their translation; but instead of mincha they read mana, which doublets was the received pronunciation in their time. We find mana in the same sense, in Baruch i. 10. Levit. ii. 3. &c. See the Greek of Jerem. xvii. 26. Dan. ii. 46. 2 Kings viii. 5, 9, xvii. 2. xx. 12. 2 Chron. vii. 7. Nehem. xiii. 5, 9, &c.

MINCHING-HAMPTON, a town of Gloucestershire, 20 miles from Bath and Bristol, and near 90 from London, with a market on Tuesdays, and two fairs. The parifh is pretty large, being bounded or hempen, cord, passing thro’ balls of wood or brass, which struck against the table when the instrument was struck, and occasioned a clear sound, which might be heard at a great distance. See Kircher’s figure of it in Plate CCCXIV.

MIN [58]

MINDELHEIM, a district of Germany, in Suabia, lying between the bishopric of Augsburg and the abbey of Kempten, which is 20 miles in length and 16 in breadth.

MINDELHEIM, a town of Germany, in the circle of Weftphalia, lies in the circle of Weftphalia, to the north of the circle of Ravenberg, and along each side of the river Wefer. It is about 22 miles square, and Minden and Peterfagen are the principal places. It was formerly a biphopic, but is now secularized; and was ceded to the elector of Brandenburg by the treaty of Weftphalia.

MINDORA, an island of Asia, in the East Indies, and one of the Philippines, 50 miles in circumference, and separated from Luconia by a narrow channel. It is full of mountains, which abound in palm-trees and all sorts of fruits. The inhabitants are idolaters, and pay tribute to the Spaniards to whom this island belongs.

MINE, in natural history, a deep pit under ground, from whence various kinds of minerals are dug out; but the term is more particularly applied to those which yield metals. Where flones only are procured, the appellation of quarries is universally bestowed upon the places from which they are dug out, however deep they may be.

The internal parts of the earth, as far as they have been yet investigated, do not consist of one uniform substance, but of various strata or beds of substances, extremely different in their appearances, specific gravities, and chemical qualities, from one another. Neither are these strata similar to one another either in their nature or appearance in different countries; so that even in the short extent of half a mile, the strata will be found quite different from what they are in another place. As little are they the same either in depth or solidity. Innumerable cracks and fissures, by the miners called lodges, are found in every one of them; but these are so entirely different in size and shape, that it is impossible to form any inferences from their size in one place to that in another. In these, lodges or fissures the metallic ore is met with; and considering the great uncertainty of the dimensions of the lodes, it is evident that the business of mining, which depends on that size, must in like manner be quite uncertain and precarious. Mr Price, in his treatise on the Cornish mines, observes, that "the comparative smallness of the largest fissures to the bulk of the whole earth is really wonderful. In the finest pottery we can make, by a microscopic view, we may discover numerous cracks and fissures, so small as to be imperceptible by any fluid, and impervious to the naked eye."
MIN [39] M IN

necessary and useful as the strata through which they pass. They are the drains that carry off the redundant moisture from the earth; which, but for them, would be too full of fens and bogs for animals to live or plants to thrive on. In these fissures, the several ingredients which form lodes, by the continual pilling of waters, and the menstrua of metals, are brought out of the adjacent strata, collected and conver- 
"nently located in a narrow channel, much to the advantage of those who search for and pursue them; for if metals and minerals were more dispersed, and scattered thinly in the body of the strata, the trouble of finding and getting at them would be endless, and the expense of procuring them exceed the value of the acquisition.

The insides of the fissures are commonly coated over with a hard, crystalline, earthy substance or rind, which very often, in the breaking of hard ore, comes off along with it, and is commonly called the capes or rails of the lode: but Mr Price is of opinion, that the proper walls of the lode are the sides of the fissure itself, and not the coat just mentioned, which is the natural plaster upon those walls, furnished perhaps by the contents of the fissures, or from oozings of the surrounding strata.

The breadth of a lode is easily known by the distance betwixt the two incrusted sides of the stones of ore; and if a lode yields any kind of ore, it is a better sign that the walls be regular and smooth, or at least that one of them be so, than otherwise; but there are not many of these fissures which have regular walls until they have been sunk down some fathoms.

Thus the inner part of the fissure in which the ore lies, is all the way bounded by two walls of stone, which are generally parallel to one another, and include the breadth of the vein or lode. Whatever angle of inclination some fissures make in the solid strata at their beginning, they generally continue to do the same all along. Some are very uncertain in their breadth, as they may be small at their upper part and wide underneath, and vice versa. Their regular breadth, as well as their depth, is subject to great variation; for though a fissure may be many fathoms wide in one particular place, yet a little further would it not perhaps be one inch wide. This excessive variation happens generally in very compact strata, when the vein or fissure is squeezed, as it were, through hard rocks which seem to compress and straiten it. A true vein or fissure, however, is never entirely obliterated, but always shews a string of metallic ore or of a veiny substance; which often serves as a leader for the miners to follow until it sometimes leads them to a large and richly impregnated part. Their length is in a great measure unlimited, though not the space bett fit for yielding metal. The richest flate for copper, according to Mr Price, is from 4o to 8o fathoms deep; for tin, from 2o to 6o; and though a great quantity of either may be raised at 8o or 10o fathoms, yet "the quality (says our author) is often too much decayed and dry for metal."

Mr Price informs us, that the fissures or veins of the Cornish mines extend from east to west; or, more properly, one end of the fissure points west and by north, or east and by south; while the other tends west and by north; thus they frequently pass through a considerable tract of country with very few variations in their directions, unless they are interrupted by some intervening cause.

But, besides this east and west direction, we are to consider what the miners call the underlyng or base- line of the vein or lode; viz. the deflection or deviation of the fissure from its perpendicular line, as it is followed in depth like the slope of the roof of a house, or the descent of the steep side of a hill. This fissure is generally to the north or south; but varies much in different veins, or sometimes in the same vein: for it will frequently slope or underlie a small space in different ways, as it may appear to be forced by hard strata on either side.—Some of the fissures do, not vary much from a perpendicular, while some deviate more than a fathom; that is, for every fathom they descend in perpendicular height, they deviate likewise as much to the south or north. Others differ so much from the perpendicular, that they assume a position almost horizontal; whence they are also called horizontal or flat lodes, and sometimes lode plots. Another kind of these has an irregular position with respect to the rest; widening horizontally for a little way, and then descending perpendicularly almost like flairs, with only a small string or leader to follow after; and thus they alternately vary and yield ore in several flat or horizontal fissures. This, by the Cornish tanners, is called (but in Mr Price's opinion erroneously) a floor or floor; which, properly speaking, is a hole or cavity impregnated with metal, making no continued line of direction or regular walls. Neither does a floor of ore descend to any considerable depth; for underneath it there appears no sign of a vein or fissure, either leading directly down or any other way. This kind of vein is very rare in Britain. The fissures most common in Britain are the perpendicular and inclined, whether their direction be north or south, east or west.

The perpendicular and horizontal fissures (according to our author) probably remain little altered from their first position, when they were formed, at the inundation of the strata immediately after the waters left the land. The perpendicular fissures are found more commonly situated in level ground, at a distance from hills, and from the sea-coast; but, with regard to the latter, we find that the upper and under masses of strata differ in their solidity and other properties.

"Hence, (says our author) it is very plain, that inclined fissures owe their deflection or underlie to some secondary cause, violence, or subduction, of the earth; for though perpendicular fissures are seldom to be seen, yet such as are inclined at very considerable depths, become more and more perpendicular as the more central strata, by reason of the vaft superincumbent weight, do not seem so likely to be driven out of their position as thefe which lie nearer the surface."

The fissures are often met with fractured as well as inclined; the reason of which, in Mr Price's opinion, has been a subduction of the earth from some extraordinary cause. "The original position (says he) must have been horizontal, or parallel to the surface of the earth: but we often find these strata very sensibly declined from that first position; now, some-
times quite reversed, and changed into perpendicular. When we see a wall lean, we immediately conclude that the foundation has given way, according to the angles which the wall makes with the horizon; and when we find the like declination in strata, we may conclude, by parity of reason, that there has been a like failure of what supported them, in proportion to that declination; or that whatever made the strata to fall so much awry, must also cause every thing included in those strata to fall proportionally. Wherever the greatest subsidence is to the north, the top of the strata will point to the north, and of consequence underlie to the south, and wherever the sequence underlie to the south, and in general, where a vein has a bad appearance at first, it will be imprudent to be at much expense with it.

Veins of metal, as has been already observed, are frequently, as it were, so comprised betwixt hard strata, that they are not an inch wide; nevertheless, if they have a string of good ore, it will generally be worth while to pursue them; and they frequently turn out well at last, after they have come into softer ground. In like manner, it is an encouragement to go on, if the branches or leaders of ore enlarge either in width or depth as they are worked; but it is a bad sign if they continue horizontal without inclining downwards; though it is not proper always to discontinue the working of a vein which has an unfavourable aspect at first. Veins of tin are worth working when only three inches wide, provided the ore be good; and copper ores when six inches wide will pay very well for the working. Some of the great mines, however, have very large veins, with a number of other small ones very near each other. There are also veins creffing one another sometimes met with, which are called contras, vulgarly cantours. Sometimes two veins run down into the ground in such a manner that they meet in the direction of their depth; in which case, the same observations apply to them which are applicable to those that meet in a horizontal direction. Sometimes a vein will suddenly disappear without giving any warning, by becoming narrower, or of worse quality; which by the miners is called a flint or leap, and is very common in the mines of Cornwall. In one day’s time they may thus be disappointed in the working of a rich vein of tin, and have no further sign of any thing to work upon: at the fractured extremity of their vein they perceive a body of clay or other matter; and the method of recovering their vein is to drive on their work in the direction of the former part, so that their new work shall make the same angle with the clay that the other part of the vein does. Sometimes they sink a shaft down from the surface; but it is generally a matter of difficulty to recover a vein when thus lost.

The method of discovering mines is a matter of so much difficulty, that it seems surprizing how those who were totally unacquainted with the nature of metals first came to think of digging them out of the earth. According to Lucretius, the discovery was made by the conflagration of certain woods, which melted the veins of metal in the earth beneath them; but this seems to be rather improbable. Aristotle, however, is of the same opinion with Lucretius, and tells us, that some shepherds in Spain, having set fire to the woods, the earth was thus heated to such a degree, that the silver near the surface of it melted and flowed into a mass; and that in a short time the metallic mass was discovered by the rending of the earth in the time of an earthquake: and the same story is told by Strabo, who ascribes the discovery of the mines of Andalusia to this accident. Cadmus is said by some to have been the first who discovered gold; while others ascribe this to Thoas the Thracian, to Mercury the son of Jupiter, or to Piuis king of
of Egypt; where he having left his own country, went into
Egypt, where he was elected king after the death of
Mizraim the son of Ham: and, on account of his dis-
covery, was called the Golden God. Others say, that
Ecalis or Eactus the son of Jupiter, or Sol the son of
Oceanus, was the first discoverer; but Ephesides attri-
butes the discovery not only of gold, but of all other
metals, to Prometheus. The bronzes and copper mines
mines of
Cyprus were first discovered by Cinara the son of
Agryopa; and Hesiod ascribes the discovery of the iron
mines of Crete to the Cretan Daedylus Ideri. The ex-
traction of lead or tin from its ore in the island of
Caffite, according to several ancient authors, was
discovered by Midacritus.—The scripture, however,
avcribes the invention of bronzes and iron, or at least
of the methods of working them, to Tubal Cain before
the flood.

In more modern times, we know that mines have
been frequently discovered by accident; as in sea-cliffs,
among broken craggy rocks, by the washing of the
tides or floods, also by irrigations and torrents of wa-
ter issuing out of hills and mountains, and sometimes
by the wearing of high roads. Mr Price mentions
another way by which mines have been discovered, ea-
by fiery corruptions; which he says, he has heard
from persons whose veracity he is unwilling to
question. "The timbers (says he) generally compare
these effluvia to blazing stars or other whimsical like-
nesses, as their fears or hopes suggest; and search with
uncommon eagerness the ground over which these
jack-a-lanterns have appeared and pointed out. We
have heard but little of these phenomena for many
years; whether it be, that the present age is credu-
lous than the foregoing, or that the ground being
more perforated by innumerable new pits funk every
year, some of which, by the flannary laws, are pre-
vented from being filled up, has given these vapours a
more gradual vent, it is not necessary to enquire as to
the fact itself is not generally believed."

Mines, however, are now most commonly discovered
by investigating the nature of such veins, ores, and
stones, as may seem most likely to turn to account;
but there is a particular sagacity, or habit of judging
from particular signs, which can be acquired only by
long practice. Mines, especially those of copper, may
also be discovered by the harsh and disagreeable taste
of the waters which issue from them; though it is pro-
able that this only happens when the ore lies above
the level of the water which breaks out; for it does
not seem likely that the taste of the ore could afcour,
unless we were to suppose a pond or lake of water
standing above it. The presence of copper in any wa-
ter is easily discovered by immersing in it a bit of po-
Iified iron, which will thus instantly be turned of a
copper colour, by reason of the precipitation of the
metal upon it. A candle, or piece of tallow put into
water of this kind, will in a short time be tinged of a
green colour.

Another and still more remarkable method of dis-
covering mines is said to be by the virgula divinatoria,
or "divining rod;" which, however incredible the flo-
ries related concerning it may be, is still relied on
by some, and among others by Mr Price. It is not
known who was the inventor of this method; but A-
gricola supposes that it took its rise from the magi-
cians, who pretended to discover mines by enchantment.

It is mentioned of it, however, before the 11th
century, since which time it has been frequently used;
and the Copricular Philosophy has even been called
in to account for it. But before we pretend to ac-
count for phenomena so very extraordinary as those
reported of the virgula divinatoria, it is necessary, in
the first place, to determine whether or not they exist.
Mr Price has been already hinted, believes in it,
though he owns that by reason of his constitution of
mind and body he is almost incapable of co-operating
with its influence. The following account, however,
gives from Mr William Cookworthy of Plymouth,
a gentleman of known veracity and great chemical
abilities.

He had the first information concerning this rod
from one Captain Ribeira, who deferted from the
Spanish service in Queen Anne's reign, and became
captain-commandant in the garrison of Plymouth; in
which town he satisfied several intelligent persons of
the virtues of the rod, by many experiments on pieces
of metal hid in the earth, and by an actual discovery
of a copper mine near Oakhampton, which was wrought
for some years. This captain very readily showed the
method of using the rod in general, but would not by
any means discover the secret of distinguishing the dif-
ferent metals by it; though, by a constant attention
to his practice, Mr Cookworthy discovered it. Cap-
tain Ribeira was of opinion, that the only proper rods
for this purpose were those cut from the nut or fruit-
trees; and that the virtue was confined to certain per-
sons, and those comparatively speaking but few:
but Mr Price says that the virtue resides in all per-
sons and in all rods under certain circumstances.
"The rod (says he) is attracted by all the metals, by
coals, limetones, and springs of water, in the follow-
5. Tin; 6. Lead; 7. Coals; 8. Limetone and springs
of water. One method of determining the different
attractions of the rod is this: Stand, holding the rod
with one foot advanced; put a guinea under that
foot, and an halfpenny under the other, and the rod will
be drawn down; shift the pieces of money, and the
rod will be drawn towards the face, or backwards to
the gold, which proves the gold to have the stronger
attraction.

"The rods formerly used were shoots of one year's
growth that grew forked; but it is found, that two
separate shoots tied together with packthread or other
vegetable substance answer rather better than such as
are naturally forked, as the shoots of the latter are
defiled of an equal frize. They are to be tied together
by the greater ends, the small ones being held in the
hands. Hazle rods cut in the winter, such as are ufed
for fishing rods, and kept till they are dry, do bef-
though, where these are not at hand, apple-tree fik-
cers, rods from peach trees, currants, or the oak, though
green, will answer tolerably well."

Our author next proceeds to describe the manner of
holding the rod; of which he gives a figure, as he says
it is difficult to be described. The small ends being
crooked, are to be held in the hands in a position flat
or parallel to the horizon, and the upper part in an
elevation not perpendicular to it, but at an angle of
about 70 degrees. "The rod (says he) being per-

The toe of the right foot is within the femidiameter of the piece of metal or other subj ect of the rod, it will be repelled towards the face, and continue to be so while the foot is kept from touching or being directly over the subj ect; in which case it will be fe n s iti bly and strongly attracted, and be drawn quite down. The rod should be firmly and steadily grasped; for if, when it has begun to be attracted, there be the least imaginable jerk or opposition to its attraction, it will not move any more till the hands are opened, and a fresh grasp taken. The stronger the grasp the livelier the rod moves, provided the grasp be steady and of an equal strength. This observation is very necessary; as the operation of the rod in many hands is defeated purely by a jerk or counteraction: and it is from thence concluded, that there is no real efficacy in the rod, or that the person who holds it wants the virtue: whereas, by a proper attention to this circumstance in using it, five persons in fix have the virtue, as it is called; that is, the nut or fruit-bearing rod will an s wer in their hands. If a rod, or the least piece of one of the nut-bearing or fruit kind, be put under the arm, it will totally destroyed the operation of the virgula divinatoria, in regard to all the subj ects of it, except water, in th ose hands in which the rod naturally operates. If the least animal thread, as filk, or worsted, or hair, be tied round or fixed on the top of the rod, the same subst ances tied round or fixed on the top of the rod, will make it work in those hands, in which without these additions it is not attracted."

Such are the accounts of this extraordinary rod, to which it is probable that few will attent; and we believe the instances of mines having been discovered by it to be but very rare. Another and very ancient mode of discovering mines, less certain than the divining rod, but extremely difficult and precarious, is that called floating; that is, tracing them by loose stones, fragments, or fleot, which may have been separated and carried off to a considerable distance from the ve in, and are found by chance in running waters, on the superficies of the ground, or under the skirts of the mountains, and there found many times both middling fort of stones and small ones also of metal. Then they consider the situation of that place, and whence these stones can tumble, which of necessity must be from higher ground, and follow the track of them up the hill as long as they can find any of them," &c.

"Another way (says Mr Price) of discovering lodes is by working drifts across the country, as we call it, that is, from north to south, and vice versa. I tried the experiment in an adventure under my management, where I drove all open at grafs about two feet in the field, very much like a level to convey water upon a mill wheel: by so doing I was sure of cutting all lodes in my way; and did accordingly discover five cour ses, one of which has produced above 180 tons of copper ore, but the others were never wrought upon. This method of discovering lodes is equally cheap and certain; for 100 fathoms in shallow ground may be driven at 50 s. expense.

In that kind of ground called by our author favible, and which he explains by the phra se tender flanding, he tells us, that "a very effectual, proving, and confquential way is, by driving an adit from the lowest ground, either north or south; whereby there is a certainty to cut all lodes at 50, 30, or 40 fathoms deep, if the level admits of it. In driving adits or levels across, north or south, to unwater mines already found, there are many fresh veins discovered, which frequently prove better than those they were driving to."

After the mine is found, the next thing to be con sidered is, whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its situation, as to wood, water, carriage, healthiness, and the like; and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting.

Particularly the form and situation of the spot should be well considered. A mine must either happen, 1. In a mountain; 2. In a hill; 3. In a valley; or, 4. In a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits or avenues, may be here readily cut, both to drain the water and to form gang-ways for bringing out the lead, &c. In all the four cases, we are to look out for the veins which the rains or other accidental thing may have hid bare; and if such a vein be found, it may be proper to open the mine at that place, especially if the vein prove tolerably large and rich: otherwise the most commodious place for situation is to be chosen for the purpose, viz. neither on a flat, nor on the tops of mountains, but on the sides. The best situation for a mine, is a mountaneous, woody, wholesome spot; of a face easy ascent, and bordering on a navigable river.
The places abounding with mines are generally healthy, as standing high, and every where exposed to the air; yet some places where mines are found prove poisonous, and can upon no account be dug, though ever so rich; the way of examining a suspected place of this kind, is to make experiments upon brutes, by exposing them to the effluvia or exhalations to find the effects.

Devonshire and Cornwall, where there are a great many mines of copper and tin, is a very mountainous country, which gives an opportunity in many places to make adits or subterraneous drains to some valley at a distance, by which to carry off the water from the mine, which otherwise would drown them out from getting the ore. These adits are sometimes carried a mile or two, and dug at a vast expense, as from 2000 l. to 4000 l. especially where the ground is rocky; and yet they find this cheaper than to draw up the water out of the mine quite to the top, when the water runs in plenty and the mine is deep. Sometimes, indeed, they cannot find a level near enough to which an adit may be carried from the very bottom of the mine; yet they find it worth while to make an adit at half the height to which the water is to be raised, thereby saving half the expense.

The late Mr. Collar, considering that sometimes from small streams, and sometimes from little springs or collections of rain-water, one might have a good deal of water above ground, thought not a sufficient quantity to turn an overhot-wheel, thought that if a sufficient fall might be had, this collection of water might be made useful in raising the water in a mine to the adit, where it may be carried off.

But now the most general method of draining mines is by the steam-engine. See Steam-Engine.

Mine, in the military art, denotes a subterraneous canal or passage, dug under the wall or rampart of a fortification, intended to be blown up by gunpowder.

The alley or passage of a mine is commonly about four feet square; at the end of this is the chamber of the mine, which is a cavity of about five feet in width and in length, and about six feet in height; and here the gunpowder is flowed. The passage of the mine is the trail, for which there is always a little aperture left.

Two ounces of powder have been found, by experiment, capable of raising two cubic feet of earth; consequently 200 ounces, that is, 12 pound 8 ounces, will raise 200 cubic feet, which is only 16 feet short of a cubic toise, because 200 ounces joined together have proportionally a greater force than 2 ounces, as being an united force.

All the turnings a miner uses to carry on his mines, and through which he conducts the sucs, should be well filled with earth and dung; and the masonry in proportion to the earth to be blown up, as 3 to 2. The entrance of the chamber of the mine ought to be firmly shut with thick planks, in the form of a St. Andrew's cross, so that the inclosure be secure, and the void spaces shut up with dung or tempered earth. If a gallery be made below or on the side of the chamber, it must absolutely be filled up with the strongest masonry, half as long again as the height of the earth; for this gallery will not only burst, but likewise obstruct the effect of the mine. The powder should always be kept in sacks, which are opened when the mine is charged, and some of the powder fired about: the greater the quantity of earth to be raised is, the greater is the effect of the mine, supposing it to have the due proportion of powder. Powder has the same effect upon masonry as upon earth, that is, it will proportionably raise either with the same velocity.

The branches which are carried into the solidity of walls do not exceed three feet in depth, and two feet six inches in width nearly; this fort of mine is most excellent to blow up the strongest walls.

The weight of a cubic foot of powder should be 80 lb. 1 foot 1 inch cube will weigh 100 lb. and 1 foot 2 inches and 1/4, 150 lb. and 20 lb. of powder will be 1 foot 5 inches cube; however, there is a diversity in this, according to the quantity of saltpetre in the gunpowder.

If, when the mines are made, water be found at the bottom of the chamber, planks are laid thereon, upon which the powder is placed either in sacks or barrels of 100 lb. each. The fausilfes must have a clear passage to the powder, and be laid in an auger or wooden trough, through all the branches. When the powder is placed in the chamber, the planks are laid to cover it, and others again across these; then one is placed over the top of the chamber, which is shaped for that purpose: between that and those which cover the powder, props are placed, which shore it up; some inclining towards the outside, others to the inside of the wall; all the void spaces being filled with earth, dung, brick, and rough stones. Afterwards planks are placed at the entrance of the chamber, with one across the top, whereon they buttress three strong props, whose other ends are likewise propped against another plank situated on the side of the earth in the branch; which props being well fixed between the planks with wedges, the branch should then be filled up to its entrance with the aforesaid materials. The fausilfes which pass through the sides of the branches which pass through the sides of the branches must be exactly the same length with that in the middle, to which they join; the part which reaches beyond the entrance of the mine is that which conveys the fire to the other three; the fausilfes being of equal length, will spring together.

From a great number of experiments, it appears, 1. That the force of a mine is always towards the weakest side; so that the disposition of the chamber of a mine does not at all contribute to determine this effect. 2. That the quantity of powder must be greater of less, in proportion to the greater or less weight of the bodies to be raised, and to their greater or less cohesion; so that you are to allow for each cubicathom

| Of loose earth, | - | 9 or 10 lb. |
| Firm earth and strong sand, | 11 or 12 |
| Flat clayey earth, | 15 or 16 |
| New masonry, not strongly bound, | 15 or 20 |
| Old masonry, well, | 25 or 30 |

3. That the aperture, or entonnoir of a mine, if rightly changed, is a cone, the diameter of whose base is double the height taken from the centre of the mine.

4. That when the mine has been overcharged, its entonnoir is nearly cylindrical, the diameter of the upper
Mineral waters, properly so called, are those in which gas, or sulphureous, saline, or metallic substances, are discovered by chemical trials. As many of these waters are employed successfully in medicine, they are also called medicinal waters.

Mineral waters receive their peculiar principles by passing through earths containing salts, or pyritous substan­ces that are in a state of decomposition. Some of these waters are valuable from the quantity of useful salts which they contain, particularly of common salt, great quantities of which are obtained from these waters; and others are chiefly valued for their medicinal qualities. The former kind of mineral waters is an object of manufacture, and from them is chiefly extracted that salt only which is most valuable in commerce. See Salt.

Many of those waters have been accurately analyzed by able chemists and physicians. But notwithstanding these attempts, we are far from having all the certainty and knowledge that might be defined on this important subject; for this kind of analyses is perhaps the most difficult of any in chemistry.—Almost all mineral waters contain several different substan­ces, which being united with water may form with each other numberless compounds. Frequently some of the principles of mineral waters are in so small a quantity, that they can scarcely be perceived; although they may have some influence on the virtues of the water, and also on the other principles contained in the water.—

The chemical operations used in the analyses of mineral waters, may sometimes occasion essential changes in the substances that are to be discovered. And also, these waters are capable of suffering very-considerable changes by motion, by heat, and by exposure to air.

Probably also the variations of the atmosphere, subterranean changes, some secret junction of a new spring of mineral or of pure water, lastly the exhaustion of the minerals whence waters receive their peculiar principles, are causes which may occasionally change the quality of mineral waters.

We need not therefore wonder that the results of analyses of the same mineral waters made by different chemists, whose skill and accuracy are not questioned, should be very different.

The consequences of what we have said on this subject are, That the examination of mineral waters is a very difficult task; that it ought not to be attempted but by profound and experienced chemists; that it requires frequent repetitions, and at different times; and lastly, that no fixed general rules can be given concerning these analyses.

As this matter cannot be thoroughly explained without entering into details connected with all the parts of chemistry, we shall here mention only the principal results, and the most essential rules, that have been indicated by the attempts hitherto made on this subject.

We may admit the division or arrangement of mineral waters into certain clastics, proposed by some of the best chemists and naturalists.

Some of these waters are called cold, because they are not naturally hotter than the atmosphere. Some of them are even colder, especially in summer. Those are called hot mineral waters, which in all seasons are hotter than the air. These are of various degrees of heat, and some of them are almost as hot
MIN [ 45 ] MIN

Mineral. as boiling water. In some mineral waters certain volatile, spirituous, and elatic principles may be perceived, by a very sensible piquant taste: this principle is called the gas or spirit of the waters.

The waters which contain this principle are generally lighter than pure water. They sparkle and emit bubhles, at their spring, but especially when they are shaken, and poured from one vessel into another. They sometimes break the bottles containing them, when these are well corked, as fermenting wines sometimes do. When mixed with ordinary wine, they give to it the piquancy and sparkling quality of Champaigne wine.

This volatile principle, and all the properties of the water dependent upon it, are lost merely by exposure to air, or by agitation. The waters containing this principle are distinguished by the name of spirituous mineral waters, or acidulous waters.

Other divisions of mineral waters may be made relatively to some of their predominant principles. Hence some waters are called acidulous, alkaline, martial, neutral, &c.

When a mineral water is to be examined, we may observe the following rules:

Experiments ought to be made near the spring, if possible.

The situation of the spring, the nature of the soil, and the neighbouring rising grounds, ought to be examined.

Its sensible qualities, as its smell, taste, colour, are to be observed.

Its specific gravity and heat are to be ascertained by the hydrostatical balance and the thermometer.

From the properties abovementioned of spirituous mineral waters, we may discover whether it be one of this class. For greater certainty we may make the following trial. Let the neck of a wet bladder be tied to the neck of a bottle containing some of this water. By shaking the water, any gas that it may contain will be disengaged, and will swell the bladder. If the neck of the bladder be then tied with a string above the bottle, and be cut below this string, so as to separate the bladder from the bottle, the quantity and nature of the contained gas may be further examined.

Lastly, we must observe the changes that are spontaneously produced upon the water in close and open vessels, and with different degrees of heat. If by these means any matter be crystallized or deposited, it must be set apart for further examination.

These preliminary experiments and observations will almost certainly indicate, more or less definitely, something concerning the nature of the water, and will point out the method to be followed in our further inquiry.

We must then proceed to the decomposition of the water, either without addition, and merely by evaporation and distillation, or with the addition of other substances, by means of which the matters contained in the water may be precipitated and discovered. It is not material which of these two methods be first practiced, but it is quite necessary that the one should succeed the other. If we begin by evaporating and distilling, these operations must be sometimes interrupted, that the several principles which rise at different times of the distillation may be obtained and examined separately, and also to allow the several faults that may be contained to crystallize by the evaporation and by cold.

The substances which have hitherto been met with in mineral waters are,

1. Vitriolic Acid. This acid is sometimes found pure and unmixed with any other substance, though more frequently joined with iron or copper. In its pure state, it is most frequently found in the neighbourhood of volcanoes, where, in the opinion of Dr Donald Monro, it is most probably “distilled from mines of vitriol or of pyrites-stone, decomposed by subterranean fire.” It seems, however, more probably to proceed from the decomposition of sulphur; for neither vitriol nor pyrites will at all give a pure acid. This only can be obtained from the fumes of sulphur, which we know abound in all such places. Dr Vandellius, in a book intitled De Thermis Agri Patavini, published in 1761, mentions a cave near to the town of Latera, about 30 miles from Viterbo, in Italy, where a clear acid water drops from the crevices of the rocks, and is collected by the country people in glazed earthen vessels. This has a mild agreeable taste, and is found to be a pure vitriolic acid much diluted. The cavern, however, is so filled with noxious vapours, that it cannot be entered without danger of suffocation, except in winter, or when it blows a north wind. A similar native vitriolic water is mentioned by Theophilus Griflionius, near the town of Salvena. Varenius also mentions a spring in the province of Nota in Sicily, the waters of which are so pure, that the neighbouring people use it instead of vinegar. In some waste coal pits, the water takes four, and effervesces with alkalis; but in all these the acid is mixed with much vitriol, or other matter. Dr Monro mentions acid dews collected in the East Indies: this acid he supposes to be the vitriolic, and that it probably imparts some acidey to waters upon which the dews fall.

2. Nitrous and marine acids are never found in waters pure, though the former is frequently found combined with calcareous earth, and the latter with fojuble alkali, calcareous earth, or magnesia.

3. Fixed air enters into the composition of all waters; but abounds particularly in those of the mineral kind, at least such as are cold. It imparts an agreeable acidulous taste to fuch water as it is mixed with, and is found by undoubted experiments to be that which gives the power and efficacy to the cold kind. It is known to be a solvent of iron, and that by its means this metal is very often dissolved in waters; and Dr Dejean of Leyden, in a letter to Dr Monro in the year 1777, supposes it to be the medium by which sulphur also is dissolved. “Having been lately at Aix-La-Chapelle (says he), I mixed a solution of arzenic in the marine acid with some of the water of the emperor’s bath, and immediately a true and genuine sulphur was precipitated to the bottom of the vessel in which the water was contained: which convinced me that the sulphur was dissolved by means of fixed air, though Sir Torbern Bergman thinks otherwise, and that the sulphur is suspended by means of phlogiston, and the matter of heat united in the waters; and he says, that if the concentrated nitrous acid be added to these waters, it feizes the phlogiston, precipitates the sulphur, and takes away the hepaticinal.” If sulphur is by this medium suspended in
indeed, grains, that duum be alkali. Think that it is a native frequently found along with it in the same water. These are very much impregnated with this acid, and are thought to be native of. Dr Nichola Andrea speaks of a water at Selliata, in Calabria, which is so strongly impregnated with this kind of salt, that he thinks it would be worth while to prepare it from thence in the way of trade. It is very probable that such waters are frequently to be met with in countries where the soil is impregnated with mineral alkali.

7. Glauber's salt. Many mineral waters contain a portion of this salt, though the quantity is commonly very small. However, M. Boulloc, in the memoirs of the academy of sciences at Paris for 1724, makes mention of the waters of a spring in the neighbourhood of a village about three leagues from Madrid, which, by evaporation, yields a true Glauber's salt. This salt, he says, is found in a concrete state about the fides of the spring, resembling the icicles which in winter hang from the roofs of houses. From this circumstance, it would seem that the water of the spring was very richly impregnated with the salt; and Dr Nichola Andrea speaks of a water at Selitaria, in Calabria, which is so strongly impregnated with this kind of salt, that he thinks it would be worth while to prepare it from thence in the way of trade. It is very probable that such waters are frequently to be met with in countries where the soil is impregnated with mineral alkali.

8. Common nitre. In some of the barren provinces of Bengal, the earth is so strongly impregnated with this salt, that the surface is covered with a nitrous crust resembling hoar-frost; and in such places the waters are strongly impregnated with it, as may naturally be supposed. In colder countries, however, this impregnation is more rare, though infinches of perfect nitre being found in springs are not wanting in Europe; but no natural combination of nitric acid with foffil alkali, or cubic nitre, has yet been met with in any part of the world.

9. Sea salt. This abound not only in the waters of the ocean, but in great numbers of salt springs; and there are but few waters so pure as not to contain a small portion of it.

10. Aerated foffil alkali. This is found in Seltzer, and other waters of that kind, but combined with such a quantity of fixed air, that the acid taste of the alkali is entirely covered, and the water has a brisk acidulous one. By evaporating the water, however, this superfluous quantity of air is dissipated, and the alkali then appears in its more acid state.

11. Gypsum, or felenites. This composition of the vitriolic acid and lime is extremely common in mineral waters. For a long time it was supposed to be a simple earth or stone, on account of its difficult solubility in water, requiring 700 or 800 times its own weight of water to dissolve it artificially, though Dr Rutty informs us, that the water in which it is originally dissolved will contain four or five times that proportion. There are to appearance several kinds of this substance; but whether they arise from foreign mixture, or from any difference in the calcarious earths among themselves, we know not. It is not, however, considered as a medicinal ingredient, nor indeed is the internal use of it thought to be very safe.

12. Epiton salt. Bergman and some other chemists have reduced all the calcarious purging salts in which the vitriolic acid is concerned; but Dr Monro observes, that these salts not only crystallize in various modes, but have different degrees of solubility in water. Thus the Epiton salt, properly so called, dissolves in an equal quantity of water, while the calcarious nitres, or purging salts from mineral waters, require from 10 to 50 times their weight to dissolve them. This matter would require the analysis of a great number of water samples to decide, but it is certain that the quantity of water required is very considerable.
the iron dissolved in its stead. Sometimes the quantity of copper is so great, that it is found advantageous to extract it in this way, as is the case in a certain stream in Ireland.

16. Vitriolated iron is found in considerable quantity in several waters both of England, Scotland and Ireland, as well as in many countries on the continent. Some authors have imagined, that there is a kind of volatile vitriol with which waters are sometimes impregnated. An anonymous author, in a work intitled *delle Terme Portense*, published at Rome in 1768, informs us, that having fixed a glass receiver to a hole through which the vapour of the water rises from the aqueduct below, he found in it a month afterwards, as well as in the mouth of the hole, a concrete and incrusted sub stance, like flatalcrite, which by experiment proved to be a true salt of iron, with a superabundant quantity of acid. Hence he concludes that this water, as it rises from the spring, is impregnated with a fine volatile martial vitriol, in such small proportion that it cannot be discovered in any quantity that may be analysed in retorts or stills, though it may be discovered by confining for a long time the vapour, which is naturally and constantly sublimed from the whole body of the thermal water discharged from the spring, as it passes through the aqueducts. The water of this spring is strongly sulphureous, and its heat 92 degrees of Fahrenheit.

Another kind of supposed volatile vitriol is that composed of iron, dissolved by fixed air. The notion of this being a volatile substance arose from observing that there are some waters which taste strongly chalybeate at the fountain, but, after running for a little way, los es it entirely. This, however, is founded on a mistake: for it is only one of the ingredients, viz. the fixed air, which flies off when it is combined with earth: after which the iron precipitates in a similar manner.

20. Vitriolated zinc. This has been found native in the bowels of the earth; and thence has been supposed, not without reason, to be an ingredient in mineral waters: but none have yet brought any decisive experiments on this subject, except Dr Rutty and Dr Gmelin, who both say that they have obtained a white vitriol from mineral waters which were at the same time impregnated with iron and some other ingredients.

21. Muriated magnesia. Waters impregnated with this salt are mentioned both by Bergman and Scheele; but the particular properties of them are not known.

22. Arsenic has been supposed sometimes to be an ingredient in mineral waters: though no certain proofs of its existence have been brought. Poisonous springs, supposed to be impregnated with it, are mentioned by Varenius; and Dr Baldafelli tells us of a small spring (near to the Aqua Sante, in the country of Sicily), the waters of which kill any animal that drinks them. He supposes this to be owing to arsenic, but was afraid to analyse the water.

23. Poffel oils. Almost all waters, even those which are accounted the most pure, contain some portion of an oily matter though generally so small that it cannot be perceived without evaporating a large quantity of the liquid. Some contain it in great quantity; inasmuch that, besides impregnating the water as strongly as possible, a great quantity falls to the bottom. 

18. Vitriolated copper. This salt is seldom found, except in waters which flow from copper mines. The water impregnated with it is emetic and purgative, and may justly be accounted poisonous rather than medicinal. On dipping clean iron into such water, the copper is instantly precipitated in its metallic state, and
MIN [ 48 ] MIN

Sulphur. This is a common ingredient in mineral waters; and its presence is known by the strong hepatic smell they emit, as well as by their blackening silver. &c. Sulphureous waters are frequently very clear and transparent when taken up at the fountain; but when kept in open vessels, or bottles not well stoppered, they soon deposit the sulphur they contain in the form of a dirty white powder, and lose their sulphureous smell. The bottom of the wells containing such waters, or of the channels in which they run, assume a black colour, and a raggy kind of matter is deposited on such substances as they run over for some time; and when these are taken up and dried, they appear covered with a true sulphur. Some waters contain this ingredient in very considerable quantity. From that of Harrowgate it may be separated by filtration; and Father de Térére, in the second part of his Histoire Naturelle des Aulnins, tells us, that when he was in the island of Guadaloupe, and amusing himself one day with evaporating in a tin plate some sulphureous water which he found near the burning mountain, there remained on the plate a layer of sulphur about the thickness of a leaf of paper. Dr Monro mentions his having obtained a true sulphur, by evaporation, from a mineral water at Caille-Leod, in the county of Ross, in Scotland. Dr Brown, in his Travels, informs us, that having cauèd some of the pipes which carry off the water from the duke's bath at Baden, in Austria, to be opened, he took from thence a quantity of fine sulphur in powder, something like flower of brimstone, which had been sublimed from the waters. A similar kind of sulphur is obtained from the upper part of the pipes and conduits which convey the waters of Aix-la-Chapelle from their sources.

From these and other facts of a similar nature, Dr Monro concludes, that sulphur is dissolved by some means or other in the water. Great differences however have taken place among chemists concerning the mode in which sulphur is thus dissolved. Sulphur, we know, may be dissolved by means of an alkali, as well as by calcareous earth; and there are some instances of alkaline waters containing sulphur, though we are not absolutely certain that the alkaline fyll is the bond of union between the sulphur and them. Dr Vandelli, in his treatise de Thermae agri Paullini, already quoted, mentions a substance found in the conduits of the waters of the baths at Aponum, which he calls crystallized sulphur; and says that it dissolves in the waters by boiling, recovering afterwards its solid form. This substance has not been examined; but we know of no other mineral with which sulphur readily assumes a crystalline form than terra pendorosa.—This compound is easily dissolved in water, and communicates to it a most powerful taste and smell of hepatic sulphur. Great part of the terra pendorosa, though not the whole, may be separated by fixed air, so that it is probably this permanent compound which Vandelli observed. Dr Lucas supposed that the sulphureous waters contain both an acid and phlogiston; and Sir Torbern Bergman, that they are impregnated only with the hepatic gas; and that this gas conficts of sulphur united with phlogiston, from which the sulphur may be precipitated by the nitrous acid.

For an account of the cause of heat in mineral waters, see the article SPRINGS.

Having now mentioned the principal substances that form almost all these waters, we shall next show the proofs by means of which they may be discovered in water, without decomposing the water by evaporation or by distillation.

If any portion of disengaged acid or alkali be contained in water, it may be known by the taste, by changing the colour of violets or of turnip, and by adding the precise quantity of acid or of alkali that is necessary for the separation of the contained disengaged saline matter.

Sulphur, and liver of sulphur, may be discovered in waters by their singular smell, and by the black colour which these substances give to white metals or to their precipitates, but especially to silver.

Vitriolic salts with earthy bases may be discovered in water by two processes: 1. By adding some fixed alkali, which decomposes all their fols, and precipitates their earthy bases; and, 2. By adding a solution of mercury in nitrous acid, which also decomposes these fols, and forms a turbid mineral with their acid. But for this purpose the solution of mercury ought to have a superabundant quantity of acid; for this solution when perfectly saturated, forms a precipitate with any kind of water, as M. Rouelle has very justly remarked: and indeed, all metallic solutions in any acids are strictly capable of decomposition by water alone, and so much more easily as the acid is more perfectly saturated with the metal.

Martial vitriol or iron combined with any acid, or even with gas, shows itself in waters by blackening an infusion of galls, or by forming a Prussian blue with the phlogisticated alkaline lixivium.

The vitriol of copper, or copper dissolved by any acid, may be discovered by adding some of the volatile spirit of sal ammoniac, which produces a fine blue colour; or by the addition of clean iron, upon the surface of which the copper is precipitated in its natural or metallic state.

Glauber's salt is discovered by adding a solution of mercury in nitrous acid, and forming with it a turbid mineral: or by crystallization.

Common salt contained in waters forms with a solution
The process of silver in nitrous acid a white precipitate, or luna cornes. It may also be known by its crystallization.

Marine salt with earthy bases produces the same effect upon solution of silver. It also forms a precipitate when fixed alkali is added. The acrimony, bitterness, and deliqueency of this salt, serve to distinguish it.

The proofs related for the examination of mineral waters, are only those which are most essential. Many others may be made to confirm the former proofs: but waters is the chief cause of their lightness, piquancy, general, anG waters, are only effect of substance what ever, dissolved in solution of vitriolic acid by the sulphur, or salts: if this matter contained a fhell in exposed to a red heat. If this matter contained but a fels in this matter, ferve to.

This proof related in nitric acid, which are which are added. The acrimony, ferfey,ottie acid, and the other is fixed air. See ALTERLOGY, FIXED Air, and Gas, piufim. Air united superabundantly with spiritual waters is the chief cause of their lightness, piquancy, and sparkling.

When the nature and quantities of the principles contained in a mineral water are ascertained by suitable experiments, we may imitate artificially this water, by adding to pure water the same proportions of the same substances, as Mr Venel has done in examining several waters, especially that of Selters.

We may easily perceive the necessity of using no vessels in these experiments, but such as are perfectly clean and rinsed with distilled water; of weighing the products of the experiments very exactly; of making the experiments upon a large quantity of water as is possible, especially the evaporation, crystallizations, and distillations; and of repeating all experiments several times. We may further observe, that the mixtures from which any precipitates might be expected ought to be kept two or three days, because many of these precipitates require that time, or more, to appear, or to be entirely deposited.

An ALPHABETICAL Table of the most noted Mineral Waters in Europe, exhibiting their Medicinal Properties and Contents.

</table>

See Aix-la-Chapelle and Baden, in the order of the alphabet.
Names of Springs. | Countries in which they are found. | Contents and Qualities of the Water. | Medicinal Virtues.  
--- | --- | --- | ---  
Bagnigge | Middlesex, near London. | Epsom salt and murinated magnesia. Cold. A spring contains iron and fixed air. Strongly purgative, three half pints being a dose. The cold bathing also proves purgative when the bowels contain any vitiated matter. Strongly emetic and cathartic. Sometimes useful in the jaundice and dropy, scurvy, chronic obstructions. Used like a bath in cutaneous diseases. Taken in the dose of a pint, containing only about seven drams and an half of sea-salt, so that a great part of the virtue must reside in the aerated calcareous earth. Powerfully corrosor, and very useful in all kinds of weakness. Used as a bath, and taken internally.  
Balemore | Worcestershire in England. | A fine cold chalybeate, containing iron rendered soluble by fixed air, along with some other salt supposed to be oflalkali, and probably foffile alkali. Corroborative and astringent. Drunk to the quantity of two pints, or two and an half.  
Balaruc | Languedoc in France. | Hot, and contain some purging salts. Diuretic and diaphoretic. Useful in diuresis.  
Ballycastle | Antrim in Ireland. | Chalybeate and sulphureous. Cold. Similar in virtue to that of Ballycastle. Used in cutaneous diseases. Taken internally to the quantity of a quart or three pints.  
Ballyfellan | Near Kilkenny in Ireland. | Iron, fixed air, and probably foffile alkali. Corroborative and astringent. Drunk to the quantity of two pints, or two and an half.  
Bagniers | Biggore in France. | Earth and sulphur. Hot.  
Barreges | Biggore in France. | Sea-salt, foffile alkali, calcareous earth, felenites, sulphur, and a fine bituminous oil. Hot. Used as bathing and internally to the quantity of a quart or three pints.  
Barunet, and Northall | Hertfordshire in England. | Epsom salt, and aerated calcareous earth. Powerfully corrosor, and very useful in all kinds of weakness. Used as a bath, and taken internally.  
Bath | Somersatshire in England. | Iron, aerated calcareous earth, felenites, Glauber's salt, and sea-salt. Hot. Used as a bath; and drank from four to eight ounces at a time, to two quarts per day. Useful in consumptions, diabetes, fluor albus, &c.  
Bandola | Italy. | Iron, fixed air, foffile alkali, and a little sulphur. Cold. Diuretic and corrosor. Similar to Harrowgate.  
Bristol | Somersatshire in England. | Calcareaeous earth, sea-salt, Epsom salt Glauber's salt, and felenites. Hot. Used as a bath; and drank from four to eight ounces at a time, to two quarts per day. Useful in consumptions, diabetes, fluor albus, &c.  
Buxton | Derbyshire in England. | A small quantity of sea-salt, foffile alkali, Epsom-salt, and aerated calcareous earth. Hot. Here is also a fine cold chalybeate spring. Useful in gout, rheumatism, and other disorders in which tepid baths are serviceable. Used as baths, and drank to the quantity of five or six pints per day. 

Caroline
Names of Springs. Countries in which they are found. Contents and Quality of the Water. Medicinal Virtues.

Carlton, Nottinghamshire in England. Iron dissolved in fixed air, along with a bituminous oil, which gives it the smell of horse-dung. Cold. Diuretic and corroborative.

Carrickfergus, Antrim in Ireland. Seems from its bluish colour to contain a very small quantity of copper. Cold. Weakly purgative.

Carrickmore, Cavan in Ireland. Foffile alkali, fixed air, and some purging salt. Cold. Purgative and diuretic.

Cafle-Leod, Ross-shire in Scotland. Aerated earth, felenites, Glauber's salt, and sulphur. Cold. Resembles the German Spaw; and is in considerable repute. Diuretic, diaphoretic, and corroborant; useful in cutaneous diseases.

Chau de Fontaine, Liege in Germany. Aerated earth, foffile alkali, and fixed air. Hot. Resembles those of Aix la Chapelle and Buxton. Purgative and corroborant; taken in the quantity of from one to three or four pints. Is useful in cases of indigestion and scorbutic disorders; also in the gravel. Diuretic and corroborative.

Cleves, Germany. Iron, fixed air, and other ingredients of Pyrmont water. Diuretic and corroborant.

Codfalwood, Staffordshire in England. Sulphur, fixed air, and aerated earth. Refembles the Aiferon water.

Commer, or Cumner, Berkshire in England. Some purging salt, and probably aerated earth; the water is of a whitish colour. Purgative, in the quantity of one, two, or three quarts. Purgative, diuretic, and corroborant.

Coolauran, Fermanagh in Ireland. Iron, fixed air, and aerated earth. Diuretic.

</tbody>
</table>
MINEHEAD, a town of Somersetshire, 166 miles from London. It is an ancient borough, with a harbour in the Briolf channel, near Dunfer castel, much frequented by passengers to and from Ireland. It was incorporated by Queen Elizabeth, with great privileges, on condition the corporation should keep the quay in repair; but its neglect, and they were at the expense of new-building the quay. In pursuance of another act, confirming the former, a new head has been built to the quay, the beach cleared, &c., so that the biggest ship may enter, and ride safe in the harbour. The town contains about 500 houses, and 2000 souls. It was formerly governed by a portreeve, and now by two constables chosen yearly at a court-leet held by the lord of the manor. Its chief trade is with Ireland, from whence about 40 vessels used to come hither in a year with wool; and about 4000 chaldrons of coals are yearly imported at this place. Watchet and Poriock, from South Wales, which lies directly opposite to it, about seven leagues over, the common breadth of this channel all the way from Holmes to the Land's End. Here are several rich merchants, who have some trade also to Virginia and the West Indies; and they correspond much with the merchants of Barnef:aple and Briolf in their foreign commerce. Three or four thousand barrels of herrings, which come up the Severn in great shoals about Michaelmas, are caught, cured, and shipped off here every year, for the Mediterranean, &c. The market here is on Wednesday, and fair on Whitsun-Wednesday.

MINERALOGY,
MINERALOGY.

It is that science which teaches us the properties of mineral bodies, and by which we learn how to characterize, distinguish, and classify them into a proper order.

INTRODUCTION.

MINERALOGY seems to have been in a manner coeval with the world. Precious stones of various kinds appear to have been well known among the Jews and Egyptians in the time of Moses; and even the most rude and barbarous nations appear to have had some knowledge of the ores of different metals. As the science is nearly allied to chemistry, it is probable that the improvements both in chemistry and mineralogy have nearly kept pace with each other; and indeed it is but of late, since the principles of chemistry were well understood, that mineralogy has been advanced to any degree of perfection. The best way of studying mineralogy, therefore, is by applying chemistry to it; and not contenting ourselves merely with inspecting the outsides of bodies, but decompounding them according to the rules of chemistry. This method has been brought to the greatest perfection by Mr. Pott of Berlin, and after him by Mr. Cronstedt of Sweden. To obtain this end, chemical experiments in the large way are without doubt necessary: but as a great deal of the mineral kingdom has already been examined in this manner, we do not need to repeat all those experiments in their whole extent, unless some new and particular phenomena should discover themselves in those things we are examining; else the tediousness of those processes might discourage some from going farther, and take up much of the time of others that might be better employed. An easier way may therefore be adopted, which even for the most part is sufficient, and which, though made in miniature, is as scientific as the common manner of proceeding in the laboratories, since it imitates that, and is founded upon the same principles. This consists in making the experiments upon a piece of charcoal with the concentrated flame of a candle directed through a blow-pipe. The heat occasioned by this is very intense; and the mineral bodies may here be burnt, calcined, melted and fused, &c. as well as in any great works.

For a description of the blow-pipe, the method of using it, the proper fluxes to be employed, and the different subjects of examination to which that instrument is adapted, see the article Blow-pipe, where all those particulars are concisely detailed. It may not be improper here, however, to resume those details at greater length; avoiding, at the same time, all unnecessary repetitions. After which we shall exhibit a scientific arrangement of the mineral kingdom according to the most approved system.

PART I. EXPERIMENTAL MINERALOGY; with a DESCRIPTION of the NECESSARY APPARATUS (A).

SECT. I. Of experiments upon Earths and Stones.

When any of these substances are to be tried, we must not begin immediately with the blow-pipe; but some preliminary experiments ought to go before, by which those in the fire may afterwards be directed. For instance, a stone is not always homogenous, or of the same kind throughout, although it may appear to the eye to be so. A magnifying glass is therefore necessary to discover the heterogeneous particles, if there be any; and these ought to be separated, and every part tried by itself, that the effects of the different things, examined together, may not be attributed to one alone. This might happen with some of the finer minerals, which are now and then found mixed with small particles of quartz, scarcely to be perceived by the eye.

The trapp (in German schwartzlein) is also sometimes mixed with very fine particles of felspar (pottam fustilans) or of calcareous spar, &c. After this experiment, the hardness of the stone in question must be tried with steel. The flint and garnets are commonly known to strike fire with steel; but there are also other stones, which, though very seldom, are found so hard as likewise to strike fire. There is a kind of trapp of that hardness, in which no particles of felspar are to be seen. Coloured glasses resemble true gems; but as they are very soft in proportion to these, they are easily detected by means of the file. The common quartz-crystals are harder than coloured glasses, but softer than the gems. The loadstone discovers the presence of iron, when it is not mixed in too small a quantity in the stone, and often before the stone is roasted. Some kinds of haematites, and particularly the cærulecents, greatly resemble some other iron ores; but this distinguishes itself from them by a red colour when poured, the others giving a blackish powder, and so forth.

The management of the Blow-pipe has been described under that article; but a few particulars may be here recapitulated, or added. The candle ought to be snuffed often, but so that the top of the wick may retain some fat in it, because the flame is not hot enough when the wick is almost burnt to ashes; but only the top must be snuffed off, because a low wick gives too small a flame. The blue flame is the hottest; this ought, therefore, to be forced

forced out when a great heat is required, and only the point of the flame must be directed upon the subject which is to be aflayed. M. Magellan recommends, as being most cleanly and convenient, that the candle be made of wax, and the wick should be thicker than ordinary. Its upper end must be bended towards the matter intended to be heated, and the flame of air must be directed along the surface of the bended part, so as not absolutely to touch it.

The piece of charcoal made use of in these experiments must not be of a disposition to crack. If this should happen, it must gradually be heated until it does not crack any more, before any aflay is made upon it. If this be not attended to, but the aflay made instantly with a strong flame, small pieces of it will split off in the face and eyes of the aflayer, and often throw along with them the matter that was to be aflayed. Charcoal which is too much burnt consumes too quick during the experiment, leaving small holes in it, wherein the matter to be tried may be loft; and charcoal that is burnt too little, catches flame from the candle, burning by itself like a piece of wood, which likewise hinders the process.

Of those things that are to be aflayed, only a small piece must be broken off for that purpose, not bigger than that the flame of the candle may be able to act upon it at once, if required; which is sometimes necessary, as, when the matter requires to be made red hot throughout, the piece ought to be broken as thin as possible, at least the edges; the advantage of which is obvious, the fire having then more influence upon the subject, and the experiment being more quickly made.

Some of the mineral bodies are very difficult to be kept steady upon the charcoal during the experiment, before they are made red hot; because, as soon as the flame begins to act upon them, they split afunder with violence, and are dispersed. Such often are those which are of a soft confluence or a particular figure, and which preserve the same figure in however minute particles they are broken; for instance, the calcareous spar, the fparry gypsum, fparry flour, white fparry hematite ore, the potters ore, the tafficated mock-lead or blende, &c. even all the common flues which have no determinate figure. These not being so compact as common hard flues, when the flame is immediately urged upon them, the heat forces itself through and into their clefts or pores, and causes this violent expansion and dispersion. Many of the clays are likewise apt to crack in the fire, which may be for the most part ascribed to the humidity, of which they always retain a portion.

The only way of preventing this inconvenience is to heat the body as slowly as possible. It is best, first of all, to heat that place of the charcoal where the piece is intended to be put on; and afterwards lay it thereon; a little cracking will then ensue, but commonly of no great consequence. After that the flame is to be blown very slowly towards it, in the beginning not directly upon, but somewhat above it, and so approaching nearer and nearer with the flame until it become red hot. This will do for the most part; but there are nevertheless some, which, notwithstanding all the precautions, it is almost impossible to keep on the charcoal. Thus the flues are generally the most difficult; and as one of their principal characters is discovered by their effects in the fire per se, they ought necessarily to be tried that way. To this purpose, it is best to make a little hole in the charcoal to put the flour in, and then to put another piece of charcoal as a covering upon this, leaving only a small opening for the flame to enter, as this flue will nevertheless split and fly about, a larger piece thereof than before-mentioned must be taken, in order to have at least something of it left.

But if the experiment is to be made upon a flue whose effects one does not want to see in the fire per se, but rather with fluxes, then a piece of it ought to be forced down into melted borax, when always some part of it will remain in the borax, notwithstanding the greatest part may sometimes fly away by cracking.

1. Of substances to be tried in the fire per se. As the flues undergo great alterations when exposed to the fire by themselves, whereby some of their characteristic, and often the most principal, are discovered, they ought first to be tried that way, observing what has been said before concerning the quantity of matter, direction of the fire, &c. The following are generally the resuits of this experiment.

Calcaceous earth or flues, when it is pure, does not melt by itself, but becomes white and friable, so as to break freely between the fingers; and, if suffered to cool, and then mixed with water, it becomes hot, just like common quick-lime. As in these experiments only very small pieces are used, this last effect is best discovered by putting the proof on the outside of the hand, with a drop of water to it, when instantly a very quick heat is felt on the skin. When the calcareous substance is mixed with the vitriolic acid, as in gypsum, or with a clay, as in marle, it commonly melts by itself, yet, more or less difficultly in proportion to the differences of the mixtures. Gypsum produces generally a white, and marle a grey, glass or flag. When there is any iron in it, as a white iron ore, it becomes dark, and sometimes quite black, &c.

The silex never melts alone, but become generally more brittle after being burnt. Such of them as are coloured become colourless, and the sooner when it does not arise from any contained metal; for instance, the topazes, amethysts, &c. some of the precious flues, however, excepted: And such as are mixed with a quantity of iron grow dark in the fire, as some of the jaspers, &c.

Garnets melt always into a black flag, and sometimes so easily that they may be brought into a round globe upon the charcoal.

The argillacea, when pure, never melt, but become white and hard. The flame effects follow when they are mixed with phlogiston. Thus the soap-rock is easily cut with the knife; but being burnt it cuts glass, and would strike fire with the feel, if as large a piece as is necessary for that purpose could be tried in this way. The soap-rocks are sometimes found of a dark brown and nearly black colour, but nevertheless become quite white in the fire like a piece of China ware. Hence care must be taken not to urge the flame from the top of the wick, there being for the most part a footy smoke, which commonly will darken all that it touches; and if this is not observed, a mistake in the experiment might easily happen. But if
it is mixed with iron, as it is sometimes found, it does not so easily part with its dark colour. The argillaceous when mixed with lime melt by themselves, as above-mentioned. When mixed with iron, as in the boles, they grow dark or black; and if the iron is not in too great a quantity, they melt alone into a dark flag; the same happens when they are mixed with iron and a little of the vitriolic acid, as in the common clay, &c. *Misc. and of fableum become somewhat hard and brittle in the fire, and are more or less refractory, though they give some marks of fusibility.

The flux discover one of their chief characteristics by giving a light like phosphorus in the dark, when they are slowly heated; but lose this property, as well as their colour, as soon as they are made red hot.- They commonly melt in the fire into a white opaque flag, though some of them not very easily.

Some sorts of the zeolites melt easily, and foam in the fire, sometimes nearly as much as borax, and become a frothy flag, &c.

A great many of those mineral bodies which are impregnated with iron, as the boles, and some of the white iron ores, &c. as well as some of the other iron ores, viz. the bloodstone, are not attracted by the loadstone before they have been thoroughly roasted, &c.

2. Of substances heated with fluxes. After the mineral bodies have been tried in the fire by themselves, they ought to be heated with fluxes to discover if they can be melted or not, and some other phenomena attending this operation. For this purpose, three different kinds of fluxes are used as fluxes, viz. talcia, borax, and talca fusible microsilicum; (see the article Blow-Pipe.)

The talcia is, however, not so much used in these small experiments, its effects upon the charcoal rendering it for the most part unfit for it; because, as soon as the flame begins to act upon it, it melts instantly, and is almost wholly absorbed by the charcoal. When this flux is employed to make any experiment, a very little quantity is wanted at once, viz. about the cubical contents of an eighth part of an inch, more or less. This is laid upon the charcoal, and the flame blown upon it with the blow-pipe; but this flux commonly is in a form of powder, it is necessary to go on very gently, that the force of the flame may not disperse the minute particles of the flux. As soon as it begins to melt, it runs along on the charcoal, almost like melted tallow; and when cold, it is a glassy matter of an opaque dull colour spread on the coal. The moment it is melted, the matter which is to be tried ought to be put into it, because otherwise the greatest part of the flux will be soaked into the charcoal, and too little of it left for the intended purpose. The flame ought then to be directed on the matter itself; and if the flux spreads too much about, leaving the proof almost alone, it may be brought to it again by blowing the flame on its extremities, and directing it towards the subject of the experiment. In the ashy made with this flux, it is true, we may find whether the mineral bodies which are melted with it have been dissolved by it or not; but we cannot tell with any certainty whether this is done hastily and with force, or gently and slow; nor whether a less or a greater part of the matter has been dissolved; neither can it be well distinguished if the matter has imparted any weak tincture to the flux; because this flux always bubbles upon the charcoal during the experiment, nor is it clear when cold, so that scarcely any colour, except it be a very deep one, can be discovered, although it may sometimes be coloured by the matter that has been tried.

The following are entirely soluble in this flux with effervescence: Agate; chalcedony; carnelian; Turkey ftone, &c. (cos Turcica); fluor mineralis; onyx; opal; quartz; common flint; ponderous spar. The following are divisible in it with or without effervescence, but not entirely soluble: Amanthius; aebutius; basaltus; chrysolite; granate; hornblend; jasper; marlilite; mica; the mineral of alum from Tolfa; petroflex; aluminae and roof-flate from Helsingia; emerald; fletites; common flint; schoeler; talc; trapp; tripoli; tourmalin. And the following are neither fusible nor divisible in it: Diameter; hyacinth; ruby; fapphire.

The other two fluxes, viz. borax and the talca microsilicum, are very well adapted to these experiments, because they may by the flame be brought to a clear un.coloured and transparent glass; and as they have no attraction to the charcoal, they keep themselves always upon it in a round globular form. The talca fusible microsilicum is very scarce, and perhaps not to be met with in the shops; it is made of urine.

The following are fusible in borax, with more or less effervescence: Fluor mineralis; marl; mica; the mineral of alum from Tolfa; aluminas and roof-flate from Helsingia; ponderous spar; schoeler; talc; tourmalin. And the following without effervescence: Agate; diamond; amanthius; aebutius; basaltus; chalcedony; carnelian; chrysolite; cos turcica; granate; hyacinth; jasper; lapis ponderosus; onyx; opal; petroflex; quartz; ruby; fapphire; common flint; fletite; trapp; tripoli; topaz; zeolite; hydrophanes.

In the microsilicum flux, the following are soluble with more or less effervescence: Basaltus; bole; fluor mineralis; marl; mica; the mineral of alum from Tolfa; aluminas and roof-flate from Helsingia; common flint; t. The following without visible effervescence: Agate; diamond; amanthius; aebutius; chalcedony; carnelian; chrysolite; granate; hyacinth; jasper; onyx; opal; petroflex; quartz; ruby; fapphire; common flint; emerald; talc; topaz; trapp; tripoli; zeolite; hornblend; hydrophanes; lathomarga; fletites.

Calcaceous earth, ponderous spar, gypsum, and other additaments, often afflit the solution, as well in the microsilicum flux as in borax. To which it is necessary to add, that in order to observe the effervescence properly, the matter added to the flux should be in the form of a small particle rather than in fine powder; because in this last there is always air between the particles, which being afterwards driven off by the heat afford the appearance of a kind of effervescence (a).

(a) In the above lists, the articles marked † effervesc very little; those marked ‡ not at all; those marked ❀ require a larger quantity of the flux and a longer continuance of heat than the rest; those marked ✡ are more difficultly dissolved than the others.
The quantity of those two salts required for an experiment is almost the same as the 

**MINERALOGY.**

**Part I.**

The quantity of those two salts required for an experiment is almost the same as the *salts*; but as the former are crystallized, and consequently include a great deal of water, particularly the borax, their bulk is considerably reduced when melted, and therefore a little more of them may be taken than the before mentioned quantity.

Both those salts, especially the borax, when exposed to the flame of the blow-pipe, bubble very much and foam before they melt to a clear glass; which for the most part depends on the water they contain. And as this would hinder the affayer from making due observations on the phenomena of the experiment, the salt which is to be used must first be brought to a clear glass before it can serve as a flux; it must therefore be kept in the fire until it become so transparent that the cracks in the charcoal may be seen through it. This done, whatsoever is to be tried is put to it, and the fire continued.

Here it is to be observed, that for the affayers, making due observations on the phenomena of the experiment, the salt which is to be used must first be brought to a clear glass before it can serve as a flux; because it may then be better distinguished in what manner the flux acts upon the matter during the experiment. If this be not observed, the flux, communicating itself with every point of the surface of the mineral body, spreads all over it, and keeps the form of this salt, which commonly is flat, and by that means hinders the operator observing all the phenomena which may happen.

Besides, the flux being in too small a quantity in proportion to the body to be tried, will be too weak to act with all its force upon it. The best proportion therefore is about a third part of the mineral body to the flux; and as the quantity of the flux abovementioned makes a globe of a due size in regard to the greatest heat that is possible to procure in these experiments, so the size of the mineral body must be a third part less here than when it is to be tried in the fire by itself.

The *salts* as has been already observed, is not of much use in these experiments; nor has it any particular qualities in preference to the two last mentioned salts, except that it dissolves the zeolites easier than they do.

The microcosmic salt flows almost the fame effects in the fire as the borax, only differing from it in a very few circumstances; of which one of the principal is, that when melted with manganese, it becomes of a crimson hue instead of a jacinth colour, which borax takes. This salt is, however, for its scarcity, still very little in use, borax alone being that which is commonly employed. Whenever a mineral body is melted with any of these two salts on mineral bodies may be put to it, and the flux continued. When the flux is put to it, and the fire continued. Here it is to be observed, that for the affayers, when metals are often disguised, as has been already observed, is not of much use in these experiments; nor has it any particular qualities in preference to the two last mentioned salts, except that it dissolves the zeolites easier than they do.

The *salts* as has been already observed, is not of much use in these experiments; nor has it any particular qualities in preference to the two last mentioned salts, except that it dissolves the zeolites easier than they do.

The microcosmic salt flows almost the same effects in the fire as the borax, only differing from it in a very few circumstances; of which one of the principal is, that when melted with manganese, it becomes of a crimson hue instead of a jacinth colour, which borax takes. This salt is, however, for its scarcity, still very little in use, borax alone being that which is commonly employed. Whenever a mineral body is melted with any of these two last mentioned salts, in the manner already described, it is easily seen. Whether it quickly dissolves; in which case an effervescence arises, that lasts till the whole be dissolved: Whether the solution be slowly performed; in which case few and small bubbles only rise from the matter; or, Whether it can be dissolved at all; because if not, it is observed only to turn round in the flux, without the least bubble, and the edges look as sharp as they were before.

In order farther to illustrate what has been said about these experiments, we shall give a few examples of the effects of borax upon the mineral bodies. — The calcareous substances, and all those stones which contain any thing of lime in their composition, dissolve readily and with effervescence in the borax. The effervescence is the more violent the greater the portion of lime contained in the stone. This cause, however, is not the only one in the gypsum, because both the constituents of this do readily mix with the borax, and therefore a greater effervescence arises in melting gypsum with the borax than lime alone. — The *salts* do not dissolve; some few excepted which contain a quantity of iron. — The argillaceous, when pure, are not acted upon by the borax; but when they are mixed with some heterogeneous bodies, they are dissolved, though very slowly; such are, for instance, the stone-marrow, the common clay, &c.

The granites, zeolites, and trapp, dissolve but slowly. The *salts*, *opals*, and *micas*, dissolve for the most part very easily; and so forth. Some of these bodies melt to a colourless transparent glass with the borax; for instance, the calcareous substances when pure, the foids, some of the zeolites, &c. Others tinge the borax with a green transparent colour, *viz.* the granites, trapp, some of the argillaceous, and some of the micas, and asbestos. This green has its origin partly from a small portion of iron which the granites particularly contain, and partly from phlogiston.

Borax can only dissolve a certain quantity of the mineral body proportional to its own. Of the calcareous kind it dissolves a vast quantity; but turns at last, when too much has been added, from a clear transparent to a white opaque flag. When the quantity of the calcareous matter exceeds but little in proportion, the glass looks very clear as long as it remains hot: but as soon as it begins to cool, a white half opaque cloud is seen to arise from the bottom, which spreads over the third, half, or more of the glass globe, in proportion to the quantity of calcareous matter; but the glass or flag is nevertheless shining, and of a glaify texture when broken. If more of this matter be added, the cloud rises quicker and is more opaque, and so by degrees till the flag becomes quite milk white. It is then no more of a shining, but rather dry appearance, on the surface; is very brittle, and of a grained texture when broken.

**Sect. II. Of Experiments upon Metals and Ores.**

What has been hitherto said relates only to the stones and earths: We shall now proceed to describe the manner of examining metals and ores. An exact knowledge and nicety of procedure are so much the more necessary here, as the metals are often so disguised in their ores, as to be very difficultly known by their external appearance, and liable sometimes to be mistaken one for the other: Some of the cobalt ores, for instance, resemble much the pyrites arsenical; there are also some iron and lead ores, which are nearly like one another, &c.

As the ores generally consist of metals mineralized with sulphur or arsenic, or sometimes both together, they ought first to be exposed to the fire by themselves, in order not only to determine with which of these they are mineralized, but also to set them free from those volatile mineralizing bodies: This serves instead of calculation, by which they are prepared for further assays.

Here:
Here it must be repeated, that whenever any metal or fusible ore is to be tried, a little concavity must be made in that place of the charcoal where the matter is to be put; because, as soon as it is melted, it forms itself into a globular figure, and might then roll from the charcoal, if its surface was plain; but when borax is put to it, this inconvenience is not so much to be feared.

Whenever an ore is to be tried, a small bit being broke off for the purpose, it is laid upon the charcoal, and the flame blown on it slowly. Then the sulphur or arsenic begins to part from it in form of smoke: these are easily distinguished from one another by their smell; that of sulphur being sufficiently known, and the arsenic smelling like garlic. The flame ought to be blown very gently as long as any smoke is seen to part from the ore; but after that, the heat must be augmented by degrees, in order to make the calcination as perfect as possible. If the heat be applied very strongly from the beginning upon an ore that contains much sulphur or arsenic, the ore will presently melt, and yet lose very little of its mineralizing bodies, by that means rendering the calcination very imperfect. It is, however, impossible to calcine the ores in this manner to the utmost perfection, which is easily seen in the following instance, viz. in melting down a calcined potter's o're with borax, it will be found to bubble upon the coal, which depends on the sulphur which is still left, the vitriolic acid of this uniting with the borax, and causing this motion. However, lead in its metallic form, melted in this manner, bubbles upon the charcoal, if any sulphur remains in it. But as the lead as well as some of the other metals, may raise bubbles upon the charcoal, although they are quite free from the sulphur, only by the flames being forced too violently on it, these phenomena ought not to be confounded with each other.

The ores being thus calcined, the metals contained in them may be discovered, either by being melted alone or with fluxes; when they show themselves either in their pure metallic state, or by tinging the flag with a colour peculiar to each of them. In these experiments it is not to be expected that the quantity of metal contained in the ore should be exactly determined; this must be done in larger laboratories. This cannot, however, be looked upon as any defect, since it is sufficient for a mineralogist only to find out what part of metal is contained in the ore. There is another circumstance, which is a more real defect in the miniature laboratories, which is, that some ores are not at all capable of being tried by so small an apparatus; for instance, the gold ore called pyrites aureus, which consists of gold, iron, and sulphur. The greatest quantity of gold which this ore contains is about one ounce, or one ounce and a half, out of 100 pounds of the ore, the rest being iron and sulphur: and as only a very small bit is allowed for these experiments, the gold contained therein can hardly be discerned by the eye, even if it could be extracted; but it goes along with the iron in the flag, this last metal being in so large a quantity in proportion to the other, and both of them having an attraction for each other. The blende and black-jacks, which are mineral zinc ores, containing zinc, sulphur, and iron, cannot be tried this way, because they cannot be perfectly calcined, and besides the zinc flies off when the iron forifies. Neither can those blends, which contain silver or gold mineralized with them, be tried in this manner, which is particularly owing to the imperfect calcination. Nor are the quicksilver ores fit for these experiments: the volatility of that semi-metal makes it impossible to bring it out of the poorer fort of ores: and the rich ores, which sweat out the quicksilver when kept close in the hand, not wanting any of these affays, &c. These ores ought to be assayed in larger quantities, and even with such other methods as cannot be applied upon a piece of charcoal.

Some of the rich silver ores are easily tried: for instance, minera argenti vitrea, commonly called silver-glafls, which consists only of silver and sulphur. When this ore is exposed to the flame, it melts instantly, and the sulphur goes away in some, leaving the silver pure upon the charcoal in a globular form. If this silver should happen to be of a dirty appearance, which often is the case, then it must be melted anew with a very little borax: and after it has been kept in fusion for a minute or two, so as to be perfectly melted and red-hot, the proof is suffered to cool: it may then be taken off the coal; and being laid upon the flesh plate, the silver is fenned from the flag by one or two strokes of the hammer. Here the use of the blow-pipe is manifest; for this ought first to be placed upon the plate, to hinder the proof from flying off by the violence of the stroke, which otherwise would happen. The silver is then found inclosed in the flag of a globular form, and quite shining, as if it was polished. When a large quantity of silver is contained in a lead ore, viz. in a potter's o're, it can likewise be discovered through the use of the blow-pipe, of which more will be mentioned hereafter.

Tin may be melted out of the pure tin ores in its metallic state. Some of these ores melts very easily, and yield their metal in quantity, if only exposed to the fire by themselves; but others are more refractory; and as these melts very slowly, the tin, which sweats out in form of very small globules, is instantly burnt to ashes before these globules have time to unite in order to compose a larger globule, which, might be seen by the eye, and not so soon destroyed by the fire; it is therefore necessary to add a little borax to these ores at the beginning, and then to blow the flame violently at the proof. The borax does here preserve the metal from being too soon calcined, and even contributes to the reader collecting of the small metallic particles, which soon are seen to form themselves into a globule of metallic tin at the bottom of the whole mass, nearest to the charcoal. As soon as so much of the metallic tin is produced as is sufficient to convince the operator of its presence, the fire ought to be discontinued, though the whole of the ore be not yet melted; because the whole of this kind of ore can be seldom or never reduced into metal by means of these experiments, a great proportion being always calcined; and if the fire is continued too long, perhaps even the metal already reduced may likewise be burnt to ashes; for the tin is very soon deprived of its metallic state by the fire.

Most part of the lead ores may be reduced to a metallic state upon the charcoal. The minera plumbi calciforae, which are pure, are easily melted into lead; but
MINERALOGY.

but such of them as are mixed with an acher ferri, or any kind of earth, as clay, lime, &c. yield very little of lead, and even nothing at all, if the heterogenea are combined in any large quantity: this happens even with the minera plumbi calciformes arsine mixta. These therefore are not to be tried but in larger laboratories. However, every mineral body suspected to contain any metallic substance may be tried by the blow-pipe, so as to give sufficient proofs whether it contain any or not, by its effects being different from those of the flones or earths, &c.

The minera plumbi minerales which leave the lead in a metallic form, if not too large a quantity of iron is mixed with it. For example, when a tellurated or flesh-grained lead ore is exposed to the flame, its sulphur, and even the arsenic if there be any, begins to fume, and the ore itself immediately to melt into a globular form; the rest of the sulphur continues then to fly off, if the flame be blown slowly upon the mass; but, on the contrary, very little of the sulphur will go off, if the flame be forced violently on it: in this case, it rather happens that the lead itself crackles and dilates, throwing about very minute metallic particles. The sulphur being driven out as much as possible, which is known by finding no sulphureous vapour in the flame, the whole is suffered to cool, and then a globule of metallic lead will be left upon the coal.

If any iron is contained in the lead-ore, the lead, which is melted out of it, is not of a metallic shining, but rather of a black and uneven surface: a little borax must in this case be melted with it, and as soon as no bubble is seen to rise any longer from the metal into the borax, the fire must be discontinued: when the mass is grown cold, the iron will be found scorified with the borax, and the lead left pure and of a shining colour.

Borax does not scorify the lead in those small experiments when it is pure: if the flame is forced with a violence on it, a bubbling will ensue, resembling that which is observed when borax dissolves a body melted with it; but when the fire ceases, the flag will be perfectly clear and transparent, and a quantity of very minute particles of lead will be seen spread upon the borax, which have been torn off from the mass during the bubbling.

If such a lead ore is rich in silver, this last metal may likewise be discovered by this experiment; because as the lead is volatile, it may be forced off, and the silver remain. To effect this, the lead, which is melted out of the ore, must be kept in constant fusion with a slow heat, that it may be consumed. This end will be sooner obtained, and the lead part quicker, if during the fusion the wind through the blow-pipe be directed immediately, though not forcibly, upon the melted mass itself, until it begin to cool; at which time the fire must be directed on it again. The lead, which is already in a volatilitytive state, will by this artifice be driven out in form of a subtle smoke; and by thus continuing by turns to melt the mass, and then to blow off the lead, as has been said, until no smoke is any longer perceived, the silver will at last be obtained pure. The same observation holds good here also, which was made about the gold, that, as none but very little bits of ores can be employed in these experiments, it will be difficult to extract the silver out of a poor ore: for some part of it will fly off with the lead, and what might be left is too small to be discerned by the eye. The silver, which by this means is obtained, is easily distinguished from lead by the following external marks, viz. that it must be red-hot before it can be melted: it cools sooner than lead: it has a silver colour; that is to say, brighter and whiter than lead: and is harder under the hammer.

The minera cupri calciformes (at least some of them), when not mixed with too much flene or earth, are easily reduced to copper with any flux; if the copper is not found not to have its natural bright colour, it must be melted with a little borax, which purifies it. Some of these ores do not all discover their metal if not immediately melted with borax; the heterogenea contained in them hindering the fusion before these are scorified by the flux.

The grey copper ores, which only consist of copper and sulphur, are tried almost in the same manner as above-mentioned. Being exposed to the flame by themselves, they will be found instantly to melt, and part of their sulphur to go off. The copper may afterwards be obtained in two ways: the one, by keeping the proof in fusion for about a minute, and afterwards suffering it to cool; when it will be found to have a dark and uneven appearance externally, but which after being broken discovers the metallic copper of a globular form in its centre, surrounded with a regular, which still contains some sulphur and a portion of the metal: the other, by being melted with borax, which last way sometimes makes the metal appear sooner.

The minera cupri pyriticae, containing copper, sulphur, and iron, may be tried with the blow-pipe if they are not too poor. In these experiments the ore ought to be calcined, and after that the iron scorified. For this purpose a bit of the ore must be exposed to a slow flame, that as much of the sulphur as possible may part from it before it is melted, because the ore commonly melts very soon, and then the sulphur is more difficultly driven off. After being melted, it must be kept in fusion with a strong fire for about a minute, that a great part of the iron may be calcined; and after that, some borax must be added, which scorifies the iron, and turns with it to a black flag. If the ore is very rich, metallic copper will be had in the flag after the scorification. If the ore be of a moderate richness, the copper will still retain a little sulphur, and sometimes iron: the product will therefore be brittle, and must with great caution be separated from the flag, that it may not break into pieces; and if this product is afterwards treated in the same manner as before said, in speaking of the grey copper-ores, the metal will soon be produced. But if the ore is poor, the product after the first scorification must be brought into fusion, and afterwards melted with some fresh borax, in order to calcine and scorify the remaining portion of iron; after which it may be treated as mentioned in the preceding paragraph. The copper will in this last case be found in a very small globule.

The copper is not very easily scorified with this apparatus, when it is melted together with borax, unless it has first been exposed to the fire by itself for a while in order to be calcined. When only a little of this metal is dissolved, it instantly tinges the flag of a reddish
Metals and this difh brown colour, but as soon as this flag is kept in fusion for a little while, it becomes quite green and transparent; and thus the presence of the copper may be discovered by the colour, when it is concealed in heterogeneous bodies, so as not to be discovered by any other experiment.

If metallic copper is melted with borax by a slow fire, and only for a very little time, the glafs or flag becomes of a fine transparent blue or violet colour, inclining more or less to the green: but this colour is not properly owing to the copper, but it may rather be to its phlogiston; because the same colour is to be had in the same manner from iron; and these glusses, which are coloured with either of these two metals, soon lose their colour if exposed to a strong fire, in which they become quite clear and colourless. Besides, if this glafs, tinged blue with the copper, is again melted with more of this metal, it becomes of a good green colour, which for a long time keeps unchanged in the fire.

The metals, when pure, can never be melted by the means of the blow-pipe alone; nor do they yield their metal when melted with fluxes, because they require too strong a heat to be brought into fusion; and as both the ore and the metal itself very soon lose their phlogiston in the fire, and cannot be supplied with a sufficient quantity from the charcoal, fo likewise are they very soon calcined in the fire. This easy calculation is also the reason why the fluxes, for infance borax, readily scorify this ore, and even the metal itself. The iron loses its phlogiston in the fire sooner than the copper, and is therefore more easily scorified.

The iron is, however, discovered without much difficulty, although it were mixed but in a very small quantity with heterogeneous bodies. The ore, or those bodies which contain any large quantity of the metal, are all attracted by the loadstone, some without any previous calculation, and others without having been roaled. When a clay is mixed with a little iron, it commonly melts by itself in the fire; but if this metal is contained in a limestone; it does not promote the fusion, but gives the stone a dark and sometimes a deep black colour, which always is the character of iron. A minera ferris californianae pura cristallifata, is commonly of a red colour: This being expoed to the flame, becomes quite black; and is then readily attracted by the loadstone, which it was not before. Besides these signs, the iron discovers itself, by tinging the flag of a green transparent colour, inclining to brown, when only a little of the metal is scorified; but as soon as any larger quantity thereof is dissolved in the flag, this becomes first a blackish brown, and afterwards quite black and opaque.

Bismuth is known by its communicating a yellowish brown colour to borax; and arsenic by its volatility and garlic smell. Antimony, both in form of regulus and ore, is wholly volatile in the fire when it is not mixed with any other metal except arsenic; and is known by its particular smell, easier to be distinguished when once known than described. When the ore of antimony is melted upon the charcoal, it bubbles constantly during its volatilizing.

Zinc ores are not easily tried upon the coal; but the regulus of zinc exposed to the fire upon the charcoal burns with a beautiful blue flame, and forms itself almost instantly into white flowers, which are the common flowers of zinc.

Cobalt is particularly remarkable for giving to the glass a blue colour, which is the zaffire or smalt. To produce this, a piece of cobalt ore must be calcined in the fire, and afterwards melted with borax. As soon as the glafs, during the fusion, from being clear, seems to grow opaque, it is a sign that it is already tinged a little: the fire is then to be discontinued, and the operator must take hold, with the nippers, of a little of the glafs, whilst yet hot, and draw it out flowly in the beginning, but afterwards very quick, before it cools, whereby a thread of the coloured glass is procured, more or less thick, wherein the colour may be easie be seen than in a globular form. This thread melts easily, if only put in the flame of the candle without the help of the blow-pipe. If this glafs be melted again with more of the cobalt, and kept in fusion for a while, the colour becomes deeper; and thus the colour may be bettered at pleasure.

When the cobalt ore is pure, or at least contains but little iron, a cobalt regulus is almost instantly produced in the borax during the fusion; but when it is mixed with a quantity of iron, this last metal ought first to be separated, which is easily performed since it scorifies sooner than the cobalt; therefore, as long as the flag retains any brown or black colour, it must be separated, and melted again with fresh borax, until it shows the blue colour.

Nickel is very seldom to be had; and as its ores are seldom free from mixtures of other metals, it is very difficultly tried with the blow-pipe. However, when this femimetal is mixed with iron and cobalt, it is easily freed from these heterogeneous metals, and reduced to a pure nickel regulus by means of scorification with borax; because both the iron and cobalt sooner scorify than the nickel. The regulus of nickel itself is of a green colour when calcined; it requires a pretty strong fire before it melts, and tingles the borax with a hueaith colour. Manganese gives the same colour to borax; but its other qualities are quite different, so as not to be confounded with the nickel.

By means of the foregoing explanations, and those given under the article Blow-Pipe, any gentleman, who is a lover of this science, will be able, in an easy manner, to amuse himself in discovering the properties of those works of nature, with which the mineral kingdom furnishes us; or more usefully to employ himself by finding out what sorts of stones, earths, ores, &c. there are on his estate, and to what economical purposes they may be employed. The scientific mineralist may, by examining into the properties and effects of the mineral bodies, discover the natural relation these bodies stand in to each other, and thereby furnish himself with materials for establishing a mineral system, founded on such principles as Nature herself has laid down in them; and this in his own study, without being forced to have recourse to great laboratories, crucibles, furnaces, &c. which is attended with much trouble, and is the reason why few can have an opportunity of gratifying their desire of knowledge in this
MINERALOGY.

A traveller, who has seldom an opportunity of carrying many things along with him, may very well be contented with this laboratory and its apparatus, which are sufficient for most part of such experiments as can be made on a journey. There are, however, other things very useful to have at hand on a journey, which ought to make a separate part of a portable laboratory, if the manner of travelling does not oppose it; this consists of a little box including the different acids, and one or two mortars, in order to try the mineral bodies in liquid menstrua if required.

These acids are, the acid of nitre, of vitriol, and of common salt. Most of the flones and earths are attacked, at least in some degree, by the acids; but the calcareous are the safest of all to be dissolved by them, which is accounted for by their calcareous properties. The acid of nitre is that which is most used in these experiments; it dissolves the limestone, when pure, perfectly, with a violent effervescence, and the solution becomes clear: when the limestone enters into some other body, it is nevertheless discovered by this acid, through a greater or less effervescence in proportion to the quantity of the calcareous particles, unless there are so few as to be almost concealed from the acid by the heterogeneous ones. In this manner a calcareous body, which sometimes nearly resembles a felsigne or argillaceous one, may be known from the latter, without the help of the blow-pipe, only by pouring one or two drops of this acid upon the subject, which is very convenient when there is no opportunity nor time of using this instrument.

The gypsea, which consists of lime and the vitriolic acid, are not in the least attacked by the acid of nitre, if they contain a sufficient quantity of their own acid; because the vitriolic acid has a stronger attraction to the lime than the acid of nitre: but if the calcareous subsistence is not perfectly saturated with the acid of vitriol, then an effervescence arises with the acid of nitre, more or less in proportion to the want of the vitriolic acid. These circumstances are often very essential in distinguishing the calcarea and gypsea from one another.

The acid of nitre is likewise necessary in trying the zeolites, of which some species have the singular effect to dissolve with effervescence in the above-mentioned acid; and within a quarter of an hour, or even sometimes not until several hours after, to change the whole solution into a clear jelly, of so firm a consistence, that the glass wherein it is contained may be reversed without its falling out.

If any mineral body is tried in this menstruum, and only a small quantity is suspected to be dissolved, though it was impossible to distinguish it with the eye during the solution, it can be easily discovered by adding to it ad futuratem a clear solution of the alkalii, when the dissolved part will be precipitated, and fall to the bottom. For this purpose the solid foce may be very useful.

The acid of nitre will suffice for making experiments upon flones and earths; but if the experiments are to be extended to the metals, the other two acids are also necessary.

Another instrument is likewise necessary to a complete

MINERALOGY.

Part I.

Mort le ores, may be separated from each other, and from the adherent rock, by means of water. This trough is very common in laboratories, and is used of different sizes; but here only one is required of a moderate size, such as 12 inches and a half long, three inches broad at the one end and one inch and a half at the other end, sloping down from the sides and the broad end to the bottom, where it is three quarters of an inch deep. It is made of much smaller dimensions. It is commonly made of wood, which ought to be chosen smooth, hard, and compact, wherein are no pores in which the minute grains of the pounded matter may conceal themselves. It is to be observed, that if any such matter is to be washed as is suspected to contain some native metal, such as silver or gold, a trough should be procured for this purpose of a very shallow slope; because the minute particles of the native metal have then more power to assemble together at the broad end, and separate from the other matter.

The management of this trough, or the manner of washing, consists in this: That when the matter is mixed with about three or four times its quantity of water in the trough, this is kept very loose between two fingers of the left hand, and some light strokes given on its broad end with the right, that it may move backwards and forwards; by which means the heaviest particles assemble at the broad and lower end, from which the lighter ones are to be separated by inclining the trough and pouring a little water on them. By repeating this process, all such particles as are of the same gravity may be collected together, and separated from those of different gravity, provided they were before equally pounded: though such as are of a clayey nature, are often very difficult to separate from the rest, which, however, is of no great consequence to a skilful and experienced washer.

The washing process is very necessary, as there are often rich ores, and even native metals, found concealed in earths and sand in such minute particles as not to be discovered by any other means.

SECTION III. Description of an Improved Portable Laboratory for Assaying Minerals.

The chief pieces and implements of the portable laboratories are represented in Plate XCIX. at Blow-Pipe, and in Plate CCCXIII. annexed to the present article.

1. The first contains those belonging to the Dry Laboratory, so called on account of its containing whatever is required to try all kinds of faults in the dry way by fire, without any of the humid memorandum. They are made to pack in a box of the size of an odlavo book, lined with green velvet, and covered with black fish-skin; the inside divided into different compartments, suited to the size, form, and number of the implements it is to contain. Of these the principal are described under Blow-Pipe. We must here, however, add the following remarks and alterations of that instrument by Mr Magellan.

D and Q (fig. 13.) are the two pieces that form the blow-pipe, which is here represented entire. This very useful instrument has been considerably improved of late in England. The mouth-piece aa is made of ivory, to avoid the disagreeable sensation of having a piece of metal a long time between the teeth and lips, which, if not of silver or gold, may be very noxious to the operator; a circumstance that has been hardly noticed before.

1. If the mouth-piece aa be made of a round form, it cannot be held for any length of time between the teeth and lips, to blow through it, without flaining the muscles of the mouth, which produces a painful sensation. It must, therefore, have such an external figure, as to adapt itself accurately to the lateral angles of the lips, having a flattish oval form externally, with two opposite corners to fit those internal angles of the mouth, when it is held between the lips, as may be seen in that represented in the figure.

2. The small globe b is hollow, for receiving the moisture of the breath; and must be composed of two hemispheres, exactly screwing into one another in BB; the male-screw is to be in the lower part, and foldered on the crooked part of the tube QD, at such a distance, that the inside end of the crooked tube be even with the edge of the hemisphere, as represented by the dotted lines in the figure. But the upper hemisphere is to be foldered at the end of the straight tube D. By these means, the moisture arising from the breath falls into the hollow of the lower hemisphere, where it is collected round the upper inside end of the crooked part Q of the blow-pipe, without being apt to fall into it.

3. The small nozzles, or hollow conical tubes, advised by Meflrs Engeftrom, Bergman, and others, are wrong in the principle; because the wind that paffes from the mouth through such long cones loses its velocity by the lateral friction, as happens in hydraulic spouts; which, when formed in this manner, do never throw the fluid so far as when the fluid paffes through a hole of the same diameter, made in a thin plate of a little metallic cap that screws at the end of the large pipe. It is on this account that the little cap s is employed, having a small hole in the thin plate, by which serves as a cover to it; and there are several of these little caps, with holes of smaller and larger sizes, to be changed and applied whenever a flame is required to be more or less strong.

4. Another convenience of these little caps is, that even in case any moisture should escape falling into the hemisphere bb, and pass along with the wind through the crooked pipe Q, it never can arrive at nor obstruct the little hole of the cap s, there being room enough under the hole in the inside, where this moisture must be stopped till it is cleaned and wiped out.

The stream of air that is impelled by the blow-pipe (as seen in fig. 3.) upon the flame, must be constant and even, and must last as long as the experiment continues to require it. This labour will fatigue the lungs, unless an equal and uninterrupted inspiration can at the same time be continued. To succeed in this operation without inconvenience, some labour and practice are necessary, as already explained under the detached article.

Every assay ought always to begin by the exterior flame, which must be first directed upon the mass under examination; and, when its efficacy is well known, then the interior blue flame is to be employed.
Part I.

27. Vitriol of iron (cop-
28. Nitrous solution of permu-
per.)
31. Phlogisticated alkali.
32. Lime-Water.
33. Lime-water phlogisti-
34. Caustic volatile alkali,
cated by the Prussian blue.
35. Mild volatile alkali.
36. Rectified spirit (al-
37. Ether.
38. Spirituous tincture
of galls.

The following tests are very useful for these alloys, viz. 39. Spirituous solutions of soap; 40. Spirituous solution of violets; 41. Tincture of limes; 42. Tincture of Brail
wood; 43. Tincture of turmeric; 44. Oil of olives;
45. Oil of linseed; 46. Oil of turpentine; 47. Essential oil of wild-foreset; 48. Hepar sulphuris; 49. Sugar of lead; 50. Solution of alum.

The method of applying the above tests of acids and re-agents may be seen in Bergman’s treatises of the Analysis of Waters, and of Affaying by the Hu-
mid Way; in Kirwan’s Elements of Mineralogy; in the Elements of Chemistry of Dijon; in the Memoirs of the same Academy; in Fourcroy’s Lectures of Chem-
istry, &c.

III. The Lamp-furnace Laboratory, for experiments both by the humid and the dry way, is a very curious and useful, though small apparatus. It is an improvement of that which was contrived by M. de Mercutie, in con-sequence of the information he received from his friend the president de Viry, who, at Upsal how advantageously the late eminent professor Bergman availed himself of this convenience for many analytical procexes in miniature, by the use of very small glass vessels about one inch diameter, and other implements of proportional size, for performing various chemical operations. (See the Dijon Memoirs for 1783, Part 1, p. 171.)
There can be no doubt but that whenever these proceeees are properly conducted, though in miniature, the lamp-furnace will prove amply sufficient to perform in a few minutes, and with very little expense, the various solutions, digestions, and distillations, which otherwise would require large vesseis, hlls, retorts, reverberatory furnaces, &c. to ascertain the component parts of natural bodies: though it is not always sufficient to ascertain their proper quantities. In this last case, operations must be performed in great laboratories, and on a large scale, at a considerable expense. But the substances are sometimes too valuable; as, for instance, when precious stones are examined; and of course the last way never can be attempted in such cases.

These small processes have likewise another advantage before noticed, which cannot be obtained in works at large. It confines in one's being able to observe the gradual progress of each operation; of easily retarding or urging it, as it may require; and of ascertaining at pleasure each step of every experiment, together with the phenomena attending the same.

The large round cavity in the middle of the parallelogram, fig. 5, is to receive the lamp \( L \), fig. 3, when all the implements are packed up in their case of black silk skin: and the cover of the lamp is represented by, fig. 12.

But if the operator has the double bellows, fig. 14 and 15, he fixes them, at a due distance, to the stand by the brass clamp \( y \). He then uncrews the tube pipe at \( s \), joins the mouth \( n \) of the flexible tube of the hemispherical receiver, passing each orifice through the leather tube fig. 11, and tying both ends with waxed thin pack-thread. If he works with his foot on the pedal, the string of which is seen hanging from the end of the bellows, fig. 15. (and is always up, on account of the weight \( z \), then the air is absorbed by the bellows fig. 15 from whence it is propelled by the motion of the foot on the pedal to the bellows, fig. 14. whose constant weight \( r \) drives it out through the flexible pipe, fig. 10. It of course enters the curved piece \( x \) of the blow-pipe, and drives the flame up to the piece \( m \) of the ore, that is to be examined upon the charcoal.

[N. B. 1. This double bellows is packed up by itself in a mahogany case, about 9 inches long, 6½ wide, and about 3½ deep, outside measure. 2. The leaf blowing bellows, fig. 14, has an inside valve, which opens when the upper surface of it is at its greatest height; in order to let the superfluous air escape out, as it would otherwise Issue with great velocity out of the tube, fig. 11, and spoil the operation.] If the operator chooses to apply the vital or dephlogisticated air in his process, let him fill the glass jar \( b \), fig. 17, with this air; and put it within the tube marked by \( abeh \), filled with water, fastening the neck of the jar within by a cross-board \( cd \), which has a hole in it for that purpose: then introducing the two ends of the flexible hollow tube, fig. 16, both to the mouth of the jar and to the hole of the bellows fig. 15, he opens the hole \( m \) of the jar, that was stopped with the stopple \( n \); the column of the water passes in through \( m \), and forces up the vital air, which enters the bellows, and of course, by the alternate motion of the pedal, passes through the end of the blow-pipe, to urge the flame upon the piece of ore \( m \), fig. 2, on the charcoal \( g \). But the dephlogisticated air may be also received at the same time that it is produced, by tying the pipe, fig. 16, to the mouth of an earthen retort, or even of a glass retort well-coated, according to the method of Mr Willis, described in the Transactions of the Society of Arts, Vol. V. p. 96. This leaf confines in dissolving two ounces of borax in a pint of boiling water, and adding to the solution as much flaked lime as is necessary to form a thin paste. This glass retort is to be covered all over with tins, by means of a painter's brush, and then suffered to dry. It must then be covered with a thin paste made of linseed oil and flaked lime, except the neck that enters into the receiver. In two or three days it will dry of itself; and the retort will then bear the great fire without cracking. Two ounces of good nitre being urged in the retort, by a good fire on a chafing-dish, will afford about 700 or 800 ounce-measures of dephlogisticated air.

To make any other kind of chemical affairs, the forceps of fig. 2, which supports the charcoal, is taken off by uncrewing the screw \( b \); the blow-pipe is also taken off, by loofening the screw \( n \); the hoop fig. 7, is put in its place, where the metallic basin of fig. 19, is put filled with sand; the piece of fig. 8, is fast on the other pillar \( r \), fig. 1, to hold the matras, fig. 18, upright, or the receiver fig. 20, &c.

In the same manner, the retort, fig. 9, may be put in the sand-bath instead of the matras, with its receiver fig. 20, which may be supported on a bit of cork or wood, hollowed to its figure, and held by the pillars, instead of the charcoal fig. 2.

But if the operation is to be made in the naked fire,
MINERALOGY.

PART II. ARRANGEMENT (A) of MINERAL BODIES (B).

The bodies belonging to the mineral kingdom are divided into four different classes, viz.

1. **Earths** (c), or those substances which are not ductile, are mostly indiffusible in water or oil, and preserve their constitution in a strong heat.

2. **Salts**: these diffuse in water, and give it a taste; and when the quantity of water required to keep them in diffusion is evaporated, they are solidified again into solid and angular bodies.

3. **Inflammables**, which can be diffused in oils, but not in water, and are inflammable.

4. **Metals**, the heaviest of all bodies: some of which are malleable, and some can be compounded.

Here, however, it must be observed, that these classes are unavoidably blended one with another; and therefore some exceptions must be allowed in every one of them: for instance, in the first class, the calcareous earth is in some measure diffusible in water, and pipe-clay with some others diminish somewhat in their bulk when kept for a long time in a calcining heat.

In the third class, the calx of arseneous has nearly the same properties as salts; and there is no possible definition of salt that can exclude the arseneous, though at the same time it is impossible to arrange it elsewhere than among the semimetals. In the fourth class, it is to be observed, that the metals and semimetals, perfect or imperfect, have not the same qualities common to them all, because some of them may be calcined, or deprived of their phlogiston, in the same degree of fire in which others are not in the least changed, unless particular artificial processes are made use of: of some of them also may be made malleable, while others are by no means to be rendered so. That the convex surface metals take after being melted, is a quality not particularly belonging to them, because every thing that is perfectly fluid in the fire, and has not an attraction for the vessel in which it is kept, or to any added matter, takes the same figure, as we find borax, 

---

(a) According to the system of Cronfield; (b) altered, augmented, and improved from the Observations of other Mineralogists.

(b) Of the different bodies enumerated in the following classification, full explanations are given under their respective names as they occur in the course of this Work. See also Metallurgy, and Chemistry.

(c) By *earths* the author (Mr Cronfield) does not mean (strictly speaking) only earths, but includes under that title all the kinds of stones or solids not inflammable, saline, or metallic.

---

Notes:

- The text is a continuation of the discussion on the use of small retorts and receivers for chemical operations, emphasizing the importance of proper equipment and safety measures.
- It highlights the need for careful handling and selection of apparatus to ensure successful chemical reactions, particularly in the context of mineral and earth sciences.
- The text also mentions Morveau's observations on the expense of chemical operations, noting that they are more manageable for smaller scale experiments.
- The section on mineral bodies classifies them into four main categories: earths, salts, inflammables, and metals, each with distinct properties and uses.

---

**Summary:**

- The text is focused on the practical aspects of chemical operations, particularly with respect to the use of retorts and receivers.
- It underscores the importance of choosing appropriate glassware and apparatus for different types of chemical processes.
- The discussion includes observations on the cost and efficiency of chemical operations, as well as the practicalities of managing various types of mineral bodies in the laboratory environment.
MINERALOGY.

Part II.

Class I. Earths.

Earths, are those mineral bodies, not ductile, for the most part not dissoluble in water or oils, and which preserve their constitution in a strong heat.

(b) Calcaneous earth is most commonly found in the form of limestone; hard, compact, and of various colours; under which general name may be comprehended all the different kinds of marbles. Near Bath in England is found a kind of grey stone, rather softer than hard. This contains calcaneous earth in a mild state, and likewise some in a state of causticity: hence, when newly dug out of the earth, it will dissolve sulphur, or make lime-water without any calcination. By attraction of fixed air from the atmosphere, it soon hardens after it has been dug up.

Mr. Williams divides the lime-stones of Scotland into the following species:

1. Grey, whitish, and pure white; regularly stratified, of a granulated texture; and much used in the Highlands and building bridges. Some of it is composed of fine glittering spangles like the scales of fishes; and some is as pure white as the best refined sugar, which kind he thinks may be called Parian marble.

2. Coarse-looking grey mountain-limestone, hard and strong, of a granulated texture, difficult to work, in some places rough and unequal, in others smooth and even. Sometimes regularly stratified, at other times appearing like one vast irregular bed or rock, of various thicknesses.

3. Ash-coloured mountain-limestones, consisting of small grains of a fine smooth texture; when broken resembling flint. In the Highlands there are hills of this kind of stone, which our author informs us he has seen; some of which have regular strata, while others appear in one vast mass as a rock of granite.

4. Regularly-stratified lime-stone, found in the low countries, exhibiting a vast variety of colours; as black, blue, grey, brown, purple, red, and ash-coloured; with various mixtures, of all degrees of hardness and purity.

5. Lime-stone accompanying coal, and frequently the immediate roof of the vein. This likewise shows a great variety of colour, texture, and quality; some being so much adulterated with clay and other heterogeneous mixtures as to be good for nothing, while others are very pure and fine. These lime-stones are always found in regular strata. "They are found (says our author) as regular as the coals they accompany; and the coal-strata are more regular in continuation upon the bearing, as far as the class of strata belonging to the coal reaches, than any other that I have investigated; and I look upon it, that this observation may be of use in practice."

For discovering limestone at some distance, Mr. Williams gives the following directions:—Let them keep the line of the stretch, or bearing of the strata; and in the coal-country, they will be sure to discover it at nearly the same parallel distance from a seam of coal or other given stratum, as the place where it was last seen. But many of the mountain-limestones are not much to be depended on. Though you may have a good and plentiful quarry in one place, yet, perhaps, half a mile, or half a quarter of a mile farther forward, you cannot discover it; it is dwindled away to nothing, and yet will appear again farther forward; which makes the mountain-limestones uncertain to be discovered where you do not see them; as these rocks very frequently grow thicker or thinner, and sometimes squeeze out to nothing: and I comprehend under this denomination all the limestone not accompanying the coals and coal-metals.—The lime-stones of the coal fields are often distinguishable by containing a great variety of shells, coral, and other marine bodies, which are found blended in the heart and composition of the stone.

6. The Scotch marbles are of great variety and beauty; and the parts of the kingdom most unfit for cultivation are found to abound most in them. Afllint in Sutherland has a kind of white statuary marble, which Mr. Williams says is the purest and best he ever saw. "I am persuaded (says he) there is none better, if any so good, in all Europe, and there is enough of it to serve all Britain; perfectly solid and pure, free of any blemishes, flaws, or flaws, and blocks or slabs of any size may be cut out: but there is bad access to it; nor would it be easily quarried, there being a little cover above it, of a soft, loose, whitish limestone. This marble accompanies a prodigious rock of grey limestone, of a granulated texture, appearing in regular strata at Afllint; but it is one of those which varies in thickness as you advance along the bearing of the strata. The good white marble of Afllint is only to be seen in the bed of the river, near a considerable house a mile or two south of the church; but I cannot remember the name of the particular place."

Near Blairgourie in Perthshire, not far from the side of the high road, is an excellent, granulated, broad bedded limestone, of a sugar-loaf texture, and as white as the finest statuary marble, which Mr. Williams approves to be a good species of the true Parian marble, and that it requires only to be known and brought into use to become of great value. In the Duke of Gordon's lands, in the forest of Glenavon, there is also a kind of marble composed of broad glittering grains like spangles, as large as the scales of fishes; but the situation is remote, and difficult of access.
Part II.

MINERALS.

Clastic Earths.

1. Fine grained.
   - White. b. Semi-transparent, from Solothurn in Italy, in which native brimstone is found.

2. Very fine grained.
   - White and green. b. White and black.

C. Scaly limestone.
   1. With coarse or large scales.
      a. White. b. Reddish yellow.
   2. With small scales.
      a. White.

3. Fine glittering or sparkling.

D. Lime or calcareous spar.
   1. Transparent or diaphanous.
      a. Transparent or diaphanous.
   2. Common spar, which shows the object single.
      a. White, or colourless.
      b. Yellowish and phosphorescent.

E. Crystallized calcareous spar. Spar, Druzen (s).
   1. Transparent.
      a. Hexagonal truncated.
      b. Pyramidal.
      1. Dog's teeth; Pyramidulae dentatae.
      2. Balls of crystallized spar, Pyramidulae conica.

F. Stalactitical spar; Stalactites calcareus. Stalacities.
   1. Scaly stalacities of very fine particles.
      a. Of a globular form.
   1. White, the pea-flake.

II. Serta.

In Lochaber, near the farm houses on the north side of the ferry of Ballachyleith, is a limestone or marble rock, of a beautiful athen-grey colour, and a fine regular uniform grain or texture; capable of being raised in blocks or slabs of any size, and of receiving a fine polish. It is beautifully sprinkled with fine bright grains of mawick or pyrites, and likewise with grains or specks of beautiful lead ore of a fine texture.

About three miles south of Fort-Wilhelm, in the bed of a river, is a curious kind of marble with a black ground, flowered with white, like fine needle-work, or rather resembling the froth-flowering upon glass windows in winter; and this flowering is not only on the outside, but quite through all parts of the body of the stone.

Scotland has also chalk in abundance; some of which is regularly stratified, and much appears in thick irregular masses like sediment.

The translator of Mr. Cronfield's Treatise has adopted this German term groupen into the English language, for a cluster of regular figured bodies, as a group conveys the idea of a cluster only, whether regular or of indeterminate figures.

**Gypsum**

1. **Sparry Gypsum**
   - With fine fibres
   - White

2. **Selenite**
   - By some called *glacies mariae*
   - Pure selenites
   - Transparent
     - Yellow

**Calcereous Earths**

1. **Gypsum, Plaster-stone, or Parget.**
   - Loose and friable than a pure calcareous earth.

2. **Indurated.**
   - When burnt, without being red hot, its powder readily concretes with water into a mass, which soon hardens; and then,

3. **It readily falls into a powder in the fire.**

4. **Burnt**
   - Without being red hot, its powder readily concretes with water into a mass, which soon hardens; and then,

5. **No heat is perceived in the operation.**

6. **It is nearly as difficult to be melted by itself as the lime-stone, and shows mostly the same effects with other bodies as the lime-stone:**

7. **The acid of vitriol.**

8. **Gypsum combined with or saturated with the acid of common salt.**

9. **Of no visible particles; in French, *grignard.***

10. **Of a transparent figure.***
    - Yellow

11. **Of a sparry-like texture.***
    - White and yellow

12. **Of an irregular figure.***
    - White

**Calcereous Earths Saturated with the Acid of Common Salt.**

1. **Sal ammoniacum fixum naturale.***

2. **This is found:**
   - In sea-water
   - In salt-pits

**Calcereous Earth Combined or Saturated with Sparry Acid.**

1. **Globular, consisting of cuneated rays proceeding from the centre.***

2. **Stalactitical Gypsum.***

3. **Called fluxing, vitreous, or glassy sars; because most part of them have a sparry form and appearance:**

4. **They are only known in an indurated state, and distinguish themselves from the other earths by the following characters:**

   1. They are scarce harder than common calcareous sars, and consequently do not strike fire with steel.
   2. They do not ferment with acids neither before nor after calcination.
   3. They do not melt by themselves, but crack and split to pieces when exposed to a strong fire. But,
   4. In mixtures with all other earths they are (generally) very fusible, and especially with calcareous earth, with which they melt into a corroding glass that dissolves the strongest crucibles, unless some quartz or apyrous clay be added thereto.
   5. When heated slowly, and by degrees, they give a phosphorescent light; but as soon as they are made red-hot, they lose this quality. The coloured ones, especially the green, give the strongest light, but none of them any longer than whilst they are well warm.
   6. They melt and dissolve very easily by the addition of borax, and next to that, by the microcosmic salt, without effusion.

**Indurated Fluor.***

1. **Loose and friable.**

2. **Gypsum earth, properly so called; *gabra.***

3. **Indurated.**
   - Solid, or of no visible particles, Alabaster.
     - White, alabaster
      - Clear and transparent
      -Opaque
      -Transparent, from the Eastern countries
   - Opaline

4. **Gypsum of a scalled or granulated structure.***
   - This is the common plaster-stone.
     - With coarse scales
     - With small scales
   - Fibrous gypsum, or plaster-stone, improperly (though commonly) called *English talc* by the druggists.

5. **When the fibres coarse.**
   - White, from Livonia.
Part II.

MINERALOGY.

Calcereous Earths.

1. Solid, of an indeterminate figure; of a dull texture, semitransparent, and full of cracks in the rock.
   a. White.

2. Sparry fluor. This has nearly the figure of spar; though on close observation it is found not to be so regular, nothing but the glossy surfaces of this stone giving it the resemblance of spar.

3. Crystalised fluor.
   2. Of a cubic figure. a. Yellow. b. Violet.

V. Calcereous earth saturated with a particular acid, perhaps of the metallic kind, viz. the tungstic acid. The tungsten of the Swedes.

This resembles the garnet-stone and the tin-grains; is nearly as heavy as pure tin; very refractory in the air, and excessively difficult to reduce to metal. Iron has, however, been melted out of it to more than 30 per cent.

It is very difficultly dissolved by borax and the nitric acid.

The specimen united in this manner with the calcereous earth, being dark or black in proportion as the phlogiston, gives a black earth. They receive their colour from the phlogiston, being dark or black in proportion as the phlogiston predominates.

1. Solid and fine-grained.
   a. Reddish or fisch-coloured. b. Yellow.
2. Spathose, and with an uneven surface.
   a. White. b. Pearl-coloured.

VI. Calcereous earth united with the inflammable substance.

These have a very offensive smell, at least when rubbed. They receive their colour from the phlogiston, being dark or black in proportion as it predominates.

Calcereous earth mixed with phlogiston alone; Lapis saullus, fetid stone and spar, or swine-stone and spar.

A. Solid, or of no visible or distinct particles.
   a. Black.
   B. Grained.
   a. Blackish brown.
   C. Scaly, particulis micaceous.
      1. With coarse scales. a. Black.
   D. Sparry.
   E. Crystalised.
      1. In a globular form.

VII. Calcereous earths blended with an argillaceous earth. Marle, Marga.

1. When crude, it makes an effervescence with acids; but,
2. Not after having been burnt; by which operation it is observed to harden, in proportion as the clay exceeds the calcereous substance.
3. It easily melts by itself into a glass, and even when it is mixed with the moft refractory clay.
4. It is of great use in promoting the growth of vegetables, since the clay tempers the drying quality of the calcereous earth.

Vol. XII.

5. When burnt in a calcining heat, it readily attracts water; and, exposed to the air, in time it falls into a powder.

The varieties of this kind worthy to be taken notice of, depend on the different quantities of each of their component parts, and on the quality of the clay. The following are specified as examples.

A. Loose and compact, Marga friabilis.
   a. Reddish brown.
   b. Pale red. This, when burnt, is of a yellowish colour, and used for making earthen ware in fome places.

B. Semi-indurated; which is nearly as hard as stone when first dug up, but moulders in the open air.

C. Indurated or stone marle.
   a. In loose pieces, Marga indurata amorpha; by the Germans called duckstein or topfein.
      a. White. b. Grey, formed from a sediment which the water carries along with it.
   b. In continued strata. Hard flaty marle.

VIII. Calcereous earth united with a metallic calx.

Here, as well as in the others, such a mixture or combination is to be understood, as cannot be discovered by the eye alone without the help of some other means.

The subjects belonging to this division lose the property of raising an effervescence with acids, when they are rich in metal, or contain any vitriolic acid. However, there have been found some that contained 30 or 30 per cent. of metal, and yet have shown their calcereous nature by the nitric acid.

There are no more than three metals hitherto known to be united in this manner with the calcereous earth, viz.

1. With iron. White spar like iron ore, Minera ferri alba. The flamblein or weisse eisenerz of the Germans.
   1. This ore, however, is not always white, but commonly gives a white powder when rubbed.
   2. It becomes black in the open air, as likewise in a calcining heat.
   3. In this last circumstance it loses 30 or 40 per cent. of its weight, which by distillation has been found owing to the water that evaporates; and it is possible that some small quantity of vitriolic acid may, at the same time, evaporate with the water.
   4. It is of all the iron ores the most easy to melt, and is very corrosive when melted.

This kind is found,

A. Loose; the moulder part of the indurated fort.
   a. Black, like foot.
   b. Dark brown, somewhat resembling umbre.

B. Indurated.
   1. Solid, of no distinct particles.
      a. Red. Looks like red ochre, or the red haematites, but dissolves in the acid of nitre with a great effervescence.
   2. Scaly, particulis micaceous.
      a. White.
      b. Blackish grey.
      a. Light brown.

K 4. Drufen.
IX. The following compounds of calcareous earth with different mineral substances are added from Mr Kirwan's Elements of Mineralogy.

1. A compound of calcareous and argillaceous earths; such as,
   a. The green Campan marble from the Pyrenees. It is flinty and somewhat magnetic. According to Mr Bayen, it contains 65 parts of mild calcareous earth, 32 of the argillaceous, and 3 of semiphlogilicated iron.

2. Compounds of calcareous and argillaceous earths; such as,
   a. The red Campan marble: this is not magnetic; it contains 82 parts of mild calcareous earth, 11 of argillaceous flint, and 7 of semiphlogilicated iron.

3. Compounds of calcareous earth, mixed with two or more kinds of earth; such as,
   a. The cipolin from Rome. This is a green marble, which contains 87 parts of mild calcareous, 25 of quartz, 8 of flint, and 0.2 of iron, besides the iron contained in the argillaceous flint.

4. Compounds of calcareous earth and mica; such as,
   a. The cipolin from Autun in France: it is of a green colour, and consists of 83 parts of chalk, 12 of green mica, and 1 of iron.

5. Compounds of calcareous and felsiferous earths; such as,
   a. The pietra talchina of the Italians, which consists of white fspar with veins of talc.
   b. The piemontina of the French, which consists of white fspar with veins of talc.
   c. The pietra signore di Siena, which consists of white fspar with veins of talc.

6. Calcareous volcanic pudding-stone; such as,
   a. The cipolin from Java, in a calcareous cement, mentioned by Mr Feri.
   b. The marble mixed with veins of black or green lava, mentioned by the same author.

7. Compounds of calcareous earth, mixed with two or more kinds of earth; such as,
   a. The cipolin from Rome, which is a green marble with white zones: it strikes, though difficultly, fire with fivel; it contains 67.8 parts of mild chalk, 25 of quartz, 8 of flint, and 0.2 of iron, besides the iron contained in the argillaceous flint.

b. The calcareous porphyry, which consists of quartz, fivel-fspar, and mica in separate grains united by a calcareous cement.

b. The limefl:one interfpered with fivel and mica.

d. To these compounds belongs the pyritaceous limefl:one called by the French Pierre de St Ambroise. It is of an iron grey colour, interfpered with shining particles. Its texture is compact, and fiercely gives fire with fivel. Its specific gravity is 2.7034. It is soluble in acids, and melts with effervescence; calcines in a strong fire; makes nitre slightly detonate; and if distilled affords a small portion of vitriolic acid, and some sulphur sublimes. Its component
Part II. MINERALOGY.

Order II. Ponderous Earth.

Ponderous earth, (Terra Ponderosa): Caüx, or chalk. See Earth, Art. I. This is a particular kind of earth (like chalk in appearance, but with some very different properties), discovered in Sweden about 1774, which by its results with other bodies has some similarity to the known alkalis. It has not yet been found pure, but mixed with other substances; however, its great specific weight easily distinguishes it from the others, it being the heaviest of all earths.

1. Its specific gravity when considerably purified by art is 3.775.
2. This earth combines with aerial acid: and in this case effervesces with stronger acids.
3. With vitriolic acid it forms the ponderous spar, which is insoluble in water.
4. Its crystallization, after being combined with the nitrous, or with the muriatic acids, is hardly soluble;
5. But with acetoic acid, it becomes deliquescent.
6. When pure; viz. without any mixture of acid or alkali, it does not vitrify in the fire.
7. If deprived of the aerial acid (fixed air) by calcination, is then soluble in 900 times its weight of boiling water. This solution exposed to air, forms a cream, like that of lime-water in the same circumstances, and like it changes also the vegetable colours.
8. Whilt combined with aerial acid, it is only soluble in about 1500 times its weight of water, chiefly if the water has been impregnated also with the same aerial acid.
9. It expels the caustic volatile alkali from ammoniacal salt.
10. Mixed with brimstone it produces a heparr sulphuris, whose solution in water is but incompletely decomposed either by the nitrous or the muriatic acid, on account of the great attraction between this earth and the acid of sulphur, which is so strong that it
11. Separates this acid (the vitriolic) from the vegetable alkali.

I. Combined with aerial acid; Terra Ponderosa aerata. See Chemistry-Index.

A. Spar-like gypsum.
1. Samitranparent, fratum Bononiense. The Bononian stone, or native phosphorus.
B. Ponderous Drufen spar.
1. Jagged, crista ram. These resemble cock's combs, and are found in clots and fissures accreted on the surfaces of balls of the same substance.
2. White.
3. Reddish.
II. United with phlegiston and the vitriolic acid.

Order III. Magnesian, Micaceous, and Asbestine Earths.

§ 1. Magnesian Earths.

Magnesia is a white, loose, and light earth, only known since the beginning of this century. It is generally found combined or mixed with other heterogeneous substances, as other simple earths are.

1. When pure its specific gravity is 2.330, and then,
2. It neither hardens, contracts, nor melts by the application of heat, even by the solar rays.
3. But it melts afly with borax, or microcosmic salt; though it is scarcely affected by fixed alkalies or calces of lead.
4. Mixed with other earths, it produces by fire different hard mafises.
5. It gives no causticity except to the volatile alkali: and,
6. Does not effervescce with any acid.
7. When mixed with water it shows a very small degree of heat, but without any effervescence. And when the water exceeds the weight of magnesia about 7.692 times, it is totally dissolved.
8. and 9. Being put in water and afterwards dried, it contains 878 parts of its weight; though when saturated with aerial acid, it will absorb and retain after being dried 88 parts of water.
10. This earth combined with aerial acid is more soluble in cold than in hot water.
11. Combined with vitriolic acid it crystallizes into a bitter salt, known by the name of Epfom and Seydilite or Stiebelichte salt, which is soluble in little more than its own weight of water.
12. With nitrous acid it forms a deliquescent salt.
13. With the muriatic or the acetoic acids it does not crystallize: and the mafs being dried, attracts humidity from the air.
14. It has a stronger attraction to the fluor acid than to any other (Berg.): and crystallizes with it into hexagonal prisms whose ends are formed of two low pyramids, of three rhombs (Romb de l'Ille).
15. It is not precipitated from other acids by the vitriolic, as calcareous earth is.
16. According to Lavoisier and Macquer, when magnesia is calcined, it becomes phosboroececent.

I. Magnesia combined with vitriolic and other acids.

A. When satureted with the vitriolic acid, it forms a bitter salt, called English or Epfom, Seyfburn or Seldrite salt. The salts known under these different
M I N E R A L O G Y.

Part II.

Magneisia.

Mineral Earths.

ferent names only differ from one another on account of some heterogeneous substance, which is combined in them, the vitriolated magnesia being the characteristic and principal ingredient in them all.

B. Magnesia is found not only combined with the vitriolic acid in the waters of Epfom, Sedlitz, &c., but also with the marine acid to a considerable quantity in sea-water and other salt springs.

C. It is contained frequently in fresh waters, where it is dissolved by means of a quantity of aerial acid.

II. Combined with other earths.

A. Magnesia, when combined with siliceous earth, is commonly unctuous to the touch, and more or less difficult to be cut or turned in proportion to its different degrees of hardness.

It is not diffusible in water: grows hard, and is very refractory in the fire.

When pounded and mixed with water, it will not easily cohere into a paste; however, if it is managed with care, it may be baked in the fire to a mass, which being broken, shows a dull and porous texture.

It takes for the most part, and without much labour, a fine polish. It is found,

1. Compact and soft; Smetllis, Briosaon or French chalk.
   a. White, from the Lands-End, in Cornwall.
   b. Yellow.

2. Solid and compact; of impalpable particles; Steatites or soap-rock.
   c. Yellow.

3. Solid, and of visible particles; serpentine stone.
   a. Of fibrous and coherent particles. This is composed, as it were, of fibres, and might therefore be confounded with the asbestos, if its fibres did not coalesce with one another, as not to be seen when the stone is cut and polished. The fibres themselves are large, and seem as if they were twisted.
   b. Deep green. It is sold for the lapis naphricus, and is dug at some unknown place in Germany. b. Light green, from Skienflyttan, in Weftmanland; is used by the plate-smiths instead of French chalk.
   r. Of granulated particles; fine grained serpentine stone; the Zoeblitz serpentine.
   a. Black. b. Deep green. c. Light green. d. Red. e. Bluish grey. f. White. These colours are all mixed together in the serpentine stone from Zoeblitz, but the green is the most predominant colour.

B. Porcelain earth mixed with iron; terra porcellana.

This is,

a. Diffusible in water.
   a. Red, from Montmartre, and China. The water-clinkers which are imported from certain places in Germany seem to be made of this kind.

b. Indurated.
   1. Martial soap earth.
      a. Red.
      b. Martial soap-rock.
   C. The telugite of the Swedes; lapis ollaris.

The serpentine stone has many varieties; being found, (1.) Veined or spotted with green fleasites. (2.) Red, with veins of asbestos. (3.) Red, green, yellow, or black with spots or white calcareous spar, is called patevera. The black is called muro di prato; the green verde di Siena; but these names are not restricted to this species. (4.) Veined or spotted with gypsum. (5.) Veined or spotted with bariferite. (6.) Veined or spotted with shifus.—And, (7.) With veins of quartz, feldspar, or fheer. (Kirwan's Mineralogy.)

What is commonly called serpentine is a true lapis ollaris; but being variegated with green, yellowish, and brown spots, like the skin of some common serpents, it is called by that name. Great quantities of this stone are found in Italy and Switzerland, where it is often worked into the shape of dishes and other vases. (Fr. bro.) And the gato of the Italians is nothing else but a kind of serpentine. (Kirwan.)

These are known by the following characters:

1. Their texture and composition consist of thin flexible particles, divisible into plates or leaves, having a shining surface.

2. These leaves or scales exposed to the fire lose their flexibility and become brittle, and then separate into inner leaves: but in a quick and strong fire, they curl or crumple, which is a step towards fusion; though it is very difficult to reduce them into pure glass by themselves or without addition.

3. They melt pretty easily with borax, the microcosmic salt, and the alkaline salt: and may by means of the blow-pipe be brought to a clear glass with the two former salts. The martial mica is, however, more fusible than the uncoloured ones; its specific gravity is 3.000.

A. Colourless or pure mica; daze, glimmer, or glint.

1. Of large parallel plates; Mufcovy glass. This is transparent as glass; found in Siberia and Elfdalen in the province of Wermeland.

2. Of small plates, from Silverberg, and Runneby, in the province of Blekinge.

3. Of fine particles like chaff; chaffy mica.

B. Coloured and martial glimmer.

2. Of fine and minute scales.

3. Twisted or crumpled glimmer.
   a. Light green.

   a. Black.

5. Chry-
Part II.

MINERALOGY.

Siliceous Earths.

Siliceous earth is, of all others, the most difficult to describe and to distinguish perfectly; however, it may be known by the following characters, which are common to all bodies belonging to this order.

1. In its indurated state it is hard, if not in regard to the whole, yet at least in regard to each particle of it, in a degree sufficient to strike fire with steel, and to scratch it, when rubbed against it, though the steel be ever so well tempered.

2. When pure, and free from heterogeneous particles, it does not melt by itself, neither in a reverberatory nor in a blast furnace.

3. After being burnt, it does not fall to a powder, neither in the open air nor in water, as the calcareous earth does, but becomes only a little looser and more cracked by the fire, unless it has been very slowly, and by degrees, heated.

4. It excites no effervescence with acids.

5. In the fire it melts easier of all to a glass with the fixed alkaline salt; and hence it has got the name of vitreous, though this name is, properly speaking, less applicable to this order than to a great many other earths.

To the above we may add the following properties from Bergman.

6. It is not soluble in any of the known acids, the fluoric acid only excepted. But,

7. It may be dissolved by the fixed alkali, both in the dry and wet way.

8. If the fixed alkali is only half the weight of the siliceous earth, it produces a diaphanous and hard glass: but when it is in a double or triple proportion, then the glass deliquesces of itself by attracting the humidity of the atmosphere.

9. It melts easily with borax; but

10. With microscopic salt it is more difficult, and requires a longer time to melt.

11. This earth has a great analogy to acids, as it is perfectly dissolved in that wonderful natural hot-water spout above ninety feet high at Geyser, in Iceland, where by cooling it forms a siliceous mass.

§ 1. Gems, or precious stones.

I. Diamond. Adamas gemma. — See DIAMOND.

1. Of all stones, it is the hardest.

2. Is commonly clear, or transparent; which quality, however, may, perhaps, only belong to its crystals, but not to the rock itself from which they have their origin.

3. Its specific gravity is nearest 3.5 to. When brought to Europe in its rough state, it is in the form either of round pebbles with shining surfaces, or of crysytals of an octoedrical form.

a. Colourless, or diaphanous, or the diamond properly so called.

But it also retains this name when it is tinged somewhat red or yellow. Being rubbed, it discloses some electrical qualities, and attracts the mastic.

b. Red; Ruby. Adamas ruber; Rubinus.— Which, by lapidaries and jewellers, is, in regard to the colour, divided into

1. The ruby of a deep red colour inclining a little to purple,

2. Spinell, of a dark colour.

3. The bidelberg, pale red, inclining to violet.

4. This is supposed to be the mother of the rubies.

5. The rubicell, reddish yellow.

However, all others do not agree in the characters of these stones.

II. Sapphire. Saphyrus gemma.

It is transparent, of a blue colour; and is said to be in hardness next to the ruby, or diamond.
MINERALOGY.

III. Topaz. *Topazius gemma.*

a. The pure yellow topaz; which is nearly uncoloured.

b. The yellow topaz.

c. Deep yellow, or gold coloured topaz, or oriental topaz.

d. Orange-coloured topaz.

e. The yellowish green topaz, or chrysole.

f. The yellowish green, and cloudy topaz, the *chrysobrese* (a)

g. Bluish green topaz, or the beryl.

This varies in its colours; and is called, when

1. Of a sea-green colour, the *aqua-marina.*

2. When more green, the *beryl.*

IV. Emerald. *Smaragdus gemma.*

Its chief colour is green and transparent. It is the softest of precious stones and when heated it is phosphorescent like the fluor.

V. To the precious stones belong also the jacinths, or byazins; which are chrysolites harder than quartz crystals, transparent, of a fine reddish-yellow colour when in their full lustre, and formed in prisms pointed at both ends; these points are always regular, in regard to the number of the facets, being four on each point; but the facets seldom tally; the sides also which form the main body, or column, are very uncertain in regard both to their number and shape; for they are found of four, five, fix, seven, and sometimes of eight, sides; further the column or prism is in some also so compressed, as almost to resemble the face of a spherical facetted gem.

Mr Cronstedt says, he got some jacinths of a quadrangular figure, which did not melt in the fire, but only became colourless.

VI. The amethyst is a gem of a violet colour, with great brilliancy, and as hard as the best kind of rubies or fapphires, from which it only differs by its colour. This is called the *oriental amethyst,* and is very rare: when it inclines to the purple, or rosy colour, it is more esteemed than when it is nearer to the blue.

These amethysts have the same figure, hardness, specific gravity, and other qualities, as the best fapphires or rubies; and come from the same places, particularly from Persia, Arabia, Armenia, and the West Indies.

The amethysts called *occidental,* are of the same nature as rock crystals, and have the same gradations. viz. of a violet inclining to the purple.

(a) In the *Annals of Chemistry,* Vol. I, we have the following account of the method of digging for the chrysobras, and of the earths and stones with which it is accompanied.

This precious stone is found in certain mountains in Silesia, which seem to begin those of Tradas, extending to within half a league of Olasz. These mountains appear, in general, to consist of a number of strata, horizontal or inclined, composed chiefly of substances containing magnesia, but likewise mixed with calcaceous, argillaceous, and sileceous earths. The greatest part of these consist of serpentine, mixed with albitos and amethysts, grey argillaceous earths, bones, and red or green ochres, flone marrow, fleatites, or soapstone, and tale. In those mountains also we meet with quartz, petroflxer, opal, and chalcedony, in detached fragments, and sometimes in continued veins. We also discover in them veins of silece, of the nature of granite. Sometimes the serpentine is met with at the surface; sometimes at the depth of 20 or 30 feet. The stone marrow seems here to be produced by the decomposition of a very milky species of opal agate named *calcedony:* for at the depth of 50 feet and upwards the veins of this foapy earth assume a degree of solidity, and we find nothing but hard and semitransparent calcedony.

The abovementioned strata are crossed by a great number of cracks filled with green-coloured earths and stones; but these frequently do not contain a single true chrysobras. They are sometimes found immediately under the vegetable mould, or at the depth of some feet, in flapeless masses, covered with a heavy clay, and sometimes enveloped by a stuccous earth of a beautiful green colour, which it derives from the calx of nickel. In other places, the chrysobras has been found in uneven lamina of several yards in length and breadth, either immediately under the mould, or in the upper strata of serpentine, which have little solidity; and very beautiful ones have been found at the depth of seven or eight fathoms; and some have been met with in grey clay at the depth of four fathoms. In some places also they are met with in a kind of red ochre, which is attracted by the magnet; in others they are found in the clefts of rocks. The beautiful green chrysobras is found most plentifully in the mountain of Glassendorf. In another mountain named Kofemutz, where it is also found, the pieces are so porous, and so much spotted with white, &c. that sometimes upwards of 1000 of them have not afforded one large enough for the use of the jewellers. The defects are frequently only discoverable on polishing, as the green opal, while rough, perfectly resembles the chrysobras; but, on polishing the stones in which it is contained, it is detected by its want of lustre.

The quantity in which these stones are found is not sufficient to afford the expenses of regular mining: the most profitable way, therefore, of obtaining them is by making trenches in the earth from four to six feet deep. Almost all the mountain of Kofemutz, however, has already been examined in this manner; so that they now dig for the chrysobras in quarries by uncovering a bank of earth or stone, and descending to other banks by steps in the open air, so as to throw the rubbish back from bank to bank. This method, however, cannot be continued farther than 24 or 30 feet, otherwise the produce would not defray the expense.

The only tools employed in digging for the chrysobras are a spade and pick-axe; the former to remove the earth, the latter to detach the chrysobras itself from the stones which surround it.

Various accounts have been given of the component parts of this precious stone. Lehmann thinks, that
Part II. MINERALOGY

Siliceous Earths.

The garnet, (Grana/tus.) This stone, when transparent and of a fine colour, is reckoned among the gems: but it varies more than any, both in the form of its crystals and in its colour, some being of a deep and dark red, some yellowish and purplish, and some brown, blackish, and quite opaque. In general, their lustre is less than that of other gems, as well as their hardness, which yields to the file, although they may strike fire with steel. But, as to their form, these crystals take almost all sorts of figures, as the rhomboidal, tetradecaedral, &c. and some are of an irregular form.

Their colour proceeds from the iron which enters into their composition; and, according to M. de Saunfure, even the finest oriental garnets attract the magnetic needle at a small distance.

The Syrian garnet is the finest and best esteemed. It is of a fine red, inclining to the purple colour, very diaphanous, but less brilliant than the oriental amethyst. It seems to be the amethyst santant of Pliny: the Italians call it rubino di roca.

The colour of it is owing to some ferruginous particles modified in a particular manner: but the experiments he adduces for this opinion are not satisfactory. Mr. Sage attributes the colour to cobalt from the blue colour it imparts to glasses. Mr. Achard thinks the stone contains calx of copper as well as calx of iron; because a part of the metal separable from it may be dissolved in volatile alkali. The following are the experiments of M. Klaproth upon the subject.

1. On heating pieces of very pure chrysofrofus red hot, and quenching them in water, the colour was changed from green to bluish grey; and, on repeating the operation, it became a white grey. They were found to have lost in weight one and a half per cent. and were easily pulverizable in a glass mortar.

2. Three hundred grains of chrysofrofus were mixed with double its weight of mild mineral alkali, and the mixture heated for some hours red hot, in a porcelain crucible. The mass was then powdered, and digested in distilled water. By filtration, a yellowish grey residuum was obtained, weighing 44 grains; the filtered liquor was limpid and colourless, a copious precipitate being formed with muriatic acid, which being washed and dried was found to be siliceous earth.

3. The 44 grains of yellowish grey residuum were digested in a retort, with 352 grains of aqua regia; a great part of which was evaporated. The acid which came over was returned into the retort, and filtered after a second digestion. The residuum was a very fine white siliceous earth, which, after being washed, dried, and heated red hot, weighed 20 grains.

4. The filtrated solution was of a pale green, but on super saturation with volatile alkali immediately turned of a bluish colour, precipitating a small quantity of brownish gelatinous matter; which, when collected, twice digested with nitrous acid, and afterwards strongly heated, yielded a brown calx of iron, weighing no more than a quarter of a grain: whence our author concludes, that iron does not contribute to the colour of the chrysofrofus, as we know many colourless stones which contain as great a quantity of that metal. This small quantity of calx was left after digesting the gelatinous residuum. On precipitating the soluble parts, they appeared to consist of alumina earth, in an excessively divided state; which being washed and dried, weighed half a grain.

5. To find whether the solution contained calcareous earth or not, he mixed with that, super saturated with volatile alkali, a saturated solution of mild mineral alkali, which precipitated four grains and an half of white and very pure siliceous earth.

6. Nothing more was precipitated from the solution, either by acids or alkalies, after the separation of the calcareous earth, though it still retained a bluish colour. It was poured into a retort, and evaporated to dryness; the residuum was of a yellowish colour, which became green on being dissolved in distilled water. Mild mineral alkali threw down only a little earth of a greenish white colour; which being redissolved in rediphlogistic nitrous acid, and precipitated with Prussian alkali, the liquor yielded 17 grains of a sea-green powder. This precipitate, in our author's opinion, is the colouring principle of the chrysofrofus; and this principle he afterwards found to be calx of nickel.

7. Our author likewise attempted to analyse the chrysofrofus in the mildest way by concentrated vitriolic acid; in which process his chief view was to discover whether the stone contained any volatile particles or not. On an ounce of crude chrysofrofus, therefore, when put into a retort, he poured an equal quantity of rectified vitriolic acid, and two parts of distilled water. After the latter had passed over into the receiver, the fire was increased to force over the superabundant acid; a part arose in white vapours, and some fell into the receiver with an hissing noise. Boiling water, which had been distilled, was then poured upon the residuum, and the solution filtered. The powdered chrysofrofus left on the filter had not been perfectly dissolved, and,
THE fine garnet of a red inclining to a yellow colour, is the sarrans of the ancients, the vermeille of the French, and the giacinto guarnacino of the Italians. Its name is taken from Sorian, or Surinam, a capital town of Pegu, from whence these gems are brought: when they have a brownish taint, they are then called hyacinth.

The occidental garnet is of a deep and dark red, and its hardness is less. However, some very fine hard garnets are found in Bohemia.—Garnets are also found in Hungary, at Pyrma in Silebia, at S. Sapho in the canton of Berne, in Spain, and in Norway.

The garnet melts in the focus of a good burning glafs into a brown mass, which is attracted by the lodestone; and this shows that iron enters considerably into its composition.

Some garnets are found, which contain a little gold. Thofe called zingrafjen by the Germans contain tin.

VIII. Tourmalin; Lapis electricus.

This is a kind of hard stone, lately brought into notice by its electrical properties. See TOURMALIN.

1. Its form is a prism of nine sides of different breadths, mostly truncated, and feldom terminating in a pyramid at each end, which is either composed of three pentagons, or of nine triangles.

2. When heated in the fire, it gives figns of contrary electricity on the two oppofite ends of their prismatic form. But many of these stones are not in the left electric. However, on being rubbed, they become electric in their fides, like other diaphanous gems.

3. It is as hard almost as the topaz, and striking fire with fhefl.

4. It melts by itself in a strong fire, though with difficulty.

5. With the microcosmic falt it melts perfectly; but only in part with borax.

6. With mineral alkali it is divided into a kind of powder.

7. The three mineral acids difsolve it when first reduced to a powder.

8. It bears a greater fimilarity to schoerl than to any other ftone: but its component parts show
show that it may be ranged with propriety in this place, along with other precious stones: as the argillaceous earth is also the most prevalent in its composition.

a. The oriental tourmalines are found in the island of Ceylon. They are transparent, of a dark brown yellow; and their specific gravity is from 3062 to 3295.

b. From Brazil. Transparent. These are green for the most part; but there are also some red, blue, and yellow: their specific gravity is from 3075 to 3180.

c. From Tyrol. Of so dark a green as to appear opaque. Their specific gravity is about 3050. These are found in beds of felsites and lapis-ellaris, among the micaceous veins, talcs, and hornblende of Schneeberg, Jurzagl, and Zillerthal, in the mountains of Tyrol.

d. From the mountains of Old Castile in Spain. These are transparent, and have the same properties as the preceding ones.

IX. The opal. Opala; the girafe of the Italians. This is the most beautiful of all the flint kind, owing to the changeable appearance of its colours by reflection and refraction, and must therefore be described under both these circumstances.

1. The opal of Nomius, the Sangenon of the Indians. This appears olive-coloured by reflection, and seems then to be opaque; but when held against the light, is found transparent and of a fine ruby red colour.

There is, however, another of the same kind in Sweden, which by reflection appears rather brown; but by refraction it is red, with violet veins.

2. The white opal. Its ground is white, of a glass-like complexion, from whence are thrown out green, yellow, purple, and bluish rays; but it is of a reddish or rather flame-colour when held against the light.

a. Of many colours; the oriental opal.

b. Of a milky colour.

c. Bluish, and semi-transparent. This is not

Vol. XII.

§2. Of Quartz.

This stone is very common in Europe, and easier to be known than described. It is distinguished from the other kinds of the siliceous order by the following qualities:

1. That it is most generally cracked throughout, even in the rock itself; whereby,
2. As well as by its nature, it breaks irregularly, and into sharp fragments.
3. That it cannot easily be made red-hot without cracking still more.
4. It never decays in the air.
5. Melted with potashes, it gives a more solid and fixed glas than any other of the siliceous order.
6. When there has been no interruption in its natural accretion, its substance always crystallizes into hexagonal prisms pointed at one or both ends.
7. It occurs in clefts, fissures, and small veins in rocks. It very seldom forms large veins, and still rarer whole mountains, without being mixed with heterogeneous substances.

According to Mr Kirwan, quartz neither loses its hardness nor its weight by calculation. Its texture is lamellar. These stones are in general the purest of the siliceous kind, though most contain a slight mixture of other earths; the most obvious distinction among them arises from their transparency or opacity.

Quartz is found,

1. Solid, of no visible particles, with a glossy surface. Fat Quartz.

a. Un-coloured and clear. This has no crystallized form, but is nevertheless as clear as quartz crystals of the best water.

b. White, the common fat quartz.

c. Blue
MINERALOGY.

Part II.

Siliceous Earths.

Gems.

Siliceous Earths.

c. Blue.
d. Violet.

B. Grained.

C. Sparry quartz.

This is the scarcest; and ought not to be confounded with the white felt-spar, being of a smoother appearance, and breaking into larger and more irregular planes.

D. Crystallized quartz. Rock crystal. Quartz crystal.

1. Opaque, or semi-transparent.
   a. White, or of a milk colour.
   b. Red, or of a carminian colour.
   c. Black.

2. Clear.
   a. Blackish brown, smokey topaz, or rauch topaz of the Germans.
   b. Yellow; found in Bohemia, and sold instead of topazes.
   c. Violet; the amethyst from Saxony, Bohemia, and Dammmemore in Upland (b.)
   d. Uncoloured: rock crystal, properly so called. When these coloured crystals are not clear, they are called fluss; for instance, topaz fluss, amethyst fluss, &c (c.)

2. Impure quartz.

a. Mixed with iron, in form of a black calc.—This is of a glofy texture, and contains a great quantity of iron.
b. Mixed with copper in form of a red calc.
   a. Red.

§ 3. Of Flint.

The flint (Silica pyromachus, Lapis cornus, or the hornstein of the Germans) forms a kind of intermediate substance between quartz and jasper; both which, however, it so nearly resembles, that it is not easy to point out such characters as shall readily distinguish it from them. We can only, therefore, speak of its properties comparatively.

1. It is more uniformly solid, and not so much cracked in the mass as the quartz; and,
2. It is more pellucid than the Jasper.
3. It bears being exposed to the air without decaying better than the Jasper, but not so well as the quartz.
4. It is better for making of glases than the Jasper, but is not quite so good as quartz for that purpose.
5. Whenever there has been an opportunity in this matter of its flowing into crystals, quartz crystals are always found in it; just as if the quartz made one of its constituent parts, and had in certain circumstances been squeezed out of it; this is to be seen in every hollow flint and its clefts, which are always filled up with quartz.
6. It often shows most evident marks of having been originally in a soft and fliny tough flake like glue or jelly.

The several varieties of this species have obtained more distinct names with respect to their colours than from any real difference in their substance; but these are still necessary to be retained, as the only names used by jewellers and others, who know how to value them accordingly.

I. Jade. Lapis nephriticus, Jaspachites.

The true lapis nephriticus seems to belong to this siliceous order, as it gives fire with fied, and is semi-pellucid like flint; it does not harden.

(b.) The most transparent are called false diamonds, Bristol, Kerry flints, and Alengon diamonds, &c. The coloured transparent crystals derive their tinges generally from metallic calces, though in exceeding small portions they all loss their colours when strongly heated. These are what we call false gems, viz.

The red, from Oran in Barbary, false rubies.
The yellow, from Saxony, false topazes.
The green, from Dauphiny, (very rare) false emeralds, or perosis.
The violet, from Vil in Catalonia, false amethysts.
The blue, from Puy in Valay, France, false sapphires.

There are also opal, or rainbow crystals, some of which make a very fine appearance; the various colours of which are thrown out in zones across the surface, though they never shine like the oriental opal.

(c) M. Fourcroy makes a remarkable difference between the crystals and the quartz, by affirming that the former are unalterable in the fire, in which they never loose their hardness, transparency, nor colour; whilst the quartz loses the same qualities, and is reduced by it to a white and opaque earth. He classifies the rock crystals,

1. According to their form, viz. 1. Insulated-hexagonal crystals, ending in two pyramids of six faces, which have a double refraction or show two images of the same object when looked through. 2. Hexagonal crystals united, having one or two points. 3. Tetrahedral, dodecaedral, flated crystals, and which though hexagonal have nevertheless their planes irregular. 4. Crystals in large masses, from the island of Madagascar, which have a simple refraction.
2dly. As to the colour, they are either diaphonous, redish, smokey, or blackish.
3dly. As to accidental changes, some are hollow; some contain water within one or more cavities: some are caled, viz. one within the other: some are of a round form, as the pebbles of the Rhine: some have a crust of metallic calces, or of a pyrites: some are of a geodical form, viz. crystallized in the inside of a cavity: some seem to contain amianthe, or asbestos, and others contain thurls.

The same author reckons among crystals, the oriental topaz, the hyacinth, the oriental sapphire, and the amethyst. Mr Daubenou had always looked on this last as a quartzous crystal.
den in fire, but melts by the solar heat in the focus of a burning lens into a transparent, green glaft with fome bubbles. That called by the name of circioneflon flone, which comes from the Amazon river, melts easier, in the fame solar fire, into a brown opaque glafs, which is far lefs hard than the flone itself. (Macquer.)

This flone is superior in hardness to quartz, though from its unctuity to the touch, one would fufpeft it to contain a large portion of argillaceous earth, or rather of magnetian earth, as Mr Kirwan feems to fufpeft.

Its specific gravity is from 2.970 to 3.389.—It is of a granular texture, of a greasy look, and exceedingly hard: is scarcely soluble in acids, at leaft without particular management, and is infufible in the fire. M. Sauffure feems to have extracted iron from it.

a. It is fometimes of a whitefli milky colour, from China: but moftly
b. Of a greenifh, or
c. Deep-green colour, from America.

1. Grey, yellowifh, and olive colour: there are the vulgar lapis nephritis, they being fuppofed to cure the nephritic pains by their external application to the loins.

The femi-pellucidity, hardness, and specific gravity, are the characters by which the lapis nephriticus may be diftinguifhed from other ftones.

II. Cat's eye; Pseudopalus. The fun-flone of the Turks, called ganeche. This flone is opaque, and reflects green and yellowifh rays from its surface: it is found in Siberia. It is very hard and femi-transparent, and has different points, from which light is reflected with a kind of yellow-brown radiation, somewhat fimilar to the eyes of cats, from whence it had its name. Jewellers do not fail to cut them round to the greatefl advantage. The beft of these ftones are very fcarce. One of thefe of one inch diameter was in the cabinet of the grand duke of Tufcany.

III. Hydrophane, or Oculus Mundi; also called Lapis mutabilis. The principal property which diftinguifhes this from all other ftones, is that it becomes transparent by mere infufion in aqeous fluid; but it gradually refumes its opacity when dry.

IV. The onyx. Onyx cameojua. Memphis. It is found of two forts.

a. Nail-coloured onyx, having pale fheft-coloured and white lines.

b. With black and white lines. The oriental onyx.

c. The chalcedony, or white agate, is a flint of a white colour, like milk diluted with water, more or lefs opaque: it has veins, circles, and round spots.

It is said to be fferer than the onyx, but much harder than thofe agates which are fometimes found of the fame colour.

a. The white opaque Chalcedony, or cabalong, from the Buckharith Calmucks. This was first made known by one Renesz, a Swedifh officer, who for feveral years had been in the country. The inhabitants find this flint on the banks of their rivers and work idols and domestic vef- fels out of it.

b. Of white and femi-transparent onyx; from Ceylon.

c. Bluifh grey: from Ceylon and Siberia.

VI. The carnelian. Carniolus. Is of a brownifh red colour, and often entirely brown. Its name is originally derived from its refeemble to fhef, or to water mixed with blood.

a. Red.

b. Yellowifh brown, looks like yellow amber. It is faid not to be fo hard as the chalcedony.

VII. The fardonyx. This is a mixture of the chalcedony and carnelian, sometimes flrated, and fometimes confufedly blended and mixed together.

a. Stripped with white and red ftrata; this serves as well cut in cameo as the onyx.

b. White, with red dendritical figures. This very much refembles that agate which is called the mocha fone; but with this difference, that the figures are of a red colour in this, inftead of black, as in that agate.

Between the onyx, carnelian, chalcedony, fardonyx, and agate, there feems to be no real difference, except some inexplicable degrees of hardness.

VIII. The agate; Achatas. This name is given to fints that are variega- ted with different colours, promifcuoufly blended together: and they are efteemed in proportion to their mixture of colours, their beauty, and elegance. Hence alfo they have obtained variety of names, mostly Greek, as fhe businefs of the lapidary in cutting of them, and admiring their feveral beauties and figures, had been derived from that nation alone. (p)

a. Brown opaque agate, with black veins, and dendritical figures: the Egyptian pebbles.

b. Of a Chalcedony colour; achatas chaledonifan.

c. Semi-transparent, with lines of a blackifh brown colour, and dendritical figures; the mocha fone.

d. Semi-transparent, with red dots; Gemma divi Stephani. When the points are very minute, fo as to give the flone a red appearance, it is by fome called Sardoa.

(p) On the fide of a hill near the church of Rothes in Moray, is a quantity of fintoagate of elegant red, and white colours. It is very hard, heavy, of a smooth uniform texture, and of a confiderable brightnefs; in which the red are remarkably clear, and finely mixed, and shaded through the fone. Mr Williams fays, that this is the largest and most beautiful agate rock he ever faw; and fo fide and hard as to be capable of the highest luftre in polishing.
Siliceous Earths.
Gems.

Siliceous Earths.
Gems.

MINERALOGY.

Part II.

loose and single irregular noules, and hardly in rocks, as the chert, it is a circumstance very insufficient to establish a difference between them; for there is the agate-flone, near Constantinople, running vein-like across the rock with its country of the same hardness, and as fine and transparent as those other agates which are found in round nodules at Deux-ports. We must, therefore, content ourselves with this remark concerning flints, viz. That they seem to be the only kind of flone hitherto known, of which a very large quantity has been formed in the shape of loose or separate nodules, each surrounded with its proper crust; and that the matter which constitutes this flint has been separated from the rest of the substance, in like manner as sandiver or glass-gall separates from, and twins upon, glasses, during its vitrification; though sometimes the formation of this flint may be prevented by the too sudden hardening of the matter itself.

Other species of flones, which are found in loose pieces or nodules, except ores and some sorts of flalafites, show evidently by their cracks, angles, and irregular figures, that they have been torn from rocks, rolled about, and rubbed against one another in torrents, or by some other violent motions of water.

That flints had originally been in a soft state, Mr. Cronstedt observes, is easy to be seen in the Egyptian pebbles, which have impressions of small flines, sand, and sometimes, perhaps, grafs; which, however, have not had any ingress into the very flint, but seem only to have forced the above agate gall or crust out of the way.

§ 4. Of Jaspers.

Jasper, japis, (the diafper of the Italians), is a name given to all the opaque flints whose texture resembles dry clay and which have no other known quality whereby they may be distinguished from other flints, except that they may be more easily melted in the fire; and this quality perhaps may proceed from the heterogeneous mixture, probably of iron.

I. Pure Jasper, which by no means yet known can be decamped.

II. Jasper containing iron: japis martialis Simole.

A coarse-grained.

a. Red and reddish brown; sanguine. B. Steel-grained, or fine-grained.

a. Reddish brown; looks like the red ochre or chalk used for drawing; and has partition veins, which are unequous to the touch, like a fine clay, and other like kinds.

C. Of a solid and shining texture, like a flag.

a. Liver-coloured; and, b. Deep red. c. Yellow. This last mentioned, when calcined, is attracted by the loadstone: and being affayed, yields from 12 to 15 per cent. of iron. (s.)

§ 5

(s.) Near Portfay in Banff-shire is an extensive rock of Jasper; some parts of which contain a beautiful mixture of green and red, which appear finely shaded and clouded through the body of the flone when polished. Mr. Williams is of opinion that it would be a very valuable quarry if worked.
**MINERALOGY.**

2. Crystallized.
   a. Blackish-brown.
   b. Light-green or white.

C. Garnet mixed with iron and lead.
   1. Crystallized.
   a. Reddish-brown.

II. Cockle, or shill. *Cornus cristallizatus* Wallerii; *Stannum cristalla columnaribus nigra Linnæi*.

This is a heavy and hard kind of stone which flows into crystals of a prismatic figure, and whose chief colours are black or green. Its specific gravity is the same as the garnets, viz. between 3000 and 3400, though always proportionable to their different solidity.

a. Cockle, or shill, mixed with iron.
   1. Coarse, without any determined figure.
      a. Green.
   2. Sparry.
      a. Deep green, (the mother of the emeralds), from Egypt.
      b. Pale green.
      c. White. This occurs very frequently in the scaly limetones; and its colour changes from deep green to white, in proportion as it contains more or less of iron.
   3. Fibrous, striated cockle, or shill: it looks like fibres or threads made of glafs.
      c. White.
      b. Of concentrated fibres: The starred cockle, or shill, from its fibres being laid stellarwise.
   4. Crystallized cocks, or shill.
      a. Black. To this variety belong most of these substances called *imperfecta albeïtis*; and as the cockle perfectly resembles a flag from an iron furnace, both in regard to its metallic contents and its glassey texture, it is no wonder that it is not soft enough to be taken for an albeïtus. It has, however, only for the sake of its structure, been ranked among the albeïtis. The striated cockle, or shill, compared to the albeïtis, is of a shining and angular surface (though this sometimes requires the aid of the magnifying-glasses to be discovered) always somewhat transparent, and is pretty easily brought to a glas with the blow-pipe, without being consumed as the pure albeïtis seem to be.
      b. Deep green.
      c. Light green.
      d. Reddish brown. The *tauffstein* is of this colour, and consists of two hexagonal crystals of cockle grown together in form of a cross; this the Roman Catholics use as an amulet, and is called in Latin *lapit crucifer*, or the cross stone.

The figure of the cockle crystals is uncertain, but always prismatic: the cockle from Ysfio, at Nya Köppenberge, is quadrangular; the French kind has nine sides or planes, and the tauffstein is hexagonal.

The name *cockle* for these substances is an old Cornish mineral name; but is also given sometimes to other very different matters. 

We
MINERALOGY.

III. Rowley rag. (Kirwan). This stone is of a dusky or dark grey colour, with numerous minute shining crystals: its texture is granular: by exposure to the air it acquires an ochry crust. Its specific gravity is 2.748. Heated in an open fire it becomes magnetic. In strong heat it melts per se, but with more difficulty than basaltes. According to Dr Withering's analysis, 100 parts of it contain 47.5 of siliceous earth, 32.5 of argil, and 20 of iron.

IV. Siliceous muriatic spar. (Id.) This stone is of a hard, solid, and sparry texture: of a grey, ochry, dull colour, but internally bright. It gives fire with steel: yet it effervesces with acids. In a strong heat it grows brown: but at last it melts per se. One hundred parts of this stone contain fifty parts of siliceous earth, the remainder is magnesia and iron; but in what proportion it is not mentioned. (See Journal de Physique, Supplement, vol. xiii. p. 216.)

V. Turkish stone; cos Turcica. (Id.) This stone is of a dull white colour, and often of an uneven colour, some parts appearing more compact than others, so that it is in some measure shattery. It is used as a whetstone: and those of the finest grain are the best hones for the most delicate cutting tools, and even for razors, lancets, &c. Its specific gravity is 2.598. It gives fire with steel: yet effervesces with acids. Mr Kirwan found that 100 parts of it contains 25 of mild calcareous earth, and no iron. There probably are two sorts of stones known by this name, as Mr Wallerius affirms, that which he describes neither to give fire with steel nor effervesce with acids.

VI. Ragg stone. The colour of this stone is grey. Its texture is obliquely laminar, or rather fibrous, but the laminae or fibres consist of a congeries of grains of a quartzy appearance, coarse and rough. Its specific gravity is 2.729. It effervesces with acids; and gives fire with steel. Mr Kirwan found it to contain a portion of mild calcareous earth, and a small proportion of iron. It is used as a whetstone for coarse cutting tools.

[The siliceous grit, cos arenarius, and other compounds of the siliceous earth, &c. will be found in a subsequent division of this article.]

Observations on the economical Use of the Siliceous Order.

Europeans have no farther trouble with the precious stones than either to cut them from their natural or rough figure, or to alter them when they have been badly cut in the East Indies; in which latter cir-

MINERALOGY.

Argillaceous Earths. 

It appears likewise probable that the quartz-like matter makes the grind and whetstone fit for their intended purposes. (Magellan.)

Order V. The Argillaceous Earths.

The principal character whereby those may be distinguished from other earths is, that they harden in the fire, and are compounded of very minute particles, by which they acquire a dead or dull appearance when broken.

I. Argylla aerata; lac bona.

This fanciful name was herefore thought to denote a very fine species of calcarceous earth; but Mr Sceber has lately shown, that the earth to which this name is given, is a very uncommon species of argill. It is generally found in small cakes of the hardnes of chalk; and like that, it marks white. Its hardnese is nearly as that of flitepites, and it does not feel so fat as common clay does. Its specific gravity is 1669; its colour from white. When examined with a microscope, it is found to consist of small transparent crystals; and by his experiments it appears plainly to be an argill saturated with fixed air. It effervesces with acids, and contains a very small quantity of the inflammable principle.

2. Friable and lean. 

a. White.

b. Bluish grey.

c. Black.

d. Violet.

These contain a phlogiflon, which is discovered by exposing them to quick and strong fire, in which they become quite black interiorly, affuming the appearance of the common flints, not only in regard to colour, but also in regard to hardnes; but if heated by degrees, they are first white, and afterwards of a pearl colour. The matter they seem to be, which may be judged both by their feeling smooth and unctuous, and by their shining when scraped with the nail, they contain a larger quantity of the inflammable principle. It is difficult to determine, whether this strongly inherent phlogiflon be the cause of the abovementioned pearl-colour, or prevents them from being burnt white in a strong fire; yet no heterogeneous substance can be extracted from them, except sand, which may be separated from some by means of water; but which sand does not form any of the constituent parts of the clays. If they be boiled in aqua regis in order to extract any iron, they are found to lose their viability.

II. Porcelain clay; Terra porcellana, vulgo Argylla opaca, very refractory; the kaolin of the Chinese.

1. Pure.

a. Diffusible in water.

b. Coherent and dry.

2. Friable and lean. 

a. White.

b. Bluish grey.

c. Black.

d. Violet.

These contain a phlogiflon, which is discovered by exposing them to quick and strong fire, in which they become quite black interiorly, affuming the appearance of the common flints, not only in regard to colour, but also in regard to hardnes; but if heated by degrees, they are first white, and afterwards of a pearl colour. The matter they seem to be, which may be judged both by their feeling smooth and unctuous, and by their shining when scraped with the nail, they contain a larger quantity of the inflammable principle. It is difficult to determine, whether this strongly inherent phlogiflon be the cause of the abovementioned pearl-colour, or prevents them from being burnt white in a strong fire; yet no heterogeneous substance can be extracted from them, except sand, which may be separated from some by means of water; but which sand does not form any of the constituent parts of the clays. If they be boiled in aqua regis in order to extract any iron, they are found to lose their viability.

11. Stone-marow; Lithæagna Kystil of the Tartars.

1. When dry, it is as fat and slippery as soap; but, when wet, it is not wholly diffusible in water, in which it only falls to pieces, either in large bits, or resembles a curd like mafs.

2. It breaks into irregular fealy pieces.

A. Of coarse particles; Coarse stone-marow.

a. Grey.

b. Whitish yellow, from the Crim Tartary, where it is called kektik, and is said to be used for washing instead of soap.

B. Of very fine particles; fine stone-marow.

a. Yellowish brown; Terra Leunia.—Is of a thinning texture, falls to pieces in the water with a crackling noise; it is more indurated than the preceding, but has otherwise the same qualities.

IV. Bole; (iron clay.)

This is a fine and dense clay of various colours, containing a great quantity of iron, which makes it impossible to know the natural and specific qualities of the bone itself, by any easy method hitherto in use. It is not easily soaked in water, contrary to what the porcelain and the common clays are, (I. and VI.); but either falls to pieces in form of small grains, or repels the water, and cannot be made dullife. In the fire it grows black, and is then attracted by the leadstone.

A. Loose and friable boles, or those which fall to a powder in water.

1. Flesh-coloured bole.

2. Red.

3. Fine; Bolus Armenus.

4. Coarse; Bolus communis officinalis.

5. Hard; Terra rubrica.

6. Green; Terra virte.

1. Fine.

2. Coarse.

3. Bluish grey, is dulcite as long as it is in the rock, but even then repels the water; it contains 40 per cent. of iron; which metal being melted out of it in a close vessel, the iron crystallizes on its surface.

1. Crystallized in a spherical polygonal figure.

2. Of an undeterminate figure.

B. Indurated bole.

1. Of no visible particles.

This occurs very often in form of flate, or layers, in the earth; and then is made use of as an iron ore. However, it has usually been considered more in regard to its texture than to its constituent parts; and has been called flate, in common with several other earths which are found to have a flame texture.

2. Reddish-brown; in most colilities, between the seams of coal.

b. Grey.

3. Of fealy particles.—The bornblende of the Swedes.
M I N E R A L O G Y.

Part II.

VI. Tripoli.

This is known by its quality of rubbing or wearing hard bodies, and making their surfaces to shine; the particles of the tripoli being so fine as to leave even no scratches on the surface. This effect, which is called polishing, may likewise be effected by other fine clays when they have been burnt a little. The tripoli grows somewhat harder in the fire, and is very refractory: it is with difficulty dissolved by borax, and still with greater difficulty by the microcosmic salt. It becomes white when it is heated: when crude, it imbibes water, but is not diffusible in it: it taints like common chalk, and is rough and sandy between the teeth, although no sand can by any means be separated from it. It has no quality common with any other kind of earth, by which it might be considered as a variety of any other. That which is here described is of a yellow colour, and is sold by druggists. This kind of tripoli has been lately discovered in Scotland. But the rotten-stone, so called, is another sort found in England, viz. in Derbyshire. It is in common use in England among workmen for all sorts of finer grinding and polishing, and is also sometimes used by lapidaries for cutting of stones, &c.

The tripoli is found,
   b. Yellowish.
   c. Spotted like marble.
2. Friable and compact.
   a. Granulated.
   b. Brown.
   c. Yellowish.

VII. Common clay, or brick clay.

This kind may be distinguished from the other clays by the following qualities:
1. In the fire it acquires a red colour, more or less deep.
2. It melts pretty easily into a greenish glaze.
3. It contains a small quantity of iron and of the vitriolic acid, by which the preceeding effects are produced.

It is found,
A. Diffusible in water.
1. Pure.
   a. Red clay.
   b. Flesh-coloured, or pale-red.
   c. Grey.
   d. Blue.
   e. White.
   f. Fermenting clay.
2. Mixed with lime. See Marl, above,
B. Indurated.
1. Pure.
   a. Grey flint.
   b. Red flint.
2. Mixed with phlogiston, and a great deal of the vitriolic acid. See Alum Ores, above.
3. Mixed with lime. See Lime, above.

VIII. Argillaceous fine frits.

These and many other different kinds of earth have been comprehended under the denomination of...
MINERALOGY.

Part II.

Argillaceous Earths.

of schistis; but to avoid ambiguity we will confine this name to flones of the argillaceous kind.

1. The bluish purple schilus, or common roof slate; schilus scriptarius. Its colour varies to the pale, to the slightly purple, and to the bluish.

2. The dark-blue flate, schilus scriptarius.

3. The bituminous schilus. This is of a grey colour, brown, blue, or black.

4. The argillaceous grit. This is of a grey, yellowish, or reddish white colour.

5. The argillaceous flate. This is called also sand stone and free stone, because it may be cut easily in all directions.

This flate is of a pale grey or greenish colour; either lamellar, or coarsely granular. It is found chiefly in Cornwall.

7. Toadstone.

Dr Withering, who has given an analysis of this flate, describes it as being of a dark brownish grey colour, of a granular texture, not giving fire with steel, nor effervescing with acids. It has cavities filled with crystalized spar, and is fusible per se in a strong heat. It is found in Derbyshire. See Toadstone.

For the economical uses of the argillaceous earths, see the article Clay.

Class II. Salts.

By this name those mineral bodies are called which can be dissolved in water, and give it a taste; and which have the power, at least when they are mixed with one another, to form new bodies of a solid and angular shape, when the water in which they are dissolved is diminished to a less quantity than is required to keep them in solution; which quality is called crystallisation.

In regard to the principal known circumstances or qualities of the mineral salts, they are divided into

1. Acid salts, or mineral acids.

2. Alkaline salts, or mineral alkalies.

Order I. Acid Salts.

For the characters, properties, and phenomena of these, see the article Acid, and Chemistry-Index.

Thus no more mineral acids were known than the vitriolic and marine; the boracic or soda salt being reckoned as produced artificially: but later discoveries have proved that we may reckon at least eleven mineral acids; out of which only two or three have been found in an uncombined state. Those hitherto known are the following, viz. the vitriolic, the nitrous, the marine, the sanguine, the arsenical, the molybdenic, the tungstenic, the phosphoric, the boracic, the fuscous, and the aerial. See the article Acid, and Chemistry-Index.

I. The vitriolic acid. See Chemistry-Index.

II. Nitrous acid.

This acid is by some excluded from the mineral kingdom, because they suppose it to be produced from putrefaction of organic bodies. But these bodies, when deprived of life, are again received amongst fossils, from whence their more fixed parts were originally derived. For the nature of this acid, see Chemistry-Index.

III. Acid of common or sea-salt. See Chemistry-Index, at Acid and Marine.

IV. The fluors acid, or sparly fluors acid. See Chemistry-Index.

This acid is obtained by art, as it has never been found disengaged, but united to calcareous earth, forming a sparly fluors, called Derbyshire fluors. See Fluors Cornish fluors, but John, or amethyst root, when of a spar purple colour. See p. 72. col. 2. concerning the substances arising from the combination of this acid with calcareous earth.

V. The acid of arsenic. See Chemistry-Index.

VI. The acid of molybdena. Ibid.

VII. The acid of tungsten. Ibid.

VIII. The phosphoric acid. Ibid.

IX. The boracic acid. Ibid.

X. The fuscous or amber acid. Ibid.

XI. Aerial acid, or fixed air. Ibid.

Order II. Alkaline Mineral Salts.

For the characters, properties, and phenomena of these, see the article Alkali; also Chemistry-Index, at Alkali Alkalis.

New acids are daily detected; but no additions have been made to the three species of alkali long since known. These alkali salts are,

I. Vegetable fixed alkali (A.)

(M) vegetable
M I N E R A L O G Y.

Part II.

Vegetable fixed alkali, deprived of every acid, is not found any where by itself; but it is sometimes met with in combination with the vitriolic acid or the muriatic, generally with the nitrous, rarely with the aerial.

The fixed vegetable alkali (or potash of Moreau), is of a powdery appearance, and of a dead white colour. When pure, it is much more caustic than the neutral salt; it forms with the aerial acid, and even corrodes the skin. Its properties of deliquescing, are thereby deprived of its property of deliquescing.

1. It changes the blue colours of vegetables into a deep green.
2. It has no smell when dry; but when wetted, it has a slight limiduous odour.
3. Its taste is strongly acid, burning, caustic, and urinous (n). This last sensation arises from the volatile alkali it difengages from animal subsances.
4. When exposed to the air, it attracts humidity, and is reduced into a transparent colourless liquor. According to Gellert, it attracts three times its own weight of water.
5. It likewise attracts sometimes the aerial acid from the atmosphere, and is thereby deprived of its property of deliquescing.
6. When it is dissolved in an equal weight of water, it has an oily feel, owing to its action on the fatty parts of the skin, whence it is, though improperly, called oil of tartar.
7. In a moderate heat it melts; but in a more violent fire, it is disperfed or volatilised.
8. It is a moft powerful solvent by the dry way; in a proper heat, it dissolves calcareous, argilaceous, siliceous, and metallic earths: and when the alkali is nearly equal in quantity to the earth, it forms various kinds of hard, solid, and transparent glasses.
9. But if the alkali be in quantity three or four times that of the earth, the glass is deliquescent.
10. The mild vegetable alkali unites with the vitriolic acid with a violent effevescence, and produces vitriolated tartar.

II. Fossil fixed alkalis.

A. Alkali of the sea, or of common salt (e).

1. Pure.

This has nearly the same qualities with the lixivious salt, which is prepared from the ashes of burnt vegetables. It is the same with the sal soda, or kelp: for the kelp is nothing else than the ashes remaining, after the burning of certain herbs that abound in common salt; but which common salt, during the burning of those vegetables, has lost its acid (r). The properties of the fossil alkali are as follows:

trary, that which is got from tartar, properly burned, then dissolved in boiling water, and purified by filtration and crysallification, is called salt of water. It is the best.

(b) The vegetable alkali is by no means found in the earth, except in wells of towns, as at Doway, or in the argilaceous alun-ore of la Tolfa; it is found also united to the nitrous acid, near the surface of the earth, in Spain, and in the East Indies, probably from the putrefaction of vegetables.

(c) Common vegetable alkali, salt of tartar, and potash, were formerly considered by chemists as simple alkalis; but Dr Black has demonstrated them to be true neutral salts, arising from the combination of the vegetable alkali with the aerial acid. From hence it follows, that the above common alkalis, even after any other extraneous substance has been extracted, must be freed from this acid, by putting each in a crucible, and expooting it to a strong fire, which will dil معظم this aerial acid. The alkali so purified, is to be put in a glass vessel before it be entirely cold, and kept clese with a proper stopple; otherwise the aerial acid which floats in large quantities on the atmosphere will combine again with the pure alkali. (Monges.)

(d) The alkali must be largely diluted with water, in order to be tasteless; otherwise it will act on the tongue, and corrode the parts where it touches. (Macquer.)

(e) This salt is not met with pure in Europe; but it is said to be found in both the Indies, not only in great quantity, but likewise of a tolerable purity: it is there collected in form of an effevescence in the extensive deferts, a profitable trade being carried on in it for the making of soaf and glass; and, therefore, it is very probable that the ancients meant this salt by the natron or baurus. (Magellan.)

(f) The mineral alkali is often combined with the vitriolic and marine acid, also with the aerial acid.
Part II.

MINERALOGY.

Alkaline Salts.

1. It effervesces with acids, and unites with them.
2. It turns the syrup of violets to a green colour.
3. Precipitates sublimate mercury in an orange-coloured powder.
4. Unites with fat substances, and forms soap.
5. Diffuses the siliceous earth in the fire, and makes glasses with it, &c. It distinguishes itself from the salt of the pot-ashes by the following properties (c).
6. It shoots easily into rhomboidal crystals; which
7. Fall to powder in the air, merely by the loss of their moisture (n).
8. Mixed with the vitriolic acid, it makes the "sal mirabilis" Glauber's.
9. It melts more easily, and is fitter for producing the "sal commune regeneratum, nitrum cubisum," &c. Perhaps it is also more conveniently applied in the preparation of several medicines.

10. It is somewhat volatile in the fire.

Volatile mineral alkali.

This perfectly resembles that salt which is extracted from animals and vegetables, under the name of alkali volatile or sal urinum, and is commonly considered as not belonging to the mineral kingdom; but since it is discover'd, not only in most part of the clays, but likewise in the sublimations at Solfatara, near Naples, it cannot possibly be quite excluded from the mineral kingdom (1).

Its principal qualities are,

a. In the fire it rises in forma fissa, and volatilities in the air in form of corrosive vapours, which are offensive to the eyes and nose (k).
b. It precipitates the solution of the mercurial sublimate in a white-powder.
c. It also precipitates gold out of aqua regia, and detonesates with it; because,
d. It has a re-action in regard to the acids, though not so strongly as other alkalies.

M 2

c. It

Acid with which last it retains not only the name but many of the properties of a pure alkali, because this last acid is easily expelled.

It is easily known by its crystallisation and its solubility in two times and an half of its weight of water, at the temperature of 60 degrees.

One hundred parts of this salt, when pure and recently crystallised, contain 20 of mere alkali, 16 of aerial acid, and 64 of water. (Monges.)

Mineral alkali is found in Hungary, in marshy grounds, of an argillaceous or marly nature, either mixed with water or crystallised and efflorescing. It is also found in Egypt at the bottom of lakes, and dried up by the summer's heat; and also in the province of Sothena, 28 days journey from Tripoli, where it has the name of Trena; in Syria, Persia, as well as in the East-Indies, and China, where it is called Kim. It sometimes germinates on walls, and is called by many apronitron. In its native state, it is frequently mixed with manganian earth, common salt, uric acid, and marine sepheline. (Kirwan.)

(c) This mineral alkali likewise differs from the vegetable, 1. By its taste, which is less corrosive and burning.
2. By its not deliquescing.
3. By the small degree of heat it produces if calcined, and afterwards added to water.
4. By its property of crystallizing, by evaporating the water from its solution, as is practised with neutral salts; whereas the vegetable alkali does not crystallize unless combined with a large portion of aerial acid.

(n) This alkali being a very useful commodity, and essentially necessary in a number of manufacturies, many ingenious processes have been contrived and attempted to procure it at a cheap rate, by decomposing the salt; but it is believed, that till lately none of these new manufactures have succeeded, except that of Mr. Turner, mentioned by Mr. Kirwan in the second part of the Philosophical Transactions for 1782.

The process is said to consist in mixing a quantity of lime with half its weight of common salt, which, on being trituated with water till it attains a white colour, is left to stand some hours; after which, a decomposition ensues, the alkali being left alone, whilst the acid unites to the metallic calx; and this last being urged by a proper degree of fire, produces a fine pigment of a greenish yellow colour, whose sale pays for the most part of the expenses.

Mr. Kirwan says, in the place already quoted, that if common salt perfectly dry be projected on lead heated to incandescence, the common salt will be decomposed, and a horn-like formed, according to Margraff. He adds also, that according to Scheele, if a solution of common salt be digested with litharge, the common salt will be decomposed, and a caustic alkali produced; and finally, that Mr. Scheele decomposed common salt by letting its solution flowly passes through a funnel filled with litharge.

(1) It is easily known, by its smell, though in a mild state, by its volatility, and by its action on copper; the solutions of which, in the mineral acids, are turned blue by an addition of this alkali. It is frequently found, though in small quantities, in mould, marble, crystal, chalcedon, and in some mineral waters. It probably derives its origin in the mineral kingdom, from the putrefaction or combustion of animal or vegetable substances. (Kirwan.)

The name is causticus when combined with any acid, not excepting even the aerial acid. It differs from the other two alkalies in many essential particulars. 1. By its aeriform or gaseous nature. For the volatile alkali, it is a state of purity, is nothing more than an alkaline gas diffused in water, as Dr. Priesley has demonstrated. 2. By its volatility. 3. By the nature of the salt it forms with acids, which are very different from those whose bases are formed either of the vegetable or mineral alkali. (Monges.)

(k) Pure volatile alkali, in an aerial form, resembles atmospheric air, but is more heavy. Its smell is
Neutral Salts.

Acids united to alkalies form neutral salts. These dissolved in water are in no ways disturbed by the addition of an alkali; and generally, by evaporation, concrete into crystals. If, by proper tests, they show neither acid nor alkaline properties, they are said to be perfect neutrals; but imperfect, when, from defect in quantity or strength of one ingredient, the peculiar properties of the other more or less prevail.

I. Vitriolated tartar, vitriolated vegetable alkali, or (as Morveau calls it) the vitriol of pot-ash. This is a perfectly neutral salt, which results from the combination of the vitriolic acid with the vegetable fixed alkali. According to Bergman, it seldom occurs spontaneously in nature, unless where tracks of wood have been burnt down: and Mr Bowles, quoted by Mr Kirwan, says it is contained in some earths in Spain. See Chemistry-Index.

It is easily obtained, by pouring the vitriolic acid on a solution of fixed vegetable alkali till it is saturated. Crystals of this neutral salt are then formed. This crystallisation succeeds better by evaporation than by cooling, according to Mongez.

The taste of this salt is disagreeable, though somewhat resembling common salt.

II. Common nitre, (Alkali vegetable nitrum) is known in commerce by the name of fels-petre, and is also called prismatic nitre, to distinguish it from the cubic nitre after-mentioned.—It is perfect neutral salt; resulting from the combination of the nitrous acid with the pure vegetable alkali.

According to Bergman, it is formed upon the surface of the earth, where vegetables, especially when mixed with animal-substances, putrify.—See Chemistry-Index, at Nitre.

III. Digestive salt, salt of Sylvius, (Alkali vegetable saltum). This neutral salt is sometimes, though rarely, met with on the earth, generated perhaps, as procéd for Bergman observes, by the destruction of animal and vegetable substances.

According to Macquer, this salt has been very wrongly called regenerated marine salt; and the epithet of frisburage has also been given to it, without any good reason, to evince that it has such a property. But M. de Morveau calls it nitrate de potasse with great propriety.

This salt is produced by a perfect combination of the vegetable alkali with marine acid. It has been wrongly confounded with common salt.—It is found in some bogs in Picardy, and in some mineral waters at Normandy, according to Monet, quoted by Kirwan. Mongez adds also the seawater, as containing this salt, and that it is never found in large quantities, although its component parts are abundantly produced by nature.

See Chemistry-Index, at Digestive.

IV. Mild vegetable alkali, (alkali vegetabile aeratum.) This salt was formerly considered as a pure alkali, known by the name of potash and salt of tartar: but since the discovery of the aerial acid, it is very properly classified among the neutral salts, and ought to be called aerated potash.

It results from a combination of the vegetable alkali with the aerial acid, and is hardly ever found native, unless in the neighbourhood of woods destroyed by fire.

On being exposed on a piece of charcoal, urged by the blow-pipe, it melts, and is absorbed by the coal; but,

In the metallic spoon, it forms a glassy bead, which becomes opaque when cold.

V. Vitriolated acid faturated with mineral alkali; Glauber's salt. Alkali mineral vitriolatum.

This is a neutral salt, prepared by nature (as well as by art), containing more or less of iron, or of a calcareous earth; from which arises also some difference in its effects when internally used. It shoots easily into prismatic crystals, which become larger in proportion to the quantity of water evaporated before the crystallisation. When laid on a piece of burning charcoal, or else burnt with a phlogiston, the vitriolic acid dissolves itself by the smell resembling the hepatic sulphur.

It is found in a dissolved state in springs and wells. Some of the lakes in Siberia and African, penetrating, and suffocates animals. Its taste is acid and caustic. It quickly converts blue vegetable colours to green, and produces heat during its combination with water. But if the water be frozen, it melts, producing at the same time an extreme degree of cold. It has a remarkable action on most metals, particularly copper.

This substance is obtained by the putrefactive fermentation from animal and some vegetable matters. It is this salt which causes that strong smell which is perceived in drains and privies on a change of weather. (Blengius.)

Its volatility arises from a very subtle and volatile (or phlogistic) oil, which enters as a principle into its composition. (Mongez).

(1) The solution of copper by this alkali, which is of a fine blue, presents a remarkable phenomenon. For if it be kept in a well clozed phial, the colour decays, and at length disappears, giving place to transparency. But on opening the phial, the surface or part in contact with the air becomes blue, and the colour is communicated through the whole mass. This experiment may be many times repeated with the same success.
This neutral salt is a combination of the mineral alkalii with the aerial acid or fixed air. It is
found plentifully in many places, particularly in Africa and Asia, either concreted into crys-"ta-"lized
flata, or fallen to a powder; or effervescing on old brick walls; or lastly, dissolved in springs.
It frequently originates from decomposed common salt.

This is an imperfect neutral salt, and was formerly considered as a pure alkalii; but the disco-
very of the aerial acid has shown the mistake.

1. It has nearly all the properties of the pure mineral alkalii N° 11. A. 1. (p. 90.), but with
less energy.

2. The vegetable blue colours are turned green by this salt; it effervescs with acids, and
has an urinous flavour. See Chemistry-Index, at Sea-salt.

3. It is soluble in twice its weight of cold water; but if the water is hot, an equal weight
is sufficient for its solution.

4. It effervescs when exposed to the action of the atmosphere.

5. It fuses easily on the fire, but without being decomposed.

6. Facilitates the fusion of vitrifiable earths, and produces glaist more or less fine accord-
ing to their qualities.

7. It is decomposable by lime and ponderous earths, which attract the aerial acid.

8. And also by the mineral acids, but these expel the aerial acid of this salt, by fixing
its alkaline basis. (Minerals.)

Wallerius confounds this salt with the aphyroni-trum after mentioned, and calls it hauaisrum, when
it contains some phlogiston. Mr Kulbel, quoted by Wallerius, shewed that it exists in some vege-
table earths, and takes it to be the cause of their fertility; but this (M. Magellan obvers) can
only be on account of its combination with the oily parts of them, and forming a kind of soap,
which is miscible with the watery juices.

X. Vitriolic ammoniac, (Alkali volatile vitriol'atium.)

This neutral salt was called secret salt of Glaubers, and is a combination of the volatile alkalii with
vitriolic acid. According to Bergman, it is scarcely found any where but in places where the
phlogificated flames of vitriolic acid arise from burning sulphur, and are absorbed in putrid places.
by the volatile alkali. Thus at Fahlen the acid vapour from the roasted minerals produces this
salt in the necessary-houses. Dr Withering, however, obvers, that as volatile alkalii may be ob-
tained in large quantities from pit-coal, and produced by processes not dependent upon putrefac-
tion, there is reason to believe that the vitriolic ammoniac may be formed in several ways not no-
ticed by the above author.
It is said to have been found in the neighborhood of volcanoes, particularly of Mont Vesuvius, where, indeed, it might well be expected; yet its existence seems dubious, since Mr Bergman could not find any trace of it among the various specimens of salts from Vesuvius which he examined. The reason (according to M. Magellan) probably is, that the vitriolic acid disengaged by the combustion of sulphur is in a phlogiticated state; and all its combinations in this state are easily decomposed by the marine acid, which plentifully occurs in volcanoes. It is also said to be found in the mineral lakes of Tuscany, which is much more probable, as the vitriolic acid when united to water easily parts with phlogiston, and recovers its superiority over other acids. It is said likewise that this neutral salt is found on the surface of the earth in the neighbourhood of Turin.

1. This salt is of a friable texture, and has an acrid and urinous taste.
2. Attracts the moisture of the atmosphere.
3. Is very soluble in water, it requiring only twice its weight of cold water, or an equal weight of boiling water, to be dissolved.
4. It becomes liquid on a moderate fire; but if urged,
5. It becomes red hot, and volatilizes.
6. The nitrous and muriatic acid decompose this salt by seizing the volatile alkali. But
7. Lime, ponderous earth, and pure fixed alkali, set the volatile alkali free, and combine with the vitriolic acid.
8. According to Kirwan, 100 parts of this salt contain about 42 parts of real vitriolic acid, 40 of volatile alkali, and 18 of water. This vitriolic ammoniac is easily known; for if quicklime or fixed alkali be thrown into its solution, the smell of the volatile alkali is perceived; and if this solution be poured into that of chalk or ponderous earth by the nitrous acid, a precipitate will appear.

XI. Nitrous ammoniac. (Alkali volatilis nitratum.)

This is a neutral salt, which results from the combination of the nitrous acid with the volatile alkali. It is frequently found in the mother-liquor of nitre. When mixed with a fixed alkali, the volatile betrays itself by its smell.

1. It is of a friable texture, of a sharp bitter, and of a nitrous or cooling taste.
2. According to Mongez, it attracts the moisture of the atmosphere; but Romé de l'Île affirms, that its crystals are not deliquescent: the experiment may be easily tried, and the truth ascertained.
3. It is soluble in cold water; but half the quantity of water, if boiling, is sufficient for dissolving it.
4. It liquefies on the fire, and afterwards it becomes dry.
5. It detonates with a yellow flame before it is red hot; and what is peculiar to this salt, it needs not, like common nitre, the contact of any combustible matter for its detonation;

from whence it appears that the volatile alkali itself possesses a great share of phlogiston.

6. Its component parts, viz. the nitrous acid and the volatile alkali, are not very intimately united; and of course,
7. It is easily decomposed by all the substances that have any affinity to either of them.
8. Mixed with the muriatic acid, it makes aqua regia.
9. One hundred parts of this neutral salt contain 46 of nitrous acid, 40 of volatile alkali, and 14 of water, as Mr Kirwan thinks.

XII. Native salt ammoniac. The muriatic (or marine) acid saturated with a volatile alkali.

This is of a yellowish colour, and is sublimed from the flaming crevices, or fire-springs, at Solfluara, near Naples.

XIII. Aerated or mild volatile alkali.

This neutral salt results from the combination of volatile alkali united to the aerial acid. It was formerly considered as a pure alkali:—But the discovery of the aerial acid (or fixed air) has shown it to be a true neutral salt, though imperfect; as it retains still all the properties of an alkali, though in a weaker degree, on account of its combination with the aerial acid, which is itself the most weak of all acids, and of course other stronger acids easily dislodge it from its base, and from various ammonial salts.

1. This imperfect neutral salt has an urinous taste, and a particular smell, which is very penetrating, though less pungent, than the pure volatile alkali; and in the same manner it turns the blue vegetable juices green.
But,
2. It effervesces with other acids stronger than the aerial one, which the pure or caustic volatile alkali does not.
3. It sublimes very easily with a small degree of heat;
4. And dissolves in twice its weight of cold water; but in a lesser quantity, when this salt is boiling hot.
5. It acts on metallic substances, chiefly on copper, with which a blue colour is produced.

According to Bergman, this salt was found in a well in London (Phil. Trans. for 1767), at Frankfort on the Main, and at Lauchstadt.—Mefsrs. Hierne, Henkel, and Brandt, have found also this salt in the vegetable earth, in various kinds of argl, and in some saline substances. Mr Vozel found it also in some of the incrustations at Gottingen; and Mr Maloutin in some acidulous waters in France.

M. Magellan observes, that the borax and the three aerated alkalies are called imperfect neutrals; whilst the other neutral salts have acquired the name of perfect, because these last do not exhibit any of the distinguishing properties of their component parts. The three aerated alkalies have a very distinct alkaline character, as they turn blue vegetable juices green, though not so vivid a colour as the caustic alkali.
alkali and the borax is capable of receiving almost an equal quantity of its sedative acid, without losing all its alkaline properties.

In general, those neutral salts, consisting of fixed alkalies combined with acids, are more saturated than those composed of volatile alkali called ammoniacal salts, or those called aerated which last are only composed by the combination of the aerial acid, united to any alkaline or earthy base.

The aerated alkalies are called also by the name of mild alkalies, because they possess no longer that sharp corroding quality which they exhibit when deprived of the aerial acid or fixed air; in which case they are termed caustic alkalies.

These aerated alkalies differ also from the caustic ones, not only on account of the mildness of their taste, from which comes their epithet of mild alkalies, but also by their property of crystallizing, and by their effervescing with other acids, which expel the aerial one, the weakest of all acids we know.

Order IV. Earthy Neutral Salts.

The compounds of earths and acids which possess solubility are decomposed and precipitated by mild, but not by phlogisticated alkalies.

I. Calcareous earth combined with vitriolic acid.—

Vitriolated calx; Selenite; Gypsum. See p. 72. col. 1. supra.

The gypsum, or plaster, is not only found dissolved in various waters, but also in many places it forms immense strata. It is placed by all mineralogists among the earths, which it greatly resembles, but it rather belongs to the saline substances of the neutral kind, as appears by its constituent parts. When burnt, it generates heat with water, but in a less degree than lime does.

Berg. Scag. § 59. This salt has a particular taste, neither bitter nor astringent, but earthy, when applied to the tongue, and it is owing to it that some waters, chiefly from pumps and wells, are called hard waters, because they lie heavy on the stomach. It is unalterable whilst kept in a dry place, but on being exposed to moist air, it is much altered, and suffers a kind of decomposition. When exposed to fire so as to lose the water of its crystallization, it assumes a dead-white colour; and it is then what we call plaster of Paris; but if the fire is too strong, it melts and vitriifies, after losing the vitriolic acid with which it is saturated. See Gypsum.

It is found also in the vegetable kingdom.—Mr. Model found that the white spots in the root of rhubarb are the selenitical or gypseous earth. (Journal de Phys, vol. vi, p. 14.)

What is called foill flour (farine siffile in French), generally found in the fissures of rock and gypseous mountains, is very different from the agaricus mineralis p. 71, col. 1. and from the lac lune, p. 87. col. 1. as it is a true gypseous earth, already described p. 72. col. 1., which, according to Mongez, is of a white and shining colour, though sometimes it assumes a reddish or bluish colour, on account of some martial mixture.

II. Nitre of lime, (Calx nitrata). This earthy salt is sometimes found in water, but very sparingly. It is said that the chalk hills in some parts of France become spontaneously impregnated with nitrous acid, which may be washed out, and after a certain time they will become impregnated with it again. It is a combination of the nitrous acid with calcareous earth.

Berg. Scag. § 59. 1. It is deliquecscnt, and is soluble in twice its weight of cold water, or in an equal weight of boiling water. 2. Its taste is bitter. 3. It is decomposed by fixed alkalies, which form the cubic and the prismatic nitrates. 4. But caustic volatile alkali cannot decompose it. 5. It does not deglurate in the fire; yet paper moistened with a saturated solution of it crackles in burning. 6. In a strong heat it loses its acid. 7. Its solution does not trouble that of silver in nitrous acid. 8. The vitriolic acid precipitates its basis. 9. As does likewise the acid of sugar. 10. One hundred parts of it contain, when well dried, about 33 of nitrous acid, 32 of calcareous earth, and 35 of water. It exists in old mortar, and in the mother liquor of nitre; and also in the chalk rocks near Roche Guyon, in France. (Kirwan.)

III. Muriatic chalk, or fixed salt ammoniac. Acidum, salis communis terra calcarea satura tum. This somewhat deliquesces, or attracts the humidity of the air. It is found in the sea water. It is with great impropriety that this salt has obtained the name of ammoniac, on account only of its being formed in the chemical laboratories during the decomposition of the ammoniacal salt with lime, in the process for making the caustic volatile alkali. In this case, the muriatic acid unites to the calcareous basis, while this last gives its water to the volatile alkali; which, therefore, comes over in a fluid caustic state, but if chalk is employed instead of lime, the volatile alkali receives the aerial acid instead of water, and comes over in a concrete form. In neither case, the new combination of calcareous earth with muriatic salt has any volatile alkali to deserve the name of ammoniacal salt. (Masquer.)

1. This earthy salt has a saline and very disagreeable bitter taste. It is supposed to be the cause of that bitterness and nauseous taste of sea-water. 2. It fuses in the fire, and becomes phosphorescent, after undergoing a strong heat. 3. It becomes hard, so as to strike fire with steel. 4. It is then the phosphorus of Homberg. 5. It is decomposable by ponderous earth and fixed alkalies.
M I N E R A L O G Y.

6. And also by the vitriolic or nitrous acid, which expel the muriatic acid, to unite with the calcareous bafis. *(Menges.)*

7. Its solution renders that of silver in the nitrous acid turbid, at the same time that it becomes soluble in water, and has a flight pungent bitter tafle. It is commonly found dissolved in waters, in consequence of an excess of the aerial acid. When this greatly abounds, the water is said to be hard *(cruda).* By boiling or by evaporation, it deposits streaks or crusts of calcareous matter.

But when the calcareous earth is only saturated with the aerial acid without excess, it is not easily soluble; it is then the calcareous spar, p. 71. col. 2. and is properly referred to the class of earths, p. 71. col. 1.

V. Vitriolated ponderous earth. *Terra ponderosa vitriolata; barytes vitriolata.*

This earthy tafte, known by the name of ponderous spar, is a combination of the ponderous earth described in p. 75. col. 1. with the vitriolic acid; and has been already treated of.

The nitrous ponderous earth, according to Bergman, has not yet been found, although it may perhaps exist somewhere, and of course be discovered in nature.

This earthy falt consists of marine acid united to the ponderous earth. It is said to have been found in some mineral waters in Sweden; and may be known by its easy precipitability with vitriolic acid, and by the great insolubility and weight of this resulting compound, which is the true ponderous spar of the preceding fection.

VII. Aerated ponderous earth. *Barytes aerata.*

This earthy neutral falt was found by Dr. Withering in a mine at Allon-moor in the county of Cumberland in England. He says that it is very pure, and in a large mass. This fubstance is a new acquisition to mineralogy, and may be turned to useful purposes in chemistry.

1. It effervesces with acids, and melts with the blow-pipe, though not very readily.

2. In a melting furnace, it gave some figns of fusion; but did not feel caufic when applied to the tongue, nor had it lost its property of effervescing with acids.

3. But the precipitated earth from a faturated solution of it in the marine acid, by the mild vegetable or mineral alkali being burned, and thrown into water, gave it the properties of lime-water, having an acrid tafle in a high degree: and a single drop of it added to the solutions of vitriolated falt, as the Glauber's falt, vitriolated tartar, vitriolated ammonia, alom, Epfom falt, felenite, occasioned immediately a precipitation; from whence it appears to be the nicest tefl to discover the vitriolic acid. By it the marine acid may also be eafily freed from any mixture of vitriolic acid, by means of this caflx of ponderous earth. See Chemistry n. 1049. ef. feq.

VIII. Vitriolated magnesia.

This earthy neutral falt is called by the English Epfom falt; Sel d'Angleterre by the French, and allo fel de Sedilite, de Scydshubes, fel amor, fel cebartique amor, &c. These various names are given to it, either on account of its properties, it being a very mild purgative; or from the places where it is found, besides many others, as in the waters of Egra, of Creutzbourg, Obetnental, Urb. &c. It has also been found native, mixed with common falt and coaly matter, germinating on some free ftones in coal mines. See Kirwan's Mineralogy, p. 183.

1. It has a very bitter tafle.

2. It is soluble in one part and a half of its weight of cold water: but in hot water, a given weight of it dissolves the double of this falt.

3. It effervesces when exposed to a dry atmosphere, and is reduced to a white powder.

4. Exposed to the fire, it lofs the water of its folution, the calcareous earth of lime-water shows much when applied to bergman, as in the marine acid of water. But when urged by the flame with the blow-pipe, it froths; and may be melted by being repeatedly urged with that instrument.

9. With borax it effervesces, and also when burned with the microcosmic falt.

10. According to Bergman, 100 weight of this falt contains only 19 parts of pure magnesia, 33 of vitriolic acid: and 42 of water. But according to Kirwan, 100 parts of it contain about 24 of real vitriolic acid, 19 of magnesian earth, and 57 of water.

IX. Nitrated magnesia; nitrous Epfom falt.

This earthy falt is usually found together with nitre. It is a combination of the nitrous acid with the magnesian earth.

1. It has an acrid tafle, very bitter.

2. Attracts the moisture from the atmosphere, and deliquesces.

3. Is very soluble in water.
M I N E R A L O G Y.

4. Is easily decomposable by fire.
5. The ponderous and calcareous earths decompose it, and also the alkalies.
6. On being urged by the blow-pipe, it swells up with some noise, but does not detonate.
7. If saturated solutions of nitrous eileenite and of this salt be mixed, a precipitate will appear; but,
8. Neither vitriolic acid, nor mild magnesia, will occasion any turbidity in its solution.
9. One hundred parts of this salt contain about 36 of real nitrous acid, 27 of magnesia earth, and 37 of water.

This earthy salt is a combination of magnesia earth, with the nitric acid. According to Bergman, it is found in the sea in greater plenty than any other salt except the sea-salt.

1. It has a very bitter taste: and being always mixed in the sea-water, it is the principal cause of its bitterness.
2. It is very deliquescent, and soluble in a small quantity of water.
3. All the alkalies, even the caustic volatile alkali and lime, decompose it by precipitating its basis.
4. The vitriolic, nitrous, and boracic acids expel the nitric acid from the base of this neutral salt.
5. Its solution does not trouble that of nitrous or marine eileenite; but,
6. It causes a cloud in the nitrous solution of silver.
7. The vitriolic acid throws down no soluble precipitate from the solution of this neutral salt.
8. It loses its acid in a red heat.

XII. Aerated magnesia.

Common magnesia, with an excess of aerial acid is a true neutral salt, like the aerated eileenite of p. 96, col. 1, and becomes soluble in cold water. Otherwise it is scarce soluble at all; and is then claffed among the earths.

This neutral salt is decomposable by fire, by which its water and its acid are expelled; and it may become phosporic.

When urged by fire, it agglutinates a little; and some pretended that it melts. But it must be in an impure flate to vitrify at all.

The three mineral acids, and the alkalies, dissolve this salt with effervescence, by expelling the aerial acid.

XIII. Argillaceous earth saturated with vitriolic acid.

Professor Bergman says, that the combinations of the argillaceous earth with the nitrous, nitric, and aerial acids, had not yet been found naturally formed as far as he knew. But Dr Withering affirms, that he found the vitriolic argill to exist in a considerable quantity, in the Nevil Holt water, when he analyzed that mineral water about the year 1777: and he adds, that it is probably contained also in the Ballycastle water in Ireland.

The greatest part of the clays contain a volatile alkali, which discovers itself in the distillation of the spirit of sea-salt, &c.

Order V. Metallic Salts.

The native salts belonging to this division may be distinguished by the phlogiﬁcated alkali, which precipitates them all. Those which have saline properties, according to the definition of salts formerly given, shall be mentioned here; referring the rest to the mineralized metals; as the tana e reverse, the saline quicksilver or nitric mercury, &c.
MINERALOGY.

Part II.

Metallic Neutral
Salts.

1. Vitriol of copper; blue vitriol. *Vitriolum veneris,
for Egyptian.*

This neutral metallic salt is a combination of the
vitreous acid with copper, and is found in all
sulfur waters, as they are called. Its colour is a
deep blue; and being long exposed to the air, it
degenerates into a rusty yellow blue. Urged by
the flame of the blow-pipe on a piece of charcoal,
it froths at first with noise, giving a green flame,
and the metallic particles are often reduced to a
shining globule of copper, leaving an irregularly
figured scoria. But with borax the scoria is
dissolved, and forms a green glass.

This salt rarely occurs crystallized; but is often
found naturally dissolved in water in Hungary,
Sweden, and Ireland: from this water a blue vi-
triol is generally prepared. These natural wa-
ters are called cementory or cementing ones.
According to Monet, this concrete salt, when found
naturally formed, only proceeds from the evapo-
ration of such waters. It is also occasionally ex-
tracted from sulphurated copper ores after torre-
faction. See Chemistry-Index, at vitriol.

II. Muratic copper, or marine salt of copper. *Caprum
faiLium.*

This salt has been found in Saxony, in the mine
of Johngenqestadt. 1. It is cf a greenish
colour, and foliated texture. 2. It is moderately
hard. 3. Sometimes it is transparent and crys-

tallized.

It has been taken for a kind of mica; but Pro-

fessor Bergman found it to consist of copper
and marine acid, with a little argillaceous earth.

Another specimen of a purer sort was deposited
in the museum of Upsal. This is of a bluish
green colour, and friable. It effervesced with ni-
trous acid, to which it gave a green colour: and
by adding a proper solution of silver, a luna cor-
nea was formed, by which the presence of the
muratic acid was ascertained. (Kirwan and Berg-
man.)

III. Martial vitriol; vitriol of iron. Common green
vitreous or copperas.

This is the common green vitriol, which is na-

turally found dissolved in water, and is produced
in abundance by decayed or calcined maresites.

This metallic neutral salt results from the com-
bination of the vitriolic acid with iron.
1. It is of a greenish colour when perfectly
and recently crystallized; but,
2. Effloresces by being exposed to the air, be-
comes yellowish, and is covered with a kind of
rutil. Sometimes it becomes white by long
standing.
3. It requires six times its weight of water, in
the temperature of 60 degrees, to be dissolved.
4. It has an astringent, harsh, and acridulous taste.
5. Exposed to a moderate heat, even to that of
the sunshine, it falls into a yellowish powder;
but,
6. On being exposed to a sudden heat, it melts;
and on cooling, assumes a whitish brown colour.
7. When strongly urged by fire, it loses its acid,
becomes of a dark red colour, and is then call-
ed colochar; a powder which is employed in
polishing metals, to which the artificers have
applied the improper name of crocus martius,
though this name only belongs to the yellow
preparations of the iron-calces, used in phar-
macy and in enamelling, &c.

8. Pure fixed alkali precipitates the iron from its
solution in deep green flakes; the mild alkali,
in a greenish white colour; pure volatile alka-
li, in a deep green, that it appears black;
but the mild volatile alkali precipitates it in a
greyish-green colour.

9. All vegetable astringents, as the tincture of tea,
quingua, gales, &c. precipitate the iron in a
black colour: hence they are used as tints to
discover its presence in chemical analyses;
and it is from this black precipitate that the
common writing ink is made, being diluted
in water, and there suffused by the Arabic or
Senegal gums.

10. One hundred parts of this salt, recently crys-
tallized, contain 20 of real vitriolic acid, 23 of
iron, and 55 of water.

11. Its acid is known by this, that its solu-
tion mixes without turbidity with the solu-
tions of other salts that contain vitriolic acid;
as Epsom, felenite, vitriolated tartar, &c.

12. And the basis of this metallic salt is known
by the black colour produced by the solution
of vegetable astringents.

83. On being urged by the flame thrown by the
blow-pipe, it offers the same phenomena as the
vitreol of copper, except that it does not colour
the flame.

Green vitriol is frequently found native, ei-
ther in coal mines or in the cavities of pyrita-
ceous mines, or adhering to their scaffolds in a
falselithic form. It is found also in small
round flakes, called ink-flakes, of a white, red,
grey, yellow, or black colour, which are almost
soluble in water, and contain a portion of copper
and zinc. Also sometimes in form of schilitus
or flaty pyritaceous flakes. But the greatest
part of that in use is prepared by art, from the
martial pyritis or mundus. See Chemistry,
nº 619.

IV. Aerated iron. *Ferrum aeratum.*

This metallic salt is a combination of the aeri-
al acid with iron; and is found in the light
chalybeate waters, where it is dissolved by an ex-
cess of this acid.

Mr Lane was the first who discovered in Eng-
land the action of the aerial acid on iron, when
the water is impregnated with that menstruum.
The late R. Rouelle demonstrated the same
phenomenon in France upon this and other met-
tals. But Professor Bergman seems to have pre-
ceded them both nearly about the same time,
thought neither had any knowledge of each other's
discoveries.

The great volatility of this acid is the cause why
this neutral salt is not often found. For the
mere evaporation of the ferruginous mineral wa-
ters, in order to analyze them, is sufficient to let
loose the aerial acid; so that the iron which was
there dissolved by its power falls down to the
bottom in the form of a light ore, which amounts
to nearly 1/5 of the weight of the water; and when,
Part II.

**MINERALOGY.**

V. Vitriol of cobalt, or vitriolated cobalt.

This metallic salt results from the combination of the vitriolic acid with cobalt.

1. When found native, it is always in an efflorescent state; whence it arises that, in this case,
2. Its colour is greenish, mixed with a grey tint; but,
3. It is of a rosy colour when artificially made;
4. Effloresces when exposed to the action of the atmosphere; and,
5. Takes then a greenish colour mixed with a pale purple, or a Lilac colour, as the French call it.
6. It is difficultly soluble in water; and,
7. Its solution is of a red colour.
8. The phlogilicated alkali precipitates the cobalt from the solution of this salt, which with borax gives an azure glaze.

By the above qualities, chiefly the rosy:

1. It requires little more than twice its weight of water to dissolve it in the temperature of 60 degrees of Fahrenheit's thermometer, and deposits a greyish yellow powder.
2. Its specific gravity is 2000.
3. Its taste is very rejecting.
4. It mixes uniformly with vitriolic neutral salts.
5. Precipitates nitrous or marine felenites from their solutions, by which its acid is ascertained.
6. It is precipitable in a whitish powder by alkalis and earths; but,
7. Neither iron, copper, nor zinc, precipitate it: by which circumstance its basis is sufficiently indicated.
8. If it contains any other metallic principle, this may be precipitated by adding more zinc to the solution; excepting iron, which will of itself precipitate by exposure to the air or boiling in an open vessel.
9. One hundred parts of this metallic salt contain 22 of vitriolic acid, 20 of zinc, and 58 of water.
10. Urged by fire, it loses a good part of its acid.
11. Treated with the blow-pipe it exhibits nearly the same phenomena as other metallic vitriols; except only that the flame is brilliant when the zinc is reduced, and gives out white flocks called flowers of zinc.

This neutral metallic salt is sometimes found native, mixed with vitriol of iron, and in the form of white hairy crystals; or in a vitriolic form in the mines of Hungary, or as an efflorescence on ores of zinc. It is also found dissolved in mineral waters, and generally with some proportion of vitriols of iron and copper. Bergman says it is sometimes produced by the decomposition of pseudoglaucan, or black jack; but this rarely happens, because this substance does not readily decompose spontaneously.

But that in common use is mostly prepared at Goslar, from an ore which contains zinc, copper, and lead, mineralised by sulphur and a little iron. The copper is first separated as much as possible: the remainder after torrefaction and distillation is thrown red-hot into water and lixiviated. It is never free from iron. (Kirwan, Mongez.)

VI. Vitriolated nickel, or vitriol of nickel.

This neutral metallic salt results from the combination of the vitriolic acid with nickel. It exhibits sometimes in consequence of the decomposition of the sulphureous ores of this semi-metal. It is found native, efflorescing on Kupfer-nickel; and generally mixed with vitriol of iron.—It is of a green colour, as well as its solution. It is precipitated by zinc; but when joined with iron, this last is not precipitated by the same.

Its origin is perhaps owing to the decomposition of the pyriticous and sulphureous ore of Kupfer-nickel, mentioned by Wallerius. This ore contains a great quantity of arsenic and sulphur, as well as cobalt, nickel, and iron. And if it comes to be decomposed in the bowels of the earth, it is natural to expect that the vitriolic acid of the sulphur will attack the nickel and the iron, with which it will form neutral metallic salts (Mongez, Kirwan.)

VII. Muriatic manganese. Manganeseum salis.

M. Helm is the only person who has as yet found this middle salt in some mineral waters of Sweden. It is composed by the combination of the regulus of Manganese with muriatic acid.

1. It is precipitated of a whitish yellow colour, by the Prussian (phlogilicated) alkali; and of a brownish yellow, by the mineral alkali. 2. It does not crystallise in any distinct form. 3. It abstracts the moisture of the air. 4. To obtain its basis free from iron, it must be precipitated by the mineral alkali; redissolved in nitrous acid; then calcined until this acid is expelled; and the residuum is to be treated with distilled vinegar, which will then take up only the manganate. (Kirwan.)

VIII. Muriatic manganese. Manganeseum salis.

Order. VI. TRIPLE SALTS.

The neutral salts hitherto enumerated are such as are composed of two ingredients only; but sometimes three or more are so united as not to be separated by crystallization. The vitriols that we are acquainted with are hardly ever pure; and two or three of them sometimes are joined together.

Sometimes likewise it happens that neutral salts join earthy salts, and earthy salts metallic ones. Bergman generally distinguishes compound salts according to the

三. 化学火柴

这火柴属于所有可燃的酸性的，但不能在水中，它们排斥。
It is difficult to determine what constitutes the difference between the purer forts of this class, since they all must be tried by fire, in which they all yield the same product; but those in which the fire show their differences by containing different substances, are here considered as being mixed with heterogeneous bodies: that small quantity of earthy substance, which all phlogiston leave behind in the fire, is, however, not attended to.

I. Inflammable air; fire damp.

This aeriform substance is easily known by its property of inflaming when mixed with twice or thrice its bulk of common atmospheric air; and it is asserted to be the real phlogiston almost pure. See AERIOLOGY·Index and INFLAMMABLE AIR.

It admits considerable varieties, according to the nature of the substances from which it is produced, and often gives different residua upon combustion, some of which are of the acid kind. If it is produced from charcoal, it yields an acid or fixed air; from solutions of metallic substances in the vitriolic, nitrous, or marine acids, it yields these respective acids, as M. Lavoisier asserts.

Either, converted into vapour in a vacuum, gives a permanent elastic vapour, which is inflammable. The atmosphere, which floats round the fraxinella, is inflammable from the admixture of its vapours, which seem to be of the nature of an essential oil: so that on approaching the flame of a candle under this plant, in hot weather, it takes fire in an instant; although the essential oil, extracted from this plant by distillation, is not inflammable on account of the watery particles mixed with it, as M. Bomare asserts.

Mr Scheele is of opinion, that every inflammable air is composed of a very subtile oil. This coincides with the idea entertained by chemists of their phlogiston; and is confirmed by the fact, of its being naturally found in those springs from whence it flows petrol, whose exhalations are very inflammable.

The residuum, which remains in the atmosphere after the combustion of inflammable air, is extremely noxious to animals. Doctor Priestley takes it to be a combination of phlogiston with pure air, and on this account calls it phlogistated air. But M. Lavoisier, on the contrary, considers it to be a primitive substance of an unchangeable nature, and gives it the singular name of atmospheric nephritis.

II. Hepatic air.

This air seems to consist of sulphur, held in solution in vitriolic or marine air. It is inflammable when mixed with three quarters of its bulk of common air. Nitre will take up about half the bulk of this air; and when saturated with it, will turn silver black: but if strong dephlogistated nitrous acid be dropped into this water, the sulphur will be precipitated.

One hundred cubic inches of this air may hold eight grains of sulphur in solution in the temperature of 60°; and more if hotter.

Atmospheric air also decomposes hepatic air.

It is found in many mineral waters, and particularly in the hot baths of Aix-la-Chapelle. The cause and manner of their containing sulphur which was long a problem, has at last been happily explained by Mr Bergman.

It plentifully occurs in the neighbourhood of volcanoes and in several mines.

Hepatic air is easily obtained by art, from all sorts of liver of sulphur, whether the base be an alkali, an earth, or a metal, if any acid is poured upon it; and the better, if the be made of the marine acid, because it contains phlogiston enough, and does not so strongly attract that of the hepatic sulphur. For this reason the nitrous acid is not fit for this process, as it combines itself with the phlogiston, and produces nitrous air. It may also be produced, by distilling a mixture of sulphur and powdered charcoal, or of sulphur and oil, &c. See the detached article Hispanic Air, and AERIOLOGY·Index.

III. Phlogiston combined with aerial acid; black lead, or wadd. Plumbago. See the detached article Black-Lead.

It is found,

a. Of a feel-grained and dull texture. It is naturally black, but when rubbed it gives a dark lead colour.

b. Of a fine fizzly, and coarfe-grained texture; coarse black-lead.

IV. Mineral tallow. Serum mineral.

This was found in the sea on the coasts of Finland in the year 1736. Its specific gravity is 0.770: whereas that of tallow is 0.969. It burns with a blue flame, and a smell of grease, leaving a black viscid matter, which is with more difficulty consumed.

It is soluble in spirit of wine only when tarryfied; and even then leaves an insoluble residuum; but expressed oils diffuse it when boiling.

It is also found in some rocky parts of Persia, but seems mixed with petrol, and is there called sebenemad, stenpen, kowic. Dr Herman of Strafsburg mentions a spring in the neighbourhood of that city, which contains a substance of this sort diffused through it, which separates on ebullition, and may then be collected. (Kirwan).

V. Ambergris. Ambra grisea.

It is commonly supposed to belong to the mineral kingdom, although it is said to have doubtful marks of its origin (A).

(a) Ambergris, according to the assertion of M. Aublet (in his Histoire de la Guiane), is nothing more than the juice of a tree infallated by evaporation into a concrete form. This tree grows in Guyana, and is called...
Inflammable.

VI. Amber. 

This substance is dug out of the earth, and found on the sea-coalts. - According to the experiments of M. Bourdelin, it consists of an inflammable substance, united with the acid of common salt, which seems to have given it its hardness.

This accounts very well for the claws, beaks, bones, and feathers of birds, parts of vegetables, shells, and bones of fish, and particularly for the beaks of the cuttle fish or sepia ocellopodia, that are sometimes found in the mafs of this substance. Dr Swediar, however, attended only to these facts, though he had mentioned also the other substances in his paper inserted in the Philosophical Transactions for 1783; wherein he attempts to establish an opinion, that the amber is nothing else but a preternatural hardened dung, or feces, of the physter whale. Dr Withering and Mr Kirwan have embraced this notion; as did also, inadvertently, the editors of this Work. See Ambergris.

(a) Mr Aublet brought specimens of this gum-resin, which he collected on the spot, from the cuma tree at Guiana. It is of a whitish-brown colour with a yellowish shade, and melts and burns like wax on the fire. The singularity of this gum-resin is, that it imbibles very strongly the smell of the aromatic substances which surround it; and it is well known that perfumers avail themselves very conferably of this advantage. M. Rouelle examined very carefully this substance brought over by Mr Aublet, and found that it produced the very same results as in other good kinds of amber. Besides Mr Aublet's authority, which is decisive, as being grounded upon direct proofs of fact, Rumphius, quoted by Bergman, long since mentioned a tree called Nanarius, whose infalliated juice resembles amber. It cannot therefore at present be doubted that the origin of this phlogistic substance is the vegetable kingdom, although it may be often found and reputed as a produce of the fossil kind.

This substance being analysed by Meffrs Geoffroy and Newman, quoted M. Fourcroy, yielded them the same principles as the bitumens; viz. an acid spirit, a concrete acid salt, some oil, and a charry residuum; which evidently evinces, that all these fat and oily fossil substances have their origin from the other two kingdoms of nature.

(c) Ambergris is not only brought from the East Indies, but from the coasts of the Bahama Islands, Brazil, Madagascar, Africa, China, Japan, the Molucca islands, the coasts of Coromandel, Sumatra, &c. Dr Lippert, in a treatise he published at Vienna 1782, entitled Phlogiologia Mineralis, has copied chiefly from Wallerius what he afferts of this substance. He affirms that there are eight known species of amber; five of a single colour, viz. the white and the black from the island of Nicobar, in the gulf of Bengal, the alth-coloured, the yellow, and the blackish; and two variegated, viz. the grey coloured with black specks, and the grey with yellow specks. This last he afferts to be the most esteemed on account of its very fragrant smell, and to come from the South coast of Africa and Madagascar, as well as from Sumatra; and that the black dark coloured amber is often found in the bowels of cetaceous fishes. The same author adds also from Wallerius, that by distilling the oil of yellow amber (fuscum) with three parts and a half of fuming nitrous acid, a residuum remains like rosin, which emits a perfect smell of musk; whence some conclude, that the ambergris belongs to the fossil kind: the contrary, however, is evinced in the preceding note.
MINERALOGY.

A. Opaque.
   b. White.
   c. Blackish.
B. Translucent.
   a. Colourless.
   b. Yellow.

The greatest quantity of European amber is found in Prussia; but it is, besides, collected on the coast of the province of Skone, and at Biorko; in the lake Malaren in the province of Upland; and also in France and in Siberia. It is chiefly employed in medicine and for making varnishes.

VII. Rock-oil.

This is an inflammable mineral substance, or a thin bitumen, of a light brown colour, which cannot be decomposed; but is often rendered impure by heterogeneous admixtures. By length of time it hardens in the open air, and then resembles a vegetable resin; in this state it is of a black colour, whether pure or mixed with other bodies. It is found,

A. Liquid.
   1. Naphtha.
       This is of a very fragrant smell, transparent, extremely inflammable, and attracts gold. It is collected on the surface of the water in some wells in Persia. See Naphtha.
   2. Petrol.
       This smells like the oil of amber, though more agreeable; and likewise very readily takes fire. It is collected in the same manner as the Naphtha from some wells in Italy. See Petroleum.
B. Thick and pitchy; Petroleum tenax. Barbadoes-tar.
       This resembles soft pitch.
       It is found at the Dead Sea in the Holy Land; in Persia, in the chinks of rocks, and in strata of gypsum and limestone, or floating on water; also in Siberia, Germany, and Switzerland, in coal-pits; and in America; likewise in Colnebrookdale in England.
C. Elastic petrol.
       This is a very singular fossil, found of late in England.
       By its colour and consistence, it exactly resembles the Indian-rubber, or the gum-resin, from the north part of Brazil, called caoutchouc. It is of a dark brown colour, almost black; and some is found of a yellowish brown cast, like the same gum-resin.
       With respect to its elastic consistence, it hardly can be distinguished from it, except in the cohesion of its particles, which is weaker.
       It has the same property of rubbing off from paper the traces of black-lead pencils.
       It burns likewise with a smoky flame; and also melts into a thick oily fluid; but emits a disagreeable smell, like the fossil pitch, or Barbadoes-tar.

(n) Amber, says M. Fourcroy, is found in small detached pieces, for the most part under coloured sands, dispersed in beds of pyritaceous earth; and above it is found wood, charged with a blackish bituminous matter. Hence it is strongly supposing that it is a refrinous substance, which has been altered by the vitriolic acid of the pyrites, notwithstanding that we know that acids, when concentrated, always blacken and charry refrinous substancess. In fact, the chemical analysis of this substance rather confirms that supposition.

The singular opinion of Dr Girtanner, about the yellow amber being produced by a kind of ants, may be seen in Journal de Physique for March 1786, page 227. Or see the article Amber in this Dictionary.

The colour, texture, transparency, and opacity of this substance, have shown some other varieties besides those mentioned in the text. The principal ones are the following:

6. The yellow succinum,
7. The coloured green or blue by foreign matter,
8. The veined succinum,
9. The white,
10. The pale-yellow,
11. The citron-yellow,
12. The deep-red,

The golden yellow transparent amber, mentioned in the text, is what the ancients called chrystoesrum, and the white opake was called leucochrom.

But we must be cautious about the value of the specimens remarkable for their colour, size, transparency, and the well-preferred insects they contain internally; since there is a probability of deception, several persons possessing the art of rendering it transparent and coloured, and of softening its, so as to introduce foreign substances, &c. into it at pleasure.

M. Fourcroy says, that two pieces of this substance may be united, by applying them to one another, after being wet with oil of tartar and heated. And Wallerius mentions, that pieces of yellow amber may be softened, formed into one, and even dissolved by means of oil of turnip-seed, in a gentle heat; and that according to some authors, it may be rendered pure and transparent, by boiling it in rape-seed oil, linseed oil, salt-water, &c.

Mr Macquer says, that for the purpose of making varnishes, this substance must undergo beforehand a previous decomposition by torrefaction, in order to be dissolved by linseed-oil or essential oils. See Varnish.

Besides the making of varnishes, this substance was much employed formerly in making various pieces of ornament and jewellery. The best pieces were cut, turned, carved, or plained, to make wafes, heads of canes, collars, bracelets, snuff-boxes, beads, and other toys, small fine chests, &c. But after diamonds and beautiful hard stones were brought into use, these trinkets are little considereed in Europe; nevertheless, they are still sent to Peria, China, and to various other eastern nations, who esteem them still as great curiosities.
MINERALOGY.

It is found in Moffrugfan in Norberg, and in Grengierberget, both in the province of Westmanland; and also in other places.

The pišalphalm is of a mean confidence between the asphaltum and the common petroleum. It is the very bitumen which is collected in Auvergne in France in the well called de la Pege, near Clermont Ferrand.

VIII. Jet. Gages, Saccinum nigrum.

This is a very compact bitumen, harder than asphaltum, always black, and susceptible of a good polish. It becomes electrical when rubbed; attracts light bodies like the yellow amber; and it floats on water.

It seems to be nothing else than a black amber, or succinum; but specifically lighter, on account of the greater portion of bitumen that enters into its composition. When burned, it emits a bituminous smell. See the article Jet.

IX. Mineral phlogiston united with earths.

A. With calcareous earth.

1. With pure calcareous earth. This is the fesid or flate former described.

B. United with calcareous, argillaceous, pondeorous, and sileceous earth and vitriolic acid. Lithaenbraz. See the articles Coal and Pit-coal.

This is of a black colour, and of a shining texture; it burns with a flame, and is mostly consumed in the fire; but leaves, however, a small quantity of ashes.

2. Culm-coal, called kalm by the Swedes.

This has a greater quantity of argillaceous earth and vitriolic acid, and a moderate proportion of petrol.

It has the same appearance with the preceding one, though of a more dull texture; it burns with a flame; and yet is not consumed, but leaves behind a flag of the same bulk or volume as the coal was.

From England, and among the alum rocks at Moltorp and Billingen in the province of Weltergottland.

3. Slate-coal.

This coal contains abundance of argillaceous earth. It burns with a flame by itself; otherwise it looks like other flates.

It is found at Gullerfen in the parish of Rettwik, in the province of Dalanne, and also with the coals at Boierup in Skone.

This seems to be the same with the bituminous schilus, already described among the argillaceous earths.

Mr Kirwan has put together this variety of coal with that other called Kilkenny-coal, tho' they have some different properties.

The cannel-coal is of a dull black colour; breaks easily in any direction; and, in its fracture, presents a smooth conchoidal surface, if broken transversely.

It contains a considerable quantity of petrol, in
Part II.

MINERALOGY.

in a less denfer state than other coals; and burns with a bright lively flame, but is very apt to fly in pieces in the fire. It is said, however, to be entirely deprived of this property, by being previously immersed in water for some hours.

Its specific gravity is about 1270; and being of an uniform hard texture may be easily turned in the lathe, and receive a good polish.

It is from this kind of coal that small vases, as ink-flasks, various trinkets, and other curiosities, are made in England, which appear as if made of the finest jet.

This contains the largest proportion of petroleum or asphaltum; burns with a lively flame and smoke, and more slowly, though intensely, than the cannel-coal.

The quantity of earth in this coal does not exceed one-twentieth of its weight. Its specific gravity is about 1400. It is frequently mixed with pyrites.

It is found in the county of Kilkenny, belonging to the province of Leinster in Ireland.

The quality of this coal burning almost without smoke, is mentioned in a proverb by which the good qualities of that country are expressed.

This consists of the former kinds of coal, mixed with a notable proportion of pyrites; hence it is apt to moulder and break when exposed to the air. It contains yellow spots that look like metal; and burns with a sulphureous smell, leaving either red ashes, or a flag, or both. Water acts upon it, after it has mouldered. Its specific gravity is 1500, or more.

Besides the above varieties, schistus, micaceous schistus, and gneiss, are frequently found in the neighbourhood of coal mines, so penetrated with petrol bitumen as to constitute an inferior species of coal; but the bitumen being burnt, they preserve their form, and in some measure their hardness. Also some grey flates, that are so soft as to be scraped with the nail, and are greasy to the touch, burn like coal.

All the differences of coal arise from a mixture of the varieties already mentioned; and it is observable, that wherever coals exist, flates are generally found near them. Salt or mineral springs are also often found in their neighbourhood. (Kirwan.)

7. Bovey coal. Xylanthrax.

This is of a brown, or brownish black colour, and of a yellow laminar texture. The laminæ are frequently flexible when first dug, though generally they harden when exposed to the air.

It consists of wood penetrated with petrol or bitumen; and frequently contains pyrites, alum, and vitriol. Its ashes afford a small quantity of fixed alkali, according to the German chemists; but according to Mr Mills, they contain none.

By distillation it yields an ill smelling liquor, mixed with a volatile alkali and oil, part of which is soluble in spirit of wine, and part insubstantial, being of a mineral nature.

It is found in England, France, Italy, Switzerland, Germany, Ireland, &c. (Kirwan.)

There are two sorts of inflammable substances known by this name, viz.

The first of a brown, yellowish brown, or black colour, found in moorish grounds; in Scotland, Holland, and Germany. When fresh, it is of a viscid consistency, but hardens by exposure to the air. It consists of hay mixed with calcareous earth and pyrites; and sometimes contains common salt. While hot, it is formed into oblong pieces for fuel, after the pyritaceous and stony matters are separated. When distilled, it affords water, acid, oil, and volatile alkali. Its ashes contain a small proportion of fixed alkali. They are either white or red, according as it contains more or less ochre or pyrites.

The second is found near Newbury in Berkshire. It contains but little earth; but consists chiefly of wood, branches, twigs, roots of trees, with leaves, grass, straw, and weeds. (Kirwan.)

9. Stone turf. Cronflede has ranged the turf among the foils of his appendix; but as that called in England by the name of stone-turf contains a considerable proportion of peat, it may be mentioned with propriety in this class.

Soon after it is dug out from the ground, where it keeps a soft consistence, it at first hardens; but afterwards it crumbles by long exposure to the air.

As to the other common turf, it only consists of mould interwoven with the roots of vegetables; but when these roots are of the bulbous kind, or in a large proportion, they form the worst kind of turf.

Although it may appear incredible, it is nevertheless a fact, that in England pit-turf is advantageously employed in Lancashire to smelt the iron-ore of that county. Mr Wilkinson, brother-in-law to Dr Priestley, and famous for his undertakings in the extensive ironworks, perhaps the greatest in Europe, makes use of pit-turf in his large smelting furnaces of that province.

Those foil substances, which furnish fuel for the various purposes of human life, are distinguished by the name of coal, on account of their being a succedaneum for wood and other vegetable productions, which when dry or of an elegant kind serve for the same uses. If these vegetable substances are deprived of their character by covering them after ignition, the half consumed remains, which is of a black colour, is called by the name of coal or charcoal; and from hence the foil which affords fuel has
MINERALOGY.

Part II.

Inflammables.

Pit-coal and earth-coal are synonymous, and mean coals dug out of a pit or from the earth. But the lithanthrax denotes stone-coal, and more properly indicates the cannel-coal, which has the greatest similarity to a flinty substance, by the dull appearance of its fractures and by the uniform texture of its parts.

All these coals are in general a bituminous black or brown and dark substance: for the most part they have a lamellated texture, which breaks easily, and always with a shining surface.

The varieties of pit-coals above-mentioned are the most remarkable, by which they may be distinguished from one another. But they are far from being homogeneous in each kind; as the accidental qualities, and the various proportions of their component parts, produce a far greater number of properties, which render them more or less fit for different purposes; though these are generally overlooked, and confounded with the common one of affording fuel for making fire to warm our rooms, or for culinary operations.

This foliâ bitumen, as Fournecroy remarks, being heated in contact with a body in combustion, and a free access of air, kindles the more slowly, and with more difficulty, as it is more weighty and compact. When once kindled, it emits a brisk and very durable heat, and burns for a long time before it is consumed. If extinguished at a proper time, the remaining cinders may serve several times for a new firing with a small addition of fresh coals. The matter that is burned, and produces the flame, appears very dense, as if united to another substance which retards its destruction. Upon burning, it emits a particular strong smell, which is not at all sulphurous when the earth-coal is pure, and contains no pyrites.

When the combustible, oily, and most volatile parts, contained in the earth-coal, are distilled and let on fire by the first application of heat; if the combustion is stopped, the bitumen retains only the most fixed and least inflammable part of its oil, and is reduced to a true charry state, in combination with the earthy and fixed base. Pit-coals in this charry state are called coaks, which are capable of exciting the most intense heat; and are employed all over Britain in the smelting of iron, copper, and other metallic ores, to the greatest advantage. See Coaks, Coal, Coals, and Pit-coal (x).

The coal-metals, or stone strata enclosing coals, are very numerous. Mr Williams† gives the following general account of those in Scotland.

The sandstones. Of these there is a great variety, distinguishable by colour, texture, and degrees of hardness, generally disposed into thick, midddling, and thin strata. The only species our author takes notice of is the regular broad-bedded free-stone of a laminated texture. This commonly rises in thin or middling strata; appearing at the edges of a feation, when broken or cut, to be composed of thin lamina or layers of sand, equally laid on the whole breadth of the stone, and well cemented together. A great deal of both red and white free-stone rise in layers of five or six inches, and so upwards, with regular strata of a fifth or sixth part of an inch appearing the whole length of the stone, when the edge of a flab is polished, as if so many gentle waves of water had formed the layer. The regularity of the structure of this stone corresponds exactly with the regularity of its layers; and our author is of opinion, that the flaggy grey-strata of free stone, with many of the black and grey-strata of coal metals, the grey flate, as well as many other thin strata of the coal metals, may be ranked with this free-stone for perfect and regular stratification.

Along with these he classes some of the thin argillaceous strata. "Many of the grey regularly stratified mountain limestone" (says he) are also streaked or striped; and the streaks in these appear more conspicuous when broken than the streaked free stones. Some of the hard regularly stratified mountain rocks are also stratified; and in all these three kinds of stones, the streaks are regularly and exactly parallel to the bed of the stone."

Another remarkable instance of regularity of strata is met with in the grey flaggy strata of Caithness.—Throughout all the low country of Caithness, a square of about 10 or 15 miles, there are bluish argillaceous strata, with generally a small quantity of lime in the composition of the stone, which is indurated to a greater degree than is usual in such thin strata. The stone is strong and tough, every where disposed in thin broad-bedded, regular strata; and in several parts of the country the flags are so thin and regular, and are raised so high and broad, that they are used for covering houses; and three or four of them will cover the side of a small one. Our author mentions a gentleman who has an estate on the south side of the Pentland firth, and who in a bay there raises flags of any size and thickness he pleases; and so truly flat and smooth, that he has only to square the edges to make of them good loft-floors, partitions, chests, mangers, roofs of houses; in fact, he does everything with them. The face of these flags are as smooth and true a plane, as if artificially finisht by the best workman."

In moss coal fields there are a great variety of strata of different kinds accompanying and lying between the seams of coal, of all sorts of colours, consistencies, and dimensions; all of them blended together without any certain order or regularity; so that if there be 20 seams of coal, it is possible that there may be as many different rocks; that is, the stratum which is the immediate roof of one seam of coal, shall differ from that of another seam in quality, thickness, and colour, so that perhaps no two of the twenty shall be in any respect alike.

The various kinds of coal-ribs (a) commonly met with are the following.

(a) The stratum which is placed immediately above a seam of coal, is called the roof of the coal, and that which is placed immediately below the seam, is called the pavement of the coal: which three, viz. the stratum of coal, and its roof and pavement, with the other connectant strata lying above and below them, always preserve their stations and parallelism; that is, are all stretched out and spread one above another upon the same inclining plane, and have the same line of bearing and declivity.
MINERALOGY.

X. The mineral phlogiston or bitumen, united with the vitriolic acid: sulphur or brimstone. See the article Sulphur.

This is very common in the earth, and discovers itself in many and various forms. It is found,

A. Native. Sulphur nativum.

In this the two constituent parts are mixed in due proportion in regard to each other, according to the rules of that attraction which is between them. It is easily known,

1. By its inflammability, and by its flame.
2. By its smell when burnt; and,

O 2 3. By

---

Part II.

1. Basaltes. This is very common in Scotland, where it is frequently called whin rock; and at Borrowstounness there are several thin sheets of it between the seams of coal. One of them being the immediate roof of a seam of coal there at Hillhousie lime quarry, there is a thin seam of coal beneath a beautiful bed of columnar basaltes. In the Bathgate hills to the southward of Linlithgow, also, there are several strata of coal blended with those of basaltes. These basaltic strata are always very hard, frequently very thick, and generally of a black or blackish grey colour. “There are but few people (says Mr Williams) sufficiently versed in natural history, to know that they are basaltes, as this kind of rock, both in England and Scotland, goes by the name of whin rock. In the north of Scotland it is called shurdy; and among the miners in Cornwall it has the name of cockle (b).”

2. Strata of limestone of various thicknesses are met with in different coal-fields. Sometimes the lime is the immediate roof; but sometimes there is an argillaceous stratum of about the thickness of a foot between the coal stratum and that of lime. In the coal-fields at Gilmerton, near Edinburgh, are several beds of limestone, some of them very good, and of considerable thickness. At Blackburn in Weald Lothian, also, there is a stratum of limestone five or seven feet thick, which is the immediate roof of a seam of coal about five or six feet thick. At Carlops and Spittalhaugh in Tweeddale, they have a seam of coal immediately below their lime quarries, which they work for burning their lime.

3. Psphlstone, a kind of thick and solid stratum of free stone, is one of the roofs of coal, generally without the intervention of any argillaceous stratum, though sometimes a stratum of this kind is interposed. Frequently this kind of stone is rendered very hard by a mixture of iron or pyrites. In most coal fields, thinner strata of free stone are met with as the roofs of coal seams.

4. Dogger-band, as it is called by the Scots colliers, is frequently met with as the roof of coal seams. This name is applied to various substances. Sometimes they call strata of iron-stone dogger bands; sometimes the name is restricted to the ball iron-stone; sometimes to pyrites; and sometimes the dogger band is a kind of imperfect stone, composed of several heterogeneous mixtures, among which pyrites bears a considerable proportion, and by which the whole is so strongly bound together, that it is frequently very difficult to break through it.

5. Whin-stones, properly so called, not of a basaltic nature. These roofs are always very hard, and of various colours, as black, blackish grey, brown, red, &c. sometimes not above two or three feet in thickness, but sometimes much more.

6. Psphlstone, of a softer nature than that already mentioned. This has no mixture of ferruginous matter.

7. Regular strata of free-stone, of various colours, textures, and thicknesses, but not sufficiently thick to deserve the name of psphlstone, which our author thinks they do not, unless they are above three or four feet. These thin strata of free stone are very numerous in coal fields, and very frequently form the roofs of coal seams. Some of them are three or four feet thick, while others do not exceed three or four inches. They make good roofs, easily cut through, and may be readily quarried out for other purposes.

8. Grey-bands, or grey-coloured free-stone, frequently form the roofs of coal seams. A great number of them are generally arranged in one place, lying immediately above one another; and they are frequently found of all degrees of thickness from one to twenty inches, though the most common dimensions are from two to five. By the Scots colliers these are called grey shales as well as grey bands. Frequently they are found of moderate hardness, and sufficiently strong to make good flags and covers for fewers. These roofs are strong and safe when the stone partakes of the nature of the coal, and has a black or blackish grey colour; but when they have a mixture of tarry or argillaceous matter, they are more friable.

9. Blaes, when hard, strong, and well stratified, are reckoned tolerably good coal-roads. These are always of a bluish-black or black-grey colour, and are of great variety in respect to hardness and strength. Some of the strongest and hardest are either entirely black or greyish black; while some of the different blazes of black are pretty thick, and others are but thin. The thickest, however, are not above 18 inches, and the thinnesstwo or three inches or less. The medium thickness is from one foot to three or four inches. Some of them are sufficiently hard to make a good and safe coal-roof; but they seldom acquire such a degree of hardness as to give any considerable obstruction in fucking. All of them seem to have a considerable quantity of black argillaceous matter in their composition, and the strong blaes have also a considerable quantity of sand; often also containing a large portion of empyreumatic oil, and sometimes have a considerable mixture of coaly matter. There is a great variety both in the thickness and quantity of these blaes found above seams of coal. In some places the thinnest strata make the immediate roof; in others, the thickest. Sometimes we find only five or six inches of blaes upon the coal; in others as many fathoms, or even much more; and it is common to find them of all the intermediate thicknesses.

(b) We must observe, however, that according to Bergman and other eminent mineralogists, the cockles or shires ought not to be confounded with basaltes; which last name does not at all fit their substances. See Volcanic Products in the Appendix to this article.
MINERALOGY.

3. By its producing a liver of sulphur, when mixed with a fixed alkali, like that made from artificial sulphur. It is found,
   a. Felucid, of a deep yellow colour.
   b. Opaque, white, and greyish.
   These are found in Siberia, at Bievix in Switzerland, and at Solferato near Naples.
   c. Crystallised in oeoedral prisms, with blunted points.
   d. Transparent. Mr Davila had been informed that this was brought from Normandy in France. (Brun.)

10. Whitish and off-coloured argillaceous strata, of middling strength, are frequently found to be the immediate roofs of coal. Some of these are of middling thickness, others thin. They are commonly found from two inches to two feet in thickness. A great many of these roofs are very dangerous on account of their fragility; while others are quite safe, owing to the more perfect formation of their strata, or to some ingredient in their composition.

11. streaked roofs. These are of two sorts: 1. Such as are composed chiefly of sand, with a very small mixture of clay and blaes; and, 2. Those composed principally of clay or blaes with a small quantity of sand. Some of these have large, others small, streaks or ribs. Mr Williams says that he has seen them so beautifully streaked as to resemble the finest striped cotton stuffs. These stripes or streaks always lie exactly parallel to one another, as well as to the bed of the stone, and are always spread out the whole breadth of the stratum. Their colours are various in different strata, some of the stripes being nearly black and white, others white and red, and others yellow and red. In some the stripes appear of a lighter and darker grey colour. Some of the finely streaked stones have their streaks about a quarter of an inch in diameter; sometimes less: and it is common to see stripes from a quarter to three quarters of an inch broad; but in the finely streaked stones it is rare to find them a full inch thick without some different shade on one side or other of the stripe. The second kind of these streaked roofs, viz. such as are composed of blaes, with a smaller mixture of sand, differ but little from the former; only the colours are not always so bright, nor the stripes so fine; neither is the roof quite so hard.

12. The soft blue roofs sometimes consist of pretty thick strata; others of such as are thin or of middling thickness. There are likewise arrangements or clays of regularly stratified blaes, found immediately above seams of coal, from three or four inches to several fathoms in thickness, though some are even met with little exceeding one inch in thickness; though in the same place there might be a considerable thickness of blaes above the coal, taking in all the different strata, thick and thin, which lay above it. Some of these roofs have an oily appearance on the outside, and through all the figures and joints of the strata; that is, they appear smooth and glossy, and are very slippery to the touch. Others have no appearance of this kind; but all of them are tender, weak, and fragile, so that they make a very indifferent and dangerous roof.

13. Another kind of coal roof consists likewise of blaes, but such as are imperfectly stratified. It is altogether the same in quality and colour as the last, the only difference that can be distinguished being in the different degrees of stratification. The beds of this kind are not perfect, but unequal; whence it is a bad and dangerous roof, as great pieces of it are frequently apt to fall down by reason of the inequality and different joints of the strata. Some of these blaes appear in thick, and others in thin or middling thick beds: while some have an oily smoothness, called by the Scots colliers creasty (greatly) blaes. It is owing to this oiliness particularly that these kinds of roofs are so dangerous; for the oil pervades the joints, and, rendering them slippery, makes the pieces more apt to fall out as soon as the coal is worked away from below them. Some of these have such a quantity of natural oil, that they will flame a little in the fire; and in some places there are hard blaes which will burn when fire is set to them, though they will not consume. At Pitfrran in Fife there is a species of these blaes so inflammable, that when fire is set to one corner of a hillock it will burn throughout the whole; nevertheless it is not reduced in bulk by this combustion, nor does it produce any ashes. Instead of this it becomes considerably harder than before, and acquires a pale red colour. By reason of its hardness, it is proper for being laid upon horse and foot paths, but is not so for roads over which heavy wheel-carriges pass.

14. Soft blaes not stratified at all. Of these there is no more than one bed from two or three inches to several fathoms in thickness, without any others either above or below it. They are as common as any above the coal seams; but their subidence is not always uniform throughout the whole stratum. Some of them are found divided into small angular masses, and others into larger ones; but whether these are uniform or not, they always make a bad and dangerous roof. These argillaceous strata are sometimes called beds of till; the uniform part are called dawk, and the glibous kind sgoy blaes, by the Scots colliers. Both the uniform and glibous soft blaes generally contain a quantity of ball iron-flone, though some of it contains none at all. The regular continuous strata of iron-flone are commonly found in stratified soft blaes. There is a variety of soft coal roofs of a grey colour, and of which some are regularly stratified, and some not.

Part II. Infammerables.

1. Native sulphur is found in different forms, viz. either in solid pieces of indeterminate figure, running in veins through rocks; or in small lumps, in gypsum and limestone; in consideralable quantities at Solferato, and in the neighbourhood of volcanoes; or crystallised in pale, transparent, or semi-transparent, octagonal, or rhomboidal crystals, in the cavities of quartz; and particularly in the matrices of ores; or in the form of small needles over hot springs, or near volcanoes (Kirwan). Some
Part II. MINERALOGY.

Sometimes it is formed in old privies: of this Mr Magellan saw some lumps that were found in a very old one at Paris.

2. United with clay in the aluminous ore of La Tolfa, and also at Tarnowitz in Styria. This last resembles a light grey earth: when dry, bursts or cracks in the water like marle; and possesses a strong peculiar smell like camphor. If distilled, the sulphur sublimes. One hundred parts of this earth afford eight of sulphur, besides gypsum and a quantity of iron.

3. Mixed with clay, iron, and felenite. This compound is of a grey, brown, or black colour, found near Rome, Auvergne, Spain, and Iceland.

4. With limewater in the form of a calcareous hepar. This is found at Tivoli, near Rome, and elsewhere in Italy. It is sometimes dissolved in mineral waters, three pounds of which contain as much as 25 grains of sulphur. It often forms incrustations on the brinks of these springs.

5. In the form of an alkaline hepar. This is said to be found in some waters in Russia; as will be hereafter noticed.

6. United to iron and clay of pyrites, &c. of which hereafter.

7. United to metallic substances, as hereafter specified.

B. Saturated with metals (f).

1. With iron. Pyrites, or copperas-iron; Pyrites.

15. Regularly soft grey coal-roofs.—Of these there are several sorts. Some have a considerable quantity of sand in the composition of the strata; and many of these are as regularly stratified as any coal-metals whatever. Numbers are found very thin, and others of middling thickneas; though in all cases they are too tender and friable, that they make very bad and dangerous roofs. Some of them indeed look pretty well at first; but when they soon crumble and come down, especially when they have been exposed to the air. This, in the opinion of Mr Williams, is owing partly to their having too much clay in their composition, and partly to the want of a sufficient quantity of natural cement to connect the several particles of the roof together.

16. Soft grey regular strata, or grey bands of an argillaceous kind; and of these there is likewise a considerable variety. Some are of a dark, others of a lighter grey; some thick, others thin; they are very numerous in coal-fields, and are frequently to be found as the immediate roofs of coal. These, as well as the black kinds, are found in all quantities or degrees of thicknees above different coals, from a few inches up to several fathoms; but whether they be in great or small quantity, the roof they compose is generally very frail and tender.

17. Soft grey argillaceous beds, imperfectly stratified. These differ little or nothing in substance from the former; the only difference is in the stratification. Many of the strata of the former are of a middling thicknees, or rather thin, finely and regularly spread out, and every part of each stratum of an equal thicknees. But this sort, though it has the appearance of strata, is clumsy and irregular; that is, the several beds are unequal, and divided by many irregular joints into unequal misshapen masses, which makes this a very bad roof; the masses being apt to separate at the joints, and to fall down when the coal is worked out from below them.

18. Soft grey argillaceous beds of metal or coal roofs not stratified at all. These are of two kinds, viz. 1. such as are found broken or formed in the stratum into glebes or masses; and, 2. such as are found in one uniform mass throughout the whole bed, without any division into masses or strata. These grey soft roofs are of all degrees of thicknees, from a few inches up to many fathoms, as well as the black; and there is but very little difference between them in any respect excepting the colour. But in this, as well as in the black unstratified blues, and that both in the glebes and uniform beds, ball or glebes iron-iron is frequently found; and strata of iron-iron are also found in the stratified soft grey blues.

19. White and afo-coloured soft argillaceous coal roiefs; and of these there is also a great variety. Some of this kind are regularly stratified, others imperfectly, and some not at all. Some of the whitish argillaceous roofs are compounded of gritty sand and clay; others appear to be chiefly composed of pure clay; and some of a loamy clay. Those which are regularly stratified and mixed with sand, either coarse or fine, are of great variety with regard to thicknees and the arrangements of the strata; but all of them are tender and fragile, and thus make very troublesome and dangerous roofs.

20. White argillaceous roofs, stratified, and of a homogeneous quality, or not mixed with sand. Some of these are finely and perfectly stratified, and are of different degrees of hardnees; but in general, make but a weak roof. Some of them are found in irregular strata, with all the other varieties and imperfections already mentioned.

21. White and afo-coloured argillaceous coal-roofs, not stratified at all. Sometimes these are found in very thick beds in the coal-fields; and some of these, as well as of the black soft roofs, rise in glebes and masses of different sizes; while others are homogeneous throughout the whole bed, however thick, from two or three inches to several fathoms. Some of these beds of white argillaceous marle-like matter are found to be a sandy or loamy clay; others a pure homogeneous clay, which does not feel gritty between the fingers nor in the mouth. The shades and varieties of this kind are as numerous as those of any of the foregoing; and all of them, by the Scots colliers, are called dauf, whatever be their colour. Mr Williams informs us, that he has frequently taken some of these fine white clays to wash his hands, and has found them answer almost as well as soap.

(f) Sulphur is the most common mineraliser of metals; and therefore most of its combinations with those substances fall to be ranked hereafter among the metallic ores.
Class IV. Metallic Substances.

Metals are those minerals which, with respect to their volume, are the heaviest of all known bodies. Some of them are malleable; and some may be compounded; and, in a melting heat (o), be brought back again to their former state by the addition of the phlogiston they had lost in their decomposition. See Metalurgy, Part I. Sect. 1. and Chemistry-Index at Metallic Cales and Metals.

All the metallic substances contain phlogiston; and when, to a certain degree, deprived of it, fall into a powder like an earth; but their attractions for phlogiston are different.

Most of them, when melted in a common way, and exposed to the air, have an earthy crust formed upon the surface, which cannot again be reduced to metal without the addition of some inflammable matter. The base metals have this property.

But the noble metals, viz. platina, gold, and silver, are so firmly united to the phlogiston, that they never calcine under fusion, however long continued; and, after being changed into a calx in the liquid way, when melted in the fire, they realume their metallic form without any other phlogiston than what is contained in the matter of heat.
Part II.  

**MINERALOGY.**

Quick silver holds a kind of middle place; for, like the base metals, it may be calcined, though not readily; and, like the noble ones, it may be reduced by heat alone.

We may therefore reckon four noble or perfect metals; viz. gold, platinum, silver, and mercury; because, when calcined, they recover their phlogiston without the addition of any phlogistic substance.

But as tin, lead, copper, and iron, cannot be reduced without such addition, these are called ignoble and imperfect or base metals. Kirwan's Mineralogy.

However, all those eight metals (even mercury, when solid) are malleable to a considerable degree, and are called **entire metals.** But bismuth, zinc, antimony, arsenic, cobalt, nickel, manganese, molybdena, and wolfram, are scarce at all malleable, and hence they are called **femimetals.** Neverthe less, zinc and purified nickel are more malleable than any of the other semimetals; so that we have four perfect or noble metals, four imperfect or base, eight entire, and nine semimetals.

**N. B.** By saturating phlogiston, Professor Bergman means to express the proportionate quantities taken away from each metallic substance, when dissolved by means of acids, and of course reduced to a calciform state. The last column only expresses their attraction to this part of their phlogiston, not to that which still remains united to them in a calciform state. Withering.

(h) Mr Mongez remarks, that the following are the general properties of metals, when considered as physical bodies; viz. their opacity, great specific gravity, ductility, tenacity, crystallization, flavour, and even smell, at least in some of them.

It is from their density that their gravity and opacity proceed; this last being such, that, even reduced to the thinnest plates, no rays of light can pass through their particles, unless there remains an interstice or pore quite free from the metallic substance. Gold leaf must, however, be excepted, which exhibits a fine green by transmitted light.

As to their crystallization, it has been found to take place whenever they are pure, and left to cool very slowly by themselves, after having been perfectly fused. (See Journal de Physique for July 1781, p. 74) The flavour and smell above-mentioned are very perceptible in the reguline substances of arsenic and antimony, as well as in lead, copper, and iron.

All metals are conductors of electricity; and more perfectly so than any other bodies during their union with phlogiston.

They
MINERALOGY.

Part II.

6. When melted, it reflects a bluish-green colour from its surface.
7. It dissolves in aqua-regia, in the dephlogified marine acid, and also (according to Cretz) in an acid obtained by distilling vitriolic acid from off manganate.
8. When mixed with a volatile alkali and a little of the acid of nitre, by means of precipitation out of aqua-regia, it burns off quickly, in the least degree of heat, with a strong fulmination.
9. It is dissolved, in forma feta, by the liver of sulphur, and also somewhat by the glafs of bismuth (1).
10. It is not carried away by the antimony during the volatilization of that semi-metal, and is therefore conveniently separated from other metals by the help of crude antimony; in which proceeds the other metals are partly made volatile, and fly off with the antimony, and partly unite with the sulphur, to which the gold has no attraction, unless by means of some uniting body, or by a long digestion (x).

11. The

They are soluble either in nitrous acid and in dephlogificated marine acid, or in aqua-regia; and are precipitable in some degree by caustic alkalies; and except platina by the Prussian alkali.

When dephlogificated, they communicate a tinge to borax and to microcosmic salt, or at least render them opaque.

They assume a convex surface when melted, and even a globular form, if in a small quantity; and though they mix for the most part with one another whilst fused, yet they refuse to unite with unmetallic substances, even their own calces, iron only excepted, which does to its own calx slightly dephlogificated and to plumbago. Nickel also, and some others, may contain sulphur in their reguline flate.

Metals, when calcined, are capable of uniting with other calces and salts.

Three of the metallic calces have been found to be of an acid nature; viz., the arsenical, molybdenic, and tungstenic; from which, by analogy, the nature of other calces may be conjectured.

The phlogiston contained in metals is in a pure flate; viz., without water and aerial acid, with which it is invariably accompanied in all other compounds except acid airs and sulphur.

When metallic substances are naturally found in the earth united to their full share of phlogiston, and consequently possessing their peculiar properties, they are called native.

But when they are found more or less deprived of their phlogiston and of their properties, combined with other substances, they are then called mineralized. This is the most common state of the mineral kingdom. The substance so combined with them is called the mineralifer, and the whole is called ore; by which name are also distinguished these earths and stones in which metallic substances are contained.

But if both metallic substances are mixed together in their metallic or reguline form, without the loss of phlogiston, they are then said to be alloyed.

When the mineralifer is of a faline nature, and renders the metallic combination soluble in less than 20 times its weight of water, the compound is ranked among salts. Thus the vitriols of iron, copper, and zinc, are rather classed with salts than with ores.

The most common mineralifers are, sulphur, arsenic, and fixed air or aerial acid. The least common are the vitriolic and the marine acids. The phosphoric has been found only in two instances; viz., united to lead, discovered by Gahn; and to iron, in the siderite, as Mr. Meyer believes.

These metallic substances, mineralized by aerial acid, are called calciform ores.

M. Magellan observes, that if the new doctrine of the French chemists, who assert, that calces of metals are a compound of dephlogificated or vital air with the metallic substance, were just, all calciform ores should produce this vital air instead of aerial acid, when they are reduced to their metallic form; which is not the case; neither should all the base metals and semimetalts absolutely require the mixture of some phlogistic substance in order to their being reduced from the state of calces to their metallic form, which otherwise would be quite useless, if their reduction simply consisted in their separation from the vital or dephlogificated air.

(1) Neither sulphur nor fixed alkali, has any action on gold; but the liver of sulphur, which is a compound of both, can diffuse it in the dry way; for when a proper quantity of gold-leaves be put in a crucible together with liver of sulphur, and it be melted in a brisk fire, the gold is thoroughly diffolved; and if the whole be diluted in water, the gold will be kept in the solution, and even pass through the filter along with it.

(x) Antimony is used also to refine gold from its alloy, as it attenuates and carries off all other metallic substances.
MINERALOGY.

1. Mineralized with sulphur by means of iron. Marcatiological gold-ore; Pyrites aurum.
2. By means of quicksilver. It is found in Hungary.
3. By means of zinc and iron, or silver. The Scheinmizt blende.

See other varieties of mineralized gold ores under the detached article Gold, already referred to.

II. Silver: Argentum, Luna. See the article Silver. See also Chemistry-Index; and Metallurgy, Part II. sect. iii. and Part III. sect. iii.

This metal is,

a. Of a white shining colour.

b. Its specific gravity to water is, according to Cronstedt, as 11.091 to 1000; according to Bergman, = 10.552; and according to Kirwan, 11.095.

c. It is very tough or ductile, so that a grain of it may be fretched out to three yards in length and two inches in breadth.

d. It is unalterable in air, water, and fire.

e. It dissolves in the acid of nitre, and also by boiling in the acid of vitriol.

f. If precipitated out of the acid nitre with the common salt, or with its acid, it unites so strongly with this last acid, that it does not part from it, even in the fire itself, but melts with it into a mass like glass, which is called luna cornes (v).

Part II.

11. The phosphorus is said to have ingress into gold (t). 

12. If mixed with a less portion of silver, platina, copper, iron, and zinc, it prefers tolerably well its ductility. But,

13. When mixed with tin, it becomes very brittle; and it attracts likewise the smoke of that metal, so as to be spoiled if melted on an hearth where tin has been lately melted (m).

14. It requires a strong heat before it melts, nearly as much or a little more than copper.

15. It mixes or amalgamates readily with quicksilver. See Metallurgy, Part II. sect. i. (n).

16. It is not dissolved by the glafs of lead, and therefore remains on the cupel.

A. Native gold. With respect to the figure or the quantity in which gold is found in one place, it is by miners divided into,

1. Thin superficial plated or leaved gold; which consists of very thin plates or leaves, like paper.

2. Solid or massive, is found in form of thick pieces. 

3. Crystalized, consists of an angular figure.

4. Wash gold, or gold dust, is washed out of sands, where it lies in form of loose grains and lumps (o). See other distinctions of form under the article Gold.

B. Mineralized gold. This is an ore in which the gold is far mineralized, or fo entangled in other bodies, as not to be dissolved by the aqua-regia.

Vol. XII.

Substances mixed with it, without excepting the silver; whilft lead leaves this last behind, and even adds some of its own to the gold. Pauilot, p. 659.

(t) Gold, reduced into thin leaves, is not acted upon by the phosphoric acid in the humid way, though the fire be urged till luminous decrepidations take place; but when it passes that point which separates the humid from the dry way, Mr Margraaf observed that some purple protons were formed, which is an indication that this concrete acid had partly calcined the gold during its fusion. Elements de Chimie de Dijon, Vol. III. p. 131.

Besides this, a drop of the phosphoric acid on the solution of gold by aqua-regia precipitates the metal in its refined state, as asserted by the academicians of Dijon. Magellan.

(n) The fumes of a single grain of tin are capable of rendering hard eight ounces of gold; but it easily recovers its malleability by being melted on the fire. (Wallerus and Bomare's Mineralogy.) But when gold is mixed with arsenic, cobalt, nickel, bismuth, or with the regulus of antimony, it only loses great part of its malleability; and when in a certain proportion, it may be calcined and vitrified with them.—(Frabori.)

(m) Bergman doubts if ever gold has been found perfectly pure; and Mr Kirwan says that it is very seldom found so, being generally alloyed with silver, copper, or iron, or all three. As to the gold commonly used in toys and other objects of luxury, every one knows that it is purposely debased by the artists with copper or other metals; and of late it has been employed in various pieces of jewellery, to form ornaments of various colours: thus a great alloy of silver (viz. one-third part), gives it a shade of a green colour; a similar quantity of copper, a reddish one; a mixture of arsenic, or filings of steel, in the proportion of one-fourth part, gives it a bluish cast; so that having the yellow naturally in the pure gold, and the white in pure silver, the jewellers have almost all the colours to diversify their work. Even in the currency of money, there is none coined out of pure gold, but by common agreement, is called gold of 24 carats. The gold coin of England, France, and Portugal, only contains 22 parts of pure gold, and two of alloy, viz. it is only 22 carats, in the common saying: that of Spain is but of 21½ carats: but the ducats of Holland is of 23½ carats; and the zecchino of Venice, of 23½ carats: which last therefore, it would seem, is the purest coin of Europe. (Pauilot's Metropolis.)

(o) M. Daubenton, in his Methodical Tables of Minerals, enumerates eight forts of native gold, viz.

1. In powder; 2. In grains; 3. In small spangles; 4. In maites or lumps; 5. In filaments; 6. In branches like vegetables; 7. In lamella; and 8. In octahedral crystals.—He observes also, that gold, in its reguline state, is formed, either, 1. Into angular crystals, composed of yellow octahedres; or, 2. Into irregular yellow maites, which, being broken, show a granular substance.

(v) The marine acid attracts the calx of silver, but cannot remove its phosphited; and therefore cannot dissolve
MINERALOGY.

Part II.

Annaberg, described by Mr Jufti; (Brumich.)

11. Sandy silver-ore, without any metallic fining.

12. Silver-ore in a red-brown felicitus, described by Lehman: it is composed of argillaceous earth, micaceous hematites, sulphur, calcareous spar, fluor minerals, lead, and silver. It contains about seven or eight ounces of silver on the hundred weight.

13. Soft silver-ore. It is found among the marls and argillaceous earths; and is of various colours, either finely or mixed.

C. Dissolved and mineralized.

(1.) With sulphur alone. Glass silver-ore.

This is ductile, and of the same colour as lead; but, however, becomes blacker in the air. It has therefore, though very improperly, got the name of 'gafi-ore'; for that name rather belongs to the mineral argent cornez, or born silver-ore, if indeed any silver-ore can be considered as glassy.

It is found,

1. In crusts, plates, or leaves.

2. Grown into
   a. Snaggs, and
   b. Crystalline figures.

   It is generally either of a lamellar or a grained texture.

The glass silver-ore is the richest of all silver ores; since the sulphur, which is united with the silver in this ore, makes but a very small quantity of its weight.

(2.) Arsenico-martial silver-ore, Weill arto, Germ.

This ore contains silver and iron mineralized by arsenic; the arsenic in a larger proportion than the iron. This is the Pyrites argentee of Henckel.

1. It is a hard substance, of a white fining appearance, and of a compact, lamellar, or fibrous texture. (Kirwan, p. 7.)

2. Of a yellowish white colour, and of a striated structure, resembling blinmuth, but much harder. (Kirwan, p. 3.)—It is found near Guadalen canal in Spain.

3. Near the fame place is found also another ore of the fame kind, which is very soft and easily cut; and when cut, has a brilliant metallic appearance. It consists of conchoildal lamina. The quintal contains only from four to six ounces of silver; but it is easily reduced by evaporating the arsenic, which then leaves the silver slightly contaminated with iron. (Kirwan, p. 4.)

(3.) With

Silver is found,

a. Native or pure; which most generally is nearly of 16 carats standard. (a.)

1. Thin, superficial, plated or leaved.

2. In form,
   a. Of faggs, and coarse fibres.
   b. Of fine fibres. Capillary silver.
   c. Arborecent.
   d. Crystaline or figured. This is very rare:

   It has distinct fibres, with fining surfaces.

B. Mixed or alloyed with other metals.

The following are the known influences of these mixtures:

1. United to gold, (Bergman's Scizographia, § 154.)

2. Mixed with copper; (Berg. Sc. § 155.)

3. United to gold and copper; (Berg. Sc. § 156.)

4. Amalgamated with mercury, found in the mines of Salberg; (Poffer's notes to Brunich.)

5. United to iron; (Berg. Sc. § 157.)

6. United to lead, sometimes in such quantities as to be worth the expenses attending the separation.

7. United to arsenic; (Journal de Physique, 1778, p. 55.)

8. United to antimony; (Berg. Sc. § 159.)

9. Joined to the regulus of arsenic and iron; (Berg. Sc. § 160.)

10. Mixed with the alkaline limestone from

It does not unite with the semi-metal nickel, during the fusion.

b. It amalgamates easily with quicksilver.

c. It is in the dry way dissolved by the liver of sulphur.

d. It has a strong attraction to sulphur, so as readily to take a reddish yellow or black colour when it is exposed to liver vapours.

e. It has no attraction to arsenic; whence, when the red arsenical silver ore, or rothgulden erza of the Germans, is put into the fire, the arsenic flies off, and leaves the sulphur (which in this compound was the medium unius), behind, united with the silver in form of the glass silver-ore, or glasses etz.

m. It is not dissolved by the glasses of lead, and consequently it remains on the cupel.

m. It is exhaled or carried off by volatile metals and acids; as by the vapours of antimony, zinc, lead, the acid of common salt.

a. According to Cronstedt, it melts more easily than copper; and this was a general opinion. But the contrary, as Mr Magellan remarks, has been proved by means of the nice thermometer lately invented by Wedgewood.—See Thermometer.

Silver is found,

a. Native or pure; which most generally is nearly of 16 carats standard. (a.)

1. Thin, superficial, plated or leaved.

2. In form,
   a. Of faggs, and coarse fibres.
   b. Of fine fibres. Capillary silver.
   c. Arborecent.
   d. Crystaline or figured. This is very rare:

   It has distinct fibres, with fining surfaces.

B. Mixed or alloyed with other metals.

The following are the known influences of these mixtures:

1. United to gold, (Bergman's Scizographia, § 154.)

2. Mixed with copper; (Berg. Sc. § 155.)

3. United to gold and copper; (Berg. Sc. § 156.)

4. Amalgamated with mercury, found in the mines of Salberg; (Poffer's notes to Brunich.)

5. United to iron; (Berg. Sc. § 157.)

6. United to lead, sometimes in such quantities as to be worth the expenses attending the separation.

7. United to arsenic; (Journal de Physique, 1778, p. 55.)

8. United to antimony; (Berg. Sc. § 159.)

9. Joined to the regulus of arsenic and iron; (Berg. Sc. § 160.)

10. Mixed with the alkaline limestone from

The vitriolic acid being distilled also over the manganese, dissolves silver, gold, and mercury, as Dr Crell afferts, (Journal de Physique, Oct. 1785, p. 297.)

Silver is precipitated from the vitriolic and nitrous acids by the marine; and from the nitrous, in great measure, by the vitriolic, (Kirwan.)

(a.) Wallerus distinguishes seven species of silver: (see the article Silver). Daubenton reckons eight varieties of native white silver, arising from their peculiar forms.
Part II.

MINERALOGY.

(3.) With sulphur and arsenic. The red or ruby-like silver ore. The *rothgulden* of the Germans.

The colour of this ore varies as the proportion of the ingredients varies in the mixture, viz. from dark grey to deep red; but when it is rubbed or pounded, it always gives a red colour.

a. Grey arsenical silver ore.
   1. Plated, crusted, or leaved.
   2. Solid.

b. The red arsenical silver ore:
   1. Plated crusted, or leaved;
   2. Solid or scaly;
   3. Crystalised (a.)

   In this last form it shows the most beautiful red colour, and is often semi-transparent. It contains about 60 per cent. in silver.

(4.) With sulphur, little arsenic, and iron. — *Schwartz erz, Schwartz gulden, Silber und Silbermalm, German.*

This is a friable, weathered, decayed ore.

a. Of a black or footy colour; and is therefore called by the Germans *federerz,* or *raffiger-erz.*

(5.) With sulphurated arsenic and copper. The *weissgulden* of the Germans.

This, in its solid form, is of a light grey colour, and of a dull and feeled-grained texture. Its proportion of silver is from 10 to 20 per cent.

(6.) With sulphurated arsenic and iron. The *weigerz,* or white silver ore of the Germans.

This is an arsenicous pyrites, which contains Silver; it occurs in the faxon mines, and so exactly resembles the common arsentic pyrites, as not to be distinguished from it by sight alone, or without other means.

(7.) With sulphurated antimony.

a. Of a dark grey and somewhat brownish colour; the *obererz* of the Germans.

b. Of a blackish blue colour:
   1. In form of capillary crystals. *Federcrterz,* or plumose silver ore.

(8.) With iron, arsenic, and cobalt, mineralised by sulphur.

This ore looks like the *weissgulden* described above; but is distinguished by the rufh coloured particles of cobalt, dispersed through dark brown, blackish, or grey, and sometimes shining solid masses. It is to this species of ores that the silver goose dung ore belongs.

(9.) With sulphurated copper and antimony. — The Dal *fablerz.*

This resembles both in colour and texture the dark-coloured weissgulden. When rubbed, it gives a red powder.

a. Solid.

b. Crystalised.

(10.) With sulphurated zinc. The *geechlende* of the Germans.

This is a zinc ore, mock lead, or blende, which contains silver, and is found among rich silver and gold ores.

a. Of a metallic changeable colour.
   1. Solid and with fine scales;
   2. In form of balls. The *kugelriet,* or ball ore.

b. Black mock lead, or blende, found in Saxony. This is also found,
   1. Solid and with fine scales;
   2. And in form of balls.

(11.) With sulphurated lead; potters ore. *Galena; kleiglaze.*

(12.) With sulphurated lead and antimony, called *fireperm.*

(13.) With sulphurated iron. *Silberhalitgier kies; marcasite holding silver.*

(14.) With sulphurated and arsenical cobalt; dendrites being sometimes found in the stone. These kinds keep well in water; but generally wither in the air, and lose the silver they contain.

(15.) Mineralised by sulphur, with regulus of antimony and barytes. The butter-milk ore. This is found in the form of thin particles, on granular *spar,* (*Kirwan,* p. 13.)

(16.) Combustible silver ore.

This is a black and brittle substance, and leaves about 6 per cent. of silver in its ashes. It is in fact a coal in which silver is found. (*Kirwan,* p. 14.)

(17.) With the acid of common salt. *Minera argenti cornes.* *Hornetz,* or horn-silver ore.

This is the scarcef t colour, changeable or varying on the surface, semi-transparent, and somewhat dudile both when crude and when melted. It cannot be decomposed without some admixture of such substances as attract the acid of sea-salt.

III. Platina del Pinto; *Juan blanca.*

This metal is a recent discovery of our times; and is described with great accuracy by Scheffer, in the Acts of the Royal Academy of Sciences at Stockholm for the year 1752; as also by Dr Lewis, in the Philosophical Transactions for the year 1754, vol. xlvii. and by many other writers. By these descriptions we are convinced of the resemblance this metal bears to gold; and therefore we must allow it to be called *white gold.* It has, however, a variety of distinguishing qualities.

(a) Walelius mentions the fix following varieties of this notable ore in his *Specie 588,* viz. 1. The red opaque, like cinnabar, from Andreaeburg in the Hartz, and from Salberg in Weimannia: 2. The bluish, from Freiberg and Annaberg: 3. The grey, from Freiberg and Andreaeberg: 4. The red transparent amorphous, of the garnet colour, from Potosi and Ioachimthal: 5. The red transparent, crystalised into prismatic decaedres, or dodecaedres, from Hungary, Allace, and the Duchy of Deux Ponts: 6. The only superficially red ore, from Salberg and Ebenfriderichsdorf.
M I N E R A L O G Y.

Perfect Metals. Quicksilver.

Ities besides its colour, which afferits its peculiar nature: All which, with its history, ues, &c. are particularly described under the detached article PLATINA. See also CHEMISTRY-INDEX; and METALLURGY, Part II. Sect. ii.

1. It is of a white colour.
2. It is fo refractory in the fire, that there is no degree of heat yet found by which it can be brought into fusion by it, the burning-glass excepted. But, when mixed with other metals and semimetals, it melts very easily, and especially with arsenic, both in its metallic form and in form of a calx or glafs.

IV. Quicksilver, mercury. Hydrazyrum, Argentum vi­num, Mercurius. See the article QUICKSILVER; CHEMISTRY-INDEX, at Mercury; and METALLURGY, Part II. sect. VIII.

Mercury distinguishes itself from all metals by the following qualities (s).

a. Its colour is white and shining, little darker than that of silver.
b. It is fluid in the cold, and divisible by the least force; but, as it only sticks to a few bodies to which it has an attraction, it is said that it does not wet.
c. It is volatile in the fire.
d. It attracts the other semimetals and metals: and unites with them all except cobalt and nickel, with which it cannot by any means yet known be made to mix. This union is called amalgamation. This amalgamation, or mixture of metallic bodies, according to the residuums with which they unite or mix, is in the following progression, viz. gold, silver, lead, tin, zinc, bifimth, copper, iron, and the regularus of antimony; the three latter, however, do not very readily amalgamate. The iron requires a solution of the vitriol of iron, as a medium to promote the union.
e. It dissolves in spirit of nitre, out of which it is precipitated by a volatile alkali, and common salt, in the form of white powder; but if a fixed alkali is used, a yellow powder or calx is obtained (r).

(s) It were almost superfluous, fays Mr Kirwan, to mention any other character of quicksilver than its liquidity, to distinguish it from other metals. In regard to this property, Bergman observes, that mercury constitutes one extremity among the metals, and platina the other; since it requires to be melted only such a degree of heat as is rarely wanting in our atmosphere, and boils at the 660 degrees nearly after lead melts. See the table at p. 111. Note. But when the cold is increased to the temperature denoted by 40 degrees below 0 both of Fahrenheit's and of the Swedish thermometer, which both coincide in that point (since 212—32, or 180 : 100:: 32 : 40, or 72 : 40), this metal concretes like any other metal, and becomes quite solid; (see Philosophical Transactions for 1783, p. 303.) Mercury in its common state, therefore, according to Bergman (Tract of Elæis. Atrack.), is to be considered as a metal in fusion; and since in its solid state it is nearly as malleable as lead, by no means ought to be placed among the semimetals, otherwise every other entire metal should be considered as brittle, for none is malleable when in fusion.

(r) 1. Mercury is dissolved with great rapidity by nitrous acid: the liquor is of a greenish-blue colour, but loses it afterwards and becomes limpid. This solution, when made without heat, is used as a test for the analysis of mineral waters, and has different properties from that made with the help of heat. In the first case, fays Bergman, very little phlogiston is left, and the falt easily crystallizes, being white and scarcely acrid. It is not precipitated by diluted water; but by caustic vegetable alkali, it is precipitated of a yellowish colour; by mild alkali, the precipitation is white; by mineral alkali, it is yellow, but it soon grows also white; by volatile alkali, it turns to a greyish-black colour; by Glanoper's falt or by pure vitriolic acid, the precipitation is white, granulated, and in a small quantity; nor, if this precipitant has been sparingly used, does this colour appear in less than an hour; by mutriatic acid, or common salt, the precipitation is also white, but in a large quantity, and in curdles.

2. But if the mercurial solution be put over a sand-heat, it may be charged with a quantity of mercury equal almost to its weight. According to the chemists of Dijon, 10 ounces of nitrous acid may dissolve eight ounces of mercury. The action of the solvent becomes stronger with the heat; emits great quantity of vapours; and if not taken from the fire, will be too far evaporated. Diluted water will precipitate from this solution a white calx, because it is more dephtoglitzated, and the solvent is overcharged with it; and the water changing the density of the liquor, diminishes the adhesion of the calx, as Fourcroy remarks. This white calx will turn yellow, if boiling water be poured on it. The vegetable alkali precipitates it of a brownish yellow, which by degrees assumes a pale yellow tinge: the mild vegetable, and the mineral alkalies, produce nearly the same colour; though when this last is employed, the colour turns afterwards to white. The precipitation by volatile alkali is quite white also; that by the vitriolic acid is yellow; and finally, a copious, white mucilaginous matter is the precipitate by the marine acid.

3. This solution by nitrous acid is very caustic; corrodes and destroys animal substances; when it falls on the skin, scalds it of a deep purple brown colour, which appears black: the pains do not go off before the separation of the epidermis, which falls away in scales or a kind of hairs. It is used in surgery as a powerful escharotic, and is called mercurial water.

4. The same solution, by cooling, is susceptible of forming crystals, which vary from one another according to circumstances: for the most part they are like needles; are very caustic; reddens the skin; and detonates when put on burning coals, provided they be dry. They are called mercurial niter, which fuses when heated in a crucible; exhales reddish fumes; assumes a deep yellow colour, which afterwards turns to orange, and...
MINERALOGY.

Part II. Perfect Metals. QuickSilver.

6. But it requires a boiling heat to dissolve it in oil of vitriol (v).

8. It is not affected by the acid of common salt, unless it be previously dissolved by other acids (v); in which case only they both unite with one another, and may be sublimed together; this sublimate is a strong poison.

b. It unites with sulphur by grinding; and then produces a black powder called athiops mineralius (w), which sublimes into a red fritted body called filidius cinnabar.

i. The sulphur is again separated from the quicksilver, by adding iron or lime, to which the sulphur attaches itself, leaving the quicksilver to be distilled over in a metallic form; but if a fixed alkali be used, some part of the quicksilver will remain distilled in the residuum, which is a liver of sulphur.

QuickSilver is found,

A. Native, or in a metallic state. Mercurium nativus, or virgineus.

This is found in the quicksilver mines at Idra in Friuli, or the Lower Austria, in clay, or in a black flaty lapis ollarius, out of which it runs, either spontaneously, or by being warmed even in the hands.

B. Untied in gold or silver. Hydrargyrum argentum vel aurum adunatum.

Mr Kirwan affirms, on the authorities of Monet and Lin, Von Gemlin, that in Sweden and Germany mercury has been found united to silver in the form of a somewhat hard and brittle amalgam.

Romé de l’Ife had a specimen of this natural amalgam from Germany, which is imbedded in a quartzose mass, and mixed with cinnabar, as Mr Mongez affirms; and he adds, that in the royal cabinet, at the king’s garden at Paris, is deposited another fine specimen of this mercurial ore, which was found crystallized in the mine called Carolina at Munchel-lansberg in the duky of Deux Ponts. M. de l’Ife speaks also very positively of a specimen of native gold from Hungary, which seems to be a natural amalgam of gold and mercury. It is composed of quadrangular prisms, of a greyish yellow colour, and of a brittle texture. This specimen is also in the king’s cabinet at the royal garden at Paris.

Mr Kirwan, speaking of the method of examining the purity of gold by the moil way, supposes, with Sir Torbern Bergman, that there are natural amalgamations of mercury with gold and silver; and Neumann observes, that sometimes a mineral, containing gold or silver, is met with among mercurial ores, although this is a great rarity.

It is evident, therefore, that there naturally exist and at last to a brilliant red: in this state it is called red precipitate, or corannum corallinum. It must be made in a muffle with a gentle heat, if it is designed to be corrosive for chirurgical purposes.

(v) 1. The vitriolic acid, concentrated and boiling hot, seizes on mercury, and presently reduces it if urged by heat to a kind of white powder, which turns yellow by the aflfusion of hot water, but does not dissolve in it: this is called turbid mineral: but if cold water, instead of hot, was poured in the white mass, the powder would not change its white colour into yellow as was said above about the nitrous solution.

2. If Mercury be rarefied by heat into vapours, and these meet with those of marine acid in the same state, a corrosive sublimate will be formed. This metallic salt breathes into crystals pointed like daggers, which are the strongest of all poisons. But there are various other processes found in chemical authors to make this salt with more or less trouble. See Chemistry, n° 814—818.

3. If corrosive sublimate be mixed with tin and distilled, a very smoking liquor is produced, called by the name of its inventor the smoking liquor of Libavius. See Chemistry, n° 816.

The muriatic acid in the sublimate is not saturated, and from hence proceeds its great corrosive power; for if a fresh quantity of mercury be added to it, and sublimed a second or third time, a sweet, or mixed sublimate, called mercius dulcis, is produced, which is not poisonous, and is given internally as a purgative, or an emetic, according to the dose. See Chemistry, n° 819.

(w) The academicians of Dijon say, that the true proportion to make this athiops is, that of one part of brimstone with four of mercury. Fourcroy directs only one of mercury, with three of flowers of sulphur, to be triturated, till the mercury is extinguished. A black powder is then produced, which is the athiops mineral. The combination is better effected when the mercury is mixed with the fused sulphur: by agitating this mixture, it becomes black, and easily takes fire; it should be then taken from the fire, and the flame should be extinguished a little after, stirring the mass till it becomes into solid clots. If this sublimate be exposed to a great degree of heat, it takes fire, the sulphur is consumed, and a sublimate remains which is of a violet colour when pulverized. This powder being put into matrasses, till their bottom become red by the force of fire, is sublimed after some hours, and artificial cinnabar is found in the top of the vessels crystallized into brown red needles.

Mercury, divided by means of a rapid and continual motion, as that of a mill-wheel, gradually changes itself into a very fine black powder, which is called athiops fer fiz, on account of its colour; in order to distinguish it from this athiops mineralius mentioned in the text.
it various ores of quicksilver, amalgamated with silver, gold, and other minerals, although they be but seldom met with.

C. Mineralized.

[1.] With sulphur.

a. Pure cinnabar, Cinnabaris natae.

b. Indurated or solid cinnabar. It is of a deep red colour; and, with respect to its texture, is either,

1. Steel-grained;
2. Radiated;
3. Composed of small cubes, or fealy; or
4. Crystalized, in a cubical form; it is transparent, and deep red like a ruby.

b. Impure cinnabars.

(1.) A mercurial ore is found in Idria, says Gellert, where the mercury lies in an earth or stone, as if it were in a dead form; and has the appearance of a red-brown iron-stone; but it is much heavier than that. It contains from three quarters to seven eighths of the purest mercury; leaves, after distillation, a very black earth behind; and gives some marks of cinnabar.

(2.) Liver ore, which is most common in Idria, and has its name from its colour.—Outwardly it resembles an indurated iron-clay; but its weight discovers that its contents are metallic. It yields sometimes 80 pounds of quicksilver per hundred weight.

3. Burning ore; branderz in German. This ore may be lighted at the candle; and yields from nine to 10 pounds of quicksilver per hundred weight. Brunnich.

Sir Torbern Bergman inferred this ore in the 177th section of his Scigraphia, and seems doubtful whether this be a different species from the cinnabar; as the iron is perhaps, says he, only mechanically diffused therein. Mr Mongez remarks, that there are but a few instances of cinnabar in which iron is not found in its calcined form; though, in the act of the ore being reduced, it passes to its metallic state, and becomes capable of being acted on by the loadstone.

Another pyriticous ore of cinnabar was found at Meniet; near St Lo in Lower Normandy. It consists in grains of different sizes, of a red brown colour; they had a vitriolic taste, and sulphureous smell. Found also at Almaden in Spain, and at Stahberg in the Pa

MINERALOGY.

Part II.

IMPERFECT METALS.

Tin.

This seems to be a native precipitate per se, or calx of mercury. It is said to have been lately found in Idria, in hard compact masses of a brownish-red colour; see Journal de Physique for January 1784, p. 61. If this account can be relied upon, it will prove, that quicksilver, even in a calciform state is naturally found mineralized with silver by means of sulphur.

[4.] With sulphur and copper.

This ore is blackish grey, of a glaffy texture, and brittle; crackles and splits excessively in the fire; and when the quicksilver and sulphur are evaporated, the copper is discovered by its common opaque red colour in the glass of borax, which, when farther forced in the fire, or diluted, becomes green and transparent. It is found at Mufchlanberg in the duchy of Deux Ponts.

[5.] Mineralized by the marine and vitriolic acids.

Mineralogy owes the discovery of this ore to Mr Woulfe, who published an account of it in the Philosophical Transactions for 1776. It was found in the duchy of Deux Ponts, at the mine distinguished by the name of Obermoehel. It had a spar-like appearance. This ore is either bright and white, or yellow or black. It was mixed with cinnabar in a fliny matrix; and being well mixed with one-third of its weight of vegetable alkali, afforded cubic and octagonal crystals; that is, salt of Sylvius and vitriolated tartar.

The marine salt of this mercury is in the state of sublimate corrosive.

Order II. IMPERFECT OR BASE METALS.

I. Tin. Stannum; Jupiter. (See the detached article Tin; Allo Chemistry-Index; and Metallurgy, Part II. sect. vi. and Part III. sect. vi.)

This is distinguished from the other metals by the following characters and qualities. It is,

a. Of a white colour, which verges more to the blue than that of silver.

b. It is the most fusible of all metals; and,

c. The least ductile; that is, it cannot be extended or hammered out so much as the others (x).

d. In

(x) Tin is sufficiently ductile to be beaten into very thin leaves. But ductility and extensibility are two different properties, let's connected with one another than is generally imagined. Iron and steel are drawn into exquisite fine wire, but cannot be beat into very thin leaves. Tin, on the other hand, is beat into fine leaves, and may be extended between rollers to a considerable surface. The tin-sheet used in various arts, is commonly about 1/2 th part of an inch; but may be extended twice as much in its dimensions without difficulty. Notwithstanding this extensibility, tin cannot be drawn into wire, on account of the weak cohesion of its particles. A tin wire, however, of one tenth of an inch diameter, is able to support a weight of 40½ pounds, according to Fourcroy. Gold and silver possess both properties of ductility and extensibility the most eminentiy of all metallic bodies; whilst lead, notwithstanding its flexibility and softness, cannot be made either into leaves or wire of any fineness.
Mineralogy.

d. In breaking or bending, it makes a crackling noise.

e. It has a smell particular to itself, and which cannot be described.

f. In the fire it is easily calcined to white ashes, which are 25 per cent. heavier than the metal itself. During this operation, the philogiton is seen to burn off in form of small sparkles among the ashes or calx.

g. This calx is very refractory; but may, however, with a very strong degree of heat be brought to a glass of the colour of colophony. But this calx is easily mixed in glass compositions, and makes with them the white enameled.

b. It unites with all metals and femimetals; but renders most of them very brittle, except lead, bismuth, and zinc.

t. It amalgamates easily with quicksilver.

i. It dissolves in aqua-regia, the spirit of fea-salt, and the vitriolic acid; but is only corroded into a white powder by the spirit of nitre. The vegetable acid, soaps, and pure alkaline solutions, which with them the white calx, or rather in an hard malleable tin, in a granular form, and also in a masy form, without any determinate figure. Tin-fione. It resembles a garnet of a blackish brown colour, but is much heavier; and has been considered at the English tin-mines as a fione containing no metal, until some years ago it began to be melted to great advantage.

b. Crystallized.

a. Tin fpar, or white tin ore. This is generally of a white, or grey colour; sometimes it is yellowish, semi-transparent, and crystallized, either of a pyramidal form, or irregularly.

b. Tin-grains. This ore, like the garnets, is of a spherical polygonal figure; but seems more unctuous on its surface.

1. In large grains.

B. Mixed with metals.

1. With the calx of iron, as in the garnet.

2. With manganèse. See the Semimetals.

C. Mineralized.

1. With sulphur and iron.

2. With sulphur. Aurum mufivum.

This was discovered by Professor Bergman, among some minerals which he received from Siberia. He observed two sorts of it, analogous to the two artificial combinations of tin with sulphur.

1. One nearly of the colour of zinc, and of a fibrous texture, which contained about 20 per cent. of sulphur, and the remainder tin.

2. The other enveloped the former like a crust; resembled aurum mufivum; and contained about 40 per cent. of sulphur, a small proportion of copper, and the remainder tin. Mem.Stockb.for.1721.p.328.

At Huel Rock, in St Agnes in Cornwall, there has been found a metallic vein, nine feet wide, at 20 yards beneath the surface. Mr Rafpe was the first who discovered this to be a sulphurated tin-ore: it is very compact, of a bluish white colour, approaching to grey steel, and similar to the colour of grey copper ore: it is lamellar in its texture, and very brittle. It contains of sulphur, tin, copper, and some iron. Mr Rafpe proposes to call it bell metal ore.

According to Mr Klaproth's analysis of this ore, 119 grains contain 30 of pure sulphur; 41 of tin; 43 of copper; two of iron; and three grains of the flory matrix. In another specimen of the same sulphurated tin-ore from Cornwall, there were in the hundred 25 parts of sulphur, 34 of tin, 36 of copper, three of iron, and two of the flory matrix.
The properties of lead are as follows.

a. It is of a bluish white colour when fresh broke, but soon dulls or fullies in the air.

b. It is very heavy; viz. to water as 11,325 to 1000.

c. It is the softest metal next to gold; but it has no great tenacity, and is not in the least fomentous.

d. It is easily calcined; and by a certain art in managing the degrees of the fire, its calx becomes white, yellow, and red.

e. This calx melts easier than any other metallic calx to a glass, which becomes of a yellow colour, and fomentansparent. This glass brings other bodies, and the imperfect metals, into fusion with it.

f. It dissolves, 1st, in the spirit of nitre; 2dly, in a diluted oil of vitriol, by way of digestion; 3dly, in the vegetable acid; 4thly, in alkaline solutions; and 5thly, in expressed oils, both in the form of metal and of calx.

g. It gives a sweet taste to all solutions.

h. It amalgamates with quicksilver.

i. With the spirit of sea-salt it has the same effect as silver, whereby is produced a *saturatus cornus*.

k. It does not unite with iron, when it is alone added to it in the fire.

l. It works on the cupel, which signifies that its glafs enters into certain porous bodies, defilts of phlogiston and alkaline fals.

m. It melts in the fire before it is made red-hot, almost as easily as the tin.

n. Its calx or glass may be reduced to its metallic state by pot-ashes.

[1.] Native Lead.

For proofs of lead being naturally found in its metallic state, see the article Lead.—It may be here added, that Henckel likewise affirms its existence, in his *Flora Saturni*; (See Kirwan's *Elements of Mineralogy*, p. 297, 298.) Wallerius affirms, that it has been so found in Poland, a specime of which was kept in the collection of Richer; and adds, that a similar one found at Schneberg, was seen in the collection of Spener. (*Mineralogy*, vol. ii. p. 301.)

Dr Lawson, in his English edition of Cramer's *Art of Assaying Metals*, says, that some pure native malleable lead had been lately found in New England; (p. 147.) And lately, Professor Bergman did not hesitate to infer, by itself alone, the *plumbum nativum*, in Sect. 180. of his *Stiographia*.

[2.] Calciform Lead.

Lead is found,

A. In the form of a calx.

a. Pure.

b. Indurated lead ipar, or ipasoe lead ore.

i. White, from Mendip-hills, in England.

ii. Crystallized in a prismatic figure.

i. White, from Norrgrufva in Westmanland.

2. Yellowish green, from Zchopau in Saxony.

i. With the calx of arsenic, arsenical lead ipar.

ii. Indurated.

a. White. Mr Cronfledt has tried such an ore from an unknown place in Germany, and found that no metallic lead could be melted from it by means of the blow-pipe, as can be done out of other lead ipars; but it must be performed in a crucible. (See the article Lead, par. iii.)

3. With a calcareous earth.

This ore effervesces with aqua-fortis, and contains 40 per cent. of lead; on which account it is placed here rather than among the calcareous earths.

B. Mineralized.

i. With sulphur alone: the *bley-skweiff*, or *bleyglans*, of the Germans.

a. Steel-grained lead ore.

b. Radiated, or antimonated lead ore.

c. Tefellated, or potter's lead-ore.

At Villach in Austria there is said to be found a potter's lead-ore, which contains not the least portion of silver.

ii. Mineralized by the vitriolic acid.

This ore was discovered by Mr Monnet. It occurs sometimes, though rarely, in the form of a white ponderous calx; and seems to originate from the spontaneous decomposition of the sulphurated lead-ores abovementioned.

iii. By the acid of phosphorus.

This ore was lately discovered by Ghan; and is of a greenish colour, by reason of a mixture of iron. See the article Lead, par. 6.

iv. With sulphurated silver. *Gahlena*; also called *bleyglans* by the Germans. Potter's ore.

a. Steel-grained.

b. With small scales.

c. Fine-grained.

d. Of a fine cubical texture; and,

e. Of coarse cubes. These two varieties are found in all the Swedish silver-mines.

f. Crystallized.

The steel-grained and fealy ores are of a dim and dull appearance when they are broken, and their particles have no determined angular figure: they are therefore in Swedish commonly called *bley-skweief*; in opposition to the cubical ores, which are called *bleyglans*. The most part of the ores called *bleyglans* contain silver, even to 24 ounces per cent. of which we have influences in the mines of Salberg, where it has been observed, that the coarse cubical lead ores are generally the richest in silver, contrary to what is commonly taught in books; the reason of which may perhaps be, that, in making the assays on those two ores, the coarse cubical can be chosen purer or freer.
MINERALS.

Part II.

1. Imperfect Metals.

Lead.

I. Cuprum, Venus, &c. (See the article Copper; Also Chemistry-Index; and Metallurgy, Part II. sect. iv. and Part III. sect. iv.)

This metal is,

a. Of a red colour.

b. It is pretty soft and tough.

c. The calx of copper being dissolved by acids becomes green, and by alkalies blue.

d. It is easily calcined in the fire into a blackish blue sub stance, which, when rubbed to a fine powder, is red; when melted together with glass, it tinges it first reddish brown, and afterwards of a transparent green or sea-green colour.

e. It dissolves in all the acids, and likewise in alkaline solutions. It is easier dissolved when in form of a calx than in a metallic state, especially by the acids of vitriol and sea-salt, and the vegetable acid.

f. Vitriol of copper is of a deep blue colour; but the vegetable acid produces with the copper a green salt, which is verdigris.

g. It can be precipitated out of the solutions in a metallic state; and this is the origin of the precipitated copper of the mines called Ziment copper.

h. It is not easily amalgamated with quicksilver; but requires for this purpose a very strong triation, or the admixture of the acid of nitre.

i. It becomes yellow when mixed with zinc, which

has a strong attraction to it, and makes brass, pinchbeck, &c.

k. When the metal is exposed to the fire, it gives a green colour to the flame in the moment it begins to melt, and continues to do so afterwards, without losing any thing considerable of its weight.

[1.] Native copper.

Copper found naturally in a metallic state, is called virgin or native copper. It is met with,

1. Solid.

2. Friable, in form of small, and somewhat coherent grains. Precipitated or ziment copper.

[2.] Calciform.

Copper, in form of a calx, is found,

1. Pure.

a. Loose or friable; Oedo venus.

1. Blue; Cuprum montanum. Very seldom found perfectly free from a calcareous sub stance.

2. Green; Viride montanum. Both this and the former colour depend on meniria, which often are edulcorated or washed away.

3. Red. This is an effulorescence of the glass copper ore.

b. Indurated. Glas copper-ore.

a. Red. This is sometimes as red as sealing wax, and sometimes of a more liver brown colour.

It is always found along with native copper, and seems to have lost its phlogiston by way of effulorescence, and to be changed into this form. It is likewise found with the sulphurated copper, improperly called glas copper ore.

a. Loose or friable; Oedo venus friabilis impura.

1. Mixed with a calcareous substance; Cuprum montanum. In this state copper-blue is mostly found. It ferments during the solution in aqua fortis.

2. Mixed with iron. Black. It is the decomposition of the Fahlun copper ore.

b. Indurated.

1. Mixed with gypsum, or plaster. Green.

3. Mixed with lime. a. Blue. This is the Lapis Armentus, according to the accounts given of it by authors.

3.) Cupreous stones.

Analogous to the calciform copper ores, are,

1. The lapis armentus. See the detached article.

2. The turquoise. Icile Copper, no 7.

[3.] Dissolved and mineralised; Cuprum mineralisatum.

a. With sulphur alone. Grey copper-ore; also called, improperly, glas copper-ore.

a. Solid, without any certain texture, and very soft, so that it can be cut with a knife almost as easily as black lead.

b. Fine cubical. In Smoland this is sometimes
Copper.

1. With sulphurated iron. *Minera cupri pyriticæa*; yellow copper ore. Marcasital copper ore; *Pyrites cupri*. This is various both in regard to colour and in regard to the different proportion of each of the contained metals; for in

instance,

a. Blackish grey, inclining a little to yellow; *Pyrites cupri griseus*. When decayed or weathered, it is of a black colour; is the richest of all the varieties of this kind of copper ore, yielding between 50 and 60 per cent. and is found in Spain and Germany.

b. Reddish yellow, or liver brown, with a blue coat on the surface; *Minera cupri lasserae*. This ore yields between 40 and 50 per cent. of copper, and is commonly said to be blue, though it is as red, when fresh broken, as a red copper regular.

c. Yellowish green; *Pyrites cupri flavo viridefens*. This is the most common in the north part of Europe: and is, in regard to its texture, found,

1. Solid, and of a shining texture.
2. Steel grained, of a dim texture.
3. Coarse-grained, of an uneven and shining texture.
4. Crystallised marcasital copper ore.

a. Of long octahedral crystals.

d. Pale yellow. This cannot be described but as a marcasite, though an experienced eye will easily discover some difference between them. It yields 22 per cent. of copper.

e. Liver-coloured.

f. With sulphurated silver, arsenic, and some iron, yellow copper-ore; which contains only a few ounces of silver. This ore is found in Hungary and Germany, where it is called black copper ore.

g. With sulphurated arsenic and iron. White copper ore.

h. Pyriticus copper, with arsenic and zinc. According to Mr Monnet, this ore is found at Catharineberg in Bohemia. It is of a brown colour; of a hard, solid, compact, granular texture; and contains from 18 to 30 per cent. of copper.

i. Disolved by the vitriolic acid; *Vitriolum venetius*. See the article copper, n° xiii.

j. With phlogiston. Copper coal ore, consisting of the calces of copper, mixed with a bituminous earth.

k. Mineralized by the muriatic acid. This ore was found in Saxony, and had been generally mistaken for a micaceous sub Lazith, which in fact it greatly resembles. It has not yet been found in large masses, but only in a superficial form, like a crust over other ores. It is moderately hard and friable; of a fine green colour; and sometimes of a bluish green, crystallised in a cubic form, or with a foliated texture, or in little scales resembling green mica or talc. This ore is easily dissolved by nitrous acid: the solution takes a green colour; and the metal may be precipitated on a polished plate of iron. If some drops of a nitrous solution of silver be mixed with it, a white powder of *luna cornea* will be precipitated, which discovers the presence of the muriatic acid in this ore.

The uses of copper are very numerous, although not thoroughly known to every one. Several of these have been mentioned under the detached article, and in *Chemistry*. Others of great importance may be here added. Its great ductility, lightness, strength, and durability, render it of very extensive utility. Blocks, or bars of copper, are reduced into flat sheets of any thickness, by being first heated by the reverberation of the flame, in a low vaulted furnace, properly constructed for the purpose; and then immediately applied between large rollers of steel, or rather of case-hardened iron, turned by a water-wheel or by the strength of horses, so that the hot metal is there quickly squeezed; and the operation is repeated, bringing the rollers every time nearer to one another, till the metallic sheet acquires the intended thickness.

These copper sheets are very advantageously employed in sheathing the bottoms of men of war and other vessels, which by this means are prevented from being attacked by the sea worms, and are kept clean from various marine concretions, so as to fail with considerably greater swiftness. Copper sheets are also employed to cover the tops of buildings instead of tiles or earthen tiles, as is used in Sweden; and some architects have begun to introduce the use of copper covering into Great Britain, which is much lighter, and may be used with great advantage, although it must be much dearer in prime cost.

Sundry preparations of copper are employed in painting, staining, and for colouring glasses and enamels. See *Glass and Enamel*.

The solution of copper in aqua-fortis stains marble and other stones of a green colour; when precipitated with chalk or whiting, it yields the green and the blue verditer of the painters. According to Lewis, a solution of the same metal in volatile spirits stains ivory and bones: when macerated for some time in the liquor, they become of a fine blue colour, which, however, tarnishes by exposure to the air, and becomes green afterwards.

The same author prepared elegant blue glusses, by melting common glasse, or powdered flint and fixed alkaline salt, with blue vitriol, and with an amalgam of copper; fine green ones were made with green verditer, and with blue verditer, as well as with the precipitate of copper made by fixed alkalis, and with a precipitate by zinc; and a reddish glass was produced by the caux and fcoria of copper made by fire alone. Even in this vitreous state, it seems as if a continuance of fire had the same effect in regard to colour, as air has upon copper in other forms; as some of the most beautiful blue glasses, by continued fusion, have changed.
Part II. MINERALOGY.

changed to a green colour. See farther the article Brass in the Glass-trade.

Verdigris is a preparation of copper dissolved by the vegetable acids, which act on this metal, dissolving it very slowly, but in considerable quantities. It produces a fine green pigment for painting both in oil and water colours, inclining more or less to the bluish according to circumstances.

So great is the tenacity of copper, that a wire of a tenth of an inch in diameter is capable of supporting 299.5 pounds weight before it breaks. Copper may be drawn into very fine wire, and beaten into extremely thin plates. The German artists, chiefly those of Nuremburg and Aulburg, are said to possess the best method for giving to these thin plates of copper a fine yellow colour like that of gold. See the articles Brass-Colour and Brass-Leaf.

The parings or shreds of these very thin leaves of yellow copper being well ground on a marble plate, are reduced to a powder similar to gold, which ferves to cover, by means of some gum-water, or other adhesive fluid, the surface of various moulding or other pieces of curious workmanship, giving them the appearance of real bronze, and even of fine gold; at a very trifling expense; because the gold colour of this metallic powder may be easily raised and improved by firing it on a wide earthen bafon over a slow fire.

In some of its states, copper is as difficultly extended under the hammer as iron, but proves fouter to the file, and never can be made hard enough to strike a spark with flint or other stones; from whence proceeds the use that is made of this metal for chisels, hammers, hoops, &c. in the gun-powder works.

The vitriolic acid does not act on copper unless concentrated and boiling; during this solution a great quantity of sulphurous gas flies off; afterwards a brown thickish matter is found, which contains the calx of the metal partly combined with the acid. By solution and filtration, a blue solution is obtained, which being evaporated to a certain degree, produces after cooling long rhombohedral crystals of a beautiful blue colour, called vitriol of copper; but if this solution be merely exposed a long time to the air, it affords crystals, and a green calx is precipitated, a colour which all calces of this metal assume when dried by the air. Blue vitriol, however, is seldom formed by dissolving the metal directly in the vitriolic acid. That fold in the shops is mostly obtained from copper pyrites. It may also be made by stratifying copper-plates with sulphur, and cementing them together for some time; because the vitriolic acid of the sulphur being disengaged, attacks and corrodes the metal, forming a metallic salt, which by affusion of water yields perfect crystals of blue vitriol. See Vitriol.

The nitrous acid, on the contrary, dissolves copper when cold with great rapidity; and a great quantity of smothering air or gas flies off, which, on being received in a pneumatic apparatus, and mixed in a glass tube with atmospheric air, shows its good or bad quality for the respiration of living animals, according as the common bulk is more or less diminished. This is one of the most important of Dr Priestley’s discoveries; and various instruments known by the name of calomel have been since invented for making these experiments with ease and satisfaction. See Eudiometer.

But the most common use of copper is to make allsorts of large stills, boilers, pots, funnels, and other vessels employed by distillers, dyers, chemists, and various other manufacturers, who make use of large quantities of hot liquors in their various operations.

Although copper when pure is extremely valuable, on account of its ductility, lightness, and strength, it is, however, less useful on many occasions from the difficulty of forming large masses of work; as it is not an easy matter to cast copper solid, so as to retain all its properties entire. For if the heat be not sufficiently great, the metal proves deficient in toughness when cold; and if the heat be raised too high, or continued for a length of time, the copper blisters on the surface when cast in the moulds; so that the limits of its fusion are very contracted. And from these circumstances pure copper is rendered less applicable to several purposes.

We find, however, that the addition of a certain proportion of zinc removes almost all these inconveniences, and furnishes a mixed metal more fusible than copper, very ductile and tenacious when cold, which does not so readily scorify in a moderate heat, and which is less apt to rust from the action of air and moisture.

Copper is the basis of sundry compound metals for a great number of mechanical and economical uses of life, such as brafs (v), prince’s-metal, tombac, bell-metal, white copper, &c. See Chemistry, n° 1154, &c.

If the mixture is made of four to fix parts of copper, with one part of zinc, it is called Prince’s-metal. If more of the copper is taken, the mixture will be of a deeper yellow, and then goes by the name of tombac.

(v) Brafs is frequently made by cementing plates of copper with calamine, where the copper imbibes one-fourth or one-fifth its weight of the zinc which rises from the calamine. The process consists in mixing three parts of the calamine and two of copper with charcoal dust in a crucible, which is exposed to a red heat for some hours, and then brought to fusion. The vapours of the calamine penetrate the heated plates of copper, and add thereby to its fusibility. It is of great consequence for the success of this process to have the copper cut into small pieces, and intimately blended with the calamine. See Chemistry, n° 1154.

In most foreign founderies the copper is broken small by mechanical means with a great deal of labour; but
Bell-metal is a mixture of copper and tin, forming a compound extremely hard and fono rous, and is less subject to alterations by exposure to the air than any other cheap metal. On this account it is advantageously employed in the fabrication of various utensils and articles, as cannons, bells, flat-trees, &c. in the composition of which, however, other metals are mixed in various proportions, according to the fancy and experience of the artist.

White-copper is prepared with arsenic and nitre, as mentioned under Chemistry, n° 1157.

But the principal kind of white-copper is that with which speculums of reflecting telescopes are made. See the article Speculum.

VII. Iron; Ferrum, Mart. This metal is, a. Of a blackish blue shining colour. b. It becomes dudle by repeated heating between coals and hammering. c. It is attracted by the leadstone, which is an iron ore; and the metal itself may also be rendered magnetic. d. Its specific gravity to water is as 7.645, or 8.000: 1000. e. It calcines easily to a black fealy calx, which, when pounded, is of a deep red colour. f. When this calx is melted in great quantity with glass compositions, it gives a blackish brown colour to the glass; but in a small quantity a greenish colour, which at last vanishes if forced by a strong degree of heat.

at Bristol the workmen employ an easier method. A pit is dug in the ground of the manufacture about four feet deep, the sides of which are lined with wood. The bottom is made of copper or brafs, and is moveable by means of a chain. The top is made of brafs with a space near the centre, perforated with small holes, which are luted with clay; through them the melted copper is poured, which runs in a number of fireams into the and this is perpetually renewed by a fresh stream of melted copper produces when thrown into cold water; which end is obtained by calamine.

It is a wonderful thing, says Cramer, that zinc itself, being simply melted with copper, robs it of all its malleability; but if it be applied in form of vapour from the calamine, the sublimates, or the flowers, it does not cause the metal to become brittle.

The method mentioned by Cramer to make brafs from copper, by the volatile emanations of zinc, seems to be preferable to any other process, as the metal is then preferred from the heterogeneous parts contained in the zinc itself, or in its ore. It consists in mixing the calamine and charcoal with moistened clay, and ramming the mixture to the bottom of the melting pot, on which the copper, mixed also with charcoal, is to be placed above the rammed matter. When the proper degree of heat is applied, the metallic vapour of the zinc contained in the calamine will tranpire through the clay, and attach itself to the copper, leaving the iron and the lead which were in the calamine retained in the clay, without mixing with the upper metal. Dr Watfon says that a very good metallurgist of Bristol, named John Champion, has obtained a patent for making brafs by combining zinc in the vapours form with heated copper plates; and that the brafs from this manufacture is reported to be of the finest kind: but he knows not whether the method there employed is the same with that mentioned by Cramer.

Brafs is sometimes made in another way, by mixing the two metals directly; but the heat requisite to melt the copper makes the zinc burn and flame out, by which the copper is defrauded of the due proportion of zinc. If the copper be melted separately, and the melted zinc poured into it, a considerable and dangerous explosion ensues; but if the zinc is only heated and plunged into the copper, it is quickly imbibed and retained. The union, however, of these two metals succeds better if the flux composed of inflammable substanaces be first fused in the crucible, and the copper and zinc be poured into it. As soon as they appear thoroughly melted, they are to be well tilled, and expeditiously poured out, or else the zinc will be inflamed, and leave the red copper behind.
Part II.

MINERALOGY.

125

a. In lumps of an indeterminate figure. All these are of a blackish brown, or a light brown colour.

b. Indurated. The blood-foane; Hematites.

1. Of an iron colour; Hematites carbonifera.

This is of a bluish grey colour; it is not attracted by the lodestone, yields a red powder when rubbed, and is hard.

a. Solid, and of a dim appearance when broken.

b. Cubical, and of a shining appearance when broken.

c. Fibrous, is the most common terrillon of Sweden.

1. Black.

2. Bluish grey. When this is found along with marcasite, it is not only attracted by the lodestone, but is of itself really a lodestone.

e. Crystallized.

1. In octaedrical crystals.

2. In polyedrical crystals.

3. In a cellular form.

These varieties are the most common in Sweden, and are very seldom blended with marcasite or any other heterogeneous substance except their different beds. It is remarkable, that these ores are found along with marcasite, those particles which have lain nearest to the marcasite are attracted by the lodestone, although they yield a red or reddish brown powder, like those which are not attracted by the lodestone: it is likewise worth observation, that they generally contain a little sulphur, if they are imbedded in a limestone rock.

2. Blackish brown blood-foane; Hematites nigroscura. Kidney ore. This yields a red or brown powder when it is rubbed; it is very hard, and is attracted by the lodestone.

a. Solid, with a glaftif texture.

b. Radiated.

c. Crystallized.

1. In form of cones, from Siberia.

2. In form of concentric balls, with a faceted surface. These are very common in Germany, but very scarce in Sweden.

a. Solid, and dim in its texture.

b. Scaly. The eifernam of the Germans. This is commonly found along with the iron-coloured iron glimmer, and linear the hands.

c. Crystallized, in concentric balls, with a flat or faceted surface.

4. Yellow blood-foane; Hematites flavus.

a. Solid.

b. Fibrous.

The varieties of the colours in the blood-foane are the same with those produced in the calces of iron made by dry or liquid men-

furia and afterwards exposed to different degrees of heat.

B. Mixed with heterogeneous substances.

b. With a siliceous earth. The martial jasper of Sinople.

c. With a garnet earth. Garnet and cockle or fliril.

d. With an argillaceous earth. The bole.

e. With a micaceous earth. Mica.

f. With manganese.

h. With an unknown earth, which hardens in water. Tarras; Cementum.

1. Loofe or granulated; Terra Ponzolana.

This is of a reddish brown colour, is rich in iron, and is pretty fusible.

2. Indurated; Cementum induratum. This is of a whitifh yellow colour, contains likewise a great deal of iron, and has the fame quality with the former to harden soon in water when mixed with mortar. This quality cannot be owing to the iron alone, but rather to some particular modification of it occasioned by some accidental causes, because these varieties rarely happen at any other places except where volcanoes have been, or are yet, in the neighbourhood.

[3.] Dissolved or mineralized.

A. With sulphur alone.

1. Perfectly saturated; Ferrum sulphure satureatum. Marcasite.

This is either attracted by the lodestone, or is a lodestone itself attracting iron; it resembles iron, and yields a black powder when rubbed.

1.) Magnetic iron ore. The lodestone, Magnæ.

a. Steel-grained, of a dim texture, from Hogberget in the parish of Gagneoil in Dalane: it is found at that place almost to the day, and is of as great strength as any natural lodestones were ever commonly found.

b. Fine grained, from Saxony.

c. Coarse-grained, from Spetalgrufvan at Norberg, and Kiergrufvan, both in the province of Weilmanland. This lores very soon its magnetic virtue.

3. With coarse scales, found at Sandfddf in Norway. This yields a red powder when rubbed.

2.) Refractory iron ore. This in its crude state is attracted by the lodestone.

a. Giving a black powder when rubbed; Tritura atræ. Of this kind are,

1. Steel-grained.

2. Fine grained.

3. Coarse.
MINERALOGY.

3. Coarse grained.

This kind is found in great quantities in all the Swedish iron mines, and of this moft part of the fufible ores confifl, because it is commonly found in fuch kinds of rocks as are very fufible: and it is as feldom met with in quartz as the hematites is met with in limestone.

4. Fine-grained. Emery. This is imported from the Levant: it is mixed with mica, is strongly attracted by the lodestone, and smells of sulphur when put to the fire.

5. Of large shining cubes.

6. Coarse grained.

Iron is the moft common metal in nature, and at the fame time the moft ufeful in common life; notwithstanding which, its qualities are perhaps very little known.

Iron has a particular and very fefible smell when strongly rubbed or heated; and a fypbic taste, which it communicates to the water in which it is extinguifhed after ignition. Its tenacity, ductility, and malleability, are very great. It exceeds every other metal in elâficity and hardness, when properly tempered. An iron wire of one-tenth of an inch thick is able to fupport 450 pounds weight without breaking, as Wallerius afferts.

Iron drawn into wire as fliender as the finest hairs.

It is more easily malleable when ignited than when cold; whereas other metals, though duftile when cold, become quite brittle by heat.

It grows red-hot sooner than other metals; nevelherhefs it melts the moft difliculty of all, platinum and manganeffe excepted. It does not tinge the flame of burning matters into blufht or greenifh colours, like other imperfect metals, but brightens and whitens it; hence the filings of iron are used in compositions of fire-works, to produce what is called white-fire.

Iron, or rather fleet, expands the leaf of all hard metals by the action of heat; but brafs expands the moft: and on this account these two metals are employed in the contruction of compound pendulums for the best fort of regulating clocks for astronomical purpofes.

Iron, in the act of fufion, inleat of continuing to expand, like the other metals, shrinks, as Dr. Lewis observes; and thus becomes fo much more dense as to throw up fhuch part as is unmelted to the surface; whilst pieces of gold, silver, copper, lead, and tin, put in the refpeotive metals in fusion, fink quickly to the bottom. But in its return to a confiftent state, instead of shrinking, like other metals, it expands; fentibly rising in the veffel, and affuming a convex furface, whilst the others fubfide, and appear concave.

This property of iron was firft taken notice of by Ramor, and excellently fits it for receiving impressions from the moulds into which it is caft, being forced into their minutest cavities. Even when poured thick into the mould, it takes, nevertheless, a perfect impression; and it is obferved, that cast iron is fomewhat larger than the dimensions of the mould, whilst cast figures of other metals are generally smaller.

The vitriolic acid difolves iron readily, and forms green vitriol.

This acid requires to be diluted with 304 times its quantity of water, to enable it effeotually to difsolve iron; and, during the difsolution; a strong aerial fluid aries, called inflammable air, which, on being mixed with atmofpheric air, takes fire at the approach of the flame of a candle. A glafs philal, of about two ounces measure, with one third of inflammable air, and the reft of common air, produces a very loud report if opened in the fame circumference; and if it be filled with two-thirds of inflammable air, mixed with one of dephlogifotated air, the report will be as loud as the explosion of a piftol with gunpowder.

Dilute nitrous acid difolves iron; but this fialine combination is incapable of cryfallisfing. Strong nitrous acid corrodes and dephlogifotates a confiderable quantity of iron, which falls to the bottom.

Marine acid likewise difolves iron, and this folution is also incryfallisfable.

The Pruflian acid precipitates iron from its folutions in the form of Pruflian blue.

This metal is likewife fentiufly acted upon by alkaline and neutral liquors, and corroded even by thofe which have no perceptible fialine impregnation; the oils themfelves, with which iron utenfils are ufually rubbed to prevent their rusting, often promote this effect in fome meafeure, unlefs the oils have been previously boiled with latharge or calcas of lead.

Galls, and other aftringent vegetables, precipitate iron from its folutions, of a deep blue or purple colour, of fo intense a fhade as to appear black. It is owing to this property of iron that the common writing ink is made. The infufion of galls, and alfo the Pruflian alkalies, are teats of the preience of iron by the colours they produce on any fluid. Acids, however, difolve the coloured precipitates by theformer; and hence it arihes that the marine acid is fuccefsfully applied to take off ink spots and iron stains from white linens. Alkalies, however, convert thefe iron precipitates into a brown ochre.

Iron has a frong affinity with sulphur. If a bar of iron be ftrongly ignited, and a roll of brimstone be applied to the heated end, it will combine
bine with the iron, and form a fusible mass, which will drop down. A vessel of water ought to be placed beneath for the purpose of receiving and extinguishing it, as the fumes would otherwise be very inconvenient to the operator.

A mixture of iron filings and bismuth in powder, moistened with water, and pressed so as to form a paste, will in a few hours swell, become hot, fume, and even burst into flame, if the quantity is large. The reductum furnishes martial vitriol. This process is similar to the decomposition of martial pyrites; from which some philosophers account for hot spring-waters and spontaneous fires. The mixture of water in this paste seems to be unnecessary to enable the vitriolic acid of the sulphur to act on the iron.

For other chemical properties of this metal, see Chemistry-Index; for its electrical and magnetic properties, see Electricity and Magnetism. For a more particular account of its nature and uses, and the methods of making and manufacturing it, see the articles Iron and Steel; also Metallurgy, Part II. sect. vii. and Part III. sect. v.

Order III. Semimetals.

I. Bismuth; tin-glaafs. Vijnutum, Bijmutum, Marcasita officinalis. It is,
a. Of a whitish yellow colour.
b. Of a laminated texture, soft under the hammer, and nevertheless very brittle.
c. It is very fusible; calcines and scorifies like lead, if not rather easier; and therefore it works on the cuppel. It is pretty volatile in the fire.
d. Its glafs or flag becomes yellowish brown, and has the quality of retaining some part of the gold, if that metal has been melted, calcined, and vitrified with it.
e. It may be mixed with the other metals, except cobalt and zinc, making them white and brittle.
f. It dissolves in aqua-fortis, without imparting to it any colour; but to the aqua-regia it gives a red colour, and may be precipitated out of both these solutions with pure water into a white powder, which is called Spanish white. It is also precipitated by the acid of sea-felt; which last unites with it, and makes the Vijnutum corneum.
g. It amalgamates easily with quicksilver. Other metals are so far attenuated by the bismuth, when mixed with it, as to be strained or forced along with the quicksilver through skins or leather.

Bismuth is found in the earth.
A. Native. This resembles a regulus of bismuth, but consists of smaller scales or plates.
1. Superficial, or in crusts.
2. Solid, and composed of small cubes.
B. In form of calxes.

1. Powdery or friable; Ochra vijmuti. This is of a whitish yellow colour; it is found in form of an effucrecence.

It has been customary to give the name of flowers of bismuth to the pale red calx of cobalt, but it is wrong; because neither the calx of bismuth, nor its solutions, become red, this being a quality belonging to the cobalt.

C. Mineralized bismuth. This is, with respect to colour and appearance, like the coarse teffelated potter's lead ore; but it consists of very thin square plates or flakes, from which it receives a radiated appearance when broken crosswise.

1. With sulphur.
a. With large plates or flakes.
b. With fine or small scales.
2. With sulphurated iron.
a. Of coarse wedge-like scales.

This mineralized bismuth ore yields a fine radiated regulus; for which reason it has been ranked among the antimonial ores by those who have not taken proper care to melt a pure regulus ore deficient of sulphur from it; while others, who make no difference between regulus and pure metals, have still more positively asserted it to be only an antimonial ore.

3. With sulphur and arsene.
a. Of a whitish yellow or ash colour. It has a shining appearance; and is composed of small scales or plates, intermixed very small yellow flakes: It is of a hard and solid texture: Sometimes strikes fire with hard feel: Has a disagreeable smell, when rubbed: Does not effervesce with aqua-fortis; but is partially dissolved by the fame acid (a).
b. Grey, of a striated form; found at Helsingland in Sweden, and at Annaberg in Saxony.
c. With variegated colours of red, blue, and yellow grey; found at Schneeburg in Saxony.
d. With green fibres like an amianthus; at Mifnia in Germany, and at Gillebeck in Norway.
e. With yellow red shining particles, called mines de bismuth Tigrées in French, at Georgeinstadt in Germany, and at Annaberg in Saxony.
f. The mineræ bismuthi arenacea, mentioned by Wallerius and Bomare, belongs also to the same kind of the arseneated ores.

4. By vitriolic acid. This ore is called vijmutum blut by the Germans. It is said to be of a yellowish, reddish, or variegated colour; and to be found mixed with the calx of bismuth, intercrusting other ores. Kirwan, p. 334.

Ufer, &c. of Bismuth. See the article Bismuth. Also Chemistry-Index; and Metallurgy, Part II. sect. x. and Part III. sect. viii.

II.
M I N E R A L O G Y.

a. Its colour comes nearest to that of lead, but it does not so easily tarnish.
b. It shows a texture when it is broken, as if it were compounded of flat pyramids (a).
c. Its specific gravity to water is as 6900 or 7000 to 1000.
d. It melts in the fire before it has acquired a glowing heat; but when it has gained that degree of heat, it burns with a flame of a changeable colour, between blue and yellow. If in an open fire, the calx rifes in form of soft white flowers; but if in a covered vessel, with the addition of some inflammable, it is distilled in a metallic form: in which operation, however, part of it is sometimes found vitrified.
e. It unites with all the metals (b) except bliflemuth and nickel, and makes them volatile. It is, however, not easy to unite it with iron without the addition of sulphur. It has the strongest attraction to gold and copper, and this last metal acquires a yellow colour by it; which has occasioned many experiments to be made to produce new metallic compositions.
f. It is dissolvd by all the acids: of these the vitriolic acid has the strongest attraction to it; yet it does not dissolve it, if it is not previously diluted with much water.
g. Quicksilver amalgamates easier with zinc than with copper, by which means it is separated from compositions made with copper.
h. It seems to become electrical by friction.
Zinc is found,
A. Native.
Zinc has been met with native, though rarely, in the form of thin and flexible filaments, of a grey colour, which were easily inflamed when applied to a fire. And Bomare affirms that he has seen many small pieces of native zinc among the calamine-mines in the duchy of Limbourg and in the zinc-mines at Goslar, where this semimetal was always surrounded by a kind of ferruginous yellow earth, or ochraceous substances. See the detached article Zinc.
B. In form of calx.

(a) It cannot be reduced into power under the hammer like other semimetals. When it is wanted very much divided, it must be granulated, by pouring it while fused into cold water; or filed, which is very tedious, as it fluffs and fills the teeth of the file. But if heated the most possible without fusing it, Macquer afferts, that it becomes so brittle as to be pulverized in a mortar.

(b) It brightens the colour of iron almost into a silver hue; changes that of copper to a yellow or gold colour, but greatly debases the colour of gold and destroys its malleability. It improves the colour and lustre of lead and tin, rendering them firmer, and confequently fitter for sundry mechanic uses. Lead will bear an equal weight of zinc, without losing too much of its malleability.—The process for giving the yellow colour to copper, by the mixture of zinc, and of its ore called calamine, has been described above under the Use of Copper.

(c) The varieties of pseude-galena, or black-jack, are in general of a lamellar or scaly texture, and frequently of a quadrangular form, resembling galena. They all lose much of their weight when heated, and burn with a blue flame; but their specific gravity is considerably inferior to that of true galena. Almost all contain a mixture of lead-ore. Most of them exhale a sulphureous smell when scraped, or at least when vitriolic or marine acid is dropped on them.
MINERALOGY.

III. Antimony; Antimonium Sibinium. This femimetal is,

a. Of a white colour almost like silver.

b. Brittle; and in regard to its texture, it conflicts Vol. XII.

d. Blackish-brown.

c. Whitish-yellow.

b. Brittle; and in regard to its texture, it consists

c. Reddish-brown.

of shining planes of greater length than breadth.

d. In the fire it is volatile, and volatilizes part of

the other metals along with it, except gold and

platina. It may, however, in a moderate fire,

be calcined into a light-grey calx, which is pretty

refractory in the fire; but melts at last to a glass

of a reddish-brown colour.

e. It dissolves in spirit of fea-salt and aqua-regia,

but is only corroded by the spirit of nitre into

a white calx; it is precipitated out of the aqua­

regia by water.

c. It has an emetic quality when its calx, glafs, or

metal, is dissolved in an acid, except when in the

spirit of nitre, which has not this effect.

f. It amalgamates with quicksilver, if the regulus,

when fused, is put to it; but the quicksilver ought

for this purpose to be covered with warm water:

it amalgamates with it likewise, if the regulus of

antimony be previously melted with an addition

of lime.

Antimony is found in the earth.

A. Native. Regulus antimonii nativus.

This is of a silver colour, and its texture is

compofed of pretty large shining planes.

This kind was found in Carls Ort, in the

mine of Salberg, about the end of the last cen­
tury; and specimens thereof have been preferved

in collections under the name of an arle­nicial

pyrites, until the mine-master Mr Von Swab dis­
covered its real nature, in a treatife he com­
municated to the Royal Academy of Sciences at

Stockholm in the year 1748. Among other re­
markable observations in this treatife, it is said,

first, That this native antimony easily amalga­
mated with quicksilver; doublets, because it was

imbided in limetone; fine, according to Mr

Pott's experiments, an artificial regulus of antio­

mony may, by means of lime, be dipofed to an

amalgamation: Secondly, That when brought

in form of a calx, is shot into cryftals during the

cooling.

B. Mineralized antimony.

(1) With sulphur.

This is commonly of a radiated texture,

compofed of long wedge-like flakes or plates;

it is nearly of a lead-colour, and rough to the

touch.

a. Of coarse fibres.

b. Of small fibres.

c. Steel-grained, from Saxony and Hungary.

d. Cryftallized, from Hungary.

1. Of prismatical, or of a pointed pyramidal

figure, in which last circumference the

points are concentrical.

Cronstedt mentions a specimen of this,
in which the cryftals were covered with

very miniture cryftals or quartz, except at the

extremities, where there was always

a little hole; this specimen was given for

a fio ferri lapar.

(2.) With sulphur and arfenic. Red antimony

ore; Antimonium falace.

This is of a red colour, and has the same

texture with the preceding, though its fibres

are not fo coarse.

R. 

a. With
3. With small fibres.
4. With abrupt broken fibres, from Braunfdorlf in Saxony, and from Hungary.

All antimonial ores are somewhat arsenical, but this is more so than the preceding kinds.

(3.) With sulphurated silver. Plumose silver-ore, or federerz of the Germans.
(4.) With sulphurated silver, copper, and arsene; the dal fabberts of the Germans.
(5.) With sulphurated lead; radiated lead-ore.
(6.) By the aerial acid.

This ore was lately discovered by Mongez, among those of native antimony from the mine of Chalanges in Dauphiny. It consists of a group of white crystallized filaments of a needle-form appearance, diverging from a common centre, like zeolite. They are infoluble in nitrous acid; and, on being urged by the flame of a blow-pipe, upon a piece of charcoal, they are dissipated into white fumes, or antimonial flowers, without any smell of arsene; from whence it follows, that these needle-formed crystals are a pure calx of antimony, formed by its combination with, or mineralized by, the aerial acid. See Kirwan, p. 325, and Journal de Physique for July 1787, p. 67.

Uses, &c. By the name of antimony is commonly understood the crude antimony (which is composed of the metallic part and sulphur) as it is melted out of the ore; and by the name of regulus, the pure semimetal.

1. Though the regulus of antimony is a metallic sublimate, of a considerably bright white colour, and has the splendor, opacity, and gravity of a metal, yet it is quite unmeltable, and falls into powder instead of yielding or expanding under the hammer; on which account it is classed among the semimetals.

2. Regulus of antimony is used in various metallic mixtures, as for printing types, metallic speculums, &c. and it enters into the best sort of pewter ware.

3. It mixes with, and dissolves various metals; in particular it affects iron the most powerfully; and what is very remarkable, when mixed together, the iron is prevented from being attacked by the loadstone.

4. It affects copper next, then tin, lead, and silver; promoting their fusion, and rendering them all brittle and unmeltable; but it will neither unite with gold nor mercury; though it may be made to combine with this last by the interpolation of sulphur. In this case it resembles the common Ethiops, and is hence called antimonial Ethiops.

5. Regulus of antimony readily unites with sulphur and forms a compound of a very faint metallic splendor: it assumes the form of long needles adhering together laterally; it usually forms naturally in this shape. This is called crude antimony.

6. But though antimony has a considerable affinity to sulphur; yet all the metals, except gold and mercury, have a greater affinity to that com-

pound. If therefore iron, copper, lead, silver, or tin, be melted with antimony, the sulphur will unite with the metal, and be separated from the regulus, which, however, takes up some part of the metal, for which reason it is called marial regulus, regulus venum, &c.

7. When gold is mixed, or fatted by the mixture of other metals, it may be fatted with antimony; for the sulphur combines with the base metals, which, being the lighter, rise up into clouds, while the regulus remains united at the bottom with the gold; which being urged by a stronger degree of heat, is freed from the semimetal, which is very volatile. This method of refining gold is the safest of all.

8. But the most numerous purposes to which this metal has been applied are those of the chemical and pharmaceutical preparations. Lemery, in his Treatise on Antimony, describes no less than 200 processes and formulæ; among which there are many good and many useless ones. The following deserve to be mentioned on account of their utility.

9. Antimony melts as soon as it is moderately red hot, but cannot sustain a violent degree of fire, as it is thereby dissipated into smoke and white vapours, which adhere to such cold bodies as they meet with, and are collected into a kind of farina or powder, called flowers of antimony.

10. If it be only moderately heated, in very small pieces, so as not to melt, it becomes calcined into a greyish powder defiluted of all splendor, called calx of antimony. This calx is capable of enduring the most violent fire; but at last it will run into a glass of a reddish-yellow colour, similar to that of the hyacinth. The infusion made of this coloured antimonial glass, in acidulous wine (such as that of Bourdeaux) for the space of 5 or 6 hours, is a very violent emetic.

11. If equal parts of nitre and regulus of antimony be debarculated over the fire, the grey calx which remains is called liver of antimony.

12. If regulus of antimony be melted with two parts of fixed alkali, a mass of a reddish-yellow colour is produced, which being dissolved in water, and any acid being afterwards added, a precipitate is formed of the same colour, called golden sulphur of antimony.

13. Fixed nitre, viz. the alkaline salt that remains after the debarcation of nitre, being boiled with small pieces of regulus of antimony, the solution becomes reddish; and, on cooling, deposits the antimony in the form of a red powder, called mineral kermes.

14. Equal parts of the glass, and of the liver of antimony, well pulverized and mixed with an equal quantity of pulverized cream of tartar, being put into as much water as will dissolve the cream of tartar, and boiled for 12 hours, adding now and then some hot water to replace what is evaporated, the whole is to be filtered while hot; then being evaporated to dryness, the saline matter that remains is the emetic tartar.

15. The regulus of antimony being pulverized, and distilled
distilled with corrosive sublimate of mercury; a thick white matter is produced, which is extremely corrosive, and is called butter of antimony. This thick sub stance may be rendered limpid and fluid by repeated distillations.

16. On mixing the nitrous acid with this butter of antimony, a kind of aqua regia is distilled, called bselforic spirit of nitre.

17. The white matter that remains from this last distillation may be redistilled with fresh nitrous acid; and the remainder being washed with water, is called bowsar mineral, which is neither volatile nor caustic as the antimonial butter. This butter being mixed with water, a precipitate falls to the bottom, which is very improperly called mercu rius vitae, for it is in fact a very violent emetic.

18. But if, instead of the regular, crude antimony be employed, and the same operation be performed, the reguline part separates from the sulphur, unites to the mercury, and produces the substance which is called cinna bar of antimony.

19. Crude antimony being projected in a crucible, in which an equal quantity of nitre is fused, detonates; is calcined, and forms a compound called by the French fondant de Retrou, or antimoine diaphoretique non lavé. This being distilled in hot water, falls to the bottom after it is cold; and after decantation is known, when dry, by the name of diaphoretic antimony. This preparation excites animal perspiration, and is a good sudorific. The same preparation may be more expeditiously made by one part of antimony with two and a half of nitre, mixed together and deflagrated: the residue of which is the mere calx of antimony, void of all emetic power.

20. And if the detonation be performed in a tubed retort, having a large receiver, containing some water adapted to it, both a cyphus of antimony and the antimonial flowers may be obtained at the same time, as Neumann afferts.

21. When nitre is deflagrated with antimony over the fire, the alkaline basis of the nitre unites with the calx of the femimetal, which may be separated by an acid, and is called materia perliata. See farther the article Antimony; also Metallurgy, Part II. sect. ix.

IV. Arfenic. In its metallic form, is,

a. Nearly of the same colour as lead, but brittle, and changes sooner its shining colour in the air, first to yellow, and afterwards to black.

b. It appears laminated in its fractures, or where broken.

c. Is very volatile in the fire, burns with a small flame, and gives a very disagreeable smell like garlic.

d. It is, by reason of its volatility, very difficult to be reduced, unless it is mixed with other metals: However, a regulus may be got from the white arfenic, if it is quickly melted with equal parts of pot ash and soap; but this regulus contains generally some cobalt, most of the white arsenic being produced from the cobalt ores during their calcination. The white arsenic, mixed with a phlogiston, sublimes likewise into octahedral crystals of a metallic appearance, whose specific gravity is 8,308.

e. The calx of arfenic, which always, on account of its volatility, must be got as a sublimation, is white, and easily melts to a glass, whose specific gravity is 5,000. When sulphur is blended in this calx, it becomes of a yellow, orange, or red colour; and according to the degrees of colour it is called orpiment or yellow arsenic; sandarach, re algar, or red arsenic; and also rubius arsenic.

f. This calx and glass are dissoluble in water, and in all liquids; though not in all with the same facility. In this circumstance arsenic resembles the metals: for which reason it also might be ranked in that class.

g. The regulus of arsenic dissolves in spirit of nitre; but as it is very difficult to have it perfectly free from other metals, it is yet very little examined in various menstrua.

h. It is poisonous, especially in form of a pure calx or glass: But probably it is less dangerous when mixed with sulphur, since it is proved by experience, that the men at mineral works are not so much affected by the smoke of this mixture as by the smoke of lead, and that some nations make use of the red arsentic in small doses as a medicine.

i. It unites with all metals, and is likewise much used by nature itself to dissolve, or, as we term it, to mineralize, the metals, to which its volatility and dissolubility in water much greatly contribute. It is likewise most generally mixed with sulphur.

j. It absorbs or expels the phlogiston, which has coloured glasses, if mixed with them in the fire.

Arsenic is found,

[1.] Native; called Scherboen cobalt and Flügelstein by the Germans. It is of a lead colour when fresh broken, and may be cut with a knife, like black lead, but soon blackens in the air. It burns with a small flame, and goes off in smoke.

A. Solid and teffaceous; Scherboen cobalt.

B. Scaly.

C. Friable and porous; Flügelstein.

(1.) With shining figures. This is by some called Spigel cobalt.

[2.] In form of a calx.

A. Pure, or free from heterogeneous substances.

1. Loose or powdery.

2. Indurated, or hardened. This is found in form of white semi-transparent crystals.

B. Mixed.

A. With sulphur.

1. Hardened.

a. Yellow. Orpiment; Auripigmentum.

b. Red. Native realgar, or sandarach.

c. With the calx of tin, in the tin-grains.

d. With sulphur and silver; in the rothgulden or red silver ore.

e. With calx of lead, in the lead-spar.

f. With calx of cobalt, in the efflorescence of cobalt.
Cobalt.

This femimetal is, in a metallic form.

A. With sulphur and iron. Arsenical pyrites or marcasite. These kinds in Cornwall are called silver or white marcasite and plate marcasite.

This alone produces red arsenic when calcined. It is of a deeper colour than the following.

B. With iron only. This differs with regard to its particles; being,

1. Steel-grained.
2. Coarse-grained.
3. Crystalised.

a. In an octahedral figure. This is the most common kind.

b. Prismatical. The sulphurous marcasite is added to this kind when red arsenic is to be made; but in Sweden it is scarcer than the sulphurous arsenical pyrites.

C. With cobalt, almost in all cobalt ores.

D. With silver.

E. With copper.

F. With antimony. See under Silver, Copper, and Antimony, p. 442.

For the Uses of Arsenic, see the detached article on Arsenic, and Chemistry-Index; also Metallurgy, Part II. sect. xii. and Part III. sect. viii.

V. Cobalt.

This femimetal is,

a. Of a whitish grey colour, nearly as fine-tempered steel.

b. Is hard and brittle, and of a fine-grained texture; hence it is of a dully, or not shining appearance.

c. Its specific gravity to water is 6000 to 1000.

d. It is fixed in the fire, and becomes black by calcination; it then gives to glasses a blue colour, inclining a little to violet, which colour, of all others, is the most fixed in fire.

e. The concentrated oil of vitriol, aquafortis, and the spirit of sea salt.

f. When united with the calx of arsenic in a flow (not a brilk) calcining heat, it assumes a red colour: the same colour is naturally produced by way of efflorescence; and is then called the bloom or flowers of cobalt. When cobalt and arsenic are melted together in an open fire, they produce a blue flame.

g. It does not amalgamate with quicksilver by any means hitherto known.

h. Nor does it mix with bismuth, when melted with it, without addition of some medium to promote their union.

[1.] Native cobalt. Cobalt with arsenic and iron in a metallic form.

Pure native cobalt has not yet been found; that which passes for such, according to Kirwan, is mineralised by arsenic. Bergman, however, in his Scagriplia, has entered this present ore under the denomination of native cobalt; and certain it is, that among all the cobaltic ores, this is the nearest to the native state of this femimetal. It always contains a small quantity of iron, besides the arsenic, by which it is mineralised.

This is of a dim colour when broken, and not unlike steel. It is found,

a. Steel-grained, from Loos in the parish of Farila in the province of Helfingeland, and Schneeberg in Saxony.

b. Fine-grained, from Loos.

c. Coarse-grained.

d. Crystalised:

1. In a dendritical or arboreous form.

2. Polyhedral, with shining surfaces.

3. In radiated nodules.

[2.] Calciform cobalt. Cobalt is most commonly found in the earth mixed with iron.

A. In form of a calx.

1.) With iron without arsenic.

a. Loose or friable; cobalt ochre. This is black, and resembles the artificial zaffire.

b. Indurated: Mineral cobalt vitrea. The schlacken or flag cobalt. This is like-wise of a black colour, but of a glassy texture, and seems to have lost that sub stance which mineralised it, by being decayed or weathered.

1.) With arsenical acid; cobalt-blut, Germ. Ochra cobalti rubra; bloom, flowers, or efflorescence of cobalt.

a. Loose or friable. This is often found of a red colour like other earths, spread very thin on the cobalt ores; and is, when of a pale colour, erroneously called flowers of bismuth.

b. Indurated. This is commonly crystallised in form of deep red semitransparent rays or radiations: It is found at Schneeberg in Saxony.

B. Mineralised.

1.) With sulphurated iron.

This ore is of a light colour, nearly resembling tin or silver. It is found crystallised in a polygonal form.

a. Of a flaky texture.

b. Coarse-grained.

This ore is found in Baffngraufa at Raddarhytten in Westmanland, and discovers not the least mark of arsenic. The coarse-grained becomes flimy in the fire, and sticks to the fliring hook during the calcination in the same manner as many regulo do: It is a kind of regule prepared by nature. Both these give a beautiful colour.

2.) With sulphur, arsenic, and iron. This resembles the arseniated cobalt ore, being only rather of a whiter or lighter colour. It is found.

a. Coarse-grained.

b. Crystalised:

1. In a polygonal figure, with shining surfaces, or glanze cobolt. It is partly of a white or light colour, and partly of a somewhat reddish yellow.
M I N E R A L G O Y.

It is very heavy, and of a liver colour, that is, dark red. When pulverized and roasted under a muffle, it forms green excrescences, and smokes; but its smoke has no particular smell: and no sublimate, whether fulphureous or arsenical, can be caught. It is soluble in acids, and the solution is green; but a polished iron plate discovers no copper.

B. In form of a calx. Nickel ochre, acerated nickel.
1. Mixed with the calx of iron. This is green, and is found in form of flowers on kupfernickel.

C. Mineralised.
1. With sulphurated and arsenicated iron and cobalt; kupfernickel. This is of a reddish yellow colour; and is found,
a. Of a flaggy texture.
b. Fine-grained; and
c. Scaly. These two are often from their colour confounded with the liver-coloured marmosite.
2. With the acid of vitriol. This is of a beautiful green colour, and may be extracted out of the nickel ochre, or efflorescence of the Kupfernickel.

For a full account of this semimetal, see the article, Nickel, and Chemistry-Index.

VII. Manganese. Manganesium.
The ores of this kind are in Swedish called brunfen; in Latin sideracum, or magnesia nigra, in order to distinguish them from the magnesia alba officinalis; and in French mangané, &c.
1. Manganese consists of a substance which gives a colour both to glasses and to the solutions of fats, or, which is the same thing, both to dry and to liquid menthias, viz.
a. Borax, which has dissolved manganese in the fire, becomes transparent, of a reddish brown or hyacinth colour.
b. The microcosmic salt becomes transparent with it, of a crimson colour, and moulders in the air.
c. With the fixed alkali, in compositions of glasses, it becomes violet; but if a great quantity of manganese is added, the glass is in thick lumps, and looks black.
d. When scorified with lead, the glass obtains a reddish brown colour.
e. The lixivium of deflagrated manganese is of a deep red colour.
2. It deflagrates with nitre, which is a proof that it contains some phlogiston.
3. When reckoned to be light, it weighs as much as an iron ore of the same texture.
4. When melted together with vitreous compositions, it ferments during the solution: but it ferments in a still greater degree when it is melted with the microcosmic salt.
5. It does not excite any effervescence with the nitrous acid: aqua-regia, however, extracts the colour out of the black manganese, and dissolves likewise a great portion of it, which by means of an alkali is precipitated to a white powder.
6. Such
M I N E R A L O G Y.

6. Such colours as are communicated to glasses by manganese, are easily destroyed by the calx of arsenic or tin: they also vanish of themselves in the fire.

7. It is commonly of a loose texture, so as to colour the fingers like foot, though it is of a metallic appearance when broken.

Manganese is found,

[1.] Native; of the discovery and qualities of which, an account is given under the article Manganese in its alphabetical order. See also Chemistry-Index.

[2.] Calciiform.

A. Loose and friable.

a. Black; which seems to be weathered or decayed particles of the indurated kind.

B. Indurated.

1.) Pure, in form of balls, whose texture consists of concentric fibres. Pura sphærica radiis concentricis.

a. White; very scarce.

2.) Mixed with a small quantity of iron.

a. Black manganese, with a metallic brightness. This is the most common kind, and is employed at the glass-houses and by the potters. It is found,

1. Solid, of a flaggy texture.
2. Steel-grained.
3. Radiated.
4. Crystallised, in form of coherent hemispheres.

VIII. Molybdena.

A. Lamellar and shining, its colour similar to that of the potter's lead ore.

This substance resembles plumbago or blacklead; and has long been confounded with it, even by Crofiedt. But it possesses very different properties; in particular,

1. Its laminae are larger, brighter; and, when thin, slightly flexible. They are of an hexagonal figure.
2. It is of a lead colour, and does not strike fire with hard steel.
3. Its specific gravity is 4.569, according to Kirwan; and 4.785, according to Briffon.
4. When rubbed on white paper, it leaves traces of a dark brown or bluish colour, as the plumbago or black lead does; but they are rather of an argentine gloss; by which circumstance the molybdena, according to Dr d'Arcet, may be easily distinguished from black-lead, as the traces made by this last are of a less brilliant, and of a deeper tinge.
5. In an open fire, it is almost entirely volatile and infufible. Microscopic falt or borax scarcely affect it; but it is acted upon with much effervescence by mineral alkali, and forms with it a reddish mass, which smells of sulphur.
6. It consists of an acid of peculiar nature (see Chemistry-Index) united to sulphur. A small proportion of iron is commonly found in it, but this seems merely fortuitous: 100 parts of molybdena contain about 45 of this acid and 55 of sulphur.

7. It is decomposed either by detention with nitre, or by solution in nitrous acid.

8. This acid is soluble in 570 times its weight of water in the temperature of 60; the solution reddens that of litmus, precipitates sulphur from the solution of liver of sulphur, &c. The specific gravity of the dry acid is 3.450.

9. This acid is precipitable from its solution in water by the Prussian alkali, and also by tincture of galls: the precipitate is reddish brown.

10. If this acid be distilled with three times its weight of sulphur, it reproduces molybdena.

11. The solution of this acid in water unites to fixed alkalies, and forms crystallisable salts; as it also does with calcareous earth, magnesia, and argil: these last combinations are difficultly soluble. It acts also on the base metals, and with them assumes a bluish colour.

12. This solution precipitates silver, mercury, or lead, from the nitrous acid, and lead from the marine, but not mercury.

13. It also precipitates barytes from the nitrous and marine acids, but no other earth. Molybdenous barofelenite is soluble in cold water.

14. This acid is itself soluble in the vitriolic acid by the assistance of heat; and the solution is blue when cold, though colourless while hot; it is also soluble in the marine acid, but not in the nitrous.

15. Molybdena tartar and ammoniac precipitate all metals from their solutions by a double affinity. Gold, sublimate corrosive, zinc, and manganese, are precipitated white; iron or tin, from the marine acid, brown; cobalt, red; copper, blue; alum and calcareous earth, white.

16. This acid has been lately reduced by Mr Hielm; but the properties of the regulus thus obtained are not yet published.

17. Mr Pelletier obtained also the regulus or molybdena, by mixing its powder with oil into a paste, and exposing it with powdered charcoal in a crucible to a very violent fire for two hours. See Chemistry-Index, n. 14, p. 97.

18. This fémimetal being urged by a strong fire for an hour, produces a kind of silvery flowers, like those of antimony.

19. Molybdena is said to be soluble in melted sulphur; which seems highly probable, as sulphur is one of its component parts.

See farther the article Molybdena, and Chemistry-Index.

IX. Wolfram. Wolfrænum, Spuma Lupis, Lat. See the detached article Wolfram.

This mineral has the appearance of manganese, blended with a small quantity of iron and tin.

1. With coarse fibres.

a. Of an iron colour, from Altenberg in Saxony. This gives to the glass compositions, and also to borax and the micrococmic salt, an opaque whitish yellow colour, which at last vanishes.

X. Siderite. See those words in the order of the XI. Saturnite. See also page 12.
THOUGH the Saxa, and fossils commonly called
Petifications, cannot, in all respects, be ranked in a
mineral system, for the reasons formerly given ; yet
as these bodies, especially the latter, occupy a con­
siderable place in most mineral collections, and the
former must necessarily be taken notice of by the miners
in the observations they make in subterranean
generally, it appeared proper to subjoin them in such an
order as might answer the purpose for which they are
regarded by miners and mineralogists.

Order I. Saxa. Petre.

These may be divided into two kinds.
1. Compound Saxa, are stones whose particles, con­
stituting of different substances, are so exactly fitted and
joined together, that no empty space, or even cement,
can be perceived between them ; which seems to indi­
cate, that some, if not all, of these substances have
been soft at the infant of their union.
2. Conglutinated stones, are stones whose particles
have been united by some cementitious substance,
which, however, is seldom perceivable, and which of­
ten has not been sufficient to fill every space between
the particles; in this case the particles seem to have
been hard, worn off, and in loose, single, unfigured
pieces, before they were united.

I. Compound Saxa.

A. Ophites. Scaly limestone with kernels or
bits of ferpentine in it.
1. Kolmord marble. It is white and green.
2. Serpentine antic, is white, with round pieces
of black fleatties in it. This must not be
confounded with the serpentine verde antico.
3. The Haraldji marble. White, with qua­
drangular pieces of a black fleatties.
4. The marmor pinnæ volu di Genova. Dark
green marble, with white veins. This kind
receives its fine polish and appearance from
the serpentine flock.
B. Steiffen or gejtefein. Granitello.
1. Of ditinct particles. In some of these the
quartzose particles predominate, and in others
the micaueous ; in the last case it is com­monly flat, and easy to split.
2. Of particles which are wrappt up in one an­other.
a. Whitish grey.
b. Greenish.
c. Reddish.

(p) Great part of the hill of Bineves in Lochaber is compos'd of a kind of porphyry. It is remarkably fine,
beautiful, and of an elegant reddish colour; "in which (says Mr Williams) the pale rose, the blufh, and the
yellowish white colours, are finely blended and shaded through the body of the flock ; which is of a jelly like
texture, and is undoubtedly one of the finest and most elegant stones in the world. On this hill allo is found a
kind of porphyry of a greenish colour, with a tinge of brownish red. It is smooth, compact, and heavy ; of
a close uniform texture, but has no brightness when broken. It has angular specks in it of a white quartzy
substance."
MINERALOGY.

Part II.

Appendix, Siga.

The name of porfido, the Italians applying the same name also to the black kind.

G. The trap of the Swedes. Saxum compositum jaftide mariali mollis, seu argilla mariali idurata. See the article TRAPP.

This kind of stone sometimes constitutes or forms whole mountains; as, for example, the mountain called Hunnberg in the province of Westergotland, and at Drammen in Norway; but it is often found in form of veins in mountains of another kind, running commonly in a serpentine manner, contrary or across to the direction of the rock itself. It is not homogeneous, as may be plainly seen at those places where it is not prefixed close together; but where it is prefixed close it seems to be perfectly free from heterogeneous substances. When this kind is very coarse, it is interspersed with felsfpat; but it is not known if the finer parts likewise contain any of it. Besides this, there are also some fomes particles in it, and something that resembles a calcareous spar; this, however, does not ferment with acids, but melts as easy as the stone itself, which becomes a black solid glass in the fire. By calcination it becomes red, and yields in affrays 12 or more per cent. of iron. No other fort of ore is to be found in it, unless now and then somewhat merely superficial lies in its fissures; for this stone is commonly, even to a great depth in the rock, cracked in acute angles, or in form of large rhomboidal dice. It is employed at the glass houses, and added to the composition of which bottles are made. In the air it decays a little, leaving a powder of a brown colour; it cracks commonly in the fire, and becomes reddish brown if made red-hot. It is found,

1. Of coarse chaffy particles.
   a. Dark grey.
   b. Black.

2. Coarse-grained.
   a. Dark grey.
   b. Reddish.

3. Of fine imperceptible particles.
   a. Black. The touchstone; Leop hydria.
   b. Bluish.
   c. Grey.
   d. Reddish.

The black variety (3. a.) is sometimes found so compact and hard, as to take a polish like the black agate; it melts, however, in the fire to a black glass; and is, when calcined, attracted by the load-ore.

H. Amphibolite. The carpolithi or fruit-stone rocks of the Germans.

It is a martial Jasper, in which elliptical kernels of calcareous spar and serpentine stone are included.

a. Red, with kernels of white limestone, and of a green fritulites. This is of a particular appearance, and when calcined is attracted by the loadstone; it decays pretty much in the air, and has some affinity with the trap, and also with the porphyry. There are sometimes found pieces of native copper in this stone.

1. The groffen of the Swedes.

Its base is hornblende, interspersed with mica. It is of a dark green colour, and in Smoland is employed in the iron furnaces as a flux to the bog-ore.

K. The granite. Saxum compositum felsfpat, mica et quartzo, quibus accidentaliter interdum horneblenne fitiatun, granatun et bifulatun immixti sunt. Its principal constituent parts are felsfpat, or rhombic quartz, mica, and quartz. See the article GRANITE.

It is found,

1. Loose or friable. This is used at the Swedish brass-works to cast the brass in, and comes from France.

2. Hard and compact.
   a. Red.
      1. Fine-grained.
      2. Coarse-grained.
   b. Grey, with many and various colours (e).

II. Con-

(e) Mr Wiegley has analyzed a species of green granite found in Saxony. The crystals are heaped together, and form very compact layers; the colour sometimes an olive green, sometimes resembling a pear, and sometimes of a reddish brown; some of them being perfectly transparent, and others nearly so. According to Mr Warren, they contain 25 per cent. of iron; whence they have been called green ore of iron. An ounce of these crystals heated red hot in a crucible lost two grains in weight, and became of the colour of honey. The remainder was put into a retort, and distilled with marine acid, with which it evidently effervesced. The residuum was lixiviated with distilled water, fresh muriatic acid added, and the distillation and lixiviation repeated. The iron precipitated from this lixivium, and reduced partly to its metallic state, weighed two drachms. M. Wiegley concludes, that the specimen contained two drams 26 grains of iron. From further experiments he concludes, that 100 parts of the substance contained 30.2 grains of siliceous earth; lime 30.8; iron 28.7; and water and fixed air 4.0.

Scotland is remarkable for a great number of excellent granites, little or nothing inferior to porphyry. Of these the following kinds are mentioned by Mr Williams.

1. The grey granite, or moor-stone as it is called in Cornwall, is very common in this country. In some places it shows no marks of strata; and in others it is disposed in thick unwieldy irregular beds, which are commonly broken transversely into huge masses or blocks of various sizes and shapes. There is a great variety in this kind of stones; some of them differing but little in appearance from basaltes; others are composed of almost equal parts of black and white grains, about the size of small peas, whence it is called peaty oakin by the
II. Conglutinated S mutually.

A. Of larger or broken pieces of stones of the same kind conglutinated together. Brecia.
1. Of limestone cemented by lime.
a. Calcareous breccia; the marni brecciatì of the Italians.
When these kinds have fine colours, they are polished and employed for ornaments in architecture and other economical uses.
b. The lunachèla of the Italians, or shell marbles. These are a compound of shells and coral, which are petrified or changed into lime, and conglutinated with a calcareous substance. When they have many colours, they

the common people. In Galloway and other places it frequently has a longitudinal grain, as if the component parts had been all moved one way by a gentle flow of water. When this kind of granite begins to undergo a spontaneous decomposition by exposure to the atmosphere, we observe that it is composed of pretty large grains of the figures of cubes, rhomboids, &c. Some of them so large as to deserve the name of fragments; and the largest of these are always of quartz or feldspath, and talc.

2. Reddish granite, of a gelatinous texture, which, Mr Williams says, is one of the finest and most elegant stones in the world. The mountains of Binevenus, he says, are principally composed of this stone; and it is found in great abundance in many other parts of Scotland, but he never saw it exhibit any marks of stratification.

3. The fine reddish granite, in which several fine shades of colour are blended together, not spread out in tints as in the former. Neither this nor the former are stratified: "On the contrary (says our author), both exhibit such a degree of uniform regularity, that in some places there is no difference between a stone and a mountain, excepting only in magnitude; as many mountains of granite are nothing more than one regularly uniform mass throughout, in which not the least mark of a bed is to be seen, nor hardly a crack or fissure, unless it be at the edge of some precipice or declivity. These two varieties of elegant red granite are met with in the Highlands and Lowlands of Scotland, in Galloway, and many other places. We often find masses of talc so large in this second variety, that some of them may be called fragments, not disposed in any order, but higgledy-piggledy through the body of the stone.

4. Stratified reddish granite, resembling the third in colour and quality, but not always quite so pure or free from admixture of other fomy matter of a different quality. This variety frequently contains larger and smaller fragments of fine laminated talc. Mr Williams, however, has seen this kind of granite disposed in pretty regular strata in the shires of Moray and Nairn, and other parts of Scotland.

5. Granite of a white and whitish colour, generally of a granulated texture, containing a great quantity of mica, or small-leaved talc, and the grains of quartz sometimes large and angular. This variety is subject to spontaneous decomposition; part frequently dissolves and falls into lakes, in such an exceedingly fine and attenuated state, that it does not sink in the water. "I have found (says Mr Williams) this substance in many places where water had been accidentally drained off, resembling fine shell marble, only much lighter. When thoroughly dry, it is the lightest fossil substance I ever handled; and, when bleached with rain, it is as white as snow. This variety of granite is either not stratified, or exhibits thick irregular beds. It frequently contains a considerable quantity of talc, in masses and scales too large to be called mica.

Our author is of opinion, that this fine white substance found from the decomposition of the granite, is the true kaolin of the Chinese, one of the component parts of porcelain ware. "The authors of the History of China (says he) informs us, that the fine porcelain ware is composed of two different fossil substances, called by them petuntfe and kaolin. We are further told, that the petuntfe is a fine white vitreous stone, compact and ponderous, and of considerable brightness in the inside when broken, which they grind to a fine powder; and that the kaolin is not a stone, but a fine white earthy substance, not vitrifiable, at least not in the heat of a common potter's furnace; that they mix the kaolin and the flour of the petuntfe together, and form a paste of this mixture, which they mould into all sorts of porcelain vessels. Now, from the best accounts of this matter which I have been able to obtain, after a good deal of search and inquiry, it appears to me, that the sediment which I have mentioned above is the true kaolin; and that as the fine white glassy quartz, which is found in irregular masses, and in irregular discontinuous veins or ribs, in some of the rocks of schistus, is the true petuntfe; and if this observation is really true, it deserves to be remarked, that Scotland is as well furnished with the best materials for making fine porcelain as most countries in the world. The species of quartz which I suppose to be petuntfe is of a pure fine uniform glassy texture, semitransparent, and of a pure snowy whiteness. A broken piece of this stone, and a newly broken piece of fine porcelain, are very like one another. There is a great quantity of petuntfe, or pure white quarts, in many places of Scotland, particularly in the north and Highlands. There is a considerable quantity of it upon the shore and washed by the tide between Banff and Cullen, generally in pretty large masses in rocks of blue schistus; and to the best of my memory it is very fine of the kind. There is also a considerable quantity of it in discontinuous ribs and masses, in rocks of blue schistus, about three or four miles north of Callendar in Montrose, upon the side of the high road which runs parallel to Lochleven, which I think also very fine. In some places this sort of quartz is tinged with a flesh colour from the neighbourhood of iron, which renders it unfit for porcelain; but there is plenty to be found of a pure white in almost all parts of Scotland, without any mineral tinge whatever. The petuntfe is perhaps a plentiful in Scotland as the petuntfe, there being many extensive lakes easily drained, which contain a considerable depth of it; and moreover, it is to be found in many places that have been lakes, which are now laid dry by accident. There is a quantity of kaolin about Vol. XII.
they are called marbles, and employed for the same purposes as the preceding (r).

Of this kind specimens from Italy are seen in collections. A coarse jasper breccia is said to be found not far from Frejus in Provence in France.

3. Of siliceous pebbles, cemented by a jaspery substance.

Of one another at first; but they are easily distinguished by trying them with acids, the marle readily effervescing of the kind commonly called potter's ore; and it is likewise remarkable, that there is no other granite in that neighbourhood but this single stratum, all the stones in this neighbourhood but this single stratum, all the stratites in it, it was found not to be marle but kaolin. These substances may easily be mistaken for one another at first; but they are easily distinguished by trying them with acids, the marle readily effervescing with the weakest, and the kaolin not at all with the strongest acid liquors.

6. Grey composite granite is a very beautiful stone, and when broken looks as if composed of small fragments of various sizes and shapes, not unlike calf's-head jelly. When polished, the fragments appear as if set or inlaid in a fine pellucid or water coloured matter. There is a single stratum of very curious composite granite, a little to the west of Lofcithemouth, in the county of Moray, in Scotland, of about six or eight feet thick. It is composed chiefly of grains and fragments of various bright and elegant colours, most of which are as large as peas, and more or less pellucid; all fine, hard, and semi-pellucid; there is about an eighth part of good lead ore in the composition of this stone, of the kind commonly called potter's ore; and it is likewise remarkable, that there is no other granite in that neighbourhood but this single stratum, all the stratites in it, it was found not to be marle but kaolin. These substances may easily be mistaken for one another at first; but they are easily distinguished by trying them with acids, the marle readily effervescing with the weakest, and the kaolin not at all with the strongest acid liquors.

7. Granite of a loose friable texture, subject to spontaneous decomposition, and reduction to granite gravel. There is a remarkable rock of this kind near the Queen's-ferry in Scotland, on the road to Edinburgh, which appears in prodigious thick irregular strata. This rock seems to be composed chiefly of quartz, chert, and fome iron; and produces excellent materials for the high roads.

8. In many parts of the north of Scotland, in the Highlands, and in Galloway, there is found an excellent species of grey granite, composed chiefly of red and black coloured grains. This is a fine and very durable stone, very fit for all kinds of architecture.

In speaking of these stones, Mr Williams observes, that the finer and most elegant red granites, and the finest granite-like porphyries, so much resemble one another, that he does not attempt to distinguish them; and Scotland is remarkable for a great number and variety of them. "The elegant reddish granite of Bineves, near Fort William (says he), is perhaps the best and most beautiful in the world; and there is enough of it to serve all the kingdoms on earth, though they were all as fond of granite as ancient Egypt. There are extensive rocks of red granite upon the sea-shore to the west of the ferry of Ballachulish in Appin, and likewise at Strontian, as well as many other parts of Argyleshire. I have seen beautiful red granite by the road-side, near Dingwall, and in several other parts of the north of Scotland, which had been blown to pieces with gunpowder, and turned off the fields. There are extensive rocks of reddish granite about Peterhead and Sains, and both of red and grey granite in the neighbourhood of Aberdeen. The hill of Cruftell in Galloway, and several lower hills and extensive rocks in that neighbourhood, are of red and grey granite, where there are great varieties of that stone, and many of them excellent. Upon the sea-shore near Kinnedore, west of Lofcithemouth, in Moray, there is a bed of stone about eight feet thick, which I think should be called a composite granite. It is composed of large grains, or rather small pieces of bright and beautiful stones of many different colours; and all the fonsf parts are exceedingly hard, and fit to receive the highest polish. About a sixth or eighth part of it also consists of lead ore, of that species called potter's ore. The separate fonsf parts composing this stratum are all hard, fine, solid, and capable of the most brilliant polish; and if solid blocks can be raised free from all cracks and blemishes, I imagine, from the beauty and variety of colours of the fonsf part, and the quantity of bright lead ore which is blended through the composition and body of the stone, that this would be a very curious and beautiful stone when polished."

(r) The stones called Ludis Helmontii or Paracelsi, have some similarity in their form to the breccia, a. b., for they are composed of various lumps of a marly whitish-brown matter, separated into a great number of polygonous compartments, of various sizes, of a whitish-yellow crust of a red calcareous spar, sometimes...
times pyritous, which often rise a little above the external surface, and inclose each of them on the in side. According to Bomare, the ludas helmontii, found in the county of Kent, is covered with a kind of shelled felinite resembling the zeolite. The rock is for the most part of a globose figure, seldom flat, but often convex on the outside; and sometimes with a concave surface.

According to Wallerius, the ludus helmontii loses by calcination about half of its weight; and, on being urged by fire, is melted into a black glassy flag. It effervesces strongly with aqua-fortis, and this solution is of a yellow colour. But what seems very extraordinary, by adding to it some oil of tartar par deliquium, bubbles are produced, from which a great number of flender black threads or filaments are produced, sticking like a cobweb to the sides and bottom of the vessel.

These stones are found quite separate by themselves, as well as various stalagmites and crustaceous bodies, in the strata of argillaceous earth, in various parts of Europe, chiefly in Lorraine, Italy, England (in the counties of Middlesex and Kent), and elsewhere.

Wallerius ranges the ludus helmontii among the tophi, in the Spec. 425. of his system of Mineralogy. Paracelsus had attributed to these stones a lithontriptic power, and Dr Grew says that they are diuretic; but there is not the least proof of their really possessing such qualities.

(c) The breccia stratatum, or plum pudding-rock, exhibits a singular appearance as it lies in the ground; being composed of water-rounded stones of all qualities and of all sizes, from small gravel up to large rounded stones of several hundreds weight each; the interstices being filled up with lime and sand. It frequently also contains lime and iron. Sometimes it exhibits a grotesque and formidable appearance, containing many large bullets of various sizes and shapes, without any marks of regular stratification, but looking like one vast mass of bullets of unequal thickness; and in this manner frequently swelled to the size of a considerable mountain. It is frequently cemented very strongly together; so that parts of the hills composed of it will frequently overhang in dreadful precipices, less apt to break off than other rocks in the same situation; one reason for which, besides the strength of the cement, is, that the breccia, when composed of bullets, is less subject to fissures and cutters than other rocks; being frequently found in one solid mass of great extent and thickness. Some of the plum pudding-rocks are made up of smaller parts, coming near to the size of coarse gravel. It is evident however, that all the parts of the breccia, whether coarse or fine, have been rounded by agitation in water, as the rocks differ nothing in appearance from the coarser and finer gravel found upon the beach of the sea, excepting only that the parts are strongly cemented together in the rocks, and are loose upon the shores of the ocean.

Some of the breccia is composed of finely rounded stones of various and beautiful colours, about the size of plums or nuts, all very hard and fine. Were this species fawed and polished, it would appear as beautiful and elegant as any stone in Europe; much resembling mosaic work in small patterns.

In general, the breccia is regularly stratified or not according to the size of the component parts of the stone. Such rocks as are composed of round gravel and small bullets are generally very regular in their stratification, while those which contain bullets somewhat larger in size are commonly disposed in thick and coarse beds, and such rocks as are made up of the largest kind of bullets seldom show any marks of stratification at all.

Among many other places in Scotland, where breccia or pudding-stome abounds, there are extensive rocks and high cliffs of it upon the south shore at the west end of the Pentland Frith, to the westward of Thurso in Caithness, which stretch quite across the country of Caithness into Sutherland; and in Sutherland as well as Caithness, this rock is of a rough contexture, and appears in pretty high hills, deep glens, overhanging rocks, and frightful precipices, to the west of Brora, Dunrobin, and Dornoch, which gives it a grotesque and formidable appearance in that country. This range of breccia stretches also quite through Sutherland, and likewise through Ross-shire, the west side of Fardonald, and Dingwall, where it exhibits the very same phenomena as in Sutherland and in Caithness. It continues the same longitudinal line of bearing, which is nearly from north-east to south-west, quite through the highland counties of Inverness and Perthshire; and it forms considerable hills, and very high and rugged rocks, upon both sides of that beautiful piece of fresh water Lochns.

Much of the stone here as well as in other places in this range, is composed of large bullets; the rock is very hard and strong, and it hangs in frightful precipices upon both sides of the lake, through which rock...
far, since their particles are so big and plain as to be easily known from one another. These stones are a proof both of the subversions which the mountains in many centuries have undergone, and of some hidden means which nature makes use of in thus cementing different kinds of stones together. Any certain signs for the kernels or lumps in such compounds, before they deserve the name of breccia, cannot be determined, because that depends on a comparison which every one is at liberty to imagine. In some places, the kernels of porphyry have a diameter of six feet, while in others they are no bigger than walnuts. Sometimes they have a progressive size down to that of a sandstone. Most of this kind of stone is fit for ornaments, though the workmanship is very difficult and costly.

B. Conglutinated stones of granules or sands of different kinds. Sandstone; Lapis arenaceus.

In this division are reckoned those which consist of such minute particles, that all of them cannot easily be discovered by the naked eye. The greatest part, however, consist of quartz and mica; which substances are the most fit to be granulated, without being brought to a powder.

1. Cemented by clay.
   a. With an appyry or refractory clay. This is of a loose texture; but hardens, and is very refractory in the fire.
   b. With common clay.

2. With lime; resembles mortar made with coarse sand.
   a. Consisting of transparent and greenish grains of quartz and white limestone.
   b. Of no visible particles. This is of a loose texture, and hardens in the air.

3. With an unknown cement.
   a. Loose.
   b. Harder.
   c. Compact.
   d. Very hard.

4. Cemented by the rust or ochre of iron. Is found in form of loose stones at several places, and ought perhaps to be reckoned among the Mineraria or sand ores; at least when the martial ochre makes any considerable portion of the whole.

5. Grit-stone. This is of greater or less hardness, mostly of a grey, and sometimes of a yellowish colour; composed of a siliceous and micaceous sand, and rarely of a sparry kind, with greater or lesser particles closely compacted and united by an argillaceous cement. It gives some spark with steel, is indissoluble for the most part in acids, and vitrifiable in a strong fire.

N. B. The argillaceous grit has been before described, p. 89. col. 1.

6. Elastic. A singular species of sandstone, of which a specimen was shown some years ago to the Royal Academy of Sciences at Paris by the Baron de Dietrich. It is flexible and elastic; and consists of small grains of hard quartz, that strike fire with tempered steel, together with some micaceous mixture. The elasticity seems to depend on the micaceous part, and softness of the natural gluten between both. It is said, that this elastic stone was found in Brazil, and brought to Germany by his excellency the Marquis de Lavradio.

There are also two tables of white marble, kept in the palace Borghese at Rome, which have the same property. But the sparry particles of their substanse, though transparent, are rather soft; may be easily separated with the nail, and effervesce with aqua-fortis; and there is also in it a little mixture of small particles of talc or mica. See Journ. de Phys. for 1784, p. 275. See also the article Marble (Elastic.)

C. Stones and ores cemented together; Mineraria arenacea.

1. Of larger fragments.
   a. Mountain green, or viride montanum cupri, and pebbles cemented together, from Siberia.
   b. Potters lead-ore, with limestone, flate-kernels, and shells.
   c. Yellow or marcasital copper ore, with small pebbles.

2. Of smaller pieces.
   a. Potter's lead-ore with a quartzofe sand.
   b. Mountain green with sand from Siberia.
   c. Cobalt ore with sand.
   d. Martial ochre with sand.

Order II. Mineral changes, or Petrifactions.

These are mineral bodies in the form of animals or vegetables, and for this reason no others belong to this order as such as have been really changed from the subjects of the other two kingdoms of nature.

I. Earthy changes; Terra larvata.

A. Extraneous bodies changed into a lime substanse, or calcareous changes; Larva calcarea.

(1.) Loose or friable. Chalky changes; Cretae larvata.
Part II.

MINERALOGY.

Appendix.

Part -1-

a. In form of vegetables.

1. Calcined or mouldered shells; Humus calcareaus.

(2.) Indurated; Petrifia calcaria.

a. Changed and filled with solid limeflone.

1. In form of animals.

b. Changed into a calcarous spar; Petrifia calcaria spar.

1. In form of vegetables.

2. In form of vegetables.

B. Extraneous bodies changed into a flinty substance.

Siliceous changes; Larve siliceae. These are, like the flint,

1. Indurated.

a. Changed into flints.

1. Carnelians in form of shells, from the river Tomm in Siberia.

2. Agat in form of wood. Such a piece is said to be in the collection of Count Toffin.

3. Coraloids of white flint, (Millepora.)

C. Extraneous bodies changed into clay. Argillaceous changes; Larve argilactae.

A. Loose and friable.

1. In form of vegetables.

a. In form of vegetables.

A piece of white porcelain clay from Japan, with all the marks of the root of a tree, has been observed in a certain collection.

b. Changed into a clayy substance, (Millepora.)

2. In form of vegetables.

C. Extraneous bodies changed into a clayy substance.

Argillaceous changes; Larve argilactae.

A. Loose and friable.

1. In an unknown clay.

a. In form of vegetables. Ophiocolla. It is said to be changed roots of the poplar tree, and not to consist of any calcareous substance.

A sort of fofifile ivory is said to be found, which has the properties of a clay; but it is doubtful if it has been rightly examined.

II. Saline extraneous bodies, or such as are penetrated by mineral salts. Corpora peregrina infalata. Larve infalata.

A. With the vitriol of iron.

1. Animals.

a. Human bodies have been twice found in the mine at Falun in Dalarm; the last was kept a good many years in a glass-cape, but began at last to moulder and fall to pieces.

b. In form of vegetables.

These are found in water strongly impregnated with vitriol. They do not burn with a flame, but only like coal in a strong fire; neither do they decay in the air.

B. Extraneous bodies penetrated by mineral inflammable substancess, or mineral phlogiston.

A. Penetrated by the substance of pit-coals.

1. Vegetables, which commonly have been woods, or appertaining to them.

C. Penetrated by sulphur which has dissolved iron, or by marcasite and pyrites. Pyrite impregnata. Petrifia pyritacea.

1. Animals.

a. Human.

b. Bivalves.

c. Univalves.

d. Insects.

IV. Metals in form of extraneous bodies; Larve metalliferae.

A. Silver; Larve argentifera.

(1.) Native.

a. On the surfaces of shells.

(2.) Mineralized with copper and sulphur.

a. Fablertz, or grey silver ore in form of ears of corn, &c. and supposed to be vegetables, are found in argillaceous flake at Frankenberg and Tahlitteren in Heisc.

B. Copper; Larve cuprifera.

(1.) Copper in form of calx.

a. In form of animals, or of parts belonging to them.

1. Ivory and other bones of the elephant.

The Turcois or Turquoise; which is of a bluish green colour, and much valued in the east.

At Simore in Languedoc bones of animals are dug, which during the calcination assume a blue colour; but it is not probable that the blue colour is owing to copper.

(2.) Mineralized copper, which impregnates extraneous bodies; Cuprum mineralifatum corpora peregrina infalata.

a. With sulphur and iron. The yellow or marcasitical copper ore that impregnates.

1. Animals.

a. Shells.

b. In form of fish.

c. With sulphur and silver. Grey silver ore or fablertz, like ears of corn, from the slate- quarries in Heisc.

C. Changes into iron; Larve ferrifera.

(1.) Iron in form of calx, which has assumed the place or the shape of extraneous bodies; Ferrum calciforme corpora peregrina infalata.

a. Loose; Larve ochracea.

1. Of vegetables.

Roots of trees, from the lake Langelma in Finland. See the acts of the Swedifh Academy of Sciences for the year 1742.

b. Indu-
Appendix.  
VOLCANIC PRODUCTS.  

IV. Slags; Scoriae vulcanarum.  
Slags are found in great abundance in many places of the world, not only where volcanoes yet exist, but likewise where no subterraneous fire is now known: Yet, in Mr. Cronstedt's opinion, they cannot be produced but by means of fire. These are not properly to be called natural, since they have marks of violence, and of the last change that mineral bodies can suffer without the destruction of the world: nor are they artificial, according to the universally received meaning of this word. We cannot, however, avoid giving them a place here, especially after having admitted the petrifactions; and shall therefore arrange the principal of them, according to their external marks.  

A. Iceland agate; Achates islandicus niger.  
It is black, solid, and of a glaffy texture; but in thin pieces it is greenish and semitransparent like glafs-bottles, which contain much iron. The most remarkable circumstance is, that such large solid masses are found of it, that there is no possibility of producing the like in any glafs-bottle.  
It is found in Iceland, and in the island of Ascension; The jewellers employ it as an agate, though it is too soft to refit wear.  

B. Rheinish millstone; Lapis molaris Rheinana.  
Is blackish-grey, porous, and perfectly resembles a fort of flag produced by mount Vesuvius. A Appendix. variety of lava, according to Kirwan.  

C. Pumice-stone; Pumex.  
It is very porous and blistered, in consequence of which it is specifically very light. It resembles that frothy flag which is produced in the iron furnaces.  

1. White.  
2. Black.  
The colour of the first is perhaps faded or bleached, because the second kind comes in that slate from the laboratory itself, viz. the volcanoes.  

D. Pearl flag; Scoriae confertes globuli vitreis conglomeratis.  
It is compounded of white and greenish glass particles, which seem to have been conglutinated while yet soft or in fusion. Found on the Isle of Attenfion.  

E. Slag-lard or ashes; Scoriae pulverulentae cinereae vulcanarum.  
This is thrown out from volcanoes in form of larger or smaller grains. It may perhaps be the principle of the Terra Puzzolana; because such an earth is said at this time to cover the ruins of Herculaneum near Naples, which history informs us was destroyed by a volcano during an earthquake.

II. Lava.s.  
Lava has been generally understood to denote the aggregate mass of melted matters which flow out of the mouths, or burst out from the sides, of burning mountains. According to Mr. Kirwan, however, lavas are the immediate produce of liquefaction or vitrification by the volcanic fires, and "should carefully be distinguished from the subsequent productions affected by the water either in a liquid or fluid slate, which generally is ejected at the same time." And of lavas, so distinguished, he describes several varieties. See the article Lava, in the order of the alphabet; where the nature, origin, kinds, and phenomena of lavas, are copiously described and explained.

III. Basaltes.  
This fort of stone was by Cronstedt, in the first edition of his Mineralogy, ranked among the garnet earths, and confounded with the schoers; an improbity which was pointed out by Bergman in his Sciagraphia, sect. 120.—Mr. Kirwan considers basaltes as an imperfect lava, and ascribes its origin both to fire and water. He describes it as found, either, 1. In opaque triangular or polyangular columns; which is the proper basaltes; Or, 2. In amorphous masses of different magnitudes; forming solid blocks, from the smallest fire to that of whole mountains; which kind is called trapp. See the detached article Basaltes (1); where its species and varieties

(1) For the nature, history, theory, &c. of volcanoes, see the article Volcano.  
(1) In that article, p. 45. col. 1. l. 9. dele the words, "The English miners call it cockle, the German schoerl." —P 47 col. 2. l. 28. for "a kind of marble," read "a volcanic production." The Lapis Lydus, or Touchstone, mentioned in the same paragraph, should have been specified to be of the fort called Trapp.
(X) There is a great variety of basaltes in Scotland, particularly of the grey kinds; some of which are capable of the highest degree of polish. A good black kind is met with on the fourth side of Arthur's Seat near Edinburgh, where it forms a smooth perpendicular rock, with several of the columns broken off, and the fissured pieces threatening to fall down upon the passengers below. This stone is capable of receiving a fine polish; and, in the opinion of Mr. Williams, would be fit for all sorts of ornaments upon sepulchral monuments. It will polish to a bright and beautiful black which will be unfading.

There is another kind, heavy and hard, of a black, or blackish-grey colour; of which great quantities have been carried from the Frith of Forth to pave the streets of London. This, for the most part, is coarsely granulated in the inside, though sometimes the grain is pretty fine. Sometimes it is bright in the inside when broken. It is composed of grains of quartz and fihl of different sizes, and commonly contains some iron. It always appears in thick, irregular, beds, some of which are enormously thick; and seldom or never equally so; on the contrary, where it is found uppermost, it frequently swells into little hills of various sizes. Most of the small islands in the Frith of Forth are composed of this kind of stone; as well as some hills in the neighbourhood of Inverkeithing and of Edinburgh.

The known characteristick of the basaltes is to form itself into balls, columns, and other regular figures. The columnar kind assumes a pentagonal, hexagonal or heptagonal figure; but quadrangular columns are not common. They are all smooth on the outside, and lie parallel and contiguous to one another; sometimes perpendicular, sometimes inclining, in proportion to the position of the stratum which is thus divided: If the stratum lies horizontal, the columns are perpendicular; if inclining, the pillars also incline in exact proportion to the declivity of the strata, being always broken right across the stratum. Some are of one piece from top to bottom; others divided by one or more joints laid upon one another, which form a column of several parts. The rock called the Giant's Causeway in Ireland is a pretty good specimen of the jointed columnar basaltes; but there is a more beautiful species above Hillhouse lime-quarry, about a mile south of Linlithgow in Scotland; and a border one near the tower north side of Queen's Ferry, and several other places in Fife. In some places the basaltes are formed into magnificent columns of great length; and in others afford an assemblage of small and beautiful pillars resembling a range of ballustrades or organ pipes. Some of the columns on the fourth side of Arthur's Seat already mentioned are very long; and there are likewise magnificent columns of great length in the island of Egg, and others of the Hebrides. These columns, when broken, are frequently of a black, or blackish grey, in the inside; some of them being composed of small grains, which gives them an uniform and smooth texture; but much of this species of stone has larger grains in its composition, rough, sharp, and unequal, when broken. All the grains, however, are fine, hard, and bright; and the stone in general is capable of a fine polish.

The other species of basaltes which forms itself into distinct masses, assumes sometimes a quadrangular, sometimes an oval, globular, or indeterminate figure. They are found of all sizes from the size of an egg to that of a house; but though they differ in shape from the columnar basaltes, they agree in almost every other respect: whence Mr. Williams thinks that they are only to be accounted a variety of the columnar kind. It is common to see one stratum of the basaltine rocks exhibiting, in one place, regular pillars or globes; and near these, very irregular ones, differing very little from the common cutters found in all rocks; and at no great distance, the same rock is found to run into one entire mass, exhibiting no tendency to be broken or divided into any columns whatever. Of this the rock of Arthur's Seat is an instance. Some of these only produce solid masses of different figures and sizes; while others produce quantities of a softer, friable, flabby matter, of the same quality in which the hard masses of different figures are found imbedded. Pretty good specimens of the second kind or variety of basaltes are met with on the road-side between Crandum bridge and the Queen's Ferry, and in several other places in the Lothians and in Fife.

The crustate basaltes are of two kinds; 1. Such as have the crusts more dry and friable than the internal parts; and, 2. Such as are dry and friable throughout the whole mass.

The first of these has not only a crust of the friable matter adhering to it, but is likewise imbedded in a quantity of the same. Our author has seen many quarries of this kind of basaltes dug for the high roads, in which the quantity of soft friable matter greatly exceeded that of the hard masses, and in which incrusted stones of various sizes and shapes appeared. In such quarries, some of the largest masses have only a few coats of penetrable friable matter, surrounding a nucleus which varies in size, but is uniformly hard throughout; and we shall find other yolks in the same quarry imbedded in the softer matter, which, when broken, exhibit a net of stones including one another like the several coats of an onion. These crustate basaltes which envelope one another are a curious species of stone. The several coats of surrounding matter differ nothing in quality from the stones contained in them, and some of the inner crusts are often very hard; but the nucleus within, though small, is always the hardest. The decomposition by the weathering of the softer matter found surrounding and enveloping the harder masses of stone in this and the second spe-
MINERALOGY.

The stratification of basaltine rocks, has produced a phenomenon frequently met with in Great Britain, especially in Scotland, which greatly puzzles many. It is very common in low grounds, and upon some moderate eminences, to see a prodigious multitude of stones of all shapes and sizes, very hard, and pretty smooth on the outside. These stones are sometimes so numerous and large, that it is often found impracticable to clear a field of them. Where those stones are a species of basaltine, which they commonly are, and of the second species of basaltine described above, they always originate from a decomposition of the more soft or friable parts of those rocks, which moulder or fall away, and leave the harder stones detached and scattered about, and the decomposed matter diffolves by degrees, and becomes good corn mould.

Here Mr Williams takes occasion to contest the opinion of tho'se who think that stones grow or vegetate like plants. He owns indeed that they increate in bulk; but this, he says, is only in such situations as are favourable for an accretion of matter carried down and deposited by the water; in all other situations they grow less and less. "Others (says he) imagine, that these stones (on which this extraneous matter has been deposited) were rolled about; that the asperities and sharp angles were by that means worn off; and that they were all at last deposited as we see them, by the waters of the universal deluge: and, having their obtuse fides and angles, as if they had been rounded by rolling in water, makes these gentlemen confident that they are right; and if we did not frequently find stones exactly of the same figure, size, and quality in the rock, it would be very difficult to overthrow this hypothesis. I have taken great pains to investigate this point, having frequently examined circumstances; and now think to discover the stratum of rock which those detached stones originally belonged to. "The strata or beds of the several species of basaltine spread as wide, and stretch as far, as the other concomitant strata in the neighbourhood where they are found: but they often lie very flat, or with a moderate degree of declivity; and consequently, when the softer and more friable matter found in the interlaced of these rocks, which incloses and binds the harder masses in their native beds, is decomposed, the harder stones must then lie scattered wide upon the face of the ground."

The second species of the crumated basaltine, viz. that which is dry and friable throughout the whole mass, is generally of a coarse and granulated texture, and of all the various shades of grey colours; from a ruddy black to a light-coloured grey. This kind of crumated basaltine is developed when the masses are either broken or in a state of decomposition; and there are masses of it of all sizes and shapes found in the rocks, resembling the second and third species of the basaltine; appearing alike smooth on the outside, with obtuse angles; and short, resembling the basaltine in every respect: but when they are exposed to the external air and weather for any considerable time, the several incrassations decay, decompose, and crumble down by degrees. When they quarry this species of basaltine for the roads, they are able to break and pound them small with ease; but the harder species are so hard and cohesive, that they are with the greatest difficulty broken into sufficiently small parts.

Composite basaltine resembles the three last species, in figure, colour, and all other external appearances; being distinguishable from them only in the internal structure or grain of the stone. It resembles some of the granites, as confiding of much larger grains than the other basaltine. Many of the larger grains in the composite basaltine are more than an eighth part of an inch over, and some more than a fourth; appearing with smooth flat surfaces, and of a tabulated texture, exactly resembling the quartz of rocks, which forms commonly found in the composition of most of the granites. The chief, if not the only, distinguishable difference between the grains in each of them is the colour. They are evidently large grains of quartz, &c. which exhibit flat shining surfaces in both. Those grains or fragments are commonly white, yellowish, red, or black, in the composition of most of the granites; whereas they are often seen of a pale blue, or a bluish grey colour, in the composite basaltine, and some of them approaching to white. It is only in the internal structure, however, that these basaltine have any resemblance to the granites; in all the external characters, they differ nothing from the rest of their own genus.

A fifth species of basaltine is indurated through the whole stratum, solid and uniform through all its parts, and exhibiting only such cracks and fissures or cutters as are commonly met with in other hard beds of stones. Many beds of this species are frequently met with in the coal-fields, and the miners are often obliged to sink through them in their coal-pits. The Salisbury craigs at Edinburgh (says our author) might be singled out as a good example of this species of stone, were it not that part of the same stratum is formed into columns on Arthur's seat; though, I believe, this is no good exception, as it evidently appears that the beds of basaltine which are formed into columns, globes, &c. only assume those figures where they are exposed to the influence of the external air, or have but little cover of rock above them. When any of those beds strike deep under the cover of several other strata, they are not found in columns, &c. Nothing but an uniform mass then appears, although the same stratum is regularly formed near the surface; which proves that the columnar and other basaltine are formed by thinking and chipping.

The strata of basaltine spread as wide, and stretch as far in the longitudinal bearing, as the other different strata which accompany them in the countries where they are found. The rocks of basaltine also are generally found in very thick strata; and that generally in places where no other rock is found above the basaltine, the strata of it are often very unequal in thicknes. But this, in general, is only in situations where no other rock is found above it; for when it fairly enters into the surface of the earth, so as to have other regular strata above it, which is seen in several places in the Lothians, Fife, and other parts of Scotland, it then appears pretty equal in thicknes, as equal as most other beds of such great thicknes are; and yet it is remarkable, that although most of the strata of basaltine are of great thicknes, there are frequently thin strata.
MINERVA, or PALLAS, in Pagan worship, the goddess of sciences and of wisdom, sprung completely armed from Jupiter's brain; and on the day of her nativity it rained gold at Rhodes. She disputed with Neptune the honour of giving a name to the city of Athens; when they agreed that whosoever of them should produce what was most useful to mankind, should have that advantage. Neptune, with a stroke of his trident, formed a horse; and Minerva caused an olive to spring from the ground, which was judged to be most useful, from its being the symbol of peace. Minerva changed Arachne into a spider, for pretending to excel her in making tapestry. She fought the giants; favoured Cadmus, Ulysses, and other heroes; and refused to marry Vulcan, choosing rather to live in a state of celibacy. She also deprived0 Tiresias of sight, turned Medusa's locks into snakes, and performed several other exploits.

Minerva is usually represented by the poets, painters, and sculptors, completely armed, with a composted but agreeable countenance, bearing a golden bridle, a spear in her right-hand, and heregis or shield in the left, on which is represented Medusa's head encircled with snakes, and her helmet was usually entwined with olives.

Minerva had several temples both in Greece and Italy. The usual victim offered her was a white heifer, never yoked. The animals sacrificed to her were the cock, the owl, and the basilisk.

Minerva Promontorium (anc. geogr.), the seat of the Sirens, a promontory in the Sinus Paetinus, the south boundary of Campania on the Tufcan coast; so called from a temple of Minerva on it: situated to the south of Surrentum, and therefore called Surrentinum. Minervalia, or Pallastium, Minervium, E. Long. 15. 42. N. Lat. 40. 10.

MINERVALIA, in Roman antiquity, celebrated in honour of Minerva, in the month of March; at which time the scholars had a vacation, and usually made a present to their masters, called from this festival Minerval.

MINGRELIA, anciently Colchis, a part of Western Georgia, in Asia; bounded on the east by Iberia, or Georgia properly so called; on the west, by the Euxine Sea; on the north, by Armenia, and part of Pontus; and on the north, by Mount Caucasus. Colchis, or Mingrelia, is watered by a great many rivers; as the Corax, the Hippus, the Cyaneus, the Charisius, the Phasis, where the Argonauts landed, the Abyarus, the Ciffa, and the Ophis, all emptying themselves into the Euxine Sea. The Phasis does not spring from the Mountains in Armenia, near the sources of the Euphrates, the Araxes, and the Tigris, as Strabo, Pliny, Ptolemey, Dionysius, and after them Arrian, Reland, Calmet, and Sanfon, have falsely asserted; but rises in Mount Caucasus, and flows not from south to north, but from north to south, as appears from the map of Colchis or Mingrelia in Thevenot's collection, and the account which Sir John Chardin gives of that country. This river forms in its course a small island called allo Phasia; whence the peacocks, if Ibis is to be credited, were first brought to Europe, and thence called by the Greeks Phalanges. The other rivers of Colchis are considerable. The whole kingdom of Colchis was in ancient times very pleasant and fruitful, as it is still where duly cultivated; abounded in all the necessaries of life; and was enriched with many mines of gold, which gave occasion to the tale of the Golden Fleece and the Argonautic expedition so much celebrated by the ancients.

T. SIR
MIN [ 146 ] MIN

Mingrelia. Sir John Chardin tells us, that this country extends above 100 miles in length and 60 in breadth; being not near so extensive as the ancient Colchis, which reached from the frontiers of Iberia or Georgia Proper, westward to the Palus Moesitis: that it is beautifully diversified with hills, mountains, valleys, woods, and plains, but badly cultivated: that there are all the kinds of fruits which are found in England, growing wild, but tasteless and insipid for want of culture: that, if the natives understand the art of making wines, those of this country would be the finest in the world: that there are many rivers which have their sources in mount Caucausus, particularly the Pheafs, now called the Kione: that the country abounds in beeves, hogs, wild boars, flags, and other venison: and in partridges, phaenafs, and quails; that falcons, eagles, pelicans, lions, leopards, tigers, wolves, and jackals, breed on Mount Caucausus, and sometimes greatly annoy the country: that the people are generally handlime, the men strong and well made, and the women very beautiful; but both sexes very vicious and debauched: that they marry their nieces, aunts, or other relations, indifferently: and take two or three wives if they please; and as many concubines as they require to be viewed very near.

The cities of most note in this country in ancient times were Pitius; Dioscurias, or Dioecorias, which was so called from Caftor and Pollux, two of the Argonauts, by whom it is supposed to have been founded, and who in Greek are styled Dioecoras, at present known by the name of Savatapoli; Aeons the Phaeis, supposed to be the same as Hupolis; Phafs, so called from the river on which it flowed; Cyta, at the mouth of the river Cyaneus, the birth place of the famous Medea, called from thence, by the poets, Cydæs; Saraces, Zadrís Surium, Madiæ, and Zollia. As for modern cities, it does not appear that there are any here considerable enough to merit a description; or, if there are, they seem to be little, if at all, known to Europeans.

MINHO, a great river in Spain, which taking its rise in Galicia, divides that province from Portugal, and falls into the Atlantic at Caminha.

MINIATURE, in a general sense, signifies representation in a small compass, or less than the reality.

MINIATURE-Painting;

A DELICATE kind of painting, consisting of little points or dots; usually done on vellum, ivory, or paper, with very thin, simple water-colours.—The word comes from the Latin minium, “redlead;” that being a colour much used in this kind of painting. The French frequently call it mignature, from mignon, “fine, pretty;” on account of its smallness and delicacy: and it may be ultimately derived from minus “small.”

Miniature is distinguished from other kinds of painting by its smallness and delicacy of its figures and paitnjes of the colouring; on which account it requires to be viewed very near.

SECTION I. Of Drawing and designing.

To succeed in this art, a man should be perfectly skilled in the art of designing or drawing: but as most people who affect the one, know little or nothing of the other, and would have the pleasure of painting without giving themselves the trouble of learning to design (which is indeed an art that is not acquired without a great deal of time, and continual application), inventions have been found out to supply the place of it; by means of which a man designs or draws, without knowing how to design.

The first is chalking: that is, if you have a mind to do a print or design in miniature, the backside of it on another paper, must be blackened with small-coal, and then rubbed very hard with the finger wrapped in a linen cloth: afterwards the cloth must be lightly drawn over the side so blackened that no black grains may remain upon it to soil the vellum you would paint upon; and the print or draught must be fastened upon the vellum with four pins, to keep it from fluffing. And if it be another paper that is blackened, it must be put between the vellum and the print, or draught, with the blackened side upon the vellum. Then, with a blunted pin or needle, you must pass over the principal lines or strokes of the print, or draught, the contours, the plates of the drapery, and over every thing else that must be distinguished; pressing so hard, that the strokes may be fairly marked upon the vellum underneath.

Copying by squares is another convenient method for such as are but little skilled in the art of designing, and would copy pictures, or other things, that cannot be chalked. The method is this: The piece must be divided
MINIATURE-PAINTING.

I. MINIATURE.

To divide a paper or vellum into equal parts, mark off with charcoal; if the piece be clear and white, and the black can be fairly seen upon it; or with white chalk, if it be too brown and dull. After which, as many squares of equal dimensions must be made upon white paper, upon which the piece must be designed; because, if this be done immediately upon vellum, (as it will be chalked upon the vellum upon the back of it;) the vellum may be foiled with taffe touches. But when it is neatly done upon paper, it must be chalked upon the vellum in the manner before described. When the original and the paper are thus ordered, observe what is in each done upon paper, it is one is apt to find where to place the parts of the piece to be drawn upon your piece; through it you will see drawn upon the varnished paper, bladder, or silver needle, mark out upon the paper or vellum you have put uppermost, all the lines and touches you shall see drawn upon the varnished paper, bladder, tale, or ifinglass, you have made use of, and which will plainly appear through this window.

After this manner, making use of the window, or of glafs exposed to the light, you may copy all sorts of prints, designs, and other pieces, on paper or vellum; laying and fastening them under the paper or vellum upon which you would draw them. And it is a very good and very easy contrivance for doing pieces of the same size and proportion.

If you have a mind to make pieces look another way, there is nothing to be done but to turn them; laying the printed or drawn side upon the glass, and fastening the paper or vellum upon the back of it; remembering to let your lights fall on the left side.

A good method likewise to take a true copy of a picture in oil, is to give a touch of the pencil upon all the principal strokes, with lake tempered with oil; and to clap upon the whole a paper of the same size; then passing the hand over it, the touches of the lake will stick and leave the design of your piece expressed upon the paper, which may be chalked like other things. But you must remember to take off with the crumb of bread what remains of the lake upon the picture before it be dry.

You must likewise make use of pounce, made of powdered charcoal put in a linen-rag; with which the piece you would copy must be rubbed, after you have pricked all the principal strokes or touches, and fastened white paper or vellum underneath.

But aurer and easier help than all these, for one who knows nothing of designing, is a mathematical compass; it is generally made of ten-pieces of wood, in form of rulers, half a quarter of an inch thick, half an inch broad, and a foot long, or more, according as you have a mind to draw pieces of a greater or less size. To facilitate the construction of this instrument, a figure is given, with an explanation of the manner in which it is to be used.

The little board A is to be of fir, and covered with linen or any other cloth; because the piece you copy, and the vellum or paper you copy upon, must be fixed upon it. Upon this board must the compass also be fixed with a pin, by the end of the fir foot B, deep enough to keep it close, but so deep as to hinder it from turning easily. When you have a mind to reduce things, place your original on the side of the foot C, and the vellum or paper you would draw upon on the side of the foot B; removing the vellum, or drawing it nearer, according as you intend to reduce or enlarge.

In order to enlarge a piece, you have nothing to do but to change the places of your original and your copy: placing the left towards C, and the other on the side of B.

And in both one and the other method, a crayon or leaden needle must be put in the foot under which the vellum lies; and a pin, a little blunted, in that over the original, with which all the traces are to be followed; conducting the pin with one hand, and with the other pricking gently upon the crayon or needle that marks the vellum. When the crayon or needle bears sufficiently upon the vellum, you have no occasion to touch it.

By this instrument you may also draw in equal dimensions; but in order to this, the compass must be fixed in another manner upon the board; for if it is to be fastened upon it by the middle at D, your original and your copy must be fixed on each side of this middle foot, at the equal distances, or from corner to corner: that is, from C to E, when the pieces are large. One may likewise draw several copies at once of equal and different dimensions.

When your piece is marked out upon the vellum, you must pass with a pencil of very clear carmine over all the traces, to the end they may not be effaced as you work: then clean your vellum with a crumb of bread, there will no black may remain upon it.

Your vellum must be paffed upon a little plate of brafs or wood, of the size you would make your piece, to keep it firm and tight: but this passi ng must be on the edges of your vellum only, and behind the plate; for which purpose your vellum must exceed your plate above an inch on every side: for the part you paint upon must never be paffed; because it would not only give it an ill look, but you could not take it off if you would. Cut off the little flags and locks of the vellum; and wetting the fair side with a linen-cloth dipped in water, clap the other upon the plate with a clean paper between them: so much as hangs over must be paffed upon the back of the plate, drawing it equally on all sides, and hard enough to stretch it well.

SECT. II. Of Materials.

The chief colours made ufe of for painting in miniature, are

Carmine.

Venice and Florence lake.

Rose
MINIATURE-PAINTING.

Colours.

Rose pink.
Vermilion.
Red-lead.
Brown red.
Red ochre.
Ultramarine.
Verditer.
Indigo.
Gall-tone.
Yellow-ochre.
Dutch pink.
Gamboge.
Naples yellow.
Pale mallicot.
Deep yellow mallicot.
Ivory-black.
Lamp-black.
True Indian ink.
Bilfre, or wood-foot.
Raw umber.
Burnt umber.
Sap-green.
Verdigris.
Flake-white.
Crayons of all colours.
Gold and silver shells.
Leaf-gold and leaf-silver.

The seven transparent colours, which are used where writing is seen through the colour.

Lake.
Blue.
Yellow.

Liquid

Grafs-green.
Dark-green.
Purple-colour.
Brown.

Most of these colours necessary for miniature-painting may easily be prepared by attending to the directions given under the article Colour-Making.

As colours taken from earth and other heavy matter are always too coarse, be they never so well ground, especially for delicate work, because of a certain sand remaining in them; the finest parts may be drawn out by diluting them with the finger in a cup of water. When they are well steeped, let them settle a while: then pour out the clearest, which will be at top, into another vessel. This will be the finest, and must be let dry; and when it is used, must be diluted with gum-water.

If you mix a little of the gall of an ox, a carp, or an eel, particularly of the last, in green, black, grey, yellow, and brown, colours, it will not only take away their greasy nature, but also give them a lustre and brightness they have not of themselves. The gall of eels must be taken out when they are skinned, and hung upon a nail to dry; and when you would use it, it must be diluted with brandy; add a little of it mixed with the colour you have diluted already. This likewise makes the colour fir better to the vellum, which it hardly does when it is greasy: moreover, this gall hinders it from sealing.

Some colours are made clearer by fire; as yellow ochre, brown red, ultramarine, and umber: all others are darkened by it. But if you heat the said colours with a sharp fire, they change; for the brown-red becomes yellow; yellow ochre becomes red; umber reddens also. Ceru's by fire takes the colour of citron, and is often called mastic. Observe, that yellow ochre heated, becomes more tender than it was, and softer than brown red. Likewise brown red heated becomes softer than fine yellow ochre. Both are very proper. The finest and truest ultramarine, heated upon a red-hot iron, becomes more glittering; but it wanters, and is coarser and harder to work with in miniature.

All these colours are diluted in little cups of ivory, made upon purpose, or in sea-shells, with water in which gum arabic and sugar-candy are put. For instance, in a glass of water put a piece of gum as big as a walnut, and half that quantity of sugar-candy. This last hinders the colours from scaling when they are laid on, which they generally do when they want it, or the vellum is greasy.

This gum-water must be kept in a neat bottle corked; and you never must take any out of it with a pencil that has colour upon it, but with a quill or some such thing.

Some of this water is put in the shell with the colour, you would temper, and diluted with the finger till it be very fine. If it be too hard, you must let it often in the shell with the said water before you dilute it. Afterwards let it dry; and do thus with every colour, except lily-green, sap-green, and gamboge, which must be tempered with fair water only. But ultramarine, lake, and bilfre, are to be more gummned than other colours.

If you make use of sea-shells, you must let them steep two or three days beforehand in water; then cleanse them in boiling hot water, mixed with vinegar, in order to carry off a certain salt, which otherwise sticks to them, and spoils the colours that are put to them.

To know whether colours are sufficiently gummned, you have nothing to do but to give a stroke of the pencil upon your hand when they are diluted, which dries immediately; if they chap and scale, there is too much gum; if they rub out by passing the finger over them, there is too little. It may be seen likewise when the colours are laid on the vellum, by passing the finger over them. If they flick to it like a powder, it is a sign there is not gum enough, and more must be put to the water with which you temper them: but take care you do not put too much; for that makes the colour extremely hard and dry. It may be known likewise by their glueness and brightness: so the more they are gummned, the darker they paint; and when you have a mind to give a greater strength to a colour than it has of itself, you have nothing to do but to give it a great deal of gum.

Provide yourself with an ivory pallet, very smooth, as big as your hand; on one side of which the colours for the carnation, or naked parts of a picture, are to be ranged in the following manner. In the middle put a great deal of white, pretty largely spread; because it is the colour most made use of: and upon the edges, from the left to the right, place the following colours at a little distance from the white.

Mallicot.
Dutch-pink.
Orpiment.

Yellow
Let us now shew how they are to be employed. In the first place, then, when you would paint a piece, be it carnation, drapery, or any thing else, you must begin by dead-colouring; that is to say, by laying your colours on with liberal strokes of the pencil, in the smoothest manner you can, as the painters do in oil; not giving it all the force it is to have for a finishing; that is, make the lights a little brighter, and the shades less dark, than they ought to be; because in dotting upon them, as you must do after dead-colouring, the colour is always fortified, and would at last be too dark.

There are several ways of dotting; and every painter has his own. Some make their dots perfectly round; others make them a little longish; others hatch by little strokes that cross each other every way, till the work appears as if it had been wrought with dots. This last method is the belt, the boldest, and the soonest done: wherefore such as would paint in miniature ought to use it, and to inure themselves from the fink to dot in the plump and the soft way; that is to say, where the dots are loft, in a manner, in the ground upon which you work, and not so much as to make the work seem dotted. The hard and the dry way is quite the reverse, and always to be avoided. This is done by dotting with a colour much darker than your ground, and when the pencil is not moistened enough with the colour, which makes the work seem rough and uneven.

Study likewise carefully to lufe and drown your colours one in another, so that it may not appear where they disjoin; and to this end, soften or allay your colours with colours that partake of both, in such a fort that it may not appear to be your touches which cut and disjoin them. By the word cut, we are to understand what manifestly separates and divides, and does not run in and blend itself with the neighbouring colours; which is rarely practised but upon the borders of drapery.

When your pieces are finished, to heighten them a little, give them a fine air; that is to say, give, upon the prematurity of the lights, small touches with a colour yet lighter, which must be lost and drowned with the rest.

When the colours are dry upon your pallet or in your shells, in order to use them, they must be diluted with water. And when you perceive they want gum, which is seen when they easily rub off the hand or the vellum if you give a touch with them upon either, they must be tempered with gum-water instead of pure water, till they are in condition.

There are several sorts of grounds for pictures and portraits. Some are wholly dark, composed of bistre, umber, and Cologn earth, with a little black and white; others more yellow, in which is mixed a great deal of ochre; others greyer, which partake of indigo. In order to paint a ground, make a wash of the colour or mixture you would have it, or according to that of the picture or portrait you would copy; that is to say, a very light lay, in which there is hardly any thing but water, in order to soak the vellum. This put another lay over that, somewhat thicker, and strike it on very smoothly with large strokes as quick as you can, not touching twice in the same place before it be dry; because the second stroke carries off what
MINIATURE-PAINTING.

When there are clouds in the sky, you may spare the places where they are to be; that is to say, you need not lay on any blue there, but form them, if they are reddish, with vermilion, gall-stone, and white, with a little indigo; and if they are more upon the black, put in a good deal of the left; painting the lights of one and the other with maflicot, vermilion, and white, more or less of any of these colours, according to the strength you would give them, or according to that of the original you copy; rounding the whole as you dot; for it is a difficult matter to lay them very smooth at the first painting: and if the sky is not even enough, you must dot it also.

It is at your pleasure to exempt the places of the clouds, for you may lay them upon the ground of the sky; heightening the bright parts by putting a good deal of white, and fortifying the shadows by using less. This is the shortest way.

The light or stormy sky is done with indigo, black, and white, mixed together; which is laid as for a day-sky. To this mixture must be added ochre, vermilion, or brown-red, for the clouds; the lights of which are to be of maflicot, or red-lead, and a little white; now redder, now yellower, at discretion. And when it is a tempestuous sky, and lightning appears in some places, be it blue or red, it is to be done as in a day-sky, drowning and losing the whole together at the first forming or dead-colouring, and at the finishing.

SECT. IV. Of Draperies.

To paint a blue drapery, put ultramarine near the white upon your pallet; and mix a part of the one with the other, till it makes a fine pale, and has a body. With this mixture you must form the brightest parts; and then adding more ultramarine, form such as are darker; and go on after this manner till you come to the deepest plaits and the thickest shades, where you must lay pure ultramarine: and all this must be done as for a first-forming or dead-colouring; that is to say, laying the colour on with free strokes of the pencil, yet as smooth as you can; losing the lights in the shadows with a colour neither so pale as the light nor so dark as the shades. Then dot with the same colour as in the first-forming, but a small matter deeper; that the dots may be fairly seen. All the parts must be drowned one in another, and the plaits appear without intercession. When the ultramarine is not dark enough to make the deeper shadows, how well ever it be gummed, mix a little indigo with it to finish them. And when the extremities of the lights are not bright enough, heighten them with white and a very little ultramarine.

A drapery of carmine is done in the same manner as the blue; except that in the darkest places there is to be a lay of pure vermilion, before you dead-colour with carmine, which must be applied at top; and in the strongest shades, it must be gummed very much. To deepen it the more, mix a little bitre with it.

There is likewise made another red drapery, which is first drawn with vermilion, mixing white with it to dead-colour the bright places, laying it pure and unmixed for those that are darker, and adding carmine.
Sect. IV. MINIATURE-PAINTING.

The light-grey is begun with black and white, and finished with the same colour deeper.

For a brown drapery, make a lay of bistre, white, and a little brown red; and shadow with this mixture, made a little: darker.

There are other draperies, called "variable," because the lights are of a different colour from the shades. These are multil; used for the vestments of angels, for young and gay people, for scarfs and other airy attire, admitting of a great many folds, and flowing at the pleasure of the wind. The most common are the violets; of which they make two sorts; one, where the lights are blue; and the other, where they are yell w.

For the first, put a lay of ultramarine and very pale white upon the lights; and shadow with carmine, ultramarine, and white, as for drapery wholly violet; so that only the grand lights appear blue. Yet must be dotted with violet, in which there is a great deal of white, and loft incendiary in the shades.

The other is done by puttiug upon the lights only, instead of blue, a lay of mastic; working the rest as in the drapery all violet, excepting that it must be dotted, and the light parts blended with the shadowy, that is, the yellow with the violet, with a little gamboge.

The carmine-red is done like the last; that is, let the lights be done with mastic, and the shades with carmine; and to lose the one in the other, make use of gamboge.

The lake-red is done like that of carmine.

The green is done as the lake; always mixing verditer with lily or sap green, to make the shades; which are not very dark.

Several other sorts of draperies may be made at discretion, always taking care to preserve the union of the colours, not only in one sort of cloth or so, but also in a group of several figures; avoiding, as much as the subject will allow, the putting of blue near the colour of fire, of green against black; and so of other colours which cut and disjoin, and whose union is not kind enough.

Several other draperies are made of soul colours, as brown-red, bistre, indigo, &c. and all in the same manner. Likewise of other colours, simple and compound; the agreement between which is always to be minded, that the mixture may produce nothing harsh and disagreeable to the eye. No certain rule can be laid down for this. The force and effect of your colours are only to be known from use and experience, and you must work according to that knowledge.

Linen cloths are done thus. After drawing the plaits or folds, as is done in a drapery, put a lay of white over all; then dead-colour and finish the shades with a mixture of ultramarine, black, and white, using more or less of the last, according to their strength or tenderness; and in the greatest deepnings put bistre, mixed with a little white; giving only some touches of this mixture, and even of pure bistre, upon the extremities of the greatest shadows, where the folds must be drawn, and lost with the rest.

They may be done in another manner, by making a general lay of this mixture of ultramarine, black, and
MINIATURE-PAIN TINO.

and very pale white; and dead-colour (as has been
said before) with the same colour, but a little deeper.
And when the shades are dotted and finished, heighten
the lights with pure white, and lose them with the
deepenings of the linen. But of whatever sort you
make them, when they are finished, you must give a
yellowish tint of orpiment and white to certain places;
laying it lightly on, and as it were in water; so that
what is underneath may, notwithstanding, plainly
appear, as well the shadows as the dotting.

Yellow linen-cloth is done by putting a lay of
white, mixed with a little ochre. Then form and fi-
nish the shades with bistre, mixed with white and
ochre; and in the thickest shades use pure bistre: and
before you finish, give some teints here and there of
ochre and white, and others of white and ultramarine,
as well upon the shades as the lights; but let them
be very bright: and drown the whole together in dot-
tings, and it will look finely. As you finish, lighten
the extremities of the lights with malficlot and white.
You may add to this fort of linen, as well as to the
white, certain bars from space to space, as in Turkey-
mantua; that is, small stripes blue and red with ul-
tramarine and carmine; one of red between two of
blue, very bright and clear upon the lights, and deeper
upon the shades. Virgins are very often dressed
with veils of this fort (by Popish painters), and scurf
of this kind are put about necks that are bare; be-
cause they become the teint mighty well.

If you would have both these sorts of linen transpa-
rent, and the stuff or other thing that is beneath ap-
pear through them, make the first lay for them very
light and clear, and mix in the colour to shadow, with,
a little of that which is underneath, especially towards
the end of the shades; and only do the extremities of
the lights, for the yellow with malficlot and white;
and for the white, with pure white.

They must be drawn in another manner, especially
when you would have them altogether as clear as muf-
lin, lawn, or gauze. To this end form and finish what
is to be beneath, as if nothing was to be put over it.
Then mark out the light and clear folds with white or
malficlot; and a shadow with bistre and white, or
with black, blue, and white, according to the colour
you would make them of; making the rest somewhat
clearer: yet this is not necessary but for the parts that
are not to be so clear.

Crape is done the same way; excepting that the
folds of the shades and the lights, and the borders too,
are to be marked out with little filaments of black upon
what is underneath; which is likewise to be finis-
ed beforehand.

When you would make a stuff like watered tab-
by, make the waves upon it with a colour a little
lighter, or a little darker, in the lights and the shades.

There is a manner of touching draperies which dif-
tinguishes the filkens from the woollens. The last are
more terrestrial and senible; the others more light
and fading. But it must be observed that this is an
effect which depends partly upon the stuff and partly
upon the colour; and for the employing these in a
manner suitable to the subjects and the deepenings
of painting, we shall here touch upon their different qua-

ties.

We have no colour which partakes more of light,
MINIATURE-PAINTING.

Of Carnations.

For doing a building, if it be of stone, take indigo, bistre, and white, with which make the beginning or first form of it; and for shadowing it, put lefs of this last, and more bistre than indigo, according to the colour of the tone you would paint. To these you may likewise add a little ochre, both for the forming and the finishing. But to make it finer, you must give, here and there, especially for old fabrics, blue and yellow teints, some with ochre, others with ultramarine, mixing always white with them, whether before the first-forming, provided they appear through the draught, or whether upon it, losing or drowning them with the rest when you finish.

When the building is of wood, as there are many forts, it is done at discretion; but the most ordinary way is to begin or first-form with ochre, bistre, and white, and finish without, or with very little; and if the shades are deep, with pure bistre. In the other they add sometimes vermilion, sometimes green or black; in a word, just according to the colour they would give it, and they finish with dotting, as in draperies and every thing else.

Sect. V. Of Carnations, or the naked parts of Painting.

There are in carnation so many different colourings, that it would be a difficult thing to give general rules upon so variable a subject. Nor are they minded, when one has got, by custom and practice, some habit of working easily: and such as are arrived to this degree, employ themselves in copying their originals, or else they work upon their ideas, without knowing how: insomuch, that the most skilful, who do it with less reflection and pains than others, would likewise be more put to it to give an account of their maxims and knowledge in the matter of painting, if they were to be asked what colours they made use of for the shades and such a colouring, a tint here, and another there.

Nevertheless, as beginners want some instruction at the first, we will shew in general after what manner several carnations are to be done.

In the first place, after having drawn your figure with carmine, and ordered your piece, apply, for women and children, and generally for all tender colourings, a lay of white, mixed with a very little of the blue made for faces, of which we have told the composition; but let it hardly be seen.

And for men, instead of blue, they put in this first lay a little vermilion; and when they are old, a little ochre is mixed with it.

Afterwards follow all the traces with vermilion, carmine and white, mixed together; and begin all the shades with this mixture, adding white in proportion as they are weaker; and putting but little in the darkest, and none, in a manner, in certain places where strong touches are to be given: for instance, in the corner of the eye; under the nose; at the ears; under the chin; in the separation of the fingers; in all joints; at the corners of the nails; and generally in every part where you would mark out separations in shades that are obscure. Neither need you fear to give to those places all the force and strength they ought to have as soon as you begin or first-form them, because in working at top with green, the red you have put there is always weakened.

After having begun, or first-formed, or dead-coloured, with red, make blue teints with ultramarine and a great deal of white, upon the parts which fly from the eye; that is to say, upon the temples; under and in the corners of the eyes; on both sides of the mouth, above and below; a little upon the middle of the forehead; between the nose and the eyes; on the side of the cheeks; on the neck and other places where the flesh assumes a bluish cast. Yellowish teints are likewise made with ochre or orpiment, and a little vermilion mixed with white, under the eye-brows, on the sides of the nose towards the bottom, a little underneath the cheeks, and upon the other parts which rise and come nearer the eye. It is especially from these teints that the natural complexion is to be observed, in order to catch it for painting being an imitation of nature, the perfection of the art consists in the justness and simplicity of the representation, especially in face-painting.

When, therefore, you have done your first lay, your dead colouring, and your teints, you must work upon the shades, dotting with green for the carnations or naked parts, mixing according to the rule we have given for the teints, a little blue for the parts which fly from the eye; and, on the other hand, making it a little yellower for those that are more sensible; that is to say, which rise, and come nearer the eye: and at the end of the shades, on the side of the light, you must blend and lose your colour insensibly in the ground of the carnation with blue, and then with red, according to the places where you paint. If this mixture of green does not work dark enough at first, pass over the shades several times, now with red, and now with green; always dotting: and this do till they are as they should be.

And if you cannot with these colours give the shades all the force they ought to have, finish, in the darkest, with bistre mixed with orpiment, ochre, or vermilion, and sometimes with pure bistre, according to the colouring you would make, but lightly, laying on your colour very clear.

You must dot upon the clear and bright places with a little vermilion or carmine, mixed with much white, and a very small matter of ochre, in order to lose them with the shadowy, and make the teints die away insensibly into one another; taking care, as you dot, or hatch, to make your strokes follow the turnings and windings of the fleshy parts. For though the rule be to cross always, this dotting or hatching ought to appear a little more here, because it rounds the parts. And as this mixture might make a colouring too red, if it was always to be used, they work likewise in every part, to blend the teints and the shades, with blue and a little green, and much white, so mixed as to be very pale; excepting, nevertheless, that this colour must not be put upon the cheeks, nor upon the extremities of the clear parts, no more than the other mixture upon these last, which must be left with all their light; as certain places of the chin, of the nose, and of the forehead, and upon the cheeks; which ought nevertheless to be redder than the rest, as well as the feet, the hollows of the hands, and the fingers of both.
Observe, that these two last mixtures ought to be so pale, that the work shall hardly be visible; for they serve only to soften it; to unite the teints with one another, and the shades with the lights, and to drown the traces. Care must likewise be taken that you work not too much with the red mixture upon the blue teints, nor with the blue upon the others; but change the colour from time to time, when you perceive it works too blue or too red, till the work be finished.

The white of the eyes must be shadowed with this same blue, and a little flesh-colour; and the corners, on the side of the nose, with vermilion and white; giving them a little touch of carmine. The whole is softened with this mixture of vermilion, carmine, white, and a very small matter of ochre.

The apples or balls of the eyes are done with the mixture of ultramarine and white; the lids with indigo, bistre, or black, according to the colour they are of; giving to each a small touch of pure vermilion round the middle, called the crysal of the eye; and especially the upper ones, which must be heightened by little strokes of blood, or for the finishing. This gives vivacity to the eye.

The round or circumference of the eye is done with bistre and carmine; that is to say, the fists or partings, and the eye-lids, when they are large and bold; especially the upper ones; which must afterwards be softened with the red or blue mixtures we have mentioned above, to the end they may be lost in one another, and nothing seem interfected. When this is done, give a little touch of pure white upon the crysal, on the side of the eyes. This makes the eye shine, and gives life to it.

The mouth is dead-coloured with vermilion, mixed with white; and finished with carmine, which is softened as the rest. And when the carmine does not work dark enough, mix a little bistre with it. This is to be underflood of the corners in the separation in the lips; and particularly, of certain mouths half open.

The hands, and all the other parts of carnation, are done in the same manner as the faces; observing, that the ends of the fingers be a little redder than the rest. When your whole work is formed and dotted, mark the separations of all the parts with little touches of carmine and orpiment mixed together, as well in the shades as in the light places; but a little deeper and stronger in the first, and lost in the rest of the carnation.

The eye-brows and the beard are dead-coloured, as are the shades of carnations; and finished with bistre, ochre, or black, according to the colour they are of; drawing them by little strokes the way they ought to go; that is to say, give them all the nature of hair. The lights of them must be heightened with ochre and bistre, a little vermilion, and much white.

For the hair of the head, make a lay of bistre, ochre, and white, and a little vermilion. When it is very dark-coloured, use black instead of ochre. Afterwards form the shadowy parts with the same colours, putting less white in them; and finish with pure bistre, or mixed with ochre or black, by small strokes very fine, and close to each other, waving and buckling them according to the curling of the hair. The light parts must also be heightened by little strokes with ochre or orpiment, white, and a little vermilion. After which, lose the lights and the shades in each other, by working sometimes with a dark and sometimes with a light colour; but not too much with the red mixture upon the blue.

And for the hair about the forehead, through which the skin is seen, it must be first formed with the colour thereof, and that of the carnation, working and shadowing with one and the other, as if you designed to paint none. Then form it, and finish with bistre. The lights are to be heightened as the other. Grey hair is dead-coloured with white, black, and bistre, and finished with the same colour, but deeper; heightening the bright and clear parts of the hair, as well as those of the eye brows and the beard, with white and very pale blue, after having formed them as the others, with the colour of the flesh or skin; and finish with bistre.

But the most important thing is to soften one's work; to blend the teints in one another, as well as the beard and the hair about the forehead, with the other hair and the carnation; taking especial care not to work rough and dry; and that the traces, turnings, and windings of the carnation, or naked parts, be not interfected. You must likewise accustom yourself to put white in your colours only in proportion as you work lighter or darker: for the colour you use the second time must be always a little stronger and deeper than the first, unless it be for softening.

Different colourings are easily made, by putting more or less of red, or blue, or yellow, or bistre, whether for the dead-colouring, or for the finishing. That for women ought to be bluish; that for children a little red; and both fresh and florid. That for men ought to be yellower; especially when they are old.

To make a colouring of death, there must be a first lay of white and orpiment, or a very pale ochre: dead-colour with vermilion, and lake, instead of carmine, and a good deal of white; and afterwards work over it with a green mixture, in which there is more blue than any other colour, to the end the flesh may be livid and of a purple colour. The teints are done the same way as in another colouring; but there must be a great many more blue than yellow ones, especially upon the parts which fly from the sight, and about the eyes; and the half are only to be upon the parts which rise and come nearer the eye. They are made to die away in one another, according to the ordinary manner; sometimes with very pale blue, and sometimes with ochre and white, and a little vermilion; softening the whole together. The parts and contours must be rounded with the same colours. The mouth is to be, in a manner, of a quite violet. It is dead-coloured, however, with a little vermilion, ochre, and white; but finished with lake and blue; and to give it the deep strokes, they take bistre and lake, with which they likewise do the same to the eyes, the nose, and the ears. If it is a crucifix, or some martyr, upon whom blood is to be seen, after the finishing the carnation, form it with vermilion, and finish it with carmine, making in the drops of blood a little bright reflecting spark, to round them. For the crown of thorns, make a lay of sea-green and mallicot;
Sect. VI.  MINIATURE-PAINTING.

Of Carnations.

Iron is formed, or first laid, with indigo, a little black and white; and finished with pure indigo, heightening it with white.

For painting fire and flames, the lights are done with mallicot and orpiment; and for the shades, they mix vermilion and carmine.

A smoke is done with black, indigo, and white, and sometimes with bife; one may likewise add vermilion or ochre, according to the colour it is to be of.

Pearls are painted by putting a lay of white, and a little blue; they are shadowed and rounded with the same colour; deeper; a small white dot is made almost in the middle, on the side of the light; and on the other side, between the shadow and the edge of the pearl, they give a touch with mallicot, to make the reflection; and under the pearls is made a little shadow of the colour of the ground they are upon.

Diamonds are made with pure black; then they heighten them with little touches of white on the side, between the shadow and the edge of the pearl, they give a touch with mallicot, to make the reflection; and under the pearls is made a little shadow of the colour of the ground they are upon.

One great means to acquire a perfection in the art, is to copy excellent originals. We enjoy with pleasure and tranquility the labour and pains of others. But a man must copy a great number before he is able to produce as fine effects; and it is better to be a good copier than a bad author.

Sect. VI. Of Landscapes.

In the first place, after having ordered the economy of your landscape as of your other pieces, you must form the nearest grounds or lands, when they are to appear dark, with lap or lily-green, bife, and a little verditer, to give a body to your colour; then dot with this mixture, but a little darker, adding sometimes a little black to it.

For such pieces of ground as the light falls upon, and which are therefore clear and bright, make a lay of ochre and white: then shadow and finish with bife.

In some they mix a little green, particularly for shadowing and finishing.

Trees are not done till the sky be finished; one may, nevertheless, spare the places of them when they contain a good number; and however it be, such as come near the eye, are to be dead-coloured with verditer, mixing sometimes ochre; and shadowed with the same colours, adding lily green. Afterwards you must work leaves upon them by dotting without crossing: for this must be done with small length dots, of a darker colour, and pretty full of it, which must be conducted on the side the branches go, by little tufts of a little darker colour. Then heighten the lights with verditer or sea-green, and mallicot, making leaves in the same manner; and when there are dry branches or leaves, they are dead-coloured with brown-red or gallstone, with white; and finished with gallstone, without white, or with bife.

The trunks of trees are to be dead-coloured with ochre, white, and a little green, for the light and clear parts; and for the dark, they mix black, adding bife and green for shadowing one and the other. Blue and yellow teints are likewise made upon them, and little touches given here and there with white and mallicot; such as you ordinarily see upon the bark of trees.

The branches which appear among the leaves are done with ochre, verditer, and white; or with bife and white, according to the light they are placed in. They must be shadowed with bise and lily-green.

Trees, which are at a little distance, are dead-coloured with verditer and sea-green; and are shadowed with
and finished with the same colours, mixed with lily-green. When there are some which appear yellowish, lay with ochre and white, and mix with gall-flour.

For such as are in the distances and remote views, you must dead-colour with sea-green; with which, for finishing, you must mix ultramarine. Heighten the lights of one and the other with mallow, by small disjointed leaves.

It is the most difficult part of landscape, in manner of miniature, to leaf a tree well. To learn, and break one's hand to a little, the way is to copy good ones; for the manner of touching them is singular, and cannot be acquired but by working upon trees themselves; about which you must observe to make little boughs, which must be leafed, especially such as are below and toward the sky.

And generally, let your landscapes be coloured in a handsomely manner, and full of nature and truth; for it is that which gives them all their beauty.

**Sect. VII. Of Flowers.**

It is an agreeable thing to paint flowers, not only on account of the splendour of their different colours, but also by reason of the little time and pains that are bestowed in trimming them. There is nothing but delight in it: and, in a manner, no application. You maym bungle a face, if you make one eye higher than another; a small nose with a large mouth; and so of other parts. But the fears of these disproportions confine not the mind at all in flower-painting; for unless they be very remarkable, they spoil nothing. For this reason most persons of quality, who divert themselves with painting, keep to flowers.

Nevertheless, you must apply yourself to copy judiciously: and for this part of miniature, as for the rest, we refer you to nature, for the is your best model. Work, then, after natural flowers; and look for the tints and different colours of them upon your pallet: a little will make you find them easily; and to facilitate this to you at the first, we shall, in the continuance of our design, shew the manner of painting some of natural flowers are not always to be had; and one is often obliged to work after prints, where nothing is seen but graving.

It is a general rule, that flowers are designed and laid like other figures; but the manner of forming and finishing them is different: for they are first formed only by large strokes and traces, which you must turn at the first the way the small ones are to go, with which you finish; this turning aiding much thereto. And for finishing them, instead of hatching or dotting, you draw small strokes very fine, and very close to one another, without croffing; repalling several times, till your dark and your clear parts have all the force you would give them.

Of Roses.—After making your first sketch, draw with carmine the red rose, and apply a very pale lay of carmine and white. Then form the shades with the same colour, putting white least in it: and lastly, with pure carmine, but very bright and clear at the first; fortifying it more and more as you proceed in your work, and according to the darkness of the shades. This is done by large strokes. Then finish; working upon it with the same colour by little strokes, which you must make go the same way with those of the graving, if it be a print you copy; or the way the leaves of the rose turn, if you copy after a painting, or after nature; losing the dark in the clear parts, and heightening the greatest lights, and the brightest or most lightfome leaves, with white and a little carmine. You must always make the hearts of roses, at the side of the shadow darker than the rest; and mix a little indigo for shadowing the first leaves, particularly when the roses are blown, to make them seem faded. The feed is dead-coloured with gamboge; with which a little sap-green is mixed for shadowing. Roses streaked with several colours, ought to be paler than others, that the mixture of colours may be better seen; which are done with carmine; a little darker in the shades, and very clear in the lights; always hatching by strokes. For white roses you must put a lay of white, and form and finish them as the red; but with black, white, and a little bistre; and make the feed a little yellower. Yellow roses are done by putting in every part a lay of mallow, and shadowing them with gamboge, gall-flour, and bistre. Heightening the clear and light places with mallow and white.

The flies, the leaves, and the buds of all kinds of roses are formed with verditer, with which is mixed a little mallow and gamboge; and for shadowing them, they add sap-green, putting less of the other colours when the shades are deep. The outside of the leaves ought to be bluer than the inside: wherefore it must be dead-coloured with sea-green, and sap-green mixed with that for shadowing, making the veins or fibres on this side clearer than the ground, and those on the other side darker. The prickles which are upon the flies and buds of roses, are done with little touches of carmine, which are made to go every way; and for those that are upon the stalks, they are formed with verditer and carmine, and shadowed with carmine and bistre; making the bottoms of the stalks more reddish than the top: e. g., you must mix with the green, carmine and pure bistre.

Of Tulips.—As there is an infinity of tulips, different from one another, one cannot pretend to mention the colours with which they are all done. We will only touch upon the handsomest, called fleaked; and these streaks are dead-coloured with very clear carmine in some places, and with darker in others; finishing with the same colour by little strokes, which must be carried the same way with the streaks. And in others is put first a lay of vermillion. Then they form them by mixing carmine, and finish them with pure carmine. In some they put Florence-lake over the vermillion instead of carmine. Some are done with lake and carmine mixed together, and with lake alone, or with white and lake for the first forming; whether it be rose-pink or Florence-lake. There are some of a purple colour, which are formed with ultramarine, carmine, or lake, sometimes bluer and sometimes redder. The manner of doing both one and the other is the same; there is no difference but in the colours. You must, in certain places, as between the streaks of vermillion, carmine, or lake, sometimes put blue made of ultramarine and white, and sometimes a very bright purple, which is finished by strokes as the rest, and lost with the streaks. There are some likewise
likewise that have fawlor teints, that are made with
laje, alitre, and ochre, according as they are: but
this is only in fine and rare tulips, and not in the
common ones. For shadowing the bottom of them,
they ordinarily take indigo and white for such whole
streaks are of carmine. For such as are of lake, they
take black and white; with which, in some, alitre is
mixed, and in others green. Some are likewise to be
shadowed with gamboge andumber, and always by
strokes and traces, that turn as the leaves turn. Other
tulips are likewise done, called bordered; that is to say,
the tulip is not streaked but on the edges of the leaves,
where there is a border. It is white in the purple;
red in the yellow; yellow in the red; and red in the white.
The purple is laid with ultramarine, carmine, and
white; shadowing and finishing it with this mixture.
The border is spared; that is to say, let only a
light lay of white be put there, and let it be shadowed
with very bright indigo. The yellow is formed with
gamboge, and shadowed with the same colour, mixing
ochre andumber or bitre with it. The border is
laid with vermilion, and finished with a very small
matter of carmine. The red is formed with vermi­
lion, and finished with the same colour, mixing
carmine or lake with it. The bottom and the border
are done with gamboge; and for finishing, they add
lillôte andumber, or bitre. The white is shadowed
with black, blue, and white. Indian ink is
very proper for this. The shadowings of it are very
tender. It produces alone the effect of blue and
white, mixed with the other black. The border of
this white tulip is done with carmine. In all these
forts of tulips, they leave a nerve or finew in the
middle of the leaves that are brighter than the red:
and the borders are drowned at the bottom by small
strokes, turning crofwise; for they must not appear
cut and separated, as the streaked or party-coloured.
They make them likewise of several other colours.
When they happen to be fuch white bottoms on the
infide are black, as it were, they form, and finish
with indigo, and at the bottom, the mouth of the
nozzle or flalk. And if the bottom is yellow, it is formed with
gamboge, and finished by adding umber or bitre. The
leaves and the flarks of tulips are ordinarily formed with
green, and shadowed and finished with lily-
green, by large traces all along the leaves. Some
may likewise be done with verdier, mixing mallicot
with it, and shadowed with fap.green, that the green
of the shades may be yellower.

The Anemone, or Wind-flowers.—There are feral
forts of them, as well double as fingle. The lail are
ordinarily without streaks. Some are made of a purple
colour, with purple and white, shadowing them with
the fame colour; some redder; others blue; someti­
times very pale; and sometimes very dark. Others
are formed with lake and white, and finished with
the fame, putting left white; fome without any white
at all. Others are formed with vermilion, and
shadowed with the fame colour, adding carmine. We
see likewise white ones, and fome of a citron colour.
The lail are laid with mallicot; and one and the other
shadowed and finished fometimes with vermilion, and
sometimes with very brown lake, efcentially near the
feed, at the bottom; which is often likened to a blackish colour, that is done with indigo, or black and
blue, mixing for some a little bilfer; and always
working by very fine strokes and traces, and losing
the lights in the shades. There are others that are
brighter and clearer at the bottom than any where
else; and fometimes they are perfectly white there,
though the reft of the flower be dark. The feed of
all these anemones is done with indigo and black, with
a very little white, and shadowed with indigo; and
in fome it is railed with mallicot. The double ane­
omies are of feveral colours. The handfome have
their large leaves streaked. Some are done, that is,
the streaked or party-coloured, with vermilion, in
which carmine is added for the fhiawing; shadowing
the reft of the leaves with indigo; and for the small
leaves within, a lay is put of vermilion and white,
and they are shadowed with vermilion mixed with
carmine, mixing here and there fome stronger touches,
especially in the heart of the flower, next the great
leaves on the fide of the shadow. They fhirn with
carmine, by little strokes and traces, turning the fame
way with the mixed or party-colours, and the leaves.
They form and finish the streaks or party-colours of
fome others, as well as the small leaves, with pure
carmine; leaving, nevertheless, in the middle of the
lail, a little circle, in which is laid dark purple, which
is lost with the reft. And when all is finished, they
give fome touches with this fame colour round about
the small leaves, efcentially on the fide of the fha­
dow; drowning them with the large ones, the remainder
of which is shadowed either with indigo or black. In
fome, the small leaves are done with lake or purple,
though the party-colours of the large ones be done
with carmine. There are others, whose mixed colours
are done with carmine, in the middle of most of the
large leaves; putting in fome places vermilion under­
neath, and losing thefe colours with the shadows of
the bottom; which are done with indigo and white.
The small leaves are laid with mallicot, and shadowed
with very dark carmine on the fide of the shade, and
with very clear on the fide of the lail, and with indigo
in a manner pure mallicot, and giving only fome little
touches with carmine and carmine, to separate the
leaves, which may be shadowed fometimes with a very
little pale-green. There are double anemones painted
all red, and all purple. The first are formed with
vermilion and carmine, in a manner without white,
and shadowed with pure carrine, well gunned, that
they may be very dark. Purple anemones are laid with
purple and white, and finished with white. In a
word, there are double anemones as there are fingle
ones, of all colours; and they are done in the fame
manner. The green of one and the other is verdier;
which mallicot is mixed for forming, leaving thine
in a manner pure mallicot, and giving only fome little
hours with carpine and carpine, to separate the
leaves, which may be shadowed fometimes with a very
little pale-green. There are double anemones painted
all red, and all purple. The first are formed with
vermilion and carmine, in a manner without white,
and shadowed with pure carrine, well gunned, that
they may be very dark. Purple anemones are laid with
purple and white, and finished with white. In a
word, there are double anemones as there are fingle
ones, of all colours; and they are done in the fame
manner. The green of one and the other is verdier;
which mallicot is mixed for forming, leaving thine
in a manner pure mallicot, and giving only fome little
hours with carpine and carpine, to separate the
leaves, which may be shadowed fometimes with a very
little pale-green. There are double anemones painted
all red, and all purple. The first are formed with
vermilion and carmine, in a manner without white,
and shadowed with pure carrine, well gunned, that
they may be very dark. Purple anemones are laid with
purple and white, and finished with white. In a
word, there are double anemones as there are fingle
ones, of all colours; and they are done in the same
manner. The green of one and the other is verdier;
which mallicot is mixed for forming, leaving thine
in a manner pure mallicot, and giving only some little
hours with carpine and carpine, to separate the
leaves, which may be shadowed sometimes with a very
little pale-green. There are double anemones painted
all red, and all purple. The first are formed with
vermilion and carmine, in a manner without white,
MINIATURE-PAINTING.

The bottoms are ordinarily shadowed with indigo and white. There are pinks of a very pale flesh-colour, and streaked and diversified with another, a little deeper, made with vermilion and lake. Others, which are of lake and white, are shadowed and streaked without white. Others all red, which are done with vermilion and carmine as dark as possible. Others all of lake, and lastly, there are others, wherein nature or fancy is the rule. The green of one and the other is sea-green, shadowed with lily-green or sap-green.

The Red-lily.—It is laid with red lead, formed with vermilion, and in the deepest of the shades with carmine; and finished with the same colour by strokes and traces, turning as the leaves turn. The clear and light parts are heightened with red lead and white. The feed is done with vermilion and carmine. The green parts are done with verditer, shadowed with lily or sap-green.

The Day-lily.—There are three sorts of them: 1. The grindelin, a little red; 2. The grindelin, very pale; and, 3. The white.

For the first they put a lay of lake and white, and shadow and finish with the same colour deeper; mixing a little black to deaden it, especially in the darkest places.

The second are laid with white, mixed with a very little lake and vermilion, in such a manner that these two last colours are hardly seen. Afterwards they shadow with black and a little lake, working redder in the middle of the leaves, next the stalks which ought to be, as also the feed, of the same colour, particularly towards the top; and at the bottom a little greener.

The file of the feed is laid with masticot, and shadowed with sap-green.

The other day-lilies are done by putting a lay of pure white, and shading and finishing with black and white.

The stalks of these last, and the greens of them all, are done with sea-green, and shadowed with sap-green.

The Hyacinth, or Purple-flower.—There are four sorts of them:

The blue, a little dark; Others paler; The grindelin; And the white.

The first are laid with ultramarine and white; and shadowed and finished with left white. Others are laid and shadowed with pale blue. The grindelins are formed with lake and white, and a very small matter of ultramarine; and finished with the same colour a little deeper. For the last they put a lay of white; then they shadow them with black, with a little white; and finish them all by strokes and traces, following the turnings and windings of the leaves. The green and the stalks of such as are blue, are done with sea and lily-green very dark: and in the stalks of the first may be mixed a little carmine, to make them redder. The stalks of the two others, as also the green, are formed with verditer and masticot, and shadowed with sap-green.

The Piony.—A lay of Venice-lake and white must be put on all parts pretty strong; then shadow with leaf white, and with none at all in the darkest places; after which finish with the same colour by traces, turning them as for the roots; gumming it very much in the deepest of the shades; and raising the lights and the edges of the moist lightsome leaves with white and a little lake. Little veins are likewise made, which go like the strokes in hatching, but are more visible. The green of this flower is done with sea-green, and shadowed with sap green.

Cowlips.—They are of four or five colours. There are some of a very pale purple.

The grindelin, the white, and the yellow.

The purple is done with ultramarine, carmine, and white; putting leaf white for shadowing. The grindelin is laid with Venice-lake, and a very small matter of ultramarine, with much white; and shadowed with the same colour deeper. For the white, a lay of white must be put; and they must be shadowed with black and white; and finished, as the others, by strokes or strokes. The heart of these cowslips is done with masticot, in the shape of a tear, which is shadowed with gamboge, making a little circle in the middle with sap-green. The yellow are laid with masticot, and shadowed with gamboge and umber. The file, the leaves, and the buds, are formed with verditer, mixed with a little masticot, and finished with sap-green; making the fibres or veins, which appear upon the leaves, with this same colour; and heightening the lights of the largest with masticot.

The Ranunculus, or Crow-foot.—There are several sorts of them: the finest are the orange-coloured. For the first, they put a lay of vermilion, with a very small matter of gamboge; and add carmine for shadowing; finishing it with this last colour, and a little gall-floate. In the others may be put Venice-lake, instead of carmine, especially in the heart of the flower. The orange-coloured are laid with gamboge, and finished with gall-floate, vermilion, and a little carmine; leaving some little yellow streaks. The green of the stalks is done with verditer and very pale masticot; mixing lily-green to shadow them. That of the leaves is a little darker.

The Crocuses.—These are of two colours: Yellow and purple. The yellow are formed with masticot and gall-floate, and shadowed with gamboge and gall-floate: after which, upon each leaf, on the outside, are made three streaks, separate from one another, with billet and pure lake; which are left, by little traces, in the bottom. The outside of the leaves is left all yellow. The purple is laid with carmine, mixed with a little ultramarine, and very pale white. They are formed and finished with leaf white; making likewise, in some, purple stripes or streaks, very dark, as in the yellow; and in others only small veins. The feed of both is yellow, and is done with orpiment and gall-floate. For the files, they put a lay of white, and shadow with black, mixed with a little green. The green of this flower is formed with very pale verditer, and shadowed with sap-green.

The Iris.—The Perian iris is done by putting, for the inside leaves, a lay of white, and shadowing them with indigo and green together, leaving a little white separation in the middle of each leaf; and for thos
white are laid with white, and shadowed with black and white; excepting the cup or bell, which is done with mafficott and gamboge. The green is sea-green, shadowed with sap-green.

The Marigold.—It is done by putting a lay of mafficott, and then one of gamboge; shadowing it with this very colour, after vermilion is mixed with it; and for finishing, they add gall-flone and a little carmine. The green is done with verditer, shadowed with sap-green.

The Austrian Rose.—For making the Austrian rose, they put a lay of mafficott, and another of gamboge. Then they form it, mixing gall-flone; and finish it with the last colour, adding biftre and a very small matter of carmine in the deepest shades.

The Indian Pink, or French Marigold.—It is done by putting a lay of gamboge; shadowing it with this colour, after you have mixed a good deal of carmine and gall-flone with it; and leaving about the leaves a little yellow border of gamboge, very clear in the lights and darker in the shades. The feed is shadowed with biftre. The green, as well as the rofe as the pink, is formed with verditer, and finished with sap-green.

The Sun-flower.—It is formed with mafficott and gamboge, and finished with gall-flone and biftre. The green is laid with verditer and mafficott, and shadowed with sap-green.

The Passion-flower.—It is done with mafficott and gamboge, and finished with gall-flone and biftre. The green is laid with verditer and mafficott, and shadowed with sap-green.

The Passion-flower.—It is done as the rofe, and the green of the leaves likewise; but the veins are done with a darker green.

Poetical Pinks and Sweet-william.—They are done by putting a lay of lake and white; shadowing them with pure lake, with a little carmine for the laft; which are afterwards dotted on all parts with little round dots, separate from one another; and the threads in the middle are raised with white. The green of them is sea-green, which is finished with sap-green.

The Scabious.—There are two sorts of feabolous, the red and the purple. The leaves of the flirft are laid with Florentine lake, in which there is a little white; and shadowed without white: and for the middle, which is a great biffre or huifk in which the feed lies, it is formed and finished with pure lake, with a little ultramarine or indigo to made it darker. Then they make little white longifh dots over it, at a pretty distance from one another, clearer in the light than in the shade, making them go every way. The other is done by putting a lay of very pale purple, as well upon the leaves as the biffre in the middle; shadowing both with the fame colour, a little deeper: and instead of little white touches for the feed, they make them purple; and about each grain they put a lay of gamboge, very clear in the lights and darker in the shades. Then they make little white longifh dots over it, at a pretty distance from one another, clearer in the light than in the shade, making them go every way. The other is done by putting a lay of very pale purple, as well upon the leaves as the biffre in the middle; shadowing both with the fame colour, a little deeper: and instead of little white touches for the feed, they make them purple; and about each grain they make out a little circle, and this over the whole biffre or huifk in the middle. The green is formed with verditer and mafficott, and shadowed with sap-green.

The Sword or Day-lily.—It is laid with Florence lake, and very pale white; formed and finished with pure lake, very clear and bright in some places, and very dark in others; mixing even biftre in the thickest of the shades. The green is verditer, shadowed with sap-green.

Hepatica, or Liverwort.—There is red and blue. The laft is done by putting on all parts a lay of ultra­marine, white, and a little carmine or lake; shadowing...
MINIATURE-PAINTING.

The Pomegranate.—The flower of the pomegranate is laid with red lead; shadowed with vermilion and carmine; and finished with this last colour. The green is laid with verditer and malicott, and shadowed with sap-green.

The Flower of the Indian Bean.—It is done with a lay of Levant-lake and white; shadowing the middle leaves with pure lake; and adding a little ultramarine with sap green.

The Columbine.—There are columbines of several colours; the most common are the purple, the griddelin, and the red. For the purple, they lay with ultramarine, carmine, and white; and shadow with this mixture, deeper. The griddelin are done the same way, putting a great deal less ultramarine than carmine. The red are done with lake and white. There are some mixed flowers of this kind, of several colours; which must be formed and finished as the others, but paler, making the mixtures of a little darker colour.

The Lark’s Heel.—These are of different colours, and of mixed colours: the most common are the purple, the griddelin, and the red; which are done as the columbines.

Violets and Pansies.—Violets and pansies are done the same way; excepting that in the last the two middle leaves are bluer than the others, that is, the borders or edges; for the inside of them is yellow: and their little black veins are made, which take their beginning from the heart of the flower, and die away towards the middle.

The Muscipula, or Catch-fly.—There are two sorts of it, the white and the red; the last is laid with lake and white, with a little vermilion, and finished with pure lake. As for the knot or nozelle of the leaves, it is formed with white and a very small matter of vermilion, mixing bitre or gall-stone to finish it. The leaves of the white are laid with white; adding bitre and malicott upon the knots, which are shadowed with pure bitre, and the leaves with black and white. The green of all these flowers is done with verditer and malicott, and shadowed with sap-green.

The Crown Imperial.—There are of two colours, the yellow and the red. The first is done by putting a lay of orpiment, and shadowing it with gall-stone and orpiment, with a little vermilion. The other is laid with orpiment and vermilion, and shadowed with gall-stone and vermilion; making the beginning of the leaves next the flile, with lake and bitre, very dark; and veins with this mixture, both in one and the other, all along the leaves. The green is done with verditer and malicott, shadowed with sap-green and gamboge.

The Cyclamen, or Swebrood.—The red is laid with carmine, a little ultramarine, and much white; and finished with the same colour, deeper; putting, in a manner, only carmine in the middle of the leaves, next the heart, and in the rest a little more ultramarine. The other is laid with white, and shadowed with black. The stalks of one and the other ought to be a little reddish; and the green, verditer and sap-green.

The Gillyflower.—There are several sorts of gillyflowers; the white, the yellow, the purple, the red, and the mixed, of various colours. The white are laid with white, and shadowed with black; and, with a little indigo in the heart of the leaves. The yellow, with malicott, gamboge, and gall-stone. The purple are formed with purple and white; and finished with white; making the colour brighter in the heart, and even a little yellowish. The red with lake and white; shadowing them with white. The mixed-coloured are laid with white, and the mixtures are sometimes made with purple, in which there is much ultramarine; others again, in which there is more carmine. Sometimes they are of lake, and sometimes of carmine. Some are done with white, and others without white; shadowing the rest of the leaves with indigo. The seed of all is formed with verditer and malicott, and finished with sap-green.

The leaves and files are laid with the fame green, mixing sap-green to finish them.

Fruits, filhes, serpents, and all sorts of reptiles, are to be touched in the same manner as the figures of men are; that is, hatched or dotted.

Birds and all other animals are done like flowers, by strokes or traces.

Never make use, for any of these things, of white lead. It is only proper in oil. It blackens like ink, when only tempered with gum; especially if you let your work be moist, or where perfumes are. Cernis of Venice is as fine, and of as pure a white. Be not sparing in the use of this, especially in forming or dead colouring; and let it enter into all your mixtures, in order to give them a certain body, which will render your work glinsh, and make it appear soft, plump, and strong.

The taste of painters is, nevertheless, different in this point. Some use a little of it, and others none at all. But the manner of the last is meagre and dry. Others use a great deal; and doubtles it is the best method, and most followed among skilful perfons: for besides that it is speedy, one may by the use of it copy all sorts of pictures; which would be almost impossible otherwise; notwithstanding the contrary opinion of fome who say, that in miniature we cannot give the force and all the different teints we see in pieces in oil. But this is not true, at least of good painters; and eftects prove it pretty plainly: for we fee figures, landscapes, pictures, and every thing else in miniature, touched in as grand, as true, and as noble a manner (though more tender and delicate), as they are in oil.

However, painting in oil has its advantages; were they only these, that it exhibits more work, and takes up less time. It is better defended likewise against the injuries of time; and the right of birth must be granted it, and the glory of antiquity.

But miniature likewise has its advantages; and without repeating such as have been mentioned already, it is nearer and more commodious. You may easily carry
of Flowers.

MINIM, in music, a note equal to two crotchets, or half a semibreve. See Music.

MINIMS, a religious order in the church of Rome, founded by St Francis de Paula, towards the end of the 16th century. Their habit is a coarse black woolen stuff, with a woolen girdle, of the same colour, tied in five knots. They are not permitted to quit their habit and girdle night nor day. Formerly they went bare-footed, but are now allowed the use of shoes.

MINIMUM, in the higher geometry, the least quantity attainable in a given case.

MINISTER, a person who preaches, performs religious worship in public, administers the sacraments, &c.

MINISTER OF STATE, a person to whom the prince intrusts the administration of government. See Council.

FOREIGN MINISTER, is a person sent into a foreign country, to manage the affairs of his province or of the state to which he belongs. Of these there are two kinds: those of the first rank are ambassadors and envoy extraordinary, who represent the persons of their sovereigns; the ministers of the second rank are the ordinary ministers.

MINIMUM, or RED-LEAD, is a calx of lead of a vivid red colour, which colour it acquires by a slow calcination and reverberation. See Chemistry, n° 1213. The minimum in commerce is chiefly brought from Holland, where large quantities of it are manufactured.

The method in which minimum is made in large quantities in general is this—they first burn lead in a furnace into a kind of litharge, by continually stirring it while melted with an iron rake; this they afterwards grind with two pair of flones, which deliver it from one to another, the first pair grinding it coarser, the second finer; these are worked by means of a mill which moves six pair of them at once. When thus reduced to a fine powder, it is washed and then put into a furnace, and is burnt with a reverberatory fire for two or three days, all the while they continue stirring it with a large iron rake, hung on a tripod or iron hook; and toward the end of the time they watch its being of the right colour. When this is done, the fire must not be carried beyond a certain degree, left the matter cold and run together.

The processes by which minimum is prepared is described in the following manner by M. Jars. The furnace is of the reverberatory kind, with two fire-places at the ends; each fire-place being separated from the area, or body of the furnace, by a wall twelve inches high. The fire places are fifteen inches broad, and their length is equal to the breadth of the whole furnace, which is about eight or nine feet.

The length of the area from one place to the other is nine or ten feet. The quantity of lead used in one operation is about 1000 pounds, of which nine parts are lead obtained from furnaces where the ore is finelined, and one part is lead extracted from the scoria which is formed in smelting the ore. This latter kind is said to be necessary, as the former could not alone be reduced into powder. All the lead is at once put into the area, the bottom of which is level. The calc, as fast as it is formed, is drawn to one side, by means of a rake suspended by a chain before the mouth of the furnace. In four or five hours the whole quantity of the lead is calcined, or, if any pieces remain uncalcined, they are separated, and kept for the next operation. The heat employed is that of a cherry-red, and the fire-places and mouth are kept open, that the air may accelerate the calcination. The powder or calc is to be frequently stirred to prevent its concreting, and when this operation has been continued about 24 hours, the matter is taken out of the furnace, and laid on a flat pavement. Then cold water is thrown on it, to give it weight, as the workmen say; but rather (as M. Jars thinks) to make it friable. It is then to be ground in a mill, and the finer part is separated by washing, while the coarser part, reserved for some following operation, is to be placed at the mouth of the furnace in order to retain the melted lead. The fine powder, which is now of a yellow colour, is again put into the same or a similar furnace, and exposed to a very moderate fire, from 36 to 48 hours; during which time, it is stirred frequently to prevent its concreting; and the powder gradually acquires its proper red colour. The minimum is then to be taken out of the furnace, cooled, and sifted through an iron sieve placed in a calc.

The bright colour of minimum might render it valuable in painting, if it could stand with certainty in either oil or water. But as it is subject to become black, it cannot be safely trusted, except in hard varnishes; and is, therefore, seldom used in oil, or even in water, unless for very gross purposes, or as a ground for vermilion. The goodness of minimum may be distinguished by the brightness of its colour: and the adulteration to which it is liable may be detected by putting an ounce of it into a crucible with an equal quantity of charcoal dust, well mixed together, and placing the crucible in a common fire sufficient to melt lead, which is to be covered with another small crucible inverted into it. When it has been continued for some time on the fire, take it out and strike it X against
M I N [ 162 ]

MINU. A stringed instrument of music among the ancient Hebrews, having three or four cords to it. See Plate CCCXIV. Though there is reason to question the antiquity of this instrument, both because it requires a hair-bow, which was a kind of plectrum not known to the ancients, and because it so much resembles the modern viol, Kircher took the figures of this, the machul, chinor, and paltery, from an old book in Th Vatican library.

MINOR, a Latin term, literally denoting last, used in opposition to major, greater.

Minor, in law, denotes a person under age; or who by the laws of the country, is not yet arrived at the power of administering his own affairs, or the possession of his estate. Among us, a person is a minor till the age of twenty-one: before which time his acts are invalid. See Age, and Infant.

It is a maxim in the common law of England, that in the King there is no minority, and therefore he hath no legal guardian; and his royal grants and affents to acts of parliament are good, though he has not in his natural capacity attained the legal age of twenty-one. It is also provided by the custom and law of parliament, that no one shall sit or vote in either house, unless he be twenty-one years of age. This is likewise expressly declared by Stat. 7 and 8. Will. III. cap. 25, with regard to the house of commons.

Minor, in logic, is the second repition of a formal or regular syllogism, called also the affirmation.

Minor, in music, is applied to certain concords, which differ from or are lower than others of the same denomination by a lesser femitone or four commas. Thus we say, a third minor, or lesser third, or a fifth major and minor. Concords that admit of major and minor, i.e. greater and less, are said to be imperfect concords.

MINORCA, an island of the Mediterranean, situated between 39 and 40 degrees of North Latitude, and near four degrees of East Longitude. It is about 33 miles in length from north-west to south-east, in breadth from eight to twelve, but in general about ten miles; so that in five it may nearly equal the county of Huntingdon or of Bedfordshire. The form is very irregular; and the coasts are much indented by the sea, which forms a great number of little creeks and inlets, some of which might be very advantageous.

This island is one of those called by the ancient Romans Baleares, which arose from the dexterity of the inhabitants in using the fling. It fell under the power of the Romans, afterwards of the northern barbarians, who destroyed that empire. From them it was taken by the Arabs, who were subdued by the king of Majorca, and by the king of Spain. The English subdued it in 1708, and the French in the late war; but it was restored to Britain by the treaty of Paris in 1763.

The air of this island is much more clear and pure than in Britain; being seldom darkened with thick fogs: yet the low valleys are not free from mists and unwholesome vapours; and in windy weather the spray of the sea is driven over the whole island. Hence it happens that utensils of brass or iron are extremely susceptible of rust, in spite of all endeavours to preserve them; and household-furniture becomes mouldy. The summers are dry, clear, calm, and exceptionally hot; the autumns moist, warm, and unequal; at one time perfectly serene, at another cloudy and tempestuous. During the winter there are sometimes violent storms, though neither frequent nor of long continuance and whenever they cease, the weather turns by degrees to its usual serenity. The spring is always variable, but resembles the winter more than the summer. The changes of heat and cold are neither so great nor so sudden in this climate as in many others. In the compass of a year, the thermometer seldom rises above the 80th, or falls below the 48th degree. In summer there is scarcely ever a difference of four or five degrees between the heat of the air at noon and at night; and in winter the variation is still less considerable. But this must be understood of a thermometer shaded from the influence of the solar beams; for if exposed to them it will often rise 12, 14, or 16 degrees higher than what we have mentioned; and in other localities the difference between the heat of the air in the sun and shade is much greater. Yet, even in the dog days, the heat of the atmosphere, at least in open places, seldom surpasses that of human blood.

The winds are very boisterous about the equinoxes, and sometimes during the winter. At other times they are generally moderate, and, according to the observations of seamen, they rarely blow in the same direction near the islands adjacent to the gulph of Lyons as in the open sea. During the summer there is commonly a perfect calm in the mornings and evenings; but the middle of the day is cooled by refreshing breezes which come from the east, and, following the course of the sun, increase gradually till two or three in the afternoon; after which they insensibly die away as right approaches. This renders the heat of the sun less dangerous and inconvenient; and if these breezes intermit for a day or two, the natives grow languid and inactive from the heat. The northerly winds in general are clear and healthy, dispel the mists, and make a clear blue sky; whilst thofe which blow from the opposite quarter, render the air warm, moist, and unhealthy. The north wind is superior in power to all the rest; which appears from hence, that the tops of all the trees incline to the south, and the branches on the north side are bare and blasted. The next to it in force is the north-west. Both are frequent towards the close of winter and in the spring; and, being dry and cold, they shiver up the leaves of the vegetables, destroy their tender shoots, and are often exceedingly detrimental to the vineyards and ri-
MIN [ 163 ]

Minorca.  Sing corn. The piercing blasts at that season from the north-east, as they are more moist and more frequently attended with rain, are less prejudicial. The south and south-east winds are by much the most unhealthy. In whatever seasons they blow, the air is foggy, and affects the breathing; but in the summer season they are sultry and suffocating. An excessive dejection of spirits is then a universal complaint; and on exposing the thermometer to the rays of the sun, the mercury has frequently risen above the 100th degree. The west wind is usually drier than the south: the east is cold and blistering in the spring, and sultry in the summer.

The weather in Minorca is generally fair and dry; but when it rains, the flowers are heavy, though of short continuance, and they fall most commonly in the night. The sky in summer is clear, and of a beautiful azure, without clouds or rain; but moderate dews descend regularly after sunset. In autumn the weather becomes less serene; whirlwinds and thunder become frequent; and in the night-time lightning, and those meteors called falling stars, are very common. Water-spouts also are often seen at that season, and frequently break upon the shore. A sudden alteration in the weather takes place about the autumnal equinox; the skies are darkened with clouds, and the rains fall in such quantities, that the torrents thereby occasioned, pouring down from the hills, tear up trees by the root, carry away cattle, break down fences, and do considerable mischief to the gardens and vineyards. But these anniversary rains are much more violent than lasting; always falling in sudden and heavy showers, with intervals of fair weather. They are accompanied with thunder, lightning, and squalls of wind, most commonly from the north. Hail and snow are often intermixed with the rains which fall in winter and in spring; but the snow, for the most part, dissolves immediately; and ice is here an uncommon appearance.

The whole coast of Minorca lies low; and there are only a few hills near the centre, of which the most considerable, named Toro by the inhabitants, may be seen at the distance of 12 or 14 leagues from the land. The surface of the island is rough and unequal; and in many places divided by long narrow vales of a considerable depth, called barrancos by the natives. They begin towards the middle of the island, and after several windings terminate at the sea. The south-west side is more plain and regular than towards the north-east; where the hills are higher, with low marshy valleys betwixt them, the soil lies fruitful, and the whole tract unhealthy to man and beast. Near the towns and villages the fields are well cultivated, and inclosed with stone-walls; but the rest for the most part are rocky, or covered with woods and thickets. There are some pools of standing water, but very few rivulets, which is the greatest defect about the island, as the inhabitants have scarcely any wholesome water excepting what is faved from the clouds.

The soil is light, thin, and very flopy, with a good deal of sea-salt, and, in some places, of calcareous nitre intermixed. In most places there is so little earth, that the island appears to be but one large irregular rock covered here and there with mould, and an infinite variety of flones. Notwithstanding this, however, it is not only extremely proper for vineyards, but produces more wheat and barley than could at first sight be imagined; and, if the peasants may be credited, it would always yield a quantity of corn and wine sufficient for the natives, did not the violence of the winds, and the excessive drought of the weather, frequently spoil their crops. The fields commonly lie fallow for two years, and are sown the third. About the latter end of winter, or the beginning of spring, they are first broke up: and next autumn, as soon as the rains fall, they are again ploughed and prepared for receiving the proper seeds. The tillage is very easily performed; for a plough so light as to be transported from place to place on the ploughman's shoulder, and to be drawn by an heifer, or an ass sometimes filled by an hog, is sufficient for opening so thin a foil. The later the harvest happens, the more plentiful it proves. The barley is usually cut down about the 20th of May, N. S. and the wheat is reaped in June, so that the whole harvest is commonly got in by midsummer.

Bread of the finest wheat flour, well fermented and well baked, is more than half the diet of people of all ranks. Rice, pulse, vermicelli, herbs and roots from the garden, summer-fruits, pickled olives, and pods of the Guinea pepper, make up almost all the other half, to which the peasants are able to add the produce of their gardens. Of these articles the most esteemed are the home-grown vegetables, particularly artichokes and garlic, which are much relished by the natives. The fish of the sea are numerous, and the sea is very rich in shell-fish, clams, oysters, and other such delicacies. The climate of Minorca is remarkably healthy; and the natives are generally long-lived and robust. The concern of all the inhabitants is business, and the luxurious indulgence of the other nations is unknown to them. They never think of going to market, nor taste the luxury of the table, nor of the gridiron; for they are contented, as they are happy, to live on a very plain diet, and without expense; and their pertinacity in this point is so great, that they impose such stringent rules on their children, that they never depart from it, but that they are, as it were, born with it; and when they are grown to years of discretion, they are not yet able to give them up. They live on fish, greens, butter, &c. and some little oil and salt, which is the common breakfast of the peasants, well known by the name of olaga. Their ordinary meals are

X 2 very
very frugal, and consist of very little variety; but on festivals and other solemn occasions their entertainments are to the last degree profuse and extravagant, info-
much that the bill of fare of a country farmer's wed-
ding-dinner would scarce be credited.

With regard to other matters, the Minorquins are
accused of prodigious indolence in the way of busi-
ness, and neglect of the natural advantages they posses.
In the bowels of the earth are iron, copper, and lead-ores,
of none of which any use hath been made except the
lait. A lead-mine was worked to advantage some time
ago, and the ore sent into France and Spain for the
use of the potteries in those countries. The propor-
tor discontinued his work on some small discouragement;
and indeed it is said, that these people are of
all mankind the most easily put out of conceit with an
undertaking that does not bring them in mountains of
present gain, or that admits of the slightest prob-
ability of disappointing their most sanguine expecta-
tions: nor will their purse admit of many disappointments;
and thus their poverty co-operating with their natural
deadliness, the breeding of poultry, and the
There are in it a

The island is divided into what they style terminos,
of which there were anciently five, now reduced to
four, and resemble our counties. The termino of
Ciudadella, at the north-westerly extremity of the
island, is so styled from this place, which was once a
city, and the capital of Minorca. It makes a venera-
table and majestic figure, even in its present state of
decay, having in it a large Gothic cathedral, some
other churches and convents, the governor's palace,
and an exchange, which is no contemptible pile.
There are in it 600 houses, which, before the loss of
government and the courts of justice were removed to
Mahon, were fully inhabited; and there are still more
gentlemens families here than in all the rest of the
island. It hath a port commodious enough for the
vessels employed in the trade of Britain, which, though
in the possession of a maritime power, is less than it
formerly was. It is still, in the style of the officers,
the best quarters (and there are none bad) in the
country; and if there was a civil government, and
the place made a free port, the best judges are of opin-
ion it would very soon become a flourishing place
again; and the fortifications, if it should be found ne-
necessary, might then also be easily restored and im-
proved.

The termino of Ferries is the next, a narrow slip
reaching crofs from sea to sea, and the country is little
cultivated; it is therefore united to Mercandies. In this
island lies Mont-toro in the very centre of the
country, and the highest ground, some say the only moun-
tain in it; on the summit of which there is a convent,
where even in the hottest months the monks enjoy a
cool air, and at all times a most delightful prospect.
About six miles north from Mont-toro stands the
castle that covers Port Fornelles, which is a very spa-
cious harbour on the east side of the island. There are
in it shoals and foul ground, which, to those who are
unacquainted with them, render it difficult and dan-
gerous; yet the packets bound from Mahon to Mar-
folles frequently take shelter therein; and while the
Spaniards were in possession of the isle, large ships
and men of war frequented it. At a small distance
from this lies another harbour called Adaxia, which
runs far into the land; but being reputed unsafe, and
being so far from Fornelles, is now of no use. The
country about it is, however, said to be the pleasantest
and wholesomest spot in the island, and almost the only
one plentifully supplied with excellent spring-water;
so that the gardens are well laid out, and the richest
and finest fruits grow here in the highest perfection.
Alair is the next termino, in which there is nothing
remarkable.
Minors, or friers minor, an appellation which the Franciscans assume, out of shew of humility, calling themselves fratenus minoris, i. e. lesser brothers, and sometimes minorites. There is also an order of regular minors at Naples, which was established in the year 1598, and confirmed by Sextus V.

MINOS (fab. hist.), a king of Crete, son of Jupiter and Europa. He flourished about 1432 years before the Christian era. He gave laws to his subjects, which still remained in full force in the age of the philosopher Plato, about 1000 years after the death of the legislator. His justice and moderation procured him the appellation of the favourite of the gods, the confident of Jupiter, and the wise legislator, in every city of Greece; and, according to the poets, he was rewarded for his equity after death with the office of suprême and absolute judge in the infernal regions. In this capacity he is represented sitting in the middle of the shades, and holding a scepter in his hand. The dead plead their different causes before him; and the impartial judge shakes the fatal urn, which is filled with the destinies of mankind. He married Idona, by whom he had Lycaestes, who was the father of Minos II.

MINOS II was a son of Lycaestes, the son of Minos I. and king of Crete. He married Pasiphaë, the daughter of Sol and Perijice, and by her he had many children. He increased his paternal dominions by the conquest of the neighbouring islands; but showed himself cruel in the war which he carried against the Athenians, who had put to death his son Androgeus. He took Megara by the treachery of Scylla, and not satisfied with victory, he obliged the vanquished to bring him yearly to Crete seven chosen boys, and the same number of virgins to be devoured by the Minotaur. This bloody tribute was at last abolished when Theseus had destroyed the monster. When Dedalus, whose industry and invention had fabricated the labyrinth, and whose imprudence in affisting Pasiphaë in the gratification of her unnatural desires, had offended Minos, fled from the place of his confinement with wings, and arrived safe in Sicily; the incensed monarch pursued the offender, resolved to punish his infidelity. Cocalus, king of Sicily, who had hospitably received Dedalus, entertained his royal guest with dissembled friendship; and, that he might not deliver to him a man whose ingenuity and abilities he so well knew, he put Minos to death. Minos died about 35 years before the Trojan war. He was father of Androgeus, Glauceus, and Deucalion; and two daughters, Phaedra and Ariadne. Many authors have confounded the two Minos, the grandfather and the grandson; but Homer, Plutarch, and Diodorus, prove plainly that they were two different persons.

MINOTAUR (fab. hist.), a celebrated monster, half a man and half a bull, according to this verse of Ovid,

Semivirum virum, semivirumque bovem.

It was the fruit of Pasiphaë's amour with a bull. Minos refused to sacrifice a white bull to Neptune, an animal which he had received from the god for that purpose. This offended Neptune, and he made Pasiphaë the wife of Minos enamoured of this fine bull, which had been refused to his altars. Dedalus profited his talents in being subservient to the queen's unnatural desires; and by his means, Pasiphaë's horrid passions were gratified, and the Minotaur came into the world. Minos confined in the labyrinth this monster, which convinced the world of his wife's licentiousness, and reflected disgrace upon his family. The Minotaur usually devoured the chosen young men and maidens which the tyranny of Minos yearly exacted from the Athenians. Theseus delivered his country from this tribute, when it had fallen to his lot to be sacrificed to the voracity of the Minotaur; and by means of Ariadne, the king's daughter, he destroyed the monster, and made his escape from the windings of the labyrinth. — The fabulous tradition of the Minotaur, and of the infamous commerce of Pasiphaë with a favourite bull, has been often explained. Some suppose that Pasiphaë was enamoured of one of her husband's courtiers called Taurus; and that Dedalus favoured the passions of the queen, by offering his house to become the retreat of the two lovers. Pasiphaë some time after brought twins into the world, one of whom greatly resembled Minos and the other Taurus; and in the natural resemblance of their countenance with that of their supposed fathers, originated their name, and consequently the fable of the Minotaur.

MINOW, a very small species of cyprium, so well known that it needs no description.
MINSTER (Saxon, Minster or Mynster), anciently signified the church of a monastery or convent.

MINSTERLE, an ancient term for a singer and instrumental performer.

The word minstrel is derived from the French minstrel, and was not in use here before the Norman conquest. It is remarkable, that our old monkish historians do not use the word citareius, cantator, or the like, to express a minstrel in Latin; but either minst, hysfria, joculator, or some other word that implies guffle. Hence it should seem that the minstrels set off their singing by mimicry or action, or, according to Dr Brown's hypothesis, united the powers of melody, poem, and dance.

The Saxons, as well as the ancient Danes, had been accustomed to hold men of this profession in the highest reverence. Their skill was considered as something divine, their persons were deemed sacred, their attendance was solicited by kings, and they were everywhere loaded with honours and rewards. In short, poets and their art were held among them in that rude admiration which is ever shown by an ignorant people to such as excel them in intellelual accomplishments.

When the Saxons were converted to Christianity, in proportion as letters prevailed among them, this rude admiration began to abate, and poetry was no longer a peculiar profession. The poet and the minstrel became two persons. Poetry was cultivated by men of letters indiscriminately, and many of the most popular rhymes were composed amidst the leisures and retirement of monasteries. But the minstrels continued a distinct order of men, and got their livelihood by singing verses to the harp at the houses of the great. There they were still hospitably and respectfully received, and retained many of the honours shown to their predecessors the Bards and Scalds. And indeed, though some of them only recited the compositions of others, many of them still composed fongs themselves; and all of them could probably invent a few stanzas on occasion. There is no doubt but most of the old heroic ballads were produced by this order of men. For although some of the larger metrical romances might come from the pen of the monks or others, yet the smaller narratives were probably composed by the minstrels who sung them. From the amazing variations which occur in different copies of these old pieces, it is evident they made no scruple to alter each other's productions, and the reciter added or omitted whole stanzas according to his own fancy or convenience.

In the early ages, as is hinted above, this profession was held in great reverence among the Saxon tribes, as well as among their Danish brethren. This appears from two remarkable facts in history, which show that the same arts of music and song were equally admired among both nations, and that the privileges and honours conferred upon the professors of them were common to both; as it is well known their customs, manners, and even language, were not in those times very dissimilar.

When King Alfred the Great was desirous to learn the true situation of the Danish army, which had invaded his realm, he assumed the dress and character of a minstrel; and taking his harp, and only one attendant (for in the earliest times it was not usual for a minstrel to have a servant to carry his harp), he went with the utmost secrecy into the Danish camp.

And though he could not but be known to be a Saxon, the character he had assumed procured him a hospitable reception; he was admitted to entertain the king at table, and laid among them long enough to convince that assault which afterwards destroyed them. This was in the year 878.

About 60 years after, a Danish king made use of the same disguise to explore the camp of King Athelstan. With his harp in his hand, and dressed like a minstrel, Anlaff king of the Danes went among the Saxons tents, and taking his stand near the king's pavilion, began to play, and was immediately admitted. There he entertained Athelstan and his lords with his singing and his music, and was at length dismissed with an honourable reward, though his songs must have discovered him to have been a Dane. Athelstan was favored from the condescensions of this stratagem by a soldier, who had observed Anlaff bury the money which he had been given him, from some scruple of his honour or motive of superstitition. This occasioned a discovery.

From the uniform procedure of both these kings, it is plain that the same mode of entertainment prevailed among both people, and that the minstrel was a privileged character among both. Even as late as the reign of Edward II. the minstrels were easily admitted into the royal presence, as appears from a passage in Stow, which also shows the splendor of their appearance.

"In the year 1316, Edward II. did solemnly his feast at Pentecost at Westminster, in the great hall: where sitting royally at the table with his peers about him, there entered a woman adorned like a minstrel, sitting on a great horse, and as minstrels then used, who rode round about the tables, showing pastime; and at length came up to the king's table, and laid before him a letter, and forthwith turning her horse, fainted every one, and departed."—The subject of this letter was a renoncement to the king on the favours heaped on him by his minions, to the neglect of his knights and faithful servants.

The messenger was sent in a minstrel's habit, as what would gain an easy admission; and was a woman concealed under that habit, probably to disarm the king's resentment: for we do not find that any of the real minstrels were of the female sex; and therefore conclude this was only an artful contrivance peculiar to that occasion.

In the 4th year of Richard II. John of Gaunt erected at Tetbury in Staffordshire, a court of minstrels, with a full power to receive suit and service from the men of his profession within five neighbouring counties, to enact laws, and determine their controversies; and to apprehend and arrest such of them as should refuse to appear at the said court, annually held on the 16th of August. For this they had a charter, by which they were empowered to appoint a king of the minstrels, with four officers, to preside over them. These were every year elected with great ceremony; the whole form of which is described by Dr Plot; in whose time, however, they seem to have become mere musicians.

Even so late as the reign of King Henry VIII., the reciters of verses or moral speeches learnt by heart, intruded without ceremony into all companies; not only
This minstrel, the author tells us a little below, "after three lowly courtesies, cleared his voice with a hem..." and wiped his lips with the hollow of his hand for "filling his napkin; tempered a string or two with his wrist; and, after a little warbling on his harp for a prelude, came forth with a solemn song, warranted for story out of King Arthur's acts, &c."

Towards the end of the 16th century, this chev of men had lost all credit, and were sunk so low in the public opinion, that in the 39th year of Elizabeth a statute was passed by which "minstrels, wandering abroad," were included among "rogues, vagabonds, and sturdy beggars," and were adjudged to be punished as such. This act seems to have put an end to the profession, for after this time they are no longer mentioned.

MINT, the place in which the king's money is coined. See COINAGE.

There were anciently mints in almost every county in England; but the only mint at present in the British dominions is that in the tower of London. The officers of the mint are, 1. The warden of the mint, who is the chief; he oversees the other officers, and receives the bullion. 2. The master-worker, who receives bullion from the warden, causes it to be melted, delivers it to the monyers, and, when it is coined, receives it again. 3. The comptroller, who is the overruler of all the inferior officers, and sees that all the money is made to the full value. 4. The assay-master, who weighs the gold and silver, and sees that it is according to the standard. 5. The two auditors who take the accounts. 6. The surveyor of the melting; who, after the assay-master has made trial of the bullion, sees that it is cast out, and not altered after it is delivered to the melter. 7. The engraver, who engraves the tamp and dies for the coinage of the money. 8. The clerk of the irons; who sees that the irons are clean and fit to work with. 9. The melter who melts the bullion before it be coined. 10. The provost of the mint; who provides for and oversees all the monyers. 11. The blanchers; who anneal and cleanse the money. 12. The monyers; some of whom forge the money, some share it, some round and mill it, and some stamp and coin it. 13. The porters who keep the gate of the mint.

Mint was also a pretended place of privilege, in Southwark, near the King's Bench, put down by statute. If any perfon, within the limits of the mint, shall obstruct any officer in the serving of any writ or process, &c. or assault any person therein, he who shall be guilty of felony, and be transported to the plantations, &c. Stat. 9. Geo. I.

Mint-Marks. It hath been usual, from old time, to oblige the masters and workers of the mint, in the indentures made with them, "to make a privy mark in all the money that they made, as well of gold as silver, so that another time they might know, if need were, and wit which moneys of gold and silver among other of the same moneys, were of their own making, and which not." And whereas, after every trial of the pix at Westminster, the masters and workers of the mint, having there proved their moneys to be lawful and good, were immediately entitled to receive their quittance under the great seal, and to be discharged.

MINUTE, in geometry, the 60th part of a degree of a circle.

Minutes of Time, the 60th part of an hour.

Minutes, in architecture, usually denotes the 30th, part of a module. See Architecture.

Minute is also used for a short memoir, or sketch of a thing taken in writing.

MINUTIUS FELIX. See Felix.

MINEY, a name given to the inhabitants of Orchomenos in Boetia, from Minyas king of the country. The son of Minyas gave his name to the capital of the country, and the inhabitants still retained their original appellation, in contradiction to the Orchomenians of Arcadia. A colony of Orchomenians passed into Thessaly and settled in Iolchoi; from which circumstance the people of the place, and particularly the Argonauts, were called Miney. This name they received, according to the opinion of some, not because a number of Orchomenians had settled among them, but because the chief and noblest of them were descended from the daughters of Minyas. Part of the Orchomenians accompanied the sons of Codrus when they migrated to Ionia. The defendant's of the Argonauts, as well as the Argonauts themselves, received the name of Miney. They first inhabited Lemnos, where they had been born from the Lemnian women who had murdered their husbands. They were driven from Lemnos by the Pelasgians, about 1160 before the Christian era, and came to settle in Laconia, from whence they passed into Cilicia with a colony of Lacedemonians.

MINEY, in botany. See Mentha.

MINTURNæ, a town of Compania between Sinuessa and Formiae. It was in the marches in this neighbourhood that Marius concealed himself in the mud to avoid the partisans of Sylla. The people condemned him to death; but when his voice alone had terrified the executioner, they showed themselves compassionate and favoured his escape.

MINT, a very graceful kind of dance, consisting of a couple, a high step, and a balance: it begins with a beat, and its motion is triple.

The invention of the minuet seems generally to be ascribed to the French, and particularly to the inhabitants of the province of Pouitou. The word is said by Menage and Furetiere to be derived from the French minue or menu, "small, or little," and in strictness signifies a small pace. The melody of this dance consists of two strains, which, as being repeated, are called repriés, each having eight or more bars, but never an odd number. The measure is three crotchets in a bar, and thus marked ¾, though it is commonly performed in the time ⅔. Walther speaks of a minuet in Lully's opera of Roland, each strain of which contains ten bars, the sectional number being 5; which renders it very difficult to dance.

MINUTE, in architecture, usually denotes the 60th, sometimes the 30th, part of a module. See Architecture.

Minutes is also used for a short memoir, or sketch of a thing taken in writing.

MIRACLE, in its original sense, is a word of the same purport with wonder; but in its usual and more appropriate signification, it denotes "an effect contrary to the established constitution and course of things, or a sensible deviation from the known laws of nature."

That the visible world is governed by stated general rules, or that there is an order of causes and effects established in every part of the system of nature which falls under our observation, is a fact which cannot be controverted. If the Supreme Being, as some have supposed, be the only real agent in the universe, we have the evidence of experience, that, in the particular system to which we belong, he acts by stated rules. If he employs inferior agents to conduct the various motions from which the phenomena result, we have the same evidence that he has subjected those agents to certain fixed laws, commonly called the laws of nature. On either hypothesis, effects which are produced by the regular operation of these laws, or which are conformable to the established course of events, are properly called natural; and every contradiction to this constitution of the natural system, and the correspondent course of events in it, is called a miracle.

If this definition of a miracle be just, no event can be deemed miraculous merely because it is strange, or even to us unaccountable; since it may be nothing more than a regular effect of some unknown law of nature. In this country earthquakes are rare; and for monstrous births perhaps no particular and satisfactory account can be given; yet an earthquake is, as regular an effect of the established laws of nature as any of those with which we are most intimately acquainted; and under circumstances in which there would always be the same kind of production, the monster is nature's genuine issue. It is therefore necessary, before we can pronounce any effect to be a true miracle, that the circumstances under which it is produced be known, and that the common course of nature be in some degree understood: for in all those cases in which we are totally ignorant of nature, it is impossible to determine what is, or what is not, a deviation from its course. Miracles, therefore, are not, as some have represented them, appeals to our ignorance. They suppose some antecedent knowledge of the course of nature, without which no proper judgment can be formed concerning them; though with it their reality may be so apparent as to prevent all possibility of a dispute.
Deviation from notions into first principles, of which they would not evacuate. Were man, in the exercise of his mental and corporeal powers, subjected to the laws of physical necessity, the circumstances supposed would indeed never occur, and of course no miracle could be admitted. But such is not the nature of man.

Without repeating what has been said elsewhere (see Metaphysics, Part III. chap. v.), of necessity and liberty, we shall here take it for granted, that the relation between motives and actions is different from that between cause and effect in physics; and that mankind have such command over themselves, as that by their voluntary conduct, they can make themselves in a great degree either happy or miserable. We know likewise from history, that, by some means or other, almost all mankind were once sunk into the grossest ignorance of the most important truths; that they knew not the Being by whom they were created and supported; that they paid divine adoration to flocks, stones, and the vilest reptiles; and that they were slaves to the most impious, cruel, and degrading superstitions.

From this depraved state it was surely not unworthy of the common "Father of all" to reduce his helpless creatures, to enlighten their understandings that they might perceive what is right, and to prevent them from motives of sufficient force to engage them in the practice of it. But the understandings of ignorant barbarians cannot be enlightened by arguments; because of the force of such arguments as regard moral science they are not qualified to judge. The philosophers of Athens and Rome inculcated, indeed, many excellent moral precepts, and they sometimes ventured to expose the absurdities of the reigning superstition; but their lectures had no influence upon the multitude; and they had themselves imbued such erroneous notions respecting the attributes of the Supreme Being, and the nature of the human soul, and converted those notions into first principles, of which they would not permit an examination, that even among them a thorough reformation was not to be expected from the powers of reasoning. It is likewise to be observed, that there are many truths of the utmost importance to mankind, which unaided reason could never have discovered. Amongst these we may confidently reckon the immortality of the soul, the terms upon which God will be reconciled to sinners, and the manner in which that all-perfect Being may be acceptably worshipped; about all of which philosophers were in such uncertainty, that, according to Plato, "Whatever is set right, and as it should be, in the present evil state of the world, can be so only by the particular interposition of God." An immediate revelation from Heaven, therefore, was the only method by which infinite wisdom and perfect goodness could reform a bewildered and vicious race. But this revelation, at whatever time we suppose it given, must have been made directly either to some chosen individuals commissioned to instruct others, or to every man and woman for whose benefit it was ultimately intended. Were every person intended in
in the knowledge of his duty by immediate inspiration, and were the motives to prudently bring home to his mind by God himself, human nature would be wholly changed: men would not be masters of their own actions; they would not be moral agents, nor by consequence be capable either of reward or of punishment. It remains, therefore, that if God has been graciously pleased to enlighten and reform mankind, without destroying that moral nature which is essential to virtue, he can have done it only by revealing his truth to certain chosen instruments, who were the immediate instructors of their contemporaries, and through them have been the instructors of succeeding ages.

Let us suppose this to have been actually the case, and consider how those inspired teachers could communicate to others every truth which had been revealed to themselves. They might easily, if it was part of their duty, deliver a sublime system of natural and moral science, and establish it upon the common basis of experiment and demonstration; but what foundation could they lay for those truths which have not been immediately received from God, no rational being could be expected to admit? The teachers might be men of known veracity, whose simple assertion would be admitted as sufficient evidence for any fact, in conformity with the laws of nature; but as every man has the evidence of his own conscience and experience that revelations from heaven are deviations from these laws, an assertion is apparently extravagant would be rejected as false, unless supported by some better proof than the mere affirmation of the teacher. In this state of things, we can conceive no evidence sufficient to make such doctrines be received as the truths of God, but the power of working miracles committed to him who taught them. This would, indeed, be fully adequate to the purpose. For if there were nothing in the doctrines themselves impious, immoral, or contrary to truths already known, the only thing which could render the teacher's assertion acceptable, would be its implying such an intimate communion with God as is contrary to the established course of things, by which men are left to acquire all their knowledge by the exercise of their own faculties.

Let us now suppose some of those inspired teachers to tell their countrymen, that he did not desire them, on his ipse dixit, to believe that he had any preternatural communion with the Deity, but that for the truth of his assertion he would give them the evidence of his own senses; and after this declaration let us suppose him immediately to raise a person from the dead in their presence, merely by calling upon him to come out of his grave. Would not the only possible objection to the man's veracity be removed by this miracle? and his assertion that he had received such and such doctrines from God be as fully credited, as if it related to the most common occurrence? Undoubtedly it would; for when so much preternatural power was visibly communicated to this person, no one could have reason to question his having received an equal portion of preternatural knowledge. A palpable deviation from the known laws of nature, in one instance, is a sufficient proof that such a deviation is possible in another; and in such a case as this it is the witness of God to the truth of a man.

Miracles, then, under which we include prophecy, are the only direct evidence which can be given of divine inspiration. When a religion, or any religious truth, is to be revealed from heaven, they appear to be absolutely necessary to enforce its reception among men; and this is the only case in which we can suppose them necessary, or believe for a moment that they ever have been or will be performed.

The history of almost every religion abounds with relations of prodigies and wonders, and of the intercourse of men with the gods; but we know of no religious system, those of the Jews and Christians excepted, which appealed to miracles as the sole evidence of its truth and divinity. The pretended miracles mentioned by Pagan historians and poets are not said to have been publicly wrought to enforce the truth of a new religion contrary to the reigning idolatry. Many of them may be clearly shown not to have been mere natural events; (see Magic). Others of them are represented as having been performed in secret on the most trivial occasions, and in obscure and fabulous ages long prior to the era of the writers by whom they are recorded. And such, of them as at first view appear to be best attested, are evidently tricks contrived for interested purposes; to flatter power, or to promote the prevailing superstitions. For these reasons, as well as on account of the immoral character of the divinities by whom they are said to have been wrought, they are altogether unworthy of examination, and carry in the very nature of them the completest proofs of falsehood and imposture.

But the miracles recorded of Moses and of Christ bear a very different character. None of them are represented as wrought on trivial occasions. The writers who mention them were eye-witnesses of the facts; which they affirm to have been performed publickly, in attestation of the truth of their respective systems. They are indeed incorporated with their systems, that the miracles cannot be separated from the doctrines; and if the miracles were not really performed, the doctrines cannot possibly be true. Besides all this, they were wrought in support of revelations which opposed all the religious systems, superstitions, and prejudices, of the age in which they were given: a circumstance which, if itself sets them, in point of authority, infinitely above the Pagan prodigies, as well as the lying wonders of the Romish church.

It is indeed, we believe, universally admitted, that the miracles mentioned in the book of Exodus and in the four Gospels, might, to those who saw them performed, be sufficient evidence of the divine inspiration of Moses and of Christ; but to us it may be thought that they are no evidence whatever, as we must believe in the miracles themselves, if we believe in them at all, upon the bare authority of human testimony. Why, it has been sometimes asked, are not miracles wrought in all ages and countries? If the religion of Christ was to be of perpetual duration, every generation of men ought to have complete evidence of its truth and divinity.

To the performance of miracles in every age and in every country, perhaps the same objections lie as to the immediate inspiration of every individual. Were
Miracles.

...those miracles universally received as such, men would be so overwhelmed with the nature rather than with the force of their authority, as hardly to remain masters of their own conduct; and in that case the very end of all miracles would be defeated by their frequency. The truth, however, seems to be, that miracles so frequently repeated would not be received as such, and of course would have no authority; because it would be difficult, and in many cases impossible, to distinguish them from natural events. If they recurred regularly at certain intervals, we could not prove them to be deviations from the known laws of nature, because we should have the same experience for the one series of events as for the other; for the regular succession of preternatural effects, as for the established constitution and course of things.

Be this, however, as it may, we shall take the liberty to affirm, that for the reality of the Gospel miracles we have evidence as convincing to the reflecting mind, though not so striking to vulgar apprehension, as those had who were contemporary with Christ and his apostles, and actually saw the mighty works which he performed. To the admirers of Mr Hume's philosophy this assertion will appear an extravagant paradox; but we hope to demonstrate its truth from the principles which, consistently with himself, that author could not have denied. He has indeed endeavoured to prove, that "no testimony is sufficient to establish a miracle;" and the reasoning employed for this purpose is, that "a miracle being a violation of the laws of nature, which a firm and unalterable experience has established, the proof against a miracle, from the very nature of the fact, is as entire as any argument from experience can be, whereas our experience of human veracity, which (according to him) is the sole foundation of the evidence of human veracity, is far from being uniform, and can therefore never preponderate against that experience which admits of no exception." This bold and plausible argument, with equal candour and acuteness has been examined by Dr Campbell; who judiciously observes, that so far is experience from being the sole foundation of the evidence of testimony, that, on the contrary, testimony is the sole foundation of by far the greater part of what Mr Hume calls firm and unalterable experience; and that if in certain circumstances we did not give an implicit faith to testimony, our knowledge of events would be confined to those which had fallen under the immediate observation of our own senses. For a short view of this celebrated controversy, in which the Christian faith completely vanquishes the philosopher, see the word ABRIDGEMENT.

But though Dr Campbell has exposed the sophistry of his opponent's reasoning, and overturned the principles from which he reasons, we are persuaded that he might safely have joined issue with him upon those very principles. To us, at least, it appears that the testimony upon which we receive the Gospel miracles is precisely of that kind which Mr Hume has acknowledged sufficient to establish even a miracle. "No testimony (says he) is sufficient to establish a miracle, unless the testimony be of such a kind that its falsehood would be more miraculous than the fact which it endeavours to establish. When one tells me that he saw a dead man restored to life, I immediately consider with myself whether it be more probable that this person should either deceive or be deceived, or that the fact which he relates should really have happened. I weigh the one miracle against the other; and according to the superiority which I discover I pronounce my decision, and always reject the greater miracle." In this passage every reader may remark what did not escape the perpicious eye of Dr Campbell, a strange confusion of terms: but as all miracles are equally easy to the Almighty; and as Mr Hume has elsewhere observed, that "the raising of a feather, when the wind wants ever so little of a force requisite for that purpose, is as real a miracle as the raising of a house or a ship into the air;" candour obliges us to suppose, that by talking of greater and less miracles, and of always rejecting the greater, he meant nothing more but that of two deviations from the known laws of nature he always rejects that which in itself is least probable.

If, then, we can shew that the testimony given by the apostles and other first preachers of Christianity to the miracles of their Master would, upon the supposition that those miracles were not really performed, have been as great a deviation from the known laws of nature as the miracles themselves, the balance must be considered as evenly poised by opposite miracles; and whilst it continues so, the judgment must remain in a state of suspense. But if it shall appear, that in this case the false testimony would have been a deviation from the laws of nature less probable than the miracles recorded in the Gospels, the balance will be instantly destroyed; and by Mr Hume's maxim we shall be obliged to reject the supposition of falsehood in the testimony of the apostles, and admit the miracles of Christ to have been really performed.

In this argument we need not waste time in proving that those miracles, as they are represented in the writings of the New Testament, were of such a nature, and performed before so many witnesses, that no imposture could possibly be practised on the senses of those who affirm that they were present. From every page of the Gospels this is so evident, that the philosophical adversaries of the Christian faith never suppose the apostles to have been themselves deceived, but boldly accuse them of bearing false witness. But if this accustom be well founded, their testimony itself is as great a miracle as any which they record of themselves or of their Master.

It has been shown elsewhere (see Metaphysics, n° 138.), that by the law of association, which is one of the laws of nature, mankind, in the very process of learning to speak, necessarily learn to speak the truth; that ideas and relations are in the mind of every man so closely associated with the words by which they are expressed in his native tongue, and in every other language of which he is master, that the one cannot be entirely separated from the other; that therefore no man can on any occasion speak falsehood without some effort; that by no effort can a man give consistency to an unpredetermined detail of falsehood, if it be of any length, and include a number of particulars; and that it is still less possible for several men to agree in such a detail, when at a distance from each other, and cross-questioned by their enemies.

This being the case, it follows, if the testimony of the
the apostles to their own and their Master's miracles be false, either that they must have concerted a consistent scheme of falsehood, and agreed to publish it at every hazard; or that God, or some powerful agent appointed by him, must have divested all the associations formed in their minds between ideas of faith and the words of language, and arbitrarily formed new associations, all in exact conformity to each other, but all in direct contradiction to truth. One or other of these events must have taken place; because, upon the supposition of falsehood, there is no other alternative. But such a diffusion and formation of associations as the latter implies, must, to every man who shall attentively consider it, appear to be as real a miracle, and to require as great an exertion of power, as the resurrection of the dead. Nor is the supposed voluntary agreement of the apostles in a scheme of falsehood, more consistent with the event itself in which they were fat down to fabricate their pretended revelation, and to contrive a series of miracles to which they were unanimously to appeal for its truth, than it is plain, since they proved successful in their daring enterprize, that they must have clearly foreseen every possible circumstance in which they could be placed, and have prepared consistent answers to every question that could be put to them by their most inveterate and most enlightened enemies; by the statesman, the lawyer, the philosopher, and the priest. That such foreknowledge as this would have been miraculous, will not firely be denied; since it forms the very attribute which we find it most difficult to allow even to God himself. It is not, however, the only miracle which this supposition would compel us to swallow. The very refutation of the apostles to propagate the belief of false miracles in support of such a religion as that which is taught in the New Testament, is as great a miracle as human imagination can easily conceive.

When they formed this design, either they must have hoped to succeed, or they must have foreseen that they should fail in their undertaking; and in either case, they chose evil for its own sake. They could not, if they foresaw that they should fail, look for anything but that contempt, disgrace, and persecution, which were then the inevitable consequences of an unsuccessful endeavour to overthrow the established religion. Nor could their prospects be brighter upon the supposition of their success. As they knew themselves to be false witnesses and impious deceivers, they would have none hopes beyond the grave; and by determining to oppose all the religious systems, superstitions, and fanims of the age in which they lived, they willfully exposed themselves to inevitable misery in the present life, to infult and imprisonment, to stripes and death. Nor can it be said that they might look forward to power and influence when they should, through sufferings, have converted their countrymen; for so defirous were they of obtaining nothing but misery as the end of their mission, that they made their own persecution a pretext of the truth of their doctrines. They introduced the Master from whom they pretended to have received these doctrines as telling them, that "they were sent forth as sheep in the midst of wolves; that they should be delivered up to councils, and scourged in synagogues; that they should be hated of all men for his name's sake; that the broth-

...
MIRANDA DE EBRO, a town of Spain

MIRANDO DE DUERO, a strong town of Portugal, and capital of the province of Tras-Montes, with a bishop's see. It is well fortified, and seated on a rock near the confluence of the river Douro and Pheina. W. Long. 5. 40. N. Lat. 41. 30.

MIRANDOLA, a town of Italy, and capital of a duchy of the same name, situated between the duchies of Mantua and Modena. It is a pretty large place, well fortified, and has also a strong citadel and fort. It has been several times taken and retaken; the last time by the king of Sardinia in 1742. E. Long. 11. 5. N. Lat. 44. 52.

MIRANULA. See Picus.

MIREVELT (Michael Jansen), portrait-painter, was the son of a Goldsmith, and born at Delft in 1568. His father, perceiving his early inclination for the arts, placed him at first with one of the Wierixes, of whom he learned to draw in crayons and to engrave. At the age of twelve he executed a print of the Samaritan woman; and not long after a figure of Judith holding the head of Holofernes. These juvenile performances attracted the notice of Anthony Blockland, an historical painter of great note; and under his instructions Mirevelt took up the pencil. He was very successful in his attempts at painting history; but finding portraits to be more profitable, he quitted the former by degrees, and applied himself to portrait painting only. His reputation according to De Piles, was so great, that he executed what price for his pictures he pleased, never taking less than 150 florins a piece. The portraits drawn and painted by this artist are exceedingly numerous; and many of them were excellently engraved by William James Delft, his near relation, a very skilful artist. He died in 1641.

Mirevelt (Peter), son of Michael, was born at Delft in 1596, and died in 1632. In his manner of design, in his style of colouring, and in the delicacy of his pencil, he exactly resembled his father; and by the best judges of that time he was accounted to be in no degree inferior to him.

MIRIAM, sister of Aaron and Moses, makes two or three remarkable appearances in scripture. It was owing to her that her mother was employed by Pharoah's daughter as nurse to Moses. She put herself at the head of the women of Israel after their passage through the Red Sea, in order to sing the song which the men had sung before. She joined with her brother Aaron in murmuring against Moses, and was severely chastised for that action; for she became leprous, and continued separate from the rest without the camp for seven days. She died before her brothers, though in the same year with them, and was buried at the public expense.

MIRROR, a name for a looking glafs, or any polished body, whose use is to form the images of distant objects, by reflection of the rays of light. See Refraction.

MIRRORS are either plain, convex, or concave. The first reflect the rays of light in a direction exactly similar to that in which they fall upon them, and therefore represent bodies of their natural magnitude. The convex ones make the rays diverge much more than before refraction, and therefore greatly diminish the images of those objects which they show: while the concave ones, by collecting the rays into a focus, not only magnify the objects they show, but will burn very fiercely when exposed to the rays of the sun; and hence they are commonly known by the name of burning mirrors. See Burning-Mirror.

In ancient times the mirrors were made of some kind of metal; and from a passage in the Mosaic writings we learn that the mirrors used by the Jewish women were made of brass. The Jews certainly had been taught to use that kind of Mirrors by the Egyptians; from whence it is probable that brazen mirrors were the first kind used in the world. Any kind of metal, indeed, when well polished, will reflect very powerfully, but of all others silver reflects the most, tho' it has been in all countries too expensive a material for common use. Gold also is very powerful; and metals, or even wood, gilded and polished, will act very powerful as burning mirrors. Even polished ivory, or draw nicely platted together, will form mirrors capable of burning, if on a large scale.

Since the invention of glafs, and the application of quicksilver to it, became generally known, it hath been universally employed for those plain mirrors used as ornaments to houses; but in making reflecting telescopes, they have been found much inferior to metallic ones. It doth not appear that the fame superiority belongs to the metalline burning mirrors, considered merely as burning glafs; since the mirror with which Mr Macquer melted platina, though only 22 inches diameter, and which was made of quicksilvered glafs, produced much greater effects than M. Villette's metalline speculum, which considerably exceeded it in size. It is very probable, however, that this mirror of M. Villette's was by no means so well polished as it ought to have been; as the art of preparing the metal for taking the finest polish has but lately been discovered and published in the Philosophical Transctions.
MIS

MISADVENTURE, in common language, signifies any unlucky accident which takes place without being foreseen.

MISADVENTURE, in law, has an especial signification for the killing a man partly by negligence, and partly by chance. See HOMICIDE.

MISANTHROPY (formed from hatred, and aversion, a man); a general dislike or aversion to man, and mankind. In which sense it stands opposed to philanthropy, or the love of mankind.

MISARRIAGE. See ABORTION and MIDWIFERY.

MISCHNA, or Misna, (from taw, iteravit), a part of the Jewish Talmud.

The Mischna contains the text; and the Gemara, which is the second part of the Talmud, contains the commentaries on that the Gemara is, as it were, a glossary on the Mischna.

The Mischna consists of various traditions of the Jews, and of explanations of several passages of Scripture; these traditions serving as an exposition of the written law, and supplement to it, are said to have been delivered to Moses during the time of his abode on the Mount; which he afterwards communicated to Aaron, Eleazar, and his servant Joshua. By these they were transmitted to the 70 elders, by them to the prophets, who communicated them to the men of the great sanhedrim, from whom the wife men of Jerusalem and Babylon received them. According to Prideaux's account, they passed from Jeremiah to Baruch, from him to Ezra, and from Ezra to the men of the great synagogue, the last of whom was Simon the Jelt: who delivered them to Antigonus of Socho; and from him they came down in regular succession to Simeon, who took the Saviours in his arms; to Gamaliel, at whose feet Paul was educated; and last of all to Rabbi Judah the Holy, who committed them to writing in the Mischna. But Dr Prideaux, rejecting this Jewish fiction, observes, that after the death of Simon the Just, about 299 years before Christ, the Michtiial doctors arose, who, by their comments and conclusions, added to the number of those traditions which had been received and allowed by Ezra and the men of the great synagogue; so that towards the middle of the second century after Christ, under the empire of Antoninus Pius, it was found necessary to commit these traditions to writing; more especially, as their country had considerably suffered under Adrian, and many of their schools had been dissolved; and their learned men cut off; and therefore the usual method of preserving their traditions had failed. Rabbi Judah on this occasion being rector of the school at Tiberias, and president of the sanhedrim in that place, undertook the work, and compiled it in six books, each consisting of several tracts, which altogether make up the number of 63. 

PRID. CONNECT. vol. ii. p. 468, &c. ed. 9. This learned author computes, that the Mischna was composed about the 150th year of our Lord; but Dr Lightfoot says, that Rabbi Judah compiled the Mischna about the year of Christ 150, in the latter end of the reign of Commodus; or, as some compute, in the year of Christ 220. Dr Larner is of opinion, that this work could not have been finished before the year 150, or later. Colled. of Jewish and Heathen Testimonies, &c. vol. i. p. 178. Thus the book called the Mischna was formed; a book which the Jews have generally received with the greatest veneration. The original has been published with a Latin translation by Surenhusius, with notes of his own, and others from the learned Maimonides, &c. in 6 vols. fol. Amfterd. A. D. 1698-1703. (See Talmud.) It is written in a much purer style, and is not near so full of dreams and visions as the Gemara.

MISDEMEANOUR, in law, signifies a crime. Every crime is a misdemeanor; yet the law has made a distinction between crimes of an higher and a lower nature; the latter being denominated misdemeanours, the former crimes, &c. For the understanding of which distinction, we shall give the following definition from Blackstone's Commentaries, vol. iv. 5.

"A crime, or misdemeanor, is an act committed or omitted, in violation of a public law, either forbidding or commanding it. This general definition comprehends both crimes and misdemeanours; which, properly speaking, are mere synonymous terms; though, in common usage, the word crime is made to denote such offences as are of a deeper and more atrocious dye; while smaller faults, and omissions of less consequence, are comprised under the gentler name of misdemeanours only."

MISE, in law-books, is used in various senses; thus it sometimes signifies costs or expenses; in which sense it is commonly used in entering of judgments in actions personal. It is also used for the fine to be tried on the grand affize; in which case, joining of the fine upon the mere right, is putting an fine between the tenant and demandant, Who has the best or clear right.

Mise also signifies a tax or tallage, &c. An honorary gift, or customary present from the people of Wales to every new king or prince of Wales, anciently given in cattle, wine, and corn, but now in money, being 5000l. or more, is denominated a mise: so was the usual tribute or fine of 3000 marks paid by the inhabitants of the county palatine of Chester at the change of every owner of the said earldoms, for enjoying their liberties. And at Chester they have a mife-book, wherein every town and village in the county is rated what to pay towards the mise. The 27 Hen. VIII. c. 26, ordains that lords shall have all such mises and profits of their lands as they had in times past, &c.

Miss, is sometimes also corruptly used for mess, in law French medio, a messuage, or a mise place, in some manors, is such a messuage or tenement as answers the lord a heriot at the death of its owner.

2. Inf. 228.

MISENUM, or Misenum, (anc. geog.); a promontory, port, and town in Campania, situated to the south-west of Baiae, in the Sinus Puteolanus, on the north side. Here Augustus had a fleet, called Caesars Misenum, for guarding the Mare Infernum; as he had another at Ravenna for the Superbum.

On this peninsula a villa was built by Caius Marius, with a degree of elegance that gave great offence to the more autemne among the Romans, who thought it
Upon the same foundation Lucullus, the plunderer of the eastern world, erected an edifice, in comparison of which the former house was a cottage; but even his magnificence was eclipsed by the splendour of the palace which the emperors raised upon the same spot. To these proud abodes of heroes and monarchs, which have long been levelled to the ground, a few filling huts, as Mr Swinburn informs us, and a lonely public house, have succeeded; hither boatmen resort to tipple, perhaps on the identical site where the voluptuous masters of the world quaffed Chin and Falernian wines.

Mr Miseric, a parsimonious person who is at the same time rich; or a wretch covetous to extremity, whom avarice has divested of all the charities of human nature, and made even an enemy to himself.

Of this most unaccountable of all characters, many instances occur; some of them so extraordinary as almost to surpass belief. The following are here selected, as being of recent date, perfectly authentic, and the last of them in particular exhibiting an assemblage of qualities the most singular perhaps that ever centered in the same person. Too little dignified to merit a place in regular biography, yet too curious a variety of human character to pass unnoticed in this Work, the present seemed the only title under which it could with propriety be introduced.

1. In December 1790, died at Paris, literally of want, Mr Ottewald, a well-known banker. This man, originally of Neuchatel, felt the violence of the disease of avarice (for surely it is rather a disease than a passion of the mind) so strongly, that, within a few days of his death, no importunities could induce him to buy a few pounds of meat for the purpose of making a little soup for him. "Tis true (said he), I should not dislike the soup, but I have no appetite for the meat; what then is to become of that?" At the time that he refused this nourishment, for fear of being obliged to give away two or three pounds of meat, there was tied round his neck a silk bag, which contained 800 assignats of 1000 livres each. At his outlet in life, he drank a pint of beer, which served him for supper, every night at a house much frequented, from which he carried home all the bottle corks he could come at. Of theft, in the course of eight years, he had collected as many as fold for 12 louis d'ors, a sum that laid the foundation of his future fortune, the superstructure of which was rapidly raised by his uncommon success in stock-jobbing. He died possessed of three millions of livres (L. 125,000 sterling.)

2. The late John Elwes, Esq., was member for Berkshire in three successive parliaments. His family name was Meggot; and his father was a brewer of great eminence, and distinguished by no peculiarity of character: but his mother, though she was left nearly L. 100,000 by her husband, starved herself to death! At an early period of life he was sent to Westminster school, where he remained for 10 or 12 years. During that time he certainly had not misapplied his talents; for he was a good classical scholar to the left: and it is a circumstance not a little remarkable, though well authenticated, that he never read afterwards, nor had he ever any knowledge in accounts; to which may in some measure be attributed the total ignorance he was always in as to his affairs. From Welfminster school Mr Meggot removed to Geneva, where he soon entered upon pursuits more agreeable to him than study. The riding-master of the academy there had then to boast perhaps of three of the best riders in Europe, Mr Worley, Mr Elwes, and Sir Sidney Meadows. Of the three, Elwes was reckoned the most desperate; the young horses were always put into his hands, and he was the rough rider to the other two.

On his return to England, after an absence of two or three years, he was to be introduced to his uncle the late Sir Harvey Elwes, that was then living at Stoke in Suffolk, perhaps the most perfect picture of human penury that ever existed. The attempts at saving money were in him so extraordinary, that Mr Elwes perhaps never quite reached them, even at the last period of his life. Of what temperance can do, Sir Harvey was an instance. At an early period of life he was given over for a consumption, and he lived till between 80 and 90 years of age. On his death, his fortune, which was at least L. 250,000, fell to his nephew Mr Meggot, who by will was ordered to assume the name and arms of Elwes. To this uncle, and this property, Mr Elwes succeeded when he had advanced beyond the 40th year of his age. And for fifteen years previous to this period, it was that he was known in the most fashionable circles of London. He had always a turn for play; and it was only late in life; and from paying always and not always being paid, that he conceived difficulty at it. The theory which he professed, "that it was impossible to ask a gentleman for money," he perfectly confirmed by the practice; and he never violated this feeling to the latest hour of his life.

The manners of Mr Elwes were such—so gentle, so attentive, so gentlemanly, and so engaging—that rudesness could not ruffle them, nor strong ingratitude break their observance. He retained this peculiar feature of the old court to the last: but he had a praise beyond this; he had the most gallant disregard of his own person, and all care about himself, that can be imagined. The infinences in younger life, in the most imminent personal hazard, are innumerable; but when age had dispoiled him of his activity, and might have rendered care and attention about himself natural, he knew not what they were: He wished no one to afflict him: "He was as young as ever; he could walk; he could ride, and he could dance; and he hoped he should not give trouble even when he was old." He was at that time 75.

It is curious to remark how he contrived to mingle small attempts at saving with objects of the most unbounded dissipation. After fitting up a whole night at play for thousands with the most fashionable and profligate men of the time, amidst splendid rooms, gilt sofas, wax lights, and waiters attendant on his call, he would walk out about four in the morning, not towards home, but into Smithfield, to meet his own cattle, which were coming to market from Thaydonhall, a farm of his in Essex! There would this same man, forgetful of the scenes he had just left, stand in the cold and rain bartering with a carcase-butcher for a hilling! Sometimes, when the cattle did not arrive at the hour he expected, he would walk on in the mire to meet them; and more than once has gone on foot the whole
whole way to his farm without flopping, which was
17 miles from London, after fitting up the whole
night. Had every man been of the mind of Mr Elwes,
the race of innkeepers must have perished, and poth-
ditches been returned back to those who made
them; for it was the buisiness of his life to avoid both.
He always travelled on horseback. To see him setting
out on a journey, was a matter truly curious; his
first care was to put two or three eggs, boiled hard,
into his great-coat pocket, or any scraps of brood
which he found; baggage he never took: then mount-
ing one of his hunters, his next attention was to get
out of London into that road where turnpikes were
the fewest: then, flopping under any hedge where
grabs pretended itself for his horse, and a little water
for himself, he would sit down and refresh himself
and his horse together.

The chief residence of Mr Elwes at this period of
his life was in Berkshire, at his own seat at Marcham.
Here it was he had two natural sons born, who inherit
the greatest part of his property by a will made about
the year 1785. The keeping fox-hounds was the on-
ly influence in the whole life of Mr Elwes of his ever
sacrificing money to pleasure; and may be felted as
the only period when he forgot the cares, the per-
plexities, and the regret, which his wealth occasioned.
But even here every thing was done in the most frugal
manner. Scrub, in the Beaux Stratagem, when com-
pared with Mr Elwes's huntman had an idle life of
it. This famous huntman might have fixed an epoch
in the history of servants: for in a morning, getting
up at four o'clock, he milked the cows; he then
prepared breakfast for Mr Elwes or any friends he
might have with him: then, slipping on a green coat, he
hurried into the stable, saddled the horse, got the hounds
out of the kennel, and away they went into the field.
After the fatigues of hunting, he refreshed himself by
rubbing down two or three horses as quickly as he
could; then running into the house to lay the cloth,
and wait at dinner; then hurrying again into the sta-
ble to feed the horses—who diversified with an interlude
of the roads, to drink a glass or two, to milk, the dogs to feed, and eight
hunters to litter down for the night.

In the penury of Mr Elwes there was something
that seemed like a judgment from heaven. All earth-
ly comforts he voluntarily denied himself: he would
walk home in the rain in London rather than pay a
shilling for a coach; he would sit in wet cloaths fooner
than have a fire to dry them; he would eat his pro-
visions in the last stage of putrefaction sooner than
have a fresh joint from the butchers; and he wore a wig
for above a fortnight, which his biographer * now him
pick up out of a rut in a lane where they were riding.
This was the last extremity of humble economy;
for to all appearance it was the call-of-wig of some beggar.

Mr Elwes had now resided about 17 years in Suf-
folk, when the contest for Berkshire presented itself
on the dissolution of the parliament—and when, to pre-
sure the peace of that county, he was nominated by
Lord Craven. Mr Elwes, though he had retired from
public business for some years, had still left about him
some of the seeds of more active life, and he agreed to the
proposel. It came further enhanced to him, by the
agreement, that he was to be brought in by the
Vol. XI.

* Mr Tep-
ham; from whose

ed.

fresher holders for nothing. All he did on the occasion
was dining at the ordinary at Reading; and he got
into parliament for 18 pence!

Though a new man, Mr Elwes could not be called
a young-member; for he was at this time nearly 63
years old when he thus entered on public life. But
he was in possession of all his activity; and prepara-
tory to his appearance on the board of St Stephen's
Chapel, he used to attend constantly during the races
and other public meetings all the great towns where
his voters resided. At the different assemblies, he
would dance amongst the youngest to the last, after
riding over on horseback, and frequently in the rain,
to the place of meeting. A gentleman who was one
night standing by, observed on the extraordinary agi-
ty of so old a man,—"Oh! that is nothing (replied
another); for Mr Elwes, to do this, rode 20 miles in
the rain, with his shoes stuck into his boots and his bag-
wig in his pocket."

The honour of parliament made no alteration in
the dress of Mr Elwes; on the contrary, it seemed
at this time to have attained additional meanness;
and nearly to have reached that happy climax of po-
vety, which has more than once drawn on him the
complaisance of those who passed by him in the street.
For the speaker's dinners, however, he had one fait,
with which the speaker in the court of the fellows
became very familiar. The minister likewise was well
acquainted with it; and at any dinner of opposition
still was his apparel the same. The wits of the minor-
ity used to say, "that they had full as much reason
as the minister to be satisfied with Mr Elwes, as he
had the same habit with everybody." At this period
of his life Mr Elwes wore a wig. Much about the time
when his parliamentary life ceased, that wig was worn
out; so then, being older and wiser as to expense, he
wore his own hair, which like his expenses was very
fmal. All this time the income of Mr Elwes was in-
creasing hourly, and his present expenditure was next
to nothing; for the little pleasures he had once engaged
in he had now given up. He kept no house, and on-
ly one old servant and a couple of horses: he refi ned
with his nephew: his two sons had stationed in
Suffolk and Berkshire, to look after his respective
cities; and his dress certainly was no expense to him;
for had not other people been more careful than him-
self, he would not have had it even mended.
When he left London, he went on horseback to his
country-seats with his couple of hard eggs, and with-
out once stopping upon the road at any house. He
always took the most unfrequented road, and used
every shift to avoid turnpikes. Marcham was the first
he now chiefly visited; which had some reason to be
flattered with the preference, as his journey into Suf-
folk cost him only two-pence half-penny, while that in
to Berkshire amounted to four-pence!

As Mr Elwes came into parliament without ex-
pence, he performed his duty as a member would have
done in the pure days of our constitution. What
he had not bought, he never attempted to sell; and
he went forward in that straight and direct path,
which can alone satisfy a reflecting mind. Amongst
the smaller memorals of the parliamentary life of Mr
Elwes may be noted, that he did not follow the cu-
When he quitted parliament, he was, in the common phrase, "a fish out of water!" The style of Mr Elwes's life had left him no domestic scenes to which he could retire—his home was dreary and poor—his rooms received no cheerfulness from fire; and while the outside had all the appearance of a "House to be Let," the inside was a defect; but he had his penury alone to thank for this, and for the want of all the little confolations which should attend old age, and smooth the paffage of declining life. At the close of the spring 1785, he wished again to vifit, which he had not done for some years, his feat at Stoke. But then the journey was a moft fervile object to him. The famous old fervant was dead; all the horses that remained with him were a couple of worn-out broodmares; and he himself was not in that vigour of body in which he could ride 60 or 70 miles on the fufperance of two boiled eggs. The mention of a poft-chaise would have been a crime—"He afford a poft-chaffe, indeed! where was he to get the money?" would have been his exclamation. At length he was carried into the country as he was carried into parliament, free of expence, by a gentleman who was certainly not quite fo rich as Mr Elwes. When he reached Stoke—the feat of more active fenes, of somewhat refembling hofpitality, and where his fox-hounds had fpread somewhat like vivacity around,—he remarked, "he had expended a great deal of money once very foolishly; but that a man grew wifher by his foftuions.

The rooms at this feat, which were now much out of repair, and would have all fallen in but for his fon John Elwes, Esq.; who had refided there, he thought too expenfively furnifhed, as worfe things might have ferved. If a window was broken, there was to be no repair but that of a little brown paper, or that of piecing in a bit of broken glafs; which had at length been done fo frequently, and in fo many fpates, that it would have puzzled a mathematician to fay "what figure they deferved." To fave fire, he would walk about the remains of an old greenhouse, or fit with a fervant in the kitchen. During the harveft he would amufe himself with going into the fields to glean the corn on the grounds of his own tenants; and they ufed to leave a little more than common to pleaf the old gentleman, who was as eager after it as any pauper in the parish. In the advance of the feafon, his morning employment was to pick up any flary chips, bones, or other things, to carry to the fire, in his pocket—and he was one day furprifed by a neighbouring gentleman in the act of pulling down, with some difficulty, a crow's net for this purpofe. On the gentleman wondering why he gave himfelf this trouble—"Oh, Sir, (replied old Elwes), it is reafonably that thofe creatures fhould do fo. Do but fee what waffe they make! They don't care how extravagant they are!"

As no gleam of favourite paffion, or any ray of amufement, broke through this gloom of penury, his infaftible defire of faving was now become uniform and fystematic. He ufed flill to ride about the country on one of these mares—but then he rode her very economically, on the soft turf, adjoining the road, without putting himfelf to the expence of shoes, as he observed, "The turf was fo pleafant to a horfe's foot!" And when any gentleman called to pay him a vifit, and the boy who attended in the flables was profufe enough to put a little hay before his horfe, old Elwes would frily steal back into the flable, and take the hay very carefuilly away. That very fharp appetite which Mr Elwes had in some meafure restrained during the long fitting of parliament, he now indulged moft voracioufly, and on every thing he could find: To fave, as he thought, the expence of going to a butcher, he would have a whole fheep killed, and fo eat mutton to the—end of the chapter. When he occafoonally had his river drawn, though fometimes horfe-loads of small ftilt were taken, not one would he fuf­fer to be thrown in again; for he observed, "He fhould never fee them again!" Came in the laft flate of purfueation, and meat that walked about his plates would he continue to eat, rather than have new things killed before the old provision was finished. With this diet—the charnel-houfe of fufpereance—his defte kep­pace—equally in the laft fage of absolute diftuffion. Sometimes he would walk about in a tattered brown-coloured hat, and fometimes in a red and white woolen cap, like a prisoner confined for debt. His shoes he never would fuffer to be cleaned, left they fhould be worn out the fooner. But ftilt, with all this felf-denih—that penury of life to which the inha­bitant of an alm-houfe is not doomed—all did he think he was profufe, and frequently fay, "He muft be a little more careful of his property." His difqueftude on the fubjeft of money was now continual. When he went to bed, he would put five or ten guineas into a bureau; and then, full of his mo­ney, after he had retired to rest, and fometimes in the middle of the night, he would come down to fee if it was there.

The feene of mortification at which Mr Elwes was now arrived was all but a denial of the common ne­ceffaries of life: and indeed it might have admitted a doubt, whether or not, if his manors, his fift-ponds, and fome grounds in his own hands, had not furnished a fubfifence, where he had not any thing actually to buy, he would not, rather than have bought any thing, have tarved. Strange as this may appear, it is not exaggerated.—He one day, during this period, dined upon the remaining part of a moo-hef, which had been brought out of the river by a rat! and at another time an undigefled part of a pike which a larger one had almonds, but had not finished, and which were taken in this flate in a net. At the time this laft circumstance happened, he discovered a strange kind of fatisfaftion; for he faid to a friend, "Aye! this was killing two birds with one fone!" In the room of all comment—of all moral—let it be remark­ed, that at this time Mr Elwes was perhaps worth nearly eight hundred thoufand pounds! and, at this pe­riod, he had not made his will, of course was not faving from any fentiment of affection for any perfon.

The Summer of 1788 Mr Elwes paifed at his hone­ in Welbeck-freet, London; and he paifed that sum­mer without any other fociety than that of two maid­servants;
find a comfortable home. In London he was certainly soon uncomfortable: but still, with these temptations before and behind him, a journey with the expense annexed to it was unremunerative. This, however, was greatly alleviated by an offer from Mr. Partis, a gentleman of the law, to take him to his ancient seat in Berkshire with his purse perfectly whole. But there was one circumstance still very distressing— the old gentleman had now nearly worn out his last coat, and he would not buy a new one; his own, therefore, with a pious fraud, contrived to get Mr. Partis to buy him a coat and make him a present of it. Thus, formerly having had a good coat, then a bad one, and at last no coat at all, he was kind enough to accept one from a neighbour.

Mr. Elwes carried with him into Berkshire five guineas and a half, and a half crown. Left the mention of this sum may appear singular, it should be said, that previous to his journey he had carefully wrapped it up in various folds of paper, that no part of it might be lost. On the arrival of the old gentleman, Mr. George Elwes and his wife did everything they could to make the country a scene of quiet to him. But "he had that within" which baffled every effort of this kind. Of his heart it might be said, "there was no peace in Israel." His mind, cast away upon the vast and troubled ocean of his property extending beyond the bounds of his calculation, returned to a muse itself with fetching and carrying about a few guineas, which in that ocean was indeed a drop. But nature had now carried on life nearly as far as she was able, and the fund was almost run out. The first symptoms of more immediate decay was his inability to enjoy his rest at night. Frequently would he be heard at midnight as if struggling with some one in his chamber, and crying out, "I will keep my money, I will; nobody shall rob me of my property." On any one of the family going into his room, he would start from this fever of anxiety, and, as if waking from a troubled dream again hurry into bed, and seem unconscious of what had happened. At length, on the 26th of November 1789, expired this miserably rich man, whole property, nearly reaching to a million, extended itself almost through every county in England.

MISERICORDIA, in law, is an arbitrary fine imposed upon any person for an offence: this is called _misericordia_, because the amercement ought to be but small, and less than that required by magna charta. If a person be outrageously amerced in a court that is not of record, the writ called _moderata misericordia_ lies for moderating the amercement according to the nature of the fault.

MISFORTUNE. An unlucky accident.

Misfortune, or chance, in law, a deficiency of the will; or committing of an unlawful act by misfortune or chance, and not by design. In such case, the will observes total neutrality, and does not co-operate with the deed; which therefore wants one main ingredient of a crime. See _CRIME_.

Of this, when it affects the life of another, we have spoken under the article _Homicides_; and in this place have only occasion to observe, that if _any_ accidental mischief happens to follow from the performance of a lawful act, the party stands exonerated from all guilt; but...
MISPRISIONES, or misprisions, are generally denominated contempt or high misdemeanours; of which the principal is the mal-administration of such high officers as are in public trust and employment.

This is usually punished by the method of parliamentary impeachment; wherein such penalties, short of death, are inflicted, as to the wisdom of the house of peers shall seem proper; consisting usually of banishment, imprisonment, fines, or perpetual disability. Hitherto also may be referred the offence of embezzling the public money, called among the Romans, peculium; which the Julian law punished with death in a magistrate, and with deportation, or banishment, in a private person. In England it is not a capital crime, but subjects the committer of it to a discretionery fine and imprisonment.—Other misprisions are, in general, such contempt of the executive magistrate as demonstrate themselves by some arrogant and undutiful behaviour towards the king and government: for a detail of which, vide Blackstone's Comment. iv. 22.

MISSAL, the Roman mass-book, containing the several masses to be said on particular days. It is derived from the Latin word missa, which, in the ancient Christian church, signified every part of divine service.

MISSEL-BIRD, a species of Turdus.

MISSIO, among the Romans, was a full discharge given to a soldier after 20 years service, and differed from the excusatior, which was a discharge from duty after 17 years service. Every soldier had a right to claim his missio at the end of 20 years.

MISSION, in theology, denotes a power or commission to preach the gospel. Jesus Christ gave his disciples their mission in these words Go and teach all nations, &c.

The Romanists reproach the protestants, that their ministers have no mission, as not being authorized in the exercise of their ministry, either by an interrupted succession from the apostles, or by miracles, or by an extraordinary proof of a vocation.

There are many who deny any other mission necessary for the ministry than the talents necessary to discharge it.

Mission is also used for an establishment of people zealous for the glory of God and the salvation of souls; who go and preach the gospel in remote countries and among infidels.

There are missions in the East as well as in the West Indies. Among the Romanists, the religious orders of St Dominic, St Francis, St Augustine, and the Jesuits, have missions in the Levant, America, &c. The Jesuits have also missions in China, and all other parts of the globe where they have been able to penetrate. There have been also several Protestant missions for diffusing the light of Christianity through the benighted regions of Asia and America. Of this kind has been the Danish mission planned by Frederic IV. in 1706. And the liberty of private benefactors in other countries has been also extended to
MITCHELSTOWN, a poll-town of Ireland, in the county of Cork and province of Munster in Ireland, 103 miles from Dublin. Here is a college for the support of 12 decayed gentlemen and 12 decayed gentlewomen, who have £40 yearly, and handsome apartments, and a chappel at £100 a-year, with a house; divine service is daily performed in a neat chapel belonging to the college; the whole was founded by the late earl of Kingston. Here is also a most magnificent feat of Lord Kingborough.—Fair are held at this town 30th July and 12th November.

MITE, a small piece of money mentioned Luke xii. 59. and xxii. 2. In the Greek it is ἴδραρες, i. e. quarter, or a quarter of the Roman denarius, so that the mite was worth about seven farthings, or two pence halfpenny.

MITE, in zoology. See ACARUS.

MITELLA, BASTARD AMERICAN SANICLE: A genus of the digyna order, belonging to the decandria class of plants; and in the natural method ranking under the 13th order, Scrofulariae. The calyx is quinquifid; the corolla pentagynous, and inserted into the calyx; the petals pinnatifid; the capsule unilocular and bivalved, with the valves equal. There are two species, both natives of North America, differing with annual herbageal flanks from five or six to eight or nine inches in height, and producing spikes of small whitish flowers, whose petals are fringed on their edges. They are easily propagated by parting their roots; and should be planted in a sandy situation, and in a level loamy soil.

MITHRAGA, feasts of, in antiquity, were feasts celebrated among the Romans in honour of Mithras or the sun. The most ancient influence of this Mithras among the Romans occurs in an inscription dated in the third consulate of Trajan, or about the year of Christ 101. This is the dedication of an altar to the sun under the above name, thus inscribed, Den Sac Mithrae. But the worship of Mithras was not unknown in Egypt and Syria in the time of Origen, who died about the year of Christ 265; though it was common at Rome for more than a century before this time. The worship of Mithras was proscribed at Rome in the year 378, by order of Gratian, prefect of the praetorium. According to M. Fre ret, the feasts of Mithras were derived from Chalda, where they had been instituted for celebrating the entrance of the sun into the sign Taurus.

MITHRAS, OF MITHRAE, a god of Persia and Chalda, supposed to be the sun. His worship was introduced at Rome. He is generally represented as a young man, whose head is covered with a turban after the manner of the Persians. He supports his knee upon a bull that lies on the ground, and one of whose horns he holds in one hand, while with the other he plunges a dagger in his neck.

MITHRIDATE, in pharmacy; an antidote, or composition, in form of an elemtory, supposed to serve either as a remedy or a preservative against poisons. (See PHARMACY.) It takes its name from the inventor, Mithridates king of Pontus; who is said to have fortified his body against poisons with antides and preservatives, that when he had a mind to dispatch himself, he could not find any poison that would take effect. The receipt of it was found in his cabinet, written with his own hand, and was carried to Rome by Pompey. It was translated into
MITHRIDATES, the name of several kings of Pontus. See Pontus.

Mithridates VII. surnamed Eupator and the Great, succeeded to the throne at the age of 14 years, about 225 years before the Christian era. The beginning of his reign was marked by ambition, cruelty, and artifice. He murdered his own mother, who had been left by his father coheires of the kingdom; and he fortified his constitution by drinking antides against the poison with which his enemies at court attempted to destroy him. He early inured his body to hardship, and employed himself in the most manly exercises, often remaining whole months in the country, and making frozen snow and the earth the place of his repose. Naturally ambitious and cruel, he spared no pains to acquire to himself power and dominion. He murdered the two sons whom his father Laodice had had by Ariarathes King of Cappadocia, and placed one of his own children, only eight years old, on the vacant throne. These violent proceedings alarmed Nicomedes king of Bithynia, who had married Laodice the widow of Ariarathes. He fuborned a youth to be king of Cappadocia, as the third son of Ariarathes; and Laodice was sent to Rome to impose upon the senat, and assure them that her third son was now alive, and that his pretensions to the kingdom of Cappadocia were just and well founded. Mithridates, on his part, sent to Rome: Gordius the governor of his son; who solemnly declared before the king's council, that he had never declared the false pretensions of his son by his mother, who had been small. To prevent surprises, and to escape from the enemy's hands. The appointment of Glabrio to the command of the Roman forces, instead of Lucullus, was favourable to Mithridates, who recovered the greatest part of his dominions. The sudden arrival of Pompey, however, put an end to his victories. A battle in the night was fought near the Euphrates, in which the troops of Pontus laboured under every disadvantage. The engagement was by moon-light, and as the moon then shone in the face of the enemy, the lengthened shadows of the arms of the Romans having induced Mithridates to believe that the two armies were close together, the arrows of his soldiers were darted from a great distance, and their effects rendered ineffectual. An universal overthrow ensued, and Mithridates, bold in his misfortunes, rushed through the thick ranks of the enemy at the head of 800 horsemen, 500 of whom perished in the attempt to follow him. He fled to Tigranes; but that monarch refused an asylum to his father-in-law, whom he had before supported with all the collected forces of his kingdom. Mithridates found a safe retreat among the Scythians; and though destitute of power, friends, and resources, yet he mediated the overthrow of the Roman empire, by penetrating into the heart of Italy by land. The wild projects were rejected by his followers, and he sued for peace. It was denied to his ambassadors; and the victorious Pompey declared, that to obtain it, Mithridates must ask it in person. He scorned to trust himself in the hands of his enemy, and resolved to conquer or to die. His subjects refused to follow him any longer; and revolving from him, made his son Pharnaces king. The son showed himself ungrateful to his father; and even, according to some writers, he ordered him to be put to death. This unnatural treatment broke the heart of Mithridates; he obliged his wife to poison herself, and attempted to do the same himself. It was in vain: the frequent antides he had taken in the

verse by Democritus, a famous physician; and was afterwards translated by Galen, from whom we have it: though there is room to imagine it has undergone considerable alterations since the time of its royal pre­scriber.

MITHRIDATES, the name of several kings of Pontus. See Pontus.
the early part of his life, strengthened his constitution against the poison; and when this was unavailing, he attempted to flay himself. The blow was not mortal; and a Gaul who was then present, at his own request gave him the fatal stroke, about 64 years before the Christian era. Such were the misfortunes, abilities, and miserable end, of a man, who supported himself so long against the power of Rome, and who according to the declarations of the Roman authors, proved a more powerful and indefatigable adversary to the capital of Italy than the great Annibal, Pyrrhus, Pericles, or Anitocorus. Mithridates has been commended for his eminent virtues, and cen- curred for his vices. As a commander, he deserves to be ranked amongst the heroes, lions, eagles, and by the like names. They admired to see him waging war, with such success, were so much below the heroes and in the battles of the first intelligence that ever sat on a throne, according to the opinion of Cicero; and indeed no greater proof of his military character can be brought, than the mention of the great rejoicings which happened in the Roman armies and in the capital at the news of his death. No less than 12 weeks were appointed for public thank-givings to the immortal gods; and Pompey, who had sent the first intelligence of his death to Rome, and who had partly halted his fall, was rewarded with the most uncommon honours. It is said that Mithridates conquered 24 nations, whose different languages he knew, and spoke with the same ease and fluency as his own. As a man of letters he also deserves attention. He was acquainted with the Greek language, and even wrote in that dialect a treatise on botany. His skill in physic is well known; and even now there is a celebrated antidote which bears his name, and is called mithridate. Superflition as well as nature had united to render him great; and if we rely upon the authority of Julius, his birth was accompanied by the appearance of two large comets, which were seen for 70 days successively, and whose splendor eclipsed the mid-day sun, and covered the fourth part of the heavens.

MITHRIDATICUM Bellum, the Mithridatic War, one of the longest and most celebrated wars ever carried on by the Romans against a foreign power. See Pontus.

Mitra, was a cap or covering for the head, worn by the Roman ladies, and sometimes by the men; but it was looked upon as a mark of effeminacy in the Mityleneans suffered greatly from that of the high-priest, especially when it was tied upon their heads.

Mitre, a facetorial ornament worn on the head, by bishops and certain abbots on solemn occasions: being a sort of cap, pointed and cleft at top. The high-priest among the Jews wore a mitre or bonnet on his head. The inferior priests of the same nation had likewise their mitres; but in what respect they differed from that of the high-priest, is uncertain. Some contend that the ancient bishops wore mitres; but this is by no means certain.

Mitre, in architecture, is the workmen's term for an angle that is just 45 degrees, or half a right one. If the angle be a quarter of a right angle, they call it a half-mitre.

To describe such angles, they have an instrument called the mitre-square; with this they strike mitre-

MIXT, or MIXT BOBY, in chemistry, that which is compounded of different elements or principles.

Mixture, a compound or assemblage of several different bodies in the same mass. Simple mixture, consists only in the simple apposition of parts of different bodies to each other. Thus, when powders of different kinds are rubbed together, the mixture is only simple, and each of the powders retains its particular characters. In like manner, when oil and water are mixed together, though the parts of both are con-
There are 18 species, of which seven are native to the Eastern Mediterranean region. The plant is smooth and has a globular habit, with a thick, fleshy stem. The female capitulum is naked and powdery, and the proper form of this species is unknown. The growth is typically in clusters, with a sweet scent that attracts bees.

Mixture, in pharmacy, a medicine which differs from a julep in this respect, that it receives into its composition not only galls, extracts, and other substances, but also earths, powders, and such substances as cannot be dissolved.

Mizen, in the sea-language, is a particular mast or sail. The mizen-mast stands in the sternmost part of the ship. In some great ships there are two of these; when that next the main-mast is called the main-mizen, and that next the poop the bonaventure mizen.

Mizraim, or Misraim, the dual name of Egypt, used in scripture to denote the Higher and Lower Egypt, which see. It sometimes occurs singular, Major: 2 Kings xix. 16; I Kings viii. 4, Micah viii. 16.

Mnemosyne (fab. hitt.); one of the Hyades, daughter of Mnemosyne and Uranus. She received into her memory all things; and then throw hurdles before them, to prevent their progress in science.

MniuM, marshmoss; a genus of the natural order of musci, belonging to the cryptogamia class of plants. The anthera is ocreaceous; the calyptra smooth; the female caputulums naked and powdery, remote. There are 18 species, of which seven are natives of Britain; but none have any remarkable property except the two following. 1. The symphytrum is an elegant moss, frequent in bogs and on the borders of cold springs. It is two to four inches high; the stalks are simple at the base, and covered with a humble down; but higher up are red, and divided into several round, fingle, taper branches, which proceed nearly from the same point. The leaves are not more than 1/14 of an inch long, lanceolate and acute, of a white green colour; and so thinly set, that the red stalk appears between them. This moss, as it may be seen at a considerable distance, is a good mark to lead to the discovery of clear and cold springs. Linnæus informs us, that the Laplanders are well acquainted with this sign. Dr Withering informs us, that wherever this moss grows, a spring of fresh water may be found without much digging. 2. The hygrometricum grows in woods, heaths, garden-walks, walls, old trees, decayed wood, and where coals or cinders have been laid. It is fleshy, hath tips ineradly egg-shaped, nodding, and bright yellow. If the fruit-stalk is moistened at the base with a little water or steam, the head makes three or four revolutions: if the head is moistened, it turns back again.

MOA (anc. geog.), a country of Arabia Petraea; so called from Moab the son of Lot, to whom the city of this country was allotted by divine appointment, Deut. xii. 9. It was originally occupied by the Emim, a race of giants exterminated by the Moabites, ibid. Moab anciently lay to the south of Ammon, before Sihon the Amorite striped both nations of a part of their territory, afterwards occupied by the Israelites. Num. xxii. 4; and then Moab was bounded by the river Arnon to the north, the Lacus Arabum to the west, the brook Zared to the south, and the mountains Abaram to the east.

MOAT, or Drin, in fortification, a deep trench dug round the rampart of a fortified place, to prevent supplies. The brink of the moat, next the rampart, is called the 'garde; and the opposite one, the counter-garde.

A dry moat round a large place, with a strong garrison, is preferable to one full of water; because the passage may be disputed inch by inch, and the besiegers, when lodged in it, are continually exposed to the bombs, granades, and other fire-works, which are thrown incessantly from the rampart into their works. In the middle of dry moats, there is sometimes another smaller one, called counter-garde which is generally dug to deep till they find water to fill it.

The deep and broadest moats are accounted the best; but a deep one is preferable to a broad one: the ordinary breadth is about 20 fathoms, and the depth about 16.

To drain a moat that is full of water, they dig a trench deeper than the level of the water, to let it run off; and then throw hurdles upon the mud and slime, covering them with earth or bundles of reeds, to make a sure and firm passage.

MOATAZALITES, or SEPARATISTS, a religious sect among the Turks, who deny all forms and qualities in the Divine Being; or who divide God of his attributes.

There are two opinions among the Turanian divines concerning God. The first admits metaphorical forms of attributes; such as God has wisdom, by which he is wise; power, by which he is powerful; eternity, by which he is eternal, &c. The second allows God to be wise, powerful, eternal; but will not allow any form or quality in God, for fear of admitting a multiplicity. Those who follow this latter opinion are called Moatazalites; they who follow the former, Sephatites.

The Moatazalites also believed that the word of God was created in fullæs, as the schoolmen term it; and to confute of letters and sounds; copies thereof being written in books to express or imitate the original; they denied absolute predetermination, and affirmed that man is a free agent. This fact is said to have first invented the scholastic divinity, and is subdivided into no less than 20 inferior sects, which mutually brand one another with infidelity.

MOBILE, moveable; any thing susceptible of motion, or that is disposed to be moved either by itself or by some other prior mobile or mover.

Primi Monat, in the ancient astronomy, was the ninth heaven or sphere, imagined above thence of the planets and fixed stars. This was supposed to be the first
MOC

first mover, and to carry all the lower spheres round
along with it; by its rapidity communicating to them
a motion whereby they revolved in 24 hours. But
the diurnal revolution of the planets is now accounted
for without the affilance of any such primus mobile.

Perpetual Motion. See Perpetual Motion.

MOCCHO, Mocco, or Mokha; by some supposed to be
the Mofa or Musa of Ptolemy, is a port and town
on the Red Sea, of considerable trade; contains about
10,000 inhabitants, Jews, Armenians, and Mohom-
mediuns; is surrounded with walls after the ancient man-
er; has four gates and four towers, the last mounted
with cannon, but there is no ditch. It gives name
to a kingdom extending along the most southern coast
of Arabia; of which that part which lies next the sea
is a dry barren desert, in some places 10 or 12 leagues
over; but bounded by mountains, which being well
watered, enjoy an almost perpetual-spring; and be-
side coffee, the peculiar produce of this country,
yields corn, grapes, myrrh, frankincense, caftilla, balm,
gums of several sorts, mangos, dates, pomegranates,
c. The weather here is so hot and sultry in sum-
mer, especially when the south wind blows, that it
would be insupportable, if it was not mitigated by
the cool breezes that generally blow from the
summers of England; and it is very feldom
fentimented to view at a great
distance. They are from
this difference between the mode and the
tone, that the latter only determines the principal
found, and indicates the place which is most proper to
be occupied by that syllable which ought to determine
the accent of it, whereas the former regulates
the thirds, and modifies the whole scale agreeably to its
fundamental founds.

Our modes are not, like those of the ancients, cha-
racterized
MOD

The major mode is immediately generated by the
resonance of founding bodies, which exhibit the third
major of the fundamental found: but the minor mode
is not the product of nature; it is only found by
analogy and invention. This is equally true upon the
system of Sig. Tartini as upon that of M. Rameau.

This last author, in his various and successive
publications, has explained the origin of this minor mode
in different ways, of which his interpreter M. d'A-
lembert was satisfied with none. It is for this rea-
son that he has founded this origin on a different
principle, which cannot be better explained than in
the words of that eminent geometrician. See Music,
Art. 28, 29, 30, and 31.

When the mode is once determined, every note
in the scale assumes a name expressive of its relation
to the fundamental found, and peculiar to the place
which it occupies in that particular mode. We subjoin
the names of all the notes significant of their relative
values and places in each particular mode, taking the
octave of ut as an example of the major mode, and of
la as an example of the minor.

It is necessary to remark, that when the seventh
note is only a femitone distant from the highest
in the octave, that is to say, when it forms a third major
with the dominant, as $f$ natural in the major mode, or
sol sharp in the minor, that seventh found is then
a $f$ major, because it discovers the tonic and
renders the tone appreciable.

Nor does each gradation only assume that name
which is suitable to it; but the nature of each interval
is determined according to its relation to the mode.
The rules establisbed for this are as follow:

1. The second note must form a second major above
the tonic, the fourth note and the dominant should
form a fourth and fifth exactly true; and this equally
in both modes.

2. In the major mode, the mediant or third, the
fifth and the seventh from the tonic, should always be
major; for by this the mode is characterized. For
the same reason these three intervals ought always to
be minor in the minor mode: nevertheless, as it is
necessary that the sensible note should likewise there
be perceived, which cannot be effectuated without a
false relation whilst the fifth note still remains minor;
this occasions exceptions, of which in the course of
the air or harmony care must be taken. But it is always
necessary that the clef, with its transpositions, should
preserve all the intervals, as determined with relation
to the tonic, according to the species of the mode. For
this a general rule will be found at the word Clef in

As all the natural chords in the octave of ut give,
with relation to that tonic, all the intervals preferred
for the major mode, and as the caile is the same with
the octave of la for the minor mode, the preceding
example, which was only given that we might have an
opportunity of naming the notes, may likewise serve
as a formula for the rule of the intervals in each mode.

This rule is not, as one might imagine, establis-
hed upon principles that are merely arbitrary: it has its
source in the generation of harmony, at least in a
certain degree. If you give a perfect major chord
to the tonic, to the dominant, and the sub-dominant,
you will have all the sounds of the diatonic scale for
the major mode: to obtain that of the minor, leaving
still its third major to the dominant, give a third
minor to the other two chords. Such is the analogy
of the mode.

As this mixture of major and minor chords intro-
duces into the minor mode a false relation between
the fifth and the sensible note, to avoid this false relation,
they sometimes give the third major to the fourth
note in ascent, or the third minor to the dominant in
defending chiefly by inverting the chords; but these
in this case are licences.

There are properly no more than two modes, as we
have seen: but there are twelve different sounds in
the octave which may be made fundamental sounds,
and of consequence form as many keys or tones; and
as each of these tones are susceptible of the major or
minor mode, music may be composed in twenty-four
modes or manners. Nay, in the manner of writing
music, there are even thirty-four passable modes: but
in practice ten are excluded; which when thoroughly
examined are nothing else but a repetition of the other
ten, under relations much more difficult, in which all
the chords must change their names, and where it
must cost any one some trouble to know what he is
about. Such is the major mode upon a note raised
above its natural pitch by a semitone, and the minor
mode upon a note depressed by a semitone. Thus,
instead of composing upon sol sharp with a third minor,
it is much more eligible to operate upon la flat, which
will give you an opportunity to employ the same
tones; and instead of composing upon re flat with a
third minor, you will find it more convenient to choose
ut sharp for the same reason; viz. on one hand to
avoid a fa with a double sharp, which would be
equivalent to a $f$ natural; and on the other hand a $f$
with a double flat, which would become a $a$ natural.

The composer does not always continue in the same
mode, nor in the same key, in which he has begun an
air; but, whether to alter the expression or introduce
variety, modes and keys are frequently changed, ac-
cording to the analogy of harmony; yet always re-
turning to those which have been first heard: this is
called modulation.

From
From thence arises a new division of modality into such as are principal and such as are relative: the principal is that in which the piece begins and ends; the relative modes are such as the composer interweaves with the principal in the flow of the harmony. (See Modulation).

Others have proposed a third species, which they call a mixed mode, because it participates the modulation of both the others, or rather because it is composed of them; a mixture which they did not reckon an inconvenience, but rather an advantage, as it increases the variety, and gives the composer a greater latitude both in air and harmony.

This new mode, not being found by the analysis of the three chords like the two former, is not determined, like them, by harmonics essential to the mode, but by an entire scale which is peculiar to itself, as well in rising as descending; so that in the two modes abovementioned the scale is investigated by the chords; and in this mixed mode the chords are investigated by the scale. The following notes exhibit the form of this scale in succession, as well rising as descending:

\[
\text{mi fa sol la si ut re mi.}
\]

Of which the essential difference is, as to the melody, in the position of the two semitones; of which the first is found between the fifth and the second note, and the last between the fifth and the sixth; and, with respect to the harmony, the difference consists in this, that upon its tonic it carries a third minor in the beginning, and major in ending, in the accompaniment of this scale, as well in rising as descending, such as it has been given by those who composed it, and executed at a spiritual concert, May 30, 1751.

They object to its inventor. That his mode has neither chords nor harmony essential to itself, nor cadencies which are peculiar to it, and which sufficiently distinguish it from the major or minor mode. He answers to this. That the distinction of his mode is left in harmony than in melody, and left even in the mode itself than in the modulation; that in its beginning it is distinguished from the major mode by its third minor, and in its end from the minor mode by its plagal cadence. To which his opponents reply, That a modulation which is not exclusive cannot be sufficient to establish a mode; and that his mode is not to be considered as an essential difference of its own, but to be taken. If this is done, and more water added to thin it, it may be rendered much harder than if the water is made use of. In making either moulds or models, however, we must be careful not to make the mixture too thick at first; for if this is done, and more water added to thin it, the composition must always prove brittle and of a bad quality.

The particular manner of making models (or casts, as they are also called) depends on the form of the subject to be taken. The process is easy, where the parts are elevated only in a flight degree, or where they form only a right or obtuse angle with the principal surface from which they proceed; but where the parts project in smaller angles or form curves inclined towards the principal surface, the work is more difficult. This observation, however, holds good only with regard to hard and inflexible bodies: for such as are soft may often be freed from the mould, even though they have the shape last mentioned. But
though this be the use of the soft original substance, it is not so with the inflexible model when once it is cast.

The moulds are to be made of various degrees of thickness, according to the size of the model to be cast; and may be from half an inch to an inch, or, if very large, an inch and an half. Where a number of models are to be taken from one mould, it will likewise be necessary to have it of a stronger contexture than where only a few are required, for very obvious reasons.

It is much more easy to make a mould for any soft substance than a rigid one, as in any of the viscer of the animal body; for the fluidity of the mixture makes it easily accommodate itself to the projective parts of the substance; and as it is necessary to inflate these substances, they may be very readily extracted again by letting out the air which distended them.

When a model is to be taken, the surface of the original is first to be greased, in order to prevent the plaster from sticking to it; but if the substance itself is slippery, as is the case with the internal parts of the human body, this need not be done: when necessary, it may be laid over with linseed oil by means of a cloth, to prevent the plaster sticking to it; then surround the original with a frame or ridge of glazier's putty, at such a distance from it as will admit the plaster to rest upon the table on all sides of the subject for about an inch, or as much as is sufficient to give the proper degree of strength to the mould. A sufficient quantity of plaster is then to be poured over as uniformly as possible over the whole substance, until it be everywhere covered so as to give a proper substance to the mould, which may vary in proportion to the size. The whole must then be suffered to remain in this condition till the plaster has attained, its hardmess; when the frame is taken away, the mould may be inverted, and the subject removed from it; and when the plaster is thoroughly dry let it be well seasoned.

Having formed and seasoned the moulds, they must next be prepared for the casts by greasing the inside of them with a mixture of olive oil and lard in equal parts, and then filled with fine fluid plaster, and the plane of the mould formed by its rolling on the surface of the table covered to a sufficient thickness with coarse plaster, to form a strong basis or support for the cast where this support is requisite, as particularly the case where the thin and membranous parts of the body are to be represented. After the plaster is poured into the mould, it must be suffered to stand until it has acquired the greatest degree of hardmess it will receive: after which the mould must be removed: but this will be attended with some difficulty when the shape of the subject is unfavourable; and in some cases the mould must be separated by means of a small mallet and chisel. If by these instruments any parts of the model should be broken off, they may be cemented by making the two surfaces to be applied to each other quite wet; then interposing between them a little liquid plaster; and lastly, the joint smoothed after being thoroughly dry. Any small holes that may be made in the mould can be filled up with liquid plaster, after the sides of them have been thoroughly wetted, and smoothed over with the edge of a knife.

In many cases it is altogether impracticable to prepare a mould of one piece for a whole subject; and therefore it must be considered how this can be done in such a manner as to divide the mould into the fewest pieces. This may be effected by making every piece cover as much of the pattern as possible, without surrounding such projecting parts, or running into such hollows as would not admit a separation of the mould. It is impossible, however, to give any particular directions in this matter which can hold good in every instance, the number of pieces of which the mould is to consist being always determined from the shape of the pattern. Thus the mould of the human calculus will require no more than three pieces, but that of an os femoris could scarce have fewer than ten or twelve.

Where any internal pieces are required, they are first to be made, and then the outer pieces after the former have become hard.

To make a mould upon an hard and dry substance, we must, in the first place, rub the surface of it smoothly over with the mixture of oil and lard above mentioned. Such hollows as require internal pieces are then to be filled up with fluid plaster; and while it continues in this state, a wire loop must be introduced into it, by which, when hardened, it can be pulled off. The plaster should be somewhat raised in a pyramidal form round this wire, and afterwards cut smooth with a knife or yet in its soft state; preserving two or three angular ridges from the loop to the outer edge, that it may fix the more readily in the outer piece of the mould to be afterwards made upon it. Let the outer piece then be well greased, to prevent the second piece from adhering; the loop being inclosed with some glazier's putty, both to prevent the second piece from adhering and to preserve an hollow place for the cord.

To form the second or outside piece, mix a quantity of plaster proportioned to the extent of surface it is to cover and the intended thickness of the mould: when it is just beginning to thicken, or assumes such a consistence as not to run off very easily, spread it over the internal piece or pieces as well as the pattern, taking care at the same time not to go too far lest it should not deliver safely; and as the plaster becomes more tenacious, add more upon the pattern until it has become sufficiently thick, keeping the edges square and smooth like the edge of a board. The plaster should be spread equally upon all parts, which is best done by a painter's pallet-knife or apothecary's bolus-knife; but for this the instrument should be somewhat less pliable than it is commonly made.

When the outside piece is hardened, the edges are to be pared smooth, and newly made square with a small pointed knife. Little holes of a conical shape are to be made with the point of a knife about an inch distant from one another, according to the size of the piece. These are designed to receive the fluid plaster in forming the adjacent parts of the mould, and occasion points corresponding to the hollows; and are intended to preserve the edges of the different pieces readily in their proper relative situations. The third piece is then to be formed in a manner similar to the second.
Taking the upper part of the fore-head, and spreading it over the eyes, which are to be kept close, that the plaster may not come in contact with the globe; yet not closed so strongly as to cause any unnatural wrinkles. Cover then the nose and ears, plugging first up the meatus auditorii with cotton, and the nostrils with a small quantity of tow rolled up, of a proper size, to exclude the plaster. During the time that the nose is thus stopped, the person is to breathe through the mouth; in this state the fluid plaster is to be brought down low enough to cover the upper lip, observing to leave the rolls of tow projecting out of the plaster. When the operation is thus far carried on, the plaster must be suffer'd to harden; after which the tow may be withdrawn, and the nostrils left free and open for breathing. The mouth is then to be closed in its natural position, and the plaster brought down to the extremity of the chin. Begin then to cover that part of the face which is to be represented, and spread the plaster to the outsides of the arms and upwards, in such a manner as to meet and join that which is previously laid on the face: when the whole of the mass has acquired its due hardnes, it is to be cautiously lifted, without breaking or giving pain to the person. After the mould is contracted, it must be seasoned in the manner already directed; and when the mould is cast, it is to be separated from the model by means of a small mallet and chisel. The eyes, which are necessarily shown closed, are to be carved, so that the eye-lids may be represented in an elevated posture; the nostrils hollow'd out, and the back part of the head, from which, on account of the hair, no mould can be taken, must be finished according to the skill of the artist. The edges of the model are then to be neatly smoothed off and the bust fixed on its pedestal.

The method of making models in the plaster of Paris is undoubtedly the most easy way of obtaining them. When models, however, are made of such large objects that the model itself must be of considerable size, it is vain to attempt making it in the way above described. Such models must be constructed by the hand with some soft substance, as wax, clay, putty, &c. and it being necessary to keep all the proportions with mathematical exactness, the construction of a single model of this kind must be a work of great labour and expence as well as of time.

Of all those which have been undertaken by human industry, however, perhaps the most remarkable is that constructed by General Ptolemy, to represent the mountainous parts of Switzerland. It is composed of 142 compartments, of different sizes and forms, respectively numbered, and so artfully put together, that they can be separated and replaced with the greatest ease. The model itself is 204 feet long and 12 broad, and formed on a scale which represents two English miles and a quarter by an English foot; comprehending part of the cantons of Zug, Zurich, Schwitz, Underwalden, Lucerne, Berne, and a small part of the mountains of Glarus; in all, an extent of country of 18 leagues in length and 12 in breadth. The highest point of the model, from the level of the centre (which is the lake of Lucerne), is about ten inches; and as the most elevated mountain represented therein rises 1475 toiles.
MOD [ 190 ]

MODELLA. To 940 f 9 feet above the lake of Lucerne, at a gross calculation, the height of an inch in the model is about 900 feet. The whole is painted of different colours, in such a manner as to represent objects as they exist in nature; and so exactly is this done, that not only the woods of oak, beech, pine, and other trees, are distinguished, but even the strata of the several rocks are marked, each being laped upon the spot, and formed of granite, gravel, or such other substances as compose the natural mountain. So minute also is the accuracy of the plan, that it comprises not only all the mountains, lakes, rivers, towns, villages, and forests, but every cottage, bridge, torrent, road, and even every path is distinctly marked.

The principal materials employed in the construction of this extraordinary model, is a mixture of charcoal, lime, clay, a little pitch, with a thin coat of wax; and so hard that it may be trod upon without any damage. It was begun in the year 1766, at which time the general was about 50 years of age, and it employed him till the month of August 1785; during which time the top of the spot, extended to 1400 feet above the level of the Mediterranea.

MODELLA, a duchy of Italy, bounded on the north by Tuscany and the republic of Lucca, on the north by the duchy of Mantua, on the east by the Bologna and the territories of the church, and on the west by the duchy of Parma, extending in length from south to north about 56 English miles, and in breadth between 24 and 36, and yielding plenty of corn, wine, and fruits, with mineral waters. In some places also petroleum is skimmed off the surface of the water of deep wells made on purpose; and in others is found a kind of earth or tophus, which, when pulverised, is said to be an excellent remedy against fevers, dysesthesia, and hypochondriac disorders. The country of La Saffa affords several kinds of petroleums. The principal rivers are the Croffolo, Secchia, and Panaro. The family of Este, dukes of Modena, is very ancient. They had their name from Este, a small city in the district of Parma. In 1753, a duke was appointed imperial vicar-general, field-marshall, and governor, of the Milanese during the minority of the archduke Peter Leopold, who was declared governor-general of the Austrian Lombardy. The duke, though a vassal of the empire, had an unlimited power within his own dominions.

MODENA, an ancient city, in Latin Mutina, which gives name to a duchy of Italy, and is its capital. It stands 26 miles east of Parma, 44 almost south of Mantua, and 20 west of Bologna; and is a pretty large and populous, but not a handsome city. It is much celebrated by Roman authors for its grandeur and opulence; but it was a great sufferer by the siege it underwent during the troubles of the triumvirate. It hath long been the usual residence of the dukes; and is also the see of a bishop, who is suffragan to the archbishop of Bologna. Mr Keyfier says, that when Decius Brutus was besieged here by Mark Antony, Hirtius the conful made use of carrier-pigeons; and that, even at this day, pigeons are trained up at Modena to carry letters and bring back answers. This city hath given birth to several celebrated persons, particularly Tasso the poet, Correggio the great painter, Signorus the civilian and historian, da Vignola the architect, and Montecucchi the imperial general. The tutelary saint of it is named Gennianus. The ducal palace is a very noble edifice, in which, among the other fine pictures, the birth of Christ by Correggio, called la Nativé Felice, is much celebrated. The only manufacture for which this city is noted, is that of masts, of which great numbers are exported. The churches of the Jesuits, of the Theatines, and of St Dominic, are well worth viewing. In the college of St Carlo Borromeo between 70 and 80 young noblemen are continually maintained, and instructed both in the sciences and gentle exercises. St Beatrix, who was of the family of Este, is said to knock always at the gate of the palace three days before any of the family dies. Before most of the houses are covered walks or porticos, as at Bologna. The city is fortified, and on its south side it has the citadel.

MODERATION, in ethics, is a virtue consisting in the proper government of our appetites, passions, and pursuits, with respect to honours, riches, and pleasures; and in this sense it is synonymous with temperance; it is also often used to denote candour.

MODERATOR, in the schools, the person who presides at a dispute, or in a public assembly: thus the president of the annual assembly of the church of Scotland is styled moderator.

MODERN, something new, or of our time; in opposition to what is antique or ancient.

MODERN Authors, according to Naude, are all those who have wrote since Boethius. The modern philosophy commences with Galileo; the modern astronomy with Copernicus.

MODESTY, in ethics, is sometimes used to denote humility; and sometimes to express chaffity, or purity of sentiments and manners.—Modesty, in this last sense, and as particularly applied to women, is defined by the authors of the Encyclopédie Méthodique, as a natural, chary, and homely flame; a secret fear; a feeling
feeling on account of what may be accompanied with disgrace. Women who profess only the remains of a
специфическому modesty, make but feeble efforts to refist: those who have obliterated every trace of modesty from
their countenance, soon extinguish it completely in their soul, and throw aside for ever the veil of decency. She, on the contrary, who truly professes modesty, pauses over in silence attempts against her honour, and
forbears speaking of those from whom she has received an outrage, when in doing so the must reveal actions and expressions that might give alarm to virtue.

The idea of modesty is not a chimera, a popular prejudice, or an illusion arising from laws and education.
Nature, which speaks the same language to all men, has, with the unanimous consent of nations, annexed contempt to female incontinence. To refist and to attack are laws of her appointment: and while the bel lows defires on both parties, they are in the one accompanied with boldneis, in the other with flame. To individuals she has allotted long spaces of time for the purposes of self-preservation, and but moments for the propagation of their species. What arms more gentle than Modesty could she have put into the hands of that sex which she designed to make refi

If it were the custom for both sexes to make and receive advances indiscriminately, vain importunity would not be prevented: the fire of passion would never be stifled, but languish in tedious liberty; the most amiable of all feelings would scarcely warm the human breast; its object would with difficulty be attained. That obstacle which seems to remove this object to a distance, in fact brings it nearer. The veil of shame only makes the fires more attractive. Modesty kindles that flame which it endeavours to suppress: its fears, its evaions, its caution, its timid avowals, its pleasing and affecting finesse, speak more plainly what it wishes to conceal, than passion can do without it: it is Modesty, in short, which enhaces the value of a favour, and mitigates the pain of a refulal.

Since modesty is the secret fear of ignominy; and since all nations, ancient or modern, have confided the obligation of its laws; it must be absurd to violate them in the punishment of crimes, which should always have for its object the re-establishment of order. Was it the intention of those oriental nations, who when he does not express concerning the tu

Exposed women to elephants, trained for an abominable species of punishment, to violate one law by the obfervation of another? By an ancient practice among the Romans, a girl could not be put to death before she was marriageable. Tiberius found means to evade this law by ordering them to be violated by the executioner previous to the infliction of punishment; the refinement of a cruel tyrant, who sacrificed the morals to the customs of his people! When the legislature of Japan caused women to be exposed naked in the market-places, and obliged them to walk on all-fours like brutes, modesty was shocked: but when it wanted to force a mother—when it wanted to compel a son—nature received an outrage.

Such is the influence of climate in other countries, that the physical part of love poiffesse an almost irresistible force. The refilience is feeble; the attack is accompanied with a certainty of success. This is the

cafe at Patana, at Bantam, and in the small kingdoms on the coast of Guinea. When the women in these
countries (fays Mr Smith) meet with a man, they lay hold of him, and threaten to inform their husbands if he defpies their favours. But here the fexes seem to have abolished the laws peculiar to each. It is fortunate to live in a temperate climate like ours, where that fex which poiffesses the moft powerful charms exerts them to embellifh society; and where modest women, while they referve themselves for the pleasures of one, contribute to the amufement of all.

MODIFICATION, in philosophy, that which modifies a thing, or gives it this or that manner of being. Quantity and quality are accidents which modify all bodies.

Decree of Modification, in Scots law, a decree ascertaining the extent of a minister’s stipend, without proportioning it among the persons liable in payment.

MODILLIONS, in architecture, ornaments in the cornice of the Ionic, Corinthian, and Composite columns.

MODIUS, a Roman dry measure for all sorts of grain, containing 32 hemine, or 16 sextarii, or one-third of the amphora, amounting to an English peck. See Measure.

MODREVIUS (Andreas Frichius), secretary to Sigismund Augustus king of Poland, acquired considerable reputation by his learning and works. He broke off from the Roman church, favoured the Lutherans and Anti-trinitarians, and took great pains in order to unite all Christian societies under the same communion. Grotius has placed him in the class of the reconcilers of the different schemes of religion. His principal work is intituled, De republica emm-
danda.

MODULATION, the art of forming any thing to certain proportion.

MODULATION, in reading, or speaking. See Reading.

MODULATION, in music, derived from the Latin modularis. This word in our language is susceptible of several different significations. It frequently means no more than an air, or a number of musical sounds properly connected and arranged. Thus it answers to what Mr Malcolm understands by the word tone, when he does not expressly treat concerning the turning of instruments. Thus likewise it expresses the French word chant; for which reason, in the article Music, we have frequently expressed the one word by the other. But the precise and technical accception to which it ought to be confined, is the art of composing melody or harmony agreeably to the laws prescribed by any particular key, that of changing the key, or of regularly and legitimately passing from one key to another. In what remains to be said upon the subject we follow Rouffeau.

Modulation (fays he) is properly the manner of apearthing and managing the modes; but at this time the word most frequently signifies the art of conducting the harmony and the air successively through several modes, in a manner agreeable to the ear and conformed to rules.

If the different modes be produced by harmony, from whence likewise must spring the laws of modulation.
The laws are simple in conception, but difficult in practice. We proceed therefore to show what they are.

To modulate properly in the same key, it is necessary, 1. To run through all the sounds of it in an agreeable air, frequently repeating the sounds which are most essential to it, and dwelling upon these sounds with the most remarkable emphasis; that is to say, that the chord containing the sensible notes, and that of the tonic, should frequently be heard in it, but under different appearances, and obtained by different procedures to prevent monotony. 2. That repose or cadences should only be established upon these two chords: the greatest liberty, however, which ought to be taken with the rule is, that a cadence or repose may be established on the chord of the sub-dominant. 3. In short, that none of the sounds of the mode ought ever to be altered; for without quitting it we cannot introduce a sharp or a flat which does not belong to it, nor abstract any one which in reality does belong to it.

But passing from one mode to another, we must consult analogy, we must consider the relations which a key bears to the other notes in the series, and to the number of sounds common to both the modes, that from whence we pass, and that into which we enter.

If we pass from a mode major, whether we consider the fifth from the key as having the most simple relation with it except that of the octave, or whether we consider it as the first found which enters into the harmonies of the same key, we shall always find, that this fifth, which is the dominant of the mode, is the chord upon which we may establish the modulation most analogous to that of the principal key.

This dominant, which constitutes one of the harmonics of the first key, makes also one of its own peculiar key, of which it is the fundamental found. There is then a connection between these two chords. Besides, that same dominant carrying, as well as the tonic, a perfect chord major upon the principle of resonance, these two sounds are only different one from the other by the diapason, which passing from the key to the dominant is the fifth superadded, and when ascending from the dominant to the key is the seventh. Now these two chords, thus distinguished by the diapason which is suitable to each, by the founds which compose them when ranged in order, form precisely the octave, or the diatonic scale, which we call a gamut, which determines the mode.

This same series of the key, altered only by a sharp, forms the scale belonging to the mode of the dominant; which shows how striking the analogy is between these two tones, and gives the easiest opportunity of passing from one to the other by means of one single alteration alone. The mode then of the dominant is the fifth which presents itself after that of the key in the order of modulations.

The same simplicity of relations which we find between a tonic and its dominant, is likewise found between the same tonic and its sub-dominant: for that fifth, in ascending, which is formed by the dominant with the tonic, is likewise formed by the sub-dominant in descending: but that sub-dominant does not form a fifth with the tonic, except by inversion; it is directly a fourth, if we take that tonic below, as it ought to be; and which fixes the degree of their relations: for in this sense the fourth, whose ratio is 3 to 4, immediately follows the fifth, whose ratio is 2 to 3. So that, if that sub-dominant does not enter into the chord of the tonic, in return the tonic enters into its perfect chord. For let ut mi fol be the chord of the tonic, that of the sub-dominant shall be fa la ut: thus it is the ut which here forms the connection, and the two other sounds of this new chord, are exactly the two dissonances of the preceding. Besides, we need not alter more sounds for this new mode than for that of the dominant; they are both, in one and the other quite the same chords of the principal mode, except one. And a flat to the sensible note fi or B, and all the notes in the mode of ut or C will serve for that of fa or E. The mode of the sub-dominant then is scarcely less analogous to the principal mode than that of the dominant.

It ought likewise to be remarked, that after having made use of the first modulation in order to pass from a principal mode ut or C, to that of the dominant fol or G, we are obliged to make use of the second to return to the principal mode: for if fol or C be the dominant in the mode of ut or C, ut is the sub-dominant in the mode of fol: thus one of these modulations is no less necessary than the other.

The third sound which enters into the chord of the tonic is that of a third formed by its mediant; and after the preceding, it is likewise the most simple of relations. Here then is a new modulation which presents itself, and which is so much the more analogous, because, two of the sounds of the principal tonic enter likewise into the minor chord of its mediant: for the former chord being ut mi fol, the latter must be mi fol fi, where it may be perceived that mi and fol are common. But what renders this modulation a little more remote, is the number of sounds which are necessary to be altered, even for the minor mode, which is most suitable to this mi. In the article Music (234.) will be found a table for all the modes; and Rousseau, in his Musical Dictionary, has given the formula of a scale both for the major and minor: now, by applying this formula to the minor mode, we find nothing in reality, but the fourth found fa heightened by a sharp in ascending; but in rising, we find two others which are altered, viz. the principal tonic ut, and its second re, which here becomes a sensible note; it is certain that the alteration of so few sounds, and particularly of the tonic, must remove the mode and weaken the analogy.

If we should invert the third as we have inverted the fifth, and take that third below the tonic on the sixth note la, which ought here to be called a sub-mediant, or the mediant below, we shall form upon this note la a modulation more analogous to the principal tone than that of mi: for as the perfect chord of this sub-mediant is la ut mi, there once more we find, as in that of the mediant, two of the sounds which enter into the chord of the tonic, viz. ut and mi: and moreover, since the scale of this new key is composed, at least in descending, of the same sounds with that of the principal key; and since it has only two sounds altered in ascending, that is to say, one fewer than the series of the
the mediant; it follows that the modulation of this
sixth note is preferable to that of the mediant: and by
so much the more, that there the principal tonic forms
one of the sounds essential to the mode: which is more
proper for approximating the idea of the modulation.
The mi may afterwards follow.
Here then are four sounds, mi fa fol la, upon each
of which we may modulate in passing from the major
mode of ut. Re and fi remain, which are the two
harmonics of the dominant. This last being a sen-
fible note, cannot become a tone by any proper mo-
dulation, at least it cannot immediately become one:
this would be an abrupt application of ideas too much
opposed to the same found, and would likewise be to
give it a harmony too remote from the principal found,
As to the second note re, we may likewise, by favour
of a consonant procedure in the fundamental scale, mo-
dulate upon it in a third minor: but this must be only
continued for an instant, that the audience may not
have time to forget the modulation of ut, which is it-
sel altered in that place: otherwise, instead of returning
immediately to ut, we must pass through interme-
diate modes, where we must run great hazard of de-
viation.
By following the same analogies, we may modulate
in the following order, to make our exit from a minor
mode; first upon the mediant, afterwards the domi-
nant, next the sub-dominant, then the sub-mediant, or
sixth note. The mode of each of these accessory keys is
determined by its mediant taken from the principal
found. For instance, issuing from the major mode of
ut, to modulate upon its mediant, we render the mode
of that mediant minor; because fi, the dominat of
the principal found, forms a third minor with that me-
diant, which is mi. On the contrary, in our egress
from the minor mode of la, we modulate upon its me-
diant ut in the major mode; because mi, the dominat
of the tone from whence we issue, forms a third major
with the key of that into which we enter, &c.
These rules, comprehended in one general formula,
import, that the modes of the dominant and of the
sub-dominant are like that of the tonic, and that the
mediant and the sixth note require a mode opposed.
We must, however, remark, that, by the right which
we have of passing from the major to the minor, and
vice versa, upon the same key, we may likewise change
the order of modes from one key to another: but
while we thus remove ourselves from the natural mo-
dulation, we must presently think of our return; for
it is a general rule, that every piece of music ought to
terminate in that key with which it began.
In his Musical Dictionary, plate B, fig. 6, and 7,
Rouffeau has collected in two examples which are very
short, all the modes to which we may immediately pass:
the first, in passing from the major mode; and the se-
cond, from the minor. Each note indicates a parti-
cular modulation: and the value of the notes in each
example likewise shows the relative duration suitable
to each of these modes, according to its relation with
the principal.
These immediate transitions from one mode to an-
other, furnish us with the means of passing by the same
rules to modes still more remote, and thence to return
to the principal mode, of which we never should
lofe sight. But it is not sufficient to know what course
we ought to pursue; we must likewise be acquainted
with the method of entering into it. A summary there-
fore of the precepts which are given in this department
shall immediately follow.
In melody, in order to discover and introduce the
modulation which we have chosen, nothing is necessary
but to render perceptible the alterations which it cau-
ses in the sounds of that mode from whence we issue, to
make them proper for the mode into which we enter.
Are we now in the major mode of ut? there needs no
more than to found the note fa sharp, that we may
discover the mode of the dominant; or a fi flat, that
we may shew the mode of the sub-dominant. After-
wards you may run over the sounds essential to the
mode in which we enter: if it is well chosen, your
modulation will always be just and regular.
In harmony, the difficulty is a little increased: for
as it is necessary that the change of modes should be
made at the same time through all the parts, care must
be taken of the harmony, and of the air, that we may
avoid pursuing different modulations at the same time.
Huygens has happily remarked, that the prohibition
of two sixths in immediate succession proceeds upon this
rule as its principle; in reality, between two parts it
is scarcely possible to form a number of just sixths in
uninterrupted succession without operating in two dif-

erent modes.
To introduce a mode, a great many pretend that it
is sufficient to form the perfect chord of its principal
found, and this is indispensable in order to produce the
mode. But it is certain, that the mode cannot be ex-
sactly determined but by the chord containing the sen-
fible note, or the dominant: we must then cause this
chord to be heard when we enter into a new modula-
tion. The most eligible rule would be, That in the
seventh, or minor dissonance, should always be prepa-
red, at least the first time in which it is heard; but this
method is not practicable in every admissible modula-
tion: and provided that the fundamental basins proceed
by consonant intervals, that the connection of harmony
be observed, the analogy of the mode pursed, and
dissolute relations avoided, the modulation will always be
approved. Composers prescribe as another rule, That
a mode should not be changed except after a perfect
cadence; but this interdict is useless, and no person
observes it.
All the possible methods of passing from one mode
to another, are reducible to five with respect to the
major mode, and to four with respect to the minor
which, in the Musical Dictionary, plate B, fig. 8. will
be found implied in a fundamental basis intended for
each modulation. If there be any other modulation
which cannot be resolved into some one of these five,
unless that modulation be enharmonic, it must infalli-

dibly be illegitimate. See ENHARMONIC.

MODULE, in architecture, a certain measure, or
bigness, taken at pleasure, for regulating the propor-
tions of columns, and the symmetry or disposition of
the whole building. Architects generally choose the

equidistance of the bottom of the column for their
module, and this they subdivide into parts or min-
utes.

MOEBIUS (Godfrey), professor of physic at Iena, was
M O G  [ 194 ]  MO G

was born at Lauch in Thuringia in 1611. He became first physician to Frederic William elector of Brandenburg, to Augustus duke of Saxony, and to William duke of Saxe-Weimar. He wrote several medical works, which are esteemed; and died at Halle, in Saxony, in 1664.

MOENUS (Caicus), a celebrated Roman consul, conqueror of the ancient Latins, 38 B. C. He was the first who hung up the prows, &c. of the galleys he had taken at the naval engagement of Actium, upon the place where the tribunes harangued the people; from whence it was called the rostra.

MEONIA, or MEONIA. See MEONIA and LYDIA.

MESIA, or MYRIA, (anc. geog.) a country of Europe, extending from the confines of the Savus and the Danube to the shores of the Euxine. It was divided into Upper and Lower Mesia. Lower Mesia was on the borders of the Euxine, and comprehended that tract of country which received the name of Pontus from its vicinity to the sea. Upper Mesia lay beyond the other, in the inland country.

MOFFAT, a village of Scotland, in the shire of Annandale, 50 miles south-west of Edinburgh; famous for its sulphurous well, which has been in full estimation for near 150 years as a remedy in all cutaneous and scrophulous complaints; and for its chalybeate spring, perhaps the strongest in Britain, which was discovered about 45 years ago, and is of a very bracing quality. The place is chiefly supported by the company who resort thither for the benefit of their health, and contains many good and even elegant lodgings, with nothing remarkable. In his reign was discovered about 340 miles south-west of Edinburgh; famous for its sulphurous well, which has been in full estimation for near 150 years as a remedy in all cutaneous and scrophulous complaints; and for its chalybeate spring, perhaps the strongest in Britain, which was discovered about 45 years ago, and is of a very bracing quality. The place is chiefly supported by the company who resort thither for the benefit of their health, and contains many good and even elegant lodgings, with nothing remarkable.

MOFFETTA. See AMPSANCTI.

MOGODORE, or MOGADORE, a large, uniform, and well-built town in the kingdom of Morocco, situated about 350 miles south-west of Tangier on the Atlantic ocean, and surrounded on the land-side by deep and sandy bays. The European factory here consists of about a dozen mercantile houses of different nations, whose owners, from the protection granted them by the emperor, live in full security from the Moors, whom indeed they keep at a rigid distance. They export to America, mules; to Europe, Morocco leather, hides, gum arabic, gum sandarac, ostrich feathers, copper, wax, wool, elephant's teeth, fine mats, beautiful carpeting, dates, figs, raisins, olives, almonds, oil, &c. In return, they import timber, artillery of all kinds, gunpowder, woollen cloths, linens, lead, iron in bars, all kinds of hardware and trinkets, such as looking-glasses, snuff-boxes, watches, small knives, &c. tea, sugar, spices, and most of the useful articles which are not otherwise to be procured in this empire. The town is regularly fortified on the sea-side; and on the land, batteries are so placed as to prevent any incursion from the southern Arabs, who are of a turbulent disposition, and who, from the great wealth which is known to be always in Mogadore, would gladly avail themselves of any opportunity that offered to pillage the town. The enclosure, both by sea and land, consists of elegant stone arch-ways, with double gates. The market-place is handsomely built, with piazzas of the same materials; and at the water-port there is a custom house and powder magazine, both of which are neat stone buildings. Besides these public edifices, the emperor has a small but handsome palace for his personal residence. The streets of the town, though very narrow, are all in straight lines; and the houses, contrary to what we meet with in the other towns of the empire, are lofty and regular. The bay, which is little better than a road, and is very much exposed when the wind is north-west, is formed by a curve in the land, and a small island about a quarter of a mile from the shore.—Its entrance is defended by a fort well furnished with guns.

MOGULS, a celebrated nation of Asia, whose conquests formerly were the most rapid and extensive of any people recorded in history. They themselves deduce their origin from Japheth, or, as they call him, Japhes, the son of Noah. His son Turk, they say, was the first king, or khan, of those nations who are now known by the separate names of Turks Tartars, and Moguls; and the Tartars especially, affect that their proper designation is Turks. To this prince is attributed many of those inventions which barbarous nations commonly ascribe to their first sovereigns. He was succeeded by Tannak; in whose reign the whole power of Turk were divided into four large tribes, denominated the orde's of Erlat, Gialair, Kaugin, Berlais or Perlas; of which last came the famous Timur Beg, or Tamerlane.—From this time to that of Alanza Khan, we meet with nothing remarkable. In his reign the Turks being immersed in all kinds of luxury, universally apostatized into idolatry. Having two sons, Tartar and Mogul, he divided his dominions among them; and thus gave rise to the two empires of the Tartars and Moguls.

The two nations had not long existed before they began to make war upon each other, and after long contention, the event at last was, that Khan, emperor of the Moguls, was totally overthrown by Siuntz Almst ex-Khan, emperor of the Tartars; and so great was the terminated defeat, that the Mogul nation seems to have been almost exterminated. Only two of Khan's family survived this disaster. These were Kajen his eldest son, and Nagos his nephew, who were both of an age, and had both been married the same year. These two princes, with their wives, had been taken prisoners by Siuntz Khan, but found means to make their escape to their own country. Here they feized upon all the cattle which had not been carried off by the Tartars; which was easily done, as having none to dispute about the property with them; then stripping some of the slain, they took their clothes, and retired into the mountains. They passed several mountains without much difficulty; but at last advanced to the foot of one exceedingly high, which had no way over it but a very small path made by certain animals, called in the Tartar language, arilarna. This path they found themselves obliged to make use of, though it was too frightful, that only one could pass at a time, and he was in the most imminent danger of breaking his neck at the least fall. Step:

Having
Moguls. [ 195 ]

Having ascended the mountain on one side by this path, they defcended by the same on the other side; and were agreeably surprized to find themselves in a most delightful track, interspersed with rivulets and charming meadows, abounding with a vaft variety of delicious fruits, and inclofed on all sides by inaccessible mountains, in fuch a manner as to shelter them from all future purfuits of the Tartars. Here they lived fome time, and gave this beautiful country the name of Irgana-kon, in allufion to its situation; Irgana signifying, in the old language of the Moguls, a "valley," and Kon a "deep height."

In procfs of time these two families very much increafed. Kajam, whole polterity was the moft nume­rous, called his defcendants Kojath: but the people springing from Nagos were divided into two tribes; one of which received the appellation of Nagelger, and the other that of Durlandan.

These two Mogul princes and their defcendants li­ved in this place for more than 400 years; but the latter then finding it too narrow for them, meditated a return to the country from which their forefathers had been driven. For fome time, however, they found this impracticable, as the path that conduced their ance­tors had been long fince deftroyed. At laft they di­covered, that one part of the high mountain above-mentioned was not very thick in a certain place; and alfo, that it confined entirely of iron-ore. To this, having before set fire to a layer of wood, and another of charcoal, laid along the foot of the mountain, they applied 70 large bellows, and at laft melted the moun­tain in fafh a manner, that an opening was made large enough for a loaded camel to pafs; and through this paftage they all marched out with great joy.

The Moguls having thus left it as were from a new world, overthrew the Tartars in their turn; and continued to be a very confiderable nation till the time of their great hero Temujin, afterwards called Jenghis Khan, whom they extol in the moft extravagant manner. It is difficult, however, to fay, at the time Temujin made his appearance, how far the dominions of the Moguls extended, or in what elfimation they were held by their neighbours. It feems to be pretty certain, that great part of the vaft region now known by the name of Tartary, was then in a state of confider­able civilization, and likewise extremely populous, as we find mention made of many cities which the Mo­guls deftroyed; and the incredible multitudes whom they flaughrer, abundantly fhow the populousness of the country.

On the eft, the country of the Moguls and Tartars had the great defart which divides Tartary from China; on the weft, it had the empire of Karazm, founded by Mahmud Gazi; and on the fhore were the countries now known by the name of Indofhan, Siam, Pegu, Tenquin, and Cochin-China. Thus it comprehended the eftern part of modern Tartary, and all Siberia. This whole region was divided among a large number of Amacks, or tribes; who bad each, one or more khans, according as it was more or les numerous, or divided into branches. Among thefe, that of the Kara-its was the moft powerful; their prince afumed the title of Grand Khan, and among the reft, the Moguls were tributary to him; but, according to the Chinefe historians, both the one and the other were tributary to the emperor of Kitay or Katay. China was divided into two parts; the nine southern provinces were in the hands of the Chinese emperors of the Song dynasty, who kept their court at Hang-chew, the capital of the province of Chek­yang; the five northern provinces, excepting part of Shenü, were deftroyed by the Kin, a people of Eastern Tartary, from whom are defcended the Mancheh Tartars, at prefent masters of China. This vaft domi­nation was named Kitay or Katay, and was divided into two parts: that which belonged to China, was properly called Kitay; and the part which belonged to Tartary was called Karakhat, in which fome even include the territories of the Moguls, Karakit, and other tribes, which are the fubject of the prefent his­tory. The western part of the empire of Kitay was deftroyed by a Turkish prince, who had lately founded a new kingdom there, called Hya; whole capital city was Hyauchew, now Ninghya in Shenü, from whence the kingdom took its name. To the west of Hya lay Tangt; a country of great extent, and formerly very powerful; but at that time reduced to a low frate, and divided among many princes some of whom were fubjet to the emperor of Hya, and others to the em­peror of China. All Tartary to the weftward, as far as the Cafffnian fea, with the greater part of Little Buckharia, which then paffed under the general name of Turkeftan, was fubjet to Ghurkhan, Khurkhan, or Kavar Khan; to whom even the Gazi monarchs are faid to have been tributary.

Thus the Moguls, properly fO called, had but a very Defcent and birth of Temujin.

From whence they at laft defteat the Tartars.

Then was the Mogul dynasty, who kept their court in the hands of the Kins, a people of

State of Asia at the time of Jenghis Kahn.

Subjefts of his revolted fubjefts by means of Vang Khan.

This
This happened in the year 1201; but Vang Khan, instead of continuing the friend of Temujin, now became jealous, and resolved to destroy him by treachery. With this view he proposed a marriage between Temujin's son Juji and his own daughter, and another between Temujin's daughter and his own son. Temujin was invited to the camp of Vang Khan, in order to celebrate this double marriage; but, receiving intelligence of some evil intention against him, he excused himself to Vang Khan's messengers, and defrayed that the ceremony might be put off to some other time.

A few days after the departure of these messengers, Badu and Kihlik, two brothers, who kept the herds of one of Vang Khan's chief domestics, came and informed Temujin, that the grand Khan finding he had misled his aim, was resolved to set out instantly, and surprise him next morning, before he could suspect any danger. Temujin, alarmed at this intelligence, quit his camp in the night-time, and retired with the ceremony might be put off to some other time.

By this quarrel almost all the princes of Tartary were put in motion, some siding with Temujin, and others with Vang Khan. But at last fortune declared in favour of the former. Vang Khan was overthrown in a battle, when he had 4000 men; and obliged to fly for refuge to a prince named Tagyan Khan, who was Temujin's father-in-law, and his own enemy, and by whom he was ungenuinely put to death. Temujin immediately began to seize on his dominions, great part of which voluntarily submitted; but a confederacy was formed against him by a number of Vang Khan's tributaries, at the head of whom was Jamuka, a prince who had already distinguished himself by his enmity to Temujin; and even Tagyan Khan himself was drawn into the plot, through jealousy of his son-in-law's good fortune. But Temujin was well prepared; and in the year 1204 attacked Tagyan Khan, entirely routed his army, killed himself, and took Jamuka prisoner, whose head he caused instantly to be struck off; after which he marched against the other tribes who had conspired against him. Then he quickly reduced; took a city called Kafian, where he put all to the sword who had borne arms against him; and reduced all the Mogul tribes in 1205.

Temujin now, having none to oppose him, called a general diet, which he appointed to be held on the first day of the spring 1206; that is, on the day in which the sun entered Aries. To this diet were summoned all the great lords both Moguls and Tartars; and in the mean time to establish good order in the army, he divided his soldiers into bodies of 10,000, 1000, 100, and 10 men, with their respective officers, all subordinate to the generals, or those who commanded the bodies of 10,000; and these were to act under his own sons. On the day of holding the diet, the princes of the blood and great lords appeared dressed in white. Temujin, dressed in the same manner, with his crown on his head, sat down on his throne, and was complimented by the whole assembly, who wished him the continuance of his health and prosperity. After this they confirmed the Mogul empire to him and his successors, adding all those kingdoms which he had subdued, the descendants of whom were deprived of all right or title to them; and after this he was proclaimed emperor with much ceremony. During this inauguration, a pretended prophet declared that he came from God to tell the assembly, that from thenceforth Temujin should assume the name of Jenghis Khan, or the Most Great Khan of Khans; prophesying also, that all his posterity should be Khans from generation to generation. This prophecy, which was no doubt owing to Temujin himself, had a surprising effect on his subjects, who from that time concluded that all the world belonged of right to them, and even thought it a crime against heaven for any body to attempt to resist them.

Jenghis Khan having now reduced under his subjection all the wandering tribes of Moguls and Tartars, began to think of reducing those countries to the south and south west of his own, where the inhabitants were much more civilized than his own subjects; and the countries being full of fortified cities, he must of course expect to meet with more resistance. He began with the emperor of Hya, whose dominions he invaded in 1209, who at last submitted to become his tributary. But in the mean time Jenghis Khan himself was supposed to be tributary to the emperor of Kitay; who, in 1210, sent him an officer, demanding the customary tribute. This was refused, with the utmost indignation, and a war was commenced, which ended not but with the dissolution of the empire of Kitay, as mentioned under the article CHINA.

In the year 1216, Jenghis Khan resolved to carry his arms westward, and therefore left his general Muchuli to pursue his conquests in Kitay. In his journey westward he overthrew an army of 300,000 Tartars who had revolted against him; and, in 1218, sent embassadors desiring an alliance with Mohammed Karazm Shah, emperor of Gazna. His embassador was haughtily treated: however, the alliance was concluded; but soon after broken through the treachery, as it is said, of the Karazmian monarch's subjects. This brought on a war attended with the most dreadful devastations, and which ended with the entire destruction of the empire of Karazm or Gazna, as related under the article Gazna.

After the reduction of Karazm, part of the Moguls broke into Iran or Persia, where also they made large conquests, while others of their armies invaded Georgia and the countries to the west; all this time committing such enormities, that the Chinese historians say both men and spirits burnt with indignation. In 1225, Jenghis Khan returned to Hya, where he made war on the emperor for having sheltered some of his enemies. The event was, that the emperor was slain, and his kingdom conquered, or rather destroyed; which, however, was the last exploit of this most cruel conqueror, who died in 1227, as he marched to complete the destruction of the Chinefe.

The Mogul empire, at the death of Jenghis Khan, extended over a prodigious tract of country, being of his empire more than 1800 leagues in length from east to west, and upwards of 1000 in breadth from north to south.
Mogul empire.

Its princes, however, were still inaffable, and pushed on their conquests on all sides. Oktay was acknowledged emperor after Jenghiz Khan had and under his immediate government Mogultejan (the country of the Moguls properly so called), Kayy, and the countries eastward to the Tartarian sea. Jazagul his brother governed under him a great part of the western conquests. The country of the Kipjacks, and others to the east and north-east, north and north-west, was governed by Batu or Patu the son of Juj, who had been killed in the wars; while Tuli or Toley, another son of Jenghiz Khan, had Khorasan, Persia, and what part of India was conquered. On the east side the Mogul arms were still attended with success; not only the empire of Kayy, but the southern part of China, was conquered, as already related under that article n° 24—42. On the west side matters continued much in the same way till the year 1254, when Mughul, or Merkho, the fourth khan of the Moguls, (the name which was afterwards killed at a siege in China*), raised a great army, which he gave to his brother Hulagu, or Hulagui, to extend his dominions eastward. In 1255 he entered Iran, where he suppressed the Ilmashans or Afsalians, of whom an account is given under the article Assassins; and two years afterwards he advanced to Bagdad, which he took, and cruelly put the khalif to death, treating the city with no more lenity than the Moguls usually treated those which fell into their hands. Every thing was put to fire and sword; and in the city and its neighbourhood the number of slain, it is said, amounted to 1,500,000. The next year he invaded Syria; the city of Damascus was delivered up, and, as it made no resistance, the inhabitants were spared; but Aleppo being taken by storm, a greater slaughter ensued there than had taken place at Bagdad, not even the children in their cradles being spared. Some cities of this country revolted the next year, or the year after; but falling again into the hands of the Moguls, they were plundered, and the inhabitants butchered without mercy, or carried into slavery.

Hulagu died in 1264, and at his death we may fix the greatest extent of the Mogul empire. It now comprehended the whole of the continent of Asia excepting part of Indostan, Siam, Pegu, Cochinchina and a few of the countries of Lesser Asia, which had not been attacked by them; and during all these vast conquests no Mogul army had ever been conquered, except one by Jalolidin, as mentioned under the article Gahna.—From this period, however, the empire began to decline. The ambition of the khans having prompted them to invade the kingdoms of Japan and Cochinchina, they were miserably disappointed in their attempts, and lost a great number of men. The fame had succés attended them in Indostan; and in a short time this mighty empire broke into several smaller ones. The governors of Persia being of the family of Jenghiz Khan, owned no allegiance to any superior; those of Tartary did the same. The Chinese throwed off the yoke; and thus the continent of Asia wore much the same face that it had done before Jenghiz Khan began his conquests.

The successors of Hulagu reigned in Persia till the year 1335; but that year Abulfid Khan, the eighth from Hulagu, dying, the affairs of that country fell into confusion for want of a prince of the race of Jenghiz Khan to succeed to the throne. The empire, therefore, was divided among a great number of petty princes, who fought against each other almost without intermission, till, in the year 1359, Timur Bek, or Tamerlane, one of these princes, having conquered a Tartaran number of others, was crowned at Balkh, with the crowned pomegranate title of Sahib Karan; that is, "the emperor of the world." As he had just before taken that city, and destroyed one of his most formidable rivals who had flnt himself up in it, the new emperor began his reign with beheading some of the inhabitants, imprisoning others, burning their houses, and selling the women and children for slaves. In 1370 he crossed the Sihun, made war on the Gata, and attacked Karazam. Next year he granted a peace to his enemies; but two years after, he again invaded the country of the Gataes, and by the year 1379 had fully conquered the country as well as Korazan; and from that time he continued to extend his conquests in much the same manner as Jenghiz Khan had done, though with less cruelty.—In 1387 he had reduced Armenia, Georgia, and all Persia; the conquest of which last was completed by the reduction of Ispahan, 70,000 of the inhabitants of which were slaughtered on account of a faction raised by some raih or evil disposed persons.

After the reduction of Persia, Timur turned his arms northward and westward, subduing all the countries to the Euphrates. He took the city of Bagdad; subdued Syria; and having ravaged great part of Ruffia, returned to Persia in 1396, where he splendidly feated his whole army. In 1398 he invaded Indostan, crossed the Indus on the 17th of September, reduced several fortresses, and made a vast number of captives. However, as he was afraid that, in case of any emergency, these prisoners might take part with the enemy; he gave orders to his soldiers to put all their Indian flames to death; and, in consequence of this inhuman order, more than 100,000 of these poor wretches were slaughtered in less than an hour.

In the beginning of the year 1399, Timur was met by the Indian army; whom, after a desperate battle, he defeated with great slaughter, and soon after took the city of Delhi, the capital of the country. Here he seated himself on the throne of the Indian emperors, and here the tharifs, kadis, and principal inhabitants of the city, came to make their submission, and begged for mercy. The tame elephants and rhinoceroses likewise were brought to kneel before him as they had been accustomed to do to the Indian emperors, and made a great cry as if they implored his clemency. These war elephants, 120 in number, were, at his return, sent to Samaracnd, and to the province where his sons resided. After this, at the request of the lords of the court, Timur made a great feast, at which he distributed presents to the princes and principal officers.

Delhi at this time consisted of three cities, called The city of Seyri, Old Delhi, and Jehan Penah. Seyri was sur: Delhi de-mounted with a wall in form of a circle. Old Delhi was the fame, but much larger, lying south-west of the other. These two parts were joined on each side by a wall; and the third, lying between them, was called ed. Jehan Penah, which was larger than Old Delhi. Penah...
MOG. [ 198 ]

The cause of this quarrel at first was, that Bajazet had demanded tribute from a prince who was under Timur's protection, and is said to have returned an insulting answer to the Tartar ambassadors who were sent to him on that account. Timur, however, who was an enthusiastic in the cause of Mahometanism, and considered Bajazet as engaged in the cause of heaven when besieging a Christian city, was very unwilling to disturb him in so pious a work; and therefore undertook several expeditions against the princes of Syria and Georgia, in order to give the Turkish monarch time to cool and return to reason. Among other places, he again invested the city of Bagdad which had cast off its allegiance to him; and having taken it by form, made such a dreadful massacre of the inhabitants, that 120 towers were erected with the heads of the slain. In the mean time Bajazet continued to give fresh provocation, by protecting one Kara Yufef a robber, who had even insulted the caravan of Mecca; so that Timur at length resolved to make war upon him. The sultan, however, foreseeing the danger of bringing such a formidable enemy as he felt himself, thought proper to ask pardon, by a letter, for what was past, and promise obedience to Timur's will for the future. This embassy was graciously received; and Timur returned for answer, that he would forbear hostilities, provided Bajazet would either put Kara Yufef to death, send him to the Tartar camp, or expel him out of his dominions. Along with the Turkish ambassadors he sent one of his own; telling Bajazet that he would march into the confines of Anatolia, and there wait his final answer.

Though Bajazet had seemed at first willing to come to an agreement with Timur, and to dread his superior power; yet he now behaved in such an unsatisfactory manner, that the Tartar monarch desired him to prepare for war; upon which he raised the siege of Constaninople, and having met Timur with an army greatly inferior to the Tartars, was utterly defeated and taken prisoner. According to some accounts, he was treated with great humanity and honour; while others inform us, that he was shut up in an iron cage, against which he dashed out his brains the following year. At any rate, it is certain that he was not restored to liberty, but died in confinement.

This victory was followed, by the submission of many places of the Lesser Asia to Timur; the Greek emperor owned himself his tributary, as did also the sultan of Egypt. After this Timur once more returned to Georgia, which he cruelly ravaged; after which he marched to Samarcand, where he arrived in the year 1405. Here, being now an old man, this mighty conqueror began to look forward to that state which at one time or other is the dread of all living creatures; and Timur, in order to quiet the remembrance of his own confidence, came to the following curious resolution, which he communicated to his intimate friends namely, that "as the vaft conquests he had made were not obtained without some violence, which had occasioned the destruction of a great number of God's creatures, he was resolved, by way of atonement for his past crimes, to perform some good action; namely, to make war on the infidels, and exterminate the idolaters of China." This atonement however, he did not live to accomplish; for he died the same year.
MOGULS, year of a burning fever, in the 71st year of his age and 36th of his reign.

On the death of Timur, his empire fell immediately into great disorder, and the civil wars continued for five or six years; but at last peace was restored, by the settlement of Shah Rukh, Timur's son, on the throne. He did not, however, enjoy the empire in its full extent, or indeed much above one half of it; having only Karazm, Khorasan, Kandahar, Persia, and part of Indostan. Neither was he able, though a brave and warlike prince, to extend his dominions, though he transmitted them to his son Ulug Beg. He proved a wise and learned monarch; and is famous for the astronomical tables which he caused to be composed, and which are well known at this day. He was killed in 1448 by his son Abdollah, who five months after was put to death by his own soldiers. After the death of Abdollah, Abdollah, a grandson of Shah Rukh, seized the throne; but, after reigning one year, was expelled by Abuhaddh Mirza, the grandson of Miran Shah the son of Timur. His reign was one continued scene of wars and tumults; till at last he was defeated and taken prisoner by one Haflan Beg, who put him to death in 1468. From this time we may look upon the empire of Timur as entirely dissolved, though his descendants still reigned in Persia and Indostan, the latter of which is still known by the name of the Mogul empire.

On the death of the abovementioned monarch, his son Babur or Babor succeeded him, but was soon driven out by the Ulbek Tartars; after which he retired some time in Gazna, whence he made incursions into Hindostan, and at length became master of the whole empire, excepting the kingdoms of Dekan, Guzerat, and Bengal. For the transactions subsequent to this period, see the articles Hindostan and India. What remains to be supplied here is an account of the revolution that has lately happened at Delhi the capital of the Mogul empire.

Gholam Khadur, author of the revolution, was the son of Zobada Khan. His father disinfanted him, and drove him from his presence on account of his vices and crimes. Shah Allum, the king of Delhi, took him under his protection, treated him as his own son, and conferred on him the first title in the kingdom, Amere ul Omrau. He lived with the king, and raised a body of about 5000 troops of his own countrymen the Moguls, which he commanded. Gholam Khadur was of a passionate temper, haughty, cruel, ungrateful, and debauched. In the latter end of the year 1788, the king had formed suspicions that some of the neighbouring rajahs (princes) would make an attempt to plunder and destroy his territories. These suspicions were verified by the approach of a considerable army towards his capital, commanded by Ismael Beg Khan, and assisted by Scindia. Gholam Khadur told the king on this, that he had nothing to fear; for that he had an army sufficiently strong to oppose the enemy: that all the king had to do was to march out with his troops, give them a supply of cash, and he would lay his head on the enemy's being overcome. The king on this replied, that he had no money to carry on the war. Gholam Khadur said, that this objection would soon be obviated, as he (Gholam Khadur) would advance the necessary supply of cash, and that all his majesty had to do was to head the army. "This (said he) will animate them and give them confidence; the presence of a monarch is above half the battle."

The king agreed in appearance, and requested Gholam Khadur to assemble the army, pay their arrears, and inform them of his intentions. Gholam Khadur retired contented: but great was his astonishment, when he intercepted the next day a letter from the king to Scindia, directing him to make as much haste as possible, and destroy Gholam Khadur; for, says he, Khadur wishes me to act contrary to my wishes, and oppose you. On this discovery, Gholam Khadur marched out with his Moguls, crost the Jumna, and encamped on the other side opposite the fort of Delhi. He sent to the king the intercepted letter, and asked him if his conduct did not deserve to be punished by the loss of his throne? He began to besiege the fort, and carried it in a few days. He entered the palace in arms; flew to the king's chamber; insulted the old man in the most barbarous manner; knocked him down, and, kneeling on his breast, with his knife took out one of his eyes, and he ordered a servant of the king's to take out the other.

After this he gave up the palace to pillage, and went to the king's zazana (the residence of his women); where he insulted the ladies, and tore their jewels from their noses and ears, and off their arms and legs. As he had lived with the king, he was well acquainted with the different places where the king's treasures were hid; he dug up the floor of the king's own bed-room, and found there two chests, containing in specie 120,000 gold mohurs, or L. 192,000 sterling; this he took, and vam furms more. To get at the hidden jewels of the women, he practised one of the most villainous schemes that ever was thought of. The third day after these horrid cruelties, he ordered that all the king's ladies and daughters should come and pay their respects to him, and promised to set those free who could please him by their appearance and drees. The innocent, unthinking women, brought out their jewels, and adorned themselves in their richest attire to please this savage. Gholam Khadur commanded them to be conveyed into a hall, where he had prepared common drees for them; these drees he made them put on by the ladies, and taking possession of their rich drees and jewels, sent the women home to the palace to lament their loss and curse his treachery. Gholam Khadur did not even stop here; but insulted the princesses, by making them dance and sing. The most beautiful of the king's daughters, Mobarak ual Moulk, was brought to this tyrant to gratify his lust; but the refusals, and is said to have stabbed herself in order to avoid force.

Scindia soon after this came to the assistance of the king, rather to make him his prey. Gholam Khadur fled and took refuge in the fort of Agra, a large city about 150 miles from Delhi. Scindia's troops besieged him there. Perceiving at last that he must be taken if continued in the fort, he took the advantage of a dark night, stuffed his faddle with a large flock of precious stones, took a few followers, and fled from the fort towards Persia. Unluckily for him, he fell off his horse the second night after his flight; by
MOHAIL, or MOEIL, one of the Comorra islands in the Indian sea, between the north end of the island of Madagascar and the continent of Africa. The inland parts are mountainous and woody; but the lands adjoining to the sea are watered by several fine streams which descend from the mountains; and the grass is green all the year, so that it affords a moat delightful habitation. There are plenty of provisions of all kinds; and the East India ships of different nations sometimes touch here for refreshment.

MOHIOF, a large and strong city of Poland, in the province of Lithuania, and palatinate of Mičiūnai. It is well built, populous, and has a considerable trade. Near this place the Swedes obtained a great victory over the Russians in 1707.

MOIDOIRE, a Portuguese gold coin, value 1l. 7s. Sterling.

MOINE (Medietas), the half of any thing.

MOINE (Peter le), was born at Chaumont in Balligni, A.D. 1602, and died at Paris August 22, 1672, aged 70. He joined the society of Jesuits, and enjoyed several offices among them. He is chiefly known by his verses, which were collected into one volume folio in 1671. Father le Moine is the first of the French poets belonging to that famous society, who acquired reputation by this species of writing. It cannot be denied that this poet possessed genius and fancy; but his imagination was un Governed, which is particularly the case in his poem of Saint Louis. De-
incréased, but not equally. Hence, according to Dr.
Bryan Robinson, we learn, that to keep a body of
the same weight in wet weather as in dry, either
the quantity of food must be increased, or the proportion
of the meat to the drink increased; and both these may
be done by lessening the drink without making any
change in the meat.

The instrument used for determining the degree of
moisture in the air, is called an hygrometer. See Hy-
grometer.

MOIVRE (Abraham), was born at Vitri in Cham-
pagne, A. D. 1667. His father was a surgeon. At
the revolution of the edict of Nantes, he determined to
fly into England rather than abandon the religion
of his fathers. Before he left France, he had begun the
study of Mathematics; and having perfected him-
self in that science in London, he was obliged, by the
means of his circumstances, to teach it. Newton’s
principia, which accidentally fell into his hands, 
shocked him how little progress he had made in a science
of which he thought himself master. From this work
he acquired a knowledge of the geometry of in-
finites with as great facility as he had learned the ele-
mentary geometry; and in a short time he was
fit to be ranked with the most celebrated mathemati-
cians. His successes in these studies procured him a
seat in the Royal Society of London and in the
Academy of Sciences at Paris. His merit was so well
understood in the former, that he was thought capa-
cible of deciding in the famous dispute between Leib-
iniz and Newton concerning the differential calculus.
—He published a Treatise on Chances in 1718,
—and another on annuities in 1733; both extreme-
ly accurate. The Philosophical Transactions con-
tain many interesting memoirs of his composition.—
Some of them treat of the method of fluxions; others
are on the lunula of Hippocrates; others on physical
astronomy, in which he resolved many important prob-
lems; and others, in short, on the analysis of the
games of chance, in which he followed a different
course from that of Montmort. Towards the close of
his life he lost his sight and hearing; and the demand
for sleep became so great that he required 20 hours
of it in a day. He died at London, 1754, aged 87.
His knowledge was not confined to mathematics;
but he retained to the last a taste for polite literature.
He was intimately acquainted with the best authors
of antiquity; and he was frequently consulted about
difficult passages in their works. Rabeilais and Mo-
lere were his favourite French authors; he had them
by heart; and he one day observed to one of his ac-
quaintances, “that he would rather have been
Molyer than Newton.” He recited whole scenes of the Mi-
flandre; with that delicacy and force with which he
remembered to have heard them recited at Paris 70
years before, by Molière’s own company. The char-
acter indeed was somewhat similar to his own. He
judged severely of mankind; and could never conceal
his disfavour at the conversation of a fool, nor his aves-
tion to cunning and dissimulation. He was free from
the affectation of science; and no one could know him
to be a mathematician but from the accuracy of his thoughts.
His conversation was general and
instructive. Whatever he said was well digested and
clearly expressed. His style possessed more strength
and solidity than ornament and animation; but he
was always correct, as he bestowed as much pains
on his sentences as on his calculations. He could never
endure any bold assertions or indecent witfiscisms against
religion. “I show you that I am a Christian (said
he one day to a person who thought to pay him a
compliment by observing that mathematicians were
attached to no religion), by forgiving the speech you
have now made.” The practice of giving emails to
servants was not laid aside in his time; and, on this
account, when a nobleman asked him why he did not
dine oftener with his lord (replied he), I cannot afford it.

MOLA (Pietro Francia), an eminent painter,
was born, according to most authors, at Lugano, a
city belonging to the Swiss, in the year 1609.
Others affirm, that the place of his birth was Colda,
in the district of Como. He was at first the disciple
of Giuseppe d’Arpino, and afterwards of Albano.
When he quitted the school of the latter, he went
to Venice, and studied avidly the pictures of Ti-
tian, Tintoretto, Bafan, and Paolo Veronese.
He painted historical subjects and landscapes with great
success; but his genius seemed more particularly adapted
to the latter. His pictures, in both styles, are spoken of with the warmest commendations. He
died in 1665.—He had a brother, Giovanni Battista,
who was also a painter, and of some merit, but very
inferior to that of the older.

MOLA, an ancient town of Italy, in the kingdom
of Naples, and in the Terra di Lavoro, where they
pretend to have found the ruins of Cicero’s house. It is
situated on the gulf of Venice, in E. Long. 17. 50. N. Lat.
41° 5’.
MOLASES (Salt Cake), in antiquity, was barley parch-
ed, and afterwards ground to meal or flour, then mixed
with salt and frankincense, with the addition of a
little water. Thus prepared, it was sprinkled between
the horns of the victim before it was killed in sacri-
fice. This act was called immolation, and was common to the Greeks as well as Romans; with this difference, that
the mola of the Romans was of wheat. The Greeks
called it μαθωματα.

MOLARES, or Dentes molares, in anatomy, the
large teeth, called in English the grinders. See An-
atomy, p. 27.

MOLASSES, or Molasses. See MOLasses.

MOLDAVIA, a province of Turkey in Europe,
bounded on the north-east by the river Niester, which
divides it from Poland; on the east, by Besjarabia; on
the south by the Danube, which parts it from Bulga-
ria; and on the west, by Walachia and Transylvania; it
being 240 miles in length and 150 in breadth. “It
lies in a great art and fruitful soil, producing corn,
wine, rich pastures, a good breed of horses, oxen,
sheep, plenty of game, fish, fowl, honey, wax, and all
European fruits. Its principal rivers are the Danube,
Niester, Pruth, Bardalac, and Ceret. The inhabi-
Gents are Christians of the Greek church, and Jassy
is the principal town. It has been tributary to the Turks
since the year 1574; who appoint a prince who is
a native of the country, but have no regard to his be-
ing of the principal families. They pay a large yearly
tribute, besides which, they are obliged to raise a great
body of horse at their own expense.

Vol. XII.
MOLE, a river in Surry, which has taken its name from running underground. It first disappears at Boxhill, near Dorking, in the county of Surry, and emerges again near Leatherhead.

MOLE, in zoology. See TALPA.

Moles in the fields may be destroyed by taking a head or two of garlic, onion or leek, and putting it into their holes; on which they will run out as if frightened, and you may kill them with a spear or dog. Or pounded hellebore, white or black, with wheat, the white of an egg, milk, and sweet-wine, or methyglin, may be made into a paste, and pellets as big as a small nut may be put into their holes: the moles will eat this with pleasure, and will be killed by it. In places where you would not dig nor break much, the fuming their holes with brimstone, garlic or other unfavourable things, drives them away; and if you put a dead mole into a common haunt, it will make them absolutely forswear it.

Or take a mole-phear or staff, and where you see them cast, go lightly but not on the side betwixt them and the wind, left they perceive you; and at the first or second putting up of the earth, strike them with your mole-staff downright, and mark which way the earth falls most: if the casts towards the left hand, strike somewhat on the right hand; and if on the contrary, to the casting up of the plain ground, strike down, and there let it remain; then take out the tongue in the staff, and with the spattle, or flat edge, dig round about your grain to the end thereof, to see if you have killed her; and if you have miffed her, leave open the hole and step aside a little, and perhaps the will come to flop the hole again, for they love but very little air; and then strike her again; but if you miss her, pour into the hole two gallons of water, and that will make her to come out for fear of drowning: mind them going out of a morning to feed or coming home when fed, and you may take a great many.

Mole, in midwifery, a mass of fleshy matter, of a spherical figure generated in the uterus, and sometimes mistaken for a child. See MIDWIFERY.

Mole, or Mark. See NAVIS.

Mole, in architecture, a massive work formed of large stones laid in the sea by means of coffin dams, extended either in a right line or an arch of a circle, before a port, which it serves to close; to defend the vessels in it from the impetuosity of the waves, and to prevent the passage of ships without leave. Thus we say the mole of the harbour of Meffaia, &c.

Mole is sometimes also used to signify the harbour itself.

MOLES (moleS) among the Romans, was also used for a kind of mafulium, built in manner of a round tower on a square base, inflate, encompassed with columns, and covered with a dome.—The mole of the emperor Adrian, now the castle of St Angelo, was the greatest and most flatly of all the moles. It was crowned with a brazen pine apple, wherein was a golden urn containing the ashes of the emperor.

Mole-cricket, in zoology. See GRILLO-TALPA.

MOLE-HILL. Thee little hillocks of earth are a very great prejudice to the pasture lands, not only in wasting so much of the land as they cover, but in hindering the scythe in mowing. In the west of England they use a peculiar instrument for the breaking up of these; it is a flat board, very thick, and of about eight inches in diameter, into which there is fastened a perpendicular handle of three or four feet long. It has four broad and sharp iron teeth at the front, which readily cut through the hill, and spread the earth it confines of; and behind there is a large knob proper for breaking the clods with, if there are any. Some use a spade, or other common instrument in the place of this, but not so well. This however, a much better instrument even than this, for destroying these hills where they are in very great numbers. This is a kind of horse-machine; it has a sharp iron about three feet over, and with a strong back.—It is about four or five inches broad, and has two long handles for a horse to be harnessed to, and a cross-bar of iron to strengthen it at the bottom of the handles, reaching from the one handle to the other. The middle of this cross-bar is furnished with one, two, or more sharp pieces of iron like small plough-shares, to cut the mole-hills into two, three or more parts. The iron behind is of a semicircular figure. A single horse is harnessed to this machine, and a boy must be employed to drive it, and a man to hold and guide it; the sharp irons or shares are the first things that meet the hill, they run through it, break its texture, and cut it into several parts; and the circular iron following immediately behind them, cuts up the whole by the roots, and leaves the land level. This instrument will destroy as many mole-hills in one day as a common labourer can in eight, and would be of very great advantage to the kingdom if brought into general use. It is to be observed, that this leaving a naked space in the place of every hill, it will be necessary to go over the land, and sow them with hay seed, otherwise these spots will want the produce of grass the first years. The farmers in some parts of England are not willing to destroy the mole-hills, but let them stand from year to year, supposing that they get some ground by them; but the advantage by this means is so little, that it does not balance the unprofitableness and damage to the mowing.

MOLESWORTH (Robert), Viscount Moleworth, an eminent statesman and polite writer, born at Dublin in 1656, where his father was a merchant. He was attained by King James for his activity on the prince of Orange's invasion; but the latter, when he was settled on the throne, called up Mr Moleworth into the privy-council, and sent him envoy-extraordinary to the court of Denmark. Here he resided above three years, and then returned upon some dispute, without an audience of leave. Upon his return, he drew up his Account of Denmark, a work well known, in which he represented that government as arbitrary; and hence gave great offence to George prince of Denmark. The Danish envoy presented a Memorial to King William concerning it; and then furnished materials for an answer, which was executed by Dr William King. Mr Moleworth was member of the houses of commons in both kingdoms; King George I. made him a commissioner of trade and plantations, and advanced him to the peerage of Ireland, by the title of Baron Philigbow, and Viscount Moleworth of Swords.
MOLIERE (John Baptift), a famous French co­median, whose true name was Poquelin, which for some reason or other he funk for that of Moliere. He was the fon of a valet de chambre, and was born at Paris about the year 1620. He went through the study of the clasfies under the Jesuit Molina, and was designed for the bar; but at his quitting the law­schools, he made choice of the actor’s profeflion. From the prodigious fondnefs he had had for the drama, his whole study and application being di­rected to the stage, he continued till his death to ex­hibit plays, which were greatly applauded. It is said the firit motive of his going upon the stage was to en­joy the company of an actress for whom he had con­trasted a violent fondnefs. His comedies are highly ef­teemed. And it is no wonder he fo juftly repre­fented domellic feuds, and the torment of jealous hub­bands, or of those who have reafon to be fo, it being af­ferted that no man ever experienced all this more than Moliere, who was very unhappy in his wife. His laft comedy was La Malade imaginaire, which was brought on the stage in 1673; and Moliere died on the fourth night of its representation; fonie fay in ac­ting the very part of the pretended dead man, which gave fonie exercife for the weaks of the time; but ac­­cording to others he died in his bed that night, from the burfting of a vein in his lungs by coughing. The king, as a laft mark of his favour, prevailed with the archbishop of Paris to fuffer him to be buried in con­fecrated ground; though he had irritatcd the clergy by his Tartuff. The moft efteemed editions of his works are that of Amdterdam, 5 vols 12mo, 1692; and that of Paris, 6 vols 4to, 1734.

MOLINA (Lewis), a Spanifh lawyer, who was employed by Philip II. king of Spain in the councils of the Indies and of Caftrile. He is the author of a learned tratfie concerning the entails of the ancient ef­­tates of the Spanifh nobility, entitled, De Hifpano­­rum Primagenatorum Origine et Natura, publifhed in 1603, in folio. This book is likewife applicable to feveral provinces in France. Lewis Molina muft not be confounded with John Molina, a Spanifh historian; author of Croni. a antiqua d’Arragon, publifhed in 1524, in folio; and also of De las Cajas memorables d’Eftagna, in folio. The firft work appeared at Valanz, and the fecond at Accoli.

MOLINAEUS. See MOLIN.

MOLINISTS, in eccle­fiafical history, a fect in the Romifh church, who follow the doctrine and fen­timents of the Jesuit Molina, relating to fuffifent and ef­­ficient grace. He taught that the operations of divine grace were entirely confluent with the freedom of human will; and he introduced a new kind of hypo­­thefis to remove the difficulties attending the doctrines of predetermination and liberty, and to reconcile the jar­ring opinions of Aug itchines, Thomifts, Semi-Pelagi­ans, and other contentious divines. He affirmed, that the decree of predetermination to eternal glory was founded upon a previous knowledge and confideration of the merits of the elect; that the grace from whose operation these merits are derived, is not efficacious by its own intrinsic power only, but also by the con­tent of our own will, and because it is adminiftered in those circumstances, in which the Deity, by that branch of his knowledge which is called fientia media, forces that it will be efficacious. The kind of preference, denominated in the schools fientia media, is that fore­knowledge of future contingents that arifes from an acquaintance with the nature and faculties of rational beings, of the circumstances in which they fhall be placed, of the objects that fhall be prefented to them, and of the influence which their circumstances and ob­jects must have on their actions.

MOLINOS (Michael,) a Spanifh prieft, who en­deavoured to spread new doctrines in Italy. He was born in the diftrict of Saragofa in 1627; and entered into prieft’s orders, though he never held any eccle­fiafical benefice. He was a man of good fenfe and learning, and his life was exemplary; though instead of pra­ctifing aifterities, he gave himself up to contemplation and mystical devotion. He wrote a book intituled, II Guida Spirituale, containing his peculiar notions, which was greedily read both in Italy and Spain. His followers are called Quietifs; because his chief prin­ciple was, that men ought to annullate themselves in order to be united to God, and afterwards remain in quietness of mind, without being troubled for what fhall happen to the body. He was taken up in 1687; and his 68 propositions were examined by the pope and inquisitors, who decreed that his doctrine was false and pernicious, and that his books should be burned. He was forced to recant his errors publicly in the Do­minicains church, and was condemned to perpetual imprifonment. He was 60 years old when he was taken, and had been spreading his doctrine 22 years be­fore. He died in prifon in 1692.

MOLINOSTETS, a fect among the Romanists, who adhere to the doctrine of Molinos. These are the fame with what are other­wise called Quietifs.

MOLLOY (Charles, Esq.), descended from a good family in the kingdom of Ireland, was born in the city of Dublin, and received part of his education at Trinity college there, of which he afterwards became a fellow. At his firft coming to England he entered himself of the Middle Temple, and was sup­posed to have had a very confiderable hand in the writing of a periodical paper called “Foggs’s Journal,” as also fince that time to have been almoft the solo author of another well-known paper, intituled “Common Sense.” All these papers give testimony of ftrong abilities, great depth of understanding, and clearneas of reasoning. Dr king was a confiderable writer in the latter, as were lords Chesterfield and Lyttleton. Our author had large offers made him to write in de­fence of Sir Richard Walpole, but these he rejected; notwithstanding which, at the great change in the mini­stry in 1742, he was entirely neglected, as well as his fellow labourer Amherf, who conducd “The Cafe­man.” Mr Molloy, however, having married a lady of fortune, was in circumstances which enabled him to treat the ingratitude of his patriotic friends with the contempt it deferred. He lived many years after this period, dying to lately as July 16. 1787.
MOLLUGO, AFRICAN CHICKWEED: A genus of the trigynia order, belonging to the triandria clas of plants; and in the natural method ranking under the 22d order, Caryophylleæ. The calyx is pentaphylalous; there is no corolla; the capsule is trilocular, and trivalved. Its characters are these: The emplacement of the flower is composed of five oblong small leaves, coloured on their infides, and permanent; the flower has five oval petals shorter than the emplacement; and three trilly flamma, which stand near the style, terminated by single summit; it has an oval germens, having three furrows, supporting three very small cells. The germens becomes an oval capsule with three cells, filled with small kidney-flaved seeds. There are several species, few of which are admitted into gardens. Miller reckons two and Linneæus five species. This plant is said to have an aperitive virtue.

MOLUSCA, in the Linnaean sytem, is the denomination of the second genus of vermes or worms. They are simple naked animals, not included in a shell, but furnished with limbs, and comprehend eighteen subordinate genera, and one hundred and ten species. MOLO, a philosopher of Rhodes, called also Apollonius. Some are of opinion that Apollonius and Molo are two different persons, who both visited Rhodes, and there opened a school; but Molo came some time after Apollonius. Molo are two different persons, who dedicated their children to him, by making them pass through the fire, by way of sacrifice to this god. There is some probability that the Hebrews were to the fire, by way of sacrifice to this god. There is some probability that the Hebrews were dedicated to their god Moloch.

Moloch of the Ammonites.

Moloch was likewise called Milkom; as appears from what is said of Solomon, that he went after Ahabthor the abomination of the Zidonians, and Milkom the abomination of the Ammonites.

MOLOSSES, MOLASSES, or Molasses, that gross fluid matter remaining of sugar after refining, and which no boiling will bring to a confection more solid than that of syrup; hence also called syrup of sugar.

Properly, molasses are only the sediment of one kind of sugar called chyres, or brown sugar, which is the refuse of other sugars not to be whitened or reduced into loaves.

Molasses are much used in Holland for the preparation of tobacco, and also among poor people instead of sugar. There is a kind of brandy or spirit made of molasses; but by some held exceedingly unwholesome. See below.

Artificial Molasses. There has been found a method of making molasses from apples without the addition of sugar. The apple that succeeds best in this operation is a summer sweeting of a middle size, pleasant to the taste, and so full of juice that seven buffets will yield a barrel of cyder.

The manner of making it is this: the apples are to be ground and pressed, then the juice is to be boiled in a large copper, till three quarters of it be evaporated; this will be done with a moderate fire in about six hours, with the quantity of juice abovementioned, by this time it will be of the confection and taste as well as of the colour of molasses.

This new molasses serves to all the purposes of the common kind, and it is of great use in preparing cider. Two quarts of it, put into a barrel of racked cider, will preserve it, and give it an agreeable colour.

The invention of this kind of molasses was owing to Mr. Chander of Woodlock in New England, who living at a distance from the sea, and where the common molasses was very dear and scarce, provided this for the supply of his own family, and soon made the practice among people of the neighbourhood. It is to be observed, that this sort of apple, the sweeting, is of great use in making cyder, one of the very best kinds we know being made of it. The people in New-England also feed their hogs with the fallings of the orchards of these apples; and the consequences of this is, that their pork is the finest in the world.

Molasses Spirit; a very clean and pure spirit, much used in England, and made from molasses or common treacle dissolved in water, and fermented in the same manner as malt or the common malt-spirit. See Distillation, No 10.

Molasses spirit coming dearer than that of malt, it is frequently met with badly adulterated with a mixture of that spirit, and indeed seldom is to be bought without some dash of it. Many have a way of mixing malt in the fermenting liquor; by this the yield of the whole is greatly increased, and the maker may allure the buyer that the spirit is pure as it ran from the worm.

In most of the nice cafes in our compound distillery,
lery, the molosses-spirit supplies the place of a pure and clean spirit. Our cinnamon, citron, and other fine cordial waters, are made with it; for the malt spirit would impart to them a very disagreeable flavour.

Molosses spirit gives a yellow taint to the hands or other substances dipped into it; and may therefore be of use in dyeing. It is possible also that the vinegar-makers may find use for it in their way; but the most advantageous of all its uses is to the distiller himself; a quantity of it added to new treacle intended for fermentation will be of great use in the process, and increase very considerably the quantity of spirit; but the proportion in regard to the new matter must not be too great.

MOLOSSE, a people of Epirus, who inhabited that part of the country which was called Molossia or Molossus, from king Molosses, a son of Pyrrhus and Andromache. This country had the bay of Ambracia on the south, and the country of the Perrhebeans on the east. The dogs of the place were famous, and received the name of Molossus among the Romans. Dodona was the capital of the country, according to some writers. Others, however, reckon it as the chief city of Thebria.

MOLOSSUS, in the Greek and Latin poetry, a foot consisting of three long syllables. As audiri, cantabant, sapiam.

It takes its name either from a dance in use among the people called Molossi or Epirotes; or from the temple of Jupiter Molossus, where odes were sung, in which this foot had a great share; or else because the march of the Molossi, when they went to the combat, was composed of these feet, or had the cadence thereof. The same foot was also called among the ancients, Vertumus, exstipites, hippus, & canius.

MOLSA (Francis Maria), an eminent poet of the 16th century, was born at Modena. He gained so prodigious a reputation by his Latin and Italian poetry, that, as Paul Jovius tells us, "for 30 years together the patrons of wit at Rome strove to promote him." If he had behaved with the least prudence, he might easily have raised himself to considerable preferments and fortunes in the world; but he managed so ill that it was not possible to serve him. He was entirely debauched, and at the same time devoid of all prudence and decency in the management of his pleasures. Hence he defroyed his reputation, and put an absolute stop to the progress of his fortunes. He died, in 1544, of the French disease. Mofs was a great orator as well as a great poet. He met once with a favourable opportunity of displaying his talent this way; for having seen the people of Rome highly incensed against Lorenzo de Medicis, who had struck off the heads of a great number of ancient statues, he accused him of that action, and (according to Paul Jovius) made so lively an oration upon it, that he perfectly overwhelmed him with confusion and despair: and it was generally believed that Lorenzo de Medicis was so confounded at the insinu- mery with which he was branded in that oration, that, in order to efface it, he resolved to remove the city of Florence to its liberty, by assassinating Alexander de Medicis his near relation, which he did in 1537.

MOLSA (Tarquinia), daughter of Camillo Mols, knight of the order of St James of Spain, and granddaughter of Francis Maria Molis, was one of the most accomplished ladies that ever appeared in the world; wit, learning, beauty, and virtue, all uniting, in her a most extraordinary degree. Her father observing, while she was yet very young, the goodness and excellence of her genius, procured her the best masters in every branch of literature and science. Lazzaro Labadini, a celebrated grammarian of those times, taught her polite literature; and her Latin compositions in prose and verse show that she attained the art of writing, well, and composing correctly. She became learned in Aristotle under Camillo Corentan. Anthony Guarini the mathematician taught her the doctrine of the sphere; the learned poetry under Francis Patricius the famous philosopher; and logic and philosophy under P. Latoni, who also instructed her thoroughly in the Greek tongue. The rabbi Abraham taught her the principles of the Hebrew language; and John Matier Barbier formed her in the polite of the Tuscan tongue; in which she has not only written a great number of easy and elegant verses, but likewise several letters and other pieces, which are in high esteem with the polite and learned in Italy. Besides her original works, she has translated several things from Greek and Latin in a manner which shows her to have understood those languages as well as her own. Afterwards she learned music, as a relaxation and diversion from her more serious studies; and in this art she acquired a celebrated grammarian, Marier Barbier formed her in the Tuscan tongue; in which she has not taught her the principles of the Latin, and received the name of Molossa among the Romans. Dodona was the capital of the country, according to some writers. Others, however, reckon it as the chief city of Thesprotia.

MOLSOUS, in botany: A genus of the gymnoperidia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42d order, Verticillatae. The calyx is campanulated, gradually widening larger than the corolla, and spinous.

MOLUCAS, or Moluccas Islands, in the East Indian sea under the line; of which there are five principal, namely, Ternate, Timor, Machian, Motry, and Bachian. The largest of them is hardly 30 miles in circumference. They produce neither corn, rice, nor cattle, except...
MOLYBDENA, in natural history, the name of a genus of crystals of a cubic form, or composed of fixed sides, at right angles, like a dye.

MOLYN (Peter), called Tempeia and Pietro Mulier, an eminent painter, was born at Haarlem, in 1637. According to some authors, he was the disciple of Snyders, whose manner of painting he at first imitated. But his genius led him to the study of natural subjects; and he so far excelled in painting tempests, storms at sea, and shipwrecks, that he was called by way of distinction Tempeia. His pictures are very rare, and held in the greatest estimation. The name of Pietro Mulier, or du Mulieribus, was given him on account of having carried his wife to be a nun, in order to marry a young lady of Genoa with whom he was in love. But this vil- lanous transaction being discovered, he was seized, imprisoned, and capitally condemned. However, the greatness of his merit as an artist occasioned a mitigation of the sentence; but he was still detained in prison, where he diligently followed his profession, and would have continued there in all probability for life, had he not met with an opportunity of escaping to Placentia, at the time Louis XIV. bombarded the city of Genoa, after he had been in confinement 16 years. To this artist are attributed several very neat prints, executed with the graver only, in a style greatly resembling that of John Vander Veldt. They confit chiefly of candle-light pieces and dark subjects. M. Heinekin mentions Peter Molyn the elder, who was a native of Holland, and a painter; but not so eminent as Tempeia. Some suppose the prints abovementioned ought to be ascribed to the latter; as, though very neatly executed, they are laboured heavy performances, and not equal in any degree to what one might expect from the hand of an artist of so much repute as Tempeia.

MOLYNEUX (William), an excellent mathematician and astronomer, was born at Dublin in 1656, and admitted into the university of that city; which when he left, he carried with him a testimonial drawn up in an uncommon form, and in the strongest terms, signifying the high opinion conceived of his genius, the profity of his nature, and the remarkable progress he had made in letters. In 1675, he entered in the middle-temple, where he spent three years in the study of the laws of his country; but the best of his genius lay strongly toward mathematics and philosophical studies; and even at the university he conceived a dislike to scholastic learning, and fell into the methods of Lord Bacon. Returning to Ireland in June 1678, he shortly after married Lucy the daughter of Sir William Domvile the king's attorney-general. Being master of an easy fortune, he continued to indulge himself in prosecuting such branches of natural and experimental philosophy as were most agreeable to his fancy; wherein astronomy having the greatest share, he began, about 1681, a literary correspondence with Flamsteed the king's astronomer, which he kept up for several years. In 1683, he formed a design of erecting a philosophical society, at Dublin, in imitation of theirs.
MOLYNEUX (Samuel) son of the former, was born at Chelten in July 1689; and educated with great care by his father, according to the plan laid down by Locke upon that subject. When his father died, he fell under the management of his uncle, Dr. Thomas Molyneux, an excellent scholar and physician at Dublin, and also an intimate friend of Mr. Locke; who executed his trust so well, that Mr. Molyneux became afterwards a most polished and accomplished gentleman, and was made secretary to his late majesty when he was prince of Wales. Astronomy being his favourite study, as it had been his father's, he projected many schemes for the advancement of it, and was particularly employed in the years 1723, 1724, and 1725, in perfecting the method of making telescopes; one of which, of his own making, he had presented to John V. king of Portugal. In the midst of these thoughts being appointed a commissioner of the admiralty, he became so engaged in public affairs, that he had not leisure to pursue these enquiries any further; and gave his papers to Dr. Robert Smith, professor of astronomy at Cambridge, whom he invited to make use of his house and apparatus of instruments, in order to finish what he had left imperfect. Mr. Molyneux dying soon after, Dr. Smith lost the opportunity, yet, supplying what was wanting from Mr. Huygens and others, he published the whole in his "Complete Treatise of Optics."

MOMBAZA, or MOMBAZA, a town of Africa, in an island of the same name, with a castle and fort; seated on the eastern coast, opposite to the country of Momboza in Zanguebar, 70 miles south of Melinda, and subject to Portugal. E. Long. 48°. N. Lat. 14.°. 44.°.

MOMBAZA, a country of Africa in Zanguebar, subject to the Portuguese, from whence they export slaves, gold, ivory, rice, flax, and other provisions, with which they supply the settlements in Brazil. The king of this country being a Christian, had a quarrel with the Portuguese governor, took the castle by assault, turned Mahometan, and murdered all the Christians, in 1631; but in 1729 they became masters of the territory again.

MOMENT, in the doctrine of time, an instant, or the most minute and indivisible part of duration.

MOMENTUM, in mechanics, signifies the same with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity. See MECHANICS.

MOMORDICA, male BALSAM APPLE: a genus of the syngeinia order, belonging to the moloniea, class of plants; and in the natural method ranking under the 34th order, Cucurbttaceae. The male calyx is quinquifet; the corolla quinquepartite; the filaments are five in number. The female calyx is trifid; the corolla quinquepartite; the stily trifid; the fruit is an apple parting at the base with a spring. The moft remarkable species are, 1. The ballamina, or male balsam apple. This is a native of Asia; and has a trailing stalk like those of the cucumber or melon, with smooth leaves, cut into several segments, and spreading open like a hand. The fruit is oval, ending in acute points, having several deep angles, with sharp tubercles placed on their edges. It changes to a red or purplish colour when ripe, opening with an elasticity; and throwing out its seeds. 2. The chelenifer, wild or spurious cucumber, has a large fleshy root, somewhat like briony, from whence comes forth every spring several thick, rough, trailing stalks, dividing into many branches, and extending every way two or three feet; these are garnished with thick, rough, almost heart-shaped leaves of a grey colour,
coloured, standing upon long footstalks. The flowers come out from the wings of the footstalks: these are male and female, growing at different places on the same plant like those of the common cucumber; but they are much less, of a pale yellow colour, with a greenish bottom; the male flowers stand upon thick, short, footstalks, but the female flowers fit upon the young fruit; which, after the flower is faded, grows of an oval form, an inch and a half long; swelling like a cucumber, of a grey colour like the leaves, and covered over with short prickles. This species has one of its names from the property of calling out its seeds, together with the viscid juice in which the seeds are lodged, with a violent force, if touched when ripe.

Use. The first species is famous in Syria for curing wounds. The natives cut open the unripe fruit, and infuse it in sweet oil, which they expose to the sun for some days, until it becomes red; and then preserve it for use. Dropped on cotton, and applied to a sore or a wound, the Sycrians reckon it the best vulnerary mountainous plant like arbours or bowers. The elaterium of the plant is common. It is usually brought to Britain from Spain and the southern parts of France, where the plant is common. It is brought to Britain in small, flat, whitish lumps, or cakes, that are dry, and break easily between the fingers. It is of an acid, nauseous, bitter taste, and has a strong offensive smell when newly made; but the same, as well as its other properties, it loses after being kept for some time. It is used, for arbours four members to parliament. It is a borough, and returns two members to parliament: patron Lord Clermont. It gives title of baron to the family of Blayney, and has six fairs. It was anciently called Mainchen. An abbey was founded here in a very early age, of which Moe− londis, the son of Aodh was abbot. In 1462, a monastery for conventual Franciscans was erected on the site of this abbey, which was granted on the general suppression of monasteries to Edward Withe, and a cafile has been since erected on the site by Edward Lord Blayney.

MONA, two islands of this name in the sea lying between Britain and Ireland. The one described by Caesar, as situated in the mid-passage between both islands, and stretching out in length from south to north. Called Mona (Poletomey); Monapia, or Monabia (Plym). Supposed to be the Isle of Man. Another Mona, (Tacitus) an island more to the south, and of greater breadth; situated on the coast of the Orkneys, from which it is separated by a narrow strait. The ancient seat of the Druids. Now called Anglesey, the island of the Angles or English.

MON, an island of the Baltic Sea, south-west of the island of Zealand, subject to Denmark. E. Long. 12° 30'. N. Lat. 55° 00'.
Monarchy, and the imminent danger of his employing that strength to
improvident or oppressive purposes. As a democracy
is the best calculated to direct the end of a law, and
an aristocracy to invent the means by which that end
shall be obtained, a monarchy is most fit for carrying
those means into execution.

The most ancient monarchy was that of the Assyrians, which
was founded four years after the deluge. We
tually reckon four grand or universal monarchies; the
Assyrian, Persian, Grecian, and Roman; though Augustine makes them but two, viz. those of Baby-
on and Rome. Belus is placed at the head of the
series of Assyrian kings who reigned at Babylon, and is
by profane authors esteemed the founder of it, and
by some the same whom the scriptures call Nimrod. The
principal Assyrian kings after Belus were Ninus, who
built Nineveh, and removed the feast of empire to it;
Semiramis, who, disguising her sex, took possession of the kingdom instead of her son, and was killed
and succeeded by her son Ninus; and Sardanapalus,
the last of the Assyrian monarchs, and more effeminate than a woman. After his death the Assyrian empire
was split into three separate kingdoms, viz. the Median, Assyrian, and Babylonian. The first king of the
Median kingdom was Arbaces; and this kingdom
lasted till the time of Atyages, who was subdued and
divested of his kingdom by Cyrus.

In the time of Cyrus there arose a new and second monarchy called the Persian, which flourished upwards of
200 years from Cyrus, whose reign began A. M. 3468,
to Darius Codomannus, who was conquered by Alex-
ander, and the empire translated to the Greeks, A. M.
3674.-The first monarch was Cyrus, founder of the empire.
2. Cambyses, the son of Cyrus. 3. Smer-
dis. 4. Darius, the son of Hytaipis, who reigned
541 years before Christ. 5. Xerxes, who reigned 485
years before Christ. 6. Artaxerxes Longimanus, who
reigned 464 years before Christ. 7. Xerxes the second.
8. Ochus, or Darius, called Nothus, 424
years before Christ. 9. Artaxerxes Mnemon, 405
years before Christ. 10. Artaxerxes Ochus, 359 years
before Christ. 11. Arsies, 338 years before Christ.
12. Darius Codomannus, 336 years before Christ, who
was defeated by Alexander the Great, and de-
prived of his kingdom and life about 331 years before Christ; the dominion of Persia after his death
was translated to the Greeks.

The third monarchy was the Grecian. As Alexander,
when he died, did not declare who should succeed him, there started up as many kings as there were commanders. At first they governed the provinces that were divided among them under
the title of viceroys; but when the family of Alexander the Great was extinct, they took upon them the name of kings. Hence, in process of time, the whole empire of Alexander produced four distinct kingdoms, viz. 1. The Macedonian; the kings of which, after
Alexander, were Antipater, Clistander, Demetrios Poliorcetes, Seleucus Nicanor, Meleager, Antigonus Dafon, Philip, and Perrheus, under whom
the Macedonian kingdom was reduced to the form of a Roman province. 2. The Asiatic kingdom, which
upon the death of Alexander fell to Antigonus, compr-
inger that country now called Natolia, together with
some other regions beyond Mount Taurus. From this kingdom proceeded two letter ones, viz. that of
Pergamus, whose last king, Attalus, apointed the Ro-
man people to be his heir; and Pontus, reduced by the
Romans into the form of a province, when they had
subdued the last king, Mithridates. 3. The Syrian
of whose twenty-two kings the most celebrated were,
Seleucus Nicainor, founder of the kingdom; Antiochus
Euseb; Antiochus the Great; Antiochus Epiphanes;
and Tigranes, who was conquered by the Romans
under Pompy, and Syria reduced into the form of a Roman province. 4. The Egyptian which formed by the Greeks in Egypt, and flourished near
240 years under 12 kings, the principal of whom were,
Ptolemy Lagus, its founder; Ptolemy Philadelphia,
founder of the Alexandrian library; and queen Cleop-
atra, who was overcome by Augustus, in conse-
quency of which Egypt was added to the dominion of the
Romans.

The fourth monarchy was the Roman, which
lasted 244 years, from the building of the city until
the time when the royal power was abrogated. The
kings of Rome were. Romulus, its founder; Numi
Pomponius; Tullus Holitius; Aucus Martius; Tar-
quinius Priscus; Servius Tullius; and Tarquin the
Proud, who was banished, and with whom terminated
the regal power.

There seems in reality no necessity to make the
Medes, Persians, and Greeks, succeed to the whole
power of the Assyrians, to multiply the number of the monarchies. It was the same empire still; and
the several changes that happened in it did not constitute different monarchies. Thus the Babylonian
empire was successively governed by princes of different
nations, yet without any new monarchy being formed thereby. Rome, therefore, may be said to have im-
mediately succeeded Babylon in the empire of the
world. See Empire.

Of monarchies some are absolute and despotic, where
the will of the monarch is uncontrollable; others are
limited, where the prince's authority is restrained by
laws, and part of the supreme power lodged in other
hands, as in Britain. See Government.

Some monarchies again are hereditary, where the
succession devolves immediately from father to son;
and others are elective, where, on the death of the
monarch, his successor is appointed by election, as in
Poland.

Fifth-Monarchy Men, in the ecclesiastical history of England, were a set of crot-on-headed and turbulent enthusiasts who arose in the time of Cromwell, and
who expected Christ's sudden appearance upon earth
to establish a new kingdom; and, acting in conseq-quence of this allusion, aimed at the subversion of all human government.

MONARDA, Indian horehound, in botany: A
genus of the monogynia order, belonging to the dian-
dria class of plants; and in the natural method rank-
ing under the 42d order, Portulacaceae. The corolla is
unequal, with the upper lip linear, involving the fila-
ments; there are four seeds. The most remarkable
species is the zeylanica, a native of the East Indies.
It rises with an herbaceous, four-cornered, hoary stalk,
and bears leaves that are entire, nearly heart-shaped,
woolly, deep notched on the edges, and having foot-
flakes. The flowers, which are purplish and fragrant,
surround the stalk in whorls, each whorl containing
about 14 flowers: and are succeeded by four small
D d kidney
MONASTERY is only properly applied to the houses of monks, mendicant friars, and nuns. The rest are more properly called religious houses. For the origin of monasteries, see Monastic and Monk.

The houses belonging to the several religious orders which obtained in England and Wales were, cathedrals, colleges, abbeys, priories, preceptories, commanderies, hospitals, friaries, hermitages, chantries, and free chapels. These were under the direction and management of various officers. The dissolution of houses of this kind began so early as 1312, when the Templars were suppressed; and in 1323 their lands, churches, advowsons, and liberties, in England, were given by 17 Ed. II. st. 5, to the prior and brethren of the hospital of St John at Jerusalem. In the years 1399, 1437, 1441, 1459, 1497, 1505, 1508, and 1515, several other houses were dissolved, and their revenues settled on different colleges in Oxford and Cambridge. Soon after the last period, Cardinal Wolsey, by licence of the king and pope, obtained a dissolution of above 30 religious houses for the founding and endowing his colleges at Oxford and Cambridge. About the same time a bull was granted by the same pope to Cardinal Wolsey to suppress monasteries, where there were not above six monks, to the value of 8,000 ducats a-year, for endowing Windsor and King's College in Cambridge; and two other bulls were granted to Cardinals Wolsey and Campeius, where there were left from twelve monks, and to annex them to the greater monasteries; and another bull to the same cardinals to inquire about abbeys to be suppressed in order to be made cathedrals. Although nothing appears to have been done in consequence of these bulls, the motive which induced Wolsey and many others to suppress these houses was the desire of promoting learning; and Archbishop Cranmer engaged in it with a view of carrying on the Reformation. There were other causes that concurred to bring on their ruin: many of the religious were loose and vicious; the monks were generally thought to be in their hearts attached to the pope's supremacy; their revenues were not employed according to the intent of the donors; many charities in images, reigns of miracles, and counterfeit relics, had been discovered, which bought the monks into disgrace; the Observant friars had opposed the king's divorce from Queen Catherine; and these circumstances operated, in concurrence with the king's want of a supply and the people's desire to save their money, to forward a motion in parliament, that in order to support the king's state and supply his wants, all the religious houses might be conferred upon the crown which were not able to spend above £. 200 a-year; and an act was passed for that purpose 27 Hen. VIII. c. 28. By this act about 380 houses were dissolved, and a revenue of £. 30,000 or £. 32,000 a-year came to the crown; besides about £. 100,000 in plate and jewels. The suppression of these houses occasioned discontent, and at length an open rebellion: when this was appeased, the king resolved to suppress the rest of the monasteries, and appointed a new visitation; which caused the greater abbeys to be surrendered apace; and it was enacted by 31 Hen. VIII. c. 13, that all monasteries, &c. which have been surrendered since the 4th of February, in the 27th year of his majesty's reign, and which hereafter shall be rendered, shall be vested in the king.

The knights of St John of Jerusalem were also suppressed by the 32 Hen. VIII. c. 34. The suppression of these greater houses by these two acts produced a revenue to the king of above £. 100,000 a-year besides a large sum in plate and jewels. The last act of dissolution in this king's reign was the act of 37 Hen. VIII. c. 4. for dissolving colleges, free chapels, chaplains, &c. which act was farther enforced by 1 Edward VI. c. 14. By this act were suppressed 90 colleges, 110 hospitals, and 2,374 chaplains and free chapels. The number of houses and places suppressed from first to last, so far as any calculations appear to have been made, seems to be as follows:

...
Of greater monasteries, of which we have the valuation, - - 374
Of greater monasteries, - - 186
Belonging to the hospitals, - - 48
Colleges, - - 90
Hospitals, - - 110
Chancies and free chapels, - - 2374

Total 3182

Besides the friars houses and those suppressed by Wolsey, and many small houses of which we have no particular account.

The sum total of the clear yearly revenue of the several houses at the time of their dissolution, of which we have any account, seems to be as follows:

Of the greater monasteries, L. 104,919 - 13 3½
Of all those of the lesser monasteries of which we have the valuation, - - 29,702 - 1 10½
Knights hospitallers head house in London, - - 2385 - 12 8
We have the valuation of only 28 of their houses in the country, - - 3026 - 9 5
Friars houses of which we have the valuation, - - 751 - 2 0½

Total L. 140,764 - 19 3½

If proper allowances are made for the lesser monasteries and houses not included in this estimate, and for the plate, &c. which came into the hands of the king by the dissolution, and for the value of money at that time, which was at least fix times as much as at present, and also consider that the estimate of the lands was generally supposed to be much under the real worth, we must conclude their whole revenues to have been immense.

It does not appear that any computation hath been made of the number of persons contained in the religious houses.

Those of the lesser monasteries dissolved by 27 Hen. VIII. were reckoned at about 10,000
If we suppose the colleges and hospitals to have contained a proportionable number, these will make about 5347
If we reckon the number in the greater monasteries, according to the proportion of their revenues, they will be about 35,000; but as probably they had larger allowances in proportion to their number than those of the lesser monasteries, if we abate upon that account 5000, they will then be 30,000
One for each chantry and free chapel, - - 2374

Total 47,721

But as there were probably more than one person to officiate in several of the free chapels, and there were other houses which are not included within this calculation, perhaps they may be computed in one general estimate at about 50,000. As there were pensions paid to almost all those of the greater monasteries, the king did not immediately come into the full enjoyment of their whole revenues: however, by means of what he did receive, he founded six new bishoprics, viz. those of Westminster (which was changed by Queen Elisabeth into a deanery, with twelve prebends and a school), Peterborough, Chester, Gloucester, Bristol, and Oxford. And in eight other sees he founded deaneries and chapters, by converting the prioris and monks into deans and prebendaries, viz. Canterbury, Winchester, Durham, Worcester, Rochester, Norwich, Ely, and Carlisle. He founded also the colleges of Christ-church in Oxford and Trinity in Cambridge, and founded King's college there. He likewise founded professorships of divinity, law, physic, and of the Hebrew and Greek tongues, in both the said universities. He gave the house of Grey-frars and St Bartholomew's hospital to the city of London, and a perpetual pension to the poor knights of Windsor, and laid out great sums in building and fortifying many ports in the channel. It is observable, upon the whole, that the dissolution of these houses was an act, not of the church, but of the state; in the period preceding the Reformation, by a king and parliament of the Roman catholic communion in all points except the king's supremacy; to which the pope himself, by his bulls and licences, had led the way.

MONASTIC, something belonging to monks, or the monkish life. The monastic profession is a kind of civil death, which in all worldly matters has the same effect with the natural death. The council of Trent, &c. fix sixteen years for the age at which a person may be admitted into the monastical state.

St Anthony is the person who, in the fourth century, first instituted the monastic life; as St Pachomius, in the same century, is said to have first set on foot the cenobitic life, i.e. regular communities of religious. In a short time the deserts of Egypt became inhabited with a set of friars, who took upon them the monastic profession. St Basil carried the monkish humour into the east, where he composed a rule which afterwards obtained through a great part of the west.

In the 11th century the monastic discipline was grown very remiss. St Odo first began to retrieve it in the monastery of Cluny; that monastery, by the conditions of its erection, was put under the immediate protection of the holy see; with a prohibition to all powers, both secular and ecclesiastical, to disturb the monks in the possession of their effects or the election of their abbot. In virtue hereof they pleaded an exemption from the jurisdiction of the bishop, and extended this privilege to all the houses dependent on Cluny. This made the first congregation of several houses under one chief immediately subject to the pope, so as to constitute one body, or, as they now call it, one religious order. Till then, each monastery was independent and subject to the bishop. See Monx.

MONCAON, or MONZON, a town of Portugal, in the province of Entre-Douro-de-Minho, with a strong castle. The Spaniards have several times attempted to take it, but in vain. W. Long. 8. 2. N. Lat. 41. 52.

MONCON, or MONZON, a strong town of Spain, in the kingdom of Arragon. It was taken by the French in 1642, but the Spaniards retook it the following year. It is seated at the confluence of the rivers Sota and Cinca E. Long. 0. 19. N. Lat. 41. 43.

MONCRIF (François Augustin Paradis de), fe-
secretary to M. le comte de Clermont, reader to the queen, one of the 40 of the French academy, and a member of the academies of Nanci, and Berlin, was born at Paris of respectable parents, A. D. 1687, and died there, Nov. 12, 1770, aged 83.

Avec des murs digues de l'age d'or,
Il fut un ami fort, un auteur agréable ;
Il mourut vieux comme Nellor,
Mais il fit moins bravard et beaucoup plus aimable.

Such was Monceiff. He possessed an elegant mind, an engaging perfon, an unceasing desire to please, and a gentle, equable, and obliging temper. The advantage of reading in a very superior and interesting manner, of singing tender airs, and of composing agreeable couples, soon procured him a great number of friends, and many of these of the first rank. He asked permission to accompany a celebrated minifter, who was banifhed in 1757; but though his defer-terred attachment was highly admired, he was only allowed to go every year to express his gratitude to him in his retreat. He was never ashamed of the poverty of his relations, but affifed them and brought them forward by his influence at court. He had been at first a fencing-maftcr; and it is faid that he forefaw he would be obliged to employ his fword in defence of his works. Moft of them needed not this precaution. The principal are, 1. Eflai fur la neceffité et fur les moyens de plaire, in 12mo. This production is written in a lively ingenious manner, is full of excellent maxims, and has gone through many editions. In the prefent age, a greater fhare of argument would be expected; but the chief merit of the work is, that, unlike the productions of many moralifts, it contains nothing which the author himfelf did not reduce to open trade with their friends, and many of these of the firft rank. He daries that way of finging tender airs, and of making part of different performances into which he was admitted. 2. Les Ames rivales, an agreeable little romance, in which there occur fe-veral ingenious observations on French manners; the Alderera, a comedy of but ordinary merit: Pages diverfes, full of delicacy (his Romances and his Regainement iniutl are particularly diftinguifh'd for smooth verification, elegant reflections, and pleasing narration); and fome differtations which' display confiderable wit and information. These pieces are to be found in the miscellaneous works of the author, publifhed at Paris 1743, in 12mo. 3. Some little pieces of one act; which make part of different operas, called the Fragmens, Zelindor, Jennes Ainosia, the Genius tutelaires, and the Sibyle. He was devoted to lyric poetry, and cultivated it with fucces. In this species of writing we have from his pen the Empire de L'Amour, a ballet; the Trophée; the Ames reunis, a ballet which was never acted; and Enfoine, a heroic pastoral. 4. L'Histoire des Cloptts, a thrilling performance, too fervently confidered at the time, and now almost wholly fallen into oblivion. This work gave the Comte d'Argenfon an opportunity of being witty at the author's expence. When Voltaire retired into Prufiia, Monceiff applied to the minifter for the vacant place of hifioriographer: "Hiftropgrapher (said the Comte d'Argenfon), vous voulez fans dette dire hifioriographe." His works were collected, in 1761, into 4 vols, 12mo.

MONDA, or MUNDA (arc. geog.), a river of Lu-

MONDAY, the second day of the week, so called as being anciently facred to the moon; g. d. moon-day.

MONDOVI, a confiderable town of Italy, in Piedmont; with a caftle, university, and bishopp's fee. It is the largest and moft populous town of Piedmont, and is feated in E. Long. 8. 15. N. Lat. 44. 23.

MONEMUGI, an empire in the south of Africa, has Zanguebar on the eaf, Monomotapa on the north, Mutamba and Makoko on the west, and Abyssinia on the north and partly to the eaf, though its boundaries that way cannot be ascertained. It is divided into the kingdoms of Mujaco, Makoko or Anko, G兄弟, Cambate, and Afoa, aged of Monemugi. This latl lies in the middle of the torrid zone, and about the equinoctial line south of Makoko, west of Zanguebar, north of Monemotapa, and eaf of Congo and of the northern parts of Monomotopa. To ascertain its extent, is too difficult a task, being a country fo little frequented. The country known, abounds with gold, silver, copper mines, and elephants. The natives clothe themselves in filkis and cottons, which they buy of strangers and wear collars of transparent amber-beads, brought them from Cambaya: which beads serve also instead of money; gold and silver being too common, and of little value among them.

Their monarch always endeavours to be at peace with the princes round about him, and to keep an open trade with Quitoa, Melinda, and Mambaza, on the eaf, and with Congo on the west, from which places the black merchants retort with gold for goods. The Portuguese merchants report, that on the eaf side of Monemugi there is a great lake full of small islands, abounding with all sorts of fowl and cattle, and inhabited by negroes. They relate also, that on the main-land eafward they heard fometimes the ringing of bells, and that one could obferve buildings very much like churches; and that from these parts came men of a brown and tawny complexion, who traded with those islanders, and with the people of Monemugi.

This country of Monemugi affords alo abundance of palm-wine and oil, and fuch great plenty of honey, that above half of it is left, the black not being able to confume it. The air is generally very unwholefome, and excessively hot, which is the reafon why no Christians undertake to travel in this empire. De Lille gives the division of this country as follows: The Maracates, the Mefleagues, the kingdom of the B Ugas, the kingdom of Maili, and that of Maravi. But we are not acquainted with any particulars relating to these nations or kingdoms.

MONETARIUS, or Moneyer, a name which antiquaries and medalifrs give to thofe who struck the ancient coins or monies.

Many of the old Roman, &c. coins have the name of the monetarius, either written at length or at leaft the initial letters of it. See Medal.

MONEY,
Money.

Money, a piece of matter, commonly metal, to which public authority has affixed a certain value and weight to serve as a medium in commerce. See Coin, Commerce, and Medals; also the article Bank.

Money is usually divided into real or effective, and imaginary, or money of account.

I. Real Money.

1. History of Real Money. Real money includes all coins, or species of gold, silver, copper, and the like; which have course in common, and do really exist. Such are guineas, pfifoles, pieces of eight, ducats, &c.

Real money, civilians observe, has three essential qualities, viz., matter, form, and weight or value.

For the matter, copper is that thought to have been first coined; afterwards silver; and lastly gold, as being the most beautiful, scarce, cleanly, divisible, and pure of all metals.

The degrees of goodness are expressed in gold by carats; and in silver by pennyweights, &c. For there are several reasons for not coining them pure and without alloy, viz. the great loss and expense in refining them, the necessity of hardening them to make them more durable, and the scarcity of gold and silver in most countries. See Alloy.

Among the ancient Britons, iron rings, or as some say, iron plates were used for money; among the Lacedemonians, iron bars quench'd with vinegar, that they might not serve for any other use. Seneca observes, that there was anciently stamp'd money of leather, corium forma publica impressum. And the same thing was put in practice by Frederic II. at the siege of Milan; to say nothing of an old tradition among ourselves, that in the confused times of the barons wars the like was done in England: but the Hollanders, we know, coined great quantities of plate-board in the year 1574.

As to the form of money, it had been more various than the matter. Under this are comprehended the weight, figure, impression, and value.

For the impression, the Jews, though they deftined images, yet stamp'd on the one side of their thekels the golden pot which had the manna, and on the other Aaron's rod. The Dardans stamp'd two cocks fighting. The Athenians stamp'd their coins with an owl, or an ox; whence the proverb on bribed lawyers, Bu in lingua. They of Egypt, with a tortoise; whence that other saying, Viridam et spicantam vincunt sordidus.

Among the Romans, the monetariifrom sometimes impressed the images of men that had been eminent in their families on the coins: but no living man's head was ever stamp'd on a Roman coin till after the fall of the commonwealth. From that time they bore the emperor's head on one side. From this time the practice of stamping the prince's image on coins has obtained among all civilized nations; the Turks and other Mahometans alone excepted, who, in deftination of images, inscribe only the prince's name, with the year of the transmigration of their prophet.

As to the figure it is either round, as in Britain; multangular or irregular, as in Spain; square, as in some parts of the Indies; or nearly globular, as in most of the rest.

After the arrival of the Romans in Britain, the Britons imitated them, coining both gold and silver with the images of their kings stamp'd on them. When the Romans had subdued the kings of the Britons, they also suppress'd their coins, and brought in their own; which were current there from the time of Claudius to that of Valentine the younger, about the space of 500 years.

Mr. Camden observes, that the most ancient English coin he had known was that of Ethelbert king of Kent, the first Christian king in the island: in whole time all money-accounts begin to pass by the names of pounds, shillings, pence, and maunces. Pence seems borrowed from the Latin pecaunia, or rather from ponde, on account of its full weight, which was about three pence Sterling. These were coarsely stamp'd with the king's image on the one side, and either the mint-marter's, or the city's where it was coin'd, on the other. Five of these pence made their shilling, probably so called from feelingus, which the Romans used for the fourth part of an ounce. Forty of these shillings made their pound; and 400 of these pounds were a legate, or a portion for a king's daughter, as appears by the last will of king Alfred. By the nuns they translated all sums of money in their old English testament; talents by pandes; Judas's thirty pieces of silver by thyrig feelingus; tribute-money, by penining; the mite by foarthling.

But it must be observed, that they had no other real money, but pence only; the rest being imaginary monies, i.e. names of numbers or weights. Thirty of these pence made a mance, which some take to be the same with a mark; mance, as appears by an old MS. was quinta part unica. These mances or munces were reckon'd both in gold and silver. For in the year 660 we read that the king of the West Saxons oblig'd the Kentishmen to buy their peace at the price of 30,000 mances of gold. In the notes on King Canute's laws, we find this definition, that manca was as much as a mark of silver, and mance a square piece of gold, valued at 30 pence.

The Danes introduced a way of reckoning money by ores, per oras; mentioned in Domesday-book; but whether they were a several coin, or a certain sum, does not plainly appear. This however, may be gathered from the Abbey-book of Burton, that 20 ores were equivalent to two marks. They had also a gold coin called byzantine, or benant, as being coined at Constantinople, then called Byzantium. The value of which coin is not only now lost, but was so entirely forgot even in the time of King Edward III. that whereas the bishop of Norwich was fined a byzantine of gold to pay the abbot of St. Edmund's Bury for infringing his liberties (as it had been enacted by parliament in the time of the conqueror), no man then living could tell how much it was; so it was referred to the king to rate how much he should pay. Which is the more unaccountable, because but 100 years before, 200,000 bezants were exacted by the goldun for the ransom of St. Louis of France; which were then valued at 100,000 livres.

Though the coinage of money be a special prerogative of the king, yet the ancient Saxon princes communicated it to their subjects: insomuch that in every good town there was at least one mint; but at London
In the time of King Richard I. money coined in the east parts of Germany came in special request in England on account of its purity, and was called easterling money, as all the inhabitants of those parts were called Esterlings. And fiercely after some of those people skilled in coinage were sent for hither to bring the coin to perfection; which since has been called sterlings. See Sterling.

King Edward I. with a weight of the measure of an ell by the length of his arm, herein imitating Charles the Great, was the first also who established a certain standard for the coin, which is expressed to this effect by Greg. Rockley, mayor of London, and mint-master.—"A pound of money contained twelve ounces; in a pound there ought to be eleven ounces, two easterlings, and one farthing; the rest alloy. The said pound ought to weigh twenty thistles and three pence in account and weight. The ounce ought to weigh twenty pence, and a penny twenty-four grains and a half. Note, that eleven ounces two-pence sterling ought to be of pure silver, called leafsilver; and the minter must add of other weight seventeen-pence half-penny farthing, if the silver be so pure."

About the year 1320, the States of Europe first began to coin gold; and among the rest, the king Edward III. The first pieces he coined were called florines, as being coined by Florence; afterwards he coined nobles; then rote-nobles, current at 6s. and 8d. half-nobles called half-pence, at 3d. and 4d. a gold, and quarters at 20d. called farthings of gold. The succeeding kings coined rote-nobles, and double rote-nobles, great sovereigns, and half Henry nobles, angels, and thistles.

King James I. coined units, double crowns, Britain crowns; then crowns, half-crowns, &c.

2. Comparative value of Money and Commodities at different periods. The English money, though the same names do by no means correspond with the same quantity of precious metal as formerly, has not changed so much as the money of most other countries. From the time of William the Conqueror, the proportion between the pound, the shilling, and the penny, seems to have been uniformly the same as at present.

Edward III. as already mentioned, was the first of the English Kings that coined any gold; and no copper was coined by authority before James I. Thefe pieces were not called farthings, but farthing tokens, and all people were at liberty to take or refuse them. Before the time of Edward III. gold was exchanged, like any other commodity, by its weight; and before the time of James I. copper was stamped by any one person who chose to do it.

In the year 612 and 727, an ewe and lamb were rated at 1 s. Saxon money till a forintight after Easter.

Between the years 900 and 1000, two hydes of land, each containing about 120 acres, were sold for 100 shillings. In 1000, by King Ethelred's laws, a horse was rated at 30s. a mare, or a colt of a year old, at 20s. a mule, or young as, at 12s. an ox at 30s. a cow at 24s. a swine at 6d. a sheep at 1s. In 1043, a quarter of wheat was sold for 60d. Hence it is computed, that in the Saxon times there was ten times less money in proportion to commodities, than at present. Their nominal specie, therefore being about three times higher than ours, the price of every thing, according to our present language, must be reckoned thirty times cheaper than it is now.

In the reign of William the Conqueror, commodities were ten times cheaper than they are at present; from which we cannot help forming a very high idea of the wealth and power of that king; for his revenue was L. 400,000 per annum, every pound being equal to what weight of silver, consequently the whole may be estimated at L. 1,200,000 of the present computation; a sum which, considering the different value of money between that period and the present, was equivalent to L. 12,000,000 of modern estimation.

The most necessary commodities do not seem to have advanced their price from William the Conqueror to Richard I.

The price of corn in the reign of Henry III. was near half the mean price in our times. Bishop Fleetwood has shown, that in the year 1240, which was in this reign, L. 4:13:9, was worth about L. 50 of our present money. About the latter end of this reign, Robert de Hay, rector of Souleard, agreed to receive 100 s. to purchase to himself and succesor the annual rent of 5 s. in full compensation of an acre of corn.

Butchers meat, in the time of the great scarcity in the reign of Edward II. was, by a parliamentary ordinance, sold three times cheaper than our mean price at present; poultry somewhat lower, because being no way considered as a delicacy, it has risen beyond its proportion. The mean price of corn at this period was half the present value, and the mean price of cattle one-eighth.

In the next reign, which was that of Edward III. the most necessary commodities were in general about three or four times cheaper than they are at present. In those times, knights, who served on horseback in the army, had 2 s. a-day, and a foot archer 6d. which laid would now be equal to a crown a day. This pay has continued nearly the same nominally (only that in the time of the commonwealth the pay of the horse was advanced to 2 s. 6d. and that of the foot to s. though it was reduced again at the Restoration), but foldiers were proportionably of a better rank formerly.

In the time of Henry VI. corn was about half its present value, other commodities much cheaper. Bishop Fleetwood has determined, from a most accurate consideration of every circumstance, that L. 3 in this reign was equivalent to L. 25 or L. 30 now.

In the time of Henry VII. many commodities were three times as cheap here, and in all Europe, as they are at present, there having been a great increase of gold and silver in Europe since his time, occasioned by the discovery of America.
The commodities whose price has risen the most since before the time of Henry VII. are butchers meat, fowls, and fish, especially the latter. And the reason why corn was always much dearer in proportion to other eatables, according to their prices at present, is, that in early times agriculture was little underfoot. It required more labour and expense, and was more precarious, than it is at present. Indeed notwithstanding the high price of corn in the times we are speaking of, the raising of it to little answered the expense, that agriculture was almost universally quitted for grazing; which was more profitable, notwithstanding the low price of butchers meat. So that there was constant occasion for statues to refrain grazing, and to promote agriculture; and no effectual remedy was found till the bounty upon the exportation of corn; since which, about ten times more corn has been raised in this country than before.

The price of corn in the time of James I. and consequently that of other necessaries of life, was not lower, but rather higher, than at present; wool is now two thirds of the value it was then; the finer manufactures having sunk in price by the progress of art and industry, notwithstanding the increase of money. Butchers meat was higher than at present. Prince Henry made an allowance of near 4d. per pound for all the beef and mutton used in his family. This may be true with respect to London; but the price of butchers meat in the country, which does not even now much exceed this price at a medium, has certainly greatly increased of late years, and particularly in the northern counties.

The prices of commodities are higher in England than in France; besides that the poor people of France live upon much less than the poor in England, and their armies are maintained at less expense. It is computed by Mr. Hume, that a British army of 20,000 men is maintained at near as great an expense as 60,000 in France, and that the English fleet, in the war of 1744, required as much money to support it as all the Roman legions in the time of the emperors. However, all that we can conclude from this is, that money is much more plentiful in Europe at present than it was in the Roman empire.

In the 18th century the common interest which the Jews had for their money, Voltaire says, was 20 per cent. But with regard to this, we must consider the great contempt that nation was always held in, the large contributions they were frequently obliged to pay, the risk they run of never receiving the principal, the frequent confiscations of all their effects, and the violent persecutions to which they were exposed; in which circumstances it was impossible for them to lend money at all unless for most extravagant interest, and much disproportioned to its real value. Before the discovery of America and the plantation of the colonies, the interest of money was generally 12 per cent. all over Europe; and it has been growing gradually less since that time, till it is now generally about four or five.

When sums of money are paid to be raised by a whole people, in order to form a just estimate of it, we must take into consideration not only the quantity of the precious metal according to the standard of the coin, and the proportion of the quantity of coin to the commodities, but a the number and riches of the people who raise it; for populous and rich countries will much more easily raise any certain sum of money than one that is thinly inhabited, and chiefly by poor people. This circumstance greatly adds to our surprize at the vast sums of money raised by William the Conqueror, who had a revenue nearly in value equal to L12,000,000 of our money (allowance being made for the standard of coin and the proportion it bore to commodities), from a country not near to populous or rich as England is at present. Indeed, the accounts historians give us of the revenues of this prince, and the treasure he left behind him, are barely credible.

II. IMAGINARY Money or Money of account, is that which has never existed, or at least which does not exist in real specie, but is a denomination invented or retained to facilitate the stating of accounts, by keeping them still on a fixed footing, not to be changed, like current coin, which the authority of the sovereign raises or lowers according to the exigencies of the state. Of which kind are pounds, livres, marks, maravedies, &c. See the annexed Table, where the fictitious money is diligently indexed by a dagger (†).

Money of Account among the Ancients:—1. The Greeks reckoned their sums of money by drachmas, minae, and talenta. The drachma was equal to 7½ d. Sterling; 100 drachmas made the mene, equal to 3l. 4s. 7d. Sterling; 60 minae made the talent, equal to 103s. 15d. Sterling; hence 100 talents mounted to 1537s. 6d. Sterling. The mene and talentum, indeed, were different in different provinces: their proportions in Attic drachmas are as follow. The Syrian mene contained 25 Attic drachmas; the Ptolemaic 33; the Antiochic and Eubæan 100; the Babylonic 116; the greater Attic and Tyrian 133; the Aeginean and Rhodian 166. The Syrian talent contained 15 Attic minae; the Ptolemaic 20; the Antiochic 60; the Eubæan 60; the Babylonic 70; the greater Attic and Tyrian 80; the Aeginean, and Rhodian 100.

2. Roman moneys of account were the sestertius and as. The sestertius was equal to 1d. 3½ d. Sterling. One thousand of these sestertia made the decies sestertii (the adverb centes centena millia nummum) equal to 8l. 12s. 5d. Sterling. One thousand of these sestertia made the decies sestertii, equal to 8l. 12s. 4d. Sterling. The decies sestertii, they also called decies centena millia nummum. Centes sestertii, or centes. HS, were equal to 80,729l. 3r. 4d. Millies HS to 805,291l. 13r. 4d. Millies; censes HS to 888,920l. 15s. 8d.

Theory of Money.

1. Of Artificial or Material Money.

I. As far back as our accounts of the transactions of mankind reach, we find they had adopted the precious metals, that is, silver and gold, as the common measure of value, and as the adequate equivalent for every thing alienable.

The metals are admirably adapted for this purpose: they are perfectly homogeneous; when pure, they
I. Money. 

M O N E Y.

Money, or the medium of exchange, is by comparison the most perfect, most determinate, and most universal measure of value. It consists of precious metals, or their compounds, and is of the same nature which have suffered no alteration. Thus, if the foot of measure was altered at once over all England, by adding to it, or taking from it, any proportional part, of its standard length, the alteration would be best discovered by comparing the new foot with that of Paris, or of any other country, which had suffered no alteration. Just so, if the pound Sterling, which is the English unit, shall be found any how changed, and if the variation it has met with be difficult to ascertain because of a complication of circumstances, the best way to discover it, will be to compare the former and the present value of it with the money of other nations which has suffered no variation. This the course of exchange will perform with the greatest exactness.

II. The two metals being pitched upon as the most proper substances for realizing the ideal scale of money, those who undertake the operation of adjusting a standard, must constantly keep in their eye the nature and qualities of a scale, as well as the principles upon which it is formed.

The unit of the scale must constantly be the same, although realized in the metals, or the whole operation fails in the most essential part. This realizing the unit is like adjusting a pair of compasses to a geometrical scale, where the smallest deviation from the exact opening once given must occasion an incorrect measure. The metals, therefore, are to money what a pair of compasses is to a geometrical scale.

This operation of adjusting the metals to the money of account implies an exact and determinate proportion of both metals to the money-unit, realized in all the species and denominations of coin, adjusted to that standard.

The smallest particle of either metal added to, or taken away from, any coins, which represent certain determinate parts of the scale, overthrows the whole system of material money. And if, notwithstanding such variation, these coins continue to bear the same denominations as before, this will as effectually destroy their usefulness in measuring the value of things, as it would overturn the usefulness of a pair of compasses, to suffer the opening to vary, after it is adjusted to the scale representing feet, toises, miles or leagues, by which the distances upon the plan are to be measured.

III. Debating the standard is a good term; because it conveys a clear and distinct idea. It is diminishing the weight of the pure metal contained in that denomination by which a nation reckons, and which we have called the money unit. Raising the standard requires no farther definition, being the direct contrary.

IV. Altering the standard (that is, raising or debasing the value of the money-unit) is like altering the national measures of weights. This is best discovered by comparing the thing altered with things of the same nature which have suffered no alteration. Thus, if the foot of measure was altered at once over all England, by adding to it, or taking from it, any proportional part, of its standard length, the alteration would be best discovered by comparing the new foot with that of Paris, or of any other country, which had suffered no alteration. Just so, if the pound Sterling, which is the English unit, shall be found any how changed, and if the variation it has met with be difficult to ascertain because of a complication of circumstances, the best way to discover it, will be to compare the former and the present value of it with the money of other nations which has suffered no variation. This the course of exchange will perform with the greatest exactness.

V. Artificers pretend, that the precious metals, when absolutely pure from any mixture, are not of sufficient hardness to constitute a solid and lasting coin. They are found also in the mints mixed with other metals of a ruder nature; and the bringing them to a state of perfect purity occasion unnecessary expense. To avoid, therefore, the inconvenience of employing them in all their purity, people have adopted the expedient of mixing them with a determinate proportion of other metals, which hurts neither their fluidity, malleability, beauty, or lustre. This metal is called alloy; and, being considered only as a support to the principal metal, is accounted of no value in itself. So that eleven ounces of gold, when mixed with one ounce of silver acquires, by that addition no augmentation of value whatever.

This being the case, we shall, as much as possible, overlook the existence of alloy, in speaking of money in order to render language less subject to ambiguity.

2. Inca pacities of the Metals to perform the office of an invariable Measure of Value.

I. Were there but one species of such a substance as we have represented gold and silver to be; were there but one metal possessing the qualities of purity, divisibility, and durability; the inconveniences in the use of it for money would be fewer by far than they are found to be as matters stand. Such a metal might then, by an unlimited division into parts exactly equal, be made to serve as a tolerably steady and univer almeasure. But the rivalry between the metals, and the perfect equality which is found between all their physical qualities, so far as regards purity and divisibility, render them so equally well adapted to serve as the common measure of value, that they are universally admitted to pass current as money.

What is the consequence of this? that the one measures the value of the other, as well as that of every other thing. Now the moment any measure begins to be measured by another, whose proportion to it is not physically, perpetually, and invariably the same, all the usefulness of such a measure is lost. An example will make this plain.

A foot of measure is a determinate length. An English foot may be compared with the Paris foot, or with that of the Rhine; that is to say, it may be measured by them; and the proportion between their lengths

2
Money. lengths may be expressed in numbers; which proportion will be the same perpetually. The measuring the one by the other will occasion no uncertainty; and we may speak of length by Paris feet, and be perfectly well understood by others who are used to measure by the English foot, or by the foot of the Rhine.

But suppose that a youth of 12 years old takes it into his head to measure from time to time, as he advances in age, by the length of his own foot, and that he divides this growing foot into inches and decimals: what can be learned from his account of measures? As he increases in years, his foot, inches, and subdivisions, will be gradually lengthening; and were every man to follow his example, and measure by his own foot, then the foot of a measure now established would totally cease to be of any utility.

This is just the case with the two metals. There is no determinate invariable proportion between their value; and the consequence of this is, that when they are both taken for measuring the value of other things, the things to be measured, like lengths to be measured by the young man’s foot, without changing their relative proportion between themselves, change, however, with respect to the denominations of both their measures. An example will make this plain.

Let us suppose an ox to be worth 3000 pounds of weight of wheat, and the one and the other to be worth an ounce of gold, and an ounce of gold to be worth exactly 15 ounces of silver: if the case should happen, that the proportional value between gold and silver should come to be as 14 to 1, would not the ox, and consequently the wheat, be estimated at less in silver, and more in gold, than formerly? Further, would it be in the power of any state to prevent this variation in the measure of the value of oxen and wheat, without putting into the unit of their money less silver and more gold than formerly?

If therefore any particular state should fix the standard of the unit of their money at one species of the metals, while in fact both the one and the other are actually employed in measuring value; does not such a state resemble the young man who measures all by his growing foot? For if silver, for example, be retained as the standard, while it is gaining upon gold one fifteenth additional value; and if gold continue all the while to determine the value of things as well as silver; it is plain, that, to all intents and purposes, this silver measure is lengthening daily like the young man’s foot, since the same weight of it must become every day equivalent to more and more of the same commodity; notwithstanding that we suppose the fame proportion to subsist, without the least variation, between that commodity and every other species of things alienable.

Buying and selling are purely conventional, and no man is obliged to give his merchandise at what may be supposed to be the proportion of its worth. The use, therefore, of an universal measure, is to mark, not only the relative value of the things to which it is applied as a measure, but to discover in an infant the proportion between the value of those, and of every other commodity valued by a determinate measure in all the countries of the world.

Vol. XII.
MONEY

raising or debaseing the standard of the coin, according as they find it most for their present and temporary interest.

3. Methods which may be proposed for lessening the several inconveniences to which material money is liable.

The inconveniences from the variation in the relative value of the metals to one another, may in some measure be obviated by the following expedients.

1st. By considering one only as the standard, and leaving the other to seek its own value like any other commodity.

2nd. By considering one only as the standard, and fixing the value of the other from time to time by authority, according as the market-price of the metals shall vary.

3rd. By fixing the standard of the unit according to the mean proportion of the metals, attaching it to neither; regulating the coin accordingly; and upon every considerable variation in the proportion between them, either to make a new coinage, or to raise the denomination of one of the species, and lower it in the other, in order to preserve the unit exactly in the mean proportion between the gold and silver.

4th. To have two units and two standards, one of gold and one of silver, and to allow every body to fluctuate in either.

5th. Or last of all, to oblige all debtors to pay one half in gold, and one half in the silver standard.

4. Variations to which the Value of the Money-unit is expos'd from every Disorder in the Coin.

Let us suppose, at present, the only disorder to consist in a want of the due proportion between the gold and silver in the coin.

This proportion can only be established by the market-price of the metals; because an augmentation and rise in the demand for gold or silver has the effect of augmenting the value of the metal demanded. Let us suppose, that to-day one pound of gold may buy fifteen pounds of silver: If to-morrow there be a high demand for silver, a competition among merchants to have silver for gold will ensue; they will contend who shall get the silver at the rate of 15 pounds for one of gold; this will raise the price of it; and in proportion to their views of profit, some will accept of less than the 15 pounds. This is plainly a rise in the silver more properly than a fall in the gold; because it is the competition for the silver which has occasioned the variation in the former proportion between the metals.

Let us now suppose, that a state, having with great exactness examined the proportion of the metals in the market, and having determined the precise quantity of each for realising or representing the money-unit, shall execute a most exact coinage of gold and silver coin. As long as that proportion continues unvaried in the market, no inconvenience can result from that quarter in making use of metals for money of account.

But let us suppose the proportion to change; that the silver, for example, shall rise in its value with regard to gold: will it not follow, from that moment, that the unit realized in the silver, will become of more value than the unit realized in the gold-coin?

But as the law has ordered them to pass as equivalents for one another, and as debtors have always the option of paying in what legal coin they think fit, will they not choose to pay in gold? and will not then the silver coin be melted down or exported, in order to be sold as bullion, above the value it bears when it circulates in coin? Will not this paying in gold also really diminish the value of the money-unit, since upon this variation every thing must fall for more gold than before, as we have already observed.

Consequently, merchandise, which have not varied in their relative value to any other thing but to gold and silver, must be measured by the mean proportion of the metals; and the application of any other measure to them is altering the standard. If they are measured by the gold, the standard is debased; if by silver, it is raised.

If, to prevent the inconvenience of melting down the silver, the state shall give up affixing the value of their unit to both species at once, and shall fix it to one, leaving the other to seek its price as any other commodity; in that case, no doubt, the melting down of the coin will be prevented; but will this ever retrieve the value of the money-unit to its former standard? Would it, for example, in the foregoing supposition, raise the debased value of the money-unit in the gold coin, if that species were declared to be the standard? It would indeed render silver coin purely a merchandise, and, by allowing it to seek its value, would certainly prevent it from being melted down as before; because the pieces would rise conventionally in their denomination; or an aqua, as it is called, would be taken in payments made in silver; but the gold would not, on that account, rise in its value, or begin to purchase any more merchandise than before. Were therefore the standard fixed to the gold, would not this be an arbitrary and a violent revolution in the value of the money-unit, and a debasement of the standard?

If, on the other hand, the state should fix the standard to the silver, which we suppose to have risen in its value, would that ever sink the advanced value which the silver coin had gained above the worth of the former standard unit? and would not this be a violent and an arbitrary revolution in the value of the money-unit, and a raising of the standard?

The only expedient, therefore, is, in such a case, to fix the numerary unit to neither of the metals, but to contrive a way to make it fluctuate in a mean proportion between them; which is in effect the introduction of a pure ideal money of account.

The regulation of fixing the unit by the mean proportion, ought to take place at the instant the standard unit is fixed with exactness both to the gold and silver. If it be introduced long after the market-proportion between the metals has deviated from the proportion established in the coin; and if the new regulation is made to have a retrospect, with regard to the acquitting of permanent contracts entered into while the value of the money-unit had attached itself to the lowest currency in consequence of the principle above laid
6. Of the Disorder in the British Coin, so far as it occasions the melting down or the exporting of the Specie.

The defects in the British coin are three.

10s. The proportion between the gold and silver is found to be as 1 to 15 3/5, whereas the market price may be supposed to be nearly as 1 to 14 1/2.

2do. Great part of the current money is worn and light.

3rd, From the second defect proceeds the third, to wit, that there are several currencies in circulation which pass for the same value, without being of the same weight.

4th. From all these defects results the least and greatest inconvenience, to wit, that some innovation must be made, in order to set matters on a right foot.

The English, besides the unit of their money which they call the pound Sterling, have also the unit of their weight for weighing the precious metals.

This is called the pound troy, and consists of 12 ounces, every ounce of 20 penny-weights, and every penny-weight of 24 grains. The pound troy, therefore, consists of 240 penny-weights and 5760 grains.

The fineness of the silver is reckoned by the number of ounces and penny-weights of the pure metal in the pound troy of the composed mafs; or, in other words, the pound troy, which contains 5760 grains of standard silver, contains 5328 grains of fine silver, and 432 grains of copper, called alloy.

Thus standard silver is 11 ounces 2 penny-weights of fine silver in the pound troy to 18 penny-weights copper, or 111 parts fine silver to 9 parts alloy.

Standard gold is 11 ounces fine to 1 ounce silver or copper employed for alloy, which together make the pound troy; consequently, the pound troy of standard gold contains 5280 grains fine, and 480 grains alloy, which alloy is reckoned of its own value.

This pound of standard silver is ordered, by statute of the 43d of Elizabeth, to be coined into 62 shillings, 20 of which make the pound sterling; consequently the 20 shillings contain 1718.7 grains of fine silver, and 1858.06 standard silver.

The pound troy of standard gold, 1/5 fine, is ordered, by an act of king Charles II. to be cut into 44½ guineas; that is to say, every guinea contains 129.43 grains of standard gold, and 118.644 of fine gold;
The coinage in England is entirely defrayed at the expense of the state. The mint price for the metals is the very same with the price of the coin. Whoever carries to the mint an ounce of standard silver, receives for it in silver coin 5s. 2d. or 6s. 6d.; whoever carries an ounce of standard gold receives in gold coin 3l. 17s. 10d. the one and the other making exactly an ounce of the same fineness with the bullion. Coin, therefore, can have no value in the market above bullion; consequently, no loss can be incurred by those who melt it down.

When the guinea was first struck, the government (not inclining to fix the pound Sterling to the gold coin of the nation) fixed the guinea at 20 shillings, (which was then below its proportion to the silver), leaving it to seek its own price above that value, according to the course of the market.

By this regulation no harm was done to the English silver standard; because the guinea, at 118.644 grains fine silver, paid for more, than 20 shillings, or 171.87 grains fine silver, no debtor would pay with gold below its standard value; and whatever it was received for above that price was purely conventional.

Accordingly guineas fought their own price until the year 1728, then they were fixed a new, not below their value as at first, but at what was then reckoned their exact value, according to the proportion of the metals, viz. at 21 shillings; and at this they were ordered to pass current in all payments.

This operation had the effect of making the gold a standard as well as the silver. Debtors then paid indifferently in gold as well as in silver, because they were supposed to be of the same intrinsic as well as current value; in which case no inconvenience could follow upon this regulation. But in time silver came to be more demanded: the making of plate began to prevail more than formerly, and the exportation of silver to the East Indies increasing yearly, made the demand for it greater, or perhaps brought its quantity to be proportionably less than before. This changed the proportion of the metals; and by slow degrees they have come from that of 1 to 15.2 (the proportion they were supposed to have when the guineas were fixed and made a lawful money at 21 shillings) to that of 14.5, the present supposed proportion.

The consequence of this has been, that the same guinea which was worth 1804.5 grains fine silver, at the time it was fixed at 21 s. is now worth no more than 1719.9 grains of fine silver according to the proportion of 14.5 to 1.

Consequently debtors, who have always the option of the legal species in paying their debts, will pay pounds sterling no more in silver but in gold; and as the gold pounds they pay in are not intrinsically worth the silver pounds they paid in formerly according to the statute of Elizabith, it follows that the pound Sterling in silver is really no more the standard, hence nobody will pay at that rate, and hence nobody can be compelled to do it.

Besides this want of proportion between the metals, the silver coined before the reign of George I. is now become light by circulation; and the guineas coined by all the princes since Charles II. pass by tale, though many of them are considerably diminished in their weight.

Let us now examine what profit the want of proportion and the want of weight in the coin can afford to the money-jobbers in melting it down or exporting it.

Did every body consider coin only as the measure for reckoning value, without attending to its value as a metal, the deviations of gold and silver coin from perfect exactness, either as to proportion or weight, would occasion little inconvenience.

Great numbers, indeed, in every modern society, consider coin in no other light than that of money of account; and have great difficulty to comprehend what difference any one can find between a light Guinea and a heavy one, or what inconvenience there can possibly result from a guinea's being some grains of fine gold too light to be worth 21 shillings standard weight. And did every one think in the same way, there would be no occasion for coin of the precious metals at all; leather, copper, iron, or paper, would serve for commerce as well as gold and silver.

But although there be many who look no farther than at the stamp on the coin, there are others whose sole business it is to examine its intrinsic worth as a commodity, and to profit of every irregularity in the weight and proportion of metals.

By the very institution of coinage, it is implied, that every piece of the same metal, and same denomination with regard to the money-unit, shall pass current for the same value.

It is, therefore, the employment of money-jobbers, to examine, with a scrupulous exactness, the precise weight of every piece of coin which comes into their hands.

The first object of their attention is, the price of the metals in the market: a jobber finds, at present, that with 14.5 pounds of fine silver bullion, he can buy one pound of fine gold bullion.

He therefore buys up with gold coin all the new silver as fast as it is coined, of which he can get at the rate of 15.2 pounds for one in gold; these 15.2 pounds silver coin he melts down into bullion, and converts that back into gold bullion, giving at the rate of only 14.5 pounds for one.

By this operation he remains with the value of 78 of one pound weight of silver bullion clear profit upon the 153 pounds he bought; which 78 is really lost by the man who inadvertently coined silver at the mint, and gave it to the money-jobber for his gold. Thus the state loses the expense of the coinage, and the public the convenience of change for their guineas.

But here it may be asked, Why should the money-jobber melt down the silver coin? can he not buy gold with it as well without melting it down? He cannot; because when it is in coin he cannot avail himself of its being new and weighty. Coin goes by tale, not by weight; therefore, were he to come to market with his new silver coin, gold bullion being sold at the mint price, we shall suppose, viz. at 3l. 17s. 10d. Sterling money by ounce, he would be obliged to pay the price of what he brought with heavy money, which he can equally do with light.

He therefore melts down the new silver coin, and sells
fells it for bullion, at so many pence an ounce; the price of which bullion is, in the English market, always above the price of silver at the mint, for the reasons now to be given.

When you sell standard-silver bullion at the mint, you are to be paid in weighty money: that is, you receive for your bullion the very same weight in standard coin; the coinage cost nothing; but when you sell bullion in the market, you are paid in worn-out silver, in gold, in bank-notes, in short, in every species of lawful current money. Now all these payments have some defect: the silver you are paid with is worn and light; the gold you are paid with is over-rated, and perhaps also light; and the bank-notes must have the same value with the specie with which the bank pays them; that is, with light silver or over-rated gold.

It is for these reasons, that silver bullion, which is bought by the mint at 5s. 2d. per ounce of heavy silver money, may be bought at market at 65 pence the ounce in light silver, over-rated gold, or bank-notes, which is the same thing.

Further, we have seen how the imposition of coinage has the effect of raising coin above the value of bullion, by adding a value to it which it had not as a metal.

Just so, when the unit is once affixed to certain determined quantities of both metals, if one of the metals should afterwards rise in value in the market, the coin made of that metal must lose a part of its value as coin, although it retains it as a metal. Consequently, as in the first case it acquired an additional value by being coined, it must now acquire an additional value by being melted down. From this we may conclude, that when the standard is affixed to both the metals in the coin, and when the proportion of that value is not made to follow the price of the market, that species which rises in the market is melted down, and the bullion is sold for a price much exceeding the mint price as the metal has risen in its value.

If, therefore, in England, the price of silver bullion is found to be at 65 pence the ounce, while at the mint it is rated at 62; this proves that silver has risen 2s. above the proportion observed in the coin, and that all coin of standard weight may consequently be melted down with a profit of 2s. But as there are several other circumstances to be attended to, which regulate and influence the price of bullion, we shall here pass them in review, the better to discover the nature of this disorder in the English coin, and the advantages which money-jobbers may draw from it.

The price of bullion, like that of every other merchandise, is regulated by the value of the money it is paid with.

If bullion, therefore, sells in England for 65 pence an ounce, paid in silver coin, it must sell for 65 shillings the pound troy: that is to say, the shillings it is commonly paid with do not exceed the weight of 2/5 of a pound troy; for if the 65 shillings with which the pound of bullion is paid weighed more than a pound troy, it would be a shorter and better way for him who wants bullion to melt down the shillings and make use of the metal, than to go to market with them in order to get less.

We may, therefore, be very certain, that no man will buy silver bullion at 65 pence an ounce, with any shilling which weighs above 2/5 of a pound troy.

We have gone upon the supposition that the ordinary price of bullion in the English market is 65 pence per ounce. This has been done upon the authority of some late writers on this subject: it is now proper to point out the causes which may make it deviate from that value.

I. It may vary, and certainly will vary, in the price, according as the currency is better or worse. When the expences of a war, or a wrong balance of trade, have carried off a great many heavy guineas, it is natural that bullion should rise; because then it will be paid for more commonly in light gold and silver; that is to say, with pounds Sterling, below the value of 113 grains fine gold, the worth of the pound Sterling in new guineas.

II. This wrong balance of trade, or a demand for bullion abroad, becoming very great, may occasion a scarcity of the metals in the market, as well as a scarcity of the coin; consequently, an advanced price must be given for it in proportion to the greatness and height of the demand. In this case, both the specie and the bullion must be bought with paper. But the rise in the price of bullion proceeds from the demand for the metals and the competition between merchants to procure them, and not because the paper given as the price is at all of inferior value to the specie. The least discredit of this kind would not tend to diminish the value of the paper: it would annihilate it at once. Therefore, since the metals must be had, and that the paper cannot supply the want of them when they are to be exported, the price rises in proportion to the difficulties in finding metals elsewhere than in the English market.

III. A sudden call for bullion, for the making of plate. A goldsmith can well afford to give 67 pence for an ounce of silver, that is to say, he can afford to give one pound of gold for 14 pounds of silver, and perhaps for less, notwithstanding that what he gives is more than the ordinary proportion between the metals, because he indemnifies himself amply by the price of his workmanship; just as a tavern-keeper will pay any price for a fine fish, because, like the goldsmith, he buys for other people.

IV. The mint price has as great an effect in bringing down the price of bullion, as exchange has in raising it. In countries where the metals in the coin are justly proportioned, where all the currencies are of legal weight, and where coinage is imposed, the operations of trade make the price of bullion constantly to fluctuate between the value of the coin and the mint price of the metals.

Now let us suppose that the current price of silver bullion in the market is 65 pence the ounce, paid in lawful money, no matter of what weight or of what metal. Upon this the money-jobber falls to work. All shillings which are above 2/5 of a pound troy, he throws into his melting-pot, and sells them as bullion for 65s. per ounce; all those which are below that weight he carries to market, and buys bullion with them at 65s. per ounce.

What is the consequence of this?

That those who sell the bullion, finding the shillings which the money-jobber pays with perhaps not above 2/5 of
Money.

\( \frac{1}{2} \) of a pound troy, they on their side raise the price of their bullion to 66d. the ounce.

This makes new work for the money-jobber; for he must always gain. He now weighs all shillings as they come to hand; and as formerly he threw into his melting-pot those only which were worth more than \( \frac{1}{2} \) of a pound troy, he now throws in all that are in value above \( \frac{1}{2} \). He then sells the melted shillings at 66d. the ounce, and buys bullion with the light ones at the same price.

This is the consequence of ever permitting any species of coin to pass by the authority of the stamp, without controlling it at the same time by the weight: and this is the manner in which money-jobbers gain by the currency of light money.

It is no argument against this exposition of the matter to say, that silver bullion is seldom bought with silver coin; because the pence in new guineas are worth no more than the pence of shillings of 65 in the pound troy: that is to say, that 240 pence contained in \( \frac{1}{2} \) of a new guinea, and 240 pence contained in 28 shillings of 65 to the pound troy, differ no more on the intrinsic value than 0.83 of a grain of fine silver upon the whole, which is a mere trifle.

Whenever, therefore, shillings come below the weight of \( \frac{1}{2} \) of a pound troy, then there is an advantage in changing them for new guineas; and when that is the case, the new guineas will be melted down, and profit will be found in selling them for bullion, upon the principles we have just been explaining.

We have already given a specimen of the domestic operations of the money-jobbers; but these are not the most prejudicial to national concerns. The jobbers may be supposed to be Englishmen; and in that case the profit they make remains at home: but whenever there is a call for bullion to pay the balance of trade, it is evident that this will be paid in silver coin; never in gold, if heavy silver can be got; and this again carries away the silver coin, and renders it at home so rare, that great inconveniences are found for want of the leffer denominations of it. The loss however here is confined to an inconvenience; because the balance of trade being a debt which must be paid, we do not consider the exportation of the silver for that purpose as any consequence of the disorder of the coin. But besides this exportation which is necessary, there are others which are arbitrary, and which are made only with a view to profit of the wrong proportion.

When the money-jobbers find difficulty in carrying on the traffic we have described, in the English market, because of the competition among themselves, they carry the silver coin of the country, and sell it abroad for gold, upon the same principles that the East India company send silver to China in order to purchase gold.

It may be demanded, What hurt this trade can do to Britain, since those who export silver bring back the same value in gold? Were this trade carried on by natives, there would be no loss; because they would bring home gold for the whole intrinsic value of the silver. But if we suppose foreigners finding over gold to be coined at the English mint, and changing the gold into English silver coin, and then carrying off this coin, it is plain that they must gain the difference, as well as the money-jobbers. But it may be answered, That having given gold for silver at the rate of the mint, they have given value for what they have received. Very right; but so did Sir Hans Sloane, when he paid five guineas for an overgrown toad: he got value for his money: but it was value only to himself. Just so, whenever the English government shall be obliged to restore the proportion of the metals (as they must do), this operation will annihilate that imaginary value which they have hitherto set upon gold; which imagination is the only thing which renders the exchange of their silver against the foreign gold equal.

But it is farther objected, that foreigners cannot carry off the heavy silver; because there is none to carry off. Very true; but then they have carried off a great quantity already; or if the English Jews have been too sharp to allow such a profit to fall to strangers, (which may or may not have been the case), then this disorder is an effectual stop to any more coinage of silver for circulation.

7. Of the disorder in the British Coin, so far as it affects the Value of the Pound Sterling Currency.

From what has been said, it is evident, that there must be found in England two legal pounds Sterling of different values; the one worth 113 grains of fine gold, the other worth 1718.7 grains of fine silver. We call them different; because these two portions of the precious metals are of different values all over Europe.

But besides these two different pounds Sterling, which the change in the proportion of the metals have created, the other defects of the circulating coin produce similar effects. The guineas coined by all the princes since the time of Charles II. have been of the same standard weight and fineness, 44\( \frac{1}{4} \) in a pound troy of standard gold \( \frac{2}{4} \) fine; these have been constantly wearing ever since they have been coined; and in proportion to their wearing they are of less value.

If therefore, the new guineas are below the value of a pound Sterling in silver, standard weight, the old must be of less value still. Here then is another currency, that is, another pound Sterling: or indeed more properly speaking, there are as many different pounds Sterling as there are guineas of different weights. This is not all; the money-jobbers having carried off all the weighty silver, that which is worn with use and reduced even below the standard of gold, forms one currency more, and totally destroys all determinate proportion between the money-unit and the currencies which are supposed to represent it.

It may be asked, how, at this rate, any silver has remained in England? It is answered, that the few weighty shillings which still remain in circulation, have marvellously escaped the hands of the money-jobbers, and as to the rest, the rubbing and wearing of these pieces has done what the state might have done; that is to say, it has reduced them to their due proportion with the lightest gold.

The disorder, therefore, of the English coin has rendered the standard of a pound Sterling quite uncertain. To say that it is 1718.7 grains of fine silver, is quite ideal. Who are paid in such pounds? To say that it is 113 grains of pure gold, may also not be true; because there are many currencies worse than the new guineas.
What then is the consequence of all this disorder? What effect has it upon the current value of a pound Sterling? And which way can the value of that be determined?

The operations of trade bring value to an equation, notwithstanding the greatest irregularities possible; and so in fact a pound Sterling has acquired a determinate value over all the world by the means of foreign exchange. This is a kind of ideal scale for measuring the British coin, although it has not all the properties of that described above.

Exchange considers the pound Sterling as a value determined according to the combination of the values of all the different currencies, in proportion as payments are made in the one or the other; and as debtors generally take care to pay in the worst species they can, it consequently follows, that the value of the pound Sterling should fall to that of the lowest currency.

Were there a sufficient quantity of worn gold and silver to acquit all bills of exchange, the pound Sterling would come down to the value of them; but if the new gold be also necessary for that purpose, the value of it must be proportionally greater.

All these combinations are liquidated and compensated with one another, by the operations of trade and exchange: and the pound Sterling, which is so different in itself, becomes thereby, in the eyes of commerce a determinate unit; subject, however to variations, from which it never can be exempted.

Exchange, therefore, is one of the best measures for valuing a pound Sterling, present currency. Here occurs a question:

Does the great quantity of paper-money in England tend to diminish the value of the pound Sterling?

We answer in the negative. Paper money is just as good as gold or silver money, and no better. The variation of the standard, as we have already said, must influence the interests of debtors and creditors proportionately everywhere. From this it follows that all augmentation of the value of the money-unit in the species must hurt the debtors in the paper money; and all diminutions, on the other hand, must hurt the creditors in the paper money as well as everywhere else. The payments, therefore, made in paper money, never can contribute to the regulation of the standard of the pound Sterling; it is the species received in liquidation of that paper money which alone can contribute to mark the value of the British unit; because it is affixed to nothing else.

From this we may draw a principle, "That in countries where the money-unit is entirely affixed to the coin, the actual value of it is not according to the legal standard of that coin, but according to the mean proportion of the actual worth of these currencies in which debts are paid.

From this we see the reason why the exchange between England and all other trading towns in Europe has long appeared so unfavourable. People calculate the real par, upon the supposition that a pound Sterling is worth 1718.7 grains Troy of fine silver, when in fact the currency is not perhaps worth 1638, the value of a new guinea in silver, at the market proportion of 1 to 14.5: that is to say, the currency is but 95.3 per cent. of the silver standard of the 43d of Elizabeth.

No wonder then if the exchange be thought unfavourable.

From the principle we have just laid down, we may gather a confirmation of what we advanced concerning the exchange of the advanced price of bullion in the English market.

When people buy bullion with current money at a determinate price, that operation, in conjunction with the course of exchange, ought naturally to mark the actual value of the pound Sterling with great exactness.

If therefore the price of standard bullion in the English market, when no demand is found for the exportation of the metals, that is to say, when paper is found for paper upon exchange, and when merchants abroad in these matters judge exchange (that is, remittances) to be at par, if then silver bullion cannot be bought at a lower price than 65 pence the ounce, it is evident that this bullion might be bought with 65 pence in shillings, of which 65 might be coined out of the pound troy English standard silver; since 65 shillings imply 65 shillings for the 12 ounces of pound Troy.

This plainly shows how standard silver bullion should fall for 65 pence the ounce, in a country where the ounce of standard silver in the coin is worth no more than 62; and were the market-price of bullion to stand uniformly at 65 pence per ounce, that would show the value of the pound Sterling to be tolerably fixed. All the heavy silver coin is now carried off; because it was intrinsically worth more than the gold it passed for in currency. The silver therefore which remains is worn down to the market proportion of the metals, that is to say, when paper is remittances) to be at par, if then silver bullion should fall at above 65 pence per ounce. If therefore such bullion fells for 65 pence, the shillings with which it is bought must weigh no more than 88.64 grains standard silver; that is, they must lose 4.29 grains, and are reduced to 1/3 of a pound troy.

But it is not necessary that bullion be bought with shillings; no fluctuation of price is ever made farther than as so many pence Sterling per ounce. Does not this virtually determine the mean value of that money unit; would he not understand the value of it far better from that circumstance than by the course.
What everybody knows to be meant by the common phrase, influenced by extraordinary demand, (such as for the course of any exchange, or for making an extraordinary provision of plate, but when it stands at what every body knows to be meant by the common market price, is a very tolerable measure of the value of the actual money-standard in any country.

If it be therefore true, that a pound Sterling cannot purchase above 1638 grains of fine silver bullion, it will require not a little logic to prove that it is really, or has been for these many years, worth any more; notwithstanding that the standard weight of it in England is regulated by the laws of the kingdom at 1718.7 grains of fine silver.

If to this valuation of the pound Sterling drawn from the price of bullion, we add the other drawn from the course of exchange; and by this we find, that when paper is found for paper upon exchange, a pound Sterling cannot purchase above 1638 grains of fine silver in any country of Europe; upon these two authorities we may very safely conclude, as to the matter of fact at least, that the pound Sterling is not worth more, either in London or in any other trading city; and if this be the case, it is just worth 20 shillings of 65 to the pound troy.

If therefore the mint were to coin shillings at that rate, and pay for silver bullion at the market price, that is, at the rate of 65 pence per ounce in those new coined shillings, they would be in proportion to the gold; silver would be carried to the mint equally with gold; and would be as little subject to be exported or melted down.

It may be inquired in this place, how far the coinage the pound troy into 65 shillings is contrary to the laws of England?

The moment a statute pronounces a certain quantity of gold to be worth a certain quantity of silver, and orders those respective quantities of each metal to be received as equivalents of each other, and as lawful money in payments, that moment gold is made a standard as much as silver. If therefore too small a quantity of gold be ordered or permitted to be considered as an equivalent for the unit, the silver standard is from that moment debased; or indeed more properly speaking, all silver money is from that moment protracted; for who, from that time, will ever pay in silver, when he can pay cheaper in gold? Gold, therefore, by such a law, is made the standard, and all declarations to the contrary are against the matter of fact.

Were the king, therefore, to coin shillings at 65 shillings in the pound, it would be the duty of the commonwealth to send up the coinage to the weight of 65 and 3d. for which he would commit no adulteration upon the standard, the adulteration is already committed. The standard has defecned to what it is by flow degrees, and by the operation of political causes only; and nothing prevents it from falling lower but the standard of the gold coin. Let guineas be now let to seek their value as they did formerly, and let light silver continue to go by tale, we shall see the guineas up to 30 shillings in 20 years time, as was the case in 1695.

It is as absurd to say that the standard of Queen Elizabeth has not been debased by enacting that the English unit shall be acquired with 113 grains of fine gold, as it would be to affirm that it would not be debased from what it is at present by enacting that a pound of butter should every where be received in payment for a pound Sterling; although the pound Sterling should continue to consist of 3 ounces, 17 pennyweights, and 10 grains of standard silver, according to the statute of the 43 of Elizabeth. In that case, most debtors would pay in butter; and silver, as at present, acquire a conventional value as a metal, but would be looked upon no longer as a standard, or as money.

If therefore by the law of England, a pound Sterling must consist of 1718.7 grains troy of fine silver, by the law of England also, 113 grains of gold must be of the same value; but no law can establish that proportion; consequently, in which ever way a reformation be brought about, some law must be revised; consequently, expediency, and not compliance with law, must be the motive in reforming the abuse.

From what has been said, it is not at all surprising that the pound Sterling should in fact be reduced nearly to the value of the gold. Whether it ought to be kept at that value is another question. All that we here decide is, that coining the pound troy into 65 shillings would restore the proportion of the metals, and render both species common in circulation. But restoring the weight and proportion of the coin is not the difficulty which prevents a reformation of the English coinage.

8. Circumstances to be attended to in a new Regulation of the British Coin.

To people who do not understand the nature of such operations it may have an air of justice to support the unit at what is commonly believed to be the standard of Queen Elizabeth, viz. at 1718.7 grains of fine silver.

The regulating the standard of both silver and gold to 4 fine, and the pound Sterling to four ounces standard silver, as it stood during the reign of Queen Mary I. has also its advantages, as Mr Harris has observed. It makes the crown-piece to weigh just one ounce, the thilling four penny-weight, and the penny eight grains; consequently, were the new statute to bear, the secretory of the coin should regulate its currency upon certain occasions, the having the pieces adjusted to certain aliquot parts of weight would make weighing easy, and would accustom the common people to judge of the value of money by its weight, and not by the stamp.

In that case there might be a convenience in striking the gold coins of the same weight with the silver, because the proportion of their values would then constantly be the same with the proportion of the metals. The gold crowns would be worth at present £1. 13s. 6d. the half crowns 11. 16s. 3d. the gold shillings 14s. and 6d. and the half 7s. and 3d. This was anciently the practice in the Spanish mints.

The interest within the state can be nowise perfectly protected but by permitting conversions of value from the old to the new standard, whatever it be, and
Money. by regulating the footing of such conventions by act of parliament, according to circumstances.

For this purpose, we shall examine those interests which will chiefly merit the attention of government, when they form a regulation for the future of acquitting permanent contracts already entered into. Such as may be contracted afterwards will naturally follow the new standard.

The landed interest is no doubt the most considerate in the nation. Let us therefore examine, in the first place, what regulations it may be proper to make, in order to do justice to this great class, with respect to the land-tax on one hand, and with respect to their lees upon the other.

The valuation of the lands of England was made many years ago, and reasonably ought to be supported at the real value of the pound Sterling at that time, according to the principles already laid down. The general valuation, therefore, of the whole kingdom will rise according to this scheme. This will be considered as an injustice; and no doubt it would be so, if, for the future, the land-tax be imposed as herefore, without attending to this circumstance; but as that imposition is annual, as it is laid on by the landed interest itself, who compose the parliament, it is to be supposed that this great class will at least take care of their own interest.

Were the valuation of the lands to be settled according to the valuation of the pound Sterling of 1718.7 grains of silver, which is commonly supposed to be the standard of Elizabeth, there would be no great injury done; this would raise the valuation only 5 per cent, and the land-tax in proportion.

There is no class of inhabitants in all England so much at their ease, and so free from taxes, as the class of farmers. By living in the country, and by consuming the fruits of the earth without their suffering any alienation, they avoid the effect of many excises, which, by those who live in corporations, are felt upon many articles of their consumption, as well as on those which are immediately loaded with those impositions. For this reason it will not, perhaps, appear unreasonable, if the additional 5 per cent, on the land-tax were thrown upon this class, and not upon the landlords.

With respect to leases, it may be observed, that we have gone upon the supposition that the pound Sterling in the year 1728 was worth 1718.7 grains of fine silver, and 113 grains of fine gold.

There would be no injustice done the lees upon all the lands in the kingdom, were their rents to be fixed at the mean proportion of these values. We have observed how the pound Sterling has been gradually diminishing in its worth from that time by the gradual rise of the silver. This mean proportion, therefore, will nearly answer to what the value of the pound Sterling was in 1743; supposing the rise of the silver to have been uniform.

It may be farther alleged in favour of the landlords, that the gradual debasement of the standard has been more prejudicial to their interest in letting their lands, than to the farmers in disposing of the fruits of them. Proprietors cannot so easily raise their rents upon new leases, as farmers can raise the prices of their grain according to the debasement of the value of the currency.

The pound Sterling, thus regulated at the mean proportion of its worth, as it stands at present, and as it stood in 1728, may be realised in 1678.6 grains of fine silver, and 115.76 grains of fine gold; which is 2.4 per cent, above the value of the present currency. No injury, therefore, would be done to lessees, and no unreasonable gain would accrue to the landed interest, in appointing conventions of all land-rents at 2.4 per cent, above the value of the present currency.

Without a thorough knowledge of every circumstance relating to Great Britain, it is impossible to lay down any plan. It is sufficient here briefly to point out the principles upon which it must be regulated.

The next interest to be considered is that of the nation's creditors. The right regulation of their concerns will have a considerable influence in establishing public credit upon a solid basis, by making it appear to all the world, that no political operation upon the money of Great Britain can in any respect either benefit or prejudice the interest of that who lend their money upon the faith of the nation. Therefore, alfo the interest of so great a body, will serve as a rule for all creditors who are in the same circumstances, and will upon other accounts be productive of greater advantages to the nation in time coming.

In 1749, a new regulation was made with the public creditors, when the interest of the whole redeemable national debt was reduced to 3 per cent. This circumstance infinitely facilitates the matter with respect to this class, since, by this innovation of all former contracts, the whole national debt may be considered as contracted at, or posterior to, the 25th of December 1749.

Were the slate, by any arbitrary operation upon money (which every reformation much be), to diminish the value of the pound Sterling in which the parliament at that time bound the nation to acquit those capitals and the interest upon them, would not all Europe say, That the British parliament had defrauded their creditors? If therefore the operation proposed to be performed should have a contrary tendency, viz. to augment the value of the pound Sterling with which the parliament at that time bound the nation to acquit those capitals and interests, must not all Europe also agree, That the British parliament had defrauded the nation?

This convention with the ancient creditors of the state, who, in consequence of the debasement of the standard, might have justly claimed an indemnification for the loss upon their capitals, lent at a time when the pound Sterling was at the value of the heavy silver, removes all causes of complaint from that quarter. There was in the year 1749 an innovation in all their contracts; and they are now to be considered as creditors only from the 25th of December of that year.

Let the value of the pound Sterling be inquired into during one year preceding and one posterior to the transactions of the month of December 1749. The sums borrowed and paid back by the nation during that period, will furnish data sufficient for that calculation. Let this value of the pound be specified.
Money.

In troy grains of fine silver and fine gold bullion, without mentioning any denomination of money according to the exact proportion of the metals at that time. And let this pound be called the pound of national credit.

This first operation being determined, let it be enacted that the pound Sterling, by which the state is to borrow for the future, and that in which the creditors are to be paid, shall be the exact mean proportion between the quantities of gold and silver above specified, according to the actual proportion of the metals at the time such payments shall be made; or that the sums shall be borrowed or acquitted, one half in gold and one half in silver, at the respective requisitions of the creditors or of the state, when borrowing. All debts contracted posterior to 1749 may be made liable to conversions.

The consequence of this regulation will be the insensible establishment of a bank-money. Nothing would be more difficult to establish, by a positive resolution, than such an invariable measure; and nothing will be found so easy as to let it establish itself by its own advantages. This bank-money will be liable to much fewer inconveniences than that of Amsterdam. There the persons transacting must be upon the spot; here, the Sterling currency may, every quarter of a year, be adjusted by the exchequer to this invariable standard, for the benefit of all debtors and creditors who incline to profit of the stability of this measure of value.

This scheme is liable to no inconvenience from the variation of the metals, let them be ever so frequent or hard to be determined; because upon every occasion where there is the smallest doubt as to the actual proportion, the option competent to creditors to be paid half in silver and half in gold will remove.

Such a regulation will also have this good effect, that it will give the nation more just ideas of the nature of money, and consequently of the influence it ought to have upon prices.

If the value of the pound Sterling shall be found to have been by accident less in December 1749 than it is a present; or if at present the currency be found below what it has commonly been since 1749; in justice to the creditors, and to prevent all complaints, the nation may grant them the mean proportion of the value of the pound Sterling from 1749 to 1760, or any other which may to parliament appear reasonable.

This regulation must appear equitable in the eyes of all Europe; and the strongest proof of it will be, that it will not produce the smallest effect prejudicial to the interest of the foreign creditors. The course of exchange with regard to them will stand precisely as before.

A Dutch, French, or German creditor, will receive the same value for his interest in the English stocks as heretofore. This must silence all clamours at home, being the most convincing proof, that the new regulation of the coin will have made no alteration upon the real value of any man's property, let him be debtor or creditor.

The interest of every other denomination of creditors, whose contracts are of a fresh date, may be regulated upon the same principles. But where debts are of an old standing, justice demands, that attention be had to the value of money at the time of contracting. Nothing but the stability of the English coin, when compared with that of other nations, can make such a proposal appear extraordinary. Nothing is better known in France than this stipulation added to obligations, *argent au cours de ce jour*; that is to say, That the sum shall be repaid in coin of the same intrinsic value with what has been lent. Why should such a clause be thought reasonable for guarding people against arbitrary operations upon the numerary value of the coin, and not be found just upon every occasion where the numerary value of it is found to be changed, let the cause be what it will?

The next interest we shall examine is that of trade. When men have attained the age of 21, they have no more occasion for guardians. This may be applied to traders; they can parry with their pen every inconvenience which may result to other people from the changes upon money, provided only the laws permit them to do themselves justice with respect to their engagements. This class demands no more than a right to convert all reciprocal obligations into denominations of coin of the same intrinsic value with those they have contracted in.

The next interest is that of buyers and sellers; that is, of manufacturers with regard to consumers, and of servants with respect to those who hire their personal service.

The interest of this class requires a most particular attention. They must, literally speaking, be put to school, and taught the first principles of their trade, which is buying and selling. They must learn to judge of price by the grains of silver and gold they receive; they are children of a mercantile mother, however warlike the father's disposition. If it be the interest of the state that their bodies be rendered robust and active, it is no less the interest of the state that their minds be instructed in the first principles of the trade they exercise.

For this purpose, tables of conversion from the old standard to the new must be made, and ordered to be put up in every market, in every shop. All duties, all excises, must be converted in the same manner. Uniformity must be made to appear every where. The smallest deviation from this will be a stumbling-block to the multitude.

Not only the interest of the individuals of the class we are at present considering, demands the nation's care and attention in this particular, but the prosperity of trade, and the well-being of the nation, are also deeply interested in the execution.

The whole delicacy of the intricate combinations of commerce depends upon a just and equitable vibration of prices, according as circumstances demand it. The more, therefore, the industrious classes are instructed in the principles which influence prices, the more easily will the machine move. A workman then learns to fix his price without regret, and can raise it without aversion. When principles are not understood, prices cannot gently fall, they must be pulled down; and merchants dare not suffer them to rise, for fear of abuse, even
The last interest is that of the bank of England, which naturally must regulate that of every other. Had this great company followed the example of other banks, and established a bank-money of an invariable standard as the measure of all their debts and credits, they would not have been liable to any inconvenience upon a variation of the standard.

The bank of England was projected about the year 1694, at a time when the current money of the nation was in the greatest disorder, and government in the greatest distress both for money and for credit. Commerce was then at a very low ebb; and the only, or at least the most profitable, trade of any, was jobbing in coin, and carrying backwards and forwards the precious metals from Holland to England. Merchants profited also greatly from the effects which the utter disorder of the coin produced upon the price of merchandise.

At such a juncture the resolution was taken to make a new coinage; and upon the prospect of this, a company was found, who, for an exclusive charter to hold a bank for 13 years, willingly lent the government upwards of a million Sterling at 8 per cent. (in light money we suppose), with a prospect of being repaid both interest and capital in heavy. This was not all: part of the money lent was to be applied for the establishment of the bank; and no less than 4000l. a-year was allowed to the company, above the full interest, for defraying the charge of the management.

Under such circumstances the introduction of bank-money was very superfluous, and would have been very impolitic. That invention is calculated against the raising of the standard; but here the bank profited of that rise in its quality of creditor for money lent; and took care not to commence debtor by circulating their paper until the effect of the new regulation took place. That is, after the general re-coinage of all the clipped silver.

From that time till now, the bank of England has been the basis of the nation’s credit, and with great reason has been constantly under the most intimate protection of every minister.

The value of the pound Sterling, as we have seen, has been declining ever since the year 1601, the standard being fixed to silver during all that century, while the gold was constantly rising. No sooner had the proportion taken another turn, and silver begun to rise, than the government of England threw the standard virtually upon the gold, by regulating the value of the guineas at the exact proportion of the market. By these operations, however, the bank has constantly been a gainer (in its quality of debtor) upon all the paper in circulation; and therefore has lost nothing by not having established a bank-money.

The interest of this great company being established upon the principles we have endeavoured to explain, it is very evident, that the government of England never will take any step in the reformation of the coin which in its consequences can prove hurtful to the bank. Such a step would be contrary both to justice and to common sense. To make a regulation which, by raising the standard, will prove beneficial to the public creditors, to the prejudice of the bank (which we may call the public debtor), would be an operation upon public credit like that of a person who is at great pains to support his house by props upon all sides, and who at the same time blows up the foundation of it with gunpowder.

We may therefore conclude, that with regard to the bank of England, as well as every other private banker, the notes which are constantly payable upon demand must be made liable to a conversion at the actual value of the pound Sterling at the time of the new regulation.

That the bank will gain by this, is very certain; but the circulation of their notes is so extensive, that it would be absurd to allow to the then possessors of them that intensification which naturally should be shared by all those through whose hands they have passed, in proportion to the debasement of the standard during the time of their respective possession.

Besides these considerations, which are in common to all states, the government of Great Britain has one peculiar to itself. The interest of the bank, and that of the creditors, are diametrically opposite: every thing which raises the standard hurts the bank; every thing which can sink it hurts the creditors: and upon the right management of the one and the other, depends the solidity of public credit. For these reasons, without the most certain prospect of conducting a restitution of the standard to the general advantage as well as approbation of the nation, no minister will probably ever undertake so dangerous an operation.

We shall now propose an expedient which may remove at least some of the inconveniences which would result from so extensive an undertaking as that of regulating the respective interests in Great Britain by a positive law, upon a change in the value of their money of account.

Suppose then, that, before any change is made in the coin, government should enter into a transaction with the public creditors, and ascertain a permanent value for the pound Sterling for the future, specified in a determined proportion of the fine metals in common bullion, without any regard to money of account, to any coin whatever.

This preliminary step being taken, let the intended alteration of the standard be proclaimed a certain time before it is to commence. Let the nature of the change be clearly explained, and let all such as are engaged in contracts which are dissoluble at will upon the pretensions stipulated, be acquitted between the parties, or innovated as they shall think proper; with certification, that, posterior to a certain day, the stipulations formerly entered into shall be binding according to the denominations of the money of account in the new standard.

As to permanent contracts, which cannot at once be fulfilled and dissolved, such as leases, the parliament may either prescribe the methods and terms of conversion; or a liberty may be given to the parties to annul the contract, upon the debtor’s refusing to perform his agreement according to the new standard. Contracts, on the other hand, might remain in force, with respect to creditors who would be satisfied with payments made on the footing of the old standard. If the rise intended should not be very considerable, no great injustice can follow such a regulation.
Money.

Annuities are now thoroughly understood, and the value of them is brought to so nice a calculation, that nothing will be easier than to regulate these upon the footing of the value paid for them, or of the subject effected by them. If by the regulation, land-rents are made to rise in denomination, the annuities charged upon them ought to rise in proportion; if in intrinsic value, the annuity should remain as it was.

9. Regulations which the Principles of this Inquiry point out as expedient to be made by a new Statute for regulating the British Coin.

Let us now examine what regulations it may be proper to make by a new statute concerning the coin of Great Britain, in order to preserve always the same exact value of the pound Sterling realized in gold and in silver, in spite of all the incapacities inherent in the metals to perform the functions of an invariable scale or measure of value.

1. The first point is to determine the exact number of grains of fine gold and fine silver which are to compose it, according to the then proportion of the metals in the London market.

2. To determine the proportion of these metals with the pound troy: and in regard that the metals of value, according to the then proportion of the metals. Then of or measure of value.

3. To fix the mint-price within certain limits; that is to say, to leave to the king and council, by proclamation, to carry the mint price of bullion up to the value of the coin, as is the present regulation, or to sink it to per cent. below that price, according as government shall incline to impose a duty upon coinage.

4. To order, that silver and gold coin shall be struck of such denominations as the king shall think fit to appoint; in which the proportion of the metals above determined shall be constantly observed through every denomination of the coin, until necessity shall make a new general coinage unavoidable.

5. To have the number of grains of the fine metal in every piece marked upon the exergue, or upon the legend of the coin, in place of some initial letters of titles, which not one person in a thousand can decipher; and to make the coin of as compact a form as possible, diminishing the surface of it as much as is consistent with beauty.

6. That it shall be lawful for all contracting parties to stipulate their payments either in gold or silver coin, or to leave the option of the species to one of the parties.

7. That where no particular stipulation is made, creditors shall have power to demand payment, half in one species, half in the other: and when the sum cannot fall equally into gold and silver coins, the fractions to be paid in silver.

8. That in buying and selling, when no particular species has been stipulated, and when no act in writing has intervened, the option of the species shall be competent to the buyer.

9. That all sums paid or received by the king’s receivers, or by bankers, shall be delivered by weight, if demanded.

10. That all money which shall be found under the legal weight, from whatever cause it may proceed, may be rejected in every payment whatsoever; or if offered in payment of a debt above a certain sum, may be taken according to its weight, at the then mint price, in the option of the creditor.

11. That no penalty shall be incurred by those who melt down or export the nation’s coin; but that wallowing, clipping, or diminishing the weight of any part of it shall be deemed felony, as much as any other theft, if the person doing it afterwards make it circulate for lawful money.

To prevent the inconveniences resulting from the variation in the proportion between the metals, it may be provided,

12. That upon every variation of proportion in the market-price of the metals, the price of both shall be changed, according to the following rule:

Let the price of the pound troy fine gold in the coin be called G.

Let the price of ditto in the silver be called S.

Let the new proportion between the market-price of the metals be called P.

Then state this formula:

$$\frac{G}{S} = \frac{P}{2}$$

This will be a rule for the mint to keep the price of the metals constantly at par with the price of the market; and coinage may be imposed, as has been described, by fixing the mint price of them at a certain rate below the value of the fine metals in the coin.

13. As long as the variation of the market-price of the metals shall not carry the price of the rising metal so high as the advanced price of the coin above the bullion, no alteration need be made on the denomination of either species.

14. So soon as the variation of the market price of the metals shall give a value to the rising species, above the difference between the coin and the bullion; then the king shall alter the denominations of all the coin, silver and gold, adding to the coins of the rising metal exactly what is taken from those of the other. An example will make this plain:

Let us suppose that the coinage has been made according to the proportion of 14.5 to 1; that 20 shillings, or 4 crown-pieces, shall contain, in fine silver, 14.5 times as many grains as the guinea, or the gold pound, shall contain grains of fine gold. Let the new proportion of the metals be supposed to be 14 to 1. In that case, the 20 shillings, or the 4 crowns, will contain \( \frac{4}{5} \) more value than the guinea. Now since there is no question of making a new general coinage upon every variation, in order to adjust the proportion of the metals in the weight of the coins, that proportion might be adjudged by changing their respective denominations according to this formula:

Let the 20 shillings, or 4 crowns, in coin, be called S. Let the guinea be called G. Let the difference between the old proportion and the new, which is \( \frac{1}{14} \), be called P. Then say,

$$S = \frac{P}{2}$$

By this it appears that all the silver coin must be raised...
M O N  [ 2 2 9 ]  M O N

Money, raised in its denomination \( \frac{7}{10} \), and all the gold coin must be lowered in its denomination \( \frac{7}{10} \); yet still \( S + G \) will be equal to two pounds Sterling, as before, whether they be considered according to the old or according to the new denominations.

But it may be observed, that the imposition of coinage rendering the value of the coin greater than the value of the bullion, that circumstance gives a certain latitude in fixing the new denominations of the coin, to as to avoid minute fractions. For, providing the deviation from the exact proportion shall fall within the advanced price of the coin, no advantage can be taken by melting down one species preferably to another; since, in either case, the loss incurred by melting the coin must be greater than the profit made upon selling the bullion. The mint price of the metals, however, may be fixed exactly, that is, within the value of a farthing upon a pound of fine silver or gold.

This is easily reckoned at the mint; although upon every piece in common circulation the fractions of farthings would be inconvenient.

15. That notwithstanding of the temporary variations made upon the denomination of the gold and silver coins, all contracts formerly entered into, and all fluctuations in pounds shillings and pence, may continue to be acquitt'd according to the old denominations of the coins, payable one-half in gold and one-half in silver; unless in the case where a particular species has been fluctuated; in which case, the sums must be paid according to the new regulation made upon the denomination of that species, to the end that neither profit nor loss may result to any of the parties.

16. That notwithstanding the alterations on the mint price of the metals, and in the denomination of the coins, no change shall be made upon the weight of the particular pieces of the latter, except in the case of a general re-coining of one denomination at least; that is to say, the mint must not coin new guineas, crowns, &c. of a different weight from those already in currency, although by so doing the fractions might be avoided. This would occasion confusion, and the remedy would cease to be of any use upon a new change in the proportion of the metals. But it may be found convenient, for removing the small fractions in shillings and fixpence, to recoin such denominations altogether, and to put them to their integer numbers, of twelve and of six pence, without changing in any respect their proportion of value to all other denominations of the coin; this will be no great expense, when the bulk of the silver coin is put into 5 shilling pieces.

By this method of changing the denominations of the coin, there never can result any alteration in the value of the pound Sterling; and although fractions of value may now and then be introduced, in order to prevent the abuses to which the coin would otherwise be exposed by the artificers who melt it down, yet still the inconvenience of such fractions may be avoided in paying, according to the old denominations, in both species, by equal parts. This will also prove demonstratively, that no change is thereby made in the true value of the national unit of money.

17. That it be ordered, that shillings and fixpence shall only be current for 20 years; and all other coins, both gold and silver, for 40 years, or more. For ascertaining which term, there may be marked, upon the exergue of the coin, the last year of their currency, in place of the date of their fabrication. This term elapsed, or the date effaced, that coin shall have no more currency whatsoever; and, when offered in payment, may be received as bullion at the actual price of the mint, or refused, at the option of the creditor.

18. That no foreign coin shall have any legal currency, except as bullion at the mint price.

By these and the like regulations may be prevented, 1mo. The melting or exporting of the coin in general. 2mo. The melting or exporting one species, in order to sell it as bullion at the advanced price. 3mo. The profit in acquiring obligations preferably in one species to another. 4mo. The degradation of the standard, by the wearing of the coin, or by a change in the proportion between the metals. 5mo. The circulation of the coin below the legal weight. 6mo. The profit that other nations reap by paying their debts more cheaply to Great Britain than Great Britain can pay her's to them.

And the great advantage of it is, that it is an uniform plan, and may serve as a perpetual regulation, compatible with all kinds of denominations of coins, variations in the proportion of the metals, and with the imposition of a duty upon coining, or with the preference it free; and further, that it may in time be adopted by other nations, who will find the advantage of having their money of account preferred perpetually at the same value, with respect to the denominations of all foreign money of account established on the same principles.

A TABLE
A Table of Coins.

Showing the Quantity of Fine Metal contained in them.

The number of grains of fine metal in every coin is sought for in the regulations of the mint of the country where it is coined, and is expressed in the grains in use in that mint. From that weight it is converted into those of other countries according to the following proportions:

3840 Troy grains, 4676.35 Paris grains, 5192.8 Holland aces or grains, and 4649.06 Colonia grains, are supposed to be equal weights; and the coins in the Table are converted according to those proportions.

MONGAULT (Nicholas Hubert), an ingenious and learned Frenchman, and one of the best writers of his time, was born at Paris in 1674. At 16 he entered into the congregation of the fathers of the oratory, and was afterwards sent to Mans to learn philosophy. That of Aristotle then obtained in the schools, and was the only one which was permitted to be taught: nevertheless Mongault, with some of his engagements would in cultivating polite literature; and, in 1714, published at Paris, in 6 vols. 12mo. an edition of Tulley's Letters to Atticus, with an excellent French translation, and judicious comment upon them. This work has been often reprinted and is still reckoned admirable; for, as Middleton has observed, in the preface to his Life of Cicero, the Abbé Mongault "did not content himself with retaining the remarks of other commentators, or out of the rubbish of their volumes with selecting the best, but entered upon his task with the spirit of a true critic, and by the force of his own genius has happily illustrated many passages which all the interpreters before him had given up as inexplicable."

He published also a very good translation of Herodian from the Greek; the best edition of which is that of 1745, in 12mo. He died at Paris in 1746. He was a member of the French academy, and of the academy of inscriptions and belles lettres; and was fitted to do honour to any society.

MONGOZ, in zoology. See LEMUR.

MONK, anciently denoted, "a person who retired from
from the world to give himself up wholly to God, and to live in solitude and abstinence. The word is derived from the Latin *monachus*, and that from the Greek μοναχός, "solitary person" or *monachos*, "alone."

The original of monks seems to have been this: The perfections which attended the first ages of the Gospel forced some Christians to retire from the world, and live in deserts and places most private and unfrequented in hopes of finding that peace and comfort among beasts which were denied them among men. And this being the case of some very extraordinary persons, their example gave so much reputation to retirement, that the practice was continued when the reason of its commencement ceased. After the empire became Christian, inferences of this kind were numerous; and those whose security had obliged them to live separately and apart, became afterwards united into societies. We may also add, that the mystic theology, which gained ground towards the close of the third century, contributed to produce the same effect, and to drive men into solitude for the purposes of enthusiastic devotion.

Those, at least the ancient ones, were distinguished into *soritaires, canoniets, and faralbites.*

The *soritaires* are those who live alone, in places remote from all towns and habitats of men, as do still some of the hermits.—The *canoniets* are those who live in community with several others in the same house, and under the same superiors.—The *faralbites* were strolling monks, having no fixed rule or residence.

The houses of monks again were of two kinds, viz. *monasteries* and *laure.* See *Monastery and Laura.*

Those we call monks now-a-days are *canoniets,* who live together in a convent or monastery, who make vows of living according to a certain rule established by the founder, and wear a habit which distinguishes their order. Those that are endowed, or have a fixed revenue, are most properly called monks, *monachi,* or the Charteux, Benedictines, Bernardines, &c. The Mendiants, or those that beg, as the Capuchins and Franciscans, are more properly called *religieux and friars,* though the names are frequently confounded.

The first monks were those of St. Anthony; who, towards the close of the fourth century, formed them into a regular body, engaged them to live in society with each other, and prescribed to them fixed rules for the direction of their conduct. These regulations, which Anthony had made in Egypt, were soon introduced into Palestine and Syria by his disciple Hilarion. Almost about the same time, Aegidius or Eugenius, with their companions Gaddanas and Azyzias, instituted the monastic order in Mesopotamia and the adjacent countries; and their example was followed with such rapid success, that in a short time the whole east was filled with a lazy set of mortals, who, abandoning all human connections, advantages, pleasures, and concerns, were out a languishing and miserable life amidst the hardships of want, and various kinds of suffering, in order to arrive at a more close and rapturous communication with God and angels.

From the east this gloomy institution passed into the west, and first into Italy and its neighbouring islands; though it is uncertain who transplanted it thither. St. Martin, the celebrated bishop of Tours, created the first monasteries in Gaul, and recommended this religious solitude with such power and efficacy, both by his instructions and his example, that his funeral was said to have been attended by no less than 2000 monks. From hence the monastic discipline extended gradually its progres through the other provinces and countries of Europe. There were besides the monks of St. Basil (called in the east *Calagi,* from καλαγός "good old man") and those of St. Jerome, the hermits of St. Augustin, and afterwards those of St. Benedict and St. Bernard; at length came those of St. Francis and St. Dominic, with a legion of others; all which fee under their proper heads, *Benedictines,* &c.

Towards the close of the 5th century, the monks, who had formerly lived only for themselves in solitary retreats, and had never thought of affuming any rank among the ecclesiastical order, were now gradually distinguished from the populace, and endowed with such opulence and honourable privileges, that they found themselves in a condition to claim an eminent station among the supports and pillars of the Christian community. The fame of their pious foundation was increased, by the pious advice, or more great, that bishops and prelates were often chosen out of their order; and the passion of erecting edifices and convents, in which the monks and holy virgins might serve God in the most commodious manner, was at this time carried beyond all bounds. However, their licentiousness, even in this century, was become a proverb; and they are said to have excited the most dreadful tumults and seditions in various places. The monastic orders were at first under the immediate jurisdiction of the bishops, from which they were exempted by the Roman pontiff about the end of the 7th century; and the monks, in return, devoted themselves wholly to advance the interests and to maintain the dignity of the bishop of Rome. This immunity which they obtained was a fruitful source of licentiousness and disorder, and occasioned the greatest part of the vices with which they were afterwards unjustly charged. In the 8th century the monastic discipline was extremely relaxed both in the eastern and western provinces, and all efforts to restore it were ineffectual. Nevertheless, this kind of institution was in the highest esteem, and nothing could equal the veneration that was paid about the close of the 9th century to such as devoted themselves to the sacred gremium and indulgence of a convent. This veneration induced several kings and emperors to call them to their courts, and to employ them in civil affairs of the greatest moment. Their reformation was attempted by Louis the Meck, but the effect was of short duration. In the 11th century they were exempted by the pope from the authority of their sovereigns, and new orders of monks were continually established; insomuch that in the council of Lateran that was held in the year 1215, de crees were passed, by the advice of Innocent III., to prevent any new monastic institutions; and several were entirely suppressed. In the 15th and 16th centuries, it appears, from the testimonies of the best writers, that the monks were generally lazy, illiterate, profligate, and licentious Epicureans, whose views in life were confined to opulence, idleness, and pleasure. However, the Reformation had a manifest influence.
influence in restraining their excesses, and rendering them more circumspect and cautious in their external conduct.

Monks are distinguished by the colour of their habits into black, white, grey, &c. Among the monks, some are called monks of the choir, others professed monks, and others lay monks; which last are defined for the service of the convent, and have neither clericate nor literature.

Cloistered monks are those who actually reside in the house; in opposition to extra-monks, who have benefits depending on the monastery.

Monks are also distinguished into reformed, whom the civil and ecclesiastical authority have made masters of ancient convents, and put in power to retrieve the ancient discipline, which had been relaxed; and ancients, who remain in the convent, to live in it according to its establishment at the time when they made their vows, without obliging themselves to any new reform.

Anciently the monks were all laymen, and were only distinguished from the rest of the people by a particular habit and an extraordinary devotion. Not only the monks were prohibited the priesthood, but even priests were expressly prohibited from becoming monks, as appears from the letters of St. Gregory. Pope Syricius was the first who called them to the clericate, on occasion of some great scarcity of priests, that the church was then suppos'd to labour under; and since that time, the priesthood has been usually united to the monastical profession.

Monk (George), a personage memorable for having been the principal agent in restoring Charles II. to his crown, was descended from a very ancient family, and born in Devonshire in 1608. Being an unprovided younger son, he dedicated himself to arms from his youth, and obtained a pair of colours in the expedition to the Isle of Rhé; he served afterwards in the Low Countries with reputation in both King Charles’s northern expeditions; and did such service in quelling the Irish rebellion, that he was appointed governor of Dublin, but was superseded by parliamentary authority. Being made major-general of the Irish brigade employed in the siege of Nantwich in Cheshire, he was taken prisoner by Sir Thomas Fairfax, and remained confined in the Tower of London until the year 1646; when, as the means of liberty, he took the covenant, and accepted a command in the Irish service under the parliament. He obtained the command in chief of all the parliamentary forces in the north of Ireland, where he did signal services, until he was called to account for a treaty made with the Irish rebels; a circumstance which was only obviated by his future good fortune. He served in Scotland under Oliver Cromwell with such successe, that he was left there as commander in chief; and he was one of the commissioners for uniting that kingdom with the new-created commonwealth. He served at sea also against the Dutch; and was treated so kindly on his return, that Oliver is said to have grown jealous of him. He was, however, again sent to Scotland as commander in chief, and continued there five years; when he dissembled so well, and improved circumstances so dexterously, that he aided the defires of a wearied people, and restored the king without any disturbance; for which he was immediately rewarded both with honours and profit: (See BRITAIN, n° 154, &c.)—He was created duke of Albermarle, with a grant of 7000 l. per annum estate, beside other emoluments; and enjoyed the confidence of his matter without forfeiting that of the people. After his death in 1670, there was published a treatise composed by him while he remained prisoner in the Tower, intitled 'Observations on Military and Political Affairs,' a small folio.

MONKEY, in zoology. See APE and SIMIA.
MONMOUTH (James, duke of), son to Charles II. by Mrs Lucy Walters, was born at Rotterdam in 1649. Upon the Restoration, he was called over to England, where the king received him with all imaginable joy, created him earl of Orkney (which was changed into that of Monmouth), and he took his seat in the house of peers in the ensuing session of parliament. He married Anne, the heiress of Francis earl of Buccleugh; and hence it came to pass that he had also the title of Buccleugh, and took the surname of Scot, according to the custom of Scotland. In 1668 his father made him captain of his life-guard of horse; and in 1672 he attended the French king in the Netherlands, and gave proofs of bravery and conduct. In 1673 the king of France made him lieutenant general of his army, with which he came before Maastricht, and behaved himself with incredible gallantry, being the first who entered it himself. He returned to England, was received with all possible respect, and was received chancellor of the university of Cambridge. After this he went to assist the prince of Orange to raise the siege of Mons, and did not a little contribute towards it. He returned to England; and was sent, in quality of his father's general, to quell an insurrection in Scotland, which he effected; but soon after he fell into disgrace; for, being a Protestant, he was deluded into ambitious schemes, upon the hopes of the exclusion of the duke of York; he conspired against his father and the duke; and when the latter came to the throne by the title of James II. he openly appeared in arms, encouraged by the Protestant army; but coming to a decisive battle before he had sufficient forces to oppose the royal army, he was defeated, taken soon after concealed in a ditch, tried for high treason, condemned, and beheaded in 1685, aged 36. See BRITAIN, n° 242. 249—255.

MONMOUTH, the capital of the county of Monmouthshire in England, 129 miles from London. It has its name from its situation at the confluent of the Monow or Mynyw, and the Wye, over each of which it has a bridge, and a third over the Frathy. Here was a castle in William the Conqueror’s time, which Henry III. took from John Baron of Monmouth. It afterwards came to the house of Lancaster, who bestowed many privileges upon the town. Here Henry V. summoned the Monmouth, was born. The famous historian Geoffrey was also born at this place. Formerly it gave the title of earl to the family of Carey, and of duke to king Charles the Second’s eldest natural son; but now of earl to the Mordaunts, who are also earls of Peterborough. It is a populous and well built place, and carries on a
Monmouth

considerable trade with Bristol by means of the Wye. It has a weekly market, and three fairs.

Monmouthshire, a county of England; anciently reckoned a part of Wales, but in Charles the Second's time taken out of the Oxford circuit, and made an English county. It is bounded on the north by Herefordshire, on the east by Gloucestershire, on the south by the river Severn, and on the west by the Welsh counties of Brecknock and Glamorgan. Its extent from north to south is about 30 miles, from east to west 26, and in circumference 110. It is subdivided into four hundreds; and contains seven market-towns, 127 parishes, about 8,694 houses, 38,900 inhabitants; but sends only three members to parliament, that is, one for Monmouth, and two for the county. The air is temperate and healthy; and the soil fruitful, though mountainous and woody. The hills feed sheep, goats, and horned cattle; and the valleys produce plenty of grass and corn. This county is extremely well watered by several fine rivers; for, besides the Wye, which runs from Gloucestershire, the Mynow, which runs between it and Herefordshire, and the Rumney, which divides it from Glamorganshire, it has, peculiar to itself, the Usk, which enters this county a little above Abergavenny, runs mostly southward, and falls into the Severn by the mouth of the Ebwth; which last river runs from north to south, in the western side of the county. All these rivers, especially the Wye and Usk, abound with fish, particularly salmon and trout.

Monnoyer (Bernard de la), born at Dijon in 1641, was a man of fine parts and great learning. He was admirably formed for poetry; and used to win the first prizes instituted by the members of the French academy, till he discontinued to write for them (it is said) at the solicitation of the academy; a circumstance which, if true, would reflect higher honour on him than a thousand prizes. All his pieces are in a most exquisite taste; and he was no less skilful in Latin poetry than in the French. Menage and Bayle have both belauded the highest encomiums on his Latin poetry. His Greek poems are likewise looked upon as very good; and fo are his Italian, which are written with great spirit. But poetry was not La Monnoyer's only province: to a perfect skill in poetry, he joined a very accurate and extensive knowledge of the languages. He had great skill in criticism; and no man applied himself with greater affinity to the study of history, ancient and modern. He was perfectly acquainted with all the scarce books that had any thing curious in them; very well versed in the history of the learned; and what completes all, is the wonderful clearness with which he polished these various kinds of knowledge. He wrote Remarks on the Menagiana; in the last edition of which, in 4 vols 12mo, printed in 1715, are included several pieces of his poetry, and a curious dissertation on the famous book De tribus Impagioribus. His Dissertation on Pomponius Latus, at least an extract of it, is inserted in the new edition of Baillot's Jugemens des Lettres, published in 1722, with a great number of remarks and corrections by La Monnoyer. He also embellished the Anti-Baillot of Menage with a multitude of corrections and notes. It would employ several pages to enumerate the various services this ingenious and learned man did to the republic of letters; as well by enriching it with productions of his own, as by the assiduity with which he communicated very freely upon all occasions to the learned of his time. Thus, among others, he favoured Bayle with a great number of curious particulars for his Dictionary, and was highly applauded by him on that account. He died at Paris, October 15th, 1728, in his 85th year.

—Mr de Sallinger published at the Hague A Collection of Poems by La Monnoyer, with his eulogium, from whence many of the above particulars are taken. He also left behind him a Collection of Letters, mostly critical; several curious Differtations; 300 Select Epigrams from Martial, and other poets ancient and modern, in French verse; several other works in prose and verse, in French, Latin, and Greek, all ready for the press.

Monnoyer (John Baptista), one of the greatest masters (according to Mr Walpole) that has appeared for painting flowers. They are not so exquisitely finished as Van Huynum's, but his painting and composition are in bolder lines. He was born at Liége in 1635; and educated at Antwerp as a painter of history, which he soon changed for flowers. Going to Paris in 1663, he was received into the academy with applause; and employed at Versailles, Trianon, Marly, and Meudon; and painted in the hotel de Brézéville, and other houses. The duke of Montague brought him to England, where much of his hand is to be seen, at Montague-house, Hampton-court, the duke of St Alban's at Windsor, Kennington, Lord Carlisle's, Burlington-house, &c. But his most curious work is said to be a looking glass at Kennington palace, which he adorned with flowers for Queen Mary, who held him in such high esteem, that she honoured him with her presence nearly the whole time he was busied in the performance. Baptista passed and repassed several times between France and England; but having married his daughter to a French painter who was suffered to alter and touch upon his pictures, Baptista was offended and returned to France no more. He died in Pall-mall in 1699. His son Antony, called young Baptista, painted in his father's manner, and had merit.

Monoceros, unicorn, in astronomy, a southern constellation formed by Hevelius, containing in his catalogue 19 stars, and in the Britannic Catalogue 31.

Monoceros, in zoology. See Monodon.

Monochord; an instrument by which we are enabled to try the several proportions of musical sounds and intervals, as well as the natural as in tempered scales. Originally it had, as its name implies, only one string; but it is better contrived with two, as we have by means of this additional string an opportunity of judging of the harmony of two tempered notes in every possible variety of temperament (see Temperament and Tuning). It consists of a bras rule placed upon a sound-board, and accurately divided into different scales according to the purposes for which it is chiefly intended. Above this rule the strings are to be stretched over two fixed bridges, between which there is a moveable fret, so contrived as to divide at pleasure one of the strings into the same proportional parts as are engraved upon the scales beneath. The figure of the instrument, the manner of striking

Mons.
The following table contains the chief scales that have hitherto been computed. In column 1st is given the natural scale, or scale of perfect intervals. The second column contains a new tempered scale, which seems better adapted than any other to keyed instruments, when chiefly designed for lefson-playing, or playing without accompaniments. The third is a scale proposed by Mr. Emerson in his "Mechanics," and since recommended by Mr. Jones in his "Phylogographical Disquisitions," and by Mr. Cavallo in the "Philosophical Transactions," for 1788. The fourth and fifth exhibit the systems of mean tones, and of equal harmony, calculated by Dr. Smith for instruments of a more perfect construction than those now in ufe.

N. B. Mr. Jones propofes to have the two numbers which are denoted by fars refeitively altered to the numbers 756 and 531.

The method of tuning any instrument by means of the monochord is as follows: Firt, you must tune the C of the monochord to the concert pitch by means of a tuning-fork; next, you are to put the middle C of your instrument in perfect unison with the C of the monochord: Then move the sliding fret to the next division on the scale, and proceed in the same manner with all the feveral notes and half notes within the compass of an octave. When this is done with accuracy, the other keys are all to be tened, by comparing them with the octave which is already tempered. [The monochord is here supposed to be made to the pitch of C; but this may be varied at the will of the contrufor.]

The curious reader who may wish for further information respecting the construction and ufe of monochords, will be highly gratified in perufing the appendix of Mr. Atwood's "Treatif on Rectilinear Motion," and Mr. Jones's ingenious and entertaining observations on the scale of music, monochord, &c. in his "Phylogographical Disquisitions."

Monochord is also used for any musical instrument that conflits of only one thing or chord; in this fens the trumpet marine may properly be called a monochord.

Monoculus, in zoology; the name of a genus of insects of the order of apertus, in the Linnean fystem. Its body is short, of a roundish figure, and covered with a firm crustaceous skin: The fore-legs are ramose, and serve for leaping and swimming; it has but one eye, which is large, and compos'd of three smaller ones.

Of this genus, many of which have been reckoned among the microcopic animals, authors enumerate a great number of species. The figure in Plate CCCXV. represents the quadricornis, or four-horned monoculus, a very small species about half a line in length, and of an affen grey colour. From the head arife four antennae, two forwards and two backwards; all four furnished with a few hairs, which give them the figure of a branch. Between the antennae, on the fore part of the head, is situated a fingle eye. From the head to the tail the body goes down, decreasing in shape like a pear; and is compos'd of seven or eight rings, which grow continually more ftraitened. The tail is long, divided into two; each division giving rise outwardly to three or four briefly hairs. The animal carries its eggs on the two sides of its tail in the form of two yellowish parcels filled with small grains, and which taken together, nearly equal the insect in big­nes. This minute insect is found in standing pools. A number of them being kept in a bottle of water, some will be feen loaded with their eggs, and after a while depositing the two parcels, either jointly or separately.

The name monoculus has been given to this genus, as confifting of individuals which apparently have but one eye: and from the manner in which they proceed forward in the water by leaping, they have also been called water-fleas. The branching antennae serve them instead of oars, the legs being feldom used for swimming. "The tail, forked in fome species, in Barbon's associates, others fimple, ferves them for a rudder. The group of four varies from white to green, and to red, more or lefs deep, doublef in a ratio to the fragments of the P. 360. vegetables on which they feed. The red tincture they fometimes give to the water, has made some ignorant men think that the water had turned to blood. Too weak to be carnivorous, they on the contrary fall a prey to other aquatic insects, euen to polypis. Their body, compact and hard, is fo transparent that in fome the eggs with which the abdomen is filled are discernable. The water-parrot and the shell monoculus, are remarkable. This latter is provided with a bivalvular shell, within which he thuts himself
Mangol

M. Monodon.

himself up, if drawn out of the water. The shell opens underneath, the infect puts forth its antennae, by means of which it swims very expeditiously in various directions, seeking a solid body to adhere to, and then it is that it uses its feet in walking, by stretching them out through the aperture of its shell.

"I preferred a pair of these infests (says our author), last year, in a small glafs tumblers, the one male the other female, having a bag filled with eggs affixed on each side the abdomen. In the space of 14 days the increase was astonishing; it would have been impossible to have taken a single drop of water out of the glafs without taking with it either the larva or a young monocus. I again repeated the experiment by selecting another pair; and at the expiration of the last 14 days my surprise was increased beyond measure. The contents of the glafs appeared a mass of quick-moving, animated matter; and being diversified by colours of red, green, ash-colour, white, &c. afforded with the allusion of the magnifier, considerable entertainment."

Monodon, in ichthology, a genus of fishes belonging to the order of cete; the characters of which are: There are two very long, straight, and spirally twirled teeth, which flick out from the upper jaw; and the spiracle or breathing hole, is situated on the anterior part of the skull. There is but one species, the monocrates, or horrid narwhal, which sometimes grows to 25 feet in length, exclusive of the horn; but the usual size is from 16 to 20. It is particularly noted for its horn or horns, as they are called; but which are real teeth. Of these there are always two in young animals; though the old ones have generally but one, sometimes none. From the circumstance of only one tooth being usually found, the animal has acquired the name of Unicorn Fish, or Sea Unicorn. They inhabit the northern seas, from Norway to within the arctic circle; they are plentiful in Davis's straits and the north of Greenland; where the natives, for want of wood, make rafters of the teeth. From the tooth or horn may be diffilled a very strong falt volatile; the scrapings are esteemed alethropharmic, and were used of old in malignant fevers and against the bites of serpents. The use of it to the animal seems to be chiefly as a weapon of offence, and a very powerful one it appears to be: there are many instances of its having been found in the bottoms of ships which returned from the northern seas, probably owing to the animal's having mistaken the ship for a whale, and attacked it with such fury as not to be able to get out the weapon from the wood. It may also serve as an instrument to loosen and disengage from the rocks or bottom of the sea the sea plants on which it feeds. These fishes swim swiftly, and can only be struck when numbers happen to be found together, and obstruct their own course with their teeth. Their skin is white, with black spots on the back, and has a great quantity of blubber underneath.

The tooth of this animal was in old times imprecated upon the world as the horn of an unicorn, and sold at a very high price. The heirs of the chancellor to Christianus of Denmark, valued one at 8000 imperial. There is a magnificent throne made of this species of ivory for the Danish monarchs, which is still preserved in the castle at Rosenberg. The price of this material was superior to gold.

Monody, in ancient poetry, a mournful kind of song, sung by a person all alone, to give vent to his grief. The word is derived from µονος, "alone," and µου "I sing."

Monoeïa, from µονος, alone, and εϊς a soul; the name of the 21st class in Linnaeus's sexual method. See Botany.

Monogamy, compounded of µονος solus, and γαμας "marriage," the state or condition of those who have only married once, or are restrained to a single wife. See Polygamy.

Monoglossum (anc. geog.), a mart-town of the Hither India, situated on the Ganges, into which the Indus empties itself. Said to be Mangarol on the coast of Malabar. E. Long. 74°, N. Lat. 13°.

Monogram, a character or cypher, composed of one, two, or more letters interwoven; being a kind of abbreviation of a name, anciently used as a seal, badge, arms, &c.

Mononyia, from µονος, alone, and νος a woman; the name of the first order or subdivision in the first 13 classes of Linnaeus's sexual method; consisting of plants which, besides their agreement in their class character, generally derived from the number of their flowers, have only one style, or female organ.

Monomotapa, a country of Africa, has the maritime kingdom of Sofala on the coast, the river Dindimutu Santo on the south, the mountains of Caxaria on the west, and the river Cuma on the north, which parts it from Monteummi. The air of this country is very temperate; the land fertile in pastures and all the necessaries of life, being watered by several rivers. The inhabitants are rich in black cattle, which they value more than gold. They have a vast number of elephants, as appears from the great quantity of ivory that is exported from hence. There are many gold-mines, and the rivers that run through their veins carry a great deal of gold-dust along with them. The inhabitants are lovers of war, which is the employment followed by all those who do not apply themselves to commerce. This country is divided into seven provinces or petty kingdoms, vassals to the king; viz. Monomotapa Proper, Quiveve, Manica, Inhambana, Inhemor, Sabia, and Sofala.

Monopetalous, in botany, a term applied to flowers that have only one petal or flower-leaf.

Monophysites, (from µονος solus, and φυσις nature), a general name given to all those sectaries in the Levant who only own one nature in Jesus Christ; and who maintain, that the divine and human nature of Christ were so united as to form only one nature, yet without any change, confusion or mixture of the two natures.

The monophysites, however, properly so called, are the followers of Severus, a learned monk of Palestine, who was created patriarch of Antioch in 513, and Petrus Pullenius.

The monophysites were encouraged by the emperors Anastatus, but repressed by Justin and succeeding emperors. However, this sect was restored by Jacob Baradatus, an obscure monk, informed that
of provisions, or any commodities, or the rate of of labour, are in many cases severely punished by particular statute; and, in general, by statute 2 & 3 Edward VI. c. 15, with the forfeiture of L.10. or 20 days imprisonment, with an allowance of only bread and water for the first offence: L.20 or the pillory for the second; and L.10 for the third, or else the pillory, los of one ear, and perpetual infamy. In the same manner, by a constitution of the emperor Zego, all monopolies and combinations to keep up the price of merchandise, provisions, or workmanship, were prohibited, upon pain of forfeiture of goods and perpetual banishment.

MONOSYLLABLE, in grammar, a word that consists only of one syllable, and is composed either of one or more letters pronounced at the same time. The too frequent use of monosyllables has a very bad effect in English poetry, as Dr Pope both intimates and exemplifies in the same verses.

"And ten flow words oft creep in one dull line."

MONOTHELITES, (compounded of mono single, and thesa: will, of thea: will), an ancient sect, which sprang out of the Eutychians; thus called, as only allowing of one will in Jesus Christ.

The opinion of the Monothelites had its rise in 630, and had the emperor Heraclius for an adherent: it was the same with that of the Acephalous Severians. They allowed of two wills in Christ, considered with regard to the two natures; but reduced them to one, by reason of the union of the two natures; thinking it absurd there should be two free wills in one and the same person. They were condemned by the sixth general council in 680, as being supposed to destroy the perfections of the humanity of Jesus Christ, depriving it of will and operation. Their sentiments were afterwards embraced by the Maronites.

MONOTONY, an uniformity of sound, or a fault in pronunciation, when a long series of words are delivered in one unvaried tune. See Reading.

MONOTRÖPA, Bird's-nest, A genus of the monogynia order, belonging to the monandria class of plants; and in the natural method ranking with those of which the order is doubtful. There are two species; of which the only remarkable one is the hippopithys, a native of Britain and some of the northern kingdoms of Europe. It is about five inches high, having no other leaves than oval scales, and terminated with a nodding spike of flowers, which in the seeding state becomes erect: the whole plant is of a pale yellow colour, smelling like the primrose, or like beans in bloom. The country people in Sweden give the dried plant to cattle that have a cough.

MONRÉAL. See Montreal.

MONRO (Dr Alexander, senior), a most eminent physician and anatomist, was descended by his father from the family of Monro of Milton, which had large possessions in the county of Ross; and by his mother, from that of Forbes of Culloch.

His father John, youngest son of Sir Alexander Monro of Bearcroft, was bred to physic and surgery, and
and served for some years as a surgeon in the army under King William in Flanders; but, for several successive years, obtaining leave of absence from the army in the winter, he during that season resided with his wife in London, where his son Alexander was born in the year 1697. About three years thereafter, he quitting the army, and went to settle as a surgeon at Edinburgh; where his knowledge in his profession, and engaging manners, soon introduced him into an extensive practice.

The son showed an inclination to the study of physic; and the father, after giving him the best education that Edinburgh then afforded, sent him successively to London, Paris, and Leyden, to improve himself further in his profession. At London, he attended the lectures of Messrs Haukbee and Whilton on experimental philosophy, and the anatomical demonstrations of Mr Cheffelden. At Paris, he attended the hospitals, and the lectures which were read on the different branches of physic and surgery at that time. Towards the end of autumn 1718, he went to Leyden, and studied under the great Boerhave; by whom he was particularly esteemed.

On his return to Edinburgh in autumn 1719, Messrs Drummond and Macgill, who were then conjunct nominal professors and demonstrators of anatomy to the surgeons company, having resigned in his favour, his father prevailed on him to read some public lectures on anatomy; and to illustrate them by shewing the curious anatomical preparations which he had made and sent home when abroad. He at the same time persuaded Dr Atton, then a young man, to give some public lectures on botany. Accordingly, in the beginning of the winter 1720, these two young professors began to give regular courses of lectures, the one on the materia medica and botany, the other on anatomy and surgery; which were the first regular courses of lectures on any of the branches of medicine that had ever been read at Edinburgh, and may be looked upon as the opening of that science which had ever been read at Edinburgh, and were made professors of medicine; the professorship of materia medica and botany, which Dr Atton then held, having been added to the university many years before. Immediately after these gentlemen were elected professors, they began to deliver regular courses of lectures on the different branches of medicine, and they and their successors have uniformly continued to do every winter.

The plan for a medical education at Edinburgh was still incomplete without an hospital, where students could see the practice of physic and surgery, as well as hear the lectures of the professors. A scheme was therefore proposed by Dr Monro's father, and others, particularly the members of the royal college of physicians and board of surgeons, for raising by subscription a fund for building and supporting an hospital for the reception of diseased poor; and our author published a pamphlet setting forth the advantages that would attend such an institution. In a short time a considerable sum of money was raised, a small house was fitted up, and patients were admitted into it, and regularly attended by many of the physicians and surgeons in town. The fund for this charity increasing very considerably, in a great measure from the activity and influence of that very worthy citizen and magistrate George Drummond, Esq; the foundation stone was laid of the present large, commodious, and useful hospital, the Royal Infirmary: in the planning of which Dr Monro suggested many useful hints, and in particular the elegant room for chirurgical operations was designed and executed under his direction. Provost Drummond and he were nominated the building committee; and the fabric was entirely completed in a short space of time. It has since been so largely endowed, as to be capable of receiving a great number of diseased poor, whose cases the students of physic and surgery have an opportunity of seeing daily treated with the greatest attention and care, by physicians and surgeons eminent in their profession; and a register of the particulars of all the cases which have been received into the house since its first opening has been kept, in books appropriated for that purpose, for the use of the students.

In order to make the hospital of still further use to the students, Dr Monro frequently, while he continued professor of anatomy, gave lectures on the chirurgical cases; and the late judicious physician, Dr Rutherford professor of the practice of physic, began, in the year 1748, to deliver clinical lectures to be continued every winter, on the most remarkable cases in the hospital.

Doctor Monro, though he was elected professor of anatomy in the year 1721, was not received into the university till the year 1725, when he was inducted along with that great mathematician the late Mr Colin Maclaurin, with whom he ever lived in the closest friendship. From this time he regularly every winter gave a course of lectures on anatomy and surgery, from October to May, upon a most judicious and comprehensive plan: A talk in which he perused with the greatest affiduity, and without the least interruption, for near 40 years; and so great was the reputation he had acquired, that students flocked to him from the most distant corners of his majesty's dominions.

In 1759, our professor entirely relinquished the business of the anatomical theatre to his son Dr Alexander, who had returned from abroad, and had assisted him in the course of lectures the preceding year. But after this resignation, he still endeavoured to render his labours
laborous useful to mankind, by reading clinical lectures at the hospital for the improvement of the students; of which Dr. Duncan, who was one of his pupils, has given the following account: “There I had my first happiness of being a pupil, who profited by the judicious conduct of his practice, and was improved by the wisdom and acuteness of his remarks. I have indeed to regret that I attended only the last course of lectures in which he had ever a share, and at a time when he was subjected to a disease which proved at length fatal. Still, however, from what I knew and from what I heard, I can venture to assert, that it is hardly possible to conceive a physician more attentive to practice, or a preceptor more anxious to communicate instruction. His humanity, in the former of these characters, led him to bestow the most anxious care on his patients while they were alive, and his zeal in the latter induced him to make them the subject of useful lessons when they happened to die.—In the different stations of physician, of lecturer, and of manager in the hospital, he took every measure for inquiring into the causes of diseases by dissection.—He personally attended the opening of every body; and he not only dissected, but he also instructed the students in an accurate report of the dissection, but with nice discrimination contrasted the diseased and found state of every organ. Thus, in his own person, he afforded to the students a conspicuous example of the advantages of early anatomical pursuits as the happiest foundation for a medical superstructure. His being at once engaged in two departments, the anatomical theatre and clinical chair, furnished him with opportunities both on the dead and living body, and placed him in the most favourable situation for the improvement of medicine; and from these opportunities he derived every possible advantage which they could afford.”

His father, old Mr. Monro, lived to an advanced age; and enjoyed the unpeeable pleasure of beholding a son, esteemed and regarded by mankind, the principal actor in the execution of his favourite plan, the great object of his life, the founding a seminary of medical education in his native country: The son, who survived him nearly 30 years, had the satisfaction to behold this seminary of medical education frequented by 100 of the students, many of whom came from the most distant corners of his majesty’s dominions, and to see it arrive to a degree of reputation far beyond his most sanguine hopes, being equalled by few, and inferior to none in Europe.

Few men were members of more societies than Dr. Monro: still fewer equally affiduous in their attendance of those in which he could tend to promote public utility. He was a manager of many public charities; and not only a member of different medical societies, but likewise of several others instituted for promoting literature, arts, sciences, and manufactures, in Scotland, and was one of their most useful members—While he was held in high estimation at home, he was equally esteemed and respected abroad, and was elected member of the Royal Society of London, and an honorary member of the Royal Academy of Surgery at Paris.

He was not only very active in the line of his own profession, but as a citizen and general member of the community; for, after he had resigned the anatomical chair to his son, he executed with the strictest punctuality the duties of several engagements both of a civil and political nature: He was a director of the Bank of Scotland, a Justice of the Peace, a Commissioner of High-Roads, &c. At length, after a life spent in the most active industry, he became afflicted with a tedious and painful disease, which he bore with equal courage and resignation till his death, which happened on July 10th, 1767, in the 70th year of his age.

Of his works, the first in order is his Osteology, which was written for the use of students, but is capable also of affording instruction to the old and most experienced physician; as, besides a minute description of the parts copied from nature, it extends everywhere with new and important observations immediately applicable to practice. It has been translated into many languages, and has passed through numerous editions; and has been reprinted in foreign countries in the most superb manner, accompanied with elegant and masterly engravings. His description of the Lactic Acid and Thoracic Duct contains the most accurate account of that important part of the body which has been yet published: and his Anatomy of the Nerves will transmit to posterity an excellent example of accurate dissection, faithful description, and ingenious reasoning.

The six volumes of Medical Essays and Observations, published by a society in Edinburgh, are universally known and esteemed. To that society he was appointed secretary; but, after the publication of the first volume, in which he had largely contributed, the members growing remiss in their attendance, he became the sole collector and publisher of the work: To him we are therefore in a great measure indebted for these numerous and important discoveries with which this publication has enriched every department of medical knowledge. In the two first volumes of the Physical and Literary Essays, published by the physical society in Edinburgh, in which he had the rank of one of the professors, we find several papers written by him, which are not the least ornaments of that collection. His account of the Success of Inoculation in Scotland may be considered as his last publication: It demonstrates his extensive correspondance and indefatigable industry, and has had great influence in promoting that salutary practice.

Besides these, he was also the author of several other elegant and masterly productions, which were either never published, or were published without his knowledge and from incorrect copies. A collection of all his works, properly arranged, corrected, and illustrated with copperplates, has been published by Dr. Alexander Monro, his son and successor in the anatomical chair, in a splendid quarto volume, printed for Elliot, Edinburgh, 1781; to which is prefixed a life of the author, by another of his sons, Dr. Donald, physician in London. The observation of an excellent judge, the illustrious Haller concerning our author’s Medical Essays and Observations, which now form a part of this collection, may with no less justice be applied to the whole: It is a “book which ought to be in the possession of every medical practitioner.”

MON, an ancient, large, handsome, rich, and very strong city of the Austrian Netherlands in Hainault.
Monsieur, in the plural Messieurs, a title of honour and respect used by the French in writing to persons of superior rank or quality, before the late abolition of all ranks.

Dukes, peers, archbishops, bishops, and presidents à la mortier, were complimented with the title of Monsieur. In the petitions presented to the sovereign courts, they used the term Messieurs.

Monsieur, absolutely used, was a title restrained to the dauphin of France. This custom was unknown till the time of Louis XIV. before which the dauphin was styled Monseigneur le Dauphin.

Monsieur, in the plural Messieurs, a term or title of civility, used by the French in speaking to their equals, or those a little below them, answering to Mr or Sir among the English.

Monsieur, absolutely used, was a title or quality appropriated to the second son of France, or the king's brother. The king was also called Monseigneur, but that only by the children of France.

Monsieur (Sir William), a brave English admiral, third son of Sir John Mounson of South Carlton in Lincolnshire, was born in 1569. He was employed in many expeditions against the Spaniards in Queen Elizabeth's time, and was highly honoured; the queen knighted him for his services in the earl of Essex's expedition to Cadiz, where he assisted much by his wife and moderate counsel to the earl. Military men were no favourites with James I. Therefore, on the death of the queen, he received no recompense or pay beyond the ordinary service in which he was engaged: nevertheless, as admiral of the narrow seas, he supported the honour of the British flag against the infidels of the Dutch states, of which he frequently complains in his Navy Tract; and protected the trade against the encroachments of France. He had the misfortune to fall into disgrace by his vigilance, and was imprisoned in the Tower through the resentment of some powerful courtiers; yet he was discharged, and wrote a vindication of his own conduct, intitled, "Concerning the infidels of the Dutch, and a justification of Sir William Monson." He spent his latter days in peace and privacy, which he employed in digesting his Navy Tracts, and died in 1643. Part of these tracts were printed in 1682; and they were afterwards all included in Churchill's Collection of Voyages.

Monsonia, in botany: A genus of the dodecandria order, belonging to the polyadphila class of plants. The calyx is pentaphyllous; the corolla pentapetalous and irregular; the stamens are fifteen in number, and coiled into five filaments; the style bifid; the capsule pentacoccous.

Monsun, a regular or periodical wind, in the East Indies, blowing constantly the same way, during six months of the year, and the contrary way the remaining six.

In the Indian ocean, the winds are partly general, and blow all the year round the same way, as in the Ethiopic ocean; and partly periodical, i.e., half the year blow one way, and the other half year on the opposite points; and those points and times of shifting differ in different parts of this ocean. These latter are what we call monsoons.

The shifting of these monsoons is not all at once; and in some places the time of the change is attended with calms, in others with variable winds, and particularly those of China, at ceaseing to be westerly, are very subject to be tempestuous; and such is their violence, that they seem to be of the nature of the West India hurricanes, and render the navigation of those seas very unsafe at that time of the year. These tempers the seamen call the breaking up of the monsoons.

Monsoons, then, are a species of what we otherwise call trade winds. They take the denomination monsoon from an ancient pilot, who first crossed the Indian sea by means hereof. Though others derive the name from a Portuguese word, signifying motion or change of wind, and sea.

Lucretius and Appolonius make mention of annual winds which arise every year, ostra fabria, which seem to be the same with what in the East Indies we now call monsoons. For the physical cause of these winds, see Wind.

Monster; a birth or production of a living being, degenerating from the proper and usual disposition of parts in the species to which it belongs: As, when there are too many members, or too few; or some of them are extravagantly out of proportion, either on the side of defect or excess. The word comes from the Latin monstrum, of monstrare, "showing." Whence also the box wherein relics were anciently kept to be shown, was called monstrum. Dugdale mentions an inventory of the church of York with this article, item unum monstrenum can officius sancti Petri in Beryl, & crucifix in fummittate.

Aristotle defines a monster to be a defect of nature, when, acting towards some end, it cannot attend to it, from some of its principles being corrupted.

Monsters do not propagate their kind; for which reason some rank males among the number of monsters, as also hermaphrodites.

Females which bring forth twins, are found most liable to produce monsters. The reason, probably, is owing to this; that though the twins are covered with one common chorion, yet they have each their separate amnions, which by their contiguity may chance to grow together, and so occasion a confusion or blending of the parts. Hence so many double creatures.
The Creator has established such a communication between the several parts of his creation, that we are not only naturally led to imitate one another, i.e., have a disposition to do the same things and assume the same manners with those with whom we converse; but also have certain natural dispositions which incline us to compassion as well as imitation. These things most men feel, and are sensible of; and therefore need not be proved. The animal spirits, then, are not only naturally carried into the respective parts of the body to perform the same actions and the same motions which we see others do, but also to receive in some manner their wounds, and take part in their sufferings.

"Experience tells us, that when we look attentively on any person feverely beaten, or that hath a large wound, ulcer, or the like, the spirits immediately flow into those parts of our body which answer to those we see suffer in the other; unless their course be stopped from some other principle. This flux of spirits is very sensible in persons of a delicate constitution, who frequently shudder, and find a kind of trembling in the body on these occasions; and this sympathy in bodies produces compassion in the mind.

"Now it must be observed, that the view of a wound, &c. wounds the person who views it the more strongly and sensibly, as the person is more weak and delicate; the spirits making a stronger impression on the fibres of a delicate body than in those of a robust one. Thus strong, vigorous men, &c. see an execution without much emotion, whereas weak, &c. are struck with pity and horror. As to children in full in their mother's womb, the fibres of their flesh being incomparably finer than those in women, the course of the animal spirits must necessarily produce much greater alterations.

"These things being laid down, monsters are easily accounted for. Suppose, e.g., a child born a fool, and with all its legs and arms broke in the same manner as those of criminals in some countries are; which cafe we choose to instance in, because we are told from Paris that such a monster was actually born there, and lived in one of their hospitals 20 years; the cause of this accident, according to the principles laid down, was, that the mother seeing a criminal executed, every stroke given to the poor man, struck forcibly the imagination of the woman; and, by a kind of counter-stroke, the tender and delicate brain of the child.—Now, though the fibres of the woman's brain were strangely shaken by the violent flux of animal-spirits on this occasion, yet they had strength and presence of mind enough to prevent an entire disorder; whereas the fibres of the child's brain being unable to bear the shock of these spirits, were quite ruined, and the rage was great enough to deprive him of reason all his lifetime.

"Again, the view of the execution frightening the woman, the violent course of the animal spirits was directed forcibly from the brain to all those parts of the body corresponding to the suffering parts of the criminal; and the same thing must happen in the child. But in regard the bones of the mother were strong enough to resist the impulsion of those spirits, they were not damaged; and yet the rapid course of these spirits could easily overpower and break the tender and delicate fibres of the bones of the child; the bones being the last parts of the body that are formed, and having a very flender consistence while the child is yet in the womb.

"To which it may be here added, that had the mother determined the course of these spirits towards some other part of her body, by tickling or scratching herself vehemently, the child would not in all probability have had its bones broken; but the part answering that to which the motion of the spirits was determined, would have been the sufferer. Hence appears the reason why women in the time of gestation, seeing persons, &c. marked in such a manner in the face, imprints the fame mark on the same parts of the child: and why, upon rubbing some hidden part of the body when startled at the sight of anything agitated with any extraordinary passion, the mark or impression is fixed on that hidden part rather than on the face of the child. From the principles here laid down, may most, if not all, the phenomena of monsters be easily accounted for."

Various other theories have been formed by different philosophers and physiologists. But after all, it must be confessed, that we seem as yet to be very little acquainted with Nature in her sports and errors. For each organized being there appears to exist a primitive germ or model of the different species drawn by the Creator, determined by forms and sexes, and realized in the individuals of both sexes, which must unite in order to their reproduction. From this model nature never departs, unless when compelled by circumstances which derange the primitive order so common to the species, and produce what we call monsters.

With respect to structure, we have already remarked, that monsters are of various kinds. Some have an excess or defect in certain parts; such as those which are called acephalous, or who want the head; those which have two heads, two arms, two legs, and one body, or which have two bodies and one head, or which have three legs; and those which want the arms or the legs. Others err through an extraordinary and deformed conformation, through an unnatural union of certain parts or viscera, through a great derangement in one or more of their members, and through the extraordinary place which these often occupy in consequence of this derangement or transplantation. The monster described by Dr. Eller of the academy of Berlin was of this kind. It was a fetus of nine months, 28 inches long, with an enormous head and frightful countenance; and in the middle of a broad and vaulted forehead it had a red devilish eye, without either eyebrows or eyelids, and sunk deep into a square hole.Immediately below this eye was an excrecence which strongly resembled a penis with a glans, a prepuce, and an urethra: the part covered with hair was likewise below the nape of the neck. In other monsters we meet with the unnatural union of some parts, which, from their destination and functions, ought always to be separate; and the separation of other parts, which, for the same reasons, ought constantly to be united. The reader may see the different ways in which the formation of monsters takes place in four memoirs by M. Lemery, published in L'Histoire de l'Academie des Sciences, 1738 and 1739. M. du Verney has likewise published a Memoir on the same subject.
In the volume published by the Academy of Sciences in 1724, mention is made by M. Geoffroy of a monter born in Barrois 1722. This monstrous production consisted of two children without the inferior extremities, joined together by a common navel: each of them had a nose, mouth, and four legs and feet: the other felt. The reader may like-wise consult the second part of Winslow's Memoirs on Monsters, inferred in the volume published by the Academy of Sciences in 1734, where will he find the history of two very extraordinary twin monsters, who evidenced during their life a great difference in their moral and physical qualities. We are obliged simply to refer to those Memoirs, as they are too long for abridgment.

It is observed by Haller, that in some monsters the natural structure is changed by some shock or passion: in others the structure, independent of any accident, is originally monstrous; such as when all the members are reversed from left to right, when the pelvis has fix fingers, and in many other instances, M. de Maupertius mentions, that is at Berlin a family who have had fix fingers on each hand for several generations. M. de Riville saw an instance of this at Malta, of which he has given a description. M. Renou, surgeon at Pommeraye in Anjou, has published an account of some families with fix fingers, which are to be found in several parishes of the Lower Anjou, and which have existed there for time immemorial. This deformity is perpetuated in these families even when they intermarry with persons who are free from it. Whether the propagation of these supernumerary organs, which are not only useless but inconvenient and even disagreeable, be owing to the father or mother, their children of both sexes are subject to it indiscriminately. A father or mother with fix fingers frequently have a part, and sometimes the whole, of their children, free from this deformity; but it again makes its appearance, and in a very great degree, in the third generation. From this it appears, that this fault in the conformation is hereditary. M. Reaumur has likewise published the history of a family in the island of Malta, the children of which are born with fix fingers and fix toes. But it deserves to be inquired, Whether these supernumerary fingers are real fingers? The reader may see the Journal de Physique for November 1774, p. 372. This variety of feedigatory hands and feet is not comprehended in the Recherches sur quelques conformationes monstrueuses des doigts dans l'homme, which is inserted in the Memoirs of the Academy of Sciences for 1771. In the Journal de Physique for August 1776, we find a description of a double uterus and vagina observed in a woman who died in childbirth, by Dr Purcell of Dublin: and in that for June 1788, we have an account of a man with seven fingers on each hand, by Baron Dietrich.

Several monstrous productions are to be seen in the cabinet at Chantilly. 1. Two calves joined together in the body, with each a separate head and neck, and four legs in whole. 2. Two calves united only by the pelvis, with only one anus and one tail: the whole is supported by fix legs, four before and two behind. 3. A lamb with fix legs, four of which are behind. 4. The skeleton of a ram, which has like wise fix legs. 5. A hermaphrodite deer. 6. The head of a foal which has only one eye in the middle of the forehead. 7. Som leverets with fix and eight legs. 8. A pigeon, the lips of which are divided fourfold. 9. Some festures of a hog which have a kind of tube upon their forehead one or two inches long; and another, the hinder part of which is double in every thing. 10. Two double human festures joined by the belly, with four arms and three legs. 11. A young chicken with two bodies and one head. 12. A pigeon and a duck, each with two bills. 13. A duck with two heads. 14. A pigeon with four feet. 15. A capon with three feet; the third being fixed to the anus. 16. Two heads of a calf joined together, each of them with two ears; these two heads were both fixed to one neck. 17. In the Menagerie at Chantilly there was formerly to be seen a cow with five feet, the fifth of which was connected with the dug. 18. A rabbit without ears. 19. Two ears, each having two heads. 20. Two leverets newly brought forth, well shaped in the body and legs, but connected together by means of only one head. 21. Several eggs, in the figure of which there occur some monstrous appearances and extraordinary deformities, sufficient to shew that they are contrary to the established form of nature.

Everhard Hume, Esq; F. R. S. some time ago presented to John Hunter, Esq; F. R. S. the double child, born at Calcutta in May 1783, of poor parents aged 30 and 35, and which lived to be nearly two years old. The body of this child was naturally formed; but the head had the phenomenon of appearing double; another head of the same size, and almost equally perfect, being attached to its upper part. In this extraneous and preternatural head no pulsation could be felt in the arteries of the temples, but the superficial veins were very evident; one of the eyes had been hurt by the fire, upon which the midwife, in her first alarm, threw the child; the other moved readily; but the iris was not affected by the approach of any thing to it. The external ears of this head were very imperfect; the tongue adhered to the lower jaw, except for about half an inch at the lip, which was loose: the jaw was capable of motion, but there were no teeth. The child was shown about the streets of Calcutta for a curiosity; but was rendered unhealthy by confinement, and died at last of a bite of the cobra de capello. It was dug up by the East India Company's agent for salt at Tumlock, and the skull is now in the museum of Mr Hunter.

Among the monstrous productions of the animal kingdom, we may rank those individuals which ought only to possess one sex, but in which we observe the union or the appearance of two. See the articles Androgyne and Hermaphrodite.

M. Fabri arranges mutilations of the members, distortions, gibbosities, tumors, divisions of the lips or of the palate, compressions of the intestines, and many other deformities of this kind, in the class of morbid monstrosities. In that which he calls connotatum (connaturelle) monstrosities, are placed the plurality, transposition, and infection of the parts. To explain these facts, a great many writers have had recourse to the effect of the imagination of pregnant women.—The causes of the first class of monstrosities are discussed by M. Fabri, who observes that some of them are internal with regard to the mother, and others exter-
By an internal cause, he here means all those deprivations or morbid principles which can affect the fluids, and which vitiate the form and structure of the solids; in particular the uterus, in which such deprivations have often been found to occur. To these he adds violent affections of the mind, spasmodic contractions, hybernic convulsions, and the many inconveniences of this kind to which women are extremely subject. External causes comprehend every thing which can act externally upon the fetus contained in the uterus, such as the pressure of the clothes; and in short every thing which prevents the free dilatation of the belly in women who are pregnant, violent motions, falls, blows, and all accidents of this kind. These external causes, and especially the fire, comprefs the fetus in the womb, and oblige it to remain in a very confined situation. This, according to the observation of Hippocrates, produces those embryos which are born with some entire part wounded. M. Fabri maintains, that all deformities of the fetus proceed from mechanical and accidental causes.

The name of monstrous is likewise given to animals enormous for bulk; such as the elephant among terrestrial quadrupeds, and the shark and the whale among sea animals; to other animals remarkable for fierceness and cruelty; and to animals of an extraordinary species, which, we are told, arise from the copulation of one animal with another of a different genus. According to the report of travellers, Africa abounds with monsters of this kind; and accounts of the East are full of descriptions of sea monsters, which, however, are seldom to be seen, such as saunders, mermaids &c.

Monsters are more common and more extraordinary in the vegetable than in the animal kingdom, because the different juices are more easily deranged and confounded together. Leaves are often seen, from the internal part of which other leaves spring forth: and it is not uncommon to see flowers of the ranunculus, from the middle of which issued a stalk bearing another flower. M. Bonnet informs us, that in certain warm and rainy years he has frequently met with monsters of this kind in rose-trees. This observer saw a rose, from the centre of which issued a figure stalk, of a whitish colour, tender, and without prickles, which at its top bore two flower-buds opposite to each other, and totally destitute of a calyx; a little above the buds issued a petal of a very irregular shape. Upon the prickly stalk, which supported the rose, a leaf was observed, which had the shape of trefoil, together with a broad flat pedicle. In the memoirs of the Academy of sciences for 1707, p. 448, mention is made of a rose, from the centre of the leaves of which issued a rose-branch two or three inches long, and furnished with leaves. See the same Memoirs for 1749, p. 44, and for 1724, p. 20. In the Memoirs for 1775, a very singular instance is mentioned of a monstruous observed by M. Duhamel, in an apple-tree ingrafted with clay. At the place of the inreion, there appeared a bud which produced a stalk and some leaves; the stalk and the pedicle of the leaves were of a pulpy substance, and had the most perfect resemblance both in taste and smell to the pulp of a green apple. An extraordinary chorisorium is mentioned in the Alta

Histoire. M. Bonnet, in his Recherches pour l'usage des feuilles, mentions likewise some monstrons productions which have been found in fruits with kernel, analogous in their nature to those which occur in the flowers of the ranunculus and of the rose-tree. He has seen a pear, from the eye of which issued a tuft of 13 or 14 leaves, very well shaped and many of them of the natural size. He has seen another pear which gave rise to a ligneous and knotty stalk, on which grew another pear somewhat larger than the first.—The stalk had probably flourished, and the fruit had formed. The lilium album polyanthos, observed some years ago at Brelau, which bore on its top a bundle of flowers, conhiting of 102 lilies, all of the common shape, is well known. M. Reynier has mentioned some individuals monstrons with respect to the flower, in the Journal de Physique et d'Histoire Naturelle, for November 1785. He has likewise mentioned a monstrons tulip which is seen in the gardens of some amateurs; juniper berries with horns; a balsamic with three spurs, &c.

These vegetable productions, which are so extraordinary, and so contrary to the common course of things, do nevertheless present deviations subject to particular laws, and reducible to certain principles, by distinguishing such as are perpetuated either by seed or by transplanting, from those which are only accidental and passing. Monstrosities which are perpetuated exist in the original organization of the seed of the plant, such as marked or curled leaves, &c. The word monstrous is more properly applied to those irregularities in plants which arise from frequent transplantation, and from a particular culture, such as double flowers, &c. but these monstrosities which are not perpetuated, and which arise from accidental and transient causes deranging the primitive organization of the plant, when it comes to be unfolded, as is the effect of diseases, of heat or cold, of a superfluity or scarcity of juices, or a deprivation of the vessels contributing to nutrition, of the wing of insects, of concretions and natural grafts, retain also the name of monstrous. Of this kind are knots or swellings, flancting, gall-nuts, certain stinks, and other similar defects. All the parts of plants are subject to some of these monstrosities, whichever with respect to their formation, figure, proportion, and number. Some trees are naturally of so great a size, that they may be considered as a kind of whale species in the vegetable kingdom; of this kind are the baobab and the ceiba. Others, as the oak, the yew, the willow, and many others, sometimes though rarely, attain so extraordinary a bulk that they are likewise monsters among the vegetables. It is conjectured, in short that monsters are more common in the vegetable than in the animal kingdom, because in the latter the methods of propagation are not so numerous. Plants are seldom monstrons in all their parts; some are monstrons only through excess in the calyx and corolla; others are so through defect only in the leaves, flamina, and fruit. Now, a monstrosity, says M. Adanson, has never changed the name or affected the immutability of a species. Every skilful succeeding botanist has arranged these monstrosities in plants among accidental circumstances, which in whatever manner they
are propagated, have always a tendency to revert to the order and regularity of their original species when they are multiplied by means of food; which method of reproduction is the most natural and the most certain for determining the species. One species may be compared with another; but a monster can only be put in comparison with an individual of the species from which it comes. The reader may consult the Observations Botaniques of M. Schletterbec, of the Society of Bafli, concerning monsters in plants, wherein he pretends to demonstrate, that in their production nature follows the same course in the vegetable as in the animal kingdom.

MONTEALE, a strong town of Spain, in the kingdom of Aragon, with a strong citadel; seated on the river Rio-martin, 44 miles south of Saragossa, and 92 north by west of Valencia. W. Long. 1°. 30'. N. Lat. 41. 9'.

Mont-d'Alber, an ancient town of France in Picardy, where the kings of France formerly had a palace and kept their court. It is seated on a mountain, 17 miles from Amiens and Compeigne, and 58 north of Paris. W. Long. 2°. 34'. N. Lat. 49. 39'.

Mont-Lher, a town of the Isle of France, 15 miles from Paris. Here are the remains of a tower, which may be seen at great distance. E. Long. 2°. 0'. N. Lat. 48. 38'.

Mont-Louis, a small but strong town of France, in the Pyrenees, with a strong citadel; seated on an eminence, 430 miles south of Paris. E. Long. 2°. 5'. N. Lat. 42. 58'.

Mont-Luiz, a town of France in Breff, and capital of the territory of Valbonne; seated in a fertile pleasant country on the river Sarine, eight miles from Lyons, and 205 south-east of Paris. E. Long. 5°. 8'. N. Lat. 45. 49'.

Mont-Luzon, a town of France in Bourbonnois; seated on the Cher, 35 miles south-west of Moulins, and 150 south of Paris. E. Long. 2°. 45'. N. Lat. 46. 22'.

Mont-Blanc. See Mont-Blanc.

MONTAUBOUR, a small fortified town of Germany, in the electorate of Treves, between Coblenz and Limburg. E. Lon. 7°. 50'. N. Lat. 50. 50'.

MONTAGNAC, a considerable town of Ais, in Natolia, and in the province of Bec-Sangol, on the sea of Marmora. It carries on a great trade, especially in fruits, and is seated on a bay of the same name, 12 miles from Burfa, and 60 south-east of Constantinople. E. Long. 29°. 40'. N. Lat. 40. 20'.

MONTAGUE (Edward), earl of Sandwich, an illustrious Englishman, who shone from the age of 19, and united the qualifications of general, admiral, and statesman; yet there were strange inconsistencies in his character. He acted early against Charles I; he perfuaded Cromwell, whom it is said he admired, to take the crown; and he was zealous for the restoraion of Charles II. All this is imputed to a fond and unaccountable passion which he had for royalty. Upon general Monk's coming into England, he sided with the fleet to Holland, and soon after he had the honour to convey his majesty to England. For this he was created knight of the garter; and on the 11th of July 1665, he was created baron. Montague of St. Necta, in the county of Huntingdon, Viscount Hinchenbrooke in the same county, and earl of Sand-wich in Kent, from one of his majesty's most honourable privy-council, made master of the king's wardrobe, admiral of the Narrow Seas, and lieutenant-admiral to the duke of York, as lord high admiral of England.

When the Dutch war broke out in 1694, and the duke of York took upon himself the command of a fleet as high-admiral, his lordship commanded the blue squadron, and by his industry and care abundance of the enemies ships were taken; and in the great battle fought on the third of June 1665, in which the Dutch lost admiral Opdam, and had 18 men of war taken and 14 destroyed, a large share of the honour of the victory was justly given to the command of the earl of Sandwich. On the return of the English navy, the command of the whole fleet was given to the earl of Sandwich, which he was ordered to put as speedily as possible in a condition to return to the coast of Holland. Accordingly the earl failed on the 5th of July with 60 men of war to the Dutch coast, when finding that their East India and Smyrna fleets were to return home north about, he steered for the coast of Norway, and found they had taken shelter in the port of Bergen, where the fleet were attacked: but leaving them there, and falling back towards the coast of Holland, he met with four Dutch East Indiamen, with several other merchant ships, under a good convoy, and took eight men of war, two of their East India ships, and 20 fall of merchant-men; and a few days after, a part of the fleet falling in with 18 of the Hollanders, the greatest part of them were also taken, with four Dutch men of war, and above 1000 prisoners. On his return he was received by the king with distinguished marks of favour; and soon after, he was sent ambassado extraordinary to the court of Madrid, to mediate a peace between the crowns of Spain and Portugal; when he had the happiness to conclude a peace between the two nations to their mutual satisfaction.

On the breaking out of the late Dutch war, his lordship went to sea with the duke of York, and commanded the blue squadron; the French admiral, count d'Etrees, commanding the white. The fleet was at sea in the beginning of the month of May; and coming to an anchor in Southwold-bay in order to take in water, we are told, that on the 27th many officers and seamen were permitted to go on shore, and were at Southwold, Dunwich, and Aldborough; when, the weather being hazy, the wind being north about, he had the honour to convey his majesty to England. For this he was created knight of the garter; and on the 11th of July 1665, he was created baron. Montague of St. Necta, in the county of Huntingdon, Viscount Hinchenbrooke in the same county, and earl of Sand-
had not that gentlemen been more solicitous about adorning the duke. When therefore he saw him fail by, heedless of the condition in which he lay, he said to those who were about him, "There is nothing left for us now, but to defend the ship to the last man." Being at length grappled by a fourth fire­ship, he begged his captain Sir Richard Haddock, and all his servants, to get into the boat and save themselves, which they did: yet some of the sailors refused to quit the admiral, and flaying endeavoured to extinguish the fire, but in vain; the ship blew up about noon. His lordship's body was found about a fortnight after, and was interred with great state in Henry VII. s chapel.—We have of his lordship's writings, 1. The Art of Metals, in which is declared the manner of their generation, translated from the Spanish of Albaro Alonso Barba, 8vo. 2. Several letters during his em­bassy to Spain, published with Arlington's letters. 3. A letter to secretary Thurloe. 4. Original letters and negotiations of Sir Richard Fanshaw, the earl of Sandwich, the earl of Sunderland, and Sir William Godolphin, wherein divers matters between the three crowns of England, Spain, and Portugal, from the year 1663 to 1678, are set in a clear light, 2 vols. 8vo.

Montagu (Charles), earl of Halifax, fourth son of George Montague of Harton in Northamptonshire, Esq.; son of Henry the first earl of Manche­ster, was born in 1661. He was educated at Westminster-school and Cambridge, shewed very early a most geniuus talent, and quickly made great progress in learning. In 1684, he wrote a poem on the death of King Charles II in which he displayed his genius to such advantage, that he was invited to London by the earl of Dorset; and upon his coming thither soon increased his fame, particularly by a piece which he wrote in conjunction with Prior, published at London in 1687, under the title of, "The Hind and the Panther transferred to the Story of the Country mouse and the City mouſe." Upon the abdication of King James II. he was chosen one of the members of the convention, and recommended by the earl of Dorset to King William, who immediately allowed him a pension of 500 l. per annum. Having given proofs of his great abilities in the house of commons, he was made one of the commissioners of the treasury, and soon after chancellor of the exchequer: in which capacity he was raised to the peerage, and made a great work of re-coining all the current money of the nation. In 1698, he was appointed first commissioner of the treasury; and in 1699 was created a peer of England, by the title of Baron Halifax in the county of York. In 1701, the house of commons impeached him of six articles, which were dis­missed by the house of Lords. He was attacked again by the house of commons in 1702, but without success. In 1705, he wrote, An Answer to Mr Bromley's Speech in relation to the occa­sional Conformity-bill. In 1706, he was one of the commissioners for the Union with Scotland; and upon passing the bill for the naturalization of the illustrious house of Hanover, and for the better security of the succession of the crown in the Protestant line, he was made choice of to carry that act to Hanover. Upon the death of Queen Anne, when the king had taken pos­session of his throne, his lordship was appointed first commissioner of the treasury, and created earl of Halifax and knight of the garter. He died in 1715. His lordship wrote several other pieces besides those above mentioned; all which, with some of his speeches, were published together in 1716 in an octavo volume.

Montagu (Lady Mary Wortley) accompanied her husband who was sent on an embassy to Constantinople in the beginning of this century. On her return she introduced the practice of inoculation into England, and thence acquired great celebrity. She cultivated the belles lettres; and at one period of her life she was the friend of Pope, and at another his enemy. While they were at enmity with each other, Lady Mary Montague embraced every opportunity of defaming the poet, who well knew how to take revenge. Both of them carried their animosity to so great a height, that they became the subject of public conversation. After a long life, full of singular and romantic adventures, she died about the year 1760. From her we have Letters, written during her travels from the year 1716 to the year 1718. They have been translated into French, and published at Rotterdam 1764, and at Paris 1783, one vol. 12 mo. They are composed in a lively, interesting, and agreeable style, and contain many curious facts relating to the manners and government of the Turks, which are not where else to be found. The Baron de Tott, who lived many years at Constantinople, attacked them with great severity; but they have been defended with equal zeal by M. Guis of Marseille, who has published a valuable work on Turkey. It need not appear extraordinary, that persons who have visited the same country should not see things in the same light. How few travellers agree in their accounts of the fame objects, which they nevertheless pretend to have seen and have examined with attention.

Montagu (Edward Wortley), son of the former, passed through such variegated scenes, that a bare recital of them would favour of the marvellous. From Westminster-school, where he was placed for education, he ran away three several times. He exchanged clothes with a chimney-sweeper, and followed, for some time that footy occupation. He next joined himself to a fisherman, and called himself in Rotherhithe. He then sailed as a cabin-boy to Spain; where he had no sooner arrived, than he ran away from the vessel, and hired himself to a driver of mules. After this vagabondifying it some time, he was discovered by the confidant, who returned him to his friends in England. They received him with a joy equal to that of the father of the prodigal son in the gospel. A private tutor was employed to recover those rudiments of learning which a life of dissipation, of blackguardism, and of vulgarity, might have obliterated. Wortley was sent to the West Indies, where he remained some time; then returned to England, acted according to the dignity of his birth, was chosen a member, and served in two successive parliaments. His expenses exceeding his income, he became involved in debt, quitted his native country, and commenced that wandering traveller he continued to the time of his death. Having visited most of the eastern countries, he contrived a partiality for their manners. He drank little wine; a great deal of coffee; wore a long beard; smok'd much; and,
and, even whilst at Venice, he was habited in the eastern style. He cut cross-legged in the Turkish fashion through choice. With the Hebrew, the Arabic, the Chaldaic, and the Persian languages, he was as well acquainted as with his native tongue. He published several pieces. One on the "Rise and Fall of the Roman Empire." Another an Exploration of "The Causes of Earthquakes." As this gentleman was remarkable for the uncommon incidents which attended his life, the close of that life was no less marked with singularity. He had been early married to a woman who aspired to no higher a character than that of an indolent wenchwoman. As the marriage was solemnized in a frollick, Wortley never deemed her sufficiently the wife of his bosom to cohabit with her. She was allowed a maintenance. She lived contented, and was too submissive to be troublesome on account of the conjugal rites. Mr. Montague, on the other hand, was a perfect patriarch in his manner. He had wives of almost every nation. When he was with Ali Bey in Egypt, he had his household of Egyptian females, each striving who should be the happiest of who could gain the greatest attendance over this Anglo-Indian-baw-baw. At Constantinople, the Greek women had charms to captivate this unsettled wanderer. In Spain, a Spanish brunette, in Italy the olive complexioned female were solicited to partake the honours of the bridal-bed. It may be asked what became of this group of wives? Mr. Montague was continually shifting the place, and consequently varying the scene. Did he travel with his wives as the patriarchs did with their flocks and herds? No such thing; Wortley, confidering his leader, the heresiarch Montanus, a Phrygian by birth; whence they are sometimes styled Phrygians and Cata­phrygians.

Montanus, it is said, embraced Christianity in hopes of rising to the dignities of the church. He pretended to inspiration; and gave out, that the Holy Ghost had instructed him in several points, which had not been revealed to the apostles. Priscilla and Maximilla, two enthusiastic women of Phrygia, presently became his disciples; and in a short time he had a great number of followers. The bishops of Asia, being assembled together, condemned his prophecies, and excommunicated those who adhered to them. Afterwards they wrote an account of what had passed to the western churches, where the pretended prophecies of Montanus and his followers were likewise condemned.

The Montanists, finding themselves exposed to the censure of the whole church, formed a schism, and set up a distinct society under the direction of those who called themselves prophets. Montanus, in conjunction with Priscilla and Maximilla, was at the head of the sect.

These sectaries made no alteration in the creed. They only held, that the Holy Spirit made Montanus his organ for delivering a more perfect form of discipline than what was delivered by the apostles. They refused communion for ever to those who were guilty of notorious crimes, and believed that the bishops had no authority to reconcile them. They held it unlawful to fly in time of persecution. They condemned second marriages, allowed the dissolution of marriage, and observed three lents.

The Montanists became separated into two branches; one of which were the disciples of Proclus, and the other
MONTANUS (Benign Arians), a most learned Spanish theologian, born in the diocese of Badajoz, about the year 1528. He alluded at the council of Trent with great reputation; and his merit and writings recommended him to Philip II. of Spain, who employed him in publishing a new polyglot bible after the Complutensian edition, which was printed by the care of Cardinal Ximenes. This bible was printed at Antwerp, whither Montanus went in 1571; and on his return to Spain he refused the bishopric which Philip offered him for his reward, but spent the rest of his days at Sevilla, where he died about the year 1598. Montanus had not only a low heterodoxy. 

MONTANAUN, a small but populous town of Italy, in the territory of the Church, with a bishop's see; seated on a mountain, near the lake Bolsena, in a country abounding with excellent wine, 12 miles south-west of Orvieto, and 45 north-west of Rome. E. Long. 12. 4. N. Lat. 42. 26.

MONTARIGIS, a considerable town of Portugal, on the road from Lisbon to Badajoz. Long. W. 9. 35. N. Lat. 38. 42. 

MONTAUBAN, a considerable town of France, in Guienne, and territory of Quercy, with a bishop's see, and an academy. The fortifications were demolished in 1629, because it took the part of the Huguenots. It is seated on the river Tarns, 20 miles north of Toulouse, and 30 miles south of Cahors. E. Long. 1. 27. N. Lat. 43. 56.

MONTBAZON, a town of France, in Touraine, with the title of a duchy; agreeably seated at the foot of a hill, on which there is an ancient castle, 153 miles south-west of Paris. E. Long. 0. 45. N. Lat. 47. 17.

MONTPELLIARD, a handsome and strong town of France, capital of a province of the same name, between Aisace and the Franche Compte. It is seated at the foot of a rock, on which there is a large, strong castle, in the form of a citadel. The prince of Montpellier has a voice and seat in the college of the princes of the empire. It was taken by the French in 1674, who demolished the fortifications, but it was restored to the prince. It is seated near the rivers Alain and Doux, 33 miles west of Bale, and 45 north-east of Bezanzon. E. Long. 6. 30. N. Lat. 47. 31.

MONTBLANC, a town of Spain, in the province of Catalonia, 15 miles north of Tarragon. E. Long. 1. 5. N. Lat. 41. 20.

MONTBRISIAC, a considerable town of France, and capital of Forez, seated on the river Veziza, 40 miles west of Vienne, and 250 south by east of Paris. E. Long. 4. 27. N. Lat. 45. 52.

MONTECCHIO, a considerable town of Italy, in the duchy of Reggio, 10 miles south-east of Parma, and eight north-west of Reggio. E. Long. 15. 54. N. Lat. 48. 8.

MONTENEGRO, a town of Italy, in the territory of the church and duchy of Spalato; seated on a mountain near the river Clitunno, 12 miles west of Spalato. E. Long. 12. 40. N. Lat. 42. 58.

MONTEFALCO, a town of Italy, in Friuli, with a castle. It belongs to the Venetians, and is near the river Ponzano, 10 miles north-west of Aquileia, and 12 north-west of Trieste. E. Long. 13. 0. N. Lat. 46. 4.
ceeded with feint marches in order to deceive Turenne, in which he obtained great honour. However, the command of that army was taken from him the next year; but it was restored to him in 1675, in order that he might make head against the great Turenne. All Europe had their eyes fixed on these two able warriors, who then made use of all the stratagems which genius and military knowledge were capable of suggesting. The marshal de Turenne was obtaining his superiority when he was taken off by a cannon ball. Monteculvi was at the death of so formidable an enemy, and bellowed upon him the greatest praise. The great prince de Conde was the only French general that could deprive Monteculvi of the superiority he had obtained by Turenne's death. That prince was therefore sent to the Rhine, and stopped the Imperial general; who considered this last campaign as the most glorious of his life, not from his being conqueror, but for his not being conquered, when he was opposed by a Turenne and a Conde. He spent the rest of his life at the Imperial court; and died at Lintz in 1680.

He wrote Memoirs; the best edition of which is that of Strasbourg, 1735.

MONTGOMERAY, a town of Jamaica, and next to Kingston the most flourishing in the island, contains above 350 houses; and carriers on a very considerable commerce with Great Britain and her remaining colonies in North America. The harbour is capacious; but rather exposed to the north winds, which at certain times in the year blow with great violence. It is the capital of the parish of St. James; in which are 70 sugar-plantations, 70 other settlements, and 27,000 slaves.

MONTESA, a very strong town of Spain, in the kingdom of Valencia. It is the seat of an order of knighthood of the same name; and is five miles from Xativa. W. Long. 0. 10. N. Lat. 39. 0.

MONTESQUIEU (Charles de Secondat) baron, a most illustrious Frenchman descended from an ancient and noble family of Guienne, was born at the castle of La Brede, near Bourdeaux, in 1689. The greatest care was taken of his education; and at the age of 20, he had actually prepared materials for his Spirit of Laws, by well digested extracts from those immense volumes of civil law which he had studied, not merely as a civilian, but as a philosopher. He became a counsellor of the parliament of Bourdeaux in 1714, and received president a morrow two years after. In 1721 he published his Persian Letters; in which, under the screen of Oriental manners, he satirized those of France, and treated of several important subjects by delicate transient glances: he did not avow this publication; but was so soon pointed out as the author, that he was without knowledge, and ever under the mark of it, united at once against the Persian Letters. He was received into the French academy in 1728; and having previously quitted his civil employments, he entirely devoted himself to his genius, and was no longer a magistrate, but a man of letters. Having thus let himself at liberty, he travelled through Germany, Italy, Switzerland, Holland, and England, in which last country he resided three years, and contracted intimacies with the greatest men then alive; for Locke and Newton were dead. The result of his observations was, "that Germany was fit to travel in, Italy to sojourn in, England to think in, and France to live in." On his return he retired for two years to his estate at La Brede, where he finished his work On the causes of the Grandeur and Decline of the Romans; which appeared in 1754. The reputation acquired by this last work only cleared the way for his greater undertaking, the Spirit of Laws, which was printed at Geneva in 2 vols 4to. 1750. This was immediately attacked by the adversaries of his Persian Letters, in a multitude of anonymous pamphlets; containing all the reproaches to which a liberal mind is exposed from craft and ignorance. M. Montesquieu drew up a defence of this work; which, for truth, moderation, and delicacy of ridicule, may be regarded as a model in its way. This great man was peaceably enjoying that fulfilment of which his great merits had procured him, when he fell sick at Paris, and died on the 10th of February 1755.—The following character of this great man is drawn by Lord Chesterfield. His virtues did honour to human nature, his writings justice. A friend to mankind, he affected their undoubted and unalienable rights with freedom, even in his own country; whose prejudices in matters of religion and government he had long lamented, and endeavoured, not without some success, to remove. He well knew, and justly admired, the happy constitution of this country, where fixed and known laws equally restrain monarchy from tyranny, and liberty from licentiousness. His works will illustrate his name, and survive him, as long as right reason, moral obligation, and the true spirit of laws, shall be understood, respected, and maintained." As to his personal qualities, we are told by his elogist, M. d'Alembert, that, "he was of a sweet, gay, and even temper. His conversation was spirited, agreeable, and instructive. Nobody told a story in a more lively manner, or with more grace and ease of affectation. He had frequent absence of mind; but always awaked from it by some unexpected stroke that re-animated the languishing conversation. Though he lived with the great, he retired whenever he could to his estate in the country, and there met his books, his philosophy, and his repose. Surrounded at his leisure-hours with peasants, after having studied men in the commerce of the world, he studied him in those simple people solely instructed by nature. With them he cheerfully conversed; he endeavoured, like Socrates, to find out their genius, and appeared as happy with them as in the most brilliant assemblies; especially when he reconciled their differences, and by his benevolence relieved them from their difficulties."

Besides the works already mentioned, M. Montesquieu wrote several small pieces, as the Temple of Gnids, Lyfimachus, and Esfay upon Tafes, which is left unfinished. His works have been collected since his death, and printed at Paris in a splendid edition, in quarto. They have likewise all of them been translated into English.

MONTÈZUMA, or Montezuma, was emperor or king of Mexico when Cortez invaded that country in 1519, invited thither, as he pretended, by the inhabitants, who are children Montezuma, in the blindness of his superition, had sacrificed to his idols. The warlike animals on which the Spanish officers were mounted, the artificial thunder with which they were armed, the wooden cales on which they had crossed the
the ocean, the armour with which they were covered, the victories which they gained wherever they went; all these circumstances, added to that foolish dispositions to wonder which always characterises a simple people, so operated upon the minds of the Mexicans, that when Cortez arrived at the city of Mexico, he was received by Montezuma as his master, and by the inhabitants as a god. At first they fell down in the streets when a Spanish valet passed by; but by degrees the court of Montezuma grew familiar with the strangers, and ventured to treat them as men. Montezuma, unable to expel them by force, endeavoured to inspire them with confidence at Mexico by expressions of friendship, while he employed secret means to weaken their power in other quarters. With this view, one of his generals, who had private orders to that purpose, attacked a party of the Spaniards who were stationed at Vera-Cruz; and, although his troops were unsuccessful, yet three or four of the Spaniards were killed. The head of one of them was carried to Montezuma. In consequence of this, Cortez did what has been reckoned one of the boldest political strokes that ever was performed. He ran to the palace, followed by fifty of his troops; and, by perusia and threats, carried the emperor prisoner into the Spanish quarter. He afterwards obliged him to deliver up those who had attacked his troops at Vera-Cruz; and, like a general who punishes a common robber, he loaded Montezuma with chains. He next obliged him to acknowledge himself in public the vassal of Charles V.; and, in name of tribute for this homage, Cortez received 600,000 marks of pure gold. Montezuma soon afterwards fell a sacrifice to his submission to the Spaniards. He and Alvaro, the lieutenant of Cortez, were besieged in the palace by 200,000 Mexicans. The emperor proposed to show himself to his subjects, that he might persuade them to desist from the attack; but the Mexicans no longer considered him in any other light but as the slave of foreign conquerors. In the midst of his speech, he received a blow with a stone which wounded him mortally; and he expired soon after. A. D. 1520.—See Cortez. This unfortunate prince left two sons and three daughters, who embraced the Christian faith. The eldest received baptism, and obtained from Charles V. lands, revenues, and the title of Count de Montezuma. He died in 1668; and his family is one of the most powerful in Spain.

MONTFAUCON (Bernard de), a very learned Benedictine of the congregation of St Maur, singularly famous for his knowledge in Pagan and ecclesiastical antiquities, was born of an ancient and noble family in Languedoc, in 1655. He served for some time in the army; but the death of his parents mortified him so with regard to the world, that he commenced Benedictine monk in 1675, and applied himself intensively to study. Though Montfaucon's life was long, healthy, retired, and laborious, his voluminous publications seem sufficiently to have employed the whole, exclusive of his greatest undertakings, for which he will be always memorable. This was his Antiquités expliquées, written in Latin and French, illustrated with elegant plates, in 10 vol. folio, to which he added a supplement of 4 vols more. He died at the abbey of St Germain in 1741.

MONTFERRAT, a province of Italy, with the title of a duchy; bounded on the east by the duchy of Monfort, Milan, and part of the territory of Genoa; on the north, by the Vercellese and Canavese; on the west, by Piedmont properly so called; and on the south by the territory of Genoa, from whence it is separated by the Apennine mountains. It contains 200 towns and castles; and is very fertile and well cultivated, abounding in corn, wine, oil, and flax. It belongs to the kingdom of Sardinia, and Calas is the capital town.

MONTFORT, a town of France, in Upper Burgundy, founded on the river Men, 12 miles from Rennes. W. Long. 1° 58'. N. Lat. 48° 8'.

MONTFORT, an handome and strong town of the Netherlands, in the United Provinces, with an ancient castle; situated on the river Vyl, seven miles from Utrecht. E. Long. 5° 0'. N. Lat. 52° 4'.

MONTFORT, a town of Germany, in the circle of Suabia, on the confines of Tirol, 16 miles south of Landau, and the lake Constance. It is capital of a province of the same name, which has been almost all purchased by the house of Austria. E. Long. 9° 51'. N. Lat. 47° 22'.

MONTFORT-DE-LEMOS, an ancient town of Spain, in the kingdom of Glicia, with a magnificent castle, where the Comarca of Lemos resides. It is seated in a fertile country, 25 miles north-east of Orense, and 55 south of Compostella. W. Long. 7° 9'. N. Lat. 42° 28'.

MONTFORT-L'AMULY, a town in the Isle of France, with the title of a duchy, 25 miles from Paris. E. Long. 2° 50'. N. Lat. 48° 45'.

MONTFORT (Simon Count de), descended from an illustrious and flourishing family, was lord of a small town of the same name ten leagues from Paris. He was one of the greatest generals of the age in which he lived; and he displayed his bravery in a voyage beyond seas, and in the wars with the English and Germans. The strength of his constitution enabled him to support without inconvenience the severest labours of the field: his majestic stature distinguished him in the midst of the battle; and the motion of his sword was sufficient to strike terror into his boldest enemies. In the greatest dangers he poised the utmost coolness and presence of mind; he observed every emergency; and was ready to bring ad infinitum, while he himself was employed in attacking the bravest who made head against him. He was appointed to conduct the crusade against the Albigenses in 1229; and the name of Simon de Montfort is highly celebrated in this war. He took Beziers and Carcassonne, raised the siege of Castelnau, and gained a great victory in 1213 over Peter king of Arragon, Raimond VI, count of Toulouse, and the counts of Foix and Comminges. Simon de Montfort was killed at the siege of Toulouse on the 27th of June 1218, by a blow with a stone discharged by the hands of a woman.

Such was the fate of one who had fulfilled the glory of his victories by the cruelty of his executions.

Some historians have given him the name of Maccabaeus and of Defender of the Faith; but men, animated with the true spirit of Christianity, have revolted against such titles. "We cannot (says the Abbé Noutte) read the accounts of his severity, or rather cruelty, towards the Albigenses without horror. He was not guided by the spirit of the religion of de-
MONTGATZ, a town of Lower Hungary, in the country of Pecszaus, with a fortress composed of three castles, seated on a craggy rock. It is, too, honored with a great moral, and art and nature have rendered it almost impregnable. It was defended by the Princess Ragotky, wife of Count Tekeli, when besieged by an army of the imperialists, who were obliged to raise the siege in 1688.

MONTGERON (Louis-Balile-Carre de), was born at Paris, A. D. 1686; his father was master of requests. He was scarcely 25 years of age when he purchased the place of counsellor in parliament, where, by his wit and external qualifications he gained considerable reputation. Deeply engaged in all the vices which flow from irreligion, he was converted by an unexpected circumstance. He went on the 7th of September 1731 to the tomb of Deacon Paris, with an intention to examine, with the rigour of the severe critic, the miracles which were reported to be performed there. But, according to his own account, he felt himself suddenly beat to the earth by innumerable flashes of light with which he was surrounded. His incredulity was converted into flaming zeal; and he became the apostle of the saint whom he formerly ridiculed. From that moment he devoted himself to the fanaticism of corvinum, with the same impetuosity of character with which he had run into the most shameful excesses. He had not long been the disciple of Janzenen, when he suffered persecution. When the chamber of inquests was abolished in 1733, he was sent into the mountains of Auvergne; which, instead of cooling, tended rather to inflame his zeal. During his exile, he formed the plan of collecting the proofs of the miracles wrought at the tomb of the Abbe Paris, and of composing what he called a Demonstration of them. On his return to Paris, he prepared to execute this plan; and on the 29th of July 1737, he actually presented to the king at Versailles a volume in quarto superfully bound. This work he accompanied with a speech, which is a mixture of zeal and argument in a tolerable style. In consequence of this work, which some consider as a master-piece of eloquence, and others as a mass of absurdities, he was committed to the Bicêtre. After a few months confinement, he was sent to an abbey of Benedictine monks in the diocese of Avignon; whence he was, in a short time carried to Viviers. He was afterwards confined in the citadel of Valence, where he died, A. D. 1754, aged 68. The work which he presented to the king was entitled La verité des Miracles opérés par l'intervention de M. Paris, &c. &c.—The critics, even to this day, form to be guided in their opinion concerning this book either by hatred or by charity. It would be easy enough (says the Abbe de St Pierre, in the second volume of his Annales, p. 593.) to maintain with the Molenbeis, that no miraculous cure was ever performed at the tomb of the Abbe Paris; and to say with the Janzenen, that these cures were performed by a supernatural power, would be the height of fanaticism. The truth is (adds the same author,) that no miracle appears ever to have been performed at this tomb except in the cure of the human body; in all other cases, there would have been the want of that imagination on which the whole miracle depended." Thus, although Montgeron ventured to compare these prodigies with the miracles of Jesus Christ and his apostles, yet we find no person raised from the dead, no multiplication of loaves, no command obeyed by the elements; and, no blind or deaf restored to their sight or hearing. It belongs to the Author of nature alone, or to those who have derived power from him, to work such miracles as are recorded by the evangelists, or in the history of the apostles. Montgeron added a second and third volume on the same subject; he left also in manuscript a work which he composed in prison contre les Incredibles. Religion, it must be confessed, had much more powerful advocates. Fortunately Pufcal and Bosuet are among the number; and it could well have wanted both Paris and Montgeron, whatever virtues they might possess in other respects.

MONTGOMERY, the capital of a county of the same name in north Wales, 158 miles from London, took its name from Roger de Montgomery, Earl of Shrewsbury, who built the castle; but it is called by the Welsh Ty Valeudd, that is, Baldwin's town; having been built by Baldwin, lieutenant of the marches of Wales, in the reign of William I. The Welch, after having put the garrison to the sword, demolished it in 1095; but Henry III. rebuilt it, and granted it the privileges of a free borough, with other liberties. It is a large and tolerably well built town, in a healthful situation and fertile soil. It sends a member to parliament, and has the title of an earldom. It had formerly a tower and castle; but they were demolished in the civil wars. It has a weekly market, and four fairs. MONTGOMERY (Gabriel de), count of Montgomery in Normandy, was remarkable for his valour and noble achievements, but still more so for being so unfortunate as to put out the eye of Henry II. on the 21st of June 1559. That prince having engaged several knights in a tournament in the concertation of the marriage of his daughter the Princess Elizabeth with Philip king of Spain, at last wilfully to break a lance with the young Montgomery, at that time lieutenant of the Scotch guard. Montgomery, as if he had foreseen the fatal consequences, again and again declined the combat, and it was with great reluctance he at length yielded, when he saw the king about to take offence at his refusal. In the course, his lance broke in the king's visor, and wounded him in the eye. Henry died on the 11th day after receiving the wound, and gave orders on his death-bed that Montgomery should not be prosecuted, or harrowed in any respect, on account of what had happened. After this unhappy accident, Montgomery retired for some time to his estate in Normandy. He next visited Italy and other foreign countries; and did not return to France till the commencement of the civil wars, when he joined the party of the Protestants, and became one of their principal leaders. In 1562, he defended Rouen against the royal army with great valour and obstinacy. The city being at length taken by storm, he
he threw himself into a galley; and, having, with equal temerity and good fortune, surmounted by dint of rowing a chain which had been thrown across the Seine at Candinbec for the purpose of preventing fugitives from England, he escaped to Havre. In 1569 Montgomery was sent to the aflilliance of Beam, which the Catholics, under the command of Terrides, had almost entirely wrenched from the hands of Janed' Alibret, queen of Navarre. He executed this commission with so great dispatch, that Terrides was obliged to raise the siege of Navarre, and to retire with great precipitation to Orthez. Montgomery pursued him to this city, which he took by assault; and before Terrides had time to recover himself, he and his principal officers were taken prisoners in the castle. After this defeat, the col of Beam submitted to the conqueror wherever he made his appearance. This expedition acquired him the greatest glory, and has been celebrated by the Catholic no less than by the Protestant historians. He was at Paris at the time of the massacre on St Bartholomew's day 1572, and lodged in the Faubourg St Germain. Some accident having retarded the execution of that quarter, he was informed of it at the very moment when it was about to begin; and he had just sufficient time to mount his horse and, in company with some Protestant gentlemen who lodged near him, to make his escape at full gallop. They were pursued as far as Montfort-l'Amaury; and Montgomery, whose escape alone is particularly attended to, owed his safety on this occasion to the swifhness of his horse, which, according to a manuscript of the time, carried him 50 leagues without halting. Having escaped this danger, he took refuge with his family, first in the island of Jersey and afterwards in England. The following year, Montgomery carried a considerable fleet, which he had armed and fitted out in England, partly on his own credit and partly on that of the inhabitants of Rochelle, to the relief of that city, which was at that time besieged by the Catholics: But, whether distrusting his forces, or for other reasons about which historians do not agree, he left the road without fighting the Catholic fleet, and went to pillage Belleisle on the coast of Brittany. Having disembarked his fleet, he returned to England to Henry de Champernon his son in law, coaft-admiral of Cornwall. On the renewal of the war in France in 1573 Montgomery, who was then in Jersey, passed over into Normandy, and joined the Protestant nobility of that province. Matignon, lieutenant-general in Lower Normandy, to whom Catharine de Medicis had given a particular charge to use his utmost endeavours to seize the person of the count, came unexpectedly upon him in Saint-Lo, and laid siege to that city. On the evening of the fifth day of the siege, Montgomery left Saint-Lo with between 60 and 80 horse, forced the guard in the suburbs, and escaped amidst a shower of musket bullets, without loosing a single man, leaving the command of the place to Coulombieres, Francois de Briqueville. Montgomery arrived at Domfront May 7, 1574, with only twenty followers, intending to make no longer a stay in that place than was necessary to recruit them after the fatigues of so rapid a march. The same day he was joined by several gentlemen, who brought to his assistance a company of forty horse. Meanwhile Matignon, informed of his escape, and enraged at having left his prey, flew at the head of a party of horse, with some companies of foot mounted on horseback, and arrived on the morning of the 9th before Domfront. He blocked up the place on all sides till the infantry and cannon which followed him should arrive. On their arrival, he attacked the city with great violence; and, as it was impossible to defend it, Montgomery was soon obliged to retire into the castle with the garrison amounting to no more than 135 men, including 80 foot soldiers who guarded the city when he entered it. He sustained a furious assault, fought with the greatest boldness and obstinacy, and exposed himself in the breach like one who wished for death. Perceiving, however, that his followers partly by the fire of the enemy, and partly by constant defection, were reduced almost to nothing, he capitulated on the 27th of May. Many Protestant historians affirm, that the articles of capitulation were violated with regard to Montgomery; but, not to mention the testimony of others, it appears evident, from the authority of D'Aubigny himself, who of all the Protestant writers is most worthy of credit, that the Count had no promife from Matignon, except personal safety and good treatment while he continued his prisoner. This general gave him no assurance of pardon from the king or the queen-mother. After the capture of Domfront, Matignon conducted his prisoner to Saint-Lo, the siege of which was still going on, in hopes that he might have some influence with his former friend and fellow-solier to persuade him to surrender. For this purpose, Montgomery was brought to the side of the ditch; and he exerted Coulombieres, who appeared on the wall, to follow his example. But Coulombieres, full of indignation, reproached him in the severest and most upbraiding terms for his cowardice in entering into a shameful capitulation, instead of dying in the breach like a soldier, with his sword in his hand. This intrepid governor spoke the true sentiments of his heart; for when the assault was made some days after, he was killed defending the breach. In the mean time, Matignon received orders from Catharine de Medicis, now regent of the kingdom by the death of Charles IX, to send Montgomery to Paris under a strong guard. When he arrived there, he was conducted to the gaol belonging to the parliament, and confined in the tower which still bears his name. Commissioners were appointed by the queen to conduct his trial. He was interrogated concerning the conspiracy imputed to the admiral Coligny; but the principal charge on which his condemnation was founded, was his hoisting the English flag on board of the fleet which he intended for the relief of Rochelle. The sentence by which he was condemned also deprived his children of the title of nobles. When Montgomery heard this part of the sentence read, 'If they have not the virtue of nobles to retrieve this loss (said he), I consent to their degradation.— After undergoing a very severe torture, he was carried to the place de Greve, drenched in mourning, and there beheaded on the 26th of June 1574. D'Aubigny, who was present at his execution, and who stood immediately behind Pervaques, says that he appeared on the scaffold with a firm and undaunted countenance; and gives us a pretty long speech which he delivered on that occasion, addressing himself first to the spectators.
MONTH, the twelfth part of a year. See Chronology, No. 17.

MONTH, in its proper acceptance, is that space of time which the moon takes up in passing from any certain point to the same again, which is called a periodic month; or it is the space of time between two conjunctions of the moon with the sun, which is called a synodical month. That space of time which the moon takes up in passing through one sign or 12th part of the zodiac, is also called (but improperly) a month.

So that there are two sorts of months: lunar, which are measured by the moon; and solar, which are measured by the sun. The lunar periodical month consists of 27 days, 7 hours, 43 minutes, 5 seconds. The lunar synodical month is 29 days; 12 hours, 4 minutes, 3 seconds, and 11 thirds. A solar month contains upon a mean calculation, 30 days, 10 hours, 29 minutes, 5 seconds.

The Jews, Greeks, and Romans, made use of lunar synodical months, but to avoid fractions, they confined alternately of 29 and 30 days. The former the Romans called cosis, and the Greeks κοσίον; the latter were termed pleni and ἄνθεων.

1. The Hebrew months were ranged differently in their facred and in their civil year.

Order of the sacred Year. | Order of the civil Year.
---|---
Nisan | Mar. 1 | Tisri |
Iyar | Apr. 2 | Mischnevan |

Caflu | Nov. 9 | Sewan |
Tothet | Dec. 10 | Thamnus |
Sebat | Jan. 11 | Ab |
Adar | Feb. 12 | Elul |

These months being lunar cannot exactly answer to our solar months; but every Jewish month must be conceived to answer to two of ours, and partake of both. As these 12 lunar months consisted only of 354 days, the Jews, in order to bring it nearer to the true year, took care every three years to intercalate a 13th month into the number, which they called Zaddar, or the second adar. The new moon was always the beginning of the month; and it is said the Jews had people posted on elevated places, to give notice to the Scribes as soon as she made her appearance: After this proclamation was made by sound of trumpet, and the feast of the new moon, the feast of the new moon, "refounded amongst the people.

2. The months of the Athenian year, as we have before observed, consisted alternately of 29 and 30 days. The first month, according to Meton's reform of the calendar, began with the first new moon after the summer solstice, and was called Hemidoxen, answering to the latter half of June, and the former...
Each month was divided into three decades of days called ἅρμονια. The first was called μήση ἅρμωνια or ἁρμώνια, or the decade of the beginning of the month; the second was μήση μεσονία or the decree of the middle; and the third was μήση τετράδες, τετράδες or τετράδες, the decade of the expiring month.

The first day of the first decade was termed ἀρετή, because the first month began with the new moon; the second day was Ἀρετή ἀρετή, the third Ἀρετή ἀρετή, &c. The first day of the second decade was πρῶτον μεσονιά, the second πρῶτον μεσονία, &c.; the days of this decade were also called ἁρμώνια τοῦ πρῶτον, i.e. the first day, &c. after 20, because the last decade began on the 20th day. This decade was also counted by inversion thus: 

| 21st, 22nd, 23rd, and so of the last day of the month, which was called ἄρετη | 
|---|---|---|---|
| 23rd, and so of the last day of the month, which was called ἄρετη | 

The Grecian months, thus confounding of 29 and 30 days alternately, fell short of the solar year 11 days 6 hours. To remedy this defect the cycle of four years, called τέτραγωνος, was invented. In this cycle, after the first two years, they added an intercalated month called ἄρετη, confounding of 22 days; and again, after the expiration of two years more, they inserted another month of 29 days, the fourth part of a day having in the space of four years amounted to a whole day. See Year.

3. The Roman year under Romulus consisted of 10 months only, and began with March, which contained 31 days, then followed April which had 30, May 31, June 30, Quintilis 31, Sextilis 30, September 30, October 31, November 30, December 30. These 10 months containing no more than 304 days, this account was in a short time found to be deficient. Numa Pompilius, therefore, took away one day from each of his six months, April, June, Sextilis, September, October, November, December; and to the six days thus obtained he added 51, which was the number that Romulus's year, in his opinion, wanted to make it perfect. Numa had now 57 days to dispose of; he therefore divided them, and constituted two other months, January and February; the former confounding of 29 and the latter of 28 days. The month of January, which he placed at the winter solstice, he made instead of March to begin the year. Thus Numa's year confounded of 355 days: but this being found 11 days 6 hours short of the solar year, he made use of the intercalation of 90 days at the expiration of eight years perpetually: which number, being made up of the 11 days and a quarter, kept the year pretty well to its place. The beginning of the year in Julius Cæsar's time had anticipated its true place 67 whole days: these he intercalated between November and December; so that the year confided, for this one time of 15 months or 445 days. This reformation was called the Julian correction, and this year the year of confusion. At the end of 12 years, by the ignorance of priests, who did not understand intercalation, 12 days had been intercalated for nine. This was observed by Augustus Cæsar, and rectified, by ordering 12 years to pass without any intercalary days.

The order and succession of months was the same as in the calendar of the Romans, all of which were reckoned backwards. The kalends were the first day of the month. The nones fell on the seventh, and the ides on the 15th, of March, May, July, October—but in all other months the nones were on the fifth, and the ides on the 13th. For the more easy comprehension of the Roman manner of dating, according to this division of the months, here follows a table.

N. B. Every leap-year, February confounding of 29 days, the 24th and 25th of that month are written festo Kal. Mart.; hence leap-year is called Bisextilis.
MONTIA, in botany: A genus of the trygonia order, belonging to the triandria class of plants; and in the natural method ranking with those with which the order is doubtful. The calyx is diphyllous; in corolla monopetalous and irregular; the capsule unicellular and trivalved.

MONTINIA, in botany; A genus of the tetrandria order, belonging to the dioecia class of plants. The perianthium of the male is quadridented superior; and there are four petals. The female calyx and corolla are as in the male; the filaments barren; the style bident; the capsule oblong and bicellular.

MONTME DEI, a small but strong town of France, in Luxemburg, seated on the river Chire, which deviates it into the upper and lower towns. It is 22 miles south-east of Sedan, 27 south-west of Luxemburg, and 135 north-east of Paris. E. Long. 5. 23. N. Lat. 49. 32.

MONTMORENCI (Francois Henry de.) See LUXEMBURG.

MONTMORENCY, a town of France, with the title of a duchy, remarkable for the tombs of the dukes of this name. It is seated on a hill, near a large valley, fertile in fruits, especially excellent cherries. E. Long. 2. 24. N. Lat. 48. 59.

MONTMORENCY (Anne de), a peer, marshal, and count of France, and one of the greatest generals of the 16th century, defended in 1512, the city of Menzies against the emperor Charles V., and obliged the count of Nassau to raise the siege. The following year he was made marshal of France; and in 1525, following king Francis I. into Italy, he was taken with that prince at the battle of Pavia, which was fought contrary to his advice. The important services he afterwards rendered the state were rewarded by the sword of count of France, with which he was precipitated by the king on the 10th of February 1538. He afterwards underwent various revolutions of fortune both at court and in the field. At last, being wounded at the battle of St Denis, which he gained on the 10th of November 1567, he died of his wounds two days after, at 74 years of age. It is said, that a cordelier attempting to prepare him for death, when he was covered with blood and wounds, after the battle of St Denis, he replied in a firm and steady voice: “Do you think that a man who has lived near 80 years with honour, has not learnt to die for a quarter of an hour?”

MONTPELIER, one of the handsomest towns of France, and the most considerable in Languedoc excepting Toulouse, is situated in E. Long. 4. 20. N. Lat. 45. 58. It hath a citadel, a bishop’s see, an university, a royal academy of sciences, and a mint. This town has been long famous for a fabulous, air and skilful physicians. In reality the air may be necessary in cataractous consumptions from its dryness and density; but it is too sharp in cafes of pulmonary imputations. The climate, according to some late travellers, is so much altered for the worse, that the inhabitants themselves scarce know it to be the same; it has been changing many years, and every year becomes worse and worse. It has been known to rain almost three months without interruption; and at intervals such thick smoky fogs, as nothing but the bank of Newfoundland could equal: and several times, for two or three days on a stretch, the sky is so heavily loaded, that neither sun, moon, nor star can be seen. In summer it is so insufferably hot, that till the cool of the evening there is no stirring out. Its situation, though on an eminence, never could be healthy: as between it and the Mediterranean (which is about three leagues distant) it is one continued marsh and swamp, ever covered with noxious vapours, which, when the sea-breeze sets in, blows directly on the town and the country adjacent; of the said effects of which, its unhealthy inhabitants, with their yellow meagre looks, are the most convincing proofs.

The town has nothing curious to induce a stranger to stay longer in it than three or four days, except he arrives there about Christmas; at which time it is very gay, as all the nobility of Languedoc meet there at that time to settle the affairs of the province, though it is not the capital, but effectedly near the centre. There is during that time a play, which, with an indifferent concert, are all the public amusements. The people in trade are reputed by the French themselves to be the greatest extortioners, and fure not to let a penny escape them, be the means to come at it ever so unjust; as an infallible, they had the confidence to charge an English sea officer that died there, 300 livres (twelve guineas and a half) for eight days lodging.

This city stands upon a rising ground fronting the Mediterranean, which is about three leagues to the southward; on the other side is an agreeable plain, extending about the same distance towards the mountains of the Cevennes. It is reckoned well built, and what the French call “in ferreto;” yet the streets are in general narrow and the houses dark. The inhabitants are suppos’d to amount to 40,000: they are sociable, gay and good tempered, and they trade very largely in wine cordials, oil, verdigrase, and salt-petre. They have several manufactures in silk and woollen goods. There are many Protestants here and at Nimes. The markets are well supplied with fish, poultry, butcher’s meat, and game, at reasonable rates. The wine of the country is strong and harsh; Burgundy is dear, and so is the sweet wine of Frontignan, though made in the neighbourhood of Cette. Liquors of various sorts are compounded and distilled at Montpellier. The environs are extremely pleasant, having on one side La Place de Peyrou, which forms a fine terrace. From thence, on a clear day, may be seen to the eastward the Alps, which form the frontiers of Italy; to the southward the Pyrenean mountains, which form those of Spain, each esteemed fifty leagues distant; and to the southward a most extensive view of the Mediterranean. Not far from thence is a noble aqueduct, built like two bridges one above the other; by this water is brought from a mountain at three leagues distance, into two basins in a small elegant temple at the west end of the place; and the king’s garden, where on certain days public lectures are held on botany. On the other side of the town is the episcopal, a beautiful v. 2, k. of white, bordered on each side by olive trees, from whence there is a pleasing prospect of the sea and the country adjacent to the town; near which is the citadel, a place of no strength though well walled in, as is commanded by several rising grounds, and has only a ditch. There are commonly kept there four battalions of infantry.

Kk 2 Should
M O N T R E A L, an island of north America, in the river St. Lawrence, about six leagues and a half in length, and three leagues over in the breadth parts. It belonged to the French; but was taken by the generals Amherst and Murray on the 8th of September 1760, without firing a gun. According to the terms of capitulation, all the French forces were to be sent to Old France; and consequently all Canada became subject to the Crown of Great Britain; which cession was confirmed by the peace of 1763. The soil of the island is exceedingly rich and good, producing all kinds of European fruits and vegetables in great abundance, with variety of garden fruits. The south side is the most inhabited, of course better cultivated; and besides the settlements, which are numerous, the island is adorned with villas, for the retirement of the more wealthy merchants during the summer season. No Indians are settled here; nor are they fond of settling on islands, from an hereditary distrust lest they should be cut off by the Europeans. Since this place has been in the possession of Britain, it has suffered much by fires, the houses being mostly built of wood. The town of Montreal, situated on this island, and formerly called Ville Marie, is the second place in Canada for extent, buildings, and strength; and besides possessing the advantage of a less rigorous climate; for delightfulness of situation is infinitely preferable to Quebec. It stands on the side of a hill, sloping down to the south, with many agreeable villas upon it, which with the island of St. Helen, and the river (which is here about two miles broad), form a most charming landscape. Though the city is not very broad from north to south, it covers a great length of ground from east to west, and is nearly as large and populous as Quebec. The streets are regular, forming an oblong square; the houses well built, and in particular the public edifices, which far exceed those of the capital in beauty and commodiousness; the residence of the knights hopitallers being extremely magnificent. There are several gardens within the walls, in which, however, the proprietors have consulted more than elegance, particularly the house of the Sistors of the Congregation, the Nunnery Hospial, the Recollets, Jesuits Seminary, and Governor. Besides these, there are many other gardens and beautiful plantations without the gates, as the garden of the General Hospial, and the improvements of Mr. Liniere, which exceed all the rest, and are at an agreeable distance on the north side of the town. The three churches and religious houses are plain, and contain no paintings, nor anything remarkably curious, but carry the appearance of the utmost neatness and simplicity. The city has six or seven gates, large and small; but its fortifications are mean and inconsiderable, being encompassed by a slight wall of masonry, sufficient only to overawe or prevent a surprize from the numerous tribes of Indians with whom they are surrounded, and who used to resort in vast bodies to the annual fair held here, which continued from the beginning of June till the latter end of August, when many solemnities were observed, at which the governor assisted, and guards were placed to preserve good order among such a concourse of different savage nations, all of whom are extremely fond of spirituous liquors, and when drunk commit great excesses. The fortifications were by no means capable of withstanding a regular attack; and though the garrison in 1760 consisted of eight battalions of regular troops, a numerous militia, and a great body of savages, M. Vaudreuil and Chevalier de Levis submitted without firing a gun. There are no guns mounted on the wall; only a dry ditch surrounds it, about seven feet deep, encompassed with a regular glacis. On the side of the town is a cavalier on an artificial eminence, with a parapet of logs or squared timbers and six or eight guns, called the citadel. Such is the strength of Montreal, the number of whose inhabitants may be between 5000 and 6000, extremely gay and well dressed. By the situation of the place, the inhabitants are well supplied with all kinds of river fish, some of which are unknown to Europeans, being peculiar to the lakes and rivers of this country. They have likewise plenty of black cattle, horses, hogs, and poultry. The neighbouring shores supply them with a great variety of game in the different seasons; and the island abounds with well-tafted soft springs, which form a multitude of pleasant rivulets. The city now drives a considerable trade in furs, &c. and vessels of 200 tons can come up to it. It stands 60 leagues above Quebec. 

MONTEFL, a town of Spain, in the kingdom of Arragon, with a castle, seated on the river Xiloca, 25 miles N. W. of Tervil, and 43 S. E. of Calataud. — W. Lon. 2. N. Lat. 41. 9.

MONTREUX, a town of Italy, in Sicily, and in the valley of Mazara, with an archbishop's see; seated on a rivulet, five miles W. of Palermo, and 50 N. E. of Mazara. E. Lon. 13. 13. N. Lat. 38. 14.

MONTREAL, or Mount Royal, a fortres of Germany, in the circle of the Lower Rhine, and elector of Trier; seated on the river Moelle, 22 miles N. E. of Trier. E. Lon. 7. 6. N. Lat. 49. 59.

MONTROSE, a handsome town of North Britain, in the shire of Angus, situated at the mouth of the river Esk, on the German Ocean, 26 miles north-east of Edinburgh, but 70 miles distance by road. The houses are neat, and many of them in the modern taste. The most remarkable public buildings are, the town-house, the church, and an elegant episcopal chapel. — Montrose is a parliament town, and a dukedom in the family of Graham. It stands between two rivers, the north and north Esk, over which there have been lately built two very handsome bridges, at a great expense. The salmon fisheries on these rivers are very valuable, and form a good branch of commerce.
The harbour is a fine semicircular basin defended by a handsome stone pier. A great number of trading vessels belong to this port.

Montrose (Marquis of). See Graham; and Britain. 

Montserrat, a mountain of Spain, in Catalonia, one of the most singular in the world for situation, shape, and composition. It stands single, towering over a hilly country like a pile of grotto work or Gothic spires; and its height so great, that to a beholder on the top, the neighbouring mountains appear to be sunk to a level with the plain. It is composed of steep rocks, which at a distance seem indented; whence it is said to have received the name of the Latin word *ferra* a "faw." It is impossible to describe the beauty, richness, and variety, of the landscapes discovered from the most elevated point: but the extensiveness of the prospect may be conceived by the reader, upon being told that the islands of Minorca and Majorca, which are ascribed to this holy image.

The number of professed monks, according to Mr Swinburne, is 76 (according to M. Bourgonne 60); of lay-brothers, 28; and of singing boys, 25; besides physician, surgeon, and servants. The church is a gloomy edifice; and the gilding is much filled with the smoke of 85 lamps of silver, of various forms and sizes, that hang round the cornice of the Sanctuary. Funds have been bequeathed by different devotees for furnishing them with oil. The choir above flairs is decorated with the life of Christ in good wooden carving. A gallery runs on each side of the chancel, for the convenience of the monks. A large iron grate divides the church from the chapel of the Virgin, where the image stands in a niche over the altar, below which burn four tapers in large silver candlesticks, the present of the duke of Medina Celi. In the sacristy, and passages leading it, are priests and cupboards full of relics and ornaments of gold, silver and precious stones; they point out, as the most remarkable, two crowns for the virgin and her son; of ineffable value; some large diamond rings; an excellent cameo of Meduзи’s head; the Roman emperors in alabaster; and the sword of St Ignatius. But as no offerings to this miraculous statue can be rejected or otherwise disposed of, the shelves are crowded with most whimsical 

On different parts of the mountain, as already noticed, are a number of hermitages. Each of these solitary retreats, which at a distance seem delusive of every thing, has a chapel, a cell, a well in the rock, and a little garden. The inhabitants of one of them, which is dedicated to St Beneto, has the privilege of making an annual entertainment on a certain day; on which day all the other hermits are invited, when they receive the sacrament from the hands of the mountain vicar, and after divine service dine together. They meet also at this hermitage, on the days of the saints to which their several hermitages are dedicated, to say mass, and commune with each other. But at other times they live in a very solitary and recluse manner, perform various penances, and adhere to very rigid rules of abstinence; nor do they ever eat flesh; nor are they allowed to keep within their walls either dog, cat, bird, or any living thing, left their attention should be withdrawn from heavenly to earthly affections. Most of these hermits are said to be persons of fortune and family, disguised with the world, who have retired thither to devote themselves to meditation, self denial, and contrition.

Montserrat, one of the Carribean Isles belonging to Great Britain. It is a very small, but very pleasant island, so called by Columbus from its resemblance to the famous mountain near Barcelona in Catalonia, it lies in W. Long. 61° 9'. N. Lat. 16° 50'. having Antigua to the north-east, St Christopher’s and Nevis
Moo [262] Moo

MONTERRAT to the north-west, and Guadaloupe lying south-south-east at the distance of about nine leagues. In its figure it is nearly round, about nine miles in extent every way, 27 in circumference, and is supposed to contain about 45,000 or 50,000 acres. The climate is warm, but less so than in Antigua, and is esteemed very healthy. The soil is mountainous, but with pleasant valleys, rich and fertile, between them; the hills are covered with cedars and other fine trees. Here are all the animals as well as vegetables and fruits that are to be found in the other islands, and not at all inferior to them in quality. The inhabitants raised formerly a considerable quantity of indigo, which was prior to them in quality. The inhabitants raised for.

The present situation of the island is to be found in the other heads 232 tierces of sugar. And the whole exportation of the island to Great Britain was from London and from Bristol. As to its produce, more especially of late years, has scarce any that of the sun 32 minutes 52 seconds. Its mean diameter as 15, or 2 days, 7 hours, 43 minutes, moving about 2500 miles every hour; and turns round her axis exactly in the time that she goes round the earth, which is the reason of her keeping always the same side towards us; and that her day and night taken together are as long as our lunar month.

The mean distance of the moon from the earth is 601 semi-diameters of the earth; which is equivalent to 240,000 miles. The mean eccentricity of her orbit is 774 of her mean distance, or in miles 13,000, which makes a considerable variation in that mean distance.

—Her diameter is to that of the earth as 100 to 355, as 11 to 40, 15, or 2180 miles; its mean apparent diameter is 31 minutes 161, and that of the sun 32 minutes 52 seconds. Its mean diameter as seen from the sun is 6 seconds.

The moon's surface contains 14,896,570 square miles, and its solidity 5,408,246,000 cubical ones. The density of the moon's body is to that of the earth as 48,911 to 39,214; to that of the sun, as 48,911 to 10,000; its quantity of matter to that of the earth, nearly as to 1 to 59.15: the force of gravity on its surface is to that on the surface of the earth as 139.2 to 427.8; and the moon's bulk to that of the earth as to 76 to 1. The moon has scarce any difference of feasons; because her axis is almost perpendicular to the ecliptic.

The different appearances of the moon are very numerous; sometimes she is increasing, then waning; sometimes hornsed, then semicircular; sometimes gibbous, then full and round. Sometimes, again, she illuminates us the whole night; sometimes only a part of it; sometimes she is found in the southern hemisphere, sometimes in the northern; all which variations having been first observed by Endymion, an ancient Grecian who watched her motions, she was fabled to have fallen in love with him. The source of most of these appearances is, that the moon is a dark, opaque, and spherical body, and only shines with the light she receives from the sun; whence only that half turned
turned towards him; at any instant, can be illuminated, the opposite half remaining in its native darkness. The face of the moon visible on our earth, is that part of her body turned towards the earth; whence, according to the various positions of the moon, with regard to the sun and earth, we observe different degrees of illumination; sometimes a large and sometimes a less portion of the enlightened surface being visible. — But for a particular account of the nature, phenomena, &c. of this secondary but interesting planet, see Astronomy-Index, at Moon.

New Observations on the atmosphere, Twilight, &c. of the Moon. M. Schroeter of the Royal Society of Gottingen has lately published a very curious and elaborate work in German, intitled Seleneographische Fragmente, &c. or Seleneographical Fragments, intended to promote a more accurate knowledge of the Moon’s surface. The several maps of the moon *, which have been delineated by Hevelius, Riccioli, Caffini, and Mayer, are well known to every person conversant with astronomical subjects. It is evident that these delineations can give only a very general idea of the spots, together with their relative position on the lunar disk; and as, with respect to us, the appearance of these must vary according to the direction in which the rays of the sun fall on them, the moon’s surface will not exactly correspond with the representation of it laid down in the map, except when it happens to be illuminated under the same angle as when this map was drawn. This consideration induced the author to apply himself to the invention of a more accurate mode of describing these phenomena than had hitherto been attempted. For this purpose, having provided himself with a telescope seven feet in length contrived by Dr Herchel, he resolved, repeatedly and under various angles of illumination, to observe and delineate very small portions of the lunar disk; in order that, by comparing his different drawings of the same objects, he might compile an accurate, topographical description of the moon’s surface; but, in this manner, to form a complete lunar atlas, was an undertaking too extensive for a single person. He therefore found himself obliged to prescribe more narrow limits to his design, and confined his plan to the delineation of the several portions of the moon’s surface under one angle only of illumination, and this a very small one, that he might obtain more distinct and accurate observations and drawings of the shadows; intending at the same time to examine such parts as appeared either more remarkable or less distinct than the rest, by repeated observations under various angles of illumination; and the present volume contains the result of his observations, with respect to the northern parts of the lunar disk.

The author observes, that, through a telescope which magnifies a thousand times, a lunar object of 160 feet in surface appears like a very small point; and that, to be distinguished with respect to shape, it must not be less than 300 feet in extent. He tells us, that for his observations he preferred those times when the sun’s rays fell on the moon under the least angle; that he carefully and repeatedly examined every object that could be distinguished, and either actually measured its apparent diameter and the length of its shadow, or compared these dimensions with others which he had already measured, and that he never used magnifiers of greater power than was absolutely necessary to render the object distinct. In order to facilitate the delineation, he applied to his telescope a projecting micrometer, divided into small figures, which, by means of a brass rod, could be placed at any distance from the eye, and always be kept parallel to the line of the moon’s horns. His maps or drawings are orthographical projections: and his scale is so constructed, that 20 seconds of the moon’s disk correspond with half an English inch on the map; thus the space of 4 seconds is represented in the compass of a decimal line, and, according to M. Schroeter’s computation, answers to a German mile or 3807 toises. The inconveniences and inaccuracy of the common method of measuring the lunar mountains, induced him to contrive objects capable of greater exactness and more general application: these he varied as the circumstances of the case required; but they are all trigonometrical calculations of the height of the mountain, or the depth of the cavity from the angle of illumination and from the length of the shadow.

If, as some have supposed, a great part of the moon’s surface be volcanic, it is natural to expect that the marks of eruption should from time to time be discernible. A single instance of this kind occurred to our author: ever since the 27th of August 1788, he had constantly seen a cavity, or, as he terms it, a volcanic crater, in the spot Hevelius, which he had never before perceived, though he had often examined this part of the moon with the utmost attention, and in the most favourable circumstances. According to his conjectures, this phenomenon must have commenced between the 24th of October 1787 and the 27th of August 1788.

He observed some alterations in the appearance of lunar objects, which, though too considerable to be attributed to the variation of light, were not sufficiently permanent to be considered as the effect of volcanoes. These he attributes to meteors; for though he does not suppose the moon to be surrounded with air, exactly like that which invests our globe, he thinks it probable that it may have an atmosphere of some kind, in which some of the elements of bodies, decomposed on its surface, may be suspended; and that some of the lunar mountains may emit nebulous vapours, not unlike the smoke of our volcanoes, which obscure and disguise the objects seen through them.

In regard to those bright points, which have been seen on the moon’s surface during eclipses, and at other times on her unenlightened part, and which some have supposed to be burning volcanoes; Schroeter, after the most attentive examination of them, imagines that most of them must be ascribed to the light reflected from the earth to the dark part of the moon’s disk, which returns it from the tops of its mountains, under various angles, and with different degrees of brightness. Some of these phenomena he supposes to be no more than optical illusions, arising from igneous meteors floating in our atmosphere, which happen to fall within the field of the telescope.

But the most interesting part of this work consists of the author’s “Remarks on the Formation and physical Constitution of the Moon’s Surface and Atmosphere.”
The surface of the moon appears to be much more unequal than that of our earth; and these inequalities have great variety both in form and magnitude. There are large irregular plains, on which are observed long and narrow strata of hills running in a serpentine direction; some of the mountains form extensive chains; others, which are in general the highest, stand alone, and are of a conical shape: some have craters; others form a circular ring enclosing a plain; and in the centre of many of these plains, as well as in the middle of some of the craters, other mountains are found, which have likewise these craters. These mountains are various with respect to colour, some being much darker than others.

The loft lofty mountain on the surface of our globe is supposed to be Chimboraco, which is not 20,000 feet in height: but there are many in the moon which are much higher; that which is distinguished by the name of Leibnitz, is not less than 25,000 feet. This elevation will appear more extraordinary, if compared with the moon's diameter, of which it is \( \frac{1}{4} \) th, whereas Chimboraco is not above \( \frac{1}{5} \) th of that of the earth; thus considered, the lunar mountains are near five times as high as any on our globe.

The craters of the moon are circular, and surrounded with an annular bank of hills; they are remarkable for their width, many of them being from 4 to 15 geographical miles in diameter: some are not deeper than the level of the moon's surface; others are 9000, 12,000, and 15,000 feet in depth, that of one, which our author calls Bernouilli, is above 18,000 feet. The height of the annular bank is seldom equal to the depth of the crater which it surrounds; but the quantity of matter in the one appears to be in general nearly equal to the capacity of the other. The principal mountains and cavities seem to be connected by a series of others of less magnitude; and sometimes by hilly strata, which, like the radii of a circle, may be traced to a common centre; this is generally either a mountain or crater, though not of the greatest height or depth.

These hilly strata, which, through smaller telescopes, appear like veins on the moon's surface, have often been mistaken for torrents of lava; none of which, however, do prevent its refracting the solar rays, having pointed out the circumstances, that the mountains in the dark hemisphere of the moon, near its luminous border, which are of sufficient height to receive the light of the sun, are the more feebly illuminated the more distant they are from that border; from which proofs of a refracting atmosphere, he also deduced the probability of the existence of a faint twilight, though his long series of observations had not yet fully evinced it. He had however, ascertained the existence of a twilight on Venus; and as one fortunate discovery often leads to another, he had no sooner succeeded in his observations on that planet, than he was induced to direct his attention, for a similar purpose, to the moon. In doing this, he applied the calculations and inferences he had made to some appearances he had already noticed on this satellite. It occurred to him, that if in fact there were a twilight on the moon, as there is on Venus and our earth, it could not, considering the greater rarity of its atmosphere, be so considerable: that the veils of it, allowing for the brightness of the luminous part of the moon, the strong light that is thence thrown upon the field of the telescope, and in some measure the reflected light of our earth, could only be traced on the limb, particular
fully at the cusps; and even this only at the time when our own twilight is not strong, but the air very clear, and when the moon, in one of its last phases, is in a high altitude, either in the spring, following the Moon two days after a new moon; or in the autumn, preceding the sun in the morning, with the same aspect: in a word, that the projection of this twilight will be the greater and more perceptible the more elevated the phase, and the higher the moon above the horizon, and out of our own twilight.

All the requisite circumstances do not often coincide. M. Schroeter, Fragment, p. 120, was so fortunate as to be favoured with a combination of them on the 24th of February 1793. And, the observation proved in every respect to complete, and the inferences deducible from it appeared to him so new and interesting, that he could not with hold the immediate communication of it to the public. His observations concerning both the Moon and Venus have been accordingly detailed in a paper sent to the Royal Society of London, and inserted in their Transactions for 1792; from which the following respecting the Moon are extracted.

"On the abovementioned evening, at 5h 40', two days and 12 hours after the new moon, when in consequence of the liberation the western border of the grey surface of the Marc Crater was 1° 20' distant from the western limb of the moon, the air being perfectly clear, I prepared my seven-feet reflector, magnifying 74 times, in order to observe the first clearing up of the dark hemisphere, which was illuminated only by the light of our earth, and more especially to ascertain whether in fact this hemisphere, which, as is well known, is always in what more luminous at the limb than in the middle, would emerge out of our view at many parts at once, or first only at the two cusps. Both these points appeared now, most distinctly and distinctly, tapering in a very sharp, faint, scarse anywhere interrupted, prolongation; each of them exhibiting, with the greatest precision, its farthest extremity faintly illuminated by the solar rays, before any part of the dark hemisphere could be distinguished. But this dark hemisphere began soon after to clear up at once at its border, though immediately only at the cusps, where, but more particularly at their points, this border displayed, on both at the same time, a luminous margin, above a minute, breadth, of a very pale grey light, which, compared with that of the farthest extremities of the cusps themselves, was of a very different colour, and relatively as faint as the twilight I discovered on the dark hemisphere of Venus, and that of our own earth, when compared with the light immediately derived from the sun. This light, however, faded away so gradually towards the cusp, as to render the border on that side perfectly undefined, the termination losing itself imperceptibly in the colour of the sky.

"I examined this light with all possible care, and found it of the same extent at both points, and fading away at both in the same gradual proportion. But I also, with the same caution, explored whether I could distinguish any part of the limb of the moon farther towards the cusp; since, if this crepuscular light had been the effect of the light reflected from our globe, it would undoubtedly have appeared more sensibly at the parts most remote from the glare of the illuminated hemisphere. But, with the greatest exertion of my visual powers, I could not discover any part of the, as yet, wholly darkened hemisphere, except one single speck, being the summit of the mountainous ridge Leibnitz, which was then strongly illuminated by the solar light; and indeed eight minutes elapsed before the remainder of the limb became visible; when not only separate parts of it, but the whole, displayed itself at once.

"This alone gave me certain hopes of an ample recompence and satisfied me that the principles I had laid down in my Selenotop, Fragm. § 555, et seq., concerning the atmospheres of the planets, and especially of the moon, are founded on truth. But a similar observation made on the 6th, after seven o'clock, afforded me several collateral circumstances, which strongly corroborate what I have there advanced on this subject. The whole limb of the dark hemisphere, illuminated only by the reflected light of our globe, appeared now so clear and distinct, that I could very readily discern not only the large but also the smaller spots, and among these Pluto, Arilarchus, Menelaus, Mussius, Copterius, &c. and even the small speck to the north-west of Arilarchus, marked Tab. XXVII. fig. 1. of the Fragments. I could apply the usual power, magnifying 161 times; and had full leisure, and the means, to examine everything carefully and repeatedly, and to take very accurate measurements.

"Although a just idea of so delicate a phenomenon as this crepuscular light cannot possibly be conveyed by a drawing, but must be gathered from actual inspection, I have, nevertheless, attempted a delineation of it, and of the southern and eastern cusps, fig. 1, and 2, as deduced from my measurements, especially at the southern cusp, in hopes thereby to render what I have farther to say concerning this observation more intelligible.

"The southern cusp (fig. 1.) extended from a to c, with a gradually fading but still resplendent solar light, of its usual pale yellow colour, and terminated at c with a mountain. That this was really the point of the cusp, appears not only from the general configuration of the falcated segment, which was sufficiently narrow even at its beginning at a, near which it was somewhat digged at b by a high mountain, but also from the narrower of its luminous curve at d and f, the breadth of which seldom exceeded 1°, and had a sensible interruption so near as a. This curve was throughout, from a to c, except where the glare of the solar rays spread some degree of light, bordered with the pale ash colour of the dark hemisphere, glimmering with the faint light reflected from our earth; out of which, however, rose the higher mountains g, h, i, c, which were now already illuminated by the sun; and farther on, not less than 30 lines, or, according to my usual projection, two minutes distant from the point c, was seen another mountain k, which belonged to the high ridge Leibnitz, and also received its light immediately from the sun.

"There can hence be no doubt of the termination of the cusp being at e; and this being well ascertained, I now distinguished with the greatest certainty the twilight extending from c to k. The most remarkable circumstances attending this light were, that it was
prominent, the arc, as yet situated in the dark hemisphere.

Thus far the observations; and now for the application of them.

I need hardly insist upon the proofs, that the very faint pyramidal glimmering light observed on the 24th of February at the extremities of both cups, could by no means be the immediate effect of the solar light; all the circumstances of the observations militating uniformly and decidedly against this supposition, which, were it true, would oblige us to admit a most unaccountable diminution of light, and thence also a density of the lunar atmosphere, that ought to exceed even the density of ours; a fact absolutely contradicted by all the lunar observations hitherto made. This light, indeed, was so very faint, that it disappeared at 7° 20', when the moon approached the horizon; whilst, on the other hand, Aritharchus, which had no light but what it received from the earth, was still very distinguishable; and the summit of Leibnitz (fig. 1, which, though far within the dark hemisphere, was, however, illuminated by the immediate solar rays) displayed a degree of brightness, which, although when compared with that of the cup d e f, it appeared very faint and dwindling, equalled, however, that of our Peak of Teneriff. Nor can it be conceived why this glimmering light broke off so suddenly at both the cups, without a progressive diminution. It can hardly be supposed, that similar, grey, prominent, flat areas, of the same form and dimensions, and comparatively of a faint light, which, whilst in the dark hemisphere, they derive immediately from the sun, exist on all parts of the moon; more especially as, at the places observed, the limb happened to exhibit throughout an exact spherical form, without the least sensible inequality; and as in both the bordering regions of the northern and southern hemispheres, especially in the latter, no such grey prominent planes are any where discernible. It may then be asked, why did this faint glimmering light appear at both cups, along equal arcs of the limb, of equal length and breadth, and of the same pyramidal form? and why did its farther extremity blend itself with the terrestrial light of the dark hemisphere, which, according to a great number of my selenotopo-graphic observations, is by no means the case, even with those grey prominent areas, which, being at some distance on the dark side of the terminating border, are nevertheless illuminated immediately by the sun?

Thence, therefore, could certainly not derive their light immediately from the sun; whence this appearance, like the similar ones on the planet Venus, can only be ascribed to the solar rays reflected by the atmosphere of the moon upon those planes, producing on them a very faint, gradually diminishing, glimmering light, which at last loses itself in the reflected terrestrial light, in the same manner as our twilight blends itself with the light of the moon. Every circumstance of the above observation seems to me to confirm this supposition; and hence the observation itself, which, though fingle, was however a most fortunate and complete one, must appear of no small degree of importance, since it not only confirms the observations and inferences on the long contested lunar atmos...
...atmosphere contained in my Selenotop. Fragn. but also furnishes us with many more lights concerning the atmosphere of planets in general than had been afforded us by all those observations collectively.

This, and the mathematical certainty that the phenomenon is in fact nothing but a real twilight in the lunar atmosphere, he further evinces by a series of theoretical deductions and calculations, which do not admit of being here stated. Among other results, it appears, that the lower and more dense part of the lunar atmosphere, which has the power of reflecting this bright crenular light, is only 1356 Paris feet in height, and hence it will clearly be explained, according to the different librations of the moon, ridges of mountains, even of a moderate height, situated at or near the terminating character, may partially intercept, or at times wholly prevent, this crenular light, either at one or the other cup, and sometimes at both. "I cannot hence (says our author) but consider the discovery here announce as a very fortunate one, both as it appears to me decisive, and as it may induce future observers to direct their attention to this phenomenon. Admitting the validity of this new observation, which I think cannot well be called in question, I proceed now to deduce from it the following inferences.

1. It confirms, to a degree of evidence, all the selenotopic observations I have been so successful as to make on the various and alternate changes of particular parts of the lunar atmosphere. If the inferior and more dense part of this atmosphere be in fact of sufficient density to reflect a twilight over a zone of the dark hemisphere 2° 34', or 16½ geographical miles in breadth, which shall in intensity exceed the light reflected upon its dark hemisphere by the almost wholly illuminated disk of the earth; and if, by an accidental computation, this dense part be found to measure 1356 feet in perpendicular height, it may, according to the frigid analogy, be ascertained, that the upper, and gradually more rarified frata, mufl, at least, reach above the highest mountains in the moon. And this will appear the more evident, if we reflect, that notwithstanding the inferior degree of gravitation on the surface of the moon, which Newton has estimated at somewhat less than one-fifth of that on our earth, the lower part of its atmosphere is nevertheless of so considerable a density. This considerable density will, therefore, fully account for the diminution of light observed at the cups, and on the high ridges Leibnitz and Doerfel, when illuminated in the dark hemisphere; as also for the several obstructions and returning serenity, the eruptions, and other changes, I have frequently observed in the lunar atmosphere. This observation also implies:

2. That the atmosphere of the moon is, notwithstanding this considerable density, much rarer than that of our earth. And this indeed is sufficiently confirmed by all our other lunar observations. I think I may assert, with the greatest confidence, that the clearer part of our twilight, when the sun is 4° below our horizon, and when we can conveniently read and write by the light we receive from it, surpasses considerably in intensity the light which the almost wholly illuminated disk of our earth reflects upon the dark hemisphere of the moon 2½ days before and after the new moon. But should we even admit an equal degree of intensity, it will, however, appear from computation, that our inferior atmosphere, which reflects as strong a light over 4° as that of the moon does over 2° 34', of their respective circumstances, must be at least eight times higher than that of the moon.

3. The striking diminution of light I noticed in my twelve years observations on Venus, likewise indicates, that the atmosphere of that planet, which in many respects similar to ours, is much denser than that of the moon, and that it will be still further corroborated, if we compare together the several measurements and computations made concerning the twilights of different planets. There is no doubt but that the faintest twilight of Venus, as seen either before or after the rising and setting of the sun across our twilight, is much brighter than that of the moon; and it appears, moreover, from computation, that the denser part of the atmosphere of Venus measures at least 15000 Paris feet in height, and spreds its twilight 67 geographical miles into the dark hemisphere, whilst the denser part of the lunar atmosphere, whose height does not exceed 1356 feet, produces a faint twilight not above 10½ geographical miles in breadth. Thus, as my successful observations on the twilight of Venus led me to the discovery of that of the moon, so did these latter reciprocally confirm the former; and thus, which ever way we contemplate the subject, must we be struck with the coincidence that prevails throughout.

4. But if the lunar atmosphere be comparatively so rare, it follows, that the inflection of light produced by it cannot be very considerable; and hence does the computation of M. Du Sejour, according to which the inflection of the four rays which touch the moon amounts to no more than 4½", receive an additional degree of authenticity. Besides which,

5. As the true extent of the brightest lunar twilight amounts to 2° 34', the obliquity of the ecliptic in the moon only to 1° 29'; the inclination of the orbit of the moon, on the contrary, to 5° 15', and its synodic period, during which it performs a revolution around its axis of 12h. 18; it follows, that its brightest twilight, to where it loses itself in the light reflected by the almost fully illuminated disk of our earth, must, at least at its nodes, last 2½, and that it will be still longer at other parts of the orbit, according to the situation of the nodes.

6. And lastly, it being a well known fact that the fixed stars, as they approach the moon, diminish in splendor at the most only a very few seconds before their occultations, it was natural for me, after the successful observations I had made on the twilight of the moon, to pay particular attention to this circumstance. On the 25th of February, at 6h. P.M. the sky being very clear, the limb of the dark part of the moon appeared uncommonly distinct; and only a few seconds of a degree from its edge was seen a telescopic star of about the 10th or 12th magnitude. I counted full 206° before its occultation, and 18½ of the same, without the least perceptible diminution of light. The star, however, began now gradually to fade, and after the remaining 1½, during which I observed it with all possible attention, it vanished in an instant. This observation agrees perfectly with the above computations.
The principal zone $dd$; and at $l$ a still more remarkable, circular, though imperfectly defined spot, somewhat brighter than the luminous interval between the zones, and perfectly similar to the remarkable luminous spot which I had observed in 1786 and 1787 on the same part of Jupiter, and which then led me to some very unexpected inferences concerning the atmosphere of that planet.

"These favourable circumstances led me to the following accurate observation, which I was certain would prove instructive to me. At 10th. 43° 50' I faw the spot $f$ at the middle of its parallel; and im-fig. 6. mediately after began the occultation; than which a more distinct and beautiful one was perhaps never seen.

"Immersion. The western, preceding, first satellite, disappeared behind the sharp bright limb of the moon, at 10th. 43° 12'.

The second satellite disappeared, without becoming at all indistinct, exactly at 10th. 44° 19'.

The western limb of Jupiter came in contact, most distinctly, with the eastern limb of the moon, at 10th. 46° 32' 1/5.

Jupiter's eastern limb disappeared, as distinctly, at 10th. 48° 20' 35'. This immersion took place, as represented in fig. 6, to the eastward of Aritharchus, at about the 27th degree of north latitude.

"The third satellite disappeared, after having been for about one or two seconds faint and indistinct, at 10th. 58° 57' 5'.

"The fourth satellite, which appeared the least of them all, became undiscernible near the limb, and vanished at about 11th. 2° 16'.

"Emerision. The two preceding first and second satellites were here likewise of use in determining precisely the emersion of both the limbs of Jupiter from the dark hemisphere of the moon.

"The first appearance of Jupiter's western limb was very distinctly at 11th. 43° 34'.

"Emerison of the eastern limb, as distinctly, at 11th. 45° 39' 5'. This emersion took place, as represented in fig. 7, to the north-eastward of Seneca (B. Tab. VIII. of the Frag.), at about the 23rd degree of north latitude.

"The emersion of the next, or third satellite, was not observed.

"That of the fourth was distinctly at 11th. 59° 1'.

"This observation gave me the more satisfaction, as it singularly contributed to confirm the discovery I had been so fortunate as to make of the twilight in the moon, and the height and density of the lower strata of its atmosphere.

"Experience has sufficiently proved, that a stronger will ever obscure a fainter light; and it follows hence, that the light of a bright flare approaching the moon, when full or nearly so, will lose something of its luster; but little can be inferred in favour of, an atmosphere either of the Moon or of Mars, from the observation of Cassini; in which, as Dr. Herchel has illustrated by some observations of his own, a flare in Aquarius, Phil. of the sixth magnitude, and as yet six minutes distant from Mars, diminished in light when both were seen, in the same field of the telescope. A mere apparent diminution of light, occasioned by the glare of a larger luminous object, when seen at the same time with a smaller
and another thing is a real indistinctness of the small luminous body, which increases in proportion as they approach nearer to each other.

"It was very natural for Jupiter to diminish in brightness when it approached so near to the moon, then almost at its full, as to be seen at the same time in the field of the telescope, which was in fact the circumstance of this observation: but I could not observe any progressive variation of light in the eastern and western, equally luminous, disks, proportional to their distances from the limb of the moon, much less a real indistinctness: and this neither when the limbs of the two planets were nearly in contact, nor when Jupiter was partly, or about one half covered by the moon.

"It was a sight truly gratifying to an eye accustomed to the light of the moon, or in general to familiar observations, to behold how Jupiter, at its immersion as well as emersion, being half or more than half covered by the moon, exhibited its belts and other parts as distinctly close to the limb of the moon as it does at some distance from it? and had I not already succeeded in numerous observations on the atmosphere of the moon, and very recently in those which enabled me to determine its twilight, I should perhaps have adopted the doubts the ancient astronomers entertained concerning the existence of a lunar atmosphere; and this the rather, as when Jupiter in its immersion was so far covered, that the luminous spot /, fig. 5., was close to the moon, I could plainly distinguish this spot, although it be in itself by no means very perceptible.

"Such, however, must have been the appearances, according to my new observations and measurements of the twilight of the moon; for if it be proved, that the extent of this twilight, to where it loses itself in the light reflected from the almost wholly illuminated disk of our earth, amounts to no more than an arc of 2° 34' of the circumference of the moon, and if it be hence demonstrable, that its greatest dilution does barely amount to 5° 8', and the perpendicular height of that part of the lower more condensed stratum of its atmosphere, which is capable of reflecting the solar rays, and of producing some other, perhaps more remarkable obclusions in the stars seen through it, does not exceed 5000 Paris feet, and hence cannot reach above one second of a degree above the limb of the moon: we need not wonder that so small a magnitude which loses itself in the inequalities of the limb, many parts of which are known to be considerably mountainous, should not become sensible, especially at the approach of a body of so large a diameter as Jupiter, and when so small a magnifying power is applied. And thus may I with confidence assert a perfect coincidence between this and my many other observations.

"The appearance, fig. 8., when Jupiter, at the emersion, the objects being particularly sharp and defined, came forth from behind the moon, which now covered no more than one-quarter of its diameter, was truly splendid and satisfactory: and I must here particularly mention the circumstance, that the part of the moon's dark hemisphere, between its bright terminating edge m n and its outer limb, bordering upon the emerging planet o p, was particularly opaque and hence produced a very striking effect.

"I omit entering here upon any further considerations; and shall conclude with observing, that, after the occultation was completely ended, the luminous spot had at 12h. 1' fo far advanced in its parallel d e as to have reached to within j, or at most y, of its whole length of the western limb; and that on the 28th of March, five days after a new moon; I observed an occultation of a very distinct, though telescopic, flare, by the dark hemisphere of the moon; in which, agreeably to the above observation, not the least gradual diminution of light or indistinctness could be perceived, the flare being seen to vanish on a sudden.

**Influence of the Moon on the human body, the weather, &c.** The vulgar doctrine concerning the influence of the moon on the changes of weather is very ancient, and has gained credit among the learned without sufficient examination; but it seems now to be pretty generally exploded by philosophers, as equally delusive of all foundation in physical theory, and unsupported by any plausible analogy. The common opinion is, that the lunar influence is exerted at the syzygies and quadratures, and for three days before and after each of these epochs. There are 24 days therefore, in each synodic month, over which the moon at this rate is supposed to predile; and as the whole conflicts but of 29 days 12 ½ hours only 55 days are exempt from her pretended dominion. Hence, though the changes of the weather should happen to have no connection whatever with the moon's aspects, and they should be distributed in an equal proportion through the whole synodic month, yet any one who shall predileat, that a change shall happen on some one of the 24 days aligned, rather than in any of the remaining 55, will always have the chances 24 to 55 in his favour. Men may, therefore, easily deceive themselves, especially in so unsettled a climate as ours. Moreover, the writers who treat of the signs of the weather, derive their prognostics from circumstances which neither argue any real influence of the moon as a cause, nor any belief of such an influence, but are merely indications of the state of the air at the time of observation: such are, the phase of the horns, the degree and colour of the light, and the number and quality of the luminous circles which sometimes surround the moon, and their circumstances attending the disappearance. (See the *Astronomy of Aratus* and the *Sphæra of Theon.* ) The vulgar soon began to consider these things as causes: which had been proposed to them only as signs: and the notion of the moon's influence on all terrestrial things was confirmed by her manifest effect upon the ocean. See, on this subject, Phil. Trans. vol. Ixv. part 2. p. 178. &c.

The famous Dr Mead was a believer in the influence of the sun and moon on the human body, and published a book to this purpose, intituled *De Horologiis Sihla in Lunae in Corpore Hominis*; but this opinion has been exploded by most philosophers as equally unreasonable in itself, and contrary to fact. As the most accurate and reliable barometer is not affected by the various positions of the moon, it is not thought likely that the human body should be affected by them. Several learned and ingenious men, however, still considered Dr Mead's doctrine as far from being unfounded.

**Herop. Moon.** It is remarkable, that the moon, during the week in which she is full in her harvest, rises, for...
Moon. 

The MooN-Cock, or Moon-Eye, in the manage. A horse is said to have moon-eyes when the weakness of his eyes increases or decreases according to the course of the moon; so that in the waxing of the moon his eyes are muddy and troubled, and at new moon they clear up; but still he is in danger of losing his eye-light quite.

Moonstone, a genus of siliceous earths, of a clear white colour: approaching to that of milk. When looked at in a certain position, it reflects a strong light like mother-of-pearl; in others, it shows spots of a carnation colour. It is found in pieces with obtuse angles, sometimes of a quadrangular figure. When broken, it appears evidently foliated. According to Werner it agrees in hardness and most other respects with feldspar. He tells us, likewise, that it is probably the andromal of Pline, the common giraffe of the Italians, and the excent by some time; he tells us it is clasped with the opal, and sometimes with the cat's eye. According to M. Magellan, this stone is of the chalcedony or pseudo-opal kind: it reflects a whitish light, with some various shades of few intermixed colours on a bluish bottom, like the face of the moon when high enough not to appear reddish by the interposition of earthy vapours. The iris, or rainbow-stone, seems to be no other than a moon-stone in which the yellow, purple, and blue rays are most conspicuously reflected. When looked at, it appears of a reddish brown; but on holding it in the light of the sun, we discover the figure of a rainbow. There are, however, several other stones which have the same appearance in the sun's light.

Moonwort in botany. See Lunaria.

MOOR (Sir Karel de), a capital painter of portraits, histories, and conversations, was born at Leyden, in 1656; and at first was a disciple of Gerard Douw, with whom he continued for a considerable time. He afterwards lodged successively under Abraham Vanden Tempel, Francis Meris, and Godfrey Schalcken. As soon as he began to follow his profession, the public in a short time did justice to his extraordinary merit; and he took the most effectual method to establish his reputation, by working with a much stronger desire to acquire fame than to increase his fortune. According to Mr. Pilkington, he painted portraits in a beautiful style, in some of them imitating the tate, the dignity, the force, and the delicacy of Vandyck; and in others, he shewed the fireking effect and spirit of Rembrandt. His pictures were always neatly and highly finished; he designed them excellently, and grouped the figures of his objects with great skill; his works were universally admired; and some of the most illustrious princes of Europe seemed solicitous to employ his pencil. The grand duke of Tuscany desired to have the portrait of De Moor, painted by himself, to be placed in the Florentine gallery; and on the receipt of it, that prince sent him in return a chain of gold and a large medal of the same metal. The imperial ambassador count Sinzendorf, by order of his master, engaged him to paint the portraits of Prince Eugene and the duke of Marlborough on horseback; and in that performance, the dignity and expression of the figures, and also the attitudes of the horses, appeared so masterly, that it was beheld with admiration, and occasioned many commendatory poems in elegant Latin verse to be published to the honour of the artist; and the emperor, on seeing that picture, created De Moor a knight of the holy Roman empire. He likewise had the honour to paint the portrait of Peter the great czar of Muscovy; and an extraordinary number of other portraits, for which he received very large prices.—His historical paintings were admirable; although he most frequently was employed to paint in a large size, yet he often painted small easel pictures, with subjects of history or conversations; and these are exceedingly valued, having all the merit of neat pencil and soft colouring added to an elegant taste of design. He died in 1738.

Moor, in country affairs, denotes an unlimited tract of land, usually over-run with heath.

Moor-Cock, or Mooy-cock, in agriculture, is a black, light, and sooty earth, very loofe, and without any admixture of stones; and with very little clay or sand.

The uppermost stratum of the fen-lands is usually of this earth, and it commonly constitutes a moderately thick or deep bed. Intermixed with water it cannot easily be worked up into a pafte: and when with labour worked up into somewhat of a firm mass, its surface appears spongy and porous; and as soon as dry, it easily moulders away to powder.

It is usefully soft to the touch, unless it be worked very closely between the fingers; then it throws a mixture of a small quantity of sand, both to the touch and to the eye. It seems indeed to confit almost entirely of pure vegetable matter; and this lying in such plenty on the surface of the fen-lands is the cause of their being so very fertile.

The great disadvantage of the places which have this soil, is their being liable to be glutted with water; and to remedy the inconveniences arising from thence, the farmers who rent these land have a custom of burning the soil at proper seasons. It burns very freely and easily, the surface readily catching flame: and a substance somewhat bituminous, usually contained among the soil, helps the burning.

MOURE, or Mores, (Edward), a late ingenious writer, was bred a linen-draper but quitted business to join the retinue of the muses: and he certainly had a very happy and pleasing talent for poetry, in his Trial of Selin the Periyan, he complimented lord Lyttleton in an elegant kind of panegyrick, couched under the appearance of accusation; and his Fables for the female sex, for easy verification, poigniant satire, and striking morals, approach nearer to the manner of Gay than any other of the numerous imitations of that author. He wrote, also three dramatic pieces? The Gamester, a tragedy; the Foundling, and Gil Blas, comedies. The success of these was not such as they merited; the first of them having met with a cold reception,
MOORING, for no other apparent reason but because it
too nearly touched a favourite and fashionable vice:
and the second having been condemned for its supposed
resemblance to Sir Richard Steele's Conciouat lovers,
but to which good judges have been inclined to give
it greatly the preference. Mr. Moore married a lady
of the name of Hamilton, daughter to Mr. Hamilton
table-decker to the princesses; who had herself a very
poetical turn, and has been paid to have assisted him
in the writing of his tragedy. One specimen of her
poetry, however, was handed about before their
marriage, and has since appeared in print in different
collections of songs, particularly in one called the Gold
finch. It was addressed to a daughter of the famous
Stephen Duck; and begins with the following stanzas:

Would you think it, my Duck? (for the fault
Your Jenny at last is quite covenanted grown.
The' millions if Fortune should lavishly pour,
I shall 'tis writ; if I had not more.

And after half a dozen stanzas more, in which, with
great ingenuity and delicacy, and yet in a
manner that expresses a sincere affection, she has quibbled
on our author's name, she concludes with the following lines:

You may wonder, my girl, who this dear one can be,
Whose merit can besti such a conquest as mine?
But you shant know his name, tho' I told you before,
It begins with the M, but I dare not say More.

In the year 1753, Mr. Moore commenced a weekly
miscellaneous paper intitled 'The World,' by Adam Fitz-
Adam; in which undertaking he was assisted by Lord
Chesterfield with some effays. This paper was collected
into volumes, and Mr. Moore died soon after.

MOORING, the act of confining and securing a
ship in a particular station, by chains or cables, which
are either fastened to the adjacent shore, or to anchors
in the bottom,

A ship may be either moored by the head, or by
the head and stern: that is to say, she may be secured
by anchors before her, without any behind; or she
may have anchors out, both before and behind her;
or her cables may be attached to posts, rings, or
moorings, which answer the same purpose.

When a ship is moored by the head with her own
anchors, they are disposed according to the circum-
stances of the place where she lies, and the time she is
to continue therein. Thus wherever a tide ebbs
and flows, it is usual to carry one anchor out towards
the flood, and another towards the ebb, particularly
where there is little room to range about; and the
anchors are laid in the same manner, if the vessel
is moored head and stern in the same place. The
situation of the anchors, in a road or bay, is usually
opposed to the reigning winds, or those which are most
dangerous; so that the ship rides therein with the
effort of both her cables. Thus if the ebb rides in a bay,
or road, which is exposed to a northerly wind and
heavy sea from the same quarter, the anchors plying
from the opposite bows ought to lie ebb and well from
each other; hence both the cables will retain the ship
in her station with equal effort against the action
of the wind and sea.

Moorings, in sea-language, are usually an assem-
bly of anchors, chains, and bridles, laid athwart
the bottom of a river or haven, to ride the shipping con-
tained therein. The anchors employed, on this occa-
sion have rarely more than one fluke, which is sunk
in the water near low-water mark. Two anchors
being fixed in this manner in the opposite side of
the river, are furnished with a chain extending across
from one to the other. In the middle of the chain is
a large square link, whose lower end terminates in a
twist, which turns round in the chain as about
an axis, whenever the ship veers about with the change
of the tide. To this twist link are attached the
bridles, which are short pieces of cable, well served,
whose upper ends are drawn into the ship at the
mooring-ports, and afterwards fastened to the masts
cable-bolts. A great number of moorings of this
kind are fixed in the harbours adjacent to the English
dock-yards, as Deptford, Chatham, Portsmouth,
Plymouth, &c.

MOORLANDS, a tract so called, in the north
part of Staffordshire, where the land rises gradually
into small hills, which run through the midst of Eng-
land in one continued ridge, rising higher and higher
to Scotland, and bounding many rivers. The soil
here is so foul and cold, that the know lies almost all
the year on the tops of the hills; and it is with very
rugged and barren: this, however, yields plenty of coal,
lead, copper, rance-marble, and mill-stones; and some
of the limestone hills bear such a sweet though short
grafs, as is very grateful to the oxen, of which there
is a very good breed. It is observed here, that the
wet wind always brings rain, and the eart and south
fair weather; that though this tract is full of bogs,
it is as healthy as any other part of the country; and
that it produces the same plants as the Peak of Derby.

MOORS. See Morocco.

Moors, in the Isle of Man, those who summon
the courts for the several headings; such as the lord's
bailiffs. Every Moor has the life office with the
English bailiff of the hundred.

MOOSE, or Elk. See Cervus.

MOOT, a difficult cafe, argued by the young bar-
rif ters and students at the inns of court, by way of
exercise, the better to qualify them for practice, and
to defend the causes of their clients. This, which is
called mootings, is the chief exercise of the inns of
court. Particular times are appointed for the arguing
moot-cafes: the place where this exercise is performed
was anciently called moot-hall; and there is a bailiff,
or surveyor of the moots, annually chosen by the
bench, to appoint the moot-men for the inns of cham-
cery, and to keep an account of the performance of
exercises. The word is formed either from the Saxon
mootan, gemootan, "meeting," or from the French me-
"word."

MOPSUS (fab. hist.), a celebrated prophet, son of
Manto and Apollo during the Trojan war. He was
confounded by Amphimachus, king of Colophon, who
wished to know what successes would attend his arms
in a war which he was going to undertake. He pre-
dicted the greatest calamities; but Calchas, who had
been a foothatter of the Greeks during the Trojan
war, promised the greatest felucca. Amphimachus
followed the opinion of Calchas; but the prediction
of Mopsus was fully verified. This had such an effect
upon Calchas, that he died soon after. His death
MORAI, in botany: A genus of the monogynia order, belonging to the triandria class of plants; and in the natural method ranking under the 6th order, Enfata. The corolla is hexapetalous; the three interior petals patent, the reft like those of the iris.

MORAI, is the name given at Otaheite in the South Sea to their burying-grounds, which are also places of worship. This is a pile of stone raised pyramidal upon an oblong base or square 267 feet long and 97 wide. On each side is a flight of steps; those at the sides being broader than those at the ends; so that it terminated not in a square of the same figure with the base, but in a ridge like the roof of a house. There were 11 of these steps to one of these morais, each of which was 4 feet high, so that the height of the pile was 44 feet; each step was formed of one course of white coral stone, which was neatly squared and polished; the rest of the mafs (for there was no hollow within) consisted of round pebbles, which from the regularity of their figure seemed to have been wrought. The foundation was of rock-stones, which were also squared. In the middle of the top flood an image of a bird carved in wood, and near it lay the broken one of a fifth carved in stone. The whole of this pyramid made part of one side of a spacious area or square 360 feet by 324, which was walled in with stone, and paved with flat stones in its whole extent. About 100 yards to the west of this building was another paved area or court, in which were several small mafs raised on wooden pillars about 7 feet high, which are called by the Indians ewattas, and seem to be a kind of altars, as upon these are placed provisions of all kinds, as offerings to their gods. On some of them are seen whole hogos, and on others the skulls of above 90, besides the skulls of many dogs. The principal object of ambition among the natives is to have a magnificent morai. The male deities (for they have them of both sexes) are worshipped by the men, and the female by the women; and each have morais, to which the other sex is not admitted, though they have also morais common to both.

MORAL PHILosophY, OR MORAls.

Moral Philosophy is, "The science of manners of duty; which it traces from man's nature and condition, and flows to terminate in his happiness." In other words, it is "The knowledge of our duty and felicity;" or, "The art of being virtuous and happy.

It is denominated an art, as it contains a system of rules for becoming virtuous and happy. whoever practises these rules, attains an habitual power or faculty of becoming virtuous and happy. It is likewise called a science, as it deduces these rules from the principles and connections of our nature, and proves that the observance of them is productive of our happiness.

It is an art, and a science, of the highest dignity, importance, and use. Its object is man's duty, or his conduct in the several moral capacities and connections which he sustains. Its office is to direct that conduct; to show whence our obligations arise, and where they terminate. Its use, or end, is the attainment of happiness; and the means it employs are rules for the right conduct of our moral powers.

Moral Philosophy has this in common with Natural Philosophy, that it appeals to nature or fact; depends on observation; and builds its reasonings on plain uncontroverted experiments, or upon the fullest induction of particulars of which the subject will admit. We must observe, in both these sciences, how nature is affected, and what her conduct is in such and such circumstances: or, in other words, we must trace the appearances of nature in any given instance; trace these to some general principles or laws of operation; and then apply these principles or laws to the explaining of other phenomena.

Therefore Moral Philosophy inquires, not how man might have been, but how he is, constituted: not into what principles or dispositions his actions may be artfully resolved, but from what principles and dispositions they actually flow: not what he may, by education, habit, or foreign influence, be made to be or do; but what, by his nature, or original constituent principles, he is formed to be and do. We discover the office, use, or destination of any work, whether natural or artificial, by observing its structure, the parts of which it consists, their connection or joint action. It is thus we understand the office and use of a watch, a plant, an eye, or hand. It is the same with a living creature of the rational or brute kind. Therefore, to determine the office, duty, or destination of man; or, in other words, what his business is, or what conduct he
History.

MORAL PHILOSOPHY.

He is obliged to pursue; we must inspect his constitution, take every part to pieces, examine their mutual relations one to the other, and the common effort or tendency of the whole.

It has not been thus, however, that the science has always been taught. The earliest moralists did not erect systems upon a just analysis of the powers of the human mind; nor have all those who thought such a foundation necessary to be laid, deduced their theories from the very same principles. As moral truths are not capable of rigid demonstration, it appears to us, that we cannot more properly introduce the system which we have adopted, than by giving our readers a short view of the most celebrated systems that have been maintained by others. They will thus have an opportunity of judging for themselves of the different theories, and of adopting that which shall appear to them to place practical virtue on the firmerst basis.

WHILE there has been a remarkable agreement among the writers on morality, as to the particular actions which are virtuous and those which are vicious; and whilst they have uniformly taught, that it is our duty and our interest to perform the one and to avoid the other; they have yet differed exceedingly concerning the principle or motive by which men are induced to purport it. One cause of this difference in opinion respecting matters of such universal importance, may perhaps be traced to the mistakes into which philosophers are apt to fall concerning the original state of man.

It is very generally taken for granted, that the first men were savages of the lowest rank, and that the race gradually civilized itself during the course of many succeeding ages. Without mutual intercourse, the progress of civilization could never have commenced; and as the practice of justice is absolutely necessary to every species of friendly intercourse, those original savages, it is supposed, must have been just in their dealings, and just upon some principle which has its foundation in human nature. But to develop the principle by which savages are influenced in their conduct, no tedious or intricate process of reasoning can be necessary. It must have a place in every mind, and be instinctive in all its decisions. Hence it has been supposed, that the principle to which modern philosophers have given the name of the moral sense is instinctive; that it is the sole judge of virtue and vice; and that its admonitions have such authority, as to enforce obedience without regard to the consequences of any action.

Other philosophers, who deny that the moral sense is instinctive, and who yet suppose that the original state of man was savage, are forced to pile hypothesis upon hypothesis, each unnatural in itself, and all contradictory to one another, in order to account for the commencement of civilization and the formation of society. It has been supposed, that the desire of self-preservation and the love of power are the governing principles in human nature; that in the savage state every man had a right to every thing which he could seize by fraud or force; that all had an innate propensity to invade each other’s property; and that hence war, rapine, and bloodshed prevailed universally, till the savages discovered the expediency of uniting under some form of government for their mutual protection.

But before the original state of man had been made the basis of such opposite theories as these, it would surely have been proper to inquire upon what grounds that state has been supposed to be savage. To us these grounds appear to be nothing better than mere speculations; the dreams of poets, and the fables of the philosophers as bend systems to their own systems. In the authentic history of our species, there is no evidence, indeed there can be no evidence, that the first men were savages; and every thing which we know of human nature leads us to believe, that had they been so, the race could never have been civilized but by the miraculous interpolation of some superior being. The only record of the earliest ages of the world to which the smallest credit is due, represents all the nations of the earth as having sprung from one pair, and that pair as having been instructed in their duty by their beneficent Creator. If this be the fact, and no sufficient theist can controvert it, the precepts of morality would be originally conveyed from one generation to another; not in a systematical or scientific form, but as the laws of the Universal Sovereign, whose authority is demanded implicit obedience. Accordingly we find, that the first teachers of morals were men of superior rank as well as of eminent talents, who formed collections of maxims derived from their ancestors, with the view of perfecting subordination, punishing manners, and educating youth. Such were the proverbs of Solomon, the words of Agur, and the wisdom of the son of Sirach. These instructors did not analyze the human mind into its various faculties, and build a system of morals either upon a particular instinct pointing to the supreme good, or upon the fitness of things discovered by reason. Short isolated sentences were the mode in which they conveyed their precepts; which they prefaced by observing, that “the fear of the Lord is the beginning of knowledge”; and enforced by the assurance, that “length of days, and long life, and peace, should they add to those who obeyed them.”

The sayings of the celebrated wise men of Greece were collections of apophthegms, made in the same manner and delivered with similar views. Thales and Pythagoras, who founded the one the Ionic and the other the Italic school, made collections of precepts for the conduct, as well as of a state as of a private life. Neither the crimes nor the thoughts of bad men (said Thales) are concealed from the gods. The only method of being just is to avoid doing that which we blame in others.” Of Pythagoras it is related by Porphyry and Laertius, that from Samos he repaired to Delos, and after presenting an offering of cakes to Apollo, there received, or pretended to receive, moral dogmas from the priestess; which he afterwards delivered to his disciples under the character of divine precepts. Amongst these were the following: That, “next to gods and demons, the highest reverence is due to parents and legislators; and that the laws and customs of our country are to be religiously observed.”

To these maxims or apophthegms, which, for the sake of delighting the ear and aiding the memory, were
were delivered in verse, succeded, as has been supposed, the mode of instruction by fable or allegory. But the truth seems to be, that this method, of communicating moral and political wisdom was as ancient as the other; for we have a beautiful specimen of it in the ninth chapter of the book which relates the transations of the judges of Israel. The tales of Efop, too, which were written at a very early period, remain lasting models of this species of art among the Greeks.

When the instructors of mankind had proceeded thus far as to give an artificial form to their precepts, they soon advanced a step farther, and reduced their observations into classes or predicaments. Pythagoras, who visited Egypt, has been supposed to have learned from its priests the method of arranging the virtues into distinct classes. But it is the opinion of an excellent writer, founded on the previous aspects of ethics, and on the comprehensive talents of the Samian philosopher, that the honour of the invention ought to be ascribed to himself. Be this as it may, it was observed by the inventor, that "all the maxims of morality might be referred to the duties which men owe to themselves, and the duties which they owe to each other." Hence the four cardinal virtues of the ancients, prudence, temperance, fortitude, and justice; of which the first three refer to the individual, and the fourth to society.

Hitherto lessons in morality had not taken a systematic form; but they were gradually approaching to it. Socrates was perhaps the first Pagan philosopher who established all his precepts on one sure and steady basis. In his lectures and discourses, he seems to have had one great object in view, to connect the moral maxims which were fitted to regulate the conduct of mankind, with sublime conceptions respecting the character and government of a supreme Being. The first principles of virtuous conduct which are common to all mankind, are, according to this excellent moralist, laws of God: and the conclusive argument by which he supports this opinion is, that no man departs from these principles with impunity. "It is frequently possible (says he) for men to screen themselves from the penalty of human laws, but no man can be unjust or ungrateful without suffering for his crime; hence I conclude, that these laws must have proceeded from a more excellent legislator than man." From this it would appear, that in the opinion of Socrates, confidence, or the moral sense, approving of any action, is the criterion by which it is known to be virtuous, and the will of God, that which obliges men to perform it.

Socrates himself left no writings behind him, nor, as far as we know, offered any regular and complete theory of ethics. His disciples, however, who were numerous and distinguished, became the founders of the celebrated Greek sects. Among them the first great question was, "what are the foundations of virtue?" and the second, "what are the distinctions between good and evil, happiness and misery?" The answers given to these important questions divided the philosophers and their disciples into distinct orders.

In answer to the former question, Plato taught, that "virtue is to be pursued for its own sake; and that being a divine attainment, it cannot be taught, but is the gift of God." This seems to differ in nothing but the name from the doctrine of those moderns who place the sole foundation of virtue in the approbation of the moral sense. The founder of the academy indeed has no such phrase as moral sense in any of his writings with which we are acquainted; but if virtue cannot be taught, and if it is to be pursued for its own sake, it must in itself be good, and the object of some feeling, whether called sense, infinite, or passion. His solution of the second question agitated among the sects is not indeed very consistent with this necessary inference from his answer to the first; but for his inconsistency, we may, "Our highest good (he says) consists in the contemplation and knowledge of the first good, which is mind or God; and all those things which are called good by men, are in reality such as far as they are derived from the first and highest good. The only power in human nature which can acquire a resemblance to the supreme good, is reason; and this resemblance consists in prudence, justice, fidelity, and temperance."

Aristotle, the founder of the Peripatetic school, was of the pupil of Plato; but of the two great moral philosophers he gives solutions somewhat different from those of his master. "Virtue (according to him) is either theoretical or practical. Theoretical virtue consists in the due exercise of the understanding; practical, in the pursuit of what is right and good. Practical virtue is acquired by habit and exercise."

This theory seems to differ little from that adopted by Cudworth, Clarke, and Price, which shall be considered afterwards. With respect to man or goods, the doctrine of Aristotle is very rational. "Pleasures (he says) are essentially different in kind. Disgraceful pleasures are wholly unworthy of the name. The purest and noblest pleasure is that which a good man derives from virtuous actions. Happiness, which consists in a conduct conformable to virtue, is either contemplative or active. Contemplative happiness, which consists in the pursuit of wisdom, is superior to active happiness, because the understanding is the higher part of human nature, and the objects on which it is employed are of the noblest kind. The happiness which arises from external possessions is inferior to that which arises from virtuous actions; but both are necessary to produce perfect felicity."

The Stoics, another celebrated sect of Greek philosophers, maintained, that "nature impels every individual to pursue whatever appears to him to be good."

According to them, "self-preservation and defence are the first law of animated nature. All animals necessarily derive pleasure from those things which are fitted to them; but the first object of pursuit is not pleasure, but conformity to nature. Every one, therefore, who has a right discernment of what is good, will be chiefly concerned to conform to nature in all his actions and pursuits. This is the origin of moral obligation."

With respect to happiness or good, the Stoical doctrine was altogether extravagant: They taught, that "all external things are indifferent, and cannot affect the happiness of man; that pain, which does not belong to the mind, is no evil; and that a
wife man will be happy in the midst of torture, because virtue itself is happiness (b).

As the Stoics held that there is but one substance, partly active and partly passive, in the universe (see *Metaphysics*, *N. 261, 262*), and as they called the active principle *God*, their doctrine, which makes virtue consist in a conformity to nature, bears no small resemblance to that of those moderns who rest moral obligation on the Divine will. It was therefore on better grounds than has been sometimes supposed, that Warburton, when characterizing the founders of the three principal sects in Greece, represented *Plato* as the patron of the moral sects; *Aristotle*, of the essential differences; and *Zeno*, of arbitrary will. These principles, when separated from each other, and treated in the manner of the ancients, may not each be able to bear the superstructure which was raised upon it; but the principles of most of the other sects were much less pure, and infinitely more dangerous.

Cudworth, whose testimony when relating the doctrines of antiquity is entitled to the fullest credit, affirms, that Aristippus, the founder of the Cyanean school, Democritus, and Protagoras, with their followers among the atomists, taught, that "the distinction between virtue and vice is merely arbitrary; that nothing is just or unjust, sacred or profane, but as it is agreeable or contrary to established laws and customs; that what is just to day, human authority may make unjust to morrow; and that present pleasure is the sovereign good of man."

With these impieties, the moral doctrines of Epicurus have very unjustly been confounded. The physical and metaphysical systems of that philosopher are indeed strange compositions of ingenuity and absurdity, truth and falsehood; and the moral precepts of many of his followers were in the highest degree licentious and impure. But his own life was exemplary; and his ethical system, if candidly interpreted, is much more rational than that of the Stoics; though it must be confessed, that no sect produced men of more determined virtue than the school of Zeno.—According to Epicurus, "the end of living, or the ultimate good which is to be sought for its own sake, is happiness. The happiest life which belongs to man, is that state in which he enjoys as many of the good things, and suffers as few of the evils incident to human nature as possible; passing his days in a smooth course of tranquility. Pleasure is, in its own nature good, as pain is in its nature evil. The one is therefore to be pursued, and the other to be avoided, for its own sake. Pleasure and pain are not only good and evil in themselves, but they are the measure of what is good or evil in every object of desire and aversion; for the ultimate reason why we pursue one thing and avoid another is, because we expect pleasure from the former, and apprehend pain from the latter. That pleasure, however, which prevents the enjoyment of a greater pleasure, or produces a greater pain, is to be shunned; and that pain, which either removes a greater pain, or procures a greater pleasure, is to be endured."

Upon these self-evident maxims, Epicurus builds his system of ethics, and proves, with great force of argument, "that a steady course of virtue produces the greatest quantity of happiness, of which human nature is capable." Without a prud' homme of the body, and a steady government of the mind to guard the one from deceit and the other from the clouds of prejudice, happiness is unattainable. By temperance we enjoy pleasure, without suffering any consequent inconvenience. *Sobriety* enables us to content ourselves with simple and frugal fare. *Gentleness*, as opposed to an irritable temper, greatly contributes to the tranquillity and happiness of life, by preserving the mind from perturbation, and arming it against the assaults of calumny and malice. *Fortitude* enables us to bear those pains which prudence cannot shun, and banishes fear from the mind; and the practice of *justice* is absolutely necessary to the existence of society, and by consequence to the happiness of every individual. These reasonings come home to every man's bosom; and had not this philosopher, by denying the providence, if not the being, of God, most unhappily excluded from his system the very possibility of a future state of retribution, his moral philosophy would have been the most practical, and of course the most useful, of any that was taught in the schools of Greece. This enormous defect, however, laid it open to the grossest corruptions; and by his followers it was in fact corrupted so as to countenance the most impure and criminal pleasures of fene.

These several systems of ethics continued to be cultivated with more or less purity through all the revolutions of the Grecian states, and they were adopted by the Romans after Greece itself became a province of the empire. They had been introduced into Egypt during the reigns of the Ptolemies, and were taught with much celebrity in the schools of Alexandria. The philosophy which was most cultivated in those schools was that of Plato, but from a desire of uniformity which took possession of the Alexandrian Platonists, many of the dogmas of Aristotle and Zeno, as well as the extravagant fictions of the calf, were incorporated with the principles of the old academy. The patrons of this heterogeneous mass have been called *eclectic* philosophers, because they professed to select from each system those doctrines which were rational and important, and to reject every thing which was false or futile; but they added nothing to the purity of Plato's ethics, and they increased the obscurity and mysticisms of his physics and metaphysics.

After the subversion of the Roman empire, every species of philosophy, if syllogistic wrangling deserve not that name, was banished for ages from the schools of Europe; and ethics, properly so called, gave place to ecclesiastical avarice, and to the study of the civil and canon law. When the Greeks, whom the fury and fanaticism of Mahomet II. had driven from Constantinople, introduced into Italy the knowledge of their own language, the cabinets of ancient philosophy were again unlocked; the systems of the different sects were adopted with the utmost avidity; and, without

---

(a) Since this short history was written, a very pleasing view of Stoicism has been given to the public in Ferguson's *Principles of moral and political Science*; a work which the student of ethics will do well to consult. Perhaps the amiable author may unintentionally have softened the austerities of the Porch, by transmuting into them something of the mild spirit of the gospel; but if so, he has much improved the system of Zeno,
MORAL PHILOSOPHY.

Accurate investigation of their respective merits, men became Platonists, Peripatetics, or Stoics, as fancy or caprice prompted them to choose their leaders. The avers of Aristotle in particular, had not left authority over his modern admirers than it had of old in the Lyceum at Athens. At length the spirit of Luther and the genius of Bacon broke their fetters, and taught men to think: for themselves as well as science as in religion. In physics, the effects produced by the writings of Bacon were great and rapid: for in physics the ancient theories were totally and radically wrong.—With respect to morals, however, the case was different. Each of the celebrated schools of antiquity was in possession of much moral truth, blended indeed with error: and long after the Stagirite and his rivals had lost all influence in physical science, philosophers of eminence followed them implicitly in the science of ethics.

At this day, indeed, there is hardly a theory of morals at all distinguished, to which something very familiar may not be found in the writings of the ancients.—Hobbes adopted the principles of Democritus and Protagoras, and taught expressly that there is no criterion of justice or injustice, good or evil, besides the laws of each state; and that it is absurd to inquire at any peril except the established interpreters of the law, whether an action be right or wrong, good or evil (a). These impious absurdities have been often confuted. Cudworth, who composed his True Intellectual System of the Universe in order to trace the metaphysical atheism of Hobbes to its source, and to expose it to the public in all its weakness, undertook likewise to overthrow his ethical system, intitled Of Eternal and Immutable Morality. That work was left unfinished: but the theory of its great author was adopted, illustrated, and very ably supported, by the Doctors Clarke and Price.

According to these three admirable scholars, "we feel ourselves irrefistibly determined to approve some actions, and to disapprove others. Some actions we cannot but conceive of as right, and others as wrong; and of all actions we are led to form some idea, as either fit to be performed, or unfit, or as neither fit nor unfit to be performed, i.e. as indifferent. The power within us which thus perceive and determines, they declare to be the understanding; and they add, that it perceives or determines immediately or by intuition, because right and wrong denote simple ideas. As there are some propositions, which when attended to necessarily determine all minds to believe them, so are there some actions whose natures are such, that when observed all rational beings immediately and necessarily approve them. He that can impartially attend, it is said, to the nature of his own perceptions, and determine that when he conceives gratitude or beneficence to be right, he perceives nothing true of them, or understands nothing, but only suffers from a sense, has a turn of mind which appears unaccountable: for the more we examine, the more indisputable it will appear to us, that we express necessary truth, when we say of some actions that they are right, and of others that they are wrong." It is added, that "we cannot perceive an action to be right without approving it, or approve it without being conscious of some degree of satisfaction and complacency; that we cannot perceive an action to be wrong without disapproving it, or disapprove it without being displeased with it; and that the just must be liked, the unjust disliked, the just loved, the unjust hated." By the patrons of this system, obligations to action and rightness of action, are held to be coincident or identical. "Virtue, they affirm, has a real, full, obligatory power, antecedently to all laws, and independently of all will; for obligation is involved in the very nature of it. To affirm that the performance of that which to omit would be wrong is not obligatory, unless conducive to private good, or enjoined by a superior power, is a manifest contradiction."* Few men have deferred better of letters and philosophy than Cudworth, Clarke, and Price; and yet their theory of morals appears to us to be contradictory and unintelligible. It is certainly romantic, and founded upon principles which, if they be denied, no man by argument can be compelled to grant. There is, say they, an absolute right and wrong, fitness and unfitness, in actions; but if so, the actions which are right and fit must be right and fit for something, because fitness, which respects no end, is wholly inconceivable. To say that any particular action is fit, and yet fit for no particular purpose, is just as absurd as to say that the angles at the base of an isosceles triangle are equal, but neither to one another, nor to any other angles: and we may with no less propriety talk of the relation of equality attaching to a particular angle, and to nothing else with which the angle is equal, than of the absolute fitness or rightness of any action or course of actions. If it be said that such actions are fit and right, because they tend to promote the harmony of the world and the happiness of men, this may be granted; but it overturns the intellectual theory from its very foundation. Actions which are fit and right only for their consequences, are approved and liked for the sake of those consequences; and the happiness of men, among whom the virtuous person himself is to be included, is the motive or ultimate obligation to their performance.

Similar to this theory, and liable to the same objections is that which resolves moral approbation into a sense of propriety; for if actions be approved because they are proper, it must be because they are proper for some end or purpose, propriety in the abstract being a word without meaning.

Many philosophers, feeling the force of these and of similar objections to the intellectual theory of Cudworth, Clarke, and Price, as well as to a sense of propriety in the abstract, have had recourse to another hypothesis apparently better founded. Observing that all mankind decide on the morality of characters and actions instantaneously, without weighing their consequences in the balance of reason, they suppose that such decisions are made by an infinitesimal common nature, implanted in the human breast by the hand that formed it. To this infinitesimal of them give the

(a) Doctrinas de jure et injurio, bono et malo, preter leges in unaquaque civitate institutias, authenticas esse nullas: et utrum aliqua action justa vel injuriosa, bona vel mala futura sit, a nemine inquirendum esse, prae terquam ab illis, quibus legum fuerunt interpretationem civitas demandaverit. De civ. 2. P. 343.
MORAL PHILOSOPHY.

Of Mr Hume.

the name of confidence, and others that of moral sense, in contradiction to external sense, the other great and universal inlet of human knowledge. By this moral sense we intuitively discover an essential difference in the quality of all thoughts and actions, and a general distinction of them into good and evil, just as the tongue and palate discover an essential difference in the tastes of all objects, and a general distinction of them into pleasant and unpleasant. The ablest advocates for this intuitive system agree, that the moral sense is the immediate and involuntary criterion of only a few general truths, which, in their joint operation upon the mind, lay the foundation of all morals. Others have carried it to what we think a very dangerous extreme; as, by affirming that we cannot prove, in regard to our moral feelings, that they are conformable to any extrinsic and external relations of things, they seem to wish that reason were the immediate and involuntary criterion of only a few general truths, which, in their joint operation upon the mind, lay the foundation of all morals. Were this true, it would in many cases be impossible to distinguish the prejudices of early education from the pure dictate of original instinct, and the most pernicious conduct might be justified with the approbation of what would be deemed the ultimate test of virtue and vice.

To remedy the defects of the intellectual and intuitive theories of morality, Mr Hume blended them together; and, upon the broader basis of reason and internal sense co-operating with each other, he reared a system which, though different from those of all his predecessors, he rendered plausible, and supported with his usual ingenuity.

According to him, sentiment and reason concur in almost all moral determinations; and he proves, that for this purpose "there is implanted in the human breast a disinterested principle of benevolence or sympathy which makes men take pleasure in the happiness of others.

The merit or demerit of actions consists wholly in their utility or natural tendency to add to the sum of human happiness; and the same he holds to be true of qualities whether bodily or mental. This utility or natural tendency is the office of reason to discover; for that faculty alone can trace relations and consequences. Such qualities or actions as reason discovers to be useful, either to the individual or to society, the instinctive principle of benevolence makes us instantly approve, and this approbation constitutes their morality. Thus, temperance, fortitude, courage, and industry, &c. reason discovers to be useful to him who possesses them; and upon this discovery they are approved of the sentiment of sympathy. They are therefore moral qualities, and the sources of the private virtues. In like manner, generosity, cheerfulness of temper, mercy and justice, are discovered to be useful to society; and are accompanied with the approbation of that sentiment of sympathy which makes every man feel a satisfaction in the felicity of all other men. They therefore constitute the social virtues. Of every quality and every action, the merit or demerit, and of consequence the degree of approbation or disapprobation which is bestowed upon it, is in exact proportion to its utility and the circumstances of the case in which it occurs. The social virtues are therefore greater than those which are private, and one social virtue is greater than another; but every quality and every action which is useful, either to society or to the individual, is more or less virtuous, provided the good of the individual be considered as subordinate to the good of the public."

This theory is ingenious: and in placing the merit of actions in their utility, it furnishes a criterion of virtue which can be employed by reason; but it seems not to be wholly free from error, and it is obviously defective. By pretending that the same sentiment of approbation is given to useful actions voluntarily performed, and to useful qualities which are merely constitutional, Mr Hume confounds the merit of virtuous habits with the value of natural talents. Yet every man's confitutions will surely tell him, that the feeling or sentiment which attaches to deeds of justice, clemency, and beneficence, is very different from that which attaches to beauty of form, strength of body, vigour of mind, and mere extent of capacity. All these actions and qualities are useful; but when we approve of the former, besides attending to their utility, we consider them as in the man's power, and attribute the merit of them immediately to himself. When we approve, or rather admire, the latter on account of their utility, we know them to be not in the man's power, and we attribute the merit of them immediately to the Author of nature.

But the defects of this theory are in practice more pernicious than its errors. The author well observes that the end of all moral speculations is to teach us our duty; and, by proper representations of the deformity of vice and beauty of virtue, to beget correspondent habits, and engage us to avoid the one and embrace the other; but the theory under review holds out no motive sufficient in all cases for this purpose.

It is indeed true, as Mr Hume affirms, that the virtues which are immediately useful or agreeable to the person possessed of them, are desirable in a view to self-interest, and that a regard to self-interest ought to engage us in their pursuit. It is likewise true, that the virtues which are useful and agreeable to others, are generally more desirable than the contrary qualities: for as by the constitution of our nature no enjoyment is sincere without some reference to company and society; so no society can be agreeable, or even tolerable, where a man feels his presence unwelcome, and discovers all around him symptoms of disgust and aversion. These considerations he deems sufficient to enforce the duties of humanity, clemency and beneficence; but he states a case himself, in which they would certainly fail to make a man abtain from his neighbour's property. The greater part of property he considers, and rightly considers, as having its foundation in human laws, which are so calculated as to preserve the peace and promote the general good of the society, at the unavoidable expense sometimes of the individual. Now, in particular incidents, a sensible knave, by secretly purloining from the hoards of a worthless miser, might make himself comfortable and independent for life, without causing any breach in the social union, and even without hurting a single individual. What then should hinder him from acting thus? His self-interest would be promoted; and if he possessed a generous spirit, he might gratify his sentiment of benevolence or sympathy by doing good with his money to the poor, which the miser never did. For enforcing the uniform practice of justice in such cases as this, Mr Hume's theory of morals contains no adequate motive; but a very sufficient
MORAL PHILOSOPHY.

A system of ethics, built upon religion, is said to be 'the doing good to mankind, in obedience to the will of God, and for the sake of everlasting happiness.' So that with them 'the good of mankind' is the subject, 'the will of God' the criterion or rule, and 'everlasting happiness' the motive, of human virtue. The moral sense, supposing it real, they consider as a very inadequate rule of conduct, as being in many cases difficult to be distinguished from prejudice; and many of them confidently deny its existence. The other rules, such as the fins of things, abstract right, the truth of things, the law of reason, &c. are considered either as unintelligible, or as relative to some end by which the rules must themselves be tried. The two great questions, which in the system of these religious philosophers demand solution, are: 1/β, By what means shall a man in every case discover precisely what is the will of God? and, 2/β, what evidence have we that there will be a future state of retribution and of everlasting happiness!

Of these two questions, the latter belongs wholly to religion; and to solve it they call in the aid of revelation, as well as that of which is called the religion of nature. The former question is in the province of morality: and to find answers to it which shall apply to every case, is the whole business of their system.

The will of God respecting human conduct may be discovered by reasoning a priori from his existence and attributes, or a posteriori from the tendency of his works. Being himself independent and all-perfect, it is inconceivable that his view in creating the world could be any other than to communicate some portion of his own felicity. (See METAPHYSICS, n° 312.) This conclusion is agreeable to what we perceive of his works, in which there are a thousand contrivances, all tending to give happiness to man, and to all animated nature; and not one of which the natural tendency is to inflict pain, or prove ultimately injurious. Mankind are linked together by various ties, and made to depend in a great measure upon each other's conduct. That conduct, therefore, which is naturally productive of the greatest sum of human happiness, must be agreeable to the will of God; or, in other words, virtuous conduct. That, of which the natural tendency is to the reverse, must be vicious; and that conduct, if there be any such, which tends to produce neither happiness nor misery, must be indifferent, i.e. neither morally good nor morally evil. It is to be observed, however, that as, previous to their own obedience or disobedience, all men stand in the same relation to their Creator, it must be his will that an equal portion of the happiness of which human nature is capable be communicated to all by whom that nature is shared. Whence it follows, that only such conduct as, if universally purged by all men in the same fixation and circumstances, would be productive of the greatest sum of human happiness, on the whole, can be agreeable to the will of the Creator; and that, in judging of the morality of actions, we are not to regard their immediate consequences in any particular case, but their natural and ultimate tendency if performed in all cases.

This is a criterion of virtue which differs widely from the local or occasional utility set up by Mr. Hume; for the particular consequences of an action and its general tendency may often be at variance, so that what might in certain circumstances be immediately useful, would yet be highly criminal and ultimately pernicious. The general tendency of actions, too, may be always known, and known with the utmost certainty; the whole of their particular consequences can never be discovered. One thing, however, is evident, that if all men in their respective stations would regulate their conduct by the natural tendency of action, the particular and general consequences of their conduct would be the same, and the greatest happiness would result from it of which human nature is in this world capable. And therefore, since it is only through the perverseness of some persons or persons concerned, that the particular consequences of any action, of which the natural tendency is to produce misery, can ever bring happiness to a single individual; it can no more be the will of God that we make these occasional and distorted consequences the rule of our conduct, than it can be his will that the vices of other men should be the basis of our virtues. According to this scheme of morals, which reëst all obligation on private happiness, the whole difference between an act of prudence and an act of duty, is this: That in the former case we consider only what we shall gain or lose in this world; in the latter, what we shall gain or lose in the world to come.

Although the patrons of this theory question the reality of the moral sense as an infallible, they allow that a sentiment of approbation or disapprobation of actions, according as they are virtuous or vicious, is generated by the associating principle (see INSTINCT, and METAPHYSICS, n° 97.); and that this sentiment, though fallacious, operates instantaneously as if it were infallive. They infilt that our earliest actions are the result of imitation; that when we first begin to trace consequences, education and the desire of immediate enjoyment are our only guides; that as our mind expands and our knowledge increases, the hopes and fears of futurity become the motives, and the will of God the rule of our conduct; and that long practice in virtue, upon these principles, produces habits by which we go on with satisfaction in the same course, without looking forward, on every particular occasion, to the ultimate consequences and first motives of our actions. Thus do habits of justice, benevolence, clemency, and moral approbation, spring, through a proper course of discipline, out of the selfish principle; and when these habits are completely formed and deeply rooted, man has attained the utmost perfection of which he is capable in this state of probation, and is fitted for another of retribution and happiness.

That these philosophers have not a just view of the defects and man nature, when they deny that there is any innate excellency principal of benevolence in man, we shall endeavour to show.
MORAL PHILOSOPHY.

CHAP. I. Of Man and his Connections.

MAN is born a weak, helpless, delicate creature, unprovided with food, clothing, and whatever else is necessary for subistence or defence. And yet, exposed as the infant is to numberless wants and dangers, he is utterly incapable of supplying the former, or securing himself against the latter. But, though thus feeble and exposed, he finds immediate and sure resources in the affection and care of his parents, who refuse no labours, and forego no dangers, to nurse and rear up the tender babe. By these powerful instincts, as by some mighty chain, does nature link the parent to the child, and form the strongest moral connection on his part, before the child has the least apprehension of it. Hunger and thirst, with all the sensations that accompany or are connected with them, explain themselves by a language strongly expressive, and irresistible moving. As the several senses bring in percepts and informations of surrounding objects, we may perceive in the young spectator early signs of a growing wonder and admiration. Bright objects and striking sounds are beheld and heard with a fort of commotion and surprise. But, without relating on any, he eagerly pafes on from object to object, still pleased with whatever is most new. Thus the love of novelty is formed, and the passion of wonder kept awake. By degrees he becomes acquainted with the most familiar objects, his parents, his brethren, and those of the family who are most conversant with him. He contracts a fondness for them, is uneasy when they are gone, and charmed to see them again. These feelings become the foundation of a moral attachment on his side; and by this reciprocal sympathy he forms the domestic alliance with his parents, brethren, and other members of the family. Hence he becomes interested in their concerns; and feels joy or grief, hope or fear, on their account, as well as his own. As his affections now point beyond himself to others, he is denominated a good or ill creature, as he stands well or ill affected to them. These, then, are the first links of the moral chain; the early rudiments, or outlines, of his character; his first rude efforts towards agency, freedom, manhood.

When he begins to make excursions from the nursery, and extends his acquaintance abroad, he forms his child a little circle of companions; engages with them in play, or in quest of adventures; and leads, or is led by them, as his genius is more or less aspiring. Though this is properly the season in which appetite and passion have the ascendancy, yet his imagination and intellectual powers open space; and as the various images of things pass before the mental eye, he forms a variety of tales; relishes some things, and dislikes others, as his parents, companions, and a thousand other circumstances, lead him to combine agreeable or disagreeable fets of ideas, or reprefent to him objects in alluring or odious lights.

As his views are enlarged, his active and social powers expand themselves in proportion; the love of action, of imitation, and of praise, emulation, curiosity, docility, a passion for command, and fondness of change. His passions are quick, variable, and plant to every impression; his attachments and disgusts quickly succeed each other. He compares things, distinguishes actions, judges of characters, and loves or hates them, as they appear well or ill affected to himself, or to those he holds dear. Mean while he soon grows sensible of the consequences of his own actions, as they attract applause, or bring contempt: he triumphs in the former; and is ashamed of the latter, wants to hide them, and blushes when they are discovered. By means of these powers he becomes a fit subject of culture, the moral tie is drawn closer, he feels that he is accountable for his conduct to others as well as to himself, and thus is gradually ripening for society and action.

As man advances from childhood to youth, his passions as well as perceptions take a more extensive range. New fentes of pleasure invite him to new pursuits; he grows sensible to the attractions of beauty, feels a peculiar sympathy with the sex, and forms a more tender kind of attachment than he has yet experienced. This becomes the cement of a new moral relation, and gives a softer turn to his passions and behaviour. In this turbulent period he enters more deeply into a relish of friendship, company, exercise, and diversion; the love of truth, of imitation, and of design, grows upon him; and as his connections spread among his neighbours, fellow-citizens, and countrymen,
MORAL PHILOSOPHY.

Of Man and his Connections.

By these simple but powerful springs, whether periodic or fixed, the life of man, weak and indigent as he is, is preserved and secured, and the creature is prompted to a constant round of action, even to supply his own numerously and ever-returning wants, and to guard against the various dangers and evils to which he is obnoxious. By these links men are connected with each other, formed into families, drawn into particular communities, and all united as by a common league into one fyllem or body, whose members feel and sympathize one with another. By this admirable adjustment of the condition of man to his state, and the gradual evolution of his powers, order is maintained, society upheld, and human life filled with that variety of passion and action which at once enlivens and diversifies it.

This is a short sketch of the principal movements of the directing power of the human mind. Yet these movements are not the whole of man; they impel to action, but do not direct it: they need a regulator to guide their motions, to measure and apply their forces; and accordingly they have one that naturally superintends and directs their action. We are conscious of a principle within us, which examines, compares, and weighs things; notes the differences, observes the forces, and foresees the consequences, of affections and actions. By this power we look back on past times, and forward into futurity, gather experiences, estimate the real and comparative value of objects, lay out schemes, contrive means to execute them, and settle the whole order and economy of life. This power we commonly distinguish by the name of reason or reflection, the business of which is not to suggest any original notions or fentiments, but to canvass, range, and make deductions from them.

We are intimately conscious of another principle within us, which approves of certain passions, affections, and actions, and disapproves of their contraries. In consequence of the decisions of this inward judge we denominate some actions and principles of conduct right, benevolent, good; and others wrong, dishonest, ill. The former excite our esteem, moral complacency, and affection, immediately and originally of themselves, without regard to their consequences, and whether they affect our interest or not. The latter do as naturally and necessarily call forth our contempt, scour, and aversion. That power by which we perceive this difference in affections and actions, and feel a consequent relish or dislike, is commonly called conscience or the moral sense.

That there is such a power as this in the mind of every man of sound understanding, is a fact which cannot be controverted; but whether it be an instinctive power, or the result of early and deep rooted associations, has been long and ably debated. The question is of importance in the science of human nature, as well as in ascertaining the standard of practical virtue; but to us it appears that the contending parties have carried their respective opinions to dangerous extremes.

When it is affirmed, as it sometimes has been, that reason has nothing to do in ethical science, but that in every possible situation our duty is pointed out and the performance of it enforced by mere sentiment, the consequence seems to be, that virtue and vice are nothing.
MORAL PHILOSOPHY.

Part I.

Of Man and his Connections.

An attempt to prove that we have from nature no such powers, thing permanent in themselves, but change their nature according to local circumstances. Certain it is, that sentiment has in similar situations approved of very different practices in different ages and different nations. An attempt to establish the universal practice of justice, and of parents protecting their children, whether well or ill formed, whether strong or weak; but in Sparta we know that theft, if dexterously practised, was approved, and not unfrequently rewarded; and that the example of lame and deformed children was not only permitted but absolutely enjoined. There is nothing which our conscience or moral sense condemns with greater severity, or views as a crime of a deeper dye, than children unkind treatment of their aged parents; yet there are savagery among whom ininitive of all kinds ought to prevail in greater purity than in civilized nations, whose moral sense permits them to put their aged and decrepitud parents to death. If this sense be inactive, and the socal judge of right and wrong, how comes it to decide so differently on the same line of conduct in different ages and distant countries? The instincts of brutes, in similar circumstances, prompt uniformly to similar actions in every age and in every region where the species is found; and the external senses of man afford in all nations the same unvaried evidence concerning their respective objects. To these observations we may add, that instincts must be calculated for the state of nature, whatever that state may be, and therefore cannot be supposed capable of directing our steps through all the labyrinths of polished society, in which duties are to be performed that in a state of nature would never have been thought of.

But though for these reasons it is apparent that mere sentiment, whether called conscience or the moral sense, would alone be a very unsafe guide to virtue in every individual case that may occur, we think that those who resolve all such sentiment into habit and the effect of education, without giving any part of it to nature, advance an opinion which is equally ill-grounded and not less dangerous. For there are, indeed, men who affirm that all benevolence is hypocrisy; friendship a cheat, public spirit a farce; fidelity a snare to procure trust and confidence; and that while all of us at bottom pursue only our private interest, we wear those fair disguises, in order to put those off their guard with whom we have to deal, and to expel them the more to our wiles and machinations. Others again, too virtuous to accute themselves and all mankind of direct knavery, yet inflict, that whatever affection one may feel, or imagine he feels, for others, no passion is or can be disinterested; that the most generous friendship, however sincere, is only a modification of self-love; and that even unknown to ourselves we seek only our own gratification, while we appear the most deeply engaged in schemes for the liberty and happiness of mankind.

Surely the mildest of these representations is an exaggerated picture of the selfishness of man. Self-love is indeed a very powerful as well as an essential principle in human nature; but that we had likewise an instinctive principle of benevolence, which, without any particular regard to our own interest, makes us feel pleasure in the happiness of other men, is a fact which we think admits of very complete proof. For, as Mr. Hume well argues, "when a man grieves for a friend who could be of no service to him, but on the contrary good in need of his constant attendance and protection, it is possible to suppose that such partial tenderness springs from self-love, which has no foundation in nature? What interested (as the same deep thinker) can a fond mother have in view, who loses her health by her affiduous attendance on the sick child, and afterwards languishes and dies of grief when freed by its death from the slavery of attendance? — Have we no satisfaction (continues he) in one man company above another's, and no desire of the welfare of our friend, even though absence or death should prevent us from all participation in it? Or what is it commonly that gives us any participation in it, even while alive and present, but our affection and regard to him?" Nor is it to contemporaries and individuals alone, that, independent of all interest, we feel a benevolent attachment. We constantly bestow praise on actions calculated to promote the good of mankind, though performed in ages very distant and in countries most remote; and he who was the author of such actions is the object of our esteem and affection. There is not perhaps a man alive, however selfish in his disposition who does not applaud the sentiment of that emperor, who, recollecting at supper that he had done nothing in that day for any one, exclaimed with regret, that the day had been lost! yet the utmost facility of imagination can discover no appearance of interest that we can have in the generosity of Titus, or find any connection of our present happiness with a character removed so far from us both in time and in place. But, as Mr. Hume justly observes, if we even feign a character consiling of all the most generous and beneficent qualities, and give instances in which these display themselves, after an eminent and most extraordinary manner, for the good of mankind, we shall instantly engage the esteem and approbation of all our audience, who will never so much as inquire in what age or country the accomplished person lived.

These are facts which cannot be controverted; and they are wholly unaccountable, if there be not in human nature an instinctive sentiment of benevolence or sympathy, which feels a disinterested pleasure in the happiness of mankind. But an end in which we feel pleasure we are naturally prompted to pursue; and therefore the same sentiment impels every man, with greater or less force, to promote the happiness of other men, which by means of it becomes in reality his own good, and is afterwards purveyed from the combined motives of benevolence and self-enjoyment. For in obeying this sentiment we all feel an inward complacency, self-appropriation, or consciousness of worth or merit; and in disobeying it, which cannot be done but with reluctance, we feel remorse, or a consciousness of unworthiness or a demerit. It appears, however, from history, that the sentiment, as it is instinctive, points only to the good of mankind, without informing us how that good is to be promoted. The means proper for this purpose must be discovered by reason; and when they are brought into view, this sentiment, confidence, or moral sense, instantly shows us that it is our duty to pursue them.

Hence we see how different lines of conduct may in similar circumstances be approved of as virtuous in different

Section 37. Of Duty, or Moral Obligation.

It is by the end or design of any power or move. The means that we must direct its motions, and estimate the force of degree of force necessary to its just action. If it want powers, the force requisite for the obtaining its end, we reckon it defective; if it has too much, so as to be carried beyond it, we say it is overcharged; and in either case it is imperfect and ill-contrived. If it has just enough to reach the scope, we esteem it right and as it should be. Let us apply this reasoning to the passions.

The defence and security of the individual being the Measure of aim of the defensive passions, that security and defence the defence must be the measure of their strength or indulgence. If they are so weak as to prove insufficient for that end, or if they carry us beyond it, i.e. raise unnecessary motions, or continue longer than is needful, they are unfit to answer their original design, and therefore are in an unfound and unnatural state. The exercise of fear or of resentment has nothing desirable in it; nor can
Part I.

MORAL PHILOSOPHY

Of Moral Obligation.

Without a certain degree of them, we are naked and exposed. With too high a proportion of them, we are miserable, and often injurious to others. Thus cowardice or timidity, which is the excess of fear, instead of saving us in danger, gives it too formidable an appearance, makes us incapable of attending to the best means of preservation, and disarms us of courage, our natural armour. Post-haste, which is the want of a due measure of fear, leads us needlessly into danger, and lulls us into a pernicious security. Revenge, i.e. excessive resentment, by the violence of its consequences, robs us of the presence of mind which is often the best guard against injury, and inclines us to pursue the aggressor with more savagery than self-defence requires. Pujillanimity, or the want of a just indignation against wrong, leaves us quite unguarded, and tends to sink our mind into a passive enraptured tameness. Therefore, "to keep the defensive passions duly proportioned to our dangers, is their natural pitch and tenor."

The private passions lead us to pursue some positive species of private good: that good therefore which is the object and end of each must be the measure of their respective force, and direct their operation. If they are too weak or flagitious to engage in the pursuit of their several objects, they are evidently deficient; but if they defeat their end by their impotency, then are they strained beyond the just tone of nature. Thus vanity, or an excessive passion for applause, betrays into such meannesses and little arts of popularity, as makes us forfeit the honour we so anxiously court. On the other hand, a total indifference, about the effect of mankind, removes a strong guard and spur to virtue, and lays the mind open to the most abandoned executions. Therefore, "to keep our private passions and desires proportioned to our wants, is the just measure and pitch of this class of affections."

The defensive and private passions do all agree in general, in their tendency or conduciveness to the interest or good of the individual. Therefore, when there is a collision of interest, as may sometimes happen, that aggregate of good or happiness, which is composed of the particular goods to which they respectively tend, must be the common standard by which their comparative degrees of strength are to be measured: that is to say, if any of them, in the degree in which they prevail, are incompatible with the greatest aggregate of good or most extensive interest of the individual, then are they unequal and disproportionate. For in judging of a particular system or constitution of powers, we call that the supreme or principal end in which the aims of the several parts or powers coincide, and to which they are subordinate; and reckon them in due proportion to each other, and right with regard to the whole, when they maintain that subordination of subordination, under which the state of every part is decided. Therefore, "to proportion our defensive and private passions in such measure to our dangers and wants as best to secure the individual, and obtain the greatest aggregate of private good or happiness, is their just balance or comparative standard in cafe of competition."

In like manner as the public or social affections point at the good of others, that good must be the measure of their force. When a particular social affections, as gratitude or friendship, which belongs to a particular social connection, viz. that of a benefactor or of a friend, is too feeble to make us act the grateful or friendly part, that affection, being insufficient to answer its end, is defective and unfixed. If, on the other hand, a particular passion of this class counteract or defeat the interest which is designed to promote, by its violence or disproportion, then is that passion excessive and irregular. Thus natural affections, if it degenerates into a passionate fondness, not only hinders the parent's from judging coolly of the interest of their offspring, but often leads them into a most partial and pernicious indulgence.

As every kind of affections points at the good of its particular object, it is possible there may be sometimes social affections a collision of interests or goods. Thus the regard due to a friend may interfere with that which we owe to a community. In such a competition of interests, it is evident that the greatest is to be chosen; and that is the greatest interest which contains the greatest sum or aggregate of public good, greatest in quantity as well as duration. This then is the common standard by which the respective forces and subordinations of the social affections must be adjusted. Therefore we conclude, that "this class of affections are found and regular when they prompt us to pursue the interest of individuals in an entire consistency with the public good"; or, in other words, "when they are duly proportioned to the dangers and wants of others, and to the various relations in which we stand to individuals or to society."

Thus we have found, by an induction of particulars, the natural pitch or tenor of the different orders of affection, considered apart by themselves, Now, as the virtue or perfection of every creature lies in following its nature, or acting suitably to its just proportion and harmony of its several powers; therefore, "the virtue of a creature endowed with such affections as must confute in observing or acting agreeably to their natural pitch and tenor."

But as there are no independent affections in the Balance of the mind, no passion that stands by itself, affection, without some relation to the rest, we cannot pronounce of any one, considered apart, that it is either too strong or too weak. Its strength and just proportion must be measured not only by its subserviency to its own immediate end, but by the respect it bears to the whole system of affection. Therefore, we say a passion is too strong, not only when it defeats its own end, but when it impairs the force of other passions, which are equally necessary to form a temper of mind fitted to a certain economy or state; and too weak, not merely on account of its insufficiency to answer its end, but because it cannot fulfil its part or office in the balance of the whole system. Thus the love of life may be too strong when it takes from the regard due to one's country, and will not allow one bravely to encounter dangers, or even death, on its account. Again, the love of fame may be too weak when it throws down the fences which render virtue more secure, or weakens the incentives which make it more active and public spirited.

If it be asked, "How far may the affections towards Limits of private good or happiness be indulged?" One limit private affections was before fixed for the particular indulgence of each, viz. their subordination to the common aggregate of good to the private system. In these therefore a due
regard is always supposed to be had to health, reputation, fortune, the freedom of action, the unimpaired exercise of reason, the calm enjoyment of one's self, which are all private goods. Another limit now results from the balance of affection just named, viz. "The security and happiness of others!" or, to express it more generally, "a private affection may be fairly indulged, when, by that indulgence, we do not violate the obligations which result from our higher relations or public connections." A just respect therefore being had to these boundaries which nature has fixed in the breast of every man, what should limit our pursuits of private happiness? Is nature fallen and pernicious? or, does the God of nature envy the happiness of his offspring?

Whether there is ever a real collision of interests betwixt the public and private system of affections, or the ends which each class has in view, will be afterwards considered; but where there is no collision, there is little or no danger of carrying either, but especially the public affections, to excess, provided both kinds are kept subordinate to a discreet and cool self-love, and to a calm and universal benevolence, which principles stand as guards at the head of each system. This then is the conduct of the passions, considered as particular and separate forces, carrying us out to their respective ends; and this is their balance or economy, considered as compound powers, or powers mutually related, acting in conjunction towards a common end, and consequently as forming a system or whole.

Now, whatever adulterous or maintains this balance, whatever in the human constitution is formed for directing the passions so as to keep them from defeating their own ends or interfering with each other, must be a principle of a superior nature to them, and ought to direct their measures and govern their proportion. But it was found that reason or reflection is such a principle, which points out the tendency of our passions, weighs their influence upon private and public happiness, and shows the best means of attaining either. It having been likewise found that there is another directing or controlling principle, which we call conscience or the moral sense, which, by a native kind or authority, judges of affections and actions, pronouncing some just and good, and others unjust and ill; it follows, that the passions, which are mere impulse or blind forces, are principles inferior and subordinate to this judging faculty. Therefore, if we would follow the order of nature, i.e. observe the mutual respects and the subordination which the different parts of the human constitution bear one to another, the passions ought to be subjected to the direction and authority of the leading or controlling principles.

We conclude, therefore, from this induction, that "the constitution or just economy of human nature consists in a regular subordination of the passions and affections to the authority of conscience and the direction of reason." That subordination is regular, when the proportion formerly mentioned is maintained; that is to say, "when the defensive passions are kept proportioned to our dangers; when the private passions are proportioned to our wants; and when the public affections are adapted to our public connections, and proportioned to the wants and dangers of others." But the natural state, or the found and vigorous con-

...
MORAL PHILOSOPHY.

Part I.

Of Moral Obligation.

Moral affections are the sentiments of passions, in the just measure and balance of which we found a right temper to consult.” For this is entirely a matter of experience, in which we must examine, as in any other natural inquiry, “what are the genuine feelings and operations of nature, and what affections or symptoms of them appear in the given instance.”

The defensive passions, as anger and fear, give us rather pain than pleasure, yet we cannot help feeling them when provoked by injury, or exposed to harm. We account the creature imperfect that wants them because they are necessary to his defence. Nay, we shoulcl in some measure condemn ourselves, if we did not have the necessary degree of resentment and censure. But if our resentment exceeds the wrong received, or our caution the evil dreaded, we then blame ourselves for having over-acted our part. Therefore, while we are in danger, to be totally destitute of them we reckon a blameable defect, and to feel them in a just i.e. necessary measure, we approve, as suited to the nature and condition of such a creature as man. But our security obtained, to continue to indulge them, we not only disapprove as hurtful, but condemn as unmoral, unbecoming, and man spirited; Nor will such a conduct afford any self-approving-joy when we cooly reflect upon it.

With regard to the private passions, such as love of life, pleasure, ease, and the like, as these aims at private good, and are necessary to the perfection and happiness of the individual, we shall reckon any creature destitute, and even blameable, that was destitute of them. Thus, we condemn the man who immoderately respects his fortune, impairs his health, or exposes his life; we not only pity him as an unfortunate tell, with a voice irresistibly audible and command-}

56 Why the private.

With regard to the public affections, as compassion, natural affections, friendship, benevolence, and the like, we approve, admire, and love them in ourselves; and, in all in whom we discover them, with an esteem and approbation, if not different in kind, yet surely far superior in degree, to what we feel towards the other passions. These we reckon necessary; just; and excellently suited to our nature and slate; and the creature which wants them we call defective, ill constituted, a kind of abortion. But the public affections we esteem as self-worthy, originally and externally amiable.

But among the private affections we make an obvious and constant distinction, viz. between those particular passions which urge us with a sudden violence, and uneasy kind of perturbation, to pursue the good of their respective objects, as pity, natural affection, and the like; and those calm dispassionate affections and desires which prompt us more steadily and uniformly to promote the happiness of others. The former we generally call passions, to distinguish them from the latter sort, which go more commonly by the name of affections or calm desire. The first kind we approve indeed, and delight in; but we feel still higher degrees of approbation and moral complacency towards the latter, and towards all limitation of the particular infinities, by the principle of unlimited benevolence. The more objects the calm affections take in, and the worther these are, their dignity rises in proportion, and with this our approbation keeps in exact pace. A character, on the other hand, which is quite divided of these public affections, which feels no love for the species, but instead of it entertain's malice, rancour, and ill will, we reckon totally immoral and unnatural.

Such then are the distinctions and dispositions we feel when these several orders of affection pass before the mental eye.

Th to what extent in which we feel ourselves moved, in the manner above described, towards those affections and passions, as they come under the mind’s review, and in which we are, instantaneously and independently of our choice or volition, prompted to a corresponding conduct, we call a state of moral obligation. Let us suppose, for instance, a parent, a friend, a benefactor, reduced to a condition of the utmost indigence and distress, and that it is in our power to give them immediate relief. To what conduct are we oblige? what duty does nature dictate and require in such a case? Attend to nature, and nature will tell, with a voice irresistibly audible and commanding to the human heart, with an authority which no man can silence without being self-condemned, and which no man can elude but at his peril, “that immediate relief ought to be given.” Again, let a friend, a neighbour, or even a stranger, have lodged a deposit in our hands, and after some time reclaim it; we sooner do these ideas of the confidence reposed in us, and of property not transferred, but deposited, occur, than we immediately and unavoidably feel and recognize the obligation to restore it. In both these cafes we should condemn and even loathe ourselves if we acted otherwise, as having done, or omitted doing, what we ought not, as having acted beneath the dignity of our nature;— contrary to our most intimate sense of right and wrong:—we should accuse ourselves as guilty of ingratitude, injustice, and inhumanity,—and be conscious of deserving the cenitire, and therefore dread the resentment, of all rational beings. But in complying with the obligation, we feel joy and self-approbation, are conscious of an inviolable harmony between our nature and duty, and think ourselves entitled to the applause of every impartial spectator of our conduct.

To describe therefore what we cannot perhaps define, a state of moral obligation, is “that state in which a creature, endowed with such senses, powers, and affections as man, would condemn himself, and think he deserved the condemnation of all others, should he refuse to fulfill it; but would approve himself, and expect the approbation of all others, upon complying with it.”

And
And we call him a moral agent, who is in such a
state of being as is subject to moral obligation. Therefore, as
man's structure and constitution produce the character of
moral obligation, we conclude that he is a moral
agent. But as man may sometimes act without knowing
what he does, as in cases of frenzy or sleep, or in many natural functions; or, knowing what he
does, he may act without choice or affection, as in cases of
necessity or compulsion; therefore to denominate an
action moral, i.e. approveable, or blamable, it must be
done knowingly and willingly, or from affection and choice.
A morally good action, then, is to fulfill a moral obligation
knowingly and willingly. And a morally bad
action or an immoral action, is, "to violate a moral
obligation knowingly and willingly." As not an action,
but a series of actions, constitute a character; as not an affection but a series of affections,
constitute a temper; and as we denominate things by
the gross, a fortiori, or by the qualities which chiefly
prevail in them; therefore to call that a "moral character,
in which a series of morally good actions prevail," and a "moral
good temper, in which a series of morally
good actions have the ascendancy," is
an action or character.
Moral character and temper good and bad.
How we come by the idea of moral obligation.
Moral obligation, the living, irresistible charms of moral
obligation, which immediately attracts the cor-
respondent passions, and prompts us to fulfill its lawful
duties.
We need not apprehend any danger from the
quickness of its decisions, nor be frightened because it looks
like infinity, and has been called so. Would we approve
one for deliberating long, or reasoning the matter much at leisure, whether he should relieve a
suffering parent, feed a starving neighbour, or re-
store the truth committed to him? Should we not suspect
the reasoner of knavery, or of very weak affections
to virtue? We employ reason, and worthily
employ it, in examining the condition, relations, and
other circumstances of the agent or patient, or of
those with whom either of them are connected, or,
in other words, the state of the case: and in complicated
cases, where the circumstances are many, it may
require no small attention to find the true state of the
case; but when the relations of the agent or patient and
the circumstances of the action are obvious, or come out such after a fair trial, we should scarce
approve him who demurs on the obligation to that
duty which the case suggests.
From what has been said, it is evident, that it is not Pleasure,
the pleasure or agreeable sensations which accompany
the exercise of the several affections, nor those
consequent to the actions, that constitute moral obligation,
or excite in us the idea of it. That pleasure is
independent of the idea of obligation; and frequently we
are obliged, and acknowledge ourselves under an
obligation, to such affections and actions as are attended
with pain; as in the trials of virtue, where we are
obliged to sacrifice private to public good, or a present
pleasure to a future interest. We have pleasure
in serving an aged parent, but it is neither the perception
nor prospect of that pleasure which gives us the
idea of obligation to that conduct.

We have now taken a general prospect of man and the survey
of his moral powers and connections, and on these proceed.

We need not the idea of obligation as
moral cases.

The same proceeding

We have therefore

The nature of

The Supreme Being has been fit to blend in the inward
whole of things, a prodigious variety of discordant and
contrary principles, light and darkness, pleasure and pain,
good and evil. There are multifarious natures, higher
and lower, and many intermediate ones between the
wide-
Of Perception and Affection.

MORAL PHILOSOPHY.

Part I.

wide-distant extremes. These are differently situated, variously adjusted, and subjected to each other, and all of them subordinate to the order and perfection of the whole. We may suppose more placed as in a centre amidst innumerable orders of beings, by his outward frame drawing to the material system, and by his inward connected with the intellectual or moral, and of course affected by the laws which govern both, or affected by that good and that ill which result from those laws. In this infinite variety of relations with which he is surrounded, and of contingencies to which he is liable, he feels strong attractions to the good, and violent repulsions or aversions to the ill. But as good and ill are often blended, and wonderfully complicated one with the other, as they sometimes immediately produce and run up into each other, and at other times lie at great distances, yet by means of intervening links introduce one another; and as these effects are often brought about in consequence of hidden relations and general laws, of the energy of which he is an incompetent judge; it is easy for him to mistake good for evil, and evil for good, and consequently he may be frequently attracted by such things as are destructive, or repel such as are salutary. Thus, by the tender and complicated frame of his body, he is subjected to a great variety of ills, to sickness, cold, heat, fatigue, and innumerable accidents. Yet his knowledge is so narrow withal, and his reason so weak, that in many cases he cannot judge, in the way of investigation or reasoning, of the connections of these effects with their respective causes, or of the various latent energies of natural things.—He is therefore informed of this connection by the experience of certain senses or organs of perception, which, by a mechanical instantaneous motion, feel the good and the ill, receiving pleasure from one, and pain from the other. By these, without any reasoning, he is taught to attract or choose what tends to his welfare, and to repel and avoid what tends to his ruin. Thus, by his senses of taste and smell, or by the pleasure he receives from certain kinds of food, he is admonished which agree with his constitution; and by an opposite sense of pain he is informed which do not suit, or are destructive of it; but is not by means of this instructed in the inward natures and constitutions of things.

Some of these senses are armed with strong degrees of uneasiness or pain, in order to urge him to seek after such objects as are a food to them. And these respect his more immediate and pressing wants; as the sense of hunger, thirst, cold, and the like; which, by their painful importunities, compel him to provide food, drink, raiment, shelter. Those instincts by which we are thus prompted with some kind of commotion or violence to attract and pursue good, or to repel and avoid ill, we call appetites and passions. By our senses then we are informed of what is good or ill to the private system, or the individual; and by our private appetites and passions we are impelled to one, and restrained from the other.

In consequence of this machinery, and the great train of wants to which our nature subjects us, we are engaged in a continued series of occupations, which often require much application of thought or great bodily labour, or both. The necessities of life, food, clothes, shelter, and the like, must be provided; conveniences must be acquired to render life still more easy and comfortable. In order to obtain these, arts, industry, manufactures, and trade, are necessary. And to secure to us the peaceable enjoyment of their fruits, civil government, policy, and laws, must be contrived, and the various bulwarks of public life carried on: thus, while man is concerned and busied in making provision, or obtaining security for himself, he is by degrees engaged in connections with a family, friends, neighbours, a community, or a commonwealth. Hence arise new wants, new interests, new cares, and new employments. The passions of one man interfere with those of another. Interests are opposed. Competitions arise, contrary courses are taken. Disappointments happen, distinctions are made, and parties formed. This opens a vast scene of distraction and embarrassment, and introduces a mighty train of good and ill, both public and private. Yet amidst all this confusion and hurry, plans of action must be laid, consequences foreseen or guarded against, inconveniences provided for; and frequently particular resolutions, must be taken, and schemes executed, without reasoning or delay.

Now what provision has the Author of our nature made for this necessitous condition? how has he fitted for it the actor, man, for playing his part in this perplexed and busy scene?

Our supreme Parent, watchful for the whole, has by public not left himself without a witness here neither, and every kind and hath made nothing imperfect, but all things are double one against the other. He has not left man to be informed, only by the cool notices of reason, of the good or ill, the happiness or misery of his fellow-creatures. He has made him sensible of their good and happiness, but especially of their ill and misery, by an immediate sympathy, or quick feeling of pleasure and of pain.

The latter we call pity or compassion. For the former, though every one who is not quite divested of humanity, feels it in some degree, we have not got a name, unless we call it congratulation or joyful congratulation.

For the pity or compassion. The former, though every one, who is not quite divested of humanity, feels it in some degree, we have not got a name, unless we call it sympathy, or that good humour which arises on seeing others pleased or happy. Both these feelings have been called in general the public of common sense, or notoriety, by which we feel for others, and are interested in their concerns as really, though perhaps less sensibly than in our own.

When we see our fellow-creatures unhappy through the fault or injury of others, we feel resentment or indignation against the unjust causers of that misery. If we are conscious that it has happened through our fault or injurious conduct, we feel shame; and both these classes of senses and passions, regarding misery and wrong, are armed with such sharp sensations of pain, as not only prove a powerful guard and security to the species, or public system, against those ills it may, but serve also to lessen or remove those ills it does, suffer. Compassion draws us out of ourselves to bear a part of the misfortunes of others, powerfully solicits us in their favour, melts us at the sight of their distress, and makes us, in some degree, unhappy till they are relieved from it. It is peculiarly well adapted to the condition of human life, because it is much more and oftener in our power to do mischief than good, and to prevent or lessen misery than to communicate
Of Perception and Affection.

74. Public affections.

There are other particular infinitesimal passions which interest us in the concerns of others, even while we are most busy about our own, and which are strongly attractive of good, and repulsive of ill to them. Such are natural affection, friendship, love, gratitude, desire of fame, love of society, of one's country, and others that might be named. Now as the private appetites and passions were found to be armed with strong feelings of desire and uneasiness, to prompt man the more effectually to subdue labours, and to encounter dangers in pursuit of those goods that are necessary to the preservation and welfare of the individual, and to avoid those ills which tend to his destruction; in like manner it was necessary, that this other class of desires and affections should be prompted with as quick sensations of pain, not only to counteract the strength of their antagonists, but to engage us in a virtuous activity for our relations, families, friends, neighbours, country. Indeed our sense of right and wrong will admonish us that it is our duty, and reason and experience further assure us that it is both our interest and best security, to promote the happiness of others; but that sense, that reason, and that experience, would frequently prove but weak and ineffectual prompters to such a conduct, especially in cases of danger and hardship, and amidst all the importunities of nature, and that constant hurry in which the private passions involve us, without the aid of those particular kind affections which mark out to us particular fibres of duty, and with an agreeable violence engage and fix us down to them.

75. Contrary balance of passions.

It is evident, therefore, that those two classes of affection, the private and public, are set one against the other, and designed to control and limit each other's influence, and thereby to produce a just balance in the whole*. In general, the violent sensations of pain and uneasiness which accompany hunger, thirst, and the other private appetites, or too great fatigue of mind as well as of body, prevent the individual from running to great excesses in the exercise of the higher functions of the mind, as too intense thought in the search of truth, violent application to business of any kind, and different degrees of romantic heroism. On the other hand, the finer senses of perception, and those general desires and affections which are connected with them, the love of action, of imitation, of truth, honour, public virtue, and the like, are widely placed in the opposite scale, in order to prevent us from sinking into the dregs of the animal life, and debasing the dignity of man below the condition of brutes. So that, by the mutual reaction of those opposite powers, the bad effects are prevented that would naturally result from their acting singly and apart, and the good effects are produced which each are severally formed to produce.

The same wholesome opposition appears likewise in the particular counter-workings of the private and public affections one against the other. Thus compulsion is adapted to counterpoise the love of ease, of pleasure, and of life, and to disfurn or to set bounds to renunciation; and resentment of injury done to ourselves, or to our friends who are dearer than ourselves, prevents an effeminate compassion or consolation, and gives us a noble contempt of labour, pain, and death.

Natural affection, friendship, love of one's country, may, zeal for any particular virtue, are frequently more than a match for the whole train of selfish passions.

—On the other hand, without that intimate overruling passion of self-love, and those private desires which are connected with it, the social and tender infinities of the human heart would degenerate into the wilderst doze, the most torturing anxiety, and disturbing frenzy.

But not only are the different orders or classes of Contrasts among those of the same classes are mutual clogs. Thus, how many are withheld from the violent outrages of resentment by fear? and how easily is fear controlled in its turn, while mighty wrongs awaken a mighty resentment! The private passions often interfere, and therefore moderate the violence of each other; and a calm self-love is placed at their head, to direct, influence, and control their particular attractions and repulsions. The public affections likewise restrain one the other: and all of them are put under the control of a calm dispassionate benevolence, which ought in like manner to direct and limit their particular motions. Thus mofl part, if not all the passions, have a twofold aspect, and serve a twofold end. In one view they may be considered as powers, impelling mankind to a certain course, with a force proportioned to the apprehended moment of the good they aim at. In another view they appear as weights, balancing the action of the powers, and controlling the violence of their impulses. By means of these powers and weights a natural peace is settled in the human breast by its all-wise Author, by which the creature is kept tolerably steady and regular in his course, amidst that variety of stages through which he must pass.

But this is not all the provision which God has made for the hurry and perplexity of the scene in which perceptions man is defined to act. Amidst those infinite attractions and repulsions towards private and public goods, and ill, mankind either cannot often foresee the consequences or tendencies of all their actions towards one or other of these, especially where those tendencies are intricate and point different ways, or those consequences remote and complicated; or, though, by careful and cool enquiry, and a due improvement of their rational powers, they might find them out, yet, disdained as they are with business, amined with studies, dissipated by pleasure, and disturbed by passion, they either have or can find no leisure to attend to those consequences, or to examine how far this or that conduct is productive of private or public good on the whole. Therefore, were it left entirely to the flow and sober deductions of reason to trace those tendencies, and make out those consequences, it is evident, that in many particular instances the businesse of life must stand still, and many important occasions of action be lost, or perhaps the grossest blunders be committed. On this account, the Deity, befores that general approbation which we bestow on every degree of kind affection, has moreover implanted in man many particular perceptions or determinations to approve of certain qualities or actions, which, in effect, tend to the advantage of society, and are connected with
MORAL PHILOSOPHY.

Of Perception and Affection.

With private good, though he does not always see that
tendency, nor mind that connection. And these per−
ceptions or determinations do without reasoning point
out, and, antecedent to views of interest, prompt to a
conduct beneficial to the public, and useful to the pri−
ivate system. Such is the fire of candor and equity,
that absence of fraud and falsehood, the senfe of
utility, justice, gratitude, greatness of mind, forti−
citude, clemency, decorum; and that disapprobation
of knavery, injustice, ingratitude, meannefs of spiri−
tuality, cruelty, and iniquity, which are natural to
the human mind. The former of their dispositions,
and the actions flowing from them, are approved, and
those of the latter kind disapproved by us, even ab−
strated from the view of their tendency or condu−
civenef: to the happiness or misery of others, or of
ourselves. 1 In one we discern a beauty, a superior
excellency, a congilony to the dignity of man; in the
other a disformity, a littleness, a debasement, of human
nature.

There are other principles also connected with the
good of society, or the happiness and perfection of the
individual, though that connection is not immedi−
ately apparent, which we behold with real complacency
and approbation, though perhaps inferior in degree, if not
in kind, such as gravity, modesty, simplicity of deport−
ment, temperance, prudent economy; and we feel some
degree of contempt and dislike where they are want−
ing, or where the opposite qualities prevail. These
and the like perceptions or feelings are either different
modifications of the moral sense, or subordinate to it, and
plainly serve the same important purpose, being ex−
pedient monitors, in the several emergencies of a vari−
ous and diversified life, of what is right, what is
wrong, what is to be pursued, and what avoided; and,
by the pleanant or painful confidences which attends
them, exerting their influence as powerful prompters
to a suitable conduct.

From a flight inspection of the above-named prin−
ciples, it is evident they all carry a friendly aspect to
society and the individual, and have a more immediate
or a more remote tendency to promote the perfec−
tion or good of both. This tendency cannot be always
foreseen, and would be often mistaken or feldom ad−
tended to by a weak, fufy, short-sighted creature like
man, both rash and variable in his opinions, a dupe to
his own partialities or to the depofits of others, liable to
ficknefs, to want, and to error. Principles, therefore,
which are fo nearly linked with private fecurity and
public good, by directing him, without operofe
reasoning, where to find one, and how to promote the
other; and, by prompting him to a conduct conduci−
tive to both, are admirably adapted to the exigencies of
his prefeft state, and wisely calculated to obtain the
ends of universal benevolence.

It were easy, by confidering the subject in another
light, to fhow, in a curious detail of particulars, how
wonderfully the infide of man, or that allifying train of
moral powers and affections with which he is en−
deed, is fitted to the several stages of that progreffive
and probationary state through which he is defined
to pass. As our faculties are narrow and limited, and
rise from very small and imperfect beginnings, they
must be improved by exercife, by attention, and re−
peated trials. And this holds true, not only of our in−
telleftual, but of our moral and active powers. The
former are liable to errors in speculation, the latter
to blunders in practice, and both often terminate in mis−
fortunes and pains. And thofe errors and blunders
are generally owing to our affections, or to our too
forward and warm animadversion of the partial goods
they naturally purfue, or to our fear of those partials if
they naturally repel. Thofe misfortunes, therefore,
lead us back to consider where our minds lay, and
whence our errors flowed; and confequently are fa−
latory pieces of trial, which tend to enlarge our
views, to correct and refine our affections, and con−
fquently improve both our intellectual and moral
powers. Our affections then are the rude materials of
our virtue, which Heaven has given us to work up
to refine and polish into an harmonious and divine
piece of workmanship. They furnish out the whole
machinery, the calms and storms, the lights and shades
of human life. They how mankind in every attitude
and variety of character, and give virtue both its
strengths and triumphs. To conduct them well in
every state, is merit; to abuse or misapply them, is
demerit.

The different fets of affections, powers, and affections,
Te a pro−
which unfold themselves in those fucceffive fages, are greffeved
both necessary and adapted to that rising and progre−
ffive state. Enlarging views and growing connec−
tions require new affections and new habits; and
thus the mind, by these continually expanding and
finding a progreffive exercife, rises to higher im−
provements, and pushes forward to maturity and per−
fecion.

In this beautiful economy and harmony of our
structure, both outward and inward, with that state
we may at once defcern the great lines of our duty
traced out in the fairft and brighteft characterts, and
compendate with admiration a more auguf: and mar−
vellous fenee of divine wisdom and goodness laid in
the human breast, than we shall perhaps find in the whole
compass of nature.

From this detail it appears, that man, by his or−
iginal frame, is made for a temperate, compaffionate,
benevolent, active, and progreffive flate. He is strongly
attracted of the good, and repuljive of the ill which be−
fals others as well as himself. He feels the highest
approbation and moral complacency in thofe affections,
and in thofe actions, which immediately and direc−
tly reflect the good of others, and the highest dif−
approbation and abhorrence of the contrary. Befides
this, he has many particular perceptions or infinu−
tes of approbation, which, though perhaps not of the fame
kind with the others, yet are accompanied with cor−
rrespondent degrees of affection, proportioned to their
repective tendencies to the public good. Therefore,
by acting agreeably to these principles, man acts
agreeable to his structure, and fulfils the benevolent
intentions of its author. But we call a thing good
when it answers its end, and a creature good, when
he acts in a conformity to his confitution. Con−
fquently, man muft be denominated good or virtuous
when he acts fitually to the principles and defination
of his nature.
MORAL PHILOSOPHY.

PART II.

Of Duty or Virtue.

CHAP. I. The principal definitions of Duty or Virtue.

WE have now considered the constitution and combinations of man, and on those erected a general system of duty or moral obligation, contant to reason, approved by the most sacred and intimate sense, suitable to his mixed condition, and confirmed by the experience of mankind. We have also traced the final causes of his moral faculties and affections to those noble purpotes they answer, with regard both to the private and the public system.

From this induction it is evident, that there is one order or clas of duties which man owes to himself: another to society; and a third to God.

The duties he owes to himself are founded chiefly on the defensive and private passions, which prompt him to pursue whatever tends to private good or happiness, and to avoid or ward off whatever tends to private ill or misery. Among the various goods which allure and solicit him, and the various ills which attack or threaten him, "to be intelligent and accurate in selecting one, and rejecting the other, or in preferring the most excellent goods, and avoiding the most terrible ills, when there is a competition among either, and to be different in using the best means to attain the goods and avoid the ills, is what we call prudence."

This, in our inward frame, corresponds to sagacity, or quickness of sense, in our outward." "To proportion our defensive passions to our dangers, we call fortitude which always implies " a just mixture of calm resignation, and animosity, and well governed caution."

And this firmness of mind answers to the strength and musling of the body. And "duty to adjust our private passions to our wants, or to the respective moment of the good we effect or pursue, we call temperance;" which does therefore always imply, in this large sense of the word, "a just balance or command of the passions." "

The second class of duties arises from the public or social affections, "the just harmony or proportion of which to the dangers and wants of others, and to the several relations we bear, commonly goes by the name of justice." This includes the whole of our duty to society, to our parents, and the general polity of nature; particularly gratitude, friendship, sincerity, natural affection, benevolence, and the other social virtues. This, being the noblest temper, and fairest composition of the soul, corresponds to the beauty and fine proportion of the pagon. The virtues comprehended under the former clas, especially prudence and fortitude, may likewise be transferred to this; and according to the various circumstances in which they are placed, and the more refined or more extensive sphere in which they operate, may be denominated private, economical, or civil prudence, fortitude, &c. Those direct our conduct with regard to the wants and dangers of those less or greater circles with which we are connected.

The third class of duties respects the deity, and arises from the public affections, and the several glorious duties to relations which he sustains to us as our creator, benefactor, God, angel, judge, &c.

We chose to consider this set of duties in the last place; because, though prior in dignity and excellency, they seem to be last in order of time, as thinking it the most simple and easy method to follow the gradual progress of nature, as it takes its rise from individuals, and spreads through the social system, and still ascends upwards, till at length it stretches to its Almiglty Parent and Head, and so terminates in those duties which are highest and last.

The duties resulting from these relations are, reverence, gratitude, love abnegation, dependence, obedience, worship, praise; which, according to the model of our finite capacities, must maintain some sort of proportion to the grandeur and perfection of the object whom we venerate, love, and obey. "This proportion or harmony is expressed by the general name of piety or devotion," which is always stronger or weaker according to the greater or less apprehended excellency of its object. This sublime principle of virtue is the enlivening soul which animates the moral system, and that cement which binds and sustains the other duties which man owes to himself or to society.

This then is the general temper and constitution of confidence in virtue, and those are the principal lines or divisions of duty. To those good dispositions which respect the several objects of our duty, and to all actions which flow from such dispositions, the mind gives its function or testimony. And this function or judgment concerning the moral quality, or the goodness of actions or dispositions, moralists call confidence. When it judges of an action that is to be performed, it is called an antecedent confidence; and when it passes sentence on an action which is performed, it is called a subsequent confidence. The tendency of an action to produce happiness, or its external conformity to a law, is termed its material goodness. But the good dispositions from which an action proceeds, or its conformity to law in every respect, constitutes its formal goodness.

When the mind is ignorant or uncertain about the moment of an action or its tendency, to private or public good; or when there are several circumstances in the case, some of which, being doubtful render the mind dubious concerning the morality of the action; this is called a doubtful or scrupulous confidence; if it mistakes concerning the same, it is called an erroneous confidence. If the error or ignorance is involuntury or involuntary, the action proceeding from that error, or from that ignorance, is reckoned innocent, or not imputable. If the error or ignorance is simple or accidental, i.e. the effect of negligence, or of affectation and wilful inadvertence, the conduct flowing from such error, or such ignorance, is criminal and imputable. Not to follow one's confidence, though erroneous and ill-informed, is criminal, as it is the guide of life; and to counteract it, shows a depraved and incorrigible spirit. Yet to follow an erroneous confidence is like-
**Part II.**

**MORAL PHILOSOPHY.**

Of Man's duty to Himself.

Man is criminal, if that error which misled the conscience was the effect of meditation, or of any criminal passion.

*Hutcheson.*

Mor. Init. lib. 2. c. 3.

If it be asked, "How an erroneous conscience shall be rectified, since it is supposed to be the only guide of life, and judge of morals?" we answer, in the very same way that we would rectify reason if at any time it should judge wrong, as it often does, viz. by giving it proper and sufficient materials for judging right, i.e., by inquiring into the whole state of the case, the relations, connections, and several obligations of the actor, the consequences and other circumstances of the action, or the furnishing of private or public good which results, or is likely to result, from the action or from the omission of it. If those circumstances are fairly and fully stated, the conscience will be just and impartial in its decision: for, by a necessary law of our nature, it approves and is well affected to the moral form; and if it seems to approve of vice or immorality, it is always under the notion or mask of some virtue. So that, strictly speaking, it is not conscience which err; for its sentence is always conformable to the view of the case which lies before it; and is just, upon the supposition that the case is truly such as it is represented to it. All the fault is to be imputed to the agent, who neglects to be better informed, or who, through weakness or wickedness, hastens to pass sentence from an imperfect evidence.

**CHAP. II. Of Man's duty to Himself. Of the Nature of Good, and the Chief Good.**

Every creature, by the constitution of its nature, is determined to love himself; to pursue whatever tends to his preservation and happiness, and to avoid what ever tends to his hurt and misery. Being endowed with sense and perception, he must necessarily receive pleasure from some objects, and pain from others. Those objects which give pleasure are called good; and those which give pain, evil. To the former he feels that attraction or motion we call desire, or love; to the latter, that impulse we call aversion, or hatred.—To objects which suggest neither pleasure nor pain, and are apprehended of no use to procure one or ward off the other, we feel neither desire nor aversion; and such objects are called indifferent. Those objects which do not of themselves produce pleasure or pain, but are the means of procuring either, we call useful or noxious. Towards them we are affected in a subordinate manner, or with an indirect and remote rather than a direct and immediate affection. All the original and particular affections of our nature lead us out to and ultimately rest in the first kind of objects, viz. those which give immediate pleasure, and which we therefore call good, directly so. The calm affection of self-love alone is conversant about such objects as are only consequentially good, or merely useful to ourselves.

But, besides those sorts of objects which we call good, merely and solely as they give pleasure, or are means of procuring it, there is an higher and nobler species of good, towards which we feel that peculiar movement we call approbation or moral complacency; and which we therefore denominate moral good. Such are our affections, and the consequent actions to them.

The perception of this is, as has been already observed, quite distinct in kind from the perception of other species; and though it may be connected with pleasure or advantage by the benevolent constitution of nature, yet it constitutes a good independent of that pleasure and that advantage, and far superior not in degree only but in dignity to both. The other, viz. the natural good, consists in obtaining those pleasures which are adapted to the peculiar fancies and passions susceptible of them, and is as various as are those fancies and passions. This, viz. the moral good, lies in the right conduct of the several fancies and passions, or their just proportion and accommodation to their respective objects and relations; and this is of a more simple and invariable kind.

By our several fancies we are capable of a great variety of pleasing sensations. Those constitute differing ends or objects ultimately purifiable for their own sake. To these ends, or ultimate objects, correspond peculiar appetites or affections, which prompt the mind to pursue them. When these ends are attained, there it rests, and looks no farther. Whatever therefore is purifiable, not on its own account, but as subservient or necessary to the attainment of something else that is intrinsically valuable for its own sake, be that value ever so great or ever so small, we call a mean, and not an end. So that ends and means constitute the materials or the very essence of our happiness. Consequently happy, i.e., human happiness, cannot be one simple uniform thing in creatures constituted, as we are, with such various fancies of pleasure, or such different capacities of enjoyment. Now, the same principle, or law of our nature, which determines us to pursue any one end or species of good, prompts us to pursue every other end or species of good of which we are susceptible, or to which our Maker has adapted an original propension. But, amidst the great multiplicity of ends or goods which form the various ingredients of our happiness, we perceive an evident gradation or subordination fitted to that gradation of fancies, passions, and affections, which prevails in our mixed and various constitution, and to that ascending series of connections which open upon us in the different stages of our progressive state.

Thus the goods of the body, or of the external senses, gradation seem to hold the lowest rank in this gradation or scale of goods. These we have in common with the brutes; and though many men are brutish enough to pursue the goods of the body with a more than brutal fury, yet, when at any time they come in competition with goods of an higher order, the unanimous verdict of mankind, by giving the last the preference condemns the first to the meanest place. Goods consisting in exterior social connections, as fame, fortune, power, civil authority, seem to succeed next, and are chiefly valuable as the means of procuring natural or moral good, but principally the latter. Goods of the intellect are still superior, as taste, knowledge, memory, judgment, &c. The highest are moral goods of the mind, directly and ultimately regarding ourselves, command of the appetites and passions, prudence, fortitude, benevolence, &c. These are the great objects of our pursuit, and the principal ingredients of our happiness.
MORAL PHILOSOPHY.

Of Man's duty to Himself.

98

Thofe of the body are health, strength, agility, hardines, and patience of change, neatness, and decency.

Good health; and a regular easy flow of spirits, are in themselves sweet natural enjoyments, a great fund of pleafure, and indeed the proper feaoning which gives a flavour and poignancy to every other pleafure.

The want of health unites us for moft duties of life, and is efpecially an enemy to the focial and humane affections, as it generally renders the unhappy fufferer peevish and fullen, difgusted at the allotments of Providence, and confequently apt to entertain fufpicions and gloomy fentiments of its Author. It obftructs the free exercife and full improvement of our reafon, makes us a burden to our friends, and ufeless to fociety. Whereas the uninterrupted enjoyment of good health is a conftant fource of good humour, and good humour is a great friend to opened and benignity of heart, enables us to encounter the various ill and difappointments of life with more courage, or to fustain them with more patience; and, in short, conduces much, if we are otherwife duly qualified, to our acting our part in every exigency of life with more firmnefs, confciency, and dignity. Therefore it imports us much to preferve and improve an habit or enjoyment, without which every other external entertainment is taftelrefs, and moft other advantages of little avail.

And this is best done by a ftrict temperance in diet and regimen, by regular exercife, and by keeping the mind fereene and untruffled by violent paflions, and unfubdued by intempe and conftant labours, which greatly impair and gradually deftroy the firft conftitutions.

Strength, agility, hardines, and patience of change, fuppo.sw health, and are unattainable without it; but they imply fomething more, and are neceffary to guard it, to give us the proper unifome of life and limbs, and to secure us againft many otherwife unavoidable ill.

The exercife of the neceffary manual, and of moft of the elegant arts of life, depends on strength and agility of body: perfonal dangers, private and public dangers, the demands of our friends, our families, and country, require them; they are neceffary in war, and ornamental in peace; fit for the employment of a country and a town life, and they exalt the entertainments and diversions of both. They are chiefly obtained by moderate and regular exercife.

Few are fo much raifed above want and dependence, or fo exempted from bufinefs and care, as not to be often expofed to inequalities and changes of diet, exercife, air, climate, and other irregularities. Now, what can be fo effectual to foee one againft the füch difficulties arising from fuch unavoidable alterations, as hardines, and a certain verfatility of conftitution which can bear extraordinary labours, and fubmit to great changes, without any feeble unifome or bad unfollows. This is best obtained, not by an over-great delicacy and minute attention to forms, or by an invariable regularity in diet, hours, and way of living, but rather by a bold and difcreet latitude of regimen. Besides, deviations from eftablifhed rules and forms of living, if kept within the bounds of fobriety and reafon, are friendly to thought and original fentiments, animate the dull scene of ordinary life and bufinefs, and agr-eably flir the paflions, which flagnate or breed ill-humour in the calms of life.

Neatnefs, cleanlinefs, and decency, to which we may add dignity of countenance, and demeanour, feem to have something refined and moral in them: at leaft we generally fee much in them indications of an orderly, gen-tele, and well-governed mind, confcientious of an inward worth, or the refpeft due to one's nature. Whereas naifnefs, florventinefs, awkwards, and indecency, are fhewed symptoms of fomething mean, carelefs, and deficient, and betray a mind untaught, illiberal, unconfcientious of what is due to one's felf or to others. How much cleanlinefs conduces to health, needs hardly to be mentioned; and how neceffary it is to maintain one's character and rank in life, and to render us agreeable to others as well as to ourfelves, is as evident as it is general. The firft are in themselves the moft easy, natural, and commodious, give one boldnefs and prefence of mind, a modeld allure, an defcern both awful and alluring; they beleaf candour and greatnefs of mind, raife the moft agreeable prejudices in one's favour, render fociety engaging, command refpeft, and often love, and give weight and authori-ty both in converfation and bufinefs; in fine, they are the colouring of virtue, which fhow it to the greatest advantage in whomfoever it is; and not only imitate, but in some measure supply it where it is wanting. Whereas the laft, viz. rudenefs, effetution, indecorum, and the like, have all the contrary effects; they are burdenome to one's felf, a difhonneur to our nature, and are certainly obnoxious. The former qualifications of goods are fettled by a liberal defcription, by preferring a juft fenfe of the dignity of our nature, by keeping the bold and polite company, but, above all, by acquiring thofe virtuous and ennobling habits which become the human countenance and form, in which we receive a cominges, openneas, fimplicity, graces andiffins; and there are others, which to our fene of decorum appear uncomely, affected, difjunguens, and awkward, quite unfuitable to the native dignity of our face and form. The firft are in themselves the moft easy, natural, and commodious, give one boldnefs and prefence of mind, a modeld allure, an defcern both awful and alluring; they beleaf candour and greatnefs of mind, raife the moft agreeable prejudices in one's favour, render fociety engaging, command refpeft, and often love, and give weight and author-ty both in converfation and bufinefs; in fine, they are the colouring of virtue, which fhow it to the greatest advantage in whomfoever it is; and not only imitate, but in some measure supply it where it is wanting. Whereas the laft, viz. rudenefs, effetution, indecorum, and the like, have all the contrary effects; they are burdenome to one's felf, a difhonneur to our nature, and are certainly obnoxious. The former qualifications of goods are fettled by a liberal defcription, by preferring a juft fenfe of the dignity of our nature, by keeping the bold and polite company, but, above all, by acquiring thofe virtuous and ennobling habits which become the human countenance and form, in which we receive a cominges, openneas, fimplicity, graces andiffins; and there are others, which to our fene of decorum appear uncomely, affected, difjunguens, and awkward, quite unfuitable to the native dignity of our face and form. The firft are in themselves the moft easy, natural, and commodious, give one boldnefs and prefence of mind, a modeld allure, an defcern both awful and alluring; they beleaf candour and greatnefs of mind, raife the moft agreeable prejudices in one's favour, render fociety engaging, command refpeft, and often love, and give weight and author-ty both in converfation and bufinefs; in fine, they are the colouring of virtue, which fhow it to the greatest advantage in whomfoever it is; and not only imitate, but in some measure supply it where it is wanting. Whereas the laft, viz. rudenefs, effetution, indecorum, and the like, have all the contrary effects; they are burdenome to one's felf, a difhonneur to our nature, and are certainly obnoxious. The firft are in themselves the moft easy, natural, and commodious, give one boldnefs and prefence of mind, a modeld allure, an defcern both awful and alluring; they beleaf candour and greatnefs of mind, raize the moft agreeable prejudices in one's favour, render fociety engaging, command refpeft, and often love, and give weight and authority both in converfation and bufinefs; in fine, they are the colouring of virtue, which fhow it to the greatest advantage in whomfoever it is; and not only imitate, but in some measure supply it where it is wanting. Whereas the laft, viz. rudenefs, effetution, indecorum, and the like, have all the contrary effects; they are burdenome to one's felf, a difhonneur to our nature, and are certainly obnoxious. The former qualifications of goods are fettled by a liberal defcription, by preferring a juft fenfe of the dignity of our nature, by keeping the bold and polite company, but, above all, by acquiring thofe virtuous and ennobling habits which become the human countenance and form, in which we receive a cominges, openneas, fimplicity, graces andiffins; and there are others, which to our fene of decorum appear uncomely, affected, difjunguens, and awkward, quite unfuitable to the native dignity of our face and form. The firft are in themselves the moft easy, natural, and commodious, give one boldnefs and prefence of mind, a modeld allure, an defcern both awful and alluring; they beleaf candour and greatnefs of mind, raize the moft agreeable prejudices in one's favour, render fociety engaging, command refpeft, and often love, and give weight and authority both in converfation and bufinefs; in fine, they are the colouring of virtue, which fhow it to the greatest advantage in whomfoever it is; and not only imitate, but in some measure supply it where it is wanting.
Part II. MORAL PHILOSOPHY.

Of Man's duty to Himself. of power, which, after securing one's self, i.e., having attained the proper independence and liberty of a rational social creature, is not directed to the good of others, is what we call ambition, or the lust of power. To what extent the frict measures of virtue will allow us to pursue either wealth or power, and civil authority, is not perhaps possible precisely to determine. That must be left to prudence, and the peculiar character, condition, and other circumstances of each m. Only thus far a limit may be set, that the pursuit of either must encroach upon no other duty or obligation which we owe to ourselves, to society, or to its parent and head. The fame reasoning is to be applied to power as to wealth. It is only valuable as an infringement of our own security, and of the free enjoyment of those original goods it may, and often does, administer to us, and as an engine of more extensive happiness to our friends, our country, and mankind.

Now the belt, and indeed the only way to obtain a How fame folded and lasting fame, is an uniform indefensible course and power are attainable.

Fortune, power, &c., whatever is called influence and weight among mankind, are goods of the second division, that is, valuable and pursuable only as they are useful, or as means to a farther end, viz. procuring or preferring the immediate objects of enjoyment or happiness to ourselves or others. Therefore love such goods on our own account, and to pursue them as ends, not the means of enjoyment, must be highly preposterous and absurd. There can be no measure, no limit, to such pursuit; all must be whim, caprice, extravagance. Accordingly such appetites, unlike all the natural ones, are increased by possession, and whetted by enjoyment. They are always precarious, and never without fears, because the objects lie without one's self; they are found without sorrow and vexation, because no accession of wealth or power can satisfy them. But if those goods are considered only as the materials or means of private or public happiness, then the fame obligations which bind us to pursue the latter, bind us likewise to pursue the former. We may, and no doubt we ought, to seek such a measure of wealth as is necessary to supply all our real wants, to raise above servile dependence, and provide us with such conveniences as are suited to our rank and condition in life. To be regardless of this measure of wealth, is to expose ourselves to all the temptations of poverty and corruption; to forfeit our natural independence and freedom; to degrade, and consequently to render the rank we hold, and the character we hold in society, valueless, if not contemptible. When these important ends are secured, we ought not to murmur or repine that we possess no more; yet we are not excluded by any obligation, moral or divine, from seeking more, in order to give us that happiness and most god-like of all powers, the power of doing good. A supine indolence in this respect is both absurd and criminal; avarice, as it robs us of an inexhaustible fund of the most refined and durable enjoyments; and criminal, as it renders us so far useless to the society to which we belong. "That pursuit of wealth which goes beyond the former end, viz. the obtaining the necessities, or such conveniences of life, as, in the estimation of reason, not of vanity or passion, are suited to our rank and condition, and yet is not directed to the latter, viz. the doing good, is what we call avarice." And "that pursuit

Avarice.
MORAL PHILOSOPHY.

Of Man's duty to Himself.

The pleasures they give.

Knowledge and taste.

Improving our intellectual powers, their immediate exercise on their proper objects yields the most rational and refined pleasures. Knowledge, and a right taste in the arts of imitation and design, as poetry, painting, sculpture, music, architecture, afford not only an innocent, but a most fertile and sublime entertainment. By these the understanding is instructed in ancient and modern life, the history of men and things, the energies and effects of passions, the consequences of virtue and vice; by these the imagination is at once entertained and nourished with the beauties of nature and art, lighted up and spread out with the novelty, grandeur, and harmony of the universe; and, in fine, the passions are agreeably roused, and suitably engaged, by the greatest and most interesting objects that can fill the human mind. He who has a taste formed to these ingenious delights, and plenty of materials to gratify it, can never want the most agreeable exercise and entertainment, nor once have reason to make that fashionable complaint of the tediousness of time. Nor can he want a proper subject for the discipline and improvement of his heart. For, being daily conversant with beauty, order, and design, in inferior subjects, he bids fair for growing in due time an admirer of what is fair and well proportioned in the conduct of life and the order of society, which is only order and design exerted in their highest subject. He will learn to transfer the numbers of poetry to the harmony of the mind and of well-weighed passions; and, from admiring the virtues of others in moral paintings, come to approve and imitate them himself. Therefore, to cultivate a true and correct taste must be both our interest and our duty, when the circumstances of our station give leisure and opportunity for it, and when the doing is not inconsistent with our higher obligations or engagements to society and mankind.

It is but attained by reading the best books, where good taste has more the ascendancy than learning, and which contain more to practice than to speculation; by studying the best models, i.e., those which profess to imitate nature most, and approach the nearest to it, and by conversing with men of the most refined taste, and the greatest experience in life.

As to the other intellectual goods, what a fund of entertainment must it be to investigate the truth and various relations of things, to trace the operations of nature to general laws, to explain by these its manifold phenomena, to understand that order by which the universe is upheld, and that economy by which it is governed! to be acquainted with the human mind, the connections, subordinations, and uses of its powers, and to mark their energy in life! how agreeable to the ingenious inquirer, to observe the manifold relations and combinations of individual minds in society, to distinguish the causes why they flourish or decay, and from thence to ascend, through the vast scale of beings, to that general mind which pervades over all, and operates unseen in every system and in every age, through the whole compass and progression of nature! Devoted to such entertainments as these, the contemplative have abandoned every other pleasure, retired from the body, to speak, and quelled themselves from social intercourse; for these, the luxury have often preferred to the hurry and din of life the calm retreats of contemplation; for these, when once they came to take them, even the gay and voluptuous have thrown up the labors pursuits of sense and appetite, and acknowledged their mental enjoyments to be the most refined, and indeed the only luxury. Besides, by a just and large knowledge of nature, we recognize the perfections of its author; and thus piety, and all those pious affections which depend on just sentiments of his character, are awakened and confirmed; and a thousand superstitious fears, that arise from partial views of his nature and works, will of course be excluded. An extensive prospect of human life, and of the periods and revolutions of human things, will conduct much to the giving a certain greatness of mind, and a noble contempt to those little competitions about power, honour, and wealth, which disturb and divide the bulk of mankind; and promote a calm endurance of those inconveniences and ills that are the common appendages of humanity. Add to all, that a just knowledge of human nature, and of those hinges upon which the fates and fortunes of men turn, will prevent our thinking either too highly or too meanly of our fellow creatures. Give not, then, scope to the exercise of friendship, confidence, and good will, at the same time brace the mind with a proper care and distrust (those nerves of prudence), and give a greater mystery in the conduct of private as well as public life. Therefore, by cultivating our intellectual abilities, we shall best promote and secure our interest, and be qualified for acting our part in society with more honour to ourselves, as well as advantage to mankind. Consequently, to improve them to the utmost of our power is our duty; they are talents committed to us by the Almighty Head of society, and we are accountable to him for the use of them.

The intellectual virtues are best improved by accurate and impartial observation, extensive reading, and tuned unconfinned converse with men of all characters, especially with those who, to private study, have joined the widest acquaintance with the world, and greatest practice in affairs; but, above all, by being much in the world, and having large dealings with mankind. Such opportunities contribute much to direct one of prejudices and a servile attachment to crude systems, to open one's views, and to give that experience on which the most useful because the most practical knowledge is built, and from which the surest maxims for the conduct of life are deduced.

The highest goods which enter into the composition of human happiness are moral goods of the mind, directly and ultimately regarding ourselves; as command of the affections and passions; prudence and caution, magnanimity, fortitude, humility, love of virtue, love of God, renunciation, and the like. These sublime goods are goods by way of eminence, goods recommended and enforced by the most intimate and awful (sense and conscientious of our nature; goods that constitute the quintessence, the very temper of happiness, that form and completion of our soul which renders us approvable and lovely in the sight of God; goods, in short, which are the elements of all our future perfection and felicity.

Most of the other goods we have considered depend their morality on ourselves, and partly on accidents which we meet. can neither foresee nor prevent, and result from causes which we cannot influence or alter. They are such goods as we may possess to-day and lose to-morrow, and
of man's duty to himself.

Of Man's duty to Himself.

and which require a felicity of constitution, and talents to attain them in full vigour and perfection, and a felicity of conjunctions to secure the possession of them. Therefore, did our happiness depend altogether or chiefly on such transient and precarious possessions, it was itself most precarious, and the highest folly to be anxious about it.—But though creatures, constituted as we are, cannot be indifferent about such goods and multy suffer in some degree, and consequently have our happiness incomplete without them, yet they weigh but little in the scale when compared with moral good. By the benevolent constitution of our nature, these are placed within the sphere of our activity, so that no man can be delirious of them unless he is first wanting to himself. Some of the widest and best of mankind have wanted most of the former goods, and all the external kind, and felt most of the opposite ills, such at least as arise from without; yet by polishing the latter, i.e. the moral goods, have declared they were happy; and to the conviction of the most impartial observers have appeared happy. The world of men have been surrounded with every outward good and advantage of fortune, and have pleased great parts; yet, for want of moral rectitude, have been and have confounded themselves, notoriously and exquisitely miserable. The exercise of virtue has supported its votaries, and made them exult in the largest share of its goods. There are particularly three virtues which go to the establishment of mankind, and the just displeasure of Almighty God.

Fortitude is that calm and steady habit of mind which either moderates our fears, and enables us bravely to encounter the prospect of ill, or renders the mind serene and invincible under its immediate pressure. It lies equally distant from rashness and cowardice; and though it does not hinder us from feeling, yet prevents our complaining or thinking under the stroke. It always includes a generous contempt of, or at least a noble superiority to, those precarious goods of which we can injure neither the possession nor continuance. The man therefore who possesseth this virtue in this ample sense of it, stands upon an eminence, and sees human things below him; the tempest indeed may reach him, but he stands secure and collected against it upon the baits of conscious virtue, which the fevered storms can seldom shake, and never overthrow.

Humility is another virtue of high rank and dignity, though often mistaken by proud mortals for meanness and pufillanimity. It is opposed to pride, which commonly includes in it a false or over-rated estimation of our own merit, an ascription of it to ourselves, as its only and original cause, an unwise comparison of ourselves with others, and in consequence of that supposed superiority, an arrogant preference of ourselves, and a supercilious contempt of them. Humility, on the other hand, seems to denote that modest and ingenuous temper of mind, which arises from a just and equal estimate of our own advantages compared with those of others, and from a sense of our deriving all originally from the Author of our being. Its ordinary attendants are meekness, a gentle forbearance, and an easy unassuming humanity with regard to the imperfections and faults of others; virtues rare indeed, but of the fairest complexion, the proper offspring of a lofty and pure parent, the best ornament of such imperfect creatures as we are, precious in the sight of God, and which sweetly allure the hearts of men.

Resignation is the mild and heroic temper of mind which arises from a sense of an infinitely wise and good providence, and enables one to acquiesce with a cordial affection in its just appointments. This virtue has something very particular in its nature, and sublime in its efficacy. For it teaches us to bear ill, not only with patience, and as being unavoidable, but it transforms, as it were, ill into good, by leading us to consider it, and every event that has the least appearance of ill, as a divine dispensation, a wife and benevolent temperament of things, sublunient to universal good, and of course including that of every individual, especially of such as calmly stoop to it. In this light, the administration itself, nay every act of it, becomes an object of affection, the evil disappears, or is converted into a balm which both heals and nourisheth the mind. For though the first unexpected access of ill may surprise the soul into grief, yet that grief, when the mind calmly reviews its object, changes into contentment, and is by degrees exalted into veneration and a divine compoence. Our private will is left in that of the Almighty, and our security against every real ill rests on the same bottom as the throne of him who lives and reigns for ever.

Before we finish this section, it may be fit to observe, Chiefly goods, that as the Deity is the supreme and inexhaustible object; source of good, on whom the happiness of the whole and formal creation
MORAL PHILOSOPHY.

Duties of Society.

Part II.

Of Man's Duty to Himself.

creation depends; as he is the highest object in nature, and the only object who is fully proportioned to the intellectual and moral powers of the mind, in whom they ultimately rest, and find their most perfect exercise and completion; he is therefore termed the Chief good of man, objectively considered. And virtue, or the proportioned and vigorous exercise of the several powers and affections on their respective objects, as above described, is, in the schools, termed the chief good, formally considered, or its formal idea, being the inward temper and native constitution of human happiness.

From the detail we have gone through, the following corollaries may be deduced.

First, It is evident, that the happiness of such a progressive creature as man can never be at a stand, or continue a fixed invariable thing. His finite nature, let it rise ever so high, admits still higher degrees of improvement and perfection. And his progression in improvement or virtue always makes way for a progression in happiness. So that no possible point can be assigned in any period of his existence in which he is perfectly happy, that is, so happy as to exclude higher degrees of happiness. All his perfection is only comparative. 2. It appears that many things must conspire to complete the happiness of so various a creature as man, subject to so many wants, and susceptible of such different pleasures. 3. As his capacities of pleasure cannot be all gratified at the same time, and must often interfere with each other in such a precarious and fleeting state as human life, or be frequently disappointed, perfect happiness, i. e. the uninterfered enjoyment of the several pleasures of which he is capable, is an unattainable in our present state. 4. That state is most to be fought after, in which the fewest competitions and disappointments can happen, which least of all impair any sense of pleasure, and opens an inexhausted source of the most refined and lasting enjoyments. 5. That state which is attended with all those advantages, is a state of course of virtue. 6. Therefore, a state of virtue, in which the moral goods of the mind are attained, is the happiest state.

Chapter III. Duties of Society.

Section I. Filial and Fraternal Duty.

As we have followed the order of nature in tracing the history of man, and those duties which he owes to himself, it seems reasonable to take the same method with those he owes to society, which constitute the second class of his obligations.

His parents are among the earliest objects of his attention; he becomes sooner acquainted with them, repels a peculiar confidence in them, and seems to regard them with a fond affection, the early propinquities of his future piety and gratitude. Thus does nature dictate the first lines of filial duty, even before a just sense of the connection is formed. But when the child is grown up, and has attained to such a degree of understanding, as to comprehend the moral tie, and be sensible of the obligations he is under to his parents: when he looks back on their tender and disinterested affection, their incessant cares and labours in nursing, educating, and providing for him, during that state in which he had neither prudence nor strength to care and provide for himself, he must be conscious that he owes to them these peculiar duties.

1. To reverence and honour them, as the instruments of nature in introducing him to life, and to that state of comfort and happiness which he enjoys; and therefore to esteem and imitate their good qualities, to alleviate and bear with, and spread, as much as possible a decent veil over their faults and weaknesses.

2. To be highly grateful to them, for those favours which it can hardly ever be in his power fully to repay: to show this gratitude by a strict attention to their wants, and a solicitous care to supply them; by a submissive deference to their authority and advice, especially by paying great regard to in the choice of a wife, and of an occupation; by yielding to, rather than peevishly contending with, their humours, as remembering how oft they have been persecuted by his; and, in fine, by footage their cares, lightening their sorrows, supporting the infirmities of age, and making the remainder of their life as comfortable and joyful as possible.

As his brethren and sisters are the next with whom the creature forms a social and moral connection, to brethren he owes a fraternal regard; and with them and sisters, he ought he to enter into a strict league of friendship, mutual sympathy, advice, assistance, and a generous intercourse of kind offices, remembering their relation to common parents, and that brotherhood of nature which unites them into a closer community of interest and affection.

Section II. Concerning Marriage.

When man arrives to a certain age, he becomes connected by a peculiar sympathy and tenderness towards the other sex: the charms of beauty engage his attention, and call forth new and softer dispositions than he has yet felt. The many amiable qualities exhibited by a fair outside, or by the mild allurement of female manners, or which the prejudiced spectator without much reasoning supposes those to include, with several other circumstances both natural and accidental, point his view and affection to a particular object, and of course contrive that general rambling regard, which was lost and useles among the undistinguished crowd, into a peculiar and permanent attachment to one woman, which ordinarily terminates in the most important, venerable, and delightful connections in life.

The state of the brute creation is very different from that of human creatures. The former are clothed with the grounds of this connection, which is generally armed by their structure, easily finds what is necessary to their subsistence, and soon attains their vigour and maturity; so that they need the care and aid of their parents but for a short while; and therefore we see that nature has assigned to them vagrant and transient amours. The connection being purely natural, and merely for propagating and rearing their offspring, no sooner is that end answered, than the connection dissolves of course. But the human race are of a more tender and defenceless constitution; their infancy and non-age continue longer; they advance slowly to strength of body and maturity of reason; they need constant attention, and a long series of cares and labours, to train them up to decency, virtue, and the various arts of life. Nature has, there-
Moral Philosophy.

Duties of Society.

134 Moral ends of marriage.

The mind is apt to be dissipated in its views and acts of friendship and humanity; unless the former be directed to a particular object, and the latter employed in a particular province. When men once indulge in this dissipation, there is no stopping their career; they grow insensible to moral attractions; and, by obstructing or impairing the decent and regular exercise of the tender and generous feelings of the human heart, they in time become unqualified for, or averse to, the forming a moral union of souls, which is the cement of society, and the source of the purest domestic joys. Whereas a rational, undepraved love, and its fair companion, marriage, collect a man's views, guide his heart to its proper object, and, by confining his affection to that object, do really enlarge its influence and use. Besides, it is but too evident from the conduct of mankind, that the common ties of humanity are too feeble to engage and interest the passions of the generality in the affairs of society. The connections of neighbourhood, acquaintance and general intercourse, are too wide a field of action for many, and those of a public or community are so for more; and in which they either care not, or know not how to exert themselves. Therefore nature, ever wise and benevolent, by implanting that strong sympathy which reigns between the individuals of each sex, and by urging them to form a particular moral connection, the union of many domestic endearments has measured out to each pair a particular share of action, proportioned to their views, and adapted to their respective capacities. Besides, by interlocking them deeply in the concerns of their own little circle, she has connected them more closely with society, which is composed of particular families, and bound them down to their good behaviour in that particular community to which they belong. This moral connection is marriage, and this share of action is a family.

2. A con spiration of councils and endeavours to promote the common interest of the family, and to educate their common offspring. In order to observe these laws, it is necessary to cultivate, both before and during the married state, the finest decency and chaste of manner; and, a just sense of what becomes their respective characters.

3. The union must be inviolable, and for life. The nature of friendship, and particularly of this species of it, the education of their offspring, and the order of society and of successions, which would otherwise be extremely perplexed, do all seem to require it. To preserve this union, and render the matrimonial state more harmonious and comfortable, a mutual esteem and tenderness, a mutual deference and forbearance, a communication of advice, and assistance and authority, are absolutely necessary. If either party keep within their proper departures, there need be no disputes about power or superiority, and there will be none. They have no separate, no separate interests, and therefore there can be no just ground for opposition of conduct.

From this detail, and the present state of things, in Polygamy, which there is pretty near a parity of numbers of both sexes, it is evident that polygamy is an unnatural state; and though it should be granted to be more fruitful of children, which however, it is not found to be, yet it is by no means so fit for rearing minds, which seems to be so much, if not more, the intention of nature than the propagation of bodies.

Sect. III. Of Parental Duty.

The connection of parents with their children is a natural consequence of the matrimonial connection, and the duties which they owe them result as naturally from that connection. The noble state of children, subject to so many wants and dangers, requires their incessant care and attention; their ignorant and uncultivated minds demand their continual instruction and culture. Had human creatures come into the world with the full strength of men, and the weakness of reason and reasoning of parents which prevail in children, they would have been too strong or too stubborn to have submitted to the government and indulgence of their parents. But as they were destitute of a progress in knowledge and virtue, it was proper that the growth of their bodies should keep pace with that of their minds, left the purposes of that propagation should have been defeated. Among other admirable purposes which this gradual expansion of their outward as well as inward structure serves, this is one, that it affords ample scope to the exercise of many tender and generous affections, which fill up the domestic life with a beautiful variety of duties and enjoyments; and are of course a noble discipline for the heart, and an hardy kind of education for the more honourable and important duties of public life.

The aforementioned weak and ignorant state of children seems plainly to invest their parents with such authority and power as is necessary to their support, protection, and education; but that authority and power can be continued to extend no farther than is necessary to answer those ends, and to last no longer than that weakness and ignorance continue; wherefore, the foundation or rod of the authority and power...
Moral Philosophy.

Part II.

Duties of Society.

139

Duties of parents.

The first class of duties which parents owe their children respect their natural life; and these comprehend protection, nurture, provision, introducing them into the world in a manner suitable to their rank and fortune, and the like.

The second order of duties regards the intellectual and moral life of their children, or their education in such arts and accomplishments as are necessary to qualify them for performing the duties they owe to themselves and to others. As this was found to be the principal design of the matrimonial alliance, so the fulfilling that design is the most important and dignified of all the parental duties. In order therefore to fit the child for acting his part wisely, and worthily as a servant, as a citizen, and a creature of God, both parents ought to combine their joint wisdom, authority, and power, and each party to employ those talents which are the peculiar excellency and ornament of their respective sex. The father ought to lay out and superintend their education, the mother to execute and manage the detail of which he is capable. The former should direct the manly exertion of the intellectual and moral powers of his child. His imagination, and the manner of those exertions, are the peculiar province of the latter. The former should advise, protect, command, and, by his experience, masculine vigour, and that superior authority which is commonly ascribed to his sex, brace and strengthen his pupil for active life, for gravity, integrity, and firmness in suffering. The business of the latter is to bend and soften her male pupil, by the charms of her conversation, and the softness and decency of her manners, for social life, for politeness of taste, and the elegant decorums and enjoyments of humanity; and to improve and refine the tenderness and modesty of her female pupil, and form her to all those mild domestic virtues which are the peculiar characteristiques and ornaments of her sex.

To conduct the opening minds of their sweet charge through the several periods of their progress, to afford them in each period, in throwing out the latent seeds of reason and ingenuity, and in gaining fresh acceptions of light and virtue; and at length, with all these advantages, to produce the young adventurers upon the great theatre of human life, to play their several parts in the sight of their friends, of society, and mankind!

Sect. IV. Herilie and Servile Duty.

In the natural course of human affairs, it must necessarily happen that some of mankind will live in plenty and opulence, and others be reduced to a state of indigence and poverty. The former need the labours of the latter and the latter provision and support

141

Hitherto we have considered only the domestic economical duties, because these are first in the progress of nature. But as man passes beyond the little circle of a family, he forms connections with relations, friends, neighbours, and others; from whence results a new

143

The condition of service.

144

With regard to captives taken in war, it is barbarous and inhuman to make perpetual slaves of them, unless some peculiar and aggravated circumstances of guilt have attended their hostility. The bulk of the subjects of any government engaged in war may be fairly esteemed innocent enemies; and therefore they have a right to that clemency which is consistent with the common safety of mankind, and the particular security of that society against which they are engaged. Though ordinary captives have a grant of their lives, yet to pay their liberty as an equivalent is much too high a price. There are other ways of acknowledging or returning the favour, than by renouncing what is far dearer than life itself. To those who, under pretence of the necessities of commerce, derive the unnatural trade of bargaining for human flesh, and confining their innocent but unfortunate fellow creatures to eternal servitude and misery, we may address the words of a fine writer; "Let avarice defend it as it will, there is an honest reluctance in humanity against buying and selling, and regarding those of our own species as our wealth and possessions."
Moral Philosophy.

Duties of Society.

A new train of duties of the more private social kind, as "friendship, chivalry, courtesy, good-natured kindness, charity, forgiveness, hospitality."

Man is admirably formed for particular social attachments and duties. There is a peculiar and strong propensity in his nature to be affected with the sentiments and dispositions of others. Men, like certain musical instruments, are fit to each other, so that the vibrations or notes excited in one rattle correspondent notes and vibrations in the other. The impulses of pleasure or pain, joy or sorrow, made on one mind, are by an instantaneous sympathy of nature communicated in some degree to all; especially when hearts are (as an humane writer expresses it) in unison of kindreds; the joy that vibrates in one communicates to the other also. We may add, that though joy thus imparted swells the harmony, yet grief vibrated to the heart of one affects the heart of another. We may add, that though joy thus imparted swells the harmony, yet grief vibrated to the heart of another, they increase and multiply prodigiously. There is a most moving eloquence in the human countenance, air, voice, and gesture, wonderfully expressive of the most latent feelings and passions of the soul, which darts them like a subtle flame into the hearts of others, and rakes correspondent feelings there: friendship, love, good-humour, joy, spread through every feature, and particularly from the eyes their softer and fiercer fires with an irresistible energy. And in like manner the opposite passions of hatred, enmity, ill humour, melancholy, diffuse a fullen and faddening air over the face, and, flashing from eye to eye, kindle a train of similar passions. By these, and other admirable pieces of machinery, men are formed for society and the delightful interchange of friendly sentiments and duties, to increase the happiness of others by participation, and their own by reound; and to diminish, by dividing, the common stock of their misery.

The first emanations of the social principle beyond the bounds of a family lead us to form a nearer conjunction of friendship or good-will with those who are any wise connected with us by blood or domestic alliance. To them our affection does commonly exert itself in a greater or less degree, according to the nearness or distance of the relation. And this proportion is admirably fitted to the extent of our powers and the indigence of our state; for it is only within those closer circles of connubialty or alliance that the generality of mankind are able to display their abilities or benevolence, and consequently to uphold their connection with society and subferviency, to a public interdict. Therefore it is our duty to regard these closer connections as the next department to that of a family, in which nature has marked out for us a sphere of activity and usefulness; and to cultivate the kind affections which are the cement of those engaging alliances.

Frequently the view of distinguishing moral qualities in some of our acquaintance may give birth to that more noble connection we call friendship, which is far superior to the alliances of connubialty. For there are of a superficial, and often of a transitory nature, of which, as they hold more of infirmity than of reason, we cannot give such a rational account. But friendship derives all its strength and beauty, and the only existence which is durable, from the qualities of the heart, or from virtues and lovely dispositions. Or, should there be wanting, they or some shadow of them must be supposed present. Therefore friendship may be defined to be, "The union of two souls by means of virtue, the common object of the mutual affection." Without virtue, or the supposition of it, friendship is only a servile league, an alliance of interest, which must dissolve of course when that interest decays or subsides no longer. It is not to much any particular passion, as a composition of some of the noblest feelings and passions of the mind. Good friends, a just taste and love of virtue, a thorough candor and benevolence of heart, or what we usually call a good temper, and a generous sympathy of sentiments and affections, are the necessary ingredients of this virtuous connection. When it is grafted on esteem strengthened by habit, and mellowed by time, it yields infinite pleasure, ever new and ever growing; is a noble support amidst the various trials and vicissitudes of life, and an high felicity to most of our other enjoyments.

To form and cultivate virtuous friendship, must be very improving to the temper, as its principal object is virtue, let off with all the allurement of countenance, air, and manners, shining forth in the native graces of manly honor, sentiments and affections, and rendered visible as it were to the friendly spectator as a conduct unaffectedly great and good; and as its principal exercises are the very energies of virtue, or its effect and emanations. So that wherever this amiable attachment prevails, it will extol our admiration and attachment to virtue, and, unless imputed in its course by unnatural prejudices, run out into a friendship to the human race. For as no one can merit, and none ought to usurp the sacred name of friend, who hates mankind; so whoever truly loves them, poises the most essential quality of a true friend.

The duties of friendship are a mutual esteem of each other, unbiirded by interest, and independent of it, a generous confidence as far distant from suspicion as from reserve, an inviolable harmony of sentiments and dispositions of deeds and interests, a fidelity unbroken by the changes of fortune, a constancy unalterable by the distance of time or place, a resignation of one's personal interest to those of one's friend, and a reciprocal, unequivocal, unreserved exchange of kind offices. But, amidst all the exertions of this moral connection, humane and generous as it is, we must remember that it operates within a narrow sphere, and its immediate operations respect only the individual; and therefore its particular impulses must still be subordinate to a more public interest, or be always directed and controlled by the more extensive connections of our nature.

When our friendship terminates on any of the other Love and sex, in whom beauty or agreeableness of perfon and beauty, external gracefulness of manners conspire to express and heighten the moral charm of a tender honet heart, and sweet, ingenious, modest temper, lighted up by good sense; it generally grows into a more soft and endearing attachment. When this attachment is improved...
DUTIES OF SOCIETY.

See Sect. ii. of this chap.

proved by a growing acquaintance with the worth of its object, is conducted by discretion, and issues at length, as it ought to do, in the moral connection formerly mentioned, it becomes the source of many amiable duties, of a communication of passions and interests, of the most refined decencies, and of a thousand nameless deep-felt joys of reciprocal tenderness and love, flowing from every look, word, and action. Here friendship acts with double energy, and the natural conspires with the moral charms to strengthen and secure the love of virtue. As the delicate nature of female honour and decorum, and the inexpressible grace of a chaste and moral conduct is, of the reverence due to mankind, our duty, and the infinite love, flowing from every look, word, and action, of the woman's sex and the scorn of ours, and to the amiable duties, of a communication of love into her own sex and the scorn of ours, and to the amiable duties, of a communication of love into every look, word, and action.

This inferior order of virtues is wanting. So seduced by its own sex and the scorn of ours, and to the amiable duties, of a communication of love into every look, word, and action, of the public, does not require a proportionable retaliation, it is agreeable to the general law of benevolence, and to the particular end of the passion (which is to prevent injury and the misery occasioned by it), to forgive personal injuries, or not to return evil for evil. This duty is one of the noble refinements which Christianity has made upon the general maxims and practice of mankind, and enforced, with a peculiar strength and beauty, by sanctions no less alluring than awful. And indeed the practice of it is generally its own reward; by expelling from the mind the most dreadful intruders upon its repose, those rancorous passions which are begot and nurtured by resentment, and by disarming and even subduing every enemy one has, except such as have nothing left of men but the outward form.

The most enlarged and humane connection of the Hospital private kind seems to be the hospitable alliance, from which all the amiable and disinterested duties we owe to strangers. If the exercise of passions of the most private and infinitive kind is beheld with moral approbation and delight, how lovely and venerable must those appear which result from a calm philanthropy, are founded in the common rights and connection of society, and embrace men, not of a particular sex, party, or nation, but all in general without distinction, and without any of the little partialities of self-love.

**MORAL PHILOSOPHY.**

**Duties of Society.**

**Sect. VI. Social duties of the Commercial kind.**

The next order of connections are those which arise from the ways and weaknesses of mankind, and from the various situations in which their different situations place them. These we may call commercial connections, and the duties which result from them commercial duties, as justice, fair-dealing, sincerity, fidelity to compact, and the like.

Though nature is perfect in all her works, yet she has observed a manifest and eminent difficulty among them. To all such as lie beyond the reach of human skill and power, and are properly of her own department, she has given the finishing hand. These man may design after and imitate, but he can never rival them, nor add to their beauty or perfection. Such are the forms and structure of vegetables, animals, and many of their productions, as the honey-comb and the spider’s web, and the like. There are others of her works which she has of design left unfinished, as it were, in order to exercise the ingenuity and power of man. She has presented him a rich profusion of materials of every kind for his convenience and use; but they are rude and unpolished, or not to be come at without art and labour. Therefore he must apply, in order to adapt them to his use, and to enjoy them in perfection. Thus nature has given him an infinite variety of herbs, grain, fruits, mineral, wood, water, earth, air, and a thousand other crude materials, to supply his numerous wants. But he must flow, plant, dig, refine, polish, build, and, in short, manufacture the various productions of nature, in order to obtain even the necessaries, and much more the conveniences and elegancies of life. These then are the price of his labour and industry, and, without that, nature will sell him nothing. But as the wants of mankind are many, and the single strength of individuals small, they could hardly find the conveniences and elegancies of life, without uniting their ingenuity and strength in acquiring these, and without mutual intercourse of good offices. Some men are better formed for some kinds of ingenuity and labour, and others for other kinds; and different soils and climates are enriched with different productions, that men, by exchanging the produce of their respective labours, and supplying the wants of one another with the superfluities of another, do in effect diminish the labours of each, and increase the abundance of all. This is the foundation of all commerce, or exchange of commodities and goods, one with another; in order to facilitate which, man have contrived different species of coin, or money, as a common standard by which to estimate the comparative values of their respective goods. But to render commerce sure and effectual, justice, fair-dealing, sincerity, and fidelity to compact, are absolutely necessary.

Justice or fair-dealing, or, in other words, a disposition to treat others as we would be treated by them, is a virtue of the first importance, and indispensable from the virtuous character. It is the cement of society, or that pervading spirit which connects its members, inspires its various relations, and maintains the order and subordination of each part to the whole. Without it, society would become a den of thieves and banditti, hating and hated, devouring and devoured, by one another.

And here it may be proper to take a view of Mr. Hume’s suppos’d case of the sensible knave and the worthless miser (§ 16). and consider what would be the duty of the former according to the theory of those moralists who hold the will of God to be the criterion or rule, and everlasting happiness the motive of human virtue.

It has been already observed, and the truth of the observation cannot be controverted, that by secretly purloining from the coffers of a miser part of that gold which there lies useless, a man might in particular circumstances, promote the good of society, or that perpetual happiness which to himself would be the criterion or standard of justice. Very different, however, is the conclusion which must be drawn by those who consider the natural tendency of actions, if universally performed, as the criterion of their merit or demerit in the sight of God. Such philosophers attend not to the particular consequences of a single action in any given case, but to the general consequences of the principle from which it flows, if that principle were universally adopted. You cannot (say they) permit one action and forbid another, without flowing a difference between them. The same fort of actions, therefore, must be generally permitted or generally forbidden. But were every man allowed to act for himself the circumstances in which the good of society would be promoted, by secretly abetting the superfluous wealth of a worthless miser, it is plain that no property could be safe; that all incitements to industry would be at once removed; and that whatever might be the immediate consequences of any particular thefts, the general and necessary consequences of the principle by which it was authorized must soon prove fatal. Were one man to purloin part of the riches of a real miser, and to consider his conduct as vindicated by his intention to employ those riches in acts of generosity, another might by the same fort of casuistry think himself authorized to appropriate to himself part of his wealth; and thus theft would spread through all orders of men, till society would be dissolved in separate, hostile, and fugitive families, mutually dreading and shunning each other. The general consequences, therefore, of encroaching upon private property tend evidently and violently to universal misery.

On the other hand, indeed, the particular and immediate consequences of that principle which considers every man’s property as sacred, may in some cases, such as that supposed, be in a small degree injurious to a few families in the neighbourhood of the miser and the knave. But that injury can never be of long duration; and it is infinitely more than counterbalanced by the general good consequences of the principle from which it accidentally results; for these consequences extend to all nations and to all ages. Without a sacred regard to property, there could neither be arts nor industry nor confidence among men, and happiness would for ever vanish from this world. But the communication of happiness being the end which...
MORAL PHILOSOPHY.

Duties of Society.

which God had in view when he created the world, and all men standing in the same relation to him, it is impossible to suppose that he does not approve, and will not ultimately reward, those voluntary actions of which the natural tendency is to increase the sum of human happiness; or that he does not disapprove, and will not ultimately punish, those which naturally tend to aggravate human misery. The conclusion is, that a strict adherence to the principle of justice is universally, and in all possible circumstances, a duty from which we cannot deviate without offending our Creator, and ultimately bringing misery upon ourselves.

Sincerity, or veracity, in our words and actions, is another virtue or duty of great importance to society, being one of the great bands of mutual intercourse, and the foundation of mutual trust. Without it, society would be the domination of mistrust, jealousy, and fraud, and conversation a traffic of lies and disimulation. It includes in it a conformity of our words with our sentiments, a correspondence between our actions and dispositions, a strict regard to truth, and an irreconcilable abhorrence of falsehood. It does not indeed require, that we expose our sentiments indiscriminately, or tell all the truth in every case; but certainly it does not, and cannot admit the least violation of truth or contradiction to our sentiments. For if these bounds are once passed, no possible limit can be assigned where the violation shall stop, and no pretence of private or public good can possibly counterbalance the ill consequences of such a violation.

Fidelity to promises, compacts, and engagements is likewise a duty of such importance to the security of commerce and interchange of benevolence among mankind, that society would soon grow intolerable without the strict observance of it. Hobbes and others who follow the same track, have taken a wonderful deal of pains to puzzle this subject, and to make all the virtues of this sort fort merely artificial, and not at all obligatory, antecedent to human conventions. No doubt compacts suppose people who make them: and promises persons to whom they are made: and therefore both suppose some society, more or less, between those who enter into these mutual engagements. But is it not a compact or promise binding, till men have agreed that they shall be binding? or are they only binding, because it is our interest to be bound by them or to fulfil them? Do not we highly approve the man who fulfils them, even though they should prove to be against his interest? and do not we condemn him as a knave who violates them on that account? A promise is a voluntary declaration by words, or by an act equally significant; of our resolution to do something in behalf of another, or for his service. When it is made, the person who makes it is by all suppos'd under an obligation to perform it. And he to whom it is made may demand the performance as his right. That perception of obligations is a simple idea, and is on the same footing as our other moral perceptions, which may be described by inferences, but cannot be defined. Whether we have a perception of such obligation quite distinct from the interest, either public or private, that may accompany the fulfilment of it must be referred to the conscience of every individual. And whether the mere sense of that obligation apart from its concomitant, is not a sufficient inducement or motive to keep one's promise, without having recourse to any selfish principle of our nature, must be likewise appealed to the conscience of every honest man.

It may, however, be not improper to remark, that in this, as in all other instances, our chief good is combined with our duty. "Men act from expectation. Expectation is in most cases determined by the affurances and engagements which we receive from others. If no dependence could be placed upon these assurances, it would be impossible to know what judgement to form of many future events, or how to regulate our conduct with respect to them. Confidence, therefore, in promises, is essential to the intercourse of human life, because without it the greatest part of our conduct would proceed upon chance. But there could be no confidence in promises, if men were not obliged to perform them." Tho' therefore, who allow not to the perceptions of the moral sense all that authority which we attribute to them, must still admit the obligation to perform promises; because such performance may be shown to be agreeable to the will of God, in the very same manner in which upon their principles we have shown the uniform practice of justice to be so.

Fair dealing and fidelity to compacts require that we take no advantage of the ignorance, passion, or incapacity of others, from whatever cause that incapacity arises;—that we be explicit and candid in making bargains, just and faithful in fulfilling our part of them. And if the other party violates his engagements, redress is to be sought from the laws, or from those who are intrusted with the execution of them. In fine, the commercial virtues and duties require that we only do not invade, but maintain the rights of others;—that we be fair and impartial in transferring, bartering, or exchanging property, whether in goods or service: and be inviolably faithful to our word and our engagements, where the matter of them is not criminal, and where they are not exerted by force. See Promise.

Sect. VII. Social Duties of the Political Kind.

We are now arrived at the last and highest order of duties respecting society, which result from the exercise of the most generous and heroic affections, and are founded on our most enlarged connections.

The social principle in man is of such an expansive nature, that it cannot be confined within the circuit of a family, of friends, or a neighbourhood; it spreads into wider systems, and draws men into larger confederacies, communities, and moral dominions. It is in those only that the higher powers of our nature attain the highest improvement and perfection of which they are capable. These principles hardly find objects in the solitary state of nature. There the principle of action rises no higher at first than natural affection towards one's offspring. There personal or family wants entirely engross the creature's attention and labour, and allow no leisure, or, if they did, no exercise for views and affections of a more enlarged kind. In so great all are employed in the same way, in providing for the animal life. And even after their utmost labour and care, single and unaided by the industry of others, they find but a forry supply of their wants, and a feeble precarious security against dangers from wild beasts; from inclement skies and fea-
Part II.

MORAL PHILOSOPHY.

Duties of Society.

From the mistakes or pertinacious passions of our fellow-creatures; from their preference of themselves to their neighbours; and from all the little circumstances of self-love. But in society, the mutual aids which men give and receive shorten the labours of each, and the combined strength of reason of individuals give security and protection to the whole body. There is both a variety and subordination of genius among mankind. Some are formed to lead and direct others, to contrive plans of happiness for individuals, their execution, and, in short, to refine and civilize human life. Others, who have not such good heads, may have as honest hearts, a truly public spirit, love of liberty, hatred of corruption and tyranny, a generous submission to laws, order, and public institutions, and an extensive philanthropy. And others, who have none of those capacities either of heart or head, may be well formed for manual exercises and bodily labour. The former of these principles has no scope in solitude, where a man's thoughts and concerns do all either centre in himself or extend no farther than a family; into which little circle all the duty and virtue of the solitary moral is crowded. But society finds proper objects and exercises for every genius, and the noblest objects and exercises for the noblest geniuses, and for the highest principles of the human constitution; particularly for that warmest and most sublime passion which God hath kindled in our bosoms, the inclination of doing good, and reverencing our nature; which may find here both employment and the most exquisite satisfaction. In society, a man has not only more leisure, but better opportunities, of applying his talents with much greater perfection and success, especially as he is furnished with the joint advice and assistance of his fellow creatures, who are now more closely united one with the other, and sustain a common relation to the same moral system or community. This then is an object proportioned to his most enlarged social affections; and in serving it he finds scope for the exercise and refinement of his highest intellectual and moral powers. Therefore society, or a state of civil government, rests on these two principal pillars. "That in it we find security against those evils which are unavoidable in solitude—and obtain those goods, some of which cannot be obtained at all, and others not so well, in that state where men depend solely on their individual fagacity and industry."

From this short detail it appears, that man is a social creature, and formed for a social state; and that society, being adapted to the highest principles and destinations of his nature, must of necessity be his natural state.

The duties suited to that state, and resulting from those principles and destination, or, in other words, from our social passions and social connections, or relation to a public system, are, love of our country, reformation, and obedience to the laws, public spirit, love of liberty, sacrifice of life and all to the public, and the like.

Love of our country, is one of the noblest passions that can warm and animate the human breast. It includes all the limited and particular affections to our parents, friends, neighbours, fellow-citizens, and countrymen. It ought to direct and limit their more confined and partial affections within their proper and natural bounds, and never let them encroach on those sacred and first regards we owe to the great public to which we belong. Were we solitary creatures, detached from the rest of mankind, and without any capacity of comprehending a public interest, or without affections leading us to desire and pursue it, it would not be our duty to mind it, nor criminal to neglect it. But as we are parts of the public system, and are not only capable of taking in large views of its interests, but by the strongest affections connected with it, and prompted to take a share of its concerns, we are under the most sacred ties to procure its security and welfare with the utmost ardour, especially in times of public trial. This love of our country does not import an attachment to any particular soil, climate or spot of earth, where perhaps we first drew our breath, though those natural ideas are often associated with the moral ones, and, like external signs or symbols, help to ascertain and bind them; but it imports an affection to that moral system, or community, which is governed by the same laws and magistrates, and whose several parts are variously connected one with the other, and all united upon the bottom of a common interest. Perhaps indeed every member of the community cannot comprehend so large an object, especially if it extends through large provinces, and over vast tracts of land; and still less can he form such an idea, if there is no public, i.e. if all are subject to the caprice and unlimited will of one man; but the preference the generality flow to their native country, the concern and longing after it which they express when they have been long absent from it; the labours they undertake and sufferings they endure to save or serve it, and the peculiar attachment they have to their countrymen, evidently demonstrate that the passion is natural, and never fails to exert itself when it is fairly engaged from foreign gloats; and is directed to its proper object. Wherever it prevails in its genuine vigour and extent, it swallows up all selfish and selfish regards; it conquers the love of ease, power, pleasures, and wealth; nay, when the amiable partialities of friendship, gratitude, private affection, or regards to a family, come in competition with it, it will teach us bravely to sacrifice all, in order to maintain the rights, and promote or defend the honour and happiness of our country.

Reformation and obedience to the laws and orders of government, to which we belong, are political duties and necessary to the very being of society, without which obedience it must soon degenerate into a state of licentiousness and anarchy. The welfare, nay, the nature of civil society, requires that there should be a subordination of orders, or diversity of rank and conditions in it;—that certain men, or orders of men, be appointed to superintend and manage such affairs as concern the public safety and happiness;—that all have their particular provinces assigned them,—that such a subordination be settled among them as none of them may interfere with another; and finally, that certain rules or common measures of action be agreed on, by which each is to discharge his respective duty to govern or be governed, and all may concour in securitg the order.
MORAL PHILOSOPHY.

Part II.

Duties of Society.

Public duties of every citizen.

A society thus constituted by common reafon, and formed on the plan of a common interest, becomes immediately an object of public attention, public veneration, public obedience, a public and inviolable attach- ment, which ought neither to be seduced by bribes, nor awed by terrors; an object, in fine, of all those extensive and important duties which arise from so glorious a confederacy. To watch over such a system; to contribute all he can to promote its good by his reason, his ingenuity, his strength, and every other ability, whether natural or acquired; to refist, and, to the utmost of his power, defeat every incoachment upon it, whether carried on by a secret corruption or open violence; and to sacrifice his ease, his wealth, his power, nay life itself; and, what is dearer still, his family and friends, to defend or save it, is the duty, the honour, the interest, and the happiness of every citizen; it will make him venerable and beloved while he lives, be lamented and honoured if he falls in so glorious a cause, and transmit his name with immortal renown to the lateft polterity.

As the people are the fountain of power and authority, the original feat of majesty, the authors of public laws, and the creators of officers to execute them; if they fhall find the power they have conferred abused by their trustees, they being majoly violated by tyranny or by usurpation, their authority prostituted to support violence or fome corruption, the laws grown pernicious through accidents unforefeen or unavoidable, or rendered ineffectual through the infidelity and corruption of the executors of them; then it is their right, and what is their right is their duty, to fubmit that delegated power, and call their trustees to an account; to refi, the usurpation, and extirpate the tyranny; to reftore their fullied majesty and proftituted authority; to fuspend, alter, or abrogate those laws, and punish their unfaithful and corrupt officers. Nor is it the duty only of the united body; but every member of it ought, according to his refpective rank, power, and weight in the community, to concur in advancing and supporting these glorious defigns.

Refiflence, therefore, being undoubtedly lawful in extraordinary emergencies, the question, among good reafoners, can only be with regard to the degree of neceflity which can justify refi, and render it expedient or commendable. And here we must acknowledge, that, with Mr Hume, "we fhall always incline to their fide that draw the bond of allegiance vol. 1. very clofe, and who confider an infringement of it as the laft refuge in desperate cafes, when the public is in the highest danger from violence and tyranny. For besides the mischiefs of a civil war, which commonly attends insurrection, it is certain, that where a defi- nation to rebellion appears among any people, it is one chief caufe of tyranny in the rulers, and forces them into many violent measures, which, had they been accompanied with fubmiffion and obedience, they would never have embraced. Thus the tyrannicide, or allaughter approved of by ancient maxims, instead of keeping tyrants and usurpers in awe, made them ten times more fierce and unrelenting; and is now juftly abolished on that account by the laws of nations, and universally condemned as a base and treacherous method of bringing to juftice those disturbers of society."

CHAP. IV. Duty to God.

Of all the relations which the human mind sustains, Divine con- that which fubsifts between the Creator and his crea- tures.
MORAL PHILOSOPHY.

Duty to God.

169 Existence of God.

It does not appear, from any true history or experience of the mind's progress, that any man, by any formal deduction of his discursive power, ever reasoned himself into the belief of a God. Whether such a belief is only some natural inclination of soul, or is derived from father to son, and from one man to another, in the way of tradition, is or is suggested to us in conformity of an immutable law of our nature, on holding the auglilt aspect and beautiful order of the universe, we will not pretend to determine. What seems most agreeable to experience is, that a sense of beauty and grandeur, and the admirable force of one thing to another, in its vast appearance, leads the mind necessarily and unavoidably to a perception of a design, or of a designing cause, the origin of all, by a progressive as simple and natural as that by which a beautiful picture or a fine building suggests to us the idea of an excellent artist. For it seems to hold universally true, that whenever we discern a tendency or co-operation of things towards a certain end, or producing a common effect, there, by a necessary law of association, we apprehend design, a designing energy or cause. No matter whether the objects are natural or artificial, still that suggestion is unavoidable, and the connection between the effect and its adequate cause obstructs itself on the mind, and it requires no nice search or elaborate deduction of reason to trace or prove that connection. We are particularly satisfied of its truth in the subject before us by a kind of direct intuition; and we do not seem to attend to the maxim we learn in schools, "That there cannot be an infinite series of causes and effects producing and produced by one another." That maxim is familiar only to metaphysicians; but all men of sound understanding are led to believe the existence of a God. We are conscious of our existence, of thoughts, sentiments, and passion, and sensible withal that these came not of ourselves; therefore we immediately recognize a parent-mind, an original intelligence, from whom we borrowed those little portions of thought and activity. And while we not only feel kind affections in ourselves, and discover them in others, but likewise behold round us such a number and variety of creatures, endowed with natures nicely adjusted to their several stations and economies, supporting and supported by each other, and all sustained by a common order of things, and sharing different degrees of happiness according to their respective capacities, we are naturally and necessarily led up to the Father of such a numerous off-pring, the fountain of such widespread happiness. As we conceive this Being before all, above all, and greater than all, we naturally, and without reasoning, ascribe to him every kind of perfection, wisdom, power, and goodness without bounds, existing through all time, and pervading all space. We apply to him those glorious epithets of our Creator, Præparator, Benefactor, the supreme Lord and Lawgiver of the whole society of rational and intelligent creatures. Not only the imperfections and wants of our being and condition, but some of the noblest affections and affections of our minds, connect us with this great and universal nature. The mind, in its progress from object to object, from one character and prospect of beauty to another, finds some blemish or deficiency in each, and soon exhausts or grows weary and dissatisfied with its object; it sees no character of excellency among men equal to that pitch of esteem which it is capable of exerting; no object within the compass of human things adequate to the strength of its affection; nor can it stay any where in this self-expansive progress, or find repose after its highest flights, till it arrives at a Being of unbounded greatness and worth, on whom it may employ its sublimest powers without exhausting the subject, and give scope to the utmost force and fulness of its love without fatiety or disgust. So that the nature of this Being corresponds to the nature of man; nor can his intelligent and moral powers obtain their entire end, but on the supposition of such a Being, and without a real sympathy and communication with him. The native propensity of the mind to reverence whatever is great and wonderful in nature, finds a proper object of homage in him who spreads out the heavens and the earth, and who sustains and governs the whole of things. The admiration of beauty, the love of order, and the complacency we feel in goodnesses, must rise to the highest pitch, and attain the full vigour and joy of their operations, when they unite in him who is the fum and source of all perfection.

It is evident from the slightest survey of morals, immediately that how punctual ever one may be in performing the duties which result from our relations to mankind, yet to be quite deficient in performing those which arise from our relation to the Almighty, must argue a strange perversion of reason or depravity of heart. If imperfect degrees of worth attract our veneration, and if the want of it would imply an insensibility, or, which is worse, an aversion, to merit, what manner of affection or immorality of character must it be that is not affected with, and much more to be ill-affected to, a Being of superlatively worth! To love society, or particular members of it, and yet to have no sense of our connection with its Head, no affection to our common Parent and Benefactor; to be concerned about the approbation or censure of our fellow-creatures, and yet to feel nothing of this kind towards him who sees and weighs our actions with unerring wisdom and justice, and can fully reward or punish them, betrays equal madness and partiality of mind. It is plain, therefore, beyond all doubt, that we are not surprised at the great Father of all, in whom every lovely and adorable quality combines to inspire veneration and homage.

As it has been observed already, that our affections depend on our opinions of their objects, and generally keep pace with them, it must be of the highest importance, and seems to be among the first duties we owe to the Author of our being, to form the least imperfect, since we cannot form perfect, conceptions of his character and administration. For such conceptions, thoughly imbied, will render our religion rational, and our dispositions refined. If our opinions are diminutive and distorted, our religion will be super-

Duty to
God.

Part II.

nation, what dependence, what generous confidence, what hope in God and his all wise providence, must arise in the soul that is possest of such amiable views of him? All those exercises of piety, and above all a superlative esteem and love, are directed to God as to their natural, their ultimate, and indeed their only adequate object; and though the immense obligations we have received from him may excite in us more lively feelings of divine goodness than a general and abstractive contemplation of it, yet the affections of gratitude and love are of themselves the generous difinterested kind, not the result of self-interest, or views of reward. A perfect character, in which we always suppose infinite goodness, guided by unerring wisdom, and supported by almighty power, is the proper object of perfect love; which, as such, we are forcibly drawn to pursue and to aspire after. In the contemplation of the divine nature and attributes, we find at last what the ancient philosophers fought in vain, the SUPREME AND SOVEREIGN GOOD; from which all other goods arise, and in which they are all contained. The Deity therefore challenges our supreeme and sovereign love, a sentiment which, whatsoever indulges, must be confounded in the love of virtue, in the desire to imitate its all-perfect pattern, and in a cheerful security that all his great concerns, those of his friends and of the universe, shall be absolutely safe under the conduct of unerring wisdom and unbounded goodness. It is in his care and providence alone that we come short of the perfection and various blemishes of our own, as it is in his happiness of all, finds perfect serenity; a serenity neither ruffled by partial ill nor foured by private disappointment.

When we consider the unalloyed purity and absolute perfection of the divine nature, and reflect withal on the imperfection and various blemishes of our own, we must link, or be convinced we ought to link, into the deepest humility and prostration of soul before him who is so wonderfully great and holy. When, further, we call to mind what low and languid feelings we have of the divine presence and majesty, what his finibility of his fatherly and universal goodness, nay, what ungrateful returns we have made to it, how far we come short of the perfection of his law and the dignity of our own nature, how much we have indulged to the selfish passions, and how little to the benevolent ones; we must be conscious that it is our duty to repent of a temper and conduct so unworthy our nature and unbecoming our obligations to its Author, and to resolve and endeavour to act a better and better part for the future.

Nevertheless, from the character which his works exhibit of him, from those delays or alleviations of punishment which offenders often experience, and from the merciful tenor of his administration in many other instances, the sincere penitent may entertain good hopes that his Parent and Judge will not be solicitous or impatient to mark iniquity, but will be propitious and favourable to him, if he honestly endeavours to avoid his former practices, and forbode his former habits, and to live in a greater conformity to the divine will for the future. If any doubts or fears should still remain, how far it may be consistent with the rectitude and equity of the divine government to let his iniquities pass unpunished, yet he cannot think it unfruitful to his paternal clemency and wisdom to contrive a method of retrieving the penitent offender, that shall unite and reconcile the majesty and mercy of his government. If reason cannot of itself suggest such a scheme, it gives at least some ground to expect it. But though natural religion cannot let in moral light and assurance on fo interesting a subject, yet it will teach the humble thief to wait with great submission for any farther intimations it may please the supreme Governor to give of his will; to examine with candour and impartiality whatever evidence shall be proposed to him of a divine relation, whether that evidence is natural or supernatural; to embrace it with generation and cheerfulness, if the evidence is clear and convincing; and finally, if it bring to light any new relations or connections, natural religion will peruse its sincere votary faithfully to comply with the obligations, and perform the duties which result from those relations and connections. This is the simple, the completion of morality!

We must farther observe, that all those affections and motives, which we supposed to regard the Deity as their immense, primary, and absolute object, are vital energies of the soul, and consequently exert themselves into act, and, like all other energies, gain strength or greater activity by that exertion. It is the very life of our understanding, our affections, and our wills; it often inflates times, and by descendent and incommunicable acts, to contemplate and adore the great Original of our existence, the Parent of all beauty and of all good; to express our veneration and love by an awful and devout recognition of his perfections; and to evidence our gratitude by celebrating his goodness, and thankfully acknowledging all his benefits. It is likewise our duty, by proper exercises of sorrow and humiliation, to confess our ingratitude and folly; to signify our dependence on God, and our confidence in his goodness, by imploing his blessing and gracious concurrence in assiting the weaknesses and curing the corruptions of our nature; and finally, to tell forth the sense of his authority, and our faith in his government, by devoting ourselves to do his will, and resigning ourselves to his disposal. These duties are not therefore obligatory, because the Deity needs or can be profited by them; but as they are apparently decent and moral, suitable to the relations he sustains of our Creator, Benefactor, Legislator, and Judge; expressive of our state and obligations; and improving to our tempers, by making us more rational, social, god-like, and consequently more happy.

We have now considered Internal piety, or the External worship of the mind, that which is in spirit and in worship, truth; we shall conclude the section with a short account of that which is External. External worship is founded on the same principles as internal, and of as strict moral obligation. It is either private or public. Devotion that is inward, or purely intellectual, is too spiritual and abstractive an operation for the bulk of mankind. The operations of their minds, such especially as are employed on the most sublime, immaterial objects, must be assisted by their outward organs, or by some help from the imagination; otherwise they will soon be dispelled by sensible impressions, or grow tiresome if too long continued. Ideas are such fleeting things, that they must be fixed; and so fable, that they must be expressed and delineated, as it were, by sensible marks and images; otherwise we cannot...
MORAL PHILOSOPHY.

PART III.

Chapter I. Of Practical Ethics, or the Culture of the Mind.

We have now gone through a particular detail of the several duties we owe to ourselves, to society, and to God. In considering the first order of duties, we shall touch upon the methods of acquiring the different kinds of goods which we are led by nature to pursue; only we left the consideration of the method of acquiring the moral goods of the mind to a chapter by itself, because of its singular importance. This chapter then will contain a brief enumeration of the arts of acquiring virtuous habits, and of forming virtuous ones, as far as is consistent with the brevity of such a work: a subject of the utmost difficulty as well as importance in morals; to which, nevertheless, the least attention has been generally given by moral writers. This will properly follow a detail of duty, as it will direct us to such means or helps as are most necessary and conducive to the practice of it.

In the first part of this inquiry we traced the order in which the passions shoot up in the different periods of human life. That order is not accidental, or dependent on the caprice of men, or even the influence of custom and education, but arises from the original constitution and laws of our nature; of which this is one, viz. "That sensible objects make the first and strongest impressions on the mind." These, by means of our outward organs, being conveyed to the mind, become objects of its attention, on which it reflects when the outward objects are no longer present, or in other words, when the impressions upon the outward organs cease. These objects of the mind's reflection are called ideas or notions. Towards these, by another law of our nature, we are not altogether indifferent; because correspondent movements of desire or aversion, love or hatred, arise, according as the objects which they denote make an agreeable or disagreeable impression on our organs. These ideas and affections which we experience in the first period of life, we refer to the body, or to sense; and the taste which is formed towards them, we call a pleasure, or a merely natural taste; and the objects corresponding to them we in general call good or pleasant.

But as the mind moves forward in its course, it extends its views, and receives a new and more complex set of ideas, in which it observes uniformity, variety, similarity, symmetry of parts, reference to an end, novelty, grandeur. These compose a vast train and diversity of imagery, which the mind compounds, divides, and moulds into a thousand forms, in the absence of those objects which first introduced it. And this more complicated imagery fuses a new train of desires and affections, full as spiritedly and engaging as any which have yet appeared. This whole class of perceptions or impressions is referred to the imagination, and forms an higher taste than the sensible, and which has an immediate and mighty influence on the finer passions of our nature, and is commonly termed a fine taste.

The objects which correspond to this taste we use to call beautiful, great, harmonious, or wonderful, in general by the name of beauty.

The mind, full pushing onwards and increasing its moral ideas stock of ideas, ascends from these to a higher species of objects, viz. the order and mutual relations of minds to each other, their reciprocal affections, characters, actions, and various affections. In these it discovers a beauty a grandeur, a decorum, more interesting and alluring than any of the former kinds. These objects, or the notions of them, passing in review before the mind, do, by a necessary law of our nature, call forth another and nobler set of affections, as admiration, esteem, love, honour, gratitude, benevolence, and others of the like tribe. This class of perfections, and their correspondent affections, we refer, because of their objects (manners), to a moral sense, and call the taste or temper they excite, moral. And the objects which are agreeable to this temper we denominate by the general name of moral beauty, in order to distinguish it from the other which is termed natural.

These different sorts of ideas or notions are the materials about which the mind employs itself, which it blends, ranges, and diversifies ten thousand different ways. It feels a strong propensity to connect and associate those ideas among which it observes any similitude or any aptitude, whether original and natural, or customary and artificial, to suggest each other. See Association.

But whatever the reasons are, whether similitude, laws of co-existence, causality, or any other aptitude or relation, association, why any two or more ideas are connected by the mind at all, it is an established law of our nature, "that when two or more ideas have often started in company,
MORAL PHILOSOPHY

Part III.

Culture of the Mind.

company, they form so strong an union, that it is very difficult ever after to separate them. Thus the

error cannot separate the idea of merit from his misdeeds; the

courtier that of dignity from his title or ribbon; the

mifer that of his piles from his hog. It is these

associations of worth or happiness with any of the different

kinds of objects or images before specified, that form our

taste or complex idea or good. By another law of our

nature, our affections follow and are governed by this
taste. And to these affections our character and conduct

are similar and proportioned; on the general tenor of

which our happiness principally depends.

As all our leading passions then depend on the di-

rection which our taste takes, and as it is always of

the same strain with our leading associations, it is worth

while to inquire a little more particularly how these

are formed, in order to detect the secret sources from

whence our passions derive their principal strength,

their various rife and falls. For this will give us the

true key to their management, and let us into the right

method of correcting the bad and improving the

good.

No kind of objects make so powerful an impres-

sion on us as those which are immediately impressed on

our senses, or strongly painted on our imaginations.

Whatever is purely intellectual, as abstratcd or scien-
tific truths, the fubtle relations and differences of

things, has a fainter sort of existence in the mind; and

though it may entertain and inform the memory, the

judgment, or the reasoning power, gives hardly any

impulse at all to the active powers, the passions, which

are the main springs of motion. On the other hand,

were the mind entirely under the direction of the

Moral Philosophy.

Part III.

Culture of the Mind.

with the title of men of pleasure, their imaginations being pregnant with moral images, with which they were ever failing to emulate, or, if they cannot do that, to palliate their gross pursuits. Thus admiration of state, of greatness, and merit, fine art, love, generous sympathy, mutual confidence, giving and receiving pleasure, are the ordinary ingredients with which they feed their gallantry and pleasurable entertainments; and by which they impose on themselves, and endeavour to impose on others, that their amours are the joint issue of good sense and virtue.

These affections, variously combined and proportioned by the imagination, form the chief private passions, which govern the lives of the generality, as the love of action, of pleasure, power, wealth, and fame; they influence the enemies, and affect the public passions, and raise joy or sorrow as they are gratified or disappointed. So that in effect these affections of good and evil, beauty and deformity, and the passions they raise, are the main hinges of life and manners, and the great sources of our happiness or misery. It is evident, therefore, that the whole of moral culture must depend on giving a right direction to the leading passions, and duly proportioning them to the value of the objects of good or pur chased, under what name ever they may appear.

Now, in order to give them this right direction and due proportion, it appears, from the foregoing detail, that those affections of ideas, upon which the passions depend, must be duly regulated; that is to say, as an exorbitant passion for wealth pleasure, or power, flows from an association or opinion that more beauty and good, whether natural or moral, enters into the enjoyment or possessin of them. If these passions to their just proportion, we must begin with correcting the opinions, or breaking the false associations, or, in other words, we must decamp the complex phantom of happiness or good, which we fondly admire; disunite those ideas that have no natural alliance; separate the original idea of wealth, power, or pleasure, from the foreign mixtures incorporated with it, which enhance its value, or give it its chief power of enchant and seduce the ingenuous minds. For instance, let it be considered how poor and inconsiderable a thing wealth is, if it is disjoined from real use, or from ideas of capacity in the possessor to do good; from independency, generosity, probity, affections, and social communication with others. By this standard let its true value be fixed; let its misapplication, or unbeneficent enjoyment, be accounted for, and infamous, and nothing worthy or estimable be ascribed to the mere possession of it, which is not borrowed from its generative use.

If that complex form of good which is called pleasure engage us, let it be analyzed into its constituent principles, of those allurements it draws from the heart and imagination, in order to heighten the low part of the indulgence; let the separate and comparative moment of each be distinctly ascertained and deduced from that gross part, and this remainder of the accumulated enjoyment will dwindle down into a poor, insipid, trivial thing. In proportion as the opinion of the good or pur chased abates, the admiration must decay, and the passions lose strength of course. One effectual way to lower the opinion, and consequently to weaken the habit founded upon it, is to prudently guide pieces of self-denial, or to abstain, to a certain pitch, from the pursuit or enjoyment of the favourite object; and that this may be the more easily accomplished, one must avoid those occasions, that company, those places, and the other circumstances, that inflamed one and endeared the other. And, as a counter-proof, let higher or even different enjoyments be brought in view, other passions played upon the former, different places frequent ed, other exercises tried, company kept with persons of a different or more correct way of thinking, both in natural and moral subjects.

As much depends on our setting out well in life, let By found of the youthful fancy, which is apt to be very florid and luxuriant, be early accustomed by instruction, example, and significant moral exercises, nay, by looks, gestures, and every other testimony of just approbation or blame, to annex ideas of merit, honour, and happiness, not to birth, dress, rank, beauty, fortune, power, popularity, and the like outward things, but to moral and truly virtuous qualities, and to those enjoyments which spring from a well-informed judgement and a regular conduct of the affections, especially those of the social and disinterested kind. Such dignified forms of purity and good, often fugitively, and, by moving pictures and examples warmly recommended to the imagination, enforced by the authority of conscience, and demonstrated by reason to be the surest means of enjoyment, and the only independent, unapproachable, and durable goods, will be the best counterbalance to meaner passions, and the firmest foundation and security to virtue.

It is of great importance to the forming a just taste, or pure and large conceptions of happiness, to study and understand what is human nature well, to remember what a complicated system it is, particularly to have deeply impressed on our mind that gradation of fancies, faculties, and powers of enjoyment formerly mentioned, and the subordination of goods resulting from these, which nature points out, and the experience of mankind confirms. Who when they think seriously, and are not under the immediate influence of some violent prejudice or passion, prefer not the pleasures of action, contemplation, friendship, and most exercises, and joys of the moral kind, as friendship, natural affections, and the like, to all sensual gratifications whatsoever? Where the different species of pleasure are blended into one complex form, let them be accurately distinguished, and be referred each to its proper faculty and sense, and examined apart what they have peculiar, what common with others, and what foreign and adventitious. Let wealth, greatness, luxury, love, fame, and the like, be tried by this test, and their true ally will be found out. Let it be further considered, whether the mind may not be easy and enjoy itself greatly, though it wants many of those elegancies and singularity in life which some poise on, or that load of wealth and power which others eagerly pursue, and under which they groan. Let the difficulty of attaining the precariousness of possessing, and the many abatements in enjoying overgrown wealth and envied greatness, of which the weary professors so frequently complain, as the hurry of business, the burden of company, of paying attendance to the forms, and giving it to the many, the cares of keeping, the tears of...
MORAL PHILOSOPHY.

Part III.

Culture of the Mind.

of losing, and the desires of encreasing what they have, and the other troubles which accompany this pithful drudgery and pompous servitude; let these and the like circumstances be often considered, that are conducive to the removing or lessening the opinion of such goods, and the attendant passion of set of passions will decay of course.

Let the peculiar bent of our nature and character be observed, whether we are most inclined to form associations and relish objects of the sensible, intellectual, or moral kind. Let that which has the attendant be particularly watched; let it be directed to right objects, improved by proportioned exercises, and guarded by proper checks from an opposite quarter. Thus the sensible turn may be exalted by the intellectual, and a taste for the beauty of the fine arts, and all may be made subservient to convey and rivet sentiments highly moral and public-spirited. This inward survey must extend to the strength and weakness of one's nature, one's conditions, connections, habits, fortune, flatteries, acquaintances, and the other circumstances of one's life, from which every man will form the justest estimate of his own dispositions and character, and the rules for correcting and improving them. And in order to do this with more advantage, let those times of critical seasion be watched when the mind is best disposed towards a change; and let them be improved by vigorous resolutions, promises, or whatever else will engage the mind to persevere in virtue. Let the conduct, in fine, be often reviewed, and the causes of its corruption or improvement be carefully observed.

It will greatly conduct to refine the moral taste, and strengthen the virtuous temper, to accustomed the mind to the frequent exercise of moral sentiments and determinations, by reading history, poetry, particularly of the picturesque and dramatic kind, the study of the fine arts; by conversing with the most eminent for good sense and virtue; but, above all, by frequent and repeated acts of humanity, compassion, friendship, politeness, and hospitality. It is exercise that gives health and strength. He that reason most frequently, becomes the wise, and most enjoys the pleasures of wisdom. He who is most often affected by objects of compassion in poetry, history, or real life, will have his soul most open to pity, and its delightful pains and duties. So he also who prides most diligently the offices of kindliness and charity, will by it cultivate that disposition from whence all his pretensions to personal merit must arise, his present and his future happiness.

An useful and honourable employment in life will administer a thousand opportunities of this kind, and greatly strengthen a sense of virtue and good affections, which must be nourished by right training, as well as our understanding. For such an employment, by enlarging one's experience, giving an habit of attention and caution, or obliging one, from necessity or interest, to keep a guard over the passions, and study the outward deceits and appearances of virtue, will by degrees produce good habit, and at length influence the love of virtue and honesty for its own sake.

It is a great inducement to the exercice of benevolence to view human nature in a favourable light, to observe the characters and circumstances of mankind on the fairest sides, to put the best construction on their actions they will bear, and to consider them as the result of partial and misdirected virtue and vice, rather than just affections, or at worst, as the effect of a parradigm solely. This will flow, beyond all convention and disposition and is, by nature, essentially good, and of course, it will of its own accord, as a kind of natural experiment, be taught to us by experience, in proportion as it is engaged in the review of our actions, in peace and in prosperity, and in the contemplation of virtue and good affections, and of whatever is pleasing and beneficial, and in the exercise of the moral sentiments and passions, as they are apt to be excited by frequent and repeated acts of humanity, kindness, and friendship, and by every act of benevolence; and, as such, it will be observed, as it is in its different circumstances be often considered, that is often dissipated. 'Let the peculiar bent of our nature and character be observed, whether we are most inclined to form associations and relish objects of the sensible, intellectual, or moral kind. Let that which has the attendant be particularly watched; let it be directed to right objects, improved by proportioned exercises, and guarded by proper checks from an opposite quarter. MORAL PHILOSOPHY.

Part III.

Motives to Virtue.

210 Influence of vice on the temper of the mind.

tradition, that we not only approve, but can give a sufficient reason for what we do.

Let any man in a cool hour, when he is disengaged from busineses, and undisturbed by passion (as such cool hours will sometimes happen), sit down, and seriously reflect with himself what state or temper of mind he would choose to feel and indulge, in order to be easy and to enjoy himself. Would he choose, for such purpose, to be in a constant dizziness and hurry of thought; to be disturbed in the exercise of his reason; to have various and often interfering phantoms of good playing before his imagination, soliciting and distracting him by turns, now soothing him with amusing hopes, then torturing him with anxious fears; and to approve this minute what he shall condemn the next? Would he choose to have a strong and painful sense of every petty injury? quick apprehensions of every impending evil, inceflant and insatiable desires of power, wealth, honour, pleasure; an irreconcilable antipathy against all competitors and rivals; insolent and tyrannical dispositions to all below him; fawning, and at the same time envious, dispositions to all above him: with dark suspicions and jealousies of every mortal? Would he choose neither to love nor be beloved of any; to have no friend in whom to confide, or with whom to interchange his sentiments or designs; no favourite, on whom to bestow his kindness, or vent his passions; in fine, to be conscious of no merit with mankind, no esteem from any creature, no good affection to his Maker, no concern for, nor hopes of, his approbation: but, instead of all these, to hate, and know that he is hated, to condemn, and know that he is condemned by all: by the good, because he is so unlike: and by the bad, because he is so like themselves; to hate or to dread the very Being that made him: and, in short, to have his breast the seat of pride and passion, petulance and revenge, deep melancholy, cool malignity, and all the other furies that ever poffessed and tortured mankind?—Would our calm inquirer after happiness pitch on such a state, and such a temper of mind, as the most likely means to put him in possession of his desired ease and self-satisfaction?

Or would he rather choose a serene and easy flow of thought: a reason clear and composed; a judgment unbiassed by prejudice, and undistracted by passion; a sober and well-governed fancy, which presents the images of things true, and unmixt with delusive and unnatural charms, and therefore admitteth no improper or dangerous fuel to the passions, but leaves the mind free to choose or reject, as becomes a reasonable creature: a sweet and sedate temper, not easily ruffled by hopes or fears, prone neither to fupicion nor revenge, apt to view men and things in the fairest lights, and to bend gently to the humours of others rather than obstinately to contend with them? Would he choose such moderation and continence of mind, as neither to be ambitious of power, fond of honour, covetous of wealth, nor a slave to pleasure; a mind of course neither elated with success, nor dejected with disappointment: such a modest and noble spirit as supports power without insolence, wears honour without pride, ues wealth without profouion or profamity; and rejoves more in giving than in receiving; such fortitude and equanimity as rife above misfortunes, or turns them into blessings: such integrity and greatness of mind, as neither flatters the vices, nor nourishes over the follies of men; as equally spurns servitude and tyranny, and will neither engage in low designs, nor abet them in others? Would he choose, in fine, such mildness and benignity of heart as takes part in all the joys, and refuses none of the forrows, of others: finds well affected to all mankind; is conscious of meritting the esteem of all, and of being beloved by the belt; a mind which delights in doing good without any show, and yet arrogates nothing on that account: rejoices in loving and being beloved by its Maker, acts ever under his eye, reigns itself to his providence, and triumphs in his approbation?—Which of these dispositions would he choose, in order to be contented, serene, and happy?—The former temper is vice, the latter virtue. Where one prevails, there misery prevails, and by the generality is acknowledged to prevail. Where the other reigns, there happiness reigns, and by the confession of mankind it acknowledged to reign. The perfection of either temper is misery or happiness in perfection. Therefore, every approach to either extreme is an approach to misery or to happiness; i.e. every degree of vice or virtue is accompanied with a proportionable degree of misery or happiness.

The principal alleviations of a virtuous man's calamities are these:—That though some of them may have been the effect of his imprudence or weakness, yet few of them are sharpened by a sense of guilt, and none of them by a consciousness of wickedness, which is the keenest sting:—that they are common with him to the best of men;—that they seldom or never attack him quite unprepared, but rather guarded with a confidence of his own sincerity and virtue, with a faith and trust in providence, and a firm resignation to its perfect orders;—that they may be removed as means of correction, or materials to give scope and stability to his virtues;—and, to name no more, they are considerably lessened, and often sweetened to him, by the general sympathy of the wise and good.

His enjoyments are more numerous, or, if less numerous, yet more intense than those of the bad man; merits for he shares in the joys of others by re bound; and every increase of general or particular happiness is a real addition to his own. It is true, his friendly sympathy with others subjects him to some pains which the hard-hearted wretch does not feel: yet to give a leafe to it, is a kind of agreeable discharge. It is such a favor as he loves, to indulge; a sort of pleasing anguish that sweetly melts the mind, and terminates in a self-approving joy. Though the good man may want means to execute, or be disappointed in the success of his benevolent purposes; yet, as was formerly observed, he is still conscious of great affection, and that consciousness is an enjoyment of a more delightful favor than the greatest triumphs of successful vice. If the ambition, covetousness, or volup tuousness, are disappointed, their passions recoil upon them with a fury proportioned to their opinion of the value of what they pursue, and their hope of success; while they have nothing within to balance the disappointment, unless it is an ulefs fun of pride, which, however, frequently turns mere accidents into mortifying affronts, and excites grief into rage and frenzy. Whereas the meek, humble,
MORAL PHILOSOPHY.

Morals to Virtue.

214. From merit to sympathy.

As the good man is conscious of loving and wishing well to all mankind, he must be sensible of his deserving the esteem and good-will of all; and this suppos'd reciprocation of social feelings is, by the very frame of our nature, a source of so intense and exhilarating joy. By this sympathy of affections and interests, he feels himself intimately united with the human race; and, being sensibly above over the whole system, his heart receives and becomes responsive to every touch given to any part. So that, as an eminent philosopher finnily expresses it, he gathers contentment and delight from the pleased and happy states of those around him, from accounts and relations of such happiness, from the very countenances, gestures, voices, and sounds, even of creatures foreign to our kind, signs of joy and contentment he can any way discern.

Nor do those generous affections stop any other natural source of joy whatever, or deaden his sense of any innocent gratification. They rather keep the several joys and powers of enjoyment open and disengaged, intense and uncorrupted by riot or abuse; as is evident to any one who considers the dissipated, unfeeling state of men of pleasures, ambition, or interest, and compares it with the serene and gentle state of a mind at peace with itself, and friendly to all mankind, unruffled by any violent emotion, and sensible of every good natured and soothing joy.

It was easy, by going through the different fets of affections mentioned formerly*, to flow, that it is only by maintaining the proportion settled there, that the mind arrives at true repose and satisfaction. If fear exceeds that proportion, it sinks into melancholy and dejection. It engenders just bounds, it ferments into rage and revenge, or subsides into a sullen gloom, which embitters every good, and renders one exquisitely sensible to every ill. The private passions, the love of honour especially, whose impulces are more generous, as its effects are more diffusive, are instruments of private pleasur; but if they are disproportioned to our wants, or to the value of their several objects, or to the balance of other passions equally necessary and more amiable, they become instruments of intense pain and misery. For, being now delirious of that counterpoise which held them at a due pitch, they grow turbulent, peevish, and revengeful, the cause of constant restlessness and torment, sometimes flying out into a wild delirium, joy, at other times settling in a deep sullen grief. The concert between reason and passion is then broke; all is dissonance and distraction within. The mind is out of frame, and feels an agony proportioned to the violence of the reigning passion.

The cafe is much the same, or rather worse, when any of the particular kind affections are out of their natural order and proportion; as happens in the case of effeminacy, pily, exorbitant love, parental dotage, or any party-pasion, where the jilt regards to society are suspended. The more social and intermixed the passion is, it breaks out into the wilder exce'ss, and makes the more dreadful havoc both within and abroad; as is but too apparent in those cafes where a false species of religion, honour, zeal, or party rage, has seized on the natural enthusiasm of the mind, and worked it up to madness. It breaks through all ties natural and civil; disregards the most sacred and solemn obligations; involves every other affection whether public or private, and transforms the most gentle natures into the most savage and inhuman.

Whereas, the man who keeps the balance of internal happiness, even, is easy and serene in his motions; mild and yet in well-proportioned affectionate; uniform and confident with himself; is not liable to disagreeable collisions of interests and passions; gives always place to the most friendly and humane affections, and never to dispositions or acts of resentment, but on high occasions, when the security of the private, or welfare of the public system, or the great interest of mankind, necessarily require a noble indignation; and even then he observes a just measure in wrath; and last of all, he proportions every passion to the value of the object he affects, or to the importance of the end he pursues.

215. Do not interfere with other affections.

To sum up this part of the argument, the benevolent and good man has eminently the advantage of the line, and is not obliged to sacrifice end to end, as a man who keeps the balance of internal happiness, even, is easy and serene in his motions; mild and yet in well-proportioned affectionate; uniform and confident with himself; is not liable to disagreeable collisions of interests and passions; gives always place to the most friendly and humane affections, and never to dispositions or acts of resentment, but on high occasions, when the security of the private, or welfare of the public system, or the great interest of mankind, necessarily require a noble indignation; and even then he observes a just measure in wrath; and last of all, he proportions every passion to the value of the object he affects, or to the importance of the end he pursues.

216. The misery of excess in the private passions.

217. In the public affections.
MORAL PHILOSOPHY.

On one's fortune, interest, &c.

It may be some be thought odd to assert, that virtue is no enemy to a man's fortune in the present state of things. But if by fortune he meant a moderate or competent share of wealth, power, or credit, not overgrown degrees of them; what should hinder the virtuous man from obtaining that? He cannot cringe or fawn, it is true, but he can be civil and obliging as well as the knave; and surely his civility is more alluring, because it has more manliness and grace in it than the mean adulation of the other; he cannot cheat or undermine; but he may be cautious, provident, watchful of occasions, and equally prompt with the rogue in improving them; he turns to profitude himself as a pander to the passions, or as a tool to the vices, of mankind; but he may have as an understanding and as good capacities for promoting their real welfare, as for undermining their security.

The common course of bufiness, he has the fame chances with the knave of acquiring a fortune, and riling in the world. He may have equal abilities, equal industry, equal attention to bufness; and in other respects he has greatly the advantage of him. People love better to deal with him; they can trufm him more; they know he will not impose on them, nor take advantage of them, and can depend more on his word than on the oath or longest securities of others. Whereas what is commonly called running, which is the offspring of ignorance, and constant companion of knavery, is not only a mean-spirited, but a very short-sighted talent, and a fundamental obstacle in the road of bufness. It may procure indeed immediate and petty gains; but it is attended with dreadful abatements, which do more than overbalance them, both as it finks a man's credit when discovered, and cramps that largeness of mind which extends to the remotest as well as the nearest interrell, and takes in the most durable equally with the most transient gains. It is therefore easy to see how much a man's credit and reputation, and consequently his fucces, depend on his honesty and virtue.

With regard to security and peace with his neighbours, it may be thought, perhaps, that the man of a quiet forgiving temper, and a flowing benevolence and courtecy, is much exposed to injury and affronts from every proud or peevish mortal, who has the power or will to do mischief. If we suppose, indeed, the quietness and gentleness of nature accompanied with cowardice and pusillanimity, this may often be the case; but in reality the good man is bold as a lion, and so much the bolder for being the calmer. Such a person will hardly be a butt to mankind. The ill natured will be afraid to provoke him, and the good-natured will not incline to do it. Besides, true virtue, which is conducted by reason, and exerted gracefully and without parade, is a most influence and commanding thing; if it cannot disarm malice and resentment at once, it will wear them out by degrees, and subdue them at length. How many have, by favours and prudently yielding, triumphed over an enemy, who would have been inflamed into tenfold rage by the fiercest opposition! In fine, virtue is the most universally popular thing that can be.

To conclude; the good man may have some enemies; but he will have more friends; and, having given to many marks of private friendship or public virtue, he can hardly be delusive of a patron to protect, or a fanfuary to entertain him, or to protect or entertain his children when he is gone. Though he should have little else to leave them, he bequeaths them the fairest and generally the most unenvied, inheritance of a good name, which, like good seed sown in the field of futility, will often raise up involuntary friends, and yield a benevolent harvest of unexpected charities. But if the fragrance of the parent's virtue prove offensive to a perverse or envious age, or even draw persecution on the friend's orphans, there is one in heaven who will be more than a father to them, and recom pense their parent's virtues by showering down blessings on them.

Part III.

Motives to Virtue from the Being and Providence of God.

Besides the interesting motive mentioned in the preceding Chapter, there are two great motives to virtue, strictly connected with human life, and resulting from the very constitution of the human mind. The firft is the Being and Providence of God: the second is the Immortality of the Soul, with future rewards and punishments.

It appears from Chap. iv. of Part II., that man, by their immediate constitution of his nature, is designed to be a Religious Creature. He is intimately connected with the Deity, and necessarily dependent on him. From that connection and necessary dependence result various obligations and duties, without fulfilling which, some of his sublime powers and affections would be incomplete and abortive. If he be likewise an immortal creature, and if his present conduct shall affect his future happiness in another state as well as in the present, it is evident that we take only a partial view of the creature if we leave out this important property of his nature, and make a partial estimate of human life? if we strike out of the account, or overlook, that part of his duration which runs out into eternity.

It is evident from the above-mentioned Chapter, Piety, that 'to have a respect to the Deity in our temper and conduct, to venerate and love his character, to adore his goodness, to depend upon and rely on ourselves to his providence, to seek his approbation, and act under a sense of his authority, is a fundamental part of moral virtue, and the completion of the highest definition of our nature.'

But as piety is an essential part of virtue, so likewise it is a great support and enforcement to the practice of it. To contemplate and admire a Being of such transcendent dignity and perfection as God, must naturally and necessarily open and enlarge the mind, give a freedom and ampleness to its powers, and a grandeur and elevation to its aims. For, as an excellent divine observer, "the greatness of an object, and the excellency of the act of any agent about a transcendent object
Moral Philosophy.

III. Motives to Virtue.

Motives to object, both mightily tend to the enlargement and improvement of his faculties. Little objects, mean company, mean cares, and mean buffets, cramp the mind, contract its views, and give it a creeping air and deportment. But when it flares above mortal cares and mortal pursuits into the regions of divinity, and converses with the greatest and best of beings, it spreads itself into a wider compass, takes higher flights in reason and goodness, becomes godlike in its air and manners. Virtue is, if one may say so, both the effect and cause of largeness of mind. It requires that one think freely, and act nobly. Now what can conduct more to freedom of thought and dignity of action, than to conceive worthily of God, to reverence and adore his unrivalled excellence, to imitate and transfigure that excellency into our own nature, to remember our relation to him, and that we are the images and representatives of his glory to the bulk of mankind? Indeed, from all actions that are base, unhandsome, unworthy our state and the relation we stand in to God will irradiate the mind with the light of wisdom, and enable it with the liberty and dominion of virtue.

The influence and efficacy of religion may be considered in another light. We all know that the presence of a friend, a neighbour, or any number of spectators, but especially an august assembly of them, uses to be a considerable check upon the conduct of one who is not lost to all sense of honour and fame, and contributes to restrain many irregular falls of passion. In the same manner as we imagine that the awe of some superior mind, who is flipp'd privy to our secret conduct, and armed with full power to reward or punish it, will impose a restraint on us in such actions as fall not under the control or animadversion of others. If we go still higher, and flipp our inmost thoughts and darkest designs, as well as our most secret actions, to lie open to the notice of the supreme and universal mind, who is both the spectator and judge of human actions, it is evident that the belief of so august a presence, and such awful inspection must carry a restraint and weight with it proportioned to the strength of that belief, and be an additional motive to the practice of many duties which would not have been performed without it.

It may be observed further, that to live under an habitual sense of the Divine and his great administration, is to be conversant with abysses, secrets, and secrets, in the highest sublunary, and to receive the delightful reflections and benign feelings which these excite while they irradiate upon him from every scene of nature and providence. How improving must such views be to the mind, in dilating and exalting it above those puny interests and competitions which agitate and in flame the bulk of mankind against each other!

Motives from the Immortality of the Soul.

The other motive mentioned was the immortality of the soul, with future rewards and punishments. The metaphorical proofs of the soul's immortality are commonly drawn from—its simple uncombined, and indivisible nature; from whence it is concluded, that it cannot be corrupted or extinguished by a dissolution or destruction of its parts—from its having a being within itself; whence it is inferred, that it can not discontinue and lose its motion—from the different properties of matter and mind, the connection and immensity of one, and the immense activity of the other; its prodigious flight of thought and imagination; its penetration, memory, foresight, and anticipations of futurity; from whence it is concluded, that a being of so divine a nature cannot be extinguished.

But as these metaphorical proofs depend on intricate reasonings concerning the nature, properties, and definitions of body and mind, with which we are not very well acquainted, they are not obvious to ordinary understandings, and are seldom so convincing as those of higher reach, as not to leave some doubts behind them. Therefore perhaps it is not so safe to rest the proof of such an important article on what many may call the fallacies of school-learning. Those proofs which are brought from analogy, from the moral character and providence of the human mind, the moral attributes of God, and the present course of things, and which therefore are called the moral arguments, are the plainest, and generally the most satisfying. We shall select only one or two from the rest.

In tracing the nature and definition of any being, we form the first judgment from his powers of action and the scope and limits of these, compared with his analogy, flat, or with that field in which they are exercised. If this being pusses through different states, or fields of action, and we find a succession of powers adapted to the different periods of his progress, we conclude that he was designed for those successive states, and reckon his nature progressive. If, besides the immediate act of powers which it him for action in his present state, we observe another act which appear superfluous if he were to be confined to it, and which point to another or higher one, we naturally conclude, that he is not designed to remain in his present state, but to advance to that for which these supernumerary powers are adapted. Thus we argue, that the insect, which has wings forming or formed, and all the apparatus proper for flight, is not designed always to creep on the ground, or to continue in the torpid state of adhering to a wall, but is designed in its season to take its flight in air. Without this farther definition, the admirable mechanism of wings and the other apparatus would be useless and absurd. The same kind of reasoning may be applied to man, while he lives only a sort of vegetative life in the womb. He is turned even there with a beautiful apparatus of organs, eyes, ears, and other delicate senses, which receive nourishment indeed, but are in a manner folded up, and have no proper exercise or use in their present confinement.

Let us flipp'some intelligent spectator, who never had any connection with man, nor the least acquaintance with human affairs, to see this odd phenomenon, a creature formed after such a manner, and placed in a situation apparently unsuitable to such various machinery: must he not be strangely puzzled about the use of this complicated structure, and reckon such a profusion of art and admirable workmanship fasten'd on the subject; or reason by way of anticipation, that a creature endowed with such various yet unexercised capacities, was designed for a more enlarged sphere.
MORAL PHILOSOPHY.

From the 

immortality of the Soul.

Motives to Virtue.

Sphere of action, in which those latent capacities shall have full play? The vast variety and yet beautiful symmetry and proportions of the several parts and organs with which the creature is endowed, and their apt cohesion with and dependence on the curios receptacle of their life and nourishment, would forbid his concluding the whole to be the birth of chance, or the bungling effort of an unskilful artist; at least would make him deny a while at to harass a sentence. But if, while he is in this state of uncertainty, we suppose him to see the babe, after a few successful struggles, throwing off his fetters, breaking loose from his little dark prison, and emerging into open day, then unfolding his recluse and dormant powers, breathing in air, gazing at light, admiring colours, sounds, and all the fair variety, of nature; immediately his doubts clear up, the propriety and excellency of the workmanship dawn upon him with full lustr, and the whole mystery of the first period is unravelled by the opening of this new scene. Though in this second period the creature lives chiefly a kind of animal-life, i.e. of sense and appetite, yet by various trials and observations he gains experience, and by the gradual evolution of the powers of imagination he ripens space for an higher life, for exerting the arts of design and imitation; and of those in which strength or dexterity are more requisite than acuteness or reach of judgment. In the succeeding sensitive or intellectual period, his understanding, which formerly crept in a lower, mounts into an higher sphere, canvases the natures, judges of the relations of things, forms schemes, deduces consequences from what is past, and from present as well as past collects future events. By this succession of states, and of correspondent culture, he grows up at length into a moral, a social, and a political creature. This is the last period at which we perceive him to arrive in this his mortal career. Each period is introductory to the next succeeding one; each life is a field of exercise and improvement for the next higher one; the life of the fetus for that of the infant, the life of the infant for that of the child, and all the lower for the higher and best. —But is this the last period of nature’s progression? Is this the acme of her plot, the summit of the drama, and dissolves the actor into eternal oblivion? Or does he appear to be invested with supernumerary powers, which have not full exercise and scope even in the last scene, and reach not that maturity or perfection of which they are capable; and therefore point to some higher scene where he is to fulfill another and more important character than he has yet sustained? If any such there are, may we not conclude by analogy, or in the same way of anticipation as before, that he is destined for that after part, and is to be produced upon a more august and solemn stage, where his sublimers powers shall have proportioned action, and his nature attain its completion?

If we attend to that curiocity, or prodigious thirst of knowledge, which is natural to the mind in every period of its progress, and consider with the endless round of business and care, and the various hardships to which the bulk of mankind are chained down, it is evident, that in this present state it is impossible to expeft the gratification of an appetite at once so insatiable and so noble. Our senses, the ordinary organs by which knowledge is let into the mind, are always imperfect, and often fallacious; the advantages of affiling or correcting them are perplexed by few; the difficulties of finding out truth amidst the various and contradictory opinions, interests, and passions of mankind, are many; and the wants of the creature, and of those with whom he is connected, numerous and urgent; so that it may be said of most men, that their intellectual organs are as much shut up and excluded from proper nourishment and exercise in that little circle to which they are confined, as the bodily organs are in the womb. Nay, those who to an altering genius have added all the affiliations of art, leisure, and the most liberal education, which narrow prospects can even they take of this unbounded scene of things from that little eminence on which they stand? and how eagerly do they still grasp at new discoveries, without any satisfaction or limit to their ambition?

But should it be said, that man is made for action and not for speculation, or frivolous searches after knowledge, we ask, For what kind of action? Is it only for bodily exercises, or for moral, political, and religious ones? Of all these he is capable; yet, by the unavoidable circumstances of his lot, he is tied down to the former, and has hardly any leisure to think of the latter, or if he has, wants the proper instruments of exercising them. The love of virtue of one’s friends and country, the generous sympathy with mankind, and zeal of doing good, which are all so natural to great and good minds, and some traces of which are found in the lowed, are seldom united with proportioned means or opportunities of exercising them; so that the moral spring, the noble energies and impulses of the mind, can hardly find proper scope even in the most fortunate condition; but are much depressed in some and almost entirely restrained in the generality, by the numerous clogs of an indigent, sickly, or embarassed life. Were such mighty powers, such godlike affections, planted in the human breast to be folded up in the narrow womb of our present existence, never to be produced into a more perfect life, nor to expiate in the ample career of immortality?

Unfatted desires of existence and happiness.

Powers in man which point to an after life.

Intellectual.

Does nature give the finishing touches to the letter and ignobler infinences of her skill, and raise every other creature to the maturity and perfection of his being; and shall he leave her principal workmanship unimproved? Does she carry the vegetative and animal life in man to their full vigour and highest delineation; and shall the suffer his intellectual, his moral, his divine life
MORAL PHILOSOPHY.

Motives to Virtue

237 Therefore man is immortal.

We must therefore conclude from this detail, that the present state, even at its best, is only the worm of man's being, in which the noblest principles of his nature are in a manner fettered, or included from a correspondent sphere of action; and therefore defined for a future and unbounded state, where they shall emancipate themselves, and exert the fulness of their strength. The most accomplished mortal, in this low and dark apartment of nature, is only the rudiments of what shall be when he takes his eternal flight, and puts on immortality. Without a reference to that state, now were a mere abortion, a rude uninfinished embryo, a monster in nature. But this being once supposed, he still maintains his rank of the master-piece of the creation; his latent powers are all suitable to the harmony and progression of nature; his noble aspirations, and the pains of his dilution, are his efforts towards a second birth, the pangs of his delivery into light, liberty, and perfection; and death, his discharge from gaol, his separation from his fellow-prisoners, and introduction into the assembly of those heroic spirits who are gone before him, and of their great eternal Parent. The fetters of his mortal coil being loosed, and his prison walls broke down, he will be bare and open on every side to the admission of truth and virtue, and their fair attendant happiness; every vital and in eternal spring will evince itself with a divine edibility in the free air of heaven. He will not then peep at the universe and its glorious Author through a dark grate or a grost medium, nor receive their reflections in his glance through the strait openings of sensible organs; but will be all eye, all ear, all ideal and divine feeling*. Let one part, however, of the analogy be attended to: That as in the womb we receive our original constitution, form, and the essential flamma of our being, which we carry along with us into the light, and which greatly affect the succeeding periods of our life; so our temper and condition in the future life will depend on the conduct we have observed, and the character we have formed, in the present life. We are here in miniature what we shall be at full length hereafter. The first rude sketch or outline of reason and virtue must be drawn at present, to be afterwards enlarged to the future and beauty of angels.

238 Immortality a guard, but an admirable incentive to virtue. For he who faithfully and ardently follows the light of knowledge, and pants after higher improvements in virtue, will be wonderfully animated and inflamed in that pursuit by a full conviction that the scene does not close with life—that his struggles, arising from the weakness of nature and the strength of habit, will be turned into triumphs—that his career in the tract of wisdom and goodness will be both fitter and smoother—and those generous arduous with which he goes towards heaven, i.e., the perfection and immortality of virtue, will find their adequate object and exercise in a sphere proportionably enlarged, incorruptible, immortal. On the other hand, what an inexpressible damp must it be to the good man to dread the total extirpation of that light and virtue, without which life, nay, immortality itself, were not worth a single wish?

Many writers draw their proofs of the immortality of the soul, and of a future state of rewards and punishments, from the unequal distribution of these here. It cannot be disbelieved that wicked men often escape the outward punishment due to their crimes, and do not feel the inward in that measure their demerit seems to require, partly from the callousness induced upon their nature by the habits of vice, and partly from the dissipation of their minds abroad by pleasure or business—and sometimes good men do not reap all the natural and genuine fruits of their virtue, through the many unforeseen or unavoidable calamities in which they are involved. To the smallest reflection, however, it is obvious, that the natural tendency of virtue is to produce happiness; that if it were universally practiced, it would, in fact, produce the greatest sum of happiness of which human nature is capable; and that this tendency is defeated only by numerous individuals, who, forsaking the laws of virtue, injure and oppress those who steadfastly adhere to them. But the natural tendency of virtue is the result of that constitution of things which was established by God at the creation of the world. This being the case, we must either conclude, that there will be a future state, in which all the moral obliquities of the present shall be made straight; or else admit, that the deigns of infinite wisdom, goodness, and power, can be finally defeated by the perverse conduct of human weaknesses. But this last supposition is so extravagantly absurd, that the reality of a future state, the only other possible alternative, may be pronounced to have the evidence of perfect demonstration.

Belief of Immortality, &c. a great support amid trials.
MORAL PHILOSOPHY.

Part III.

MORAL SCIENCE, that whereby we perceive what is good, virtuous, and beautiful, in actions, manners, and characters. See Moral Philosophy.

MORALITY. See Moral Philosophy.

MORANT (Philip), a learned and indefatigable antiquary and biographer, son of Stephen Morant, was born at St Saviour's in the Isle of Jersey, October 6, 1700; and, after finishing his education at Abingdon School, was entered December 16th, 1717 at Pembroke College, Oxford, where he took the degree of B.A. June 10th, 1721, and continued till midsummer 1722; when he was preferred to the office of preacher of the English church at Amsterdam, but never went to take possession. He took the degree of M.A. in 1724, and was preferred to the rectory of Shellow Boweis, April 20th, 1733; to the vicarage of Bromfield, January 17th, 1733-4; to the rectory of Chicksnall Smiley, September 19th, 1735; to that of St Mary's, Colchester, March 9th, 1737; to that of Wickham Bishop's, January 21st, 1742-3; and to that of Aldham, September 14th, 1745. All these benefices are in the county of Essex. In 1748 he published his History of Colchester, of which only 200 copies were printed. In 1751 he was elected F.S.A.; and in February 1768 he was appointed by the Lords sub-committees of the House of Peers to succeed Mr Blyde in preparing for the press a copy of the rolls of Parliament, a service to which he diligently attended till his death, which happened November 25th, 1770. Besides the above work, and many useful translations, abridgments, and compilations, &c., he wrote, all the Lives in the Biographia Britannica marked C; also the life of Stillingfleet, which has no mark at the end: The History of Effex, 1760, 1768, 2 vols folio: The life of King Edward the Confessor, and about 150 sermons. He prepared the rolls of Parliament as far as the 16th of Henry IV. The continuation of the task devolved upon Thomas Aítle, Esq.; who had married his only daughter.

MORANT-Point, the most easterly point or promontory of the island of Jamaica, in America. W. Lon. 75, 56. N. Lat. 17, 56.

MORASS, a marsh, fen, or low moist ground, which receives the waters from above without having any deficient to carry them off again. Somner derives the word from the Saxon mores, "lake;" Salmannas from mare, "a collection of waters;" others from the German maret, "a muddy place;" and others from mares, or mariset, à mariset, i.e. rushes. See Bog, Fen, and Draining.

In Scotland, Ireland, and the north of England, they have a peculiar kind of morasses called mosses or peat-mosses, whence the country people dig their peat or turf for firing. See Moss.

MORAT, or Morten, a rich trading, and consider.
siderable town of Switzerland, capital of a bailiwick of the same name, belonging to the cantons of Bern and Fribourg, with a castle where the bailiff resides. It is seated on the lake Morat, on the road from Avenches to Bern, 10 miles west of Bern and 10 miles north-east of Fribourg. The lake is about six miles long and two broad; the country about it being pleasant and well cultivated. The lakes of Morat and Neuchâtel are parallel to each other, but the latter is more elevated, discharging itself by means of the river Broye into the lake of Neuchâtel. According to M. de Luc, the former is 15 French feet above the level of Neuchâtel lake; and both these lakes, as well as that of Bienne, seem formerly to have extended considerably beyond their present limits, and from the position of the country appear to have been once united. Formerly the large fish named *flosurus glanis*, or the salm, frequented these lakes, but has not been caught in them for a long time past. The environs of this town and lake were carefully examined by Mr. Coxe during his residence in Switzerland, who made several excursions across the lake to a ridge of hills during his residence in Switzerland, who made several excursions across the lake to a ridge of hills, and was one of the first to examine the environs of Geneva as far as Bâle, and, on the other hand, by that stupendous chain of snowy Alps from the frontiers of Italy to the confines of Germany, and is lost at each extremity in the horizon. Morat is celebrated for the remains of a monument of this victory. It is a square building, filled with the bones of Burgundian soldiers, who were slain at the siege and in the battle; the number of which appears to have been very considerable. There are several inscriptions in the Latin and German languages commemorating the victory.

MORATA (Olympia Fulvia), an Italian lady, distinguished for her learning, was born at Ferrara, in 1526. Her father, after teaching the belles lettres in several cities of Italy, was made preceptor to the two young princes of Ferrara, the sons of Alphonso I. The uncommon abilities he discovered in his daughter determined him to give her a very extraordinary education. Meanwhile the princes of Ferrara, studying polite literature, it was judged expedient that she should have a companion in the same pursuits; and Morata being called, she was heard by the illustrious courtiers to declaim in Latin, to speak Greek, and to explain the paradoxes of Cicero. Her father dying, she was obliged to return home to take upon her the management of family-afairs, and the education of her brother and three sisters; both which she executed with the greatest diligence and success. In the mean time Andrew Grunthier, a young German, who had studied physic, and taken his doctor's degree at Ferrara, fell in love with her, and married her. She now went with her husband to Germany, taking her little brother with her, whom she instructed in the Latin and Greek tongues; and after staying a short time at Augsburg, went to Schweinfurt in Franconia, where her husband was born: but they had not been there long before that town was unhappily besieged and burnt; however, escaping the flames, they fled in the utmost distress to Hanlebur. This place they were also obliged to quit, and were reduced to the last extremities, when the elector palatine invited Grunthier to be professor of physic at Heidelberg, and he entered on his new office in 1554: but they no sooner began to taste the sweets of repose, than a difficulty, occasioned by the difficulties and hardships they had suffered, seized upon Morata, who died in 1555, in the 29th year of her age; and her husband and brother did not long survive her. She composed several works, great part of which were burnt with the town of Schweinfurt; the remainder, which consist of orations, dialogues, letters, and translations, were collected and published under the title of *Olympia Fulvia Morata, famina dolium, et plana divinæ, opera omnia que hœ- terus invento potuerunt*; quibus *Celli iuendi curiosis epístole et orationes accesserunt*, which has had several editions in octavo.

MORAVIA, a river of Turkey in Europe, which rises in Bulgaria, runs north through Servia by Niša, and falls into the Danube at Semendria, to the eastward of Belgrade.

MORAVIA, a marquise of Germany, derives the name of Mahern, as it is called by the Germans, and of Moraua, as it is called by the natives, from the river of that name which rises in the mountains of the county of Glatz, and passes through the middle of it. It is bounded to the south by Austria, to the north by Glatz and Silebia, to the west by Bohemia, and to the east by Sileia and Hungary; being about 120 miles in length and 100 in breadth. A great part of this country is over-run with woods and mountains, where the air is very cold, but much wholesome than in the low grounds which are full of bogs and lakes. The mountains, in general, are bare; but the more champaign parts tolerably fertile, yielding corn, with plenty of hemp and flax, good flaxen and pasture. Nor is it altogether destitute of wine, red and white, fruits and garden-stuff. Moravia also abounds in horst, black cattle, sheep, and goats. In the woods and about the lakes there is plenty of wild fowl, game, venison, bees, honey, hares, foxes, wolves, beavers, &c. In this country are likewise quarries of marble, baltard diamonds, amethysts, alum, iron, sulphur, falt-petre, and vitriol, with wholesome mineral-waters, and warm springs; but salt is imported. Its rivers, of which the March, Morawa, or Morau, are the chief, abound with trout, crayfish, barbels, eels, perch, and many other sorts of fish.

The language of the inhabitants is a dialect of the Scavonian, differing little from the Bohemian; but the nobility and citizens speak German and French.

Moravia was anciently inhabited by the Quadi, who were driven out by the Scavii. Its kings, who were once powerful and independent, afterwards became dependent on, and tributary to, the German emperors and kings. At last, in the year 908, the Moravian kingdom was parcelled out among the Germans, Poles, and...
MORAVIA.

and Hungarians. In 1086, that part of it properly called Moravia was declared a marquisate by the German king Henry IV. and united with Bohemia, to whole dukes and kings it hath ever since been subject. Though it is not very populous, it contains about 42 greater or walled towns, 47 smaller or open towns, and 158 market-towns, besides villages, &c. The states of the country consist of the clergy, lords, knights, and burghers; and the diets, when summoned by the regency, are held at Brunn. The marquisate is still governed by its own peculiar constitutions, under the direction of publics &c. &c. and the supreme jucicatory at Vienna. It is divided into six circles, each of which has its captain, and contributes to its sovereign about one-third of what is exacted of Bohemia. Tzowards the expenses of the military establishment of the whole Austrian hereditary countries, its year's quota is 1,800,000 florins. Seven regiments of foot, one of cuirassiers, and one of dragons, are usually quartered in it.

Christianity was planted in this country in the 6th century; and the inhabitants continued attached to the church of Rome till the 15th, when they espoused the doctrine of John Huss, and threw off popery; but after the defeat of the elector Palatine, whom they had chosen king, as well as the Bohemians, the emperor Ferdinand II. established popery; though there are still some Protestants in Moravia. The bishop of Olmutz, who stands immediately under the pope, is at the head of the ecclesiastics in this country. The supreme ecclesiastical jurisdiction, under the bishop, is vested in a consistory.

The commerce of this country is inconsiderable. Of what they have, Brunn enjoys the principal part. At Iglau and Trebits are manufactures of cloth, paper, gun-powder, &c. There are also some iron-works and glas-houses in the country.

The inhabitants of Moravia in general are open-hearted, not easy to be provoked or pacified, obedient to their masters and true to their promises; but credulous of old prophecies, and much addicted to drinking, though neither such sots or bigots as they are represented by some geographers. The boors, indeed, upon the river Hank, are said to be a thievish, unpolluted, brutal race. The sciences now begin to lift up their heads a little among the Moravians, the university of Olmutz having been put on a better footing; and a riding academy, with a learned society, have been lately established there.

MORAVIAN BROTHER. See HERHUTTERS, and UNITAS FRATRUM.

MORAW, or Morawa, a large river of Germany, which has its source on the confines of Bohemia and Silezia. It crosses all Moravia, where it waters Olmutz and Hradisch, and receiving the Taya from the confines of Lower Hungary and Upper Austria, separates these two countries as far as the Danube, into which it falls.

MORBID, among physicians, signifies "diseased or corrupt;" a term applied either to an unfound constitution, or to those parts or humours that are affected by a disease.

MORBUS COMITIALIS, a name given to the epilepsy; because if on any day when the people were assembl ed in comitia upon public business, any person suddenly seized with this disorder should fall down, the assembly was dissolved, and the business of the comitia, however important, was suspended. See COMITIA.

MORBUS REGIUS, the same with the JAUNDICE. See MEDICINE INDEX.

MORBUS, or DISCOURS, in botany. See VARIETAS.

MORDAUNT (Charles), earl of Peterborough, a celebrated commander both by sea and land, was the son of John Lord Mordaunt viscount Avalon, and was born about the year 1658. In 1675 he succeeded his father in his honours and estate. While young he served under the admirals Torrington and Narborough in the Mediterranean against the Algerines; and in 1680 embarked for Africa with the earl of Plymouth, and distinguished himself at Tangier when it was besieged by the Moors. In the reign of James II. he voted against the repeal of the test act; and distinguishing the measures of the court, obtained leave to go to Holland to accept the command of a Dutch squadron in the West Indies. He afterwards accompanied the prince of Orange into England; and upon his advancement to the throne, was sworn of the privy council, made one of the lords of the bedchamber to his majesty, also first commissioneer of the treasury, and advanced to the dignity of earl of Monmouth. But in November 1690 he was dismissed from his post in the treasury. On the death of his uncle Henry earl of Peterborough in 1697, he succeeded to that title; and, upon the accession of Queen Anne, was invested with the commissioneer of captain-general and governor of Jamaica. In 1705 he was sworn of the privy-council; and the same year declared general and commander in chief of the forces sent to Spain, and joint admiral of the fleet with Sir Cloudley Shovel, of which the year following he had the sole command. His taking Barcelonza with a handful of men, and afterwards relieving it when greatly distreessed by the enemy; his driving out of Spain the duke of Anjou, and the French army, which consisted of 25,000 men, though his own troops never amounted to 10,000; his gaining possession of Catalonia, the kingdoms of Valencia, Aragon, and the isle of Majorca, with part of Murcia and Catalonia, and thereby giving the earl of Galway an opportunity of advancing to Madrid without a blow; are astonishing instances of his bravery and conduct. For these important services his Lordship was declared general in Spain by Charles III. afterwards emperor of Germany; and on his return to England he received the thanks of the House of Lords. His Lordship was afterwards employed in several embassies to foreign courts, being knight of the garter, and made governor of Minorca. In the reign of George I. he was general of all the marine forces in Great Britain, in which post he was continued by King George II. He died in his paffage to Lisbon, where he was going for the recovery of his health, in 1735.—His Lordship was distinguished by his poiseing various shining qualities; for, to the greatest personal courage and resolution, he added all the arts and adresses of a general; a lively and penetrating genius; and a great extent of knowledge upon almost every subject of importance within the compass of
in the ^th year of Henry VIII, Sir Thomas More was made speaker of the house of commons; in which capacity he had the resolution to oppose the then powerful minister, Wolsey, in his demand of an appre-

![Image of a page from a book with text]

drative subsidy; notwithstanding which, it was not long before he was made chancellor of the duchy of Lancaster, and was treated by the king with singular familiarity. The king having once dined with Sir Thomas at Chelsea, walked with him near an hour in the garden, with his arm round his neck. After he was gone, Mr Roper, Sir Thomas's son-in-law, observed how happy he was to be so familiarly treated by the king: to which Sir Thomas replied, "I thank our lord, for Roper, I find his grace my very good lord indeed, and believe he doth as singularly favour me as any subject within this realm: howbeit, I must tell thee, I have no cause to be proud thereof; for if my head would win him a cull in France, it would not fail to go off." From this anecdote it appears, that Sir Thomas knew his grace to be a villain. In 1526 he was sent for to the Capital, with Cardinal Wolsey and others, on a joint embassy to France, and in 1529 with Bishop Tontal to Cambrai. The king, it seems, was so well satisfied with his services on these occasions, that in the following year, Wolsey being disgraced, he made him chancellor; which seems the more extraordinary, when we are told that Sir Thomas had repeatedly declared his disapprobation of the king's divorce, on which the great defectus fidei was so politically bent. Having executed the office of chancellor about three years, with equal wisdom and integrity, he resigned the seals in 1533, probably to avoid the danger of his refusing to confirm the king's divorce. He now retired to his house at Chelsea; dismissed many of his servants; sent his children with their respective families to their own houses (for hitherto he had, it seems, maintained all his children, with their families, in his own house, in the true style of an ancient patriarch); and spent his time in study and devotion: but the capricious tyrant would not suffer him to enjoy this tranquility. Though now reduced to a private station, and even to indigence, his opinion of the legality of the king's marriage with Anne Boleyn was deemed of so much importance, that various means were tried to procure his approbation: but all peroration proving ineffectual, he was, with some others, attainted in the house of lords of misprision of treason, for encouraging Elizabeth Barton, the nun of Kent, in her treasonable practices. His innocence in this affair appeared so clearly, that they were obliged to strike his name out of the bill. He was then accused of other crimes, but with the same effect; till, refusing to take the oath enjoined by the act of supremacy, he was committed to the Tower; and, after 15 months imprisonment, was tried at the bar of the King's-bench, for high treason, in denying the king's supremacy. The proof relied on the sole evidence of Rich the solicitor-general, whom Sir Thomas, in his defence sufficiently discredited; nevertheless the jury brought him in guilty, and he was condemned to suffer as a traitor. The merciful Harry, however indulged him with simple decollation; and he was accordingly beheaded on Tower-hill, on the 5th of July 1535. His body which was first interred in the Tower, was begged by his daughter Margaret, and...
More. and deposited at the chancel of the church at Chelsea, where a monument, with an inscription written by himself, had been some time before erected. This monument with the inscription is still to be seen in that church. The fame daughter, Margaret, also procured his head after it had remained 14 days upon Londonbridge, and placed it in a vault belonging to the Roper's family, under a chapel adjoining to St Dunstan's church in Canterbury. Sir Thomas More was a man of some learning, and an upright judge; a very pious religion, yet cheerful, and even affectedly witty (a). He wanted not sagacity, where religion was out of the question; but in that his faculties were so enveloped as to render him a weak and credulous enthusiast. He left one son and three daughters; of whom Margaret, the eldest, was very remarkable for her knowledge of the Greek and Latin languages. She married a Mr Roper of Well-hall in Kent, whose life of Sir Thomas More was published by Mr Hearne at Oxford in 1716. Mrs Roper died in 1544; and was buried in the vault of St Dunstan's in Canterbury, with her father's head in her arms.

Six Thomas was the author of various works, though his Utopia is the only performance that has survived in the eftem of the world; owing to the refi belonging chiefly of a polemic nature; his anfwer to Luther has only gained him the credit of having the blit knack of any man in Europe, at calling bad names in good Latin. His English works were collected and published by order of Queen Mary, in 1557; his Latin, at Basil, in 1563, and at Louvain in 1566.

More (Sir Antonio), an eminent painter, was born at Utrecht in 1519. He became a scholar of John Schorel, but seems to have studied the manner of Holbein, to which he approached nearer than to the freedom of design in the works of the great masters that he saw at Rome. Like Holbein he was a close imitator of nature, but did not arrive at his extreme delicacy of finishing; on the contrary, Antonio sometimes struck into a bold and masculine style, with a good knowledge of the chiaro furo. In 1542, he drew Philip II. and was recommended by cardinal Granvelle to Charles V., who sent him to Portugal, where he painted John III. the king, Catherine of Austria his queen, and the infant Mary first wife of Philip. For these three pictures he received 600 ducats, besides a gold chain of 1000 florins and other presents. He had 100 ducats for his common portraits. But still ampler rewards were bestowed on him when sent into England, to draw the picture of queen Mary, the intended bride of Philip. They gave him 1000 a. gold chain, and a pension of 1000 a. a quarter as painter to their majesties. He made various portraits of the queen; one was sent by cardinal Granvelle to the emperor, who ordered 200 florins to Antonio. He remained in England during the reign of Mary, and was much employed; but having neglected, as is frequent, to write the names on the portraits he drew, most of them have lost part of their value, by our ignorance of the persons represented. On the death of the queen, More followed Philip in to Spain, where he was indulged in so much familiarity, that one day the king flapping him pretty roughly on the shoulder, More returned the sport with his hand-flick; a strange liberty (Mr Walpole observes), to be taken with a Spanish monarch, and with such a monarch! A grandee interposed for his pardon, and he was ordered to retire to the Netherlands; but a messenger was dispatched to recall him before he had finished his journey. The painter, however, sensible of the danger he had escaped, modestly excused himself, and proceeded. At Utrecht he found the duke of Alva, and was employed by him to draw several of his mistresses, and was made receiver of the revenues of West Flanders; a pretenion with which they say he was so elated, that he burned his Cael and gave away his painting tools. More was a man of a lately and handsome presence; and often went to Brussels, where he lived magnificently. At what time or where he was knighted, is uncertain. He died at Antwerp in 1575, in the 50th year of his age. His portrait, painted by himself, is in the chamber of painters at Florence, with which the great duke, who bought it, so pleased, that he ordered a cartel with some Greek verses, written by Antonio Maria Salvini his Greek professor, to be affixed to the frame. Another picture of himself, and one of his wife, were in the collection of Sir Peter Lely. King Charles had five pictures painted by this master. Mr Walpole mentions a number of others that are in England. But More did not always confine himself to portraits. He painted several historic pieces, particularly one much esteemed of the resurrection of Christ with two angels, and another of Peter and Paul. A painter, who afterwards sold it to the prince of Condé, got a great deal of money by showing it at the foire St Germaine. He made a fine copy of Titian's Danae for the king; and left unfinished the Circumcision designed for the altar in the church of our Lady at Antwerp.

Morin (Henry), an eminent English divine and philosopher, in the 17th century, was educated at Eton school, and in Christ-college in Cambridge, of which he became a fellow, and spent his life in a retired way, publishing a great number of excellent works. He refused bishoprics both in Ireland and England. He was an open-hearted sincere Christian philosopher, who studied to establish men in the belief of providence against atheism. Mr Hobbes was used to say, that if his own philosophy was not true, there was none

(a) This last disposition, we are told, he could not refrain even at his execution. The day being come, he ascended the scaffold, which seemed so weak that it was ready to fall; whereupon, "I pray (said he) see me safe up, and for my coming down let me shift for myself." His prayers being ended, he turned to the executioner, and with a cheerful countenance said, "Pluck up thy spirits, man, and be not afraid to do thy office; my neck is very short, take heed therefore thou strike not awry for favoring thy honesty." Then laying his head upon the block, he bid him flay until he had put aside his beard, saying, "That had never committed any treason."
More (Alexander), was born at Calais in 1616. His father was a Scottishman, and principal of the college which the Calvinists had in that city. Alexander was sent to Geneva, where he was made professor of Greek and of Theology, and at the same time discharged the office of a pastor. His violent love of woman, and the irregularity of his conduct, excited a great number of enemies against him. Saumaise, informed of his disagreeable situation, invited him to Holland, where he was first appointed professor of Theology at Middleburgh, and afterwards professor of history at Amsterdam. The duties of these functions he discharged with great ability; and in 1655 he went to Italy, where he remained a considerable time. It was during his travels in Italy that he published his beautiful poem on the defeat of the Turkish fleet by the Venetians; and this work procured him the present of a golden chain from the republic. Having taken a dislike to Holland, he was translated to Charenton. There his sermons attracted a numerous audience, nor to a much for their eloquence as for the critical allusions and witcisms with which they were adorned. This kind of style succeeded with him, because it was natural; but in his imitators it appeared altogether ridiculous. The impertinency of his character brought him into new quarrels, especially with Daillé, who had greatly the better of him in the dispute.—This singular man died in Paris September 20th, 1670, aged 54, in the house of the duchess de Rohan. He was never married. His works are, 1. A Collection of Controversial Tracts. 2. Beautiful Orations and Poems, in Latin. 3. An answer to Milton, intituled, Alexandri, Mori fides publica. Milton has attacked him with great severity in his writings. Those sermons of his which are published, by no means justify the reputation which he had acquired for that kind of composition.

MOREA, formerly called the Peloponneseus, is a peninsula to the south of Greece, to which it is joined by the isthmus of Corinth. Its form resembles a mulberry-leaf, and its name is derived from the great number of mulberry-trees which grow there. It is about 80 miles in length, and 130 in breadth. The air is temperate, and the land fertile, except in the middle, where it is full of mountains, and is watered by a great number of rivers. It is divided into three provinces; Scania, Belvedera, and Brazzo-di-Mainia. It was taken from the Turks by the Venetians in 1687; but they lost it again in 1715. The magazines of the Morea resides at Modon. See GREECE and PELOPONNESUS.

MOREAU (James), an eminent French physician, born at Chalon-sur-Saone, was the disciple and friend of the famous Guy Patin. He drew upon himself the jealousy and hatred of the old physicians by the public theses he maintained, and afterwards vindicated in his writings. He died in a very advanced age in 1729. He wrote in French, 1. Consultations on the Rheumatism. 2. A chemical treatise on FEVERS. 3. A physical dissertation on the Dropisy; and other works which are esteemed.

MOREELSE (Paul), an eminent painter, was born at Utrecht in 1575, and studied painting under Michael Mirevelt. He was very successful, not only in portraits, but historical subjects and architecture, particularly after he had improved his taste by his studies in Italy. We have some excellent woodcuts in chiro-guro by this artist, who died in 1658.

MOREL, the name of several celebrated printers in the kings of France, who, like the Stephensons, were both men of great learning.

Frederic Morel, who was interpreter in the Greek and Latin tongues, as well as printer to the king, was heir to Vascofan, whose daughter he married. He was born in Champagne, and he died in an advanced age at Paris 1513. His sons and grandsons trode in his steps; they distinguished themselves in literature, and maintained also the reputation which he had acquired by printing. The edition of St Gregory of Nyssa, by his son Claude Morel, is held in great estimation by the learned.

Morel (Frederic), son of the preceding, and still more celebrated than his father, was professor and interpreter to the king, and printer in ordinary for the Hebrew, Greek, Latin, and French languages. He was so devoted to study, that when he was told his works would not finish till he had finished the sentence which he had begun, before it was finished, he was informed that he was actually dead; I am sorry for it (replied he coldly) she was an excellent woman. This printer acquired great reputation from the works which he published, which were very numerous and beautifully executed. From the manuscripts in the king’s library, he published several treatises of St Basil, Theodoret, St Cyrille; and he accompanied them with a translation. His edition of the works of Eumenius and Aretas, in 2 vols folio, is much esteemed. In short, after distinguishing himself by his knowledge in the languages, he died June 27, 1630, at the age of 78. His sons and grandsons followed the same profession.

Morel (William), regius professor of Greek, and director of the king’s printing house at Paris, died 1578. He compiled a Dictionnaire Gris-Latini-François, which was published in quarto in 1622, and some other works which indicate very extensive learning. His editions of the Greek authors are exceedingly beautiful. This scholar, who was of a different family from the preceding, had a brother named John, who died in prison (where he had been confined for heresy) at the age of 20, and whose body was dug out of the grave, and burnt Feb. 27, 1559. They were of the parish of Tilleul, in the county of Mortain, in Normandy.

Morel (Dom Robert), a benedictine monk of the society of Saint-Maur, was born at Chaise-Dieu in Auvergne, A. D. 1653. He was appointed keeper of the library of Saint-Germain des Pres in 1680. He was afterwards superior of different religious houses. In 1699 he disengaged himself from every care, and retired to Saint Denys, where he spent his time in composing works of practical religion. This learned monk, who enjoyed from nature a lively and fruitful imagination, excelled chiefly in subjects of piety, in a knowledge of the Christian character, and of the rules which regard the conduct of the Christian life. His conversations were sprightly and refined, his answers were prompt and ingenious, his temper was gentle, equable,
Mor.

Mor.

equable, and full of gaiety mingling with differection. His florid appearance did not debase the beauty of his mind. All his words breathed charity, piety, uprightness, sincerity, and innocence of manners. Great simplicity and modesty, the limits of which he never transgressed, concealed his excellencies from the vulgar, but made him rank higher in the estimation of the wife and sensible part of mankind. Dom Morel died about B.D. 1731 aged 70. His principal works are,

1. Effusions de cœur pour chaque jour des Jours de l'Église; Paris, 1716, in 5 vols. 12mo. P. de Tournemine, a Jéftuit, esteemed this book (which abounds in piety and alluring thoughts and expressions) so much, that he perused it constantly; and when he was obliged to go to the country he always carried a volume of it along with him. He earnestly sought to be introduced to the author, and interested on his knees that he would grant him his benediction (Histoire littéraire de la congrégation de Saint Mort, p. 504).

2. Entretiens spirituels sur les Évangiles des Dimanches et des Mefliers de toute l'année, divirés pour tous les jours de l'Année, 1720, 4 vols 12mo.

3. Entretiens spirituels, pour favor de préparation à la Mort, 12mo, 1721.

4. Initiation de N. S. L. C. a new translation, with a pathetic prayer, or an effusion of the heart, at the conclusion of every chapter, in 12mo, 1723.

6. De l'Esplance Chrétiennes et de la Conscience en la miséricorde de Dieu, 12mo, 1728.

The greater part of Morel's works are devotions; and his observations are drawn chiefly from the scriptures, and from the practical writings of the fathers. This circumstance greatly raised the reputation of his works, and at the same time excited the envy and ill-will of his enemies. By them he was treated on his knees that he would grant him his beneficence; and when he was obliged to go to the country he always carried a volume of it along with him. He earnestly sought to be introduced to the author, and interested on his knees that he would grant him his benediction (Histoire littéraire de la congrégation de Saint Mort, p. 504).

2. Entretiens spirituels sur les Évangiles des Dimanches et des Mefliers de toute l'année, divirés pour tous les jours de l'Année, 1720, 4 vols 12mo.

3. Entretiens spirituels, pour favor de préparation à la Mort, 12mo, 1721.

4. Initiation de N. S. L. C. a new translation, with a pathetic prayer, or an effusion of the heart, at the conclusion of every chapter, in 12mo, 1723.

6. De l'Espánce Chrétiennes et de la Conscience en la miséricorde de Dieu, 12mo, 1728.

The greater part of Morel's works are devotional; and his observations are drawn chiefly from the scriptures, and from the practical writings of the fathers. This circumstance greatly raised the reputation of his works, and at the same time excited the envy and ill-will of his enemies. By them he was considered a Jéftuit; and in this light he is represented in the Dictionnaire des livres Jéfuites.

Morel (Andreas), a very eminent antiquary, born at Berne in Switzerland. Having a strong passion for the study of medals, he travelled through several countries, and made large collections: in 1683 he published at Paris, in 8vo, Specimen universae rei nummariae antiquae: and the great work of which this was the specimen was to be a complete collection of all ancient medals, of which he had at that time 20,000 exactly described. Soon after this essay appeared, Louis XIV. gave him a place in his cabinet of antiquities, in which capacity he brought himself into great danger by speaking too freely of M. Louvois on account of the neglect in paying his salary, or on some other private account, as he was committed to the Bastille, where he lay for three years; nor was he released until the death of Louvois, nor till the canton of Berne had interceded in his favour. He afterward accepted an invitation from the count of Schwartz at Arnsbadt, in Germany, with whom he lived in the capacity of an antiquary, and was furnished with every thing necessary for carrying on his grand work. In 1703 he died; and in 1734 came out at Amsterdam part of this collection, in 2 vols. folio, under the title of Tresorium Morellaum, sive familiarem Romanorum nummariae omnis, diligentissime describata etque conpilata, &c. Nunc primum editis & commentariis perpetuo illustravit Sigismundus Bruyerecampus. These volumes contain an explication of 3530 medals, engraved, with their reverses.

Morena, (anc. geog.), a distif or division of Mytilene, in the Hither Asia. A part of which was occupied by Cleon, formerly at the head of a band of robbers, but afterward pried of Jupiter Abreternus, and enriched with possessions, first by Antony, and then by Caesar.

Moresby, a harbour a little above Whithaven, in Cumberland; in and about which many remains of antiquity have been dug up, such as altars and stones, with inscriptions on them; and several caverns have been found called Pit's Holes. Here is supposed to have been a Roman fortification.

Moresque, Morees, or Murillo, a kind of painting, carving, &c. done after the manner of the Moors; consisting of several grotesque pieces and compartments promiscuously intermingled, not containing any perfect figure of a man, or other animal, but a wild resemblance of birds, beasts, trees, &c. These are also called arabesques, and are particularly used in embroideries, damask-work, &c.

Morrice-dances vaguely called Morrice-dances are those altogether in imitation of the Moors, as far and in Germany, with whom he lived in the capacity of an antiquary, and was furnished with every thing necessary for carrying on his grand work. In 1703 he died; and in 1734 came out at Amsterdam part of this collection, in 2 vols. folio, under the title of Tresorium Morellaum, sive familiarem Romanorum nummariae omnis, diligentissime describata et sequens conpilata, &c. Nunc primum editis & commentariis perpetuo illustravit Sigismundus Bruyerecampus. These volumes contain an explication of 3530 medals, engraved, with their reverses.

Morgagni. See Fata.

Morgagni (John Baptii), doctor of medicine, first professor of anatomy in the University of Padua, and member of several of the most eminent societies of learned men in Europe; was born in the year 1682, at Forli, a town in the distrito of La Romagna in Italy. His parents, who were in easy circumstances, allowed him to follow that course in life his genius dictated. He began his study at the place of his nativity; but soon after removed to Bologna, where he obtained the degree of Doctor of Medicine, when he had but just reached the 16th year of his age. Here his peculiar taste for anatomy found an able preceptor in Valfalva, who bestowed on him the utmost attention; and such was the progress he made under this excellent master, that at the age of 20 he himself taught anatomy with a high reputation. Soon, however, the fame of his prelections, and the number of his pupils excited the jealousy of the public professors, and gave rise to invidious persecutions. But his abilities and prudence gained him a complete triumph over his enemies; and all opposition to him was finally terminated from his being appointed by the Senate of Bologna to fill a medical chair, which soon became vacant. But the duties of this office, although important, neither occu-
MORGAGNA, the whole of his time, nor satisfied his anxious desire to afford instruction. He still continued to labour in secret on his favourite subject, and soon after communicated the fruits of these labours to the public in his Adversaria Anatomica, the first of which was published in the year 1706, the second and third in 1717, and the three others in 1719. The publication of this excellent work spread the fame of Morgagni far beyond the limits of the state of Bologna. Such was his reputation, that the wife republic of Venice had no hesitation in making him an offer of the second chair of the theory of medicine in the university of Padua, then vacant by the death of M. Molinetti; and, to ensure his acceptance, they doubled the emoluments of that appointment. While he was in this department he published his treatise, entitled Nova institutionum medicarum idea, which first appeared at Padua in the year 1712. From this work his former reputation suffered no diminution. And soon after he rose, by different steps, to be first professor of anatomy in that celebrated university. Although Morgagni was thus finally settled at Padua, yet he gave evident proofs of his gratitude and attachment to Bologna, which he considered as his native country with respect to the sciences. He exerted his utmost efforts in establishing the academy of Bologna, of which he was one of the first associates; and he enriched their publications with several valuable and curious papers. Soon after this, the Royal societies of London and Paris received him among their number. Not long after the publication of his Adversaria Anatomica, he began, much upon the same plan, his Epistola Anatomica, the first of which is dated at Padua in the beginning of April 1726. The works of Morgagni which have already been mentioned, are to be considered, in a great measure, as firstly anatomical: but he was not more eminent as an anatomist, than as a learned and successful physician. In the year 1760, when he was not far distant from the 80th year of his age, he published his large and valuable work De causis et findibus morborum per anatomen indagatis. This last and most important of all his productions will afford convincing evidence of his industry and abilities to late posterity. Besides these works, he published, at different periods of his life, several miscellaneous pieces, which were afterwards collected into one volume, and printed under his own eye at Padua, in the year 1765. It does not appear that he had in view any favourite publications; but he intended to have favoured the world with a complete edition of all his works, which would probably have been augmented with many new observations. In this he was engaged when, on the 5th of December 1771, after he had nearly arrived at the 90th year of his age, death put a period to his long and glorious career in the learned world.

MORINGS, or MORGAGNA, Fata. See Fata.

MORGES, a handsome and rich town of Switzerland, in the canton of Bern, and capital of a bailiwick, with a castle where the bailiff resides. It is a place of some trade, on account of a canal, from which they transport merchandise to the lake of Geneva, and thereby give occasion to its Musaeus sublanaris anatomia, which was his first production, and published in 1619. Upon his return to his native country, he contracted an attachment to the countess, and eventually married her.
MORIN (John), a very learned Frenchman, born at Blois, of Protestant parents, in 1591; but converted by cardinal du Perron to the catholic religion. He published, in 1626, some Exercitations upon the original of Patriarchs and Primates, and the ancient usage of ecclesiastical censores; dedicated to pope Urban VIII. In 1628 he undertook the edition of the Septuagint Bible, with Novius's version; and placed a preface before it, in which it treats of the authority of the Septuagint, and prefers the version in the edition made at Rome by order of Sixtus V. to the present Hebrew text, which he affirms has been corrupted by the Jews. About the same time he gave a French History of the deliverance of the church by the emperor Conftantine, and of the temporal greatnesfs conferred on the Roman church by the kings of France. He afterwards published Exercitations upon the Samaritan Pentateuch; and took the care of the Sama­ritan Pentateuch, for the Polyglot then preparing at Paris. He was greatly carefled at Rome; where after living nine years at the invitation of cardinal Barbarini, he was recalled by Cardinal Richelieu, and died at Paris in 1659. His works are very numerous; and some of them as much valued by Protestants as Papifts for the oriental learning they contain.

MORIN (Simon), a celebrated fanatic of the 17th century, was born at Richemont, near Aumale, and had been clerk to Mr Charron, general paymaster of the army. He was very ignorant and illiterate; and for the oriental learning they contain.

MORIN died at liberty as a visionary; and suffered to continue so till 1661, when Des Marets de St Sorin, who, though a fanatic and visionary himself, had conceived a violent aversion to him, discovered his whole scheme and had him taken up. The means Des Marets made use of for this discovery was by pretending to be one of his disciples; and he carried his treachery and dif­simulation so far, as to acknowledge him for "the Son of man riven again." This acknowledgment fo pleased Morin, that he conferred upon him, as a particular grace the office of being his harbinger, calling him a real 'John the Baptist restored.' Then Des Ma­rets impeached him, and became his acccuer; upon which Morin was brought to a trial, and condemned to be burnt alive. This sentence was executed on him at Paris, March 14th, 1663, in the form and man­ner following: After having made the amende honourable in his shirt with a cord about his neck and a torch in his hand, before the principal gate of the church of Notre Dame, he was carried to the place of exec­ution, and there tied to a stake; and after having been whipped by the hangman, and marked with a burning iron with fleurs de lis upon the right and left shoulders. Morin gave out that he would rife again the third day; which made many of the mob gather together at the place where he was burnt.—It is said, that when the pre­dent de Lamoignon asked him, whether it was written in any part of Scripture, that the great prophet or new Messiah should pass through the fire! he cited this text by way of answer: Lyne me examinatis, et non est inventa in me ini­quiitas; that is, "Thou hast tried me with fire, and no wickedness hath been found in me." Morin died with remarkable resolution; and it was then thought the judges had been too rigorous in their sentence, and that sending him to a mad-house would have been suf­ficient. They replied in defence of themselves, that Morin had owned many impious tenets; and that not in sudden flarts and fits of heat, but in cool blood, and with deliberate obstinacy. But then a question will arise, whether a fool, any more than a madman, ought to be capitally punished for any opinion or degree of stubborness?

MORIN (Peter), was born at Paris, A. D. 1531: he went into Italy, and was employed by the learned Paulus Manucius in his printing-house at Venice.—He afterwards taught Greek and cophography at Vic­encia whence he was called to Ferrara by the duke of that name. St Charles Borromeus, informed of his profound knowledge in ecclesiastical antiquities, of his disinterestedness, of his zeal and piety, offered him his friendship, and engaged him to go to Rome in 1575. The popes Gregory XIII. and Sixtus V. employed him in an edition of the Septuagint, 1587, and in one of the Vulgate, 1590, in folio. He also spent much of his time on an edition of the Bible translated from the Septuagint, and published at Rome, 1588, in folio; on an edition of the Decretals to the
MORIN (Stephen), minister of the Protestant reformed religion at Caen, the place of his birth, was admitted a member of the Academy of Belles Lettres in that city, notwithstanding an express law which excluded Protestants. His great learning gained him this mark of distinction. After the revocation of the edict of Nantes, he retired to Leyden in 1685, and from that to Amsterdam, where he was appointed professor of Oriental languages. He died in 1700, at the age of 75, after being long subject to infirmities both of body and mind. He published eight dissertations in Latin relating to subjects of antiquity, which are extremely curious. The Dordrecht edition of 1700, 8vo, is the best, and preferable to that published at Geneva in 1683, 4to. He wrote likewise the life of Samuel Bochart.

MORIN (Henry), son to the preceding, was born at Saint-Pierre-Sur-Dive, in Normandy, and became a Roman Catholic after he had been a Protestant minister. He is the author of several dissertations which are to be found in the Memoirs of the Academy of Inscriptions, of which he was a member. He died at Caen, on the 16th of July 1728, aged 60, as much esteemed as his father.

MORIN (Lewis), was born at Mans in 1635. He went on foot to Paris to study philosophy, and collected herbs during the whole journey. He afterwards studied physic, and lived in the manner of an anchorite, on bread and water, or at most a few fruits, being his whole subsistence. Paris was to him a hermitage; with this exception, that it furnished him with books, and with the conversation and acquaintance of the learned. He received the degree of doctor of medicine in 1662; and, after several years practice, he was expectant at the Hotel-Dieu. His reputation made Madame de Guise choose him for her first physician, and the Academy of Sciences for one of its members. He died A. D. 1715, aged 80. A long and vigorous life, with a gentle and easy death, were the rewards of his temperance. The exercises of religion and the duties of his station occupied his whole time. No part of it was spent in paying or receiving visits. "Those who come to see me (said he) do me honour; those who do not come, lay me under an obligation." "It was only an Anthony (said Fontenelle) who could visit this Paul." He left a library valued at 20,000 crowns, an herbal together with a cabinet of medals; and this seems to have been his whole fortune. His mental enjoyments had been much more expensive than those of the body. An index to Hippocrates, in Greek and Latin, much more copious and better finished than that of Pinus, was found among his papers.

MORIN (John), was born at Meung near Orleans in 1705, and in 1732 he was appointed professor of philosophy at Chartres. In 1750 the bishop of Chartres rewarded his long and diligent attention to classical learning by a canonry in the cathedral. At the age of 38, Morin published his Methamime Universel, one volume 12mo, which contains a great deal of information, but much more conjecture. His next work was a Treatise on Electricity, published in 1748. His third and last performance was an answer to the Abbé Nollet, who had attacked his opinions concerning electricity. His reputation was not limited to the province in which he lived: he was well known to the academies of sciences at Paris and Rouen, with whom he frequently corresponded. He continued his application to the sciences, and displayed the virtues of the priest and the philosopher to the last hour of his life. This valuable man died at Chartres, on the 28th of March 1764, at the age of 59.

MORINA, in botany: A genus of the monogynia order, belonging to the diandria class of plants; and in the natural method ranking under the 48th order, Aggregate. The corolla is unequal; the calyx of the fruit is monophyllous and dentated; the calyx of the flower bifid; there is one seed under the calyx of the flower.

MORINORUM CASTELLUM (anc. geog.), simply Cadellum (Antoine); situated on an eminence, with a spring of water on its top, in the territory of the Morini. Now Mont Cadell, in Flanders.

MORINDA, in botany: A genus of the monogynia order, belonging to the pandentia class of plants; and in the natural method ranking under the 48th order, Aggregate. The flowers are aggregate and monopetalous; the stigmata bifid; the fruit plums aggregate, or in clusters.

MORISON (Robert), a physician and professor of botany at Oxford, was born at Aberdeen in 1620, and entered at the university there, and taught philosophy for some time in it; but having a strong inclination to botany, made great progress in it. The civil wars obliged him to leave his country; which, however, he did not do till he had first signalized his zeal for the interest of the king, and his courage, in a battle fought between the inhabitants of Aberdeen, and the Presbyterian troops on the bridge of Aberdeen, in which he received a dangerous wound on the head. As soon as he was cured of it, he went into France; and fixing at Paris, he applied assiduously to botany and anatomy. He was introduced to the duke of Orleans, who gave him the direction of the royal gardens at Blois. He exercised the office till the death of that prince, and afterwards went over to England in 1660. Charles II., to whom the duke of Orleans had presented him at Blois, sent for him to London, and gave him the title of his physician, and that of professor royal of botany, with a pension of 200 l. per annum. The Prodromus Botanicum, which he published in 1669, procured him so much reputation, that the university of Oxford invited him to the professorship of botany in 1669; which
Morisonia, which he accepted, and acquitted himself in it with great ability. He died at London in 1683, aged 63. He published a second and third part of his History of Plants, in 2 vols. folio; with this title, Plantarum Historia Oxoniensis Universa'ti. The first part of this excellent work has not been printed: and it is not known what has become of it.

MORISONIA, in botany: A genus of the polyandria order, belonging to the monadelphous class of plants and in the natural method ranking under the 24th order, putaminis. The calyx is simple and bidentiform; the corolla is tetrapetalous; there is one pistil; the berry is single, unilocular, polypermentous, and peduncellated.

MORLACHIA, a mountainous country of Dalmatia. The inhabitants are called Morlachi, or Morlabi; they inhabit the pleasant valleys of Koter, along the rivers Kerha, Cettina, Marenta, and among the inland mountains of Dalmatia. The inhabitants are by some said to be of Walachian extraction, as according to these authors is indicated even by their name; Morlachi being a contraction of Mauro-walachia, that is, Black Walachia: and the Walachians are said to be descendants of the ancient Roman colonies planted in these countries. This, however, is denied by the Abbé Fortis, who hath published a volume of travels into that country. He informs us, that the origin of the Morlachi is involved in the dark ages of barbarous ages, together with that of many other nations, remembering them so much in customs and language, that they may be taken for one people, differing in the vast tracks from the Adriatic sea to the frozen ocean. The emigrations of the various tribes of the Slav, who, under the names of Scythians, Gei, Goths, Hung, Slavini, Creuts, Avarri, and Vandals, invaded the Roman empire, and particularly the Illyrian provinces during the decline of that empire, must have strangely perplexed the genealogies of the nations which inhabited it, and which perhaps removed thither in the same manner as at more remote periods of time. The remainder of the Albiani, Asturiani, and other Illyrian people anciently settled in Dalmatia who probably could not reconcile themselves to a dependance on the Romans, might not in their own language, Vlazia; a national term, of which no veltige is found in the records of Dalmatia till the 13th century. It signifies powerful men, or men of authority; and the denomination of Mora Vlazia, corruptly Morlachi, as they are now called, may perhaps point out the original of the nation. This word may possibly signify the conquerors that came from the sea, Mor, in all the dialects of the Slavonian language, signifying the sea.

The Morlachi are so different from the inhabitants of the sea-coasts in dialect, dress, dispositions, and customs, that they seem clearly to be of a different original, or at least the colonies must have settled at such distant periods from each other, that they have had time to alter in a great measure their national character. There is also a remarkable diversity among the Morlachi themselves in several districts, probably on account of the different countries from whence they came.

With regard to the character of these people, we are informed that they are much injured by their maritime neighbours. The inhabitants of the sea-coast of Dalmatia tell many frightful stories of their avarice and cruelty: but these, in our author's opinion, are all either of an ancient date, or if any have happened in latter times, they ought rather to be ascribed to the corruption of a few individuals, than to the disposition of the nation in general; and though their tricks are frequent among them, he informs us, that a stranger may travel securely through their country, where he is faithfully escorted, and hospitably treated. The greatest danger is from the Haiducks or Banditti, of whom there are great numbers among the woods and caves of these dreadful mountains on the confines. Yet they are in no other country, or if they disturb the tranquility of others, and prove always faithful guides to travellers; the chief objects of their rapine being sheep and oxen, to supply themselves with food and shoes. Sometimes it happens, that in their extreme necessity the Haiducks go in parties to the shepherds' cottages, and rude demand something to eat; which they do not fail to take immediately by force if the least hesitation is made. It is a custom indeed they meet with a respectful, or with reluctance, as their relatiotn and fury are well known to be equal to the savage life they lead. Four Haiducks are not afraid to assault a caravan of 15 or 20 Turks, and generally plunder and put them to flight. The greatest part of the Haiducks keep upon it as a meritorious action to shed the blood of the Turks; to which cruelty they are easily led by their natural ferocity, inflamed by a mistaken zeal for religion, and the dicipulars of their fanatic priests.

As to the Morlachi themselves, they are represented as open and sincere to such a degree, that they would be taken for simpletons in any other country; and by means of this quality they have been so often duped by the Italians, that the faith of an Italian and the faith of a dog, are synonymous among the Morlachi. They are very hospitable to strangers, and their hospitality is equally conspicuous among the rich and poor. The rich prepares a roasted lamb or sheep, and the poor with equal cordiality offers what he has; nor is this generosity confined to strangers, but generally extends itself to all who are in want.
When a Morlack is on a journey, and comes to lodge at a friend's house, the eldest daughter of the family, or the new-married bride if there happens to be one, receives and kills him when he alights from his horse or at the door of the house: but a stranger is rarely favoured with these female civilities; on the contrary, the women, if they are young, hide themselves, and keep out of his way.

The Morlacchi in general have little notion of domestic economy, and readily consume in a week as much as would be sufficient for several months, whenever any occasion of mourning presents itself. A marriage, the holiday of the saint, protector of the family, the arrival of relations or friends, or any other joyful incident, consumes of course all that there is to eat and to drink in the house. Yet the Morlack is a great economisf in the use of his wearing-apparel; for rather than spoil his new cap, he takes it off let it rain ever so hard, and goes bareheaded in the storm. In the same manner he treats his shoes, if the road is dirty and they are not very old. Nothing but an absolute impossibility hinders a Morlack from being punctual; and if he cannot repay the money he borrowed at the appointed time, he carries a small present to his creditor, and requests a longer term. Thus it happens sometimes, that, from term to term, and present to present, he pays double what he owed, without reflecting on it.

Friendship, that among us is so subject to change on the slightest motives, is lasting among the Morlacchi. They have even made it a kind of religious point, and tie the sacred bond at the foot of the altar. The Scelvonian ritual contains a particular benediction for the solemn union of two male or two female friends in the presence of the congregation. The male friends thus united are called Pobratimi, and the female Pobratimini, which mean half-brothers and half-sisters. Friendships between those of different sexes are not at this day bound with so much solemnity, though perhaps in more ancient and innocent ages it was also the custom.

From these consecrated friendships among the Morlacchi and other nations of the same origin, it should seem that the facta brothers arose; a denomination frequent enough among the common people of Italy and in many parts of Europe. The difference between these and the Probratimini of Morlacchia confit not only in the want of the ritual ceremony, but in the design of unity itself. For, among the Morlacchi, the sole view is reciprocal service and advantage; but such a brotherhood among the Italians is generally commenced by bad men, to enable them the more to hurt and disturb society. The duties of the Pobratimini are, to ailton each other in every case of need or danger, to revenge mutual wrongs, and such like. The enthusiasm is often carried so far as to risk and even to lose their life for the Pobratimini, although these savage friends are not celebrated like Pyliades. If discord happens to arise between two friends, it is talked of over all the country as a scandalous novelty, and there has been some examples of it of late years, to the great affliction of the old Morlacchi, who attribute the depravation of their countrymen to their intercourse with the Italians. Wine and strong liquors, of which the nation is beginning to make daily

abuse, will of course produce the same bad effects as in the case of others.

But as the friendships of the Morlacchi are strong and sacred, so their quarrels are commonly unextinguishable. They pass from father to son; and the mothers fail not to put their children in mind of their duty to revenge their father if he has had the misfortune to be killed, and to show them often the bloody skirt and arms of the dead. And so deeply is revenge rooted in the minds of this nation, that all the millenaries in the world would not be able to eradicate it. A Morlack is naturally inclined to do good to his fellow-creatures, and is full of gratitude for the smallest benefit; but implacable if injured or insulted.

A Morlack who has killed another of a powerful family, is commonly obliged to save himself by flight, and to keep out of the way for several years. If during that time he has been fortunate enough to escape the search of his pursuers, and has got a small sum of money, he endeavours to obtain pardon and peace; and, that he may treat about the conditions in person, he asks and obtains a safe conduct, which is faithfully maintained, though only verbally granted. Then he finds mediators; and, on the appointed day, the relations of the two hostile families are assembled, and the criminal is introduced, dragging himself along on his hands and feet, the mulek, pilol, or cutlafs, with which he committed the murder, hung about his neck; and while he continues in that humble posture, one or more of the relations recites a panegyric on the dead, which sometimes rekindles the flames of revenge, and puts the poor prostrate in no small danger. It is the custom in some places for the offended party to threaten the criminal, holding all kinds of arms to his throat, and, after much intreaty, to consent at last to accept of his ransum. These pacifications cost dear in Albania; but the Morlacchia make up matters sometimes at a small expense; and every-where the business is concluded with a feast at the offender’s charge.

The Morlacks, whether they happen to be of the Roman or of the Greek church, have very singular ideas about religion; and the ignorance of their teachers daily augments the common people’s monstrous evil. They are as firmly persuaded of the reality of witches, fairies, enchantments, nocturnal apparitions, and fortillges, as if they had seen a thousand examples of them. Nor do they make the least doubt about the existence of vampires; and attribute to them, as in Transylvania, the fucking of blood of infants. Therefore, when a man dies suspected of becoming a vampire, or voodloe, as they call it, they cut his hams, and prick his whole body with pins; pretending, that after this operation he cannot walk about. There are even instances of Morlacchi, who, imagining that they may possibly thirst for children blood after death, intreat their heirs, and sometimes oblige them to promise, to treat them as vampires when they die.

The boldest Haiduk would fly trembling from the appearance of a spectre, ghost, phantam, or such like goblins as the heated imaginations of credulous and preposterous people never fail to see. Nor are they ashamed, when ridiculed for this terror; but answer, much in the words of Pindar; “Fear that proceeds from

in others, tremulous plumes of glass; and in others, artificial-flowers, which they purchase in the sea-port towns; and in the variety of these capricious and barbarous ornaments, sometimes a fancy not ineluctable is displayed. Their holiday-shirts are embroidered with red silk, and sometimes with gold, which they work themselves while they attend their flocks; and it is surprising to see how nicely this work is executed.

Both old and young women wear about their necks large strings of glass-beads, of various size and colour; and many rings of brass, tin, or silver, on their fingers. Their bracelets are of leather covered with wrought tin or silver; and they embroder their stomachers, or adorn them with beads or shells. But the use of stays is unknown, nor do they put whale-bone or iron in the stomacher. A broad woollen girdle surrounds their petticoat, which is commonly decked with shells, and of blue colour, and therefore called modrin6. Their gown, as well as petticoat, is of a kind of serge; and both reach near to the ankle; the gown is bordered with scarlet, and called fadak. Their robe of the same material is without sleeves over a linen petticoat or shift.

The girls always wear red stockings; and their shoes are like those of the men, called opanke. The sole is of undressed ox-hide, and the upper part of sheep-skin thongs knotted, which they call aputa; and these they fall on above the ankles, something like the ancient cotothurns.

The unmarried women, even of the richest females, are not permitted to wear any other sort of shoes; though after marriage they may, if they will, lay aside the opanke, and use the Turkish slippers. The girls keep their hair tressed under their caps, but when married they let it fall dishevelled on the breast; sometimes they tie it under the chin; and always have medals, beads, or bored coins, in the Turkish or American mode twisted amongst it. An unmarried woman, who falls under the imputation of want of chastity, runs the risk of having her red cap torn off her head publicly in church by the curate, and her hair cut by some relation, in token of infamy. Hence, if any of them happen to have fallen into an illicit amour, they commonly of their own accord lay aside the badge of virginity, and remove into another part of the country.

Nothing is more common among the Morlachi than marriages concluded between the old people of the respective families, especially when the parties live at a great distance and neither see nor know each other: and the ordinary motive of these alliances is the ambition of being related to a numerous and powerful family, famous for having produced valiant men. The father of the future bridegroom, or some other near relation of mature age, goes to ask the young woman, or rather a young woman of such a family, not having commonly any determinate choice. Upon this all the girls of the house are shown to him, and he chooses which pleases him best, though generally respecting the right of seniority. A denial in such cases is very rare; nor does the father of the maid inquire much into the circumstances of the family that asks her. Sometimes a daughter of the master is given in marriage to the servant or tenant, as was usual in patriarchal times; so little are the women regarded in this country. On these occasions, however, the Mor. Marachi girls enjoy a privilege which ours would also with to have, as in justice they certainly ought. For he who acts by proxy, having obtained his fair, is obliged to go and bring the bridegroom; and if, on seeing each other, the young people are reciprocally content, the marriage is concluded, but not otherwise. In some parts it is the custom for the bride to go to see the house and family of the proposed husband, before she gives a definitive answer; and if the place or persons are disagreeable to her, she is at liberty to annul the contract. But if she is contented, she returns to her father’s house, escorted by the bridegroom and nearest relations. There the marriage day is appointed: on which the bridegroom comes to the bride’s house, attended by all his friends, of greatest note, who on this occasion are called fowas, and are all armed, and on horseback, in their holiday-cloaths with a peacock’s feather in their cap, which is the distinctive ornament used by those who are invited to wadings. The company goes armed, to repulse any attack or ambush that might be intended to disturb the feast; for in old times these encounters were not unfrequent according to the records of many national heroic songs.

The bride is conducted to a church veiled, and surrounded by the svent on horseback: and the sacred ceremony is performed amidst the noise of muskets, pistols, barbaric shouts and acclamations, which continue till she returns to her father’s house, or to that of her husband, if not far off. Each of the svent has his particular inspection, as well during the cavalcade as at the marriage-feast, which begins immediately on their return from church. The parvaux precedes all the rest, singing such songs as he thinks suitable to the occasion. The bariafras brands a lance with a tife banner fastened to it, and an apple stuck on the point; there are two bariafras, and sometimes four at the more noble marriages. The firi-svent is the principal personage of the brigade; and the most respectable relation is commonly invested with this dignity. The flacheo’s duty is to receive and obey the orders of the firi-svent. The two divers, who ought to be the bridegroom’s brothers when he has any, are appointed to serve the bride. The knum corresponds to our sponsors; and the komorgia, or sekfa, is deputed to receive and guard the dowry. A crowd carries the mace, and attends to the order of the march, as master of the ceremonies; he goes singing aloud, Brereri, Davari, Dobrofriechi, Hari, Pio; names of ancient prophetical deities. Bukla is the cup-bearer of the company, as well on the march as at table; and all these offices are doubled, and sometimes tripled; in proportion to the number of the company.

The first day’s entertainment is sometimes made at the bride’s house, but generally at the bridegroom’s, whether the svent set immediately after the nuptial benediction: and at the same time three or four men run on foot to tell the good news; the first who gets to the house has a kind of towel, embroidered at the ends, as a premium. The domachi, or head of the house, comes out to meet his daughter-in-law; and a child is handed to her, before the alights, to care for it; and if there happens to be none in the house, the child is borrowed from one of the neighbours. When the

T 2

alights,
then the mother-in-law, or in her place fame other female relation, presents a corn-feed, full of different kinds of grain, nuts, almonds, and other small fruit, which the bride scatters upon the svati, by handfuls, behind her back. The bride does not sit at the great table the first day, but has one apart for herself, the two dervi, and the flatheo. The bridegroom sits at table with the svati; but in all that day, consecrated to the matrimonial union, he must neither uncloset nor cut any thing whatever. The knum carves his meat, and eats his bread. It is the domachin's business to give the toasts, and the farr-svati is the first who pledges him. Generally the bukkara, a very large wooden cup, goes round, first to the faint protector of the family; next to the prosperity of the holy faith; and sometimes to a name the most sublime and venerable. The most extravagant abundance reigns at these feasts; and each of the svati contributes, by sending a share of provisions. The dinner begins with fruit and cheeses; and the soup comes last, just contrary to our custom. All sorts of domestic fowls, kid, lamb, and sometimes venison, are heaped in prodigal quantities upon their tables; but very rarely a Morlaccho eats veal, and perhaps never, unless he has been persuaded to do it out of his own country. This abhorrence to calves flesh is very ancient among the Morlacchi. St. Jerome, against Jovinian, talks notice of it; and Tomaso Marnavich, a Bofian writer, who lived in the beginning of the last age, says, that the Dalmatians, uncorrupted by the vice of strangers, abstained from eating calves flesh as an unclean food, even to his days. The women relations, if they are invited, never dine at table with the men, it being an established custom for them to dine by themselves. After dinner, they pass the rest of the day in dancing, singing ancient songs, and in games of dexterity, or of wit and fancy; and in the evening, at a convenient hour after supper, the three ritual healths having first gone round, the knum accompanies the bridegroom to the matrimonial apartment, which commonly is the cellor or the stabel, whither the bride is also conducted by the dervi and the flatheo; but the three laft are obliged to retire, and the knum remains alone with the new-married couple. If there happens to be any bed prepared better than straw, he leads them to it: and having untied the bride's girdle, he caueth them both to undress each other reciprocally. It is not long since the knum was obliged to undress the bride entirely; but that custom is now out of use; and, instead of it, he has the privilege of kissing her as often as he pleases, where he meets her; which privilege may possibly be agreeable for the first months, but must soon become very disgusting. When they are both undressed, the knum retires, and stands liftening at the door, if there be a door. It is his business to announce the consummation of the marriage, which he does by discharging a pistol, which is answered by many of the company. The next day the bride, without her veil and virginal cap, dines at table with the svati, and is forced to hear the coarse equivocal jeers of her indelicate and sometimes intoxicated company.

These nuptial-feasts, called sdrawje by the ancient Usuri, are by our Morlacchi called sdrawvize, from whence our Italian word sdrawvize is undoubtedly derived. They continue three, six, eight, or more days, according to the ability or prodigal disposition of the family where they are held. The new-married wife gets no inconsiderable profit in these days of joy; and it usually amounts to much more than all the portion the brings with her, which often consists of nothing but her own clothes and perhaps a cow; nay, it happens sometimes that the parents, instead of giving money with the daughter, get something from the bridegroom by way of price. The bride carries water every morning to wash the hands of her guests as long as the feasting lasts; and each of them throws a small piece of money into the basin after performing that function, which is a very rare one among them, excepting on such occasions. The brides are also permitted to raise other little contributions among the svati, by hiding their shoes, caps, knives, or some other necessaries of their equipment, which they are obliged to ransom by a piece of money, according as the company rates it. And, besides all these voluntary or extorted contributions already mentioned, each guest must give some present to the new married wife at taking leave the last day of the sdrawvize: and then the also distributes some trifles in return, which commonly consist in shirts, caps, handkerchiefs, and such like.

The nuptial-rites are almost precisely the same thro' all the vast country inhabited by the Morlacchi; and those in use among the peasants and common people of the sea-coast of Dalmatia, Istria, and the islands, differ but little from them. Yet among these particular varieties, there is one of the island Zlarine, near Sebenico, remarkable enough; for there the farr-svati (who may naturally be supposed drunk at that hour) must at one blow with his naked broad sword, strike the bride's crown of flowers off her head, when she is ready to go to bed. And in the island of Pago, in the village of Novoglia (probably the Gifia of ancient Geographers) there is a custom more comical, and less dangerous, but equally savage and brutal. After the marriage contract is settled, and the bridegroom comes to conduct his bride to church, her father or mother, in delivering her over to him, makes an exaggerated enumeration of her ill qualities: "Know, since thou wilt have her, that she is good for nothing, ill-natured, obstinate, &c." On which the bridegroom, affecting an angry look, turns to the young woman, with an "Ah! since it is so, I will teach you to behave better:" and at the same time regales her with a blow or a kick, or some piece of similar galantry, which is by no means figurative. And it seems in general, that the Morlacchi women, and perhaps the greatest part of the Dalmatians, the inhabitants of the cities excepted, do not dislike a beating either from their husbands or lovers.

In the neighbourhood of Derniff, the women are obliged, during the first year after marriage, to kiss all their national acquaintances who come to the house; but after the first year they are dispensed from that compliment: and indeed they become so intolerably nattily that they are no longer fit to practice it. Perhaps the mortifying manner in which they are treated by their husbands and relations is, at the same time, both
Morlacchi, both the cause and effect of their shameful neglect of their persons. When a Morlack husband mentions his wife, he always premisses, by your leave, or begging your pardon. And when the husband has a bed-fell, the wife must sleep on the floor near it. Our author often lodged in Morlack houses, and observed that the female sex is universally treated with contempt; it is true, that the women are by no means amiable in that country; they even deform and spoil the gifts of nature.

The pregnancy and births of those women would be thought very extraordinary among us, where the ladies suffer so much, notwithstanding all the care and circumstanced used before and after labour. On the contrary, a Morlack woman neither changes her food nor interrupts her daily fatigue on account of her pregnancy; and is frequently delivered in the fields, or on the road, by herself; and takes the infant, washes it in the first water she finds, carries it home and returns the day after to her usual labour, or to feed her flock.

The little creatures, thus carelessly treated in their tenderest moments, are afterwards wraught in miserable rags, where they remain three or four months, under the same ungentle management; and when that term is elapsed, they are set at liberty, and left to crawl about the cottage and before the door, till they learn to walk upright by themselves; and at the same time acquire that singular degree of strength and health with which the Morlacchi are endowed, and are able, without the least incoherence, to expede their naked breasts to the severest frost and snow. The infants are allowed to suck their mother's milk while she has any, or till she is with child again; and if that is elapsed, they are set at liberty, and left to crawl all the relations and friends send presents of eatables to the woman in childbed, or rather to the woman delivered; and the family makes a supper of all those presents together. The women do not enter the church till 40 days after child-birth.

The Morlacchi pass their youth in the woods, at the forest of Boigny, subject to the Porte, where no women run about, without breeches, in a of the Morlackian women is somewhat extraordinary; for it is very certain, that they can give the teat to their children over their shoulders, or under their arms. They let the boys run about, without breeches, in a shirt that reaches only to the knee, till the age of 13 or 14, following the custom of Boffina, subject to the Porte, where no haraz or capitation-tax is paid for the boys till they wear breeches, they being considered before that time as children not capable of labouring, or of earning their bread. On the occasion of births, and especially of the first, all the relations and friends send presents of eatables to the woman in childbed, or rather to the woman delivered; and the family makes a supper of all those presents together. The women do not enter the church till 40 days after child-birth.

Mor

Morne-garon, a very remarkable volcanic mountain on the island of St. Vincent's in the West Indies. It was visited by Mr. James Anderson surgeon in the year 1784, who is the only person that ever ascended to the top of it, and from whose account, in the Philosophical Transactions, Vol. LXXV. the following is taken.

The mountain in question is situated on the north-west part of the island, and is the highest in it. It is constantly reported to have emitted volcanic eruptions; and the ravines at the bottom seem to corroborate the traditions of the inhabitants in this respect. The structure of it, when viewed at a distance, appears different from that of any other mountain in the island, or that Mr. Anderson had seen in the West Indies. He could perceive it divided into many different ridges, separated by deep chasms, and its summit appeared quite distinct of every vegetable production. Several ravines, that run from the bottom a great way up the mountain, were found quite distinct of water, and pieces of pumice-stone, charcoal, and several earths and minerals of a particular quality, found in them, plainly indicated some very great singularity in this mountain. Some very old men also informed our author, that they had heard it related by the captain of a ship, that between this island and St. Lucia he saw flames and smoke rising from the top of the mountain, and next morning his decks were covered with ashes and small stones.

Mr. Anderson's curiosity was so much excited by these circumstances, that he formed a resolution of going up to the top; but was informed that this was impossible, nor could he find either white man, Caribbee, or negro, who would undertake to show him the way. Having observed the huts as well as he could, with a view to discover the most proper place for attempting an ascent, he found several dry ravines that seemingly ran a great way up, though he could not be certain that they were not interred by rocks or precipices lying across. Having examined the mountain with a good glass, he thought he perceived two ridges by which there was a possibility of getting up; and though they appeared to be covered for a great way with wood, he hoped by a little cutting to open a way through it.

On the 26th of February 1784, our author began his journey, having been furnished by a Mr. Maloune, who lives within a mile of the foot of the mountain, with two stout negroes, and having another boy who waited on himself. They arrived at the bottom of the
the mountain a little before seven in the morning, having each a good cutlass to cut through the woods, or to defend themselves in case of an attack from the Caribbees or runaway negroes. Before they could get at either of the ridges, however, they had a rock to climb upwards of 50 feet high. Having scrambled up this with great difficulty, they found themselves in the bottom of a deep and narrow ravine, which having afforded a little way, they arrived at the habitation of Mr. Gafco the Frenchman. Mr. Anderfon expresses his surprise, that a young and healthy man, and a good mechanic, should extricate himself from the world among woods and precipices, where he was besides in continual danger of being swept away with his whole habitation by the torrents occasioned by the rains. He found him, however, an intelligent man, and was hospitably entertained by him.

"The difficulty (says Mr. Anderfon) in going thro' woods in the West Indies, where there are no roads or paths, is far beyond any thing an European can conceive. Besides tall trees and thick underwood, there are hundreds of different climbing plants twisted together like ropes, and running together in all directions to a great extent; and even to the tops of the highest trees. They cannot be broken by pushing on; and many of them are not to be cut without difficulty. Besides these, a species of grass, the *johannes lirifpermat*, with ferrated leaves, cuts and tears the hands and face terribly."

By reason of these obstructions, it was upwards of two hours before they got upon the ridge; but here they found their passage more difficult than before. They were now surrounded by a thick forest, rendered more impracticable by the large piles of trees blown down by the hurricanes; which obliged them in many places to creep on their hands and feet to get below them, while in others it was necessary to climb to a considerable height to get over them; at the same time that by the trunks being frequently rotten, they often tumbled headlong from a great height, and could not extricate themselves without great difficulty.

The fatigue of cutting their way through the woods soon became intolerable to the negroes; so that about four in the afternoon he could not prevail on them to go any farther. Mr. Anderfon therefore perceiving it was impossible to get to the summit that night, and his water being totally expended, returned to Mr. Gafco's, where he spent the night, determining to try another route next morning. The hospital Frenchman entertained him in the best manner he could; but though he parted with his own hammock to him, and slept on a board himself, Mr. Anderfon found it impossible to shut his eyes the whole night by reason of the cold. "His hut (says he) was built of *sagami* or large reeds, between each of which a dog might creep through, and the top was covered with dry grass. It is situated in the bottom of a deep gully, where the sun does not shine till nine in the morning; nor after four in the afternoon. It is surrounded by thick wood; and during the night the whole of the mountain is covered with thick clouds, from which it frequently rains, and which makes the night air exceedingly cold."

Early next morning Mr. Anderfon set out in company with the negro boy, who continued very faithful to him during the whole of the journey. He now determined to take his course up the ravine, and proceeded for about a mile and a half without any considerable obstruction. It now, however, began to narrow still; there were numbers of rocks and precipices to climb over, with many bushes and vines which could scarcely be got through. At last the ravine terminated at the bottom of a very high precipice. It was impossible to know the extent of this, as the top was covered with thick wood; but from the bottom upward, as far as he could see, was loose sand with ferns and tufts of grass, which as soon as he took hold of them came up by the roots. Though the ascent was plainly at the risk of his life, Mr. Anderfon relented to attempt it; and therefore telling the boy to keep at some distance behind, lest he should tumble and drive him down, he began to ascend, digging holes with his cutlass to put his feet in, and taking hold of the tufts of grass as lightly as possible. Notwithstanding all his care, however, he frequently slipped down a considerable way; but as it was only loose sand, he could easily push his cutlass into it up to the handle, and thus by taking hold of it recover himself again. At last he got up to some wild plantains, which continued all the way to the place where the trees began to grow. Here he rested for some time, waiting for the boy, who got up with much less difficulty than he had done. On getting up to the top of the precipice, he found himself on a very narrow ridge, covered with wood, and bounded by two ravines, the bottoms of which he could not see, the deficit to them appearing to be nearly perpendicular, though all the way covered with thick wood. Proceeding onwards, they found the ridge exceedingly narrow, in many places not fix feet broad; with a tremendous gulf on each side, into which they were every moment in danger of falling; so that Mr. Anderfon was obliged to lie down on his belly with great caution, in order to see through the bushes how the ridge tended.

Here a sulphurous smell of rather one like gunpowder, began to be perceived; which, Mr. Anderfon knew, must proceed from the top of the mountain, as the wind then blew that way; and as it plainly grew stronger as he advanced, he was in hopes that the top could not be very far distant. Perceiving a rising before him, he imagined, that, by getting upon it, he might have a view of the top of the mountain; but when this was done, he could only see a peak on the north-west side of the mountain, to which, by appearance, he judged himself very little nearer than when at the bottom.

The woods now became very difficult, great quantities of fallen trees lying buried among the grass; and being rotten, he was frequently buried very deep among them when he thought himself walking upon firm ground. About noon he was alarmed with a rushing among the bushes, and something like a human voice behind him; but as he was preparing to defend himself against Caribbees or runaway negroes, he was agreeably surprized with the sight of those who had formerly left him, with three others, sent by Mr. Maloune with plenty of provisioins. Encouraged by this afflailence, after refreshing themselves, they renewed their labours with fresh vigour, and Mr. Anderfon thought himself sure of reaching the top before night.
In a little time he had a fair view of the ravine on the left, which was of prodigious depth, and ran from near the top of the mountain to the sea. Its bottom seemed to be a rock nearly resembling lava in colour, and it seemed as if there had been vast torrents of sulphureous matter running upon it for some time. He now regretted much that he knew not of this ravine before he commenced his excursion, as, by palling a headland in a caros, and getting into it, he might have gained the summit without all those delays and difficulties he had encountered.

About four in the afternoon he had no prospect of the top of the mountain, but imagined that if he could get into the ravine before night, he might easily reach it next morning. After cutting through wild plantains for a great way, however, he found himself at funlet on the brink of a precipice, over which he all the fountains of nature; and are piled up very regular. Great

Mr Anderfon directed his course towards a high peak that overlooked a large excavation where the ridges met, and which he supposed to be the crater of the volcano. In his way, he found the last wood composed of a most beautiful species of trees. After that he entered into a thick long grafs intermixed with fern, which branched and ran in every direction. Thro' this they were obliged to cut their way with almost as much difficulty as they had done through the woods, and before they continued very near to the top of the mountain. The fatigue of this work soon reduced them to such a situation, that they were scarce able to stand; and they were obliged to quench their thirst, which was excessive, by chewing the leaves of the begonia obliqua, there being no water to be had in the place. Two of the negroes returned, and the rest refused to proceed any farther; so that Mr Anderfon himself was obliged to abandon the enterprise, and they all began to descend about half an hour after twelve; and as there was now a clear path all the way down, they arrived at Mr Gaffo's by funlet; and notwithstanding his extreme weariness, Mr Anderfon continued his journey to Mr Maloune's, where he arrived between fix and seven at night.

Our traveller having refreshed himself to the 4th of March, in order to sustain the fatigue of his journey, he set out about four that morning in company with a Mr Frafer, who had resolved to accompany him. They met with little difficulty till they came to the place whence they had formerly returned. Here, however, they were obliged for a quarter of a mile to cut their way through the grafs and ferns already mentioned; which being done, they met with no further obstruction. When they came within a quarter of a mile of the top, they found the climate suddenly altered, the air very cold, and the vegetable productions changed, the whole summit of the mountain being barren. On the confines of the grasy and barren regions, however, he found some beautiful plants; and he observes, that this is the only place in the West Indies where he ever found moss; but here it grows in such plenty, that he frequently funk in it up to the knees. About noon they reached the summit, and were instantly surprized with the fight of a moss extraordinary cavity. It is situated in the very centre of the mountain, at the place where all the ridges meet. Its diameter is something more than a mile, and its circumference to appearance a perfect circle. Its depth from the surrounding margin is above a quarter of a mile, and it narrows a little, but very regularly, to the bottom. Its sides are very smooth, and for the most part covered with short moss, except towards the south, where there are a number of small holes and rents. This is the only place where it is possible to go down to the bottom; and the descent is very dangerous on account of the numberless small cliffs. On the west side is a section of a red rock like granite, cut very smooth, and having the same declivity with the other parts. All the rest of the surrounding sides seem to be composed of sand, which has undergone the action of an intense fire. It has a crust quite smooth, and about an inch thick, almost as hard as rock; on breaking thro' which we met with nothing but loose sand. In the centre stands a burning mountain about a mile in circumference, of a conic form, "but quite level." Out of the middle of the summit rises a small eminence eight or ten feet high, and perfectly conical; from the apex of which a column of smoke constantly issue. It is composed of large masses of red granite-like rock, of various shapes and sizes, which appear to have been split into their present form by some terrible convulsion of nature; and are piled up very regular. Great quantities of smoke issue from most parts of the mountain, especially on the north side which appears to be burning from top to bottom; and the heat is so intense, that it is impossible to ascend it. It is even very dangerous to go round the base, as large masses of rock are constantly splitting with the heat and tumbling down. At the bottom, on the north side, is a very large rock split in two. Each of these halves, which are rent in all directions, are separated to a considerable distance from each other, and the crevices have glossy efflorescences tuffing like vitriol. There are also beautiful crystallizations of sulphur; and on all parts of the mountain are great quantities of sulphur, also alum, vitriol, &c.

From the external appearance of this mountain, Mr Anderfon conjectures that it had but lately begun to burn; as on several parts of it he saw small shrubs and

MOR

In order to sustain the fatigues of his journey, he set out about four that morning in company with a Mr Frafer, who had resolved to accompany him. They met with little difficulty till they came to the place whence they had formerly returned. Here, however, they were obliged for a quarter of a mile to cut their way through the grases and ferns already mentioned; which being done, they met with no further obstruction. When they came within a quarter of a mile of the top, they found the climate suddenly altered, the air very cold, and the vegetable productions changed, the whole summit of the mountain being barren. On the confines of the grasy and barren regions, however, he found some beautiful plants; and he observes, that this is the only place in the West Indies where he ever found moss; but here it grows in such plenty, that he frequently sunk in it up to the knees. About noon they reached the summit, and were instantly surprized with the sight of a moss extraordinary cavity. It is situated in the very centre of the mountain, at the place where all the ridges meet. Its diameter is something more than a mile, and its circumference to appearance a perfect circle. Its depth from the surrounding margin is above a quarter of a mile, and it narrows a little, but very regularly, to the bottom. Its sides are very smooth, and for the most part covered with short moss, except towards the south, where there are a number of small holes and rents. This is the only place where it is possible to go down to the bottom; and the descent is very dangerous on account of the numberless small cliffs. On the west side is a section of a red rock like granite, cut very smooth, and having the same declivity with the other parts. All the rest of the surrounding sides seem to be composed of sand, which has undergone the action of an intense fire. It has a crust quite smooth, and about an inch thick, almost as hard as rock; on breaking thro' which we met with nothing but loose sand. In the centre stands a burning mountain about a mile in circumference, of a conic form, "but quite level." Out of the middle of the summit rises a small eminence eight or ten feet high, and perfectly conical; from the apex of which a column of smoke constantly issue. It is composed of large masses of red granite-like rock, of various shapes and sizes, which appear to have been split into their present form by some terrible convulsion of nature; and are piled up very regular. Great quantities of smoke issue from most parts of the mountain, especially on the north side which appears to be burning from top to bottom; and the heat is so intense, that it is impossible to ascend it. It is even very dangerous to go round the base, as large masses of rock are constantly splitting with the heat and tumbling down. At the bottom, on the north side, is a very large rock split in two. Each of these halves, which are rent in all directions, are separated to a considerable distance from each other, and the crevices have glossy efflorescences tuffing like vitriol. There are also beautiful crystallizations of sulphur; and on all parts of the mountain are great quantities of sulphur, also alum, vitriol, &c.

From the external appearance of this mountain, Mr Anderfon conjectures that it had but lately begun to burn; as on several parts of it he saw small shrubs and
and grass which looked as if they had been but lately scorched and burnt. There were also several holes on the south from which smoke issued, that appeared to have broken out but lately, the adjacent bushes being but lately burnt. On two opposite sides, the cleft and west, of the burning mountain, are two lakes of water, about a fome's throw in breadth. They appear to be deep in the middle, and have a bottom of a kind of clay. The water is a chalky, and has a pleasant taste. These lakes probably derive their existence in a great measure, if not totally, from the rain-water running down the sides of the crater. On the north side Mr Anderson observed the traces of great torrents, that to appearance had conveyed vast quantities of water to these lakes; and by the stones at the bottom he could perceive that absorption or evaporation, or both, went on very fast. The greater part of the bottom of the crater is very level; and on the south side are some shrubs and small trees. Some pieces of pumice-stone were met with, and many stones about the size of a man's fist, rough, and blue upon one side, are scattered all over the mountain.

The motion of the clouds, on the top of this mountain was very singular. Though there were several parts higher than the crater, yet the clouds seemed always to be attracted by the latter. After entering on its east or windward side, they funk a considerable way into it; then mounting the opposite side, and whirling round the north-west side, they ran along a ridge which tended nearly north-east, and afterwards sunk into a deep ravine dividing this ridge from another on the north-west corner of the mountain, and the highest on it, lying in a direction nearly north and south. They keep in this ridge to the south end, and then whirl off in their natural direction.

From the situation of these islands to one another, and to the continent of South America, Mr Anderson conjectures, that there are submarine communications between the volcanoes in each of them, and from them to the high mountains of South America. He observes, that the crater in this island lies nearly in a line with Soufriere in Martinico; and probably from thence to a place of the same kind in Dominique, and from thence to the other islands; there being something of the kind in each, Barbadoes and Tobago excepted.

MOROC, or MAROC, a beautiful bird of Abyssinia described by Mr Bruce, who thinks its name is derived from mar “honey,” though he says that he never heard it was further concerned in the honey than destroying bees. It seems to pursue those insects out of enmity or diversion as well as for food, leaving great numbers dead on the ground, besides those which it devours for food. In consequence of this property, the moroc is never found any where but where the honey is very plentiful, tho’ the Abyssinians never take any notice of the ravages they commit among their flocks of bees.

The moroc resembles the cuckoo in size and shape, but differs in other respects. Its mouth is very wide, the opening reaching almost to his eyes; the inside of the mouth and throat yellow, the tongue sharp pointed, and capable of being drawn almost half its length out of the mouth beyond the point of its beak, and is very flexible. The head and neck are brown, without any mixture of other colours; there are like eyes a number of very small and feafock visible hairs at the root of the beak. The eyebrows are black; the beak pointed, and very little crooked; the pupil of the eye black, and surrounded with an iris of a dull and dusky red: The fore-part of the neck is light yellow, darker on each side than in the middle, where it is partly white; the yellow on each side reaches near the shoulder, or round part of the wing; and from this the whole breast and belly is of a dirty white to the under part of the tail; and from this the feathers begin to be tip’ed with white, as are all those that cover the outside of the wing. The wing has eight feathers of the largest size and fix of the second; the tail consists of twelve feathers, the longest three being in the middle: they are placed closely together; and the tail is of an equal breadth from top to bottom, the feathers being also tip’d with white. The thighs are covered with feathers of the same colour as those of the belly, reaching more than half way down the legs, which are black, as well as the feet, and marked distinctly with scales. There are two toes before and behind, each of which has a sharp and crooked claw. It makes a sharp snapping noise when it catches the bees, evidently from closing its beak; but Mr Bruce never could discover that it had any song.

This seems to be the creature mentioned by Dr Sparman under the name of cuculus indicator, which (he says) has the singular property of discovering the nests of wild bees, and leading travellers by a certain cry to the place where the treasure is deposited. According to Sparman’s account, it makes known these discoveries by the same cry to foxes as well as to the human species; but Jerome Lobo, who mentions the Abyssinian bird, does not take notice of the foxes, though he mentions its singing melodiously when it arrives at the place where the honey is deposited.

Both these accounts are fev’erely criticized by Mr Bruce, “I cannot (says he), for my own part, conceive, in a country where there are so many thousand lives, that there was any use for giving to a bird a peculiar instinct or faculty of discovering honey, when, at the same time, nature had deprived him of the power of availins himself of any advantage from the discovery: for man feems in this cafe to be made for the service of the moroc, which is very different from the common and ordinary course of things; man certainly needs him not, for on every tree, and on every hillock, he may see plenty of honey at his own deliberate disposal. I cannot then but think, with all submissioin to these natural philosophers, that the whole of this is an improbable fiction; nor did I ever hear a single perfon in Abyssinia fuggelt, that either this or any other bird had such a property. Sparman says it was not known to any inhabitant of the Cape, any more than that of the moroc was in Abyssinia; it was a secret of nature, hid from all but these two great men; and I most willingly leave it among the catalogue of their particular discoveries.”

MORNING, the beginning of the day, or the time of the sun-rising. The astronomers reckon morning, many from the time of midnight to that of mid-day. Thus an eclipse is said to begin at 11 o’clock in the morning, &c.

MORNING STAR is the planet Venus, when a little to
Nothing can be conceived more unjust and despotic than the government of Morocco, and nothing more degenerated than the character of the people. The emperor is allowed to have not only an uncontrollable power over the lives and fortunes of his subjects, but in a great measure over their consciences, such as they are; in as much as he is the only person who, as the successor of the prophet, has a right to interpret the Koran; and appoints all the judges under him, of whom the whole government of Morocco and Fez are the chief, whose business it is to explain and dispense the laws relating to their religion; and who, being his creatures and instruments, dare not fler otherwise than he directs. Whenever therefore the laws are enacted by him, and proclaimed by his governors in all the provinces, as is commonly done, that none may plead ignorance, they are everywhere received with an implicit and religious submission. On the other hand, the subjects are bred up with a notion, that those who die in the execution of his command are entitled to an immediate admittance into paradise, and those who have the honour to die by his hand to a fill greater degree of happiness in it. After this we need not wonder at finding so much cruelty, oppression, and tyranny on the one side, and so much submission, paffiveness, and misery on the other.

This latter, however, extends no farther than the Moors; for as to the mountaineers, the subjection and tribute they pay to those tyrants was always involuntary, and altogether forced; and as for the negroes, their zeal and attachment is owing merely to the great the black sway and power which they have gained in the government, on various accounts. They were first introduced, or rather their importation increased, by the policy of Muley Ismael, a late emperor, at a period when there was a great decrease of population in the empire, occasioned in some degree by the enormous cruelties exercised by its former sovereigns, who have been known not unfrequently, through a slight dispute, to abandon a whole town or province to the sword. In the character of Muley Ismael, were found the most singular incon sistencies; for it is certain, that although a tyrant of the same class, yet in other respects, as if to repair the mischief which he committed, he left nothing undone for the encouragement of population. He introduced, as above mentioned, large colonies of negroes from Guinea; built towns for them, many of which are still remaining; assigned them portions of land, and encouraged their increase by every possible means. He soon initiated them in the Mahometan faith; and had his plan been followed, the country by this time would have been populous, and probably flourishing. As the negroes are of a more lively, active, and enterprising disposition than the Moors, they might soon have been taught the arts of agriculture and their singular ingenuity might have been directed to other useful purposes. It is true, Muley Ismael, when he adopted this plan, had more objects in view than that of merely peopling his dominions. He saw plainly that his own subjects were of too capricious a disposition to form soldiers calculated for his tyrannical purposes. They had uniformly manifested an inclination to change their sovereigns, though more from the love of variety than to reform the government, or restrain the abuses of tyranny. In short, whatever revolution,
Defterism of the emperors.

A most flagrant species of defterism, which renders the emperors still more formidable to their subjects, is their making themselves their sole heirs, and, in virtue of that, seizing upon all their effects, and making only such provision for their families as they think proper; and often, on some frivolous pretence, leaving them destitute of any, according to the liking or dislike they bear to the deceased; so that, upon the whole, they are the only makers, judges, and interpreters, and in many instances likewise the executioners, of their own laws, which have no other limits than their own arbitrary will. To preserve, however, some show or shadow of justice, they allow their subjects a kind of superiority in spirituals, and a sort of liberty to the nearest subject to summon them before his tribunal. But the danger which such an attempt would bring upon a plaintiff, perhaps no less than death and seduction, it is of itself sufficient to deter any man from it; especially considering the little probability there is that the judges of it would run the risk of declaring themselves against a monarch whose creatures they are, and on whom their lives and fortunes do absolutely depend. The titles which the emperors of Morocco assume, are those of Messiah, mighty, and noble emperor of Africa, king of Fez and Morocco, Tafilalt, Sfax, Dachra, and all the Berber, and is territories in Africa; grand sheyf (or, as others write, Xarif), that is, successor, or vicegerent, of the great prophet Mohammed, &c.

The judges or magistrates that are immediately under the emperor are either spiritual or temporal, or rather ecclesiastical and military. The muftis and the kadi are judges of all religious and civil affairs; and the bailiffs, governors, alcaides, and other military officers, of those that concern the state or the army; all of them the most obsequious creatures and slaves of their prince, and no less the rapacious tyrants of his subjects, and from whom neither justice nor favour can be obtained but by mere dint of money and extortionate bribery, from the highest to the lowest. Neither can it indeed be otherwise in such an arbitrary government, where the highest posts must not only be bought of the prince at a most extravagant price, and kept only by the exorbitant a tribute, which is yearly paid to him, but where no one is sure to continue longer than he can bribe some of the courtiers to intimate to the monarch that he pays to the utmost of his power, and much beyond what was expected from him. Add to this, that these bailiffs, governors, &c., are obliged to keep their agents and spies in constant pay at court, to prevent their being supplanted by higher bidders, flanders, or other underminers. In short, power and weakness, rank and meanness, opulence and indigence, are here equally dependent, equally uncertain. There are instances of the Sultan elevating at once a common soldier to the rank of a bailiff, or making him a confidential friend; the following day he would perhaps imprison him, or reduce him again to the station of a private soldier. It is surprising that more men under these circumstances should be ambitious of rank, or desirous of riches. Yet such is the disposition of these people, that they have an unbounded thirst for rank and power with all their uncertainties; and what is more extraordinary, when they have obtained a high station, they seldom fail to afford their sovereign a plea for ill treating them, by abusing in some way or other their trust.

From what has been said, it may be reasonably Royal re-concluded that the revenue arising to the emperor from the last mentioned source, that of bribery, extortion, and confiscation, must be very confiderable, though there is no possibility to make any other conjecture of its real amount than that it must be an immense one. Another considerable branch is the piratical trade, which brings the greater income into his treasury, as he is now at any expense either for fitting of corsairs vessels out, or maintaining their men; and yet has the tenth of all the cargo and of all the captives; besides which, he appropriates to himself all the rest of them, by paying the captors 50 crowns per head, by which means heengroves all the slaves to his own service and advantage. This article is indeed a very
The climate of Morocco is in general sufficiently temperate, healthy, and not so hot as its situation might lead us to suppose. The chain of mountains which form Atlas, on the eastern side, defends it from the cold winds, that would freeze up the earth were they frequent. The summit of these mountains is always covered with snow; and their abundant descending streams form verdure through the neighbourhood, make the winter more cold, and temper the heat of summer. The sea on the west side, which extends along the coast from north to south, also refreshes the land with regular breezes, that seldom vary according to their seasons. At a distance from the sea, within land, the heat is so great that the rivulets become dry in summer; but as in hot countries dews are plentiful, the nights are always cool. The rains are tolerably regular in winter: and are even abundant, though the atmosphere is not loaded with clouds as in northern latitudes. Those rains which fall by intervals are favourable to the earth, and increase its fecundity. In January the country is covered with verdure, and enamelled with flowers. Barley is cut in March, but the wheat harvest is in June. All fruits are early in this climate; and in forward years the vintage is over in the beginning of September. Though in general there is more uniformity and less variation in hot than in northern climates, the first are nevertheless exposed to the intertemperance of weather; too heavy rains often impede the harvest; and drought has still greater inconveniences, for it injures the propagation of locusts. These fatal insects, which have so often laid desolate hot countries, sometimes commit the most dreadful ravages in the empire of Morocco. They come from the south, spread themselves over the lands, and increase to infinity when the rains of spring are not sufficiently heavy to destroy the eggs they deposit on the earth. The large locusts, which are near three inches long, are not the most destructive; as they fly, they yield to the current of wind, which hurries them into the sea, or into sandy deserts, where they perish with hunger or fatigue. The young locusts, that cannot fly, are the most ruinous; they creep over the country in such multitudes, that they leave not a blade of grass behind; and the noise of their feeding announces their approach at some distance. The devastations of locusts increase the price of provisions, and often occasion famines: but the Moors find a kind of compensation in making food of these insects; prodigious quantities of which are brought to market salted and dried like red herrings. They have an oily and rancid taste, which habit only can render agreeable; they are eaten here, however, with pleasure. The winters in Morocco are not severe, nor is there an absolute need of fire. In the coldest weather the thermometer seldom sinks to more than five degrees below the freezing point. The longest days in Morocco are not more than 14 hours, and the shortest consequently not less than ten.

The soil of Morocco is exceedingly fertile. It is soil, and most fit for the inland provinces. On the western coast it is in general light and flaky, and is better adapted to the vine and olive than the culture of wheat. They annually burn, before the September rains, the stubble, which is left rather long; and this and the dung of cattle, every day turned to pasture, form the sole manure the land receives. The soil requires but little labour, and the ploughing is so light that the furrows are scarcely six inches deep; for which reason, in some provinces, wooden ploughshares are used for cheapness. The empire of Morocco might supply itself with all necessaries, as well from the abundance and nature of its products, as from the few natural or artificial wants of the Moors occasioned by climate or education. Its wealth consists in the fruitfulness of its soil: its corn, fruits, flocks, flax, flax, gums, and wax, would not only supply its necessaries, but yield a superfluous, which might become...
become an object of immense trade and barter with other nations. Such numerous exports might return an inexhaustible treasure, were its government fixed and secure, and its subjects enjoy the fruits of their labour and their property in safety. The increase of corn in Morocco is often as sixty to one, and thirty is held to be but an indifferent harvest. The exportation of this corn is burdened by the laws, and by the prejudices of an intolerant religion, which permits them not to sell their superabundance to infidels. The property of land is besides entirely precarious; so that each individual grows little more than sufficient for his own wants. Hence it happens, when the harvest falls from the ravages of locusts or the intermixture of feasons, these people are exposed to misery, such as Europeans have no conception of, who enjoy a stable administration, which obviates and provides for all their wants.

The Moors, naturally indolent, take little care of the culture of their fruits. Oranges, lemons, and thick-skinned fruits, the trees of which require little nurture, grow in the open fields; and there are very large plantations of them found, which they take the trouble to water in order to increase their product. Their vines, which yield excellent grapes, are planted as far as the 33d degree, as in the southern provinces of France, and are equally vigorous. But at Morocco, where they yield a large and delicious grape, they are supported by vine- poles five and fix feet above the ground; and as they are obliged to be watered, the little wine made there is seldom preferred. Figs are very good in some parts of the empire, but toward the south they are scarcely ripe before they are full of worms; the heats and night dews may, perhaps, contribute to this speedy decay. Melons, for the same reason, are rarely eatable; they have but a moment of maturity; which passes so rapidly that it is with difficulty seized. Water-melons are every where rare, and in some provinces are excellent. Apricots, apples, and pears, are in tolerable plenty in the neighbourhood of Fez and Mequinez, where water is less scarce and the climate more temperate. But in the plain, which extends along the western coast, these delicate fruits are very indifferent, have less juice or taint, and the peaches there do not ripen. The tree called the prickly pear, or the Barbary fig, is plentifully found in the empire of Morocco; and is planted round vineyards and gardens, because its thick and thorny leaves, which are wonderfully prolific, form impenetrable hedges. From these leaves a fruit is produced, covered with a thorny skin, that must be taken off with care. This fruit is mild, and full of very hard, small, kernels. The olive is every where found along the coast, but particularly to the south. The trees are planted in rows, which form alleys the more agreeable because the trees are large, round, and high in proportion. They take care to water them, the better to preserve the fruit. Oil of olives might here be plentifully extracted, were taxation fixed and moderate; but such has been the variation it has undergone, that the culture of olives is so neglected as scarcely to produce oil sufficient for internal consumption. In 1768 and 1769 there were near 40,000 quintals of oil exported from Modogore and Santa-Cruz to Marseilles, and ten years after it cost 15 d. per pound. Thus do the vices of government expose nations to dearth and famine who live in the very bosom of abundance.

From the province of Daqueta to the south of the empire, there are forests of the arga tree, which is thorny, irregular in its form, and produces a species of almond exceedingly hard, with a skin as corrodive as that of walnuts. Its fruit consists of two almonds, rough and bitter, from which an oil is produced very excellent for frying. In order to use this oil, it must be purified by fire, and set in a flame which must be suffered to die away of itself; the most greasy and corrosive particles are consumed, and its acrid qualities are thus wholly destroyed. When the Moors gather these fruits, they bring their goats under the trees; and as the fruit falls the animals carefully nibble off the skins. In the same province also is found the tree which produces gum sandarac; also that which yields the transparent gum; but the latter is most productive, and affords the best gum the farther we proceed southward, where the heat and night dews may perhaps render the vegetable secretion more pure and copious.

In the province of Suz, between the 25th and 30th degrees, the inhabitants have an almond harvest, which varies little because of the mildness of the climate; but the fruit is small for which reason they take little care of the trees, and they degenerate with time. The palm tree is common on the southern provinces of Morocco; but dates ripen there with difficulty, and few are good except in the province of Suz and towards Tafilet. On the coast of Salle and Mamora there are forests of oak, which produce acorns near two inches long. They taste like chestnuts, and are eat raw and roasted. This fruit is called Bellote, and is sent to Cadiz where the Spanish ladies hold it in great estimation. The empire of Morocco also produces much wax; but since it has been subjected by the emperor to the payment of additional duties, the country people have very much neglected the care of their hives. Salt abounds in the empire, and in some places on the coast requires only the trouble of gathering. Independent of the salt-pits formed by the evaporation of the soft water, there are pits and lakes in the country whence great quantities are obtained. It is carried even as far as Tombut, whence it palls to the interior parts of Africa.

The Moors cultivate their lands only in proportion to their wants; hence two-thirds of the empire at least lie waste. Here the drew, that is, the fan or wild palm tree, grows in abundance; and from which those people, when necessity renders them industrious, find great advantage. The shepherds, mule-drivers, camel-drivers, and travellers, gather the leaves, of which they make mats, fringes, baskets, hats, boaris or large wallets to carry corn, twine, ropes, girdles, and covers for the pack-faddles. This plant, which also they heat their ovens, produces a mild and refined fruit that ripens in September and October. It is in form like the raisin, contains a kernel, and is astringent and very proper to temper and counteract the effects of the watery and laxative fruits, of which these people in summer make an immoderate use.

Unacquainted with the sources of wealth of which Mines their ancestors were polifhed, the Moors pretend there are gold and silver mines in the empire, which the em-
Morocco

...pers will not permit to be worked, left their subjects should thus find means to take off their yoke. It is not improbable but that the mountains of Atlas may contain unexplored riches; but there is no good proof that they have ever yielded gold and silver. There are known iron mines in the south; but the working of them has been found so expensive, that the natives would rather use imported iron, notwithstanding the heavy duty it pays, by which its price is doubled. There are copper mines in the neighbourhood of Santa Cruz, which are not only sufficient for the small consumption of the empire, where copper is little used, but are also an object of exportation, and would become much more so were the duties less immediate.

Neither the elephant nor the rhinoceros is to be found either in this or the other states of Barbary; but their deserts abound with lions, tigers, leopards, hyenas, and monstrous serpents. The Barbary horses were formerly very valuable, and thought equal to the Arabian. Though their breed is now said to be decayed, yet some very fine ones are occasionally imported into England. Camels and dromedaries, asses, mules, and kumrians (a most serviceable creature, begotten by an ass upon a cow), are their beasts of burden. Their cows are but small, and barren of milk. Their sheep yield but indifferent fleeces, but are very large, as are their goats. Bears, porcupines, foxes, apes, hares, rabbits, ferrets, weasels, moles, cameoles, and all kinds of reptiles, are found here. Pardises and quails, eagles, hawks, and all kinds of wild-fowl, are frequent on the coast.

As to mountains, the chief are that chain which goes under the name of Mount Atlas, and runs the whole length of Barbary from east to west, passing through Morocco, and abutting upon that ocean which separates the eastern from the western continent, and is from this mountain called the Atlantic Ocean. See Atlas. The principal rivers, besides the Malva or Mulvia above-mentioned, which rises in the deserts, and running from south to north divides Morocco from the kingdom of Algiers, are the Susa, Omminrhilh, Ralbata, Larache, Darodti, Sebron, Gourion, and Tenisf, which rise in Mount Atlas, and fall into the Atlantic Ocean. The chief capes are Cape Threeforks on the Mediterranean, Cape Sparrel at the entrance of the straits, Cape Cantin, Cape None, and Cape Rajador, on the Atlantic Ocean. Of the bays the most considerable are, the bay of Te-tuan in the Mediterranean, and the bay of Tangier in the straits of Gibraltar.

The traffic of the empire by land is either with Arabia or Negroiland: to Mecca they send caravans, consisting of several thousand camels, horses, and mules, twice every year, partly for traffic, and partly on a religious account; for numbers of pilgrims take that opportunity of paying their devotions to their great prophet. The goods they carry to the east are woolen manufactures, leather, indigo, cochineal, and other feathers; and they bring back from thence, filk, mufkins, and drugs. By their caravans to Negroiland, they send salt, filk, and woollen manufactures, and bring back gold and ivory in return, but chiefly negroes.

The caravans always go strong enough to defend themselves against the wild Arabs in the deserts of Africa and Asia; though, notwithstanding all their vigilance, some of the fragellers and baggers often fall into their hands: they are also forced to load one half of their camels with water, to prevent their perishing with drought and thirst in those inhospitable deserts. And there is still a more dangerous enemy, and that is the sand itself: when the winds rise, the caravan is perfectly blinded with dust; and there have been instances both in Africa and Asia, where whole caravans, and even armies, have been buried alive in the sands. There is no doubt also, but both men and cattle are sometimes surprized by wild beasts, as well as robbers, in those vast deserts; the hot winds also, blowing over a long tract of burning sand, are equal almost to the heat of an oven, and destroy abundance of merchants and pilgrims. If it was not for devotion, and in expectation of very great gains, no man would undertake a journey in these deserts; great are the hazards and fatigues they must of necessity undergo; but those that go to Mecca affure themselves of paradise if they die, and have uncommon honours paid them at home if they survive. People crowd to be taken into the eastern caravans; and the gold that is found in the south makes them no less eager to undertake that journey.

The natives have hardly any trading vessels, but Foreign commerce ships, bring them whatever they want from abroad; as linen and woollen cloth, stuffs, iron wrought and unwrought, arms, gunpowder, lead, and the like: for they take in return, copper, wax, hides, Moroccan leather, wool (which is very fine), gums, soap, dates, almonds, and other fruits. The duties paid by the English in the ports of Morocco are but half those paid by other Europeans. It is a general observation, that no nation is fond of trading with these states, not only on account of their despotic government, but the villainy of their individuals, both natives and Jews, many of whom take all opportunities of cheating, and when detected are seldom punished.

The land-forces of the emperor of Morocco consist principally of the black troops already mentioned, and some few white; amounting altogether to an army of about 36,000 men upon the establishment, two thirds of which are cavalry. This establishment, however, upon occasion admits of a considerable increase, as every man is supposed to be a soldier, and when called upon is obliged to act in that capacity. About 6000 of the standing forces form the emperor's body guard, forces, and are always kept near his person; the remainder are quartered in the different towns of the empire, and are under the charge of the bahaws of the provinces. They are all clothed by the emperor, and receive a trifling pay; but their chief dependence is on plunder, which they have frequent opportunities of acquiring. The soldiers have no distinction in drees from the other Moroccos; and are only marked by their accoutrements, which consist of a cloth, a very long musket, a small red leat her box to hold their balls, which is fixed in front by means of a belt, and a powder-horn slung over their shoulders. The army is under the direction of a commander in chief, four principal bahaws, and alcaides who command distinct divisions.

The black troops are naturally of a very fiery disposition,
Religion and

With respect to religion, the inhabitants of Morocco are Mohammedans, of the sect of Ali; and have a mufti or high-priest, who is also the supreme civil magistrate, and the last resort in all causes ecclesiastical and civil. They have a great veneration for their hermits, and for idiots and madmen; as well as for those who by their tricks have got the reputation of wizards; all of whom they look upon as inspired persons, and not only honour as saints while they live, but build tombs and chapels over them when dead; which places are not only religiously visited by their devotees far and near, but are esteemed inviolable sanctuaries for all sorts of criminals except in cases of treason.

Notwithstanding the natives are zealous Mohammedans, they allow foreigners the free and open profession of their religion, and their very laws, have their priests and chapels in the capital city; though it must be owned that the Christian slaves are here treated with the utmost cruelty. Here, as in all other Moslem countries, the alacrity and their comments upon it are their only written laws; and though in some instances their cadis and other civil magistrates are controlled by the arbitrary determinations of their princes, bakhaws, generals, and military officers, yet the latter have generally a very great deference and regard for their laws. Murder, theft, and adultery, are commonly punished with death; and their punishments for other crimes, particularly those against the state, are very cruel; as impaling, dragging the prisoner through the streets at a mule's heels till all his flesh is torn off; throwing him from a high tower upon iron hooks; hanging him upon hooks till he die; crucifying him against a wall; and, indeed, the punishment and condemnation of criminals is in a manner arbitrary. The emperor, or his bakhaws, frequently turn executioners; shoot the offender, or cut him to pieces with their own hands, or command others to do it in their presence.

The inhabitants of the empire of Morocco, known by the name of Moors, are a mixture of Arabian and African nations formed into tribes; with the origin of whom we are but imperfectly acquainted. These tribes, each stranger to the other, and ever divided by traditional hatred or prejudice, seldom mingle. It seems probable that most of the calls who occupy the provinces of Morocco have been repulsed from the eastern to the western Africa, during those different revolutions by which this part of the world has been agitated; that they have followed the standard of their chiefs, whose names they have preferred; and that by these they, as well as the countries they inhabit, are distinguished. At present their tribes are called cabils or califs, from the Arabic word kalsin; and they are so numerous, that it is impossible to have a knowledge of them all. In the northern provinces are enumerated Beni-Garir, Beni-Guermid, Beni-Mansor, Beni-Oriegane, Beni-Chelid, Beni-Juseph, Beni-Zarnoul, Beni-Radim, Beni-Gabara, Beni-Busriet, Beni-Gualid, Beni-Yedra, Beni-Gueaghal, Beni-Guaffle, Beni-Guasmad, &c. Towards the east are, Beni-Sayad, Beni-Toumint, Beni-Ijffait, Beni-Buahale, Beni-Tied, Beni-Soffian, Beni-Belid, Beni-Zequar, &c., and to the south, those of Beni-Fosfara, Beni-Aros, Beni-Hassen, Beni-Mager, Beni-Basil, Beni-Seba, with an infinite number of others. The people...
The Brebes and the Shells having a language common to themselves, and unknown to the Moors, both must have had the same origin, notwithstanding the difference there is in their mode of life. The Shells live on the frontiers of the empire toward the south; their population is by no means so great as that of the Brebes, nor are they so ferocious; they do not marry with other tribes; and though they practice many superstitious rites, they are faithful observers of their religion.

The Moors of the plains may be distinguished into those who lead a pastoral life, and those who inhabit the cities.

The former live in tents; and that they may allow the Moors their ground a year's rent, they annually change the place of their encampments, and go in search of fresh pasture; but they cannot take this step without acquainting their governor. Like the ancient Arabs, they are entirely devoted to a pastoral life: their encampments, which they call doubars, are composed of several tents, and form a crescent; or they are ranged in two parallel lines, and their flocks, when they return from pasture, occupy the centre. The entrance of the douhar is sometimes flutt with faggots of thorns; and the only guard is a number of dogs, that bark ineffectually at the approach of a stranger. Each douhar has a chief, subordinate to an officer of the highest rank, who has under his administration a number of camps; and several of these subordinate divisions are united under the government of a pacha, who has often 1000 douhars in his department.

The tents of the Moors, viewed in front, are of a conical figure; they are from 8 to 10 feet high, and from 20 to 25 feet long; like those of high antiquity, they resemble a boat reversed. They are made of cloth composed of goats' and camels' hair, and the leaves of the wild palm, by which they are rendered imperious to water; but at a distance their black colour gives them a very disagreeable look.

The Moors, when encamped, live in the greatest simplicity, and exhibit a faithful picture of the islaam simple way of life. The nature of their education, the temperature of the climate, and the rigour of the government, diminish the wants of the people, who find in their plains, in the milk and wool of their flocks, every thing necessary for food and clothing. Polygamy is allowed among them; a luxury so far from being injurious to a people who have few wants, that is a great convenience in the economy of those societies, because the women are entrusted with the whole care of the domestic management. In their half-clad tents, they are employed in milking the cows for daily use; and when the milk abounds, in making butter, in picking their corn, their barley, and pulse, and grinding their meal, which they do daily in a mill composed of two stones about 18 inches in diameter, the uppermost having a handle, and turning on an axis fixed in the under one; they make bread likewise every day, which they bake between two earthen plates, and often upon the ground after it has been heated by fire. Their ordinary food is the coucoufofo; which is a pate made with their meal in the form of small grains like Italian paife. This coucoufofo is drest in the vapour of boiling foup, in a hollow delf perforated with many small holes in the bottom.
Morocco.  

...and the dish is enclosed in a bottle where meat is boiled; the couscous, which is in the hollow dish, grows gradually soft by the vapour of the broth, with which it is from time to time moistened. This simple food is very nourishing, and even agreeable when one has got the better of the prejudices which every nation entertains for its own customs. The common people eat it with milk or butter indifferently; but those of higher rank, such as the governors of provinces and lieutenants, who live in the centre of the encampments, add to it some succulent broth, made with a mixture of mutton, poultry, pigeons, or hedgehogs, and then pour on it a sufficient quantity of fresh butter. These officers receive strangers in their tents with the same cordiality that Jacob and Laban showed to their guests. Upon their arrival a sheep is killed and immediately roasted; if they are not provided with a spit, they instinctively make one of wood; and this mutton roasted at a brisk fire, and served up in a wooden dish, has a very delicate colour and taste.

The women in their tents likewise prepare the wool, spin it, and weave it into cloth on looms suspended the whole length of the tent. Each piece is about five ells long and one and a half broad; it is neither dressed nor dyed, and it has no selvedges. They wash it when it is dirty; and as it is the only habit of the Moors, they wear it night and day. It is called Haick, and is the true model of the ancient draperies.

The Moors of the plain wear nothing but their woolen stuff; they have neither skirts nor drawers. Linen among these people is a luxury known only to those of the court or the city. The whole wardrobe of a country Moor in easy circumstances consists in a haick for winter, another for summer, a red haick, a hood, and a pair of slippers. The common people both in the country and in towns wear a kind of tunick of woollen cloth, white, grey, or striped, which reaches to the middle of the leg; with great sleeves and a hood; it resembles the habit of the Carthufians.

The women's dresses in the country is likewise confined to a haick, which covers the neck and the shoulders, and is fastened with a silver clasp. The ornaments they are fond of are ear-rings, which are either in the form of rings or crescents, made of silver, bracelets, and rings for the small of the leg; they wear these trinkets at their ordinary occupations; it is said they are unacquainted with the use of depilatories in other parts of the body, having the head and the ends of their fingers, with an herb called beenna, which gives them a deep farron colour; a custom that must be very ancient among the people of Asia. Abu Bcece dyed his eye-brows and beard with the same colour, and many of his sycophants imitated him. The custom may have originally been a religious ceremony, which the women have turned into an ornament; but it is more probable that the custom of painting the beard and hair, and that of having the head and using depilatories in other parts of the body, has been at first employed from motives of cleanliness in warm countries.

The marriage ceremonies of the Moors that live in tents pretty much resemble those of the same people that live in the cities. In the douhars they are generally most brilliant and gay; the strangers that pass along are invited, and made to contribute to the feast; but this is done more from politeness than from any mercenary motive.

The tribes of the plain generally avoid mixing with marriage with one another; the prejudices that divide these people are commonly perpetuated; or, if they are partially healed, they never fail to revive upon trifling occasions, such as a strayed camel, or the preference of a pasture or a well. Marriages have sometimes taken place among them, that, so far from cementing their differences, have occasioned the most tragical scenes. Husbands have been known to murder their wives, and women their husbands, to revenge national quarrels.

Parents are not incumbered with their children, however numerous they may be, for they are very early employed in domestic affairs; they tend the flocks, they gather wood, and they afflict in ploughing and reaping. In the evening, when they return from the field, all the children of the douhar assemble in a common tent, where the Imam, who himself can hardly spell, makes them read a few sentences from the Koran written on boards, and instructs them in their religion by the light of a fire made of straw, of bulrushes, and cow-dung dried in the sun. As the heat is very great...
great in the inland parts of the country, children of both sexes go quite naked till the age of nine or ten.

The douhars dispersed over the plains are always in the neighbourhood of some rivulet or spring, and they are a kind of inns for the reception of travellers. There is generally a tent erected for their use, if they have not brought one along with them. They are accommodated with poultry, milk, and eggs, and with whatever is necessary for their horses. Instead of wood for fuel, they have the cow-dung, which, when mixed with charcoal, makes a very brisk fire. The sorts that abound in the vegetables of warm countries give this arrangement a confidence which it has not perhaps in northern regions. A guard is always set on the tents of travellers, especially if they are Europeans, because the opinion of their wealth might tempt the avidity of the Moors, who are naturally inclined to thieving.

With respect to the roads, a very judicious policy is established; which is adapted to the character of the Moors, and to their manner of life. The douhars are responsible for robberies committed in their neighbourhood and in sight of their tents; they are not only obliged to make restitution, but it gives the sovereign a pretence for exacting a contribution proportioned to the abilities of the douhar. In order to temper the rigour of this law, they are made responsible only for such robberies as are committed during the day; those that happen after sun-set are not imputed to them, as they could neither see nor prevent them; on this account, people here travel only from sun rising to sun setting.

To facilitate the exchange of necessaries, there is in the fields every day except Friday, which is a day of prayer, a public market in the different quarters of each province. The Moors of the neighbourhood assemble to sell and buy cattle, corn, pulle, dried fruits, carpets, haikhs, and in short all the productions of the country. This market which is called

31

Of the

Moors who dwell in cities.

The Moors who inhabit the cities differ from the others only in having a little more urbanity and a more easy deportment. Though they have the same origin with those of the plains, they affect to decline all intercourse with them. Some writers, without any foundation, have given the name of Arabs to the inhabitants of the towns, and that of Arabs to those of the plains. But the greater part of the cities of this empire are more ancient than the invasion of the Arabs, who themselves lived in tents.

The houses in most of the towns in this empire appear at a little distance like vaulted tombs in a churchyard; and the entrance into the cell of them has but a mean appearance. The rooms are generally on the ground floor, and whitened on the outside. As the roofs are quite flat, they serve as verandas, where the Moorish women commonly sit for the benefit of the air; and in some places it is possible to get nearly over the whole town without having occasion to descend into the street.

As the better apartments are all backwards, a stable, or perhaps something worse, is the place to which visitors are first introduced. Upon entering the house, the stranger is either detained in this place or in the street till all the women are dispatched out of the way; he is then allowed to enter a square court into which four narrow and long rooms open by means of large folding doors, which as they have no windows, serve likewise to introduce light into the apartments. The court has generally in its centre a fountain; and if it is the house of a Moor of property, it is floored with blue and white chequered tiling. The doors are usually painted with various colours in a chequered form, and the upper parts of them are frequently ornamented with very curious carved work. None of the chambers have fire-places, and their vistuals are always dressed in the court-yard in an earthen stove heated with charcoal. When the visitor enters the room where he is received by the master of the house, he finds him sitting cross-legged and barefooted on a carpet, with a piece of carpeting, is in general the only furniture he finds him sitting cross-legged and barefooted on a carpet, with a piece of carpeting, is in general the only furniture he finds him sitting cross-legged and barefooted on a carpet, with a piece of carpeting, is in general the only furniture he finds him sitting cross-legged and barefooted on a carpet, with a piece of carpeting, is in general the only furniture he finds him sitting cross-legged and barefooted on a carpet, with a piece of carpeting, is in general the only furniture he finds him sitting cross-legged and barefooted on a carpet, with a piece of carpeting, is in general the only furniture he finds him sitting cross-legged and barefooted on a carpet, with a piece of carpeting, is in general the only furniture he

Their houses and furniture.

Like the latter, they have a haik, and a hood more or less fine, and have also a hood of coarse European cloth of dark blue for the winter. What farther distinguishes them from the country Moors is, that they wear a shirt and linen drawers, and an upper garment of cotton in summer, and of cloth in winter, which they call a caftian. The white or blue hood, the pur-
The women have yellow slippers, and a custom of wearing a kind of flossing of fine cloth somewhat large, which is tied below the knee and at the ankle, over which it falls in folds. This flossing is let's calculated to show what we call a handsome leg, than to make it appear thick; for to be fat is one of the rules of beauty among the Moorish women. To obtain this quality, they take infinite pains, feed when they become thin on a diet somewhat like forced-meat balls, a certain quantity of which is given them daily; and, in fine, the fame care is taken among the Moors to fatten young women as is in Europe to fatten fowls. The reason of a custom like this may be found in the nature of the climate and the quality of the aliment, which make the people naturally meagre. Our gender waiters and fine turned ankles would be imperfections in this part of Africa, and perhaps over all that quarter of the globe; so great is the contrast of taste, and so various the prejudices of nations.

The Moors present their wives with jewels of gold, silver, or pearl, but very few wear precious stones; this is a luxury of which they have little knowledge. They have rings in silver or gold; also ear-rings in the form of a crescent, five inches in circumference, and as thick as the end of the little finger. They first pierce their ears, and introduce a small roll of paper, which they daily increase in thickness, till at length they insert the kernel of the date, which is equal in size to the ear-ring. They wear bracelets in gold and solid silver, and silver rings at the bottom of their legs, some of them considerably heavy. The use of white paint is unknown among the Moorish women, and that of red but little. It is much more common to the negroes which form the tribes coming from the south, who have preferred their customs; for the Moors do not change modes which they have once adopted.

The Negroes, who constitute a large proportion of the emperor's subjects, and the occasion of whose introduction to this empire has been already mentioned, are better formed than the Moors; and as they are more lively, daring, and active, they are entrust with an important share in the executive part of government. They constitute the most considerable part of the emperor's army, and are generally appointed to the command of provinces and towns. This circumstance, naturally, creates a jealousy between the emperor and the Moors, the latter considering the negroes usurpers of a power which they have no right to assume. Besides those negroes which form the emperor's army, there are a great many others in the country, who either are or have been slaves to private Moors: every Moor of consequence, indeed, has his proportion of them in his service. To the disgrace of Europe, the Moors treat their slaves with humanity, em-
Jews.

Among the inhabitants of Morocco there is another class, of whom we must not omit to make mention. These are the Renegados, or foreigners who have renounced their religion for the faith of Mahomet. Of these there are a great number who have been originally Jews: they are held in little estimation by the Moors; and would be held in abhorrence by the Jews, if they durst freely express their aversion. The families of these apostates are called Tournadis: not having at any time married with the Moors, they still preserve their ancient characteristics, and are known almost at sight to be the progeny of those who formerly embraced the Mahometan religion. The Christian renegados are but few; and generally are fugitive peculators of Spain, or men fallen from power, who because of their misconduct, or in despair, quit one unfortunate situation for another much more deplorable.

The Jews were formerly very numerous in this empire. After being proscribed in Spain and Portugal, multitudes of them passed over to Morocco, and spread themselves throughout the towns and over the country. By the relations they themselves give, and by the extent of the places assigned them to dwell in, it would appear there were more than 30,000 families, of whom at present there is scarcely a residue of one-twelfth; the remainder either having changed their religion, funk under their sufferings, or fled from the vexations they endured, and the arbitrary taxes and tolls imposed upon them. The Jews poifeß neither lands nor gardens, nor can they enjoy their fruits in tranquillity; they must wear only black; and are obliged, when they pass near mosques or through streets in which there are sanctuaries, to walk barefoot. The lowest among the Moors imagines he has a right to ill-treat a Jew: nor dares the latter defend himself, because the koran and the judge are always in favour of the Mahometans.

Notwithstanding this state of oppression, the Jews have many advantages over the Moors; they better understand the spirit of trade; they act as agents and brokers, and profit by their own cunning and the ignorance of the Moors. In their commercial bargains many of them buy up the commodities of the country to sell again. Some have European correspondents; and others are mechanics, such as goldsmiths, tailors, gunsmiths, millers, and masons. More industrious, artful, and better informed than the Moors, the Jews are employed by the emperor in receiving the customes, coining the money, and in all affairs and intercourse which the monarch has with the European merchants, as well as in all his negotiations with the various European governments.

The Moors, who derive their language and religion from the Arabs, seem not in any manner to have participated of their knowledge. United and confounded as those of Morocco have been with the Moors of Spain, the latter of whom cultivated the arts and sciences, gave birth to Averroes, and many other great men, the Moors of this empire have preserved no traces of the genius of their ancestors. They have no conception of the speculative sciences. Education conficts merely in learning to read and write; and as the revenues of the learned are derived from these talents, the priests and talbes among them are the sole depositaries of this much knowledge; the children of the Moors are taught in their schools to read and repeat some sixty lessons, selected from the Koran, which for the sake of economy are written upon small boards. These lessons being once learned, the scholar is supposed to have obtained sufficient knowledge to leave school; on this occasion he rides on horseback through the city, followed by his comrades, who sing his praises: this to him is a day of triumph; to the scholars an incitement to emulation, a festival for the master, and a day of expense for the parents: for in all countries, wherever there are festivals and processions, there also are eating and drinking. At Fez there is some small degree more of instruction to be obtained in the schools; and the Moors who are a little wealthy send their children thither to have them instructed in the Arabic language, and in the religion and laws of their country. Here some of them also acquire a little taste for poetry.

The Moors who formerly inhabited Spain gave great application to physic and astronomy; and they have left manuscripts behind them which still remain monuments of their genius. The modern Moors are infinitely degenerate; they have not the least inclination to the study of science; they know the properties of some simples; but as they do not proceed upon principle, and are ignorant of the causes and effects of diseases, they generally make a wrong application of their remedies. Their most usual physicians are their talbes, their fakirs, and their fainis, in whom they place a superstitious confidence. Astronomy is entirely or almost unknown to the Moors; for though they likewise wander from place to place, there are few if any among them who have a knowledge of the motion of the heavens, or who are capable from principle to direct their own course by observing the course of the stars. They are therefore necessarily wholly unable to calculate the eclipses, which they always interpret to portend evil.

Superstitious people, indeed, have every where supposed eclipses were sent to prejudice some calamity.

The Moors being unable to reason on the causes of such an appearance, imagine the fun or the moon are in the power of a dragon that swallows them; and they offer up prayers that these luminaries may be delivered from an enemy so cruel and voracious.

Notwithstanding the Moors have occupied themselves little in the study of astronomy they have been eager after astrology. This imaginary science, which made so rapid a progress at Rome in despite of the edicts of the emperors, may be conceived to make still greater advances among a people wholly stupid and ignorant, and ever agitated by the dread of present evils, or the hope of a more happy futurity. Magic, the companion of astrology, has here also found its followers, and is particularly studied by the talbes in the southern parts, who successfully use it in imposing upon the Moors.
Moroccan credulity with strange dreams and ambiguous forebodings and prophecies.

In short, arts and sciences seem to be almost unknown in Morocco; or if at all cultivated, it is only by the Jews, who indeed are the only industrious and ingenious people in the country. The Moors in general may be considered as excelling in the pastoral state, following only a few mechanical trades, and leaving every thing that requires invention to the Jews, who have likewise the principal management of their commercial and pecuniary matters; and even those few of the Moors who are merchants, are obliged to have Jewish agents, for the purpose of transacting their business.

The Moroish manufactures are—The hijab, which, as was before observed, is a long garment composed of white wool and cotton, or cotton and silk woven together, and is used by the Moors for the purpose of covering their under dress when they go abroad, which they do by totally wrapping themselves in it in a careless but easy manner; silk handkerchiefs of a particular kind, prepared only at Fez; kilts chequered with cotton; carpeting, little inferior to that of Turkey; beautiful matting, made of the palmetto or wild palm tree; paper of a coarse kind; cordovan, commonly called Morocco leather; gunpowder of an inferior nature; and long-barrelled muskets, made of iron. The Moors are unacquainted with the mode of casting cannon; and therefore those few which are now in the country are obtained from Europeans.

The manufacture of glafs is likewise unknown to them; as indeed they make great use of earthen ware, and have few or no windows to their houses, this commodity may be of less importance to them than many others. They make bucker, by putting the milk into a goat-skin, with its outward coat turned inwards, and shaking it till the butter collects on the sides, when it is taken out for use. From this operation it produces always full of hair, and has an insipid flavour. Their cheese consists merely of curds hardened and dried, and has uniformly a disagreeable taste. The bread in general of the principal towns, particularly at Tangier and Saltee, is remarkably good, but in many other places it is coarse, black, and heavy.

Their looms, forges, ploughs, carpenters tools, &c. are much upon the same construction with the unimproved instruments of the same kind which are used at this time in some parts of Europe, only filled more clumsily finished. In their work, they attend more to strength than neatness or convenience; and, like all
The whole of this ceremony they repeat three times.

Their sabbath is on their Friday, and commences from six o'clock the preceding evening. On this day they use a blue flag instead of the white one. As it has been prophesied that they are to be conquered by the Christians on the sabbath-day, the gates of all the towns and of the emperor's palaces are shut when at divine service on that day, in order to avoid being surprized during that period. Their tables are not distinguished by any particular dress.

The Moors have three solemn devotional periods in the course of the year. The first, which is named Ayd de CADHER, is held in commemoration of the birth of Mahomet. It continues seven days; during which period, every person who can afford the expense kills a sheep as a sacrifice, and divides it among his friends.

The second is the Ramadan. This is held at the season when Mahomet disappeared in his flight from Mecca to Medina. Every man is obliged at that period to fast (that is, to abstain from animal-food from sun-rise to sun-set each day) for 30 days; at the expiration of which time a feast takes place, and continues a week. The third is named Lambard, and is a day fast apart by Mahomet for every person to compute the value of his property, in order for the payment of zakat, that is one-tenth of their income to the poor, and other pious uses. Although this feast only lasts a single day, yet it is celebrated with far greater magnificence than either of the others.

The Moors compute time by lunar months, and count the days of the week by the first, second, third, &c. beginning from our Sunday. They use a common creed for writing, and begin their manuscripts from right to left.

The Moors of the empire of Morocco, as well as those to the northern limits of Africa, speak Arabic; but this language is corrupted in proportion as we retire farther from Africa, where it first took birth; the intermixture which has happened among the African nations, and the frequent transflagurations of the Moors, during a succession of ages, have occasioned them to lose the purity of the Arabic language; its pronunciation has been vitiated, the use of many words lost, and other foreign words have been introduced without thereby rendering it more copious: the pronunciation of the Africans, however, is fitter to the ear and less guttural than that of the Egyptians. The language, when written, is in effect much the same at Morocco as at Cairo, except that there are letters and expressions among the Moors which differ from those of the Oriental Arabs, who, however, understand the Moors in conversation, notwithstanding their vitiated manner of pronouncing. They mutually read each other's writings with some difficulty.

There is a very sensible difference among the Moors between the Arabic of the learned and the courtiers, and that spoken by the people in general; and this difference is felt still more in the provinces of the south or of the east, and among the Moors who live in the deserts, where the Arabic is yet farther disfigured by a mixture of foreign tribes.

The Brebes and the Shells, who appear to have had the same origin, for they have preferred the same disfigured, speak a language which the Moors do not understand, and which seems to have no analogy with that of the latter. It has been conjectured to be the Punic, or the Numidian; but these people write it in Arabic characters. The Brebes count the days of the week like the Moors, and both of them employ Arabic words. The Shells enumerate the days after the same method, but in their own language.

Both the Brebes and the Shells denote the months of the year in the same manner as do the Moors and Arabs, and date from the same era; that is to say, from the year of the Hegira.

The Koran and books of prayer of the Brebes and Shells are in Arabic; as likewise are their acts and title-deeds, which are written by their talbes or learned men.

The Moors are naturally of a grave and penfive disposition, fervid in professions of friendship, but very infinacere in their attachments. They have no curiosity, no ambition of knowledge; an indolent habit, united to the want of mental cultivation, renders them perhaps even more callous than other unenlightened people to every delicate sensibility; and they require more than ordinary excitement to render them female of pleasure or of pain. This languor of temper is, however, unaccompanied with the smallest spark of courage or fortitude. When in adversity, they manifest the most abject submission to their superiors; and in prosperity their tyranny and pride is insupportable. They frequently smile, but seldom are heard to laugh loud. The most infallible mark of internal tranquility and enjoyment is when they amuse themselves with strolling or playing with their beard. When roused by resentment, their disputes rarely proceed further than violently to abuse each other in the most opprobrious language. They never fight or box with their fists like our peasantry; but when a quarrel proceeds to great extremities, they collar each other, and sometimes terminate a dispute by affai nination.

Personal cleanliness has been considered as one of the most oftho circumstances which serve to mark and determine the civilization of a people. It was in vain that Mahomet enjoined the frequency of ablution as a religious duty to the Moors. Their dress, which should be white, is but seldom washed; and their whole appearance evinces that they perform this branch of their religious ceremonies in a slovenly manner. With this degree of negligence as to their persons, we may be justly surprised to find united a most scrupulous nicety in their inhabitants and apartments. They enter their chambers barefooted, and cannot bear the slightest degree of contamination near the place where they are seated. This delicacy again is much confined to the infides of their hovels. The streets receive the whole of their rubbish and filth; and by these means the ground is soiled in most parts of the city of Morocco, that the new buildings always stand considerably higher than the old.

When a Moor receives his guests, he never rises from his seat, but rises hands, inquires after their health, and directs them to sit down, either on a carpet or a cushion placed on the floor for that purpose. Whatever be the time of day, tea is then brought in on a tea-board with short feet. This is the highest

41 Language of the Moors.

42 Their temper and disposition.

43 Morocco.
compliment that can be offered by a Moor; for tea is a very expensive and scarce article in Barbary, and is only drunk by the rich and luxurious. Their manner of preparing it is by pouring some green tea, a small quantity of tansy, the same portion of mint, and a large proportion of sugar (for the Moors drink their tea very sweet) into the tea-pot at the same time, and filling it up with boiling water. When these articles are infused a proper time, the fluid for china, the smaller the more genteel, without any the meats, it is handed round to the company. From the great esteem in which this beverage is held by the Moors, it is generally drunk by very small and slow sips, that its flavour may be the longer enjoyed; and as they usually drink a considerable quantity when ever it is introduced, this entertainment is seldom finished in less time than two hours.

The other luxuries of the Moors are fruift, of which they are uncommonly fond, and smoking tobacco, for which the greater part use wooden pipes about four feet in length, with an earthen bowl; but the princes or emperor generally have the bowls made of solid gold. Instead of the indulgence of opium, which, from the heavy duty imposed upon that article by the emperor, is too expensive to be used by the Moors, they substitute the achicha, a species of flax. This they powder and infuse in water in small quantities.

The Moors affect, that it produces agreeable ideas; but own that when it is taken to excess it most powerfully intoxicates. In order to produce this effect, they likewise mix with their tobacco an herb named in this country khash, which by smoking, occasions all the exhilarating effects of the achicha. The use of spirits as well as wine is strictly forbidden by the Koran; there are, however, very few among the Moors who do not joyfully embrace every private opportunity of drinking both to excess.

With respect to the hours for eating, the people of this country are remarkably regular. Very soon after day-break they take their breakfast, which is generally a soup of flour and water boiled thin, and which is finding in it yellow tinge. The male part of the family eat in one apartment and the female in another. The children are not permitted to eat with their parents, but take their meals afterwards with the servants; indeed in most other respects they are treated exactly as servants or slaves by their parents. The mess is put into an earthen bowl, and brought in upon a round wooden tray. It is placed in the centre of the guests, who sit crook-legged either on a mat or on the floor, and who form a circle for the purpose. Having previously washed themselves, a ceremony always performed before and after meals, each person with his spoon attacks vigorously the bowl, while they diversify the entertainment by eating with it fruit or bread. At 12 o'clock they dine, performing the same ceremonies as at breakfast. For dinner, from the emperor down to the peasant, their dish is universally cowfordo, the mode of preparing which has been already described. The dish is brought in upon a round tray and placed upon the floor, round which the family sit as at breakfast, and with their fingers commit a violent assault on its contents: they are at the same time, however, attended by a slave or domestic, who presents them with water and a towel occasionally to wash their hands. From the want of the simple and convenient invention of knives and forks, it is not uncommon in this country to see three or four people pulling to pieces the same piece of meat, and afterwards with their fingers stirring up the plate or cowfordo, of which they often take a whole handful at once into their mouth. At fun-set they set upon the same dish; and indeed supper is their principal meal.

Such is the general mode of living among the principal people in towns. There are considerable multitudes, however, who do not fare so well, but are obliged to content themselves with a little bread and fruit instead of animal food, and to sleep in the open streets. This kind of existence seems ill calculated to endure even in an active state; far more severe must it therefore be to those who exercise the laborious employment of couriers in this country, who travel on foot a journey of 300 or 400 miles at the rate of between 30 or 40 miles a-day, without taking any other nourishment than a little bread, a few figs, and water, and who have no better shelter at night than a tree. It is wonderful with what alacrity and perseverance these people perform the most fatiguing journeys at all seasons of the year. There is a regular company of them in every town, who are ready to be dispatched at a moment's warning to any part of the country their employers may have occasion to send them. They constitute in this empire the only mode of conveyance for all public and private dispatches; and as they are well known in the place to which they belong, they are very punctual in delivering every thing that is put into their hands. From their steady pace in travelling, at the rate of about four miles an hour, and from their being able to pass over parts which from the mountainous state of the country, and from the want of good roads, perons on horseback would find inaccessible, they are indeed by far the most expeditious messengers that could be employed.

As none but the very vulgar go on foot in this country, for the purpose of visiting, mules are considered as more genteel than horses; and the greatest pride of a Moor is to have such as walk remarkably fast, and to keep his footmen, of which the number is proportionable to the rank and consequence of the master, on a continued run.

As the Moors are not fond of admitting men into their houses except upon particular occasions, if the weather is fine they place a mat, and sometimes a carpet, on the ground before their door, seat themselves upon it crook-legged, and receive their friends, who form a circle, sitting in the same manner, with their attendance on the outside of the group. Upon these occasions they either drink tea or smoke and converse. The streets are sometimes crowded with parties of this kind; some engaged in playing at an inferior kind of chess or drafts, at which they are very expert; but the majority in conversation. The people of this country, indeed, are so decidedly averse to standing up, or walking about, that if only two or three
Their amusements.

The Moors have in general but few amusements; the fedentary life they lead in cities is little variegated except by the care they take of their gardens, which are rather kept for profit than pleasure. Most of these gardens are planted with the orange, the lemon tree, and the cedar, in rows, and in such great quantities, that the appearance is rather that of a forest than that of a garden. The Moors sometimes, though rarely, have music in their retreats: a state of slavery but ill agrees with the love of pleasure: the people of Fes alone, either from a difference in education, or because their organs and sensibility are more delicate, make music a part of their amusements. There are not in Morocco, as in Turkey, public coffee-houses, where people meet to inquire the news of the day; but instead of these, the Moors go to the barbers shops, which in all countries seem to be the rendezvous of Newsmongers. These shops are surrounded by benches; on which the customer, the inquisitive, and the idle, seat themselves; and when there are no more places vacant, they crouch on the ground like monkeys.

Showmen and dancers come often into the towns; round whom the people assemble and partake of the amusement for a very trifle. There are also a kind of wandering historians: the vulgar, who cannot read, and who every where are eager to hear extraordinary relations, are the more affiduous in attending these narrators, as want of more extensive information prevents the tale-teller remaining above a week in a place.

A common diversion in the towns where there are fadors, as well as in the country, is what the Moors call the game of gun-powder; a kind of military exercise that is the more pleasing to these people, inasmuch as, by the nature of their government, they all are, or are liable to become, fadors, therefore all have arms and horses. By expostions of powder, too, they manifest their felicity on their holidays. Their game of gun-powder consists in two bodies of horse, each at a distance from the other, galloping in successive parties of four and four, and firing their pieces charged with powder. Their chief art is in galloping up to the opposite detachment, suddenly stopping, firing their muskets, facing about, charging and returning to the attack; all which maneuvers are imitated by their opponents. The Moors take great pleasure in this amusement, which is only an imitation of their military evolutions.

The common topics for conversation among the Moors, are the occurrences of the place, religion, their women, but above all their horses. This last topic, horses, indeed, appears to occupy by far the greatest portion of their attention. These animals are seldom kept in stables in Morocco. They are watered and fed only once a-day, the former at one o'clock at noon, and the latter at sunset; and the mode which they use to clean them is by washing them all over in a river two or three times a week, and suffered them to dry themselves.

Notwithstanding the attachment which the Moors manifest to their horses, they most certainly use them with great cruelty. Their highest pleasure, and one of their first accomplishments, is, by means of long and sharp spurs, to make the horse go full speed, and then to flop him instantaneously; and in this they certainly manifest uncommon dexterity. The iron-work of their bridles is so constructed, that by its preffure on the horse's tongue and lower jaw, with the least exertion of the rider, it fills his mouth full of blood; and if not used with the utmost caution, throws him inevitably on his back. The bridle has only a single rein, which is so very long, that it serves the purpose of both whip and bridle. The Moorish saddle is in some degree similar to the Spanish, but the pummel is still higher and more peaked. Their stirrups, in which they ride very short, are so formed as to cover the whole of the foot. They either plate or gild them, according to the dignity, opulence or fancy of the possessor. Their saddles which are covered with red woollen cloth, or if belonging to a person of consequence, with red fatin or damask, are fastened with a strong girth round the body in the European style, and another round the shoulders. The Moors frequently amuse themselves by riding with the utmost apparent violence against a wall; and a stranger would conceive it impossible for them to avoid being dashed to pieces, when just as the horse's head touches the wall, they stop him with the utmost accuracy.

Like all other barbarous nations, the Moors are particularly fond of music, and some few have a taste for music poetry. Their fobs air for want of that variety which is introduced when the science has attained a degree of perfection, have a very melancholy fameness; but some of their quick tunes are beautiful and simple, and partake in some degree of the characteristic melody of the Scotch airs. The poetry of their fongs, the constant subject of which is love, though there are few nations perhaps who are less sensible of that passion, has certainly less merit than the music.

Their instruments are a kind of hautboy, which differs from ours only in having no keys; the mandoline, which they have learnt to play upon from their neighbours the Spaniards; another instrument, bearing some resemblance to a violin, and played upon in a similar manner, but with only two strings; the large drum, the common pipe, and the tabor. These, united, and accompanied with a certain number of voices, upon many occasions form a band, though solo music is more common in this unfocial country. Upon all days of rejoicing, this kind of music, repeated volleys of musketry, either by men on horseback or on foot and
The Moors marry very young, many of their females not being more than 12 years of age at their nuptials. As Mahometans, it is well known that their religion admits of polygamy to the extent of four wives, and as many concubines as they please: but if we except the very opulent, the people seldom avail themselves of this indulgence, since it entails on them a vast additional expense in house-keeping, and in providing for a large family. In contracting marriage, the parents of both parties are the only agents: and the intended bride and bridegroom never see each other till the ceremony is performed. The marriage ceremonies are made before the cadi, and then the friends of the bride produce her portion, or if not the husband agrees to settle a certain sum upon her in case he should die, or divorce her on account of barrenness, or any other cause. The children of the wives have all an equal claim to the effects of the father and mother, but those of the concubines can each only claim half a share.

When the marriage is finally agreed upon, the bride is kept at home eight days, to receive her female friends, who pay congratulatory visits every day. At the same time a tablet attends upon her, to converse with her relative to the solemn engagement on which she is about to enter; on these occasions he commonly accompanies his admonitions with singing a pious hymn which is adapted to the solemnity. The bridegroom, on the other hand, receives visits from his male friends in the morning, and in the evening rides through the town accompanied by them, some playing on hautboys and drums, while others are employed in firing volleys of musketry. In all their festivals, the discharge of musketry indeed forms a principal part of the entertainment. Contrary to the European mode, which particularly arms at firing with exactness, the Moors discharge their pieces as irregularly as possible, so as to have a continual succession of reports for a few minutes.

The evening is put into a square or octagonal cage about 12 feet in circumference, which is covered with fine white linen and sometimes with gauzes and silks of various colours. In this vehicle, which is placed on a mule, she is paraded round the streets, accompanied by her relations and friends: some carrying lighted torches, others playing on the hautboys, and a third party is again firing volleys of musketry. In this manner she is carried to the house of her intended husband, who returns about the same time from performing similar ceremonies. On her arrival she is placed in an apartment by herself, and her husband is introduced to her alone for the first time, who finds her sitting on a silk or velvet cushion, supposing her to be a person of consequence, with a small table before her, upon which are two wax candles lighted. Her shift, or more properly shirt, hangs down like a train behind her, and over it is a silk or velvet robe with close sleeves, which at the breast and wrists is embroidered with gold; this dres reaches something lower than the calf of the leg. Round her head is tied a black silk scarf, which hangs behind as low as the ground. Thus attired, the bride sits with her hands over her eyes, when her husband appears and receives her as his wife without any further ceremony; for the agreement made by the friends before the cadi, is the only specie contract which is thought necessary.

If the husband should have any reason to suspect that his wife has not been strictly virtuous, he is at liberty to divorce her and take another. For some time after marriage, the family and the friends are engaged in much feasting, and a variety of amusements, which last a longer or shorter time according to the circumstances of the parties. It is usually customary for the man to remain at home eight days and the woman eight months after they are first married; and the woman is at liberty to divorce herself from her husband, if she can prove that he does not provide her with a proper subsistence. If he curbs her, the law obliges him to pay her, for the first offence eight ducats; for the second, a rich dress of silk greater value; and the third time she may leave him entirely. He is then at liberty to marry again in two months.

Women suffer but little inconvenience in this country from child-bearing; they are frequently up the next day, and go through all the duties of the house with the infant upon their backs. In celebrating the rite of circumcision, the child is dressed very sumptuously; and carried on a mule, or, if the parents are in poor circumstances, on an ass, accompanied with flags flying and musicians playing on hautboys and beating drums. In this manner they proceed to the mosque, where the ceremony is performed. Children are as soon as they can be made in the least degree useful, are put to the various kinds of labour adapted to their age and strength. Others, whose parents are in better circumstances, are sometimes sent to school; and those who are intended for the church, usually continue their studies till they have nearly learnt the Koran by rote. In that cafe, they are enrolled among the talbes, or learned men of the law; and upon leaving school are paraded round the streets on a horse, accompanied by music, and a large concourse of people.

When any person dies, a certain number of women are hired for the purpose of lamentation; in the funeral performance of which, nothing can be more grand than the crying to the ear, or more unpleasing, than their frightful moans, or rather howlings; at the same time, these mercenary mourners beat their heads and tear their cheeks with their nails. The bodies are usually buried a few hours after death. Previous to interment, the corpse is washed very clean, and sewed up in a thong, with the right hand under the head, which is pointed towards Mecca, it is carried on a bier, supported upon men's shoulders, to the burying place, which is always, with great propriety, on the outside of the town, for they never bury their dead in the mosques, or within the bounds of an inhabited place. The bier is accompanied by numbers of people, two a breast, who walk very fast, calling upon God and Mahomet, and singing hymns adapted to the occasion. The grave is made very wide at the bottom and narrow at the top, and the body is deposited without any other ceremony than singing and praying in the same manner as on their way to the grave. They have no tombs in this country, but long and plain stones; and it is frequently customary for the female friends...
friends of the departed to weep over their graves for several days after their funeral.

It has often been thought surprising, that the Christian powers should suffer their marine to be infalut by those barbarians, who take the ships of all nations with whom they are not at peace, or rather who do not pay them a subsidy either in money or commodities. This forbearance has been accounted for no other than by supposing, first, that a breach with them might provoke the Forte, who pretends to be their lord paramount; secondly, that no Christian power would be fond of seeing Algiers, and the rest of that coast, in possession of another; and, thirdly, that nothing could be got by a bombardment of any of their towns, as the inhabitants would instantly carry their effects to their deserts and mountains, so that the benefit resulting from the conquest must be tedious and uncertain.

The first reason is so obvious as to require no answer; in regard to the second and third suppositions, it may be observed, that there is no necessity for taking possession of those towns without the necessity of any European power whatever. The object ought to be, not to conquer, but to render impotent, those piratical states; not to profit by plundering them, but to quash their piracies, and prevent them from being longer the nuisances and pests of the Mediterranean. Than which according to the best informed travellers, there can be nothing more easy. Hardly any force of armament would be necessary for the purpose; would the Europeans merely leave them to their own resources, and with-hold those supplies with which they have been in use to furnish them, contrary as well to good policy as to the interests of humanity. M. Lempriere, speaking of the emperor of Morocco (1790) observes, that "nothing but gross neglect or inexecutable ignorance could induce the European princes in general to remain in a kind of tributary state to a prince who had neither an army nor a fleet which deferred the name, and a people whose disposition is least united to enter into any thing than perhaps any other. What had they to fear from him? His whole fleet consisted only of a few small frigates and row-boats, ill managed and worse manned, the whole of which might have been destroyed in one day by two or three well appointed European frigates. The entrances of those ports where he laid up his shipping, if we except Tangier and Larache, are so continually hoisting up with sand, that in a short time they will only admit fishing-boats, or the very smallest craft. The towns are none of them regularly fortified except Mogodore, and that hardly produces half a dozen of men who understand the least of working the guns. And yet this contemptible power gives laws to all the coasts of Portugal and Spain, and may be said in some measure to command the entrance of the Mediterranean."

It may be said, he was too trifling a power to notice; if so, why lavish immense presents for the purpose of keeping him in temper? Tho' those who imagined they secured his friendship by these means, were much mistaken; on the contrary, they only added fuel to that flame of avarice which was not to be extinguished. If he was one day presented with a frigate, he asked for two the next; and the more his requests were indulged, the more his inordinate desires were increased. It is well known to those who have been conversant with the Moors, that to secure their friendship, you must first assert your own superiority; and then if you make them a trifling present, its value, is trebled in their estimation. The same disposition would have been found in the late emperor as in the common Moor. So far from courting an alliance, it would rather have been good policy at once to quarrel with him; the loss of a few towns, and particularly Mogodore, to which he was much attached, from its being raised under his own auspices, would soon have reduced him to good humour and submission."

Another intelligent traveller, M. Briffon, observes, how extraordinary it is, that a prince so little to be dreaded as the emperor of Morocco should oblige the different powers of Europe to fend ambassadors to him, and that he should even dictate laws to them. There is not a single foreigner who dares to send a representative to his court without making him at the same time considerable presents; and what envoy would present himself without having his hands full? How happens it that the consuls have not by common consent, represented to their respective sovereigns, that the emperor of Morocco becomes every day more and more powerful by the supplies which they themselves furnish him? Twenty years ago this prince was absolutely destitute of resources. He had neither materials nor any place for casting cannons; and he was equally in want of wood for building ships, of ropes, of nails, and even of workmen. It is France and other European powers that affit him, albeit the emperor of Morocco would be of little consideration. His superb batteries of brass cannons, 24, 36, and 48 pounders, were furnished by Holland, Spain, England, and France. England has done more than other nations, by sending him those beautiful cannons which were taken on the floating batteries. Mogodore is built in an advantageous situation, its batteries are well disposed, and there are cannon at each embrasure; but they are there only in a manner for show, as they have no carriages, and are supported only by brick-work. There are no workmen in the country capable of mounting them on carriages, nor is there wood proper for making them. Did a few vessels only wait for the falling of those small frigates, which are almost all unfit for sea except only two, nothing would be easier than to prevent them from returning, and to block up the ports of Mogodore, Rabat, and Sallee. What would become of his commerce, and above all his marine, if the Christian princes cease to affit him, contrary to the interests of humanity? Would England and Spain unite only for a moment, Tangiers, his most beautiful port, would soon be so far ruined, that it could not afford shelter to his subjects, who, deftitute of ships, would soon be obliged to give over their piracies. If the consuls of different nations have never made these observations, and in and if they have never pointed out the means of curtailing the insolence of the emperor of Morocco, it is because they are at the head of the commerce which those different powers carry on in that part of the world. I can positively affirm, that these representatives, instead of furnishing their courts with the means of diminishing the power of the emperor, never cease to add to his strength, and to incite him to make new
Morocco. [355]  

Morocco, a city of the kingdom of Morocco in Barbary, lying about 120 miles to the north of Tarudant, 90 to the east of Mogodore, and 350 to the south of Tangier. It is situated in a beautiful valley, formed by a chain of mountains on the northern side, and those of the Atlas, from which it is distant about 20 miles to the south and east. The country which immediately surrounds it is a fertile plain, beautifully diversified with clumps of palm trees and shrubs, and watered by small and numerous streams which descend from Mount Atlas. The emperor's out-gardens, which are situated at a distance of about five miles to the south of the city, and are large plantations of elvies walled in, add considerably to the beauty of the upper town.

Morocco, though one of the capitals of the empire (for there are three, Morocco, Mequinez, and Fez), has nothing to recommend it but its great extent and the royal palace. It is encompassed by remarkably strong walls built of tabby, the circumference of which is about eight miles. On these walls there are no guns mounted; but they are flanked with square towers, and surrounded by a wide and deep ditch. The city has a number of entrances, consisting of large double porches of tabby in the Gothic style, the gates of which are regularly shut every night at certain hours. As polygamy is allowed by the Mahometan religion, and is supposed in some degree to affect population, it would be difficult to form any computation near the truth with respect to the number of inhabitants which this city may contain. The mosques, which are the only public buildings, except the palace, worth noticing at Morocco, are more numerous than magnificent; one of them is ornamented with a very high and square tower, built of cut stone, which is visible at a considerable distance from the city. The streets are very narrow, dirty and irregular, and many of the houses are uninhabited and falling to ruin. Those which are decent and respectable in their appearance are built of tabby, and enclosed in gardens. That of the effendi or prime minister (according to Mr Lempriere, from whose Travels this account is transcribed), was among the best in Morocco. This house, which consisted of two stories, had elegant apartments both above and below, furnished in a style far superior to any thing our author ever saw in that country. The court, into which the lower apartments opened, was very neatly paved with glazed blue and white tiling, and had in its centre a beautiful fountain. The upper apartments were connected together by a broad gallery, the balusters of which were painted of different colours. The hot and cold baths were very large, and had every convenience which art could afford. Into the garden, which was laid out in a tolerably neat style, opened a room adjoining to the house, which had a broad arched entrance but no door, beautifully ornamented with chequered tiling; and at both ends of the apartment the walls were entirely covered with looking-glasses. The flooring of all the rooms was covered with beautiful carpeting, the walls ornamented with large and valuable looking glasses, inteminated with watches and clocks in glass cases. The ceiling was carved woodwork, painted of different colours; and the whole was in a superior style of Moorish grandeur. This and a few others are the only decent habitations in Morocco. The generality of them serve only to impress the traveller with the idea of a miserable and defecfent city.

The Elcaniferia is a particular part of the town where trifles and other valuable articles are exposed to sale. It consists of a number of small shops, formed in the walls of the houses, about a yard from the ground, of such an height within as just to admit a man to it in one of them crooks-legged. The goods and drawers are so arranged round him, that when he serves his customers, who are standing all the time out in the street, he can reach down any article he wants without being under the necessity of moving. These shops, which are found in all the other towns of the empire, are sufficient to afford a striking example of the indolence of the Moors. There are three daily markets in different parts of the town of Morocco where provisions are sold, and two weekly fairs or markets for the disposal of cattle. The city is supplied with water by means of wooden pipes connected with the neighbouring streams, which empty themselves into reservoirs placed for the purpose in the suburbs, and some few in the centre of the town.

The castle is a large and ruinous building, the outer walls of which enclose a space of ground about three miles in circumference. It has a mosque on the top of which are three large balls, formed, as the Moors allege, of solid gold. The castle is almost a town itself; it contains a number of inhabitants; who in some department or other are in the service of the emperor, and all under the direction of a particular alcaide, who is quite independent of the governor of the town. On the outside of the castle, between the Moorish town and the Jewdry are several small distinct pavilions, inclosed in gardens of orange trees, which are intended as occasional places of refuge for such of the emperor's sons or brothers as happen to be at Morocco. As they are covered with coloured tiling, they have at a small distance rather a neat appearance; but upon approaching or entering them, that effect in a great measure ceases.

The Jews, who are at this place pretty numerous, have a separate town to themselves, walled in, and under the charge of an alcaide, appointed by the emperor. It has two large gates, which are regularly shut every evening about nine o'clock; after which time no person whatever is permitted to enter or go out of the Jewdry till they are opened again in the following morning. The Jews have a market of their own; and when they enter the Moorish town, castle, or palace, they are always compelled to be bare footed.

The palace, is an ancient building, surrounded by a square wall, the height of which nearly excludes from the view of the spectator the other buildings. Its principal gates are contructed with Gothic arches.
Morocco is composed of cut stone, which conduct to several open and spacious courts; through these it is necessary to pass before we reach any of the buildings. These open courts were used by the late emperor for the purposes of transacting public business and exercising his troops. The habitable part consists of several irregular square pavilions, built of tabby, and whitened over; some of which communicate with each other, others are distinct, and most of them receive their names from the different towns of the empire. The principal pavilion is named by the Moors the douhar, and is more properly the palace and spacious courts; through these it is possible to reach any of the buildings. The other pavilions are merely for the purposes of pleasure or business, and are quite distinct from the douhar. The Mogador pavilion, named from the late emperor’s partiality to that town, has by far the fairest claim to grandeur and magnificence. This apartment was the work of Sidi Mahomet, and is lofty and square. It is built of cut stone, hand-finished, and ornamented with windows, and covered with varnished tiles of various colours; and its simplicity and irregularity of the other buildings produce a most striking effect. In the inside, besides several other apartments, we find in the pavilion a spacious room floored with blue and white chequered tiling, its ceiling covered with curiously carved and painted wood, and its fluted walls variously ornamented with looking-glasses and tassels, regularly distributed in glass-panels. To this pavilion the late emperor manifested an absolute preference, frequently retiring to it both for the purposes of business and of recreation. The apartments of the emperor have in general a much smaller complement of furniture than those of the Moors in the inferior walks of life. Handsome carpeting, a matress on the ground covered with fine linen, a couch, and a couple of European bedsteads, are the principal articles they contain. The gardens within the walls of the palace, of which he has several, are very neat; they contain orange and olive trees, variously disposed and arranged, and intersected with fountains of water, fountains, and fountains. Those on the outside are nothing more than large tracts of ground, irregularly planted with olives; having four square walks, and surrounded by walls.

Morocco or Marruecos, the skin of a goat, or some other animal resembling it, dressed in sheep or gall, and coloured of any colour at pleasure; much used in bookbinding, &c. The name is ordinarily derived from the kingdom of Morocco, whence it is supposed the manner of preparing these skins was first borrowed. There are Morocco skins brought from the Levant, Barbary, Spain, Flinders, and France; red, black, yellow, blue, &c. For the manner of preparing them, see Leather.

Morocchus, in natural history, an indurated clay called by us French chalk; serving taylors and others to mark with. The ancients esteemed it as an astringent, preferring it in the cholic, haemorrhages, and other fluxes.

Moron, a town of Spain, in Andalusia, seat in a pleasant fertile plain, and in the neighbourhood is a mine of precious stones. It is 30 miles south-east of Seville. W. Long. 5° 20', N. Lat. 37° 0'.

Morpeth, a handsome town of Northumberland, 14 miles from Newcastle, 286 miles from London, is an ancient borough by prescription, with a bridge over the Wanbeck. It had once an abbey and a castle, now in ruins, situated about a quarter of a mile south of the town and river Wanbeck, on an eminence which overlooks them both. The marketplace is conveniently situated near the centre of the town; and an elegant town-house was built by the Carlisle family in 1714, in which the quarter-sections are held for the county. It is built of hewn-stone, with a piazza. The church being a quarter of a mile distant from the town, a tower containing a good ring of bells stands near the market-place. Near the bridge is the county gaol, a modern structure. Here are a free grammar-school, a chapel near the river on the site of a chantry that was granted for the support of the foundation of the school, which was part of the old structure, and an hospital for infirm people. In 1215, the townsmen themselves burnt their town, out of pure hatred to king John, that he might find no shelter there. Here is a good market on Saturday for corn, cattle, and all necessary provisions; and there is another on Wednesday, the greatest in England except Smithfield, for live cattle. This is a poit town and a thoroughfare, with many good inns, and plenty of fish; and here are several mills.—The earl of Carlisle’s steward holds a court here twice a-year, one of them the Monday after Michaelmas, when four persons are chosen by the free burgesses, who are about 107, and preferred to the steward, who names two of them to the bailiffs, who, with seven aldermen, are its governors for the year ensuing. Its fairs are on Wednesday, Thursday, and Friday before Whitsunday, and the Wednesday before July 22. It sends two members to parliament.

Morpheus, in fabulous history, the god of sleep, or, according to others, one of the ministers of Somaus. He caused sleepers, and represented the forms of dreams. Ovid styles him the kindlest of the deities; and he is usually described in a recumbent posture, and crowned with poppies.

Morreri (Lewis), author of the Historical Dictionary, was born at Bargemont in Provence, 1643. He learned rhetoric and philosophy at Aix, and divinity at Lyons. At 18 years of age he wrote a small piece, intitled Le Pays d’Amour, and a collection of the finest French poems intitled Deux plaisirs de la Poésie. He learned Spanish and Italian; and translated out of Spanish into French the book intitled La Perfection Chrétienne de Rodriguez. He then refined the Saints Lives to the purity of the French tongue. Being ordained priest, he preached at Lyons, and undertook, when he was but 30 years of age, a new Historical Dictionary, printed at Lyons in one vol. folio, 1673. But his continual labour impaired his health; so that he died in 1680, aged 37. His second volume was published after his death; and four more volumes have since been added. He left some other works behind him.

Morrhina was, were a fort of cups or veses made use of by the ancients for drinking out of, and others.
other purposes. Authors are not agreed as to the substance of which they were made. Some say it was a stone; some assert that it was a fluid congealed by being buried under ground. All that we know concerning it is, that it was known by the name of Murba, and that Heliogabalus’s chamber pot was made of it. The word is sometimes written myrrha.

MORRISE-DANCES. See MORRIS-dances.

MORIS, DEATH, one of the infernal deities, born of Night without a father. She was worshipped by the ancients with great solemnity. She was not represented as an actually existing power, but as an imaginary being. Euripides introduces her in one of his tragedies on the stage. The moderns represent her as a skeleton armed with a scythe and a scymnetar.

MORSE, in zoology. See TRICHECUS.

MORTALITY, a term frequently used to signify a contagious disease, which destroys great numbers of either men or beasts.

Bills of Mortality, are accounts or registers specifying the numbers born, married, and buried in any parish, town or district. In general they contain only these numbers; and, even when thus limited, are of great use, by showing the degrees of healthiness and prolificness, and the progress of population in the places where they are kept. It is therefore much to be wished, that such accounts had been always correctly kept in every kingdom, and regularly published at the end of every year. We should then have had under our inspection the comparative strength of every kingdom, as far as it depends on the number of inhabitants, and its increase or decrease at different periods. But such accounts are rendered more useful, when they include the ages of the dead, and the distempers of which they have died. In this case they convey some of the most important instructions, by furnishing us with the means of ascertaining the law which governs the waste of human life, the values of annuities dependent on the continuance of any lives, or any survivorships between them, and the favourableness or unfavourableness of different situations to the duration of human life. There are but few registers of this kind; nor has this subject, though so interfering to mankind, ever engaged much attention till lately. The first bills containing the ages of the dead were those for the town of Breslaw in Silesia. It is well known what use has been made of these by Dr Halley, and after him by De Moivre. A table of the probabilities of the duration of human life at every age, deduced from them by Dr Halley, has been published in the Philosophical Transactions, (see the Abridgement, vol. iii. p. 609.) and is the first table of this sort that has ever been published. Since the publication of this table, similar bills have been established in a few towns of Great Britain, particularly in London, in the year 1728, and at Northampton in 1735.

Two improvements of these registers have been proposed: the first is, that the sexes of all that die in every period of life should be specified in them, under the denomination of boys, married men, widowers, and bachelor’s; and of girls, married women, widows, and virgins. The second is, that they should specify the numbers of both sexes dying of every distemper in every month, and at every age. See the end of the 4th essay in Dr Price’s Treatise on Reversionary Payments. Mortality.

Registers of mortality thus improved, when compared with records of the seafarers, and with the circumstances that discriminate different situations, might contribute greatly to the increase of medical knowledge; and they would afford the necessary data for determining the difference between the duration of human life among males and females; for such a difference is certainly much in favour of females, as will appear from the following facts.

At Northampton, though more males are born than females, and nearly the same number die; yet the number of living females appeared, by an account taken in 1746, to be greater than the number of males, in the proportion of 230 to 1770, or 39 to 30. At Berlin it appeared, from an accurate account which was taken of the inhabitants in 1747, that the number of female citizens exceeded the number of male citizens in the proportion of 459 to 391. And yet out of this smaller number of males, more had died for 20 years preceding 1751, in the proportion of 19 to 17.

At Edinburgh, in 1743, the number of females, was to the number of males as 4 to 3. (See Maitland’s History of Edinburgh, p. 220.) But the females that died annually from 1749 to 1758, were to the males in no higher proportion than 35 to 32.

He that will take the pains to examine the accounts in Phil. Trans. abr. vol. vii. part iv. p. 46, &c. will find, that though in the towns there enumerated, the proportion of males and females born is no higher than 19 to 18, yet the proportion of boys and girls that die is 8 to 7; and that, in particular, the still-born and chrysom males are to the still-born and chrysom females as 3 to 2.

In 39 parishes of the district of Vaucluse in Switzerland, the number of males that died during ten years before 1766 was 8170; of females 8167; of whom the numbers that died under one year of age were 1817 males and 1305 females; and under ten years of age, 3099 males and 2598 females. In the beginning of life, therefore, and before any emigrations can take place, the rate of mortality among males appears to be greater than among females. And this is rendered yet more certain by the following accounts. At Vevey, in the district of Vaucluse just mentioned, there died in the course of 20 years, ended at 1764, in the first month after birth, of males 135 to 89 females; and in the first year 225 to 162. To the same effect it appears from a table given by Suflimie, in his Gottliche Ordnung, vol. ii. p. 317, that in Berlin 223 males die in the first month, and but 168 females; and in the first year, 489 to 395; and also, from a table of Struycks, that in Holland 396 males die in the first year to 306 females.

The authorities for the facts here mentioned, and much more on this subject, may be found in the 4th essay in Dr Price’s Treatise on Reversionary Payments, and in the supplement at the end of that treatise.

We shall here only add the following table, taken from a memoir of Mr Wargentin’s, published in the collection of the Memoirs of the Royal Academy of Sciences at Stockholm, printed at Paris in 1772.
Mortality.

In all Sweden for nine years, ending in 1763, the proportion of females to males that died out of a given number living, was

Registars of mortality on the improved plan before mentioned, were established in 1772 at Chelfter, and also in 1773 at Warrington in Lancashire; and they are so comprehensive and correct, that there is reason to expect they will afford much instruction on the subject of human mortality, and the value of lives.

But the country most distinguished in this respect is Sweden: for in that kingdom exact accounts are taken of the births, marriages, and burials, and of the numbers of both sexes that die at all ages in every town and district; and also at the end of every period of five years, of the numbers living at every age: and at Stockholm a society is established, whose business it is to superintend and regulate the enumerations, and to collect from the different parts of the kingdom the registers, in order to digest them into tables of observations. These regulations were begun in Sweden in 1755; and tables, containing the result of them from 1755 to 1763, have been published in Mr Wargentin's memoir just referred to; and the most material parts of them may be found in an essay by Dr Price on the Difference between the Duration of Human Life in Towns and in Country Parishes, printed in the 65th volume of the Philos. Tran.

Part II.

In the fourth essay in Dr Price's Treatise on Reversionary Payments and Life-Annuities, the following account is given of the principles on which tables of observation are formed from registers of mortality; and of the proper method of forming them, so as to render them just representations of the number of inhabitants, and the probabilities of the duration of human life in a town or country.

In every place which just supports itself in the number of its inhabitants, without any recruits from other places; or where, for a course of years, there has been no increase or decrease; the number of persons dying every year at any particular age, and above it, must be equal to the number of the living at that age. The number, for example, dying every year at all ages from the beginning to the utmost extremity of life, must, in such a situation, be just equal to the whole number born every year. And for the same reason, the number dying every year at one year of age and upwards, at two years of age and upwards, at three and upwards, and so on, must be equal to the numbers that attain to those ages every year; or, which is the same, to the numbers of the living at those ages. It is obvious, that unless this happens, the number of inhabitants cannot remain the same. If the former number is greater than the latter, the inhabitants must decrease; if less, they must increase.

From this observation it follows, that in a town or country where there is no increase or decrease, bills of mortality which give the ages at which all die, will show the exact number of inhabitants, and also the exact law according to which human life wavers in that town or country.

In order to find the number of inhabitants, the mean numbers dying annually at every particular age and upwards must be taken as given by the bills, and placed under one another in the order of the second column of the following tables. These numbers, it has appeared, are the numbers of the living at 1, 2, 3, &c. years of age; and consequently the sum diminished by half the number born annually will be the whole number of inhabitants.

This subtraction is necessary for the following reason: In a table formed in the manner here directed, it is supposed that the numbers in the second column are all living together at the beginning of every year. Thus the number in the second column opposite to 0 in the first column, the table supposes to be all just born together on the first day of the year. The number, likewise, opposite to 1, it supposes to attain to one year of age just at the same time that the former number is born. And the like is true of every number in the second column. During the course of the year, as many will die at all ages as were born at the beginning of the year; and consequently, there will be an excess of the number alive at the beginning of the year above the number alive at the end of the year, equal to the whole number of the annual births; and the true number constantly alive together, is the arithmetical mean between these two numbers; or agreeably to the rule here given, the sum of the numbers in the second column of the table leaffened by half the number of annual births.

In such a series of numbers, the excess of each number above that which immediately follows it, will be the number dying every year out of the particular number alive at the beginning of the year; and these excesses set down regularly as in the third column of the table to which we have referred, will show the different rates at which human life wavers through all its different periods, and the different probabilities of life at all particular ages.

It must be remembered, that what has been now said goes on the supposition, that the place whose bills of mortality are given, supports itself, by procreation only, in the number of its inhabitants. In towns this very seldom happens on account of the luxury and debauchery which generally prevail in them. They are, therefore, commonly kept up by a constant accession of strangers, who remove to them from country parishes and villages. In these circumstances, in order to find the true number of inhabitants, and probabilities
Mortality. Probabilities of life, from bills of mortality containing an account of the ages at which all die, it is necessary that the proportion of the annual births to the annual settlers should be known, and also the period of life at which the latter remove. Both these particulars may be discovered in the following method.

If for a course of years there has been no sensible increase or decrease in a place, the number of annual settlers will be equal to the excess of the annual burials above the annual births. If there is an increase, it will be greater than this excess. If there is a decrease, it will be less.

The period of life at which these settlers remove, will appear in the bills by an increase in the number of deaths at that period and beyond it. Thus in the London bills the number of deaths between 20 and 30 is generally above double; and between 30 and 40 near triple the number of deaths between 10 and 20; and the true account of this is, that from the age of 18 or 20 to 35 or 50, there is an influx of people every year to London from the country, which occasions a great increase in the number of inhabitants at these ages; and consequently raises the deaths for all ages above 20 considerably above their due proportion, when compared with the number of deaths before 20. This is observable in all the bills of mortality for towns with which we are acquainted, not excepting even the Breflaw bills. Dr Halley takes notice, that these bills give the number of deaths between 10 and 20 too small. This he considered as an irregularity in them owing to chance; and, therefore, in forming his table of observations, he took the liberty so far to correct it, as to render the proportion of those who die to the living in this division of life nearly the same with the proportion which he says, he had been informed die annually of the young lads in Christ-Church Hospital. But the truth is, that this irregularity in the bills was derived from the cause we have just alluded to. During the five years for which the Breflaw bills are given by Dr Halley, the births did indeed a little exceed the burials; but it appears that this was the effect of some peculiar causes that happened to operate just at that time; for during a complete century from 1633 to 1734, the annual medium of births was 1089, and of burials 1256. This town, therefore, must have been all along kept up by a number of yearly recruits from other places, equal to about a seventh part of the yearly births.

It appears from the account in the Philosophical Transactions (Abridgment, vol. vii. p. 380, p. 46, &c.), that from 1717 to 1725, the annual medium of births at Breflaw was 1252, of burials 1507; and also that much the greatest part of the births died under 10 years of age. From a table in Sufmilch's works, vol. i. p. 98, it appears, that in reality the greater part of all that die in this town are children under five years of age.

What has been now observed concerning the period of life at which people remove from the country to settle in towns, would appear sufficiently probable were there no such evidence for it as has been mentioned; for it might be well reckoned that these people in general must be single persons in the beginning of mature life, who, not having yet obtained settlements in the places where they were born, migrate to towns in quest of employments.

Having premised these observations, it will be proper next to endeavour to explain distinctly the effect which these accessions to towns must have on tables of obervation formed from their bills of mortality. This is a subject proper to be insisted on, because mistakes have been committed about it; and because also the diffusion of it is necessary to show how near to the truth the values of lives come as deduced from such tables.

The following general rule may be given on this subject. If a place has for a course of years been maintained in a state nearly stationary, as to number of inhabitants, by recruits coming in every year, to prevent the decrease that would arise from the excess of burials above the births, a table formed on the principle, "that the number dying annually after every particular age, is equal to the number living at that age," will give the number of inhabitants, and the probabilities of life, too great, for all ages preceding that at which the recruits cease; and after this it will give them right. If the accessions are so great as to cause an increase in the place, such a table will give the number of inhabitants and the probabilities of life too little after the age at which the accessions cease; and too great if there is a decrease.

Before that age it will in both cases give them too great; but much considerably so, in the former case, or when there is an increase.

Agreeably to these observations, if a place increases not in consequence of accessions from other places, but of a constant excess of the births above the deaths, a table constructed on the principle that has been mentioned will give the probabilities of life too low through the whole extent of life; because in such circumstances the number of deaths in the first stages of life must be too great, in comparison of the number of deaths in the latter stages; and more or less so as the increase is more or less rapid. The contrary, in all respects takes place where there is a decrease arising from the excess of the deaths above the births.

For example: Let us suppose that 244 of those born in a town attain annually to 20 years of age, and that 250 more, all likewise 20 years of age, come into it annually from other places, in consequence of which it has for a course of years been just maintained in the number of its inhabitants; without any sensible increase or decrease: in these circumstances, the number of the living in the town of the age of 20 will be always 244 natives and 250 settlers, or 494 in all; and since these are supposed all to die in the town, and no more recruits are supposed to come in, 494 will be likewise the number dying annually at 20 and upwards. In the same manner it will appear, on these suppositions, that the number of the living, at every age subsequent to 20, will be equal to the number dying annually at that age and above it; and consequently that the number of inhabitants and the decrements of life, for every such age will be given exactly by the table. But for all ages before 20, they will be given much too great. For let 280 of all born in the town reach 10; in this case, 280 will be the true number of the living in the town at the age of 10; and the recruits not coming in till 20, the number given:
Mortality.

given by the bills as dying between 10 and 20 will be the true number dying annually of the living in this division of life. Let this number be 36; and it will follow that the table ought to make the numbers of the living at the ages between 10 and 20, a series of decreasing means between 280 and (280 divided by 36, or) 244. But in forming the table on the principle just mentioned, 250 (the number above 20 dying annually in the town who where not born in it) will be added to each number in this series; and therefore the table will give the numbers of the living and the probabilities of life in this division of life, almost twice as great as they really are. This observation, it is manifest, may be applied to all the ages under 20.

It is necessary to add, that such a table will give the number of inhabitants and the probabilities of life equally wrong before 20, whether the recruits all come in at 20, agreeably to the supposition just made, or only begin then to come in. In this last case, the table will give the number of inhabitants and probabilities of life too great throughout the whole extent of life, if the recruits come in at all ages above 20. But if they cease at any particular age, it will give them right only from that age; and before, it will err all along on the side of excess; but less considerably between 20 and that age than before 20. For example: if of the 250 supposed to come in at 20, only 150 then come in, and the rest at 30; the number of the living will be given too high at every age between 20 and 30; but, as just shown, they will be given 250 too high at every age before 20. In general, therefore, the number of the living at any particular age must be given by the supposed table as many too great as there are annual settlers after that age; and if those settlers come in at all ages indiscriminately, during any certain interval of life, the number of inhabitants and the probabilities of life will be continually growing less and less wrong the nearer any age is to the end of that interval. These observations prove, that tables of observation formed in the common way, from bills of mortality for places where there is an excess of the burials above the births, must be erroneous for a great part of the duration of life, in proportion to the degree of that excess. They show likewise at what parts of life the errors in such tables are most considerable, and how they may be in a great measure corrected.

All this shall be exemplified in the particular case of London.

The number of deaths between the ages of 10 and 20 is always so small in the London bills, that it seems certain few recruits come to London under 20, or at least not so many as before this age are sent out for education to schools and universities. After 20 great numbers come in till 30, and some perhaps till 40 or 50: but at every age after 50, it is probable that more retire from London than come to it. The London tables of observation therefore, being formed on the principle already mentioned, cannot give the probabilities of life right till 40. Between 30 and 40 they must be a little too high; but more so between 20 and 30, and most of all so before 20. It follows also, that these tables must give the number of inhabitants in London much too great.

The first of the following tables is formed in the manner here explained, from the London bills for 10 years, from 1759 to 1768, and adapted to 1000 born as a radix. The sum of the numbers in the second column, diminished by half the number born, is 25,757. According to this table then, for every 1000 deaths in London there are 25 ½ as many inhabitants; or, in other words, the expectation of a child just born is 25 ½; and inhabitants are to the annual burials as 25 ½ to 1. But it has appeared, that the numbers in the second column, being given on the supposition that all those who die in London were born there, must be too great; and we have from hence a demonstration, that the probabilities of life are given in the common tables of London observations too high for at least the first 30 years of life; and also, that the number of inhabitants in London must be less than 25 ½ multiplied by the annual burials. The common tables therefore, of London observations, undoubtedly need correction, as Mr. Simpson suggested, and in some measure performed; though too imperfectly, and without going upon any fixed principles, or flowing particularly how tables of observation ought to be formed, and how far in different circumstances, and at different ages, they are to be depended on. The way of doing this, and in general the right method of forming genuine tables of observation for towns, may be learned from the following rule:

"From the sum of all that die annually, after any given age, subtract the number of annual settlers after that age; and the remainder will be the number of the living at the given time."

This rule can want no explication or proof after what has been already said.

If, therefore, the number of annual settlers in a town at every age could be ascertained, a perfect table of observations might be formed for that town from bills of mortality, containing an account of the ages at which all die in it. But no more can be learned in this instance, from any bills, than the whole number of annual settlers, and the general division of life in which they enter. This, however, may be sufficient to enable us to form tables that shall be tolerably exact. For instance: Suppose the annual deaths in a town which has not increased or decreased, to have been for many years in the proportion of 4 to 3 to the annual births. It will hence follow, that ⅔ of the persons who die in such a town are settlers, or emigrants from other places, and not natives; and the sudden increase in the deaths after 20 will also show, agreeably to what was before observed, that they enter after this age. In forming, therefore, a table for such a town, a quarter of all that die at all ages throughout the whole extent of life must be deducted from the sum of all that die after every given age before 20; and the remainder will be the true number living at that given age. And if at 20, and every age above it, this deduction is omitted, or the number of the living at every such age is taken the same with the sum of all that die after it, the result will be (supposing most of the settlers to come in before 30, and all before 40) a table exact till 20; too high between 20 and 30; but nearly right for some years before 40; and after 40 exact again. Such a table,
MOR

MOR

Mortality, it is evident, will be the same with the table described at all ages above 20, and different from it only under 20. It is evident also, that on account of the numbers of the dead.

be well

the knowledge of which

is derived from the particular enquiry and information of Mr Harris, the late ingenious master of the royal mathematical school in Christ-Church hospital.

The average of lads in this school, for 30 years past, been 831. They are admitted at all ages between 7 and 11; and few stay beyond 16; they are therefore in general, lads between the ages of 8 and 16. They have better accommodations than it can be supposed children commonly have; and about 300 of them have the particular advantage of being educated in the country. In such circumstances, it may be well reckoned, that not more than 500 of children dying annually must be less than the general proportion of children dying annually at the same ages in London. The fact is, that for the last 30 years 11½ have died annually, or one in 700.

According to Table II. one in 73 dies between 10 and 20, and one in 70 between 8 and 16. That table, therefore, probably gives the decrements of life in London at these ages, too little, and the numbers of the living too great: and if this is true of these ages, it must be true of all other ages under 20; and it follows demonstrably, in conformity to what was before shown, that more people settle in London after than the fourth above supposed; and that from 20 to at least 30 or 35, the numbers of the living are given too great, in proportion to the decrements of life.

In this table the numbers in the second column are doubled at 20, agreeably to what really happens in London; and the sum of the numbers in this column diminished by half the whole number of deaths, gives the expectation of life, not of a child living annually must be less than the general proportion of children dying annually at the same ages in London. The fact is, that for the last 30 years 11½ have died annually, or one in 700.

Of every 1000 then who die in London only 730 are natives, and 250 are recruits who come to it after 18 or 20 years of age; and, consequently, in order to obtain from the bills a more correct table than the first of the following tables, 250 must be subtracted from every one of the numbers in the second column till 20; and the numbers in the third column must be kept the same, the bills always giving these right. After 20, the table is to be continued unaltered; and the result will be, a table which will give the numbers of the living at all ages in London much nearer the truth, but still somewhat too high. Such is the second of the following tables. The sum of all the numbers in the second column of this table, diminished by 500, is 20,750. For every 1000 deaths, therefore, in London, there are, according to this table, 20,750 living person in it; or for every single death 20½ inhabitants. It was before shown, that the number of inhabitants in London cannot be so great as 23 times ¼ the deaths. It now appears, (since the numbers in the second column of this table are too high,) that the number of inhabitants in London cannot be so great as even 20 times ¼ the deaths. And this is a conclusion which every one who will bellow due attention on what has been said, will find himself forced to receive. It will not be amis, however, to confirm it by the following fact, the knowledge of which

All the bills, from which the following tables are formed, give the numbers dying under 1 as well as under 2 years; and in the numbers dying under 1 are included, in the country parish in Brandenburg and at Berlin, all the still-borns. All the bills also give the numbers dying in every period of five years.

</table>

Brief of MORTANCESTRY; in Scots law; an- ciently the ground of an action at the instance of an heir, in the special case where he had been excluded from the polluction of his ancestor's estate by the super- ior, or other person pretending right.

MORTAR, a preparation of lime and sand mixed with water, which serves as a cement, and is used by masons and bricklayers in building walls of stone and brick. Under the article Cement, we have already given the theory of mortar, as delivered by Mr. Anderson; which has now received a farther confirmation by a recent discovery, that if the lime is flaked, and the mortar made up, with lime-water instead of common water, the mortar will be much better. The reason of this is, that in common water, especially such as is drawn from wells, there is always a considerable quantity of fixed air, which, mingling with the mortar previous to its being used, spoils it by reducing the quicklime in part to an inert calcareous earth like chalk; but when it is built up in a perfectly caustic state, it attracts the air so slowly, that it hardens into a kind of stony matter as hard as was the rock from whence the limestone was taken.

MORTAR, a chemical utensil very useful for the division of bodies, partly by percussion and partly by grinding. Mortars have the form of an inverted bell. The matter intended to be pounded is to be put into them,
MOR [ 365 ] MOR

them, and there it is to be struck and bruised by a long instrument called a pelle. The motion given to the pelle ought to vary according to the nature of the substances to be pounded. Those which are easily broken, or which are apt to fly-out of the mortar, or which are hardened by the stroke of the pelle, require that this instrument should be moved circularly, rather by grinding and bruising than by striking. Those substances which are softened by the heat occasioned by rubbing and percussion, require to be pounded very slowly. Lastly, those which are very hard, and which are not capable of being softened, are easily pounded by repeated strokes of the pelle. They require no bruising but when they are brought to a certain degree of fineness. But these things are better learned by habit and practice than by any directions.

As mortars are instruments which are constantly used in chemistry, they ought to be kept of all sizes and materials; as of marble, copper, glass, iron, griffitone, and agate. The nature of the substance to be pounded determines the choice of the kind of mortar. The hardnes and dissolving power of that substance are particularly to be attended to. As copper is a soft metal, soluble by almost all menstruums, and hurtful to health, good artificers have some time ago proscribed the use of this metal.

One of the principal inconveniences of pulverization in a mortar proceeds from the fine powder which rises abundantly from some substances during the operation. If these substances be precious, the loss will be considerable; and if they be injurious to health, they may hurt the operator. These inconveniences may be remedied, either by covering the mortar with a skin, in the middle of which is a hole, through which the pelle passes; or by moistening the matter with a little water when this addition does not injure it; or, lastly, by covering the mouth and nose of the operator with a fine cloth, to exclude this powder. Some substances, as corrosive sublimate, arsenic, calxes of lead, cantharides, euphorbium, &c. are so noxious, that all these precautions ought to be used, particularly when a large quantity of them is pounded.

Large mortars ought to be fixed on a block of wood, so high, that the mortar shall be level with the middle of the operator. When the pelle is large and heavy, it ought to be suspended by a cord or chain fixed to a moveable pole, placed horizontally above the mortar; this pole considerably relieves the operator, because its elasticity assists the raising of the pelle.

MORTAR PIECE, in the military art, a short piece of ordnance, thick and wide, proper for throwing bombs, carcases, shells, stones, bags filled with grape-shot, &c. See GUNNERY, n° 50.

Land Mortars, are those used in sieges, and of late in battles, mounted on beds made of solid timber, consisting generally of four pieces, those of the royal and cohorn excepted, which are but one single block; and both mortar and bed are transported on block-carriages. There is likewise a kind of land-mortars, mounted on travelling carriages, invented by count Buckeburg, which may be elevated to any degree; whereas ours are fixed to an angle of 45 degrees, and firmly lathed with ropes. The following table exhibits the weight of land-mortars and shells; together with the quantity of powder the chambers hold when full; the weight of the shells, and powder for loading them.

Sea Mortars, are those which are fixed in the bomb-veffels for bombarding places by sea; and as they are generally fired at a much greater distance than that which is required by land, they are made somewhat longer and much heavier than the land-mortars. The following table exhibits the weight of the sea-mortars and shells, and also of their full charges.

### Nature of the mortar.

To
To Charge or Load a Mortar, the proper quantity of gunpowder is put into the chamber, and if there be any vacant space they fill it up with hay; some choose a wooden plug; over this they lay a turf, some a wooden tampon fitted to the bore of the piece; and lastly the bomb; taking care that the fuse be in the axis thereof, and the orifice be turned from the muzzle of the piece: what space remains is to be filled up with hay, straw, turf, &c. so as the load may not be exploded without the utmost violence.

The quantity of gunpowder to be used is found by dividing the weight of the bomb by 30; though this rule is not always to be strictly observed.

When the proper quantity of powder necessary to charge a sea-mortar is put into the chamber, it is covered with a wad, well beat down with a rammer. After this the fixed shell is placed upon the wad, as near the middle of the mortar as possible, with the fuse-hole uppermost, and another wad pressed down close upon it, so as to keep the shell firm in its position. The officer then points the mortar according to the proposed inclination.—When the mortar is thus fixed, the fuse is opened; the priming-iron is also thrust into the touch-hole of the mortar to clear it, after which it is primed with the fine powder. This done, two of the матросы or sailors, taking each one of the matches, the first lights the fuse, and the other fires the mortar. The bomb, thrown out by the explosion of the powder, is carried to the place intended: and the fuse, which ought to be exhausted at the instant of the shell's falling, inflames the powder contained in it, and burns the shell in splinters; which, flying off circularly, occasion incredible mischief wherever they reach.

If the service of mortars should render it necessary to use pound-shots, 200 of them with a wooden bottom are to be put into the 13 inch mortar, and a quantity of powder not exceeding 5 pounds; and 100 of the above shot with 24 pounds of powder, for the 10 inch mortar, or three pounds at most.

To Elevate the Mortar fo as its axis may make any given angle with the horizon, they apply the artillery-level or gunner's quadrant. An elevation of 70 or 80 degrees is what is commonly chosen for rendering mortars serviceable in casting shells into towns, forts, &c. though the greatest range be at 45 degrees.

All the English mortars are fixed to an angle of 45 degrees, and lashed strongly with ropes at that elevation. Although in a siege there is only one cafe in which shells should be thrown with an angle of 45 degrees; that is, when the battery is so far off that they cannot otherwise reach the works: for when shells are thrown out of the trenches into the works of a fortification, or from the town into the trenches, they should have as little elevation as possible, in order to roll along, and not bury themselves; whereby the damage they do, and the terror they occasion, are much greater than if they sink into the ground. On the contrary, when shells are thrown upon magazines or any other buildings with an intention to destroy them, the mortars should be elevated as high as possible, that the shells may acquire a greater force in their fall, and consequently do greater execution.

If all mortar pieces were, as they ought to be, exactly similar, and their requisites of powder as the cubes of the diameters of their several bores, and if their shells, bombs, carcafe, &c. were also similar; then, comparing like with like, their ranges on the plane of the horizon, under the same degree of elevation, would be equal; and consequently on being well proved, i.e., the range of the grenade, bomb, carcafe, &c. being found to any degree of elevation, the whole work of the mortar-piece would become very easy and exact.

But since mortars are not thus similar, it is required, that the range of the piece, at some known degree of elevation, be accurately found by measuring; and from hence all the other ranges may be determined.

Thus, to find the range of the piece at any other elevation required; say, As the sign of double the angle under which the experiment was made, is to the sign of double the angle proposed, fo is the range known to the range required.

Suppose, for instance, it be found, that the range of a piece, elevated to 30°, is 2000 yards: to find the range of the same piece with the same charge when elevated to 45°; take the sign of 60°, the double of 30°, and make it the first term of the rule of three; the second term must be the sign of 90°, the double of 45°, and the third the given range 2000; the range of the piece will be 2310, the range of the piece at 45°. If the elevation be greater than 45°, instead of doubling it, take the sign of double its complement to 90°. As suppose the elevation of a piece to be 50°, take the sign of 80°, the double of 40°. Again, if a determinate distance to which a shot is to be cast, be given, and the angle of elevation to produce that effect be required; the range known must be the first term in the rule of three, which suppose 2000 yards; the range proposed, which we suppose 1600 yards, the second term; and the sign of 60 double of the elevation for the range of 2000 yards, the third term. The fourth term will be found the sign of 43° 52', whose half 21° 56' is the angle of elevation the piece must have to produce the desired effect. and if 21° 56' be taken from 90°, you will have 68° 4' for the other elevation of the piece, with which the same effect will likewise be produced.

Note, to avoid the trouble of finding signs of double the angles of proposed elevations, Galileo and Torricelli give us the following table, wherein the signs of the angles sought are had by inspection.

I. or

fraudulent mortgagor forfeits all equity of redemption

or, in default thereof, to be ever foreclosed. And if the effate he of greater value than

the sum lent thereon, they will allow the mortgagor at

any reasonable time to re-call or redeem his effate;

paying to the mortgagge his principal, intereft, and

expenes: for otherwise, in fidethes of law, an effate

worth 100cl. might be forfeited for n n-payment of

100cl., or a lea sum.

This reasonable advantage, al-

lowed to mortgagors, is called the equity of redemption;

and this enables a mortgagor to call on a mortg-

gage, who has poiffeion of his effate, to deliver it

back, and account for the rents and profits received

on payment of his whole debt and intereft, thereby

turning the mortuum into a kind of vivum vadium; (see Vadium). But, on the other hand, the mort-

gagee may either compel the fale of the effate, in or-

der to get the whole of his money immediately; or

els call upon the mortgagor to redeem his effate pre-

tly, or, in default thereof, to be for ever foreclosed

from redeeming the fame; that is, to lose his equity

of redemption without poibillity of recall. And al-

fo, in fome cafes of fraudulent mortgages, the frau-

dulent mortgagor forfeits all equity of redemption

whatsoever. It is not, however, usual for mortgagors to

take poiffeion of the mortgaged effate, unlefs

where the feurity is precarious, or of small; or where

the mortgagor neglects even the payment of intereft

when the mortgagge is frequently obliged to bring an

ejement, and take the land into his own hands, in

the nature of a pledge, or the pingus of the Roman

law: whereas, while it remains in the hands of the

mortgagor, it more refembls their hypothetical, which

was where the poiffeion of the thing pledged remained

with the debtor. But by statute 7 Geo. II. c. 20,

after payment or tender by the mortgagor of prin-

cipal, intereft, and cofls, the mortgagge can maintain

no ejement; but may be compelled to re-affirm

his feurities.

In Glanvil's time, when the universal me-

thod of conveyance was by livery of fein or corporal

tradition of the lands, no gage or pledge of lands

was good unless poiffeion was also delivered to the

creditor; fi non feinur eflus valli tradidit, curia domini

which the rea:on given is, to prevent subfquent and

fraudulent pledges of the fame land; cum in coli eflu

poiffe vadium res pluribus aliis creditoribus tum prius tum

poffiterius invadiari. And the frauds which have

arifen, since the exchange of these public and noto-

rious.
MORTIER, an ensign of dignity, formerly borne by the chancellor and grand presidents of the parliament of France. That borne by the chancellor was a piece of cloth of gold, edged and turned up with ermine; and that of the first president was a piece of black velvet edged with a double row of gold lace, while that of the other presidents was only edged with a single row. This they formerly carried on their heads in grand ceremonies, such as the entry of the king; but ordinarily they carried them in the hand.

MORTIFICATION, in medicine and surgery, a total extirpation of the natural heat of the body, or a part thereof. Some define mortification a disease, wherein the natural juices of any part quite lose their proper motion; and by that means fall into a fermentative one, and corrupt and destroy the texture of the part. See Surgery.

MORTIFICATION, in religion, any severe penance observed on a religious account. How ancient and how universal the practice of it has been, and for what reasons observed, see Fast.

MORTIMER (John), a late English artist, born in 1743. According to Mr Strutt, he was endowed with every requisite to make a great painter; his genius fertile, and his imagination lively. There is an originality in his works which adds greatly to their value. No man perhaps touched the heads and other extremities of his figures with more spirit; and few could draw them more correctly. When he failed, it was from his haste to express his thoughts: so that at times he did not attend with that precision which historical painting requires to the proportion of his figures; and they are sometimes heavy. This defect is, however, well repaid by the lightness of his pencil, and the freedom which appears in his works. He died at his house in Norfolk-street in 1779, aged 36. — "King John granting the Magna Charta to the barons," and the "Battle of Agincourt," two of his capital pictures, have been engraved. The first was nearly finished by Mr Ryland, and completed by Mr Bartolozzi. The latter, intended as a companion to the former, was published by Mrs Mortimer.

MORZISE, or Morzize, in carpentry, &c., a kind of joint wherein a hole of a certain depth is made in a piece of timber, which is to receive another piece called a tenon.

MORTMAIN, or Alienation in Mortmain, is an alienation of lands or tenements to any corporation, fole or aggregate, ecclesiastical or temporal; but these purchases having been chiefly made by religious houses, in consequence whereof the lands became perpetually inherent in one dead hand, this hath occasioned the general appellation of mortmain to be applied to such alienations, and the religious houses themselves to be principally considered in forming the statutes of mortmain: in deducing the history of which statutes, it will be matter of curiosity to observe the great address and subtile contrivance of the ecclesiastics in eluding from time to time the laws in being, and the zeal with which successive parliaments have pursued them through all their finesse.

how new remedies were still the parents of new evils; till the legislature at last, though with difficulty, hath obtained a decisive victory.

By the common law any man might dispose of his lands to any other private man at his own discretion, especially when the feudal restraints of alienation were worfed away. Yet in consequence of these it was always, and is still necessary, for corporations to have a licence of mortmain from the crown, to enable them to purchase lands: for as the king is the ultimate lord of every fee, he ought not, unless by his own consent, to lose his privilege of sales and other feudal profits, by the velling of lands in tenants that can never be attained or die. And such licences of mortmain seem to have been necessary among the Saxons above 60 years before the Norman conquest. But, besides this general licence from the king as lord paramount of the kingdom, it was also requisite, whenever there was a man or intermediate lord between the king and the alienor, to obtain his licence under (upon the same feudal principles) for the alienation of the specific land. And if no such licence was obtained, the king or other lord might respectively enter on the lands so alienated in mortmain, as a forfeiture. The necessity of this licence from the crown was acknowledged by the constitutions of Clarendon, in respect of advowsons, which the monks always greatly coveted, as being the groundwork of subsequent appropriations. Yet such were the influence and ingenuity of the clergy, that (notwithstanding this fundamental principle) we find that the largest and most considerable donations of religious houses happened within less than two centuries after the conquest. And (when a licence could not be obtained) their contrivance seems to have been this: That as the forfeiture for such alienations accrued in the first place to the immediate lord of the fee, the tenant who meant to alienate first conveyed his lands to the religious house, and infantly took them back again to hold as tenant to the monastery; which kind of instantaneous seisin was probably held not to occasion any forfeiture: and then, by pretext of some other forfeiture, surrender, or escheat, the society entered into those lands in right of such they newly acquired signiority, as immediate lords of the fee. But when these donations began to grow numerous, it was observed that the feudal services, ordained for the defence of the kingdom, were every day visibly withdrawn; that the circulation of landed property from man to man began to flagrate; and that the lords were curtailed of the fruits of their signiories, their escheats, wardships, rights, and the like: and therefore, in order to prevent this, it was ordained by the second of King Henry III.'s great charters, and afterwards by that printed in the common statute-books, that all such attempts should be void, and the land forfeited to the lord of the fee.

But as this prohibition extended only to religious houses, bishops and other fole corporations were not included therein; and the aggregate ecclesiastical bodies (who, Sir Edward Coke observes, in this were to be commended, that they ever had of their counsel the best learned men that they could get) found many means to creep out of this statute, by buying in lands that were bona fide holden of themselves as lords of the fee, and thereby evading the forfeiture; or by taking long leases.
Mortmain, leaves for years, which first introduced those extensive terms, for a thousand or more years, which are now so frequent in conveyances. This produced the statute de religiosis, 7 Edward I. which provided, that no person, religious or other whatsoever, should buy, or sell, or receive, under pretence of a gift, or term of years, or any other title whatsoever, nor should by any art or ingenuity appropriate to himself, any lands or tenements, in mortmain; upon pain that the immediate lord of the fee, or, on his default for one year, the lords paramount, and, in default of all of them, the king, might enter thereon as a forfeiture.

This seemed to be a sufficient security against all alienations in mortmain: but as these statutes extended only to gifts and conveyances between the parties, the religious houses now began to set up a fictitious title to the land, which it was intended they should have, and to bring an action to recover it against the tenant: who, by fraud and collusion, made no defence, and thereby judgment was given for the religious house, which then recovered the land by a sentence of law upon a supposed prior title. And thus they had the honour of inventing those fictitious adjudications of right, which are since become the great assurance of the kingdom, under the name of common recoveries. But upon this the statute of Westminster the second, 13 Edw. I. c. 32, enacting, that in such cases a jury shall try the true right of the demandants or plaintiffs to the land; and if the religious house or corporation be found to have it, they shall still recover feisin; otherwise it shall be forfeited to the immediate lord of the fee, or else to the next lord, and finally to the king, upon the immediate or other lords default. And the like provision was made by the succeeding chapter, in case the tenants set up crofts upon their lands (the badges of knights templars and hospitalers) in order to prevent them from the feudal demands of their lords, by virtue of the privileges of those religious and military orders. And so careful was this provident prince to prevent any future evasions, that when the statute of quia emptores, 18 Edward I. abolished all sub-infeudations, and gave liberty for all men to alienate their lands to be held by their next immediate lord, a provision was inserted that this should not extend to authorize any kind of alienation in mortmain. And when afterwards the method of obtaining the king's licence by writ of ad quod damnum was marked out by the statute 27 Edward I. ft. 2, it was farther provided by statute 34 Edward I. ft. 3, that no such licence should be effectual without the consent of the seignors or intermediate lords.

Yet still it was found difficult to set bounds to ecclesiastical ingenuity: for when they were driven out of all their former holds, they devised a new method of conveyance, by which the lands were granted, not to themselves directly, but to nominal feoffees to the use of the religious houses; thus distinguishing between the possession and the use, and receiving the actual profits, while the feisin of the land remained in the nominal feoffee; who was held by the courts of equity (then under the direction of the clergy) to be bound in conscience to account to his cefius que afe for the rents and emoluments of the estate. And it is to these inventions that our prudences are indebted for the introduction of uses and trusts, the foundation of modern conveyancing. But, unfortunately for the inventors themselves, they did not long enjoy the advantage of their new device; for the statute 15 Richard II. c. 5, enacts, that the lands which had been so purchased to uses should be amortized by licence from the crown, or else be sold to private persons, and that for the future uses they shall be subject to the statutes of mortmain, and forfeit like the lands themselves. And whereas the statutes had been eluded by purchasing large tracts of land adjoining to churches, and confecrating them by the name of chanter-yards, such subtle imagination is also declared to be within the compass of the statutes of mortmain. And civil or lay corporations, as well as ecclesiastical, are also declared to be within the mischief, and of course within the remedy provided by those salutary laws. And lastly, as the times of povery lands were frequently given to superstitious uses, though not to any corporate bodies; or were made liable in the hands of heirs and devices to the charge of obits, chauntaries, and the like, which were equally pernicious in a well-governed state as actual alienations in mortmain; therefore at the dawn of the Reformation, the statute 27 Hen. VIII. c. 10, declares, that all future grants of lands for any of the purposes aforesaid, if granted for any longer term than 20 years, shall be void.

But during all this time, it was in the power of the crown, by granting a licence of mortmain, to remit the forfeiture, so far as related to its own rights; and to enable any spiritual or other corporation to purchase and hold any lands or tenements in perpetuity: which prerogative is declared and confirmed by the statute 18 Edw. III. ft. 3. But as doubts were conceived at the time of the Revolution how far such licencce was valid, since the king had no power to dis pense with the statutes of mortmain by a clause of non obstante, which was the usual course, though it seems to have been unnecessary; and as, by the gradual declension of mefne figniories through the long operation of the statute of quia emptores, the rights of intermediate lords were reduced to a very small compass; it was therefore provided by the statute 7 & 8 W. III. c. 37, that the crown for the future at its own discretion may grant licences to alienate or take in mortmain, of whomsoever the tenements may be holden.

After the dissolution of monastaries under H. VIII. though the policy of the next popish successor affected to grant a security to the poofeffors of abbey-lands, yet, in order to regain so much of them as either the zeal or timidity of their owners might induce them to part with, the statutes of mortmain were suspended for 20 years by the statute 1 & 2 P. & M. c. 8. and during that time any lands or tenements were allowed to be granted to any spiritual corporation were allowed to any licence whatsoever. And long afterwards, for a much better purpose, the augmentation of poor livings, it was enacted by the statute 17 Car. II. c. 3, that appropriators may annex the great tithes to the vicarages; and that all benefices under 100l. per annum may be augmented by the purchase of lands, without licence of mortmain in either case; and the like provision hath been since made in favour of the governours of queen Anne's bounty. It hath also been held, that the statute

Vol. XII.
MOR [ 370 ]

Morton, tute 23 Hen. VIII. before-mentioned, did not extend to any thing but superfluous uses; and that therefore a man may give lands for the maintenance of a school, an hospital, or any other charitable uses. But as it was apprehended from recent experience, that persons on their death-beds might make larges and Improvident dispositions even for these good purposes, and defeat the political ends of the statutes of mortmain; it is therefore enacted by the statute 9 Geo. II. c. 36, that no lands or tenements, or money to be laid out thereon, shall be given for or charged with any charitable uses whatsoever, unless by deed indented, executed in the presence of two witnesses: 3 calendar months before the death of the donor, and enrolled in the court of chancery within six months after its execution (except flocks in the public funds, which may be transferred within six months previous to the donor's death), and unless such gift be made to take effect immediately, and be without power of revocation; and that all other gifts shall be void. The two universities, their colleges, and their scholars upon the foundation of the colleges of Eton, Winchester, and Welfmifler, are excepted out of this act: but such exemption was granted with this proviso, that no college shall be at liberty to purchase more advowsons than are equal in number to one moiety of the fellows or students upon the respective foundations.

Morton (Thomas), a learned English bishop in the 17th century, was bred at St John's College, Cambridge, and was logic-lecturer of the university. After several preferments he was advanced to the fee of Chester in 1615, and translated to that of Litchfield and Coventry in 1618; at which time he became acquainted with Antonio de Dominis archbishop of Spalatro, whom he endeavoured to diffuse from returning to Rome. While he was bishop of Litchfield and Coventry, in which fee he sat 14 years, he educated, ordained, and prefented to a living, a youth of excellent parts and memory, who was born blind; and detected the imposture of the famous boy of Bilion in Staffordshire, who pretended to be possessed with a devil. In 1632 he was translated to the fee of Durham, in which he sat with great reputation till the opening of the long parliament, which met in 1640; when he received great insults from the common people, and was committed twice to custody. The parliament, upon the dissolution of bishops' courts, voted him 800l. per annum, of which he received but a small part. He died in 1649, in the 95th year of his age and 44th of his episcopal consecration. He published Apologia Catholica, and several other works; and was a man of extensive learning, great piety, and temperance.

MORTUARY, in law, is a fort of ecclesiastical heriot, being a cultumatory gift claimed by and due to the minister in very many parishes on the death of his parishioners. They feem originally to have been only a voluntary bequest to the church; being intended, as Lyndewode informs us, from a constitution of archbishop Langham, as a kind of expiation and amends to the clergy for the personal tythes, and other ecclesiastical duties, which the laity in their life-time might have neglected or forgotten to pay. For this purpose, after the lord's heriot or bell good was taken out, the second bell chattel was referred to the church as a mortuary. And therefore in the laws of king Canute, this mortuary is called fole-pecus, or symboolum sanitatis. Mortuary.

And, in pursuance of the same principle, by the laws of Venice, where no personal tythes have been paid during the life of the party, they are paid at his death out of his merchandize, jewels, and other moveables. So also, by a similar policy in France, every man that died without bequeathing a part of his estate to the church, which was called dying without confessio, was formerly deprived of Christian burial; or, if he died intestate, the relations of the deceased, jointly with the bishop, named proper arbitrators to determine what he ought to have given to the church, in case he had made a will. But the parliament, in 1409, redressed this grievance.

It was anciently usual in England to bring the mortuary to church along with the corpse when it came to be buried; and thence it is sometimes called a corpf-prent: a term which bespeaks it to have been once a voluntary donation. However, in Bracton's time, so early as Henry III. we find it riveted into an established custom: inasmuch that the bequests of heriots and mortuaries were held to be necessary ingredients in every tittlement of chattels. Imperium in rebus, quibus recognoscat, et fo praecipue in ecclesiastico, quibus recognoscat, et po;fo fenit, et herieta ecclesiastica de aliqua loci mortuaria; the lord must have the bell good left him as a heriot; and the church the second bell as a mortuary. But yet this custom was different in different places: in quibusdam locis habet ecclesia melius animal de confrutudine; in quibusdam fecondum, vel tertium melius; et in quibusdam nihil; et idio conferuntur in confrutudine loci. This custom still varies in different places, not only as to the mortuary to be paid, but the person to whom it is payable. In Wales a mortuary or corpf-prent was due upon the death of every clergyman to the bishop of the diocese; till abolished, upon a recom pense given to the bishop, by the statute 12 Ann. ii. c. 6. And in the archdeaconry of Chester a corpf also prevailed, that the bishop, who is also archdeacon, should have, at the death of every clergyman dying therein, his bell horse or palfrey, with his furniture; his bell gown or cloak; his cup and cover; his gold ring; and his mew or kennel of hounds.

This variety of customs with regard to mortuaries, giving frequently a handle to exactions on the one side, and frauds or expensive litigations on the other, it was thought proper by statute 21 Henry VIII. c. 6. to...
to reduce them to some kind of certainty. For this purpose it is enacted, that all mortuaries, or correfpondents to parties of any parish, shall be taken in the following manner, unless where by custom lefts or none at all is due: viz. for every person who does not leave goods to the value of ten marks, nothing: for every person who leaves goods to the value of ten marks and under 30 pounds, 3l. 4d. if above 30 pounds, and under 40 pounds, 6s. 8d. if above 40 pounds, of what value forever they may be, 10s. and no more. And no mortuary shall throughout the kingdom be paid for the death of any femme-covert; nor for any child; nor for any one of full age, that is not a housekeeper; nor for any wayfaring man; but such wayfaring man's mortuary shall be paid in the parish to which he belongs. And upon this statute stands the law of mortuaries to this day.

MORUS, the mulberry-tree: A genus of the tetrandria order, belonging to the monoeia class of plants; and in the natural method ranking under the 53d order, Scabridae. The male calyx is quadripartite; and there is no corolla; the female calyx is tetraphyllous; there is no corolla; two styles; the calyx like a berry with one seed. There are seven species, viz.

Species. 1. The nigra, or common black-fruited mulberry-tree, rises with an upright, large, rough trunk, dividing into a branchy and very spreading head, rising 20 feet high, or more. It has large, heart-shaped, rough leaves; and monocious flowers, succeded in the females by large fuculent black-berries. There is a variety with jagged leaves and smaller fruit.—

2. The alba, or white mulberry-tree, rises with an upright trunk, branching 20 or 30 feet high; garnished with large, oblique, heart-shaped, smooth, light-green, shining leaves, and monocious flowers succeded by pale-whitish fruit. There is a variety with purplish fruit.

3. The papyrifera, or paper mulberry-tree of Japan, grows 20 or 30 feet high; having large palmated leaves, some trilobate, others quinquenod; and monocious flowers, succeded by small black fruit—

4. The rubra, or red Virginia mulberry-tree, grows 30 feet high; is garnished with very large, heart-shaped, rough leaves, hairy underneath; and has monocious flowers, succeded by small black fruit—

5. The tartaria, dyer's mulberry, or fulfic, has oblong leaves more extended on one side at the base, with axillary thorns. It is a native of Brazil and Jamaica. 6. The tartarica, or Tartarian mulberry, has ovate oblong leaves equal on both sides and equally ferrated. It abounds on the banks of the Weiga and the Tanais. 7. The indica, or Indian mulberry, has ovate oblong leaves, equal on both sides, but unequally ferrated.

The last three species are tender plants in this country; but the four first are very hardy, and succeed in any common soil and situation. The leaves are generally late before they come out, the buds seldom beginning to open till the middle or towards the latter end of May, according to the temperature of the feason; and when these trees in particular begin to expand their foliage, it is a good sign of the near approach of fine warm settled weather; the white mulberry, however, is generally forward in leafing than the black. The flowers and fruit come out soon after the leaves; the males in amenuts, and the females in small roundish heads; neither of which are very conspicuous, nor possess any beauty, but for observation. The female or fruitful flowers always rise on the extremity of the young shoots on short spurs; and with this singularity, that the calyxes of the flowers become the fruit, which is of the berry kind, and composed of many tubercles, each of them furnishing one seed. The fruit matures here gradually from about the end of August until the middle of September. In dry warm seasons, they ripen in great perfection; but when it proves very wet weather, they ripen but indifferently, and prove devoid of flavour.

Uses, &c. Considered as fruit-trees, the nigra is the only proper sort to cultivate here; the trees being not only the most plentiful bearers, but the fruit is larger and much finer-flavoured than that of the white kind, which is the only other sort that bears in this country. The three last species are chiefly employed to form variety in ornamental plantations; tho' abroad they are adapted to more useful purposes.

The fruit of the black mulberry is exceedingly grateful to the taste, and is considered at the same time as laxative and cooling. Like the other acid-fruits, it allays thirst (as Dr Cullen observes), partly by refrigerating, and partly by exciting an excretion of moisture from the mouth and fauces; a similar effect is also produced in the stomach, where, by correcting putrefecency, a powerful cause of thirst is removed. A syrup is made from the berries gathered before they are ripe, which, taken as a gargle, is excellent for allaying inflammations of the throat, and for cleansing ulcers in the mouth. The bark of the root, which has an acrid bitter taste, possesses a cathartic power; and has been successfully used as a vermifuge, particularly in cafes of tania; the dose is half a dram of the powder, or a dram of the infusion. The juice of the black mulberry is also employed to give a colour to certain liquors and confections. Some make from it a wine which is not disagreeable; others employ it for giving a high colour to red wine; which it likewise contributes to make sweet.—Although this juice is of no use in dyeing, it gives a red colour to the fingers and to linen, which it is very difficult to remove. Ver juice, forre, lemon, and green mulberry, resemble familiar kinds of this kind from the hands; but with respect to linen, the best way is to wet the part which has been stained, and to dry it with the vapour of sulphur; the vitriolic acid which escapes from this substance during combustion, instantly takes off the stain.—The wood of the mulberry tree is yellow, tolerably hard, and may be applied to various uses in turnery and carving; But in order to separate the bark, which is rough, thick, thready, and fit for being made into ropes, it is proper to steep the wood in water.

Mulberry trees are noted for their leaves affording the principal food of that valuable insect the silk-worm. The leaves of the alba, or white species, are preferred for this purpose in Europe; but in China, where the belt silk is made, the worms are fed to be fed with those of the morus tartarica. The advantages of white mulberry trees are not confined to the nourishment of worms: they may be cut every three or four years like fallows and poplar trees, to make faggots;
and the sheep eat their leaves in winter, before they are burnt. This kind of food, of which they are extremely fond, is very nourishing; it gives a delicacy to the flesh, and a fineness and beauty to the wool. In short, in every climate and in most fields, it might be proper, as is the case in Spain, to wait for the first hoarfrost shaking off the leaves, which are gathered and placed to dry in sheds or cart-houses, taking care always to stir them from time to time. In Spain, the sheep are fed on these leaves during the cold and frosts. By this method no injury is done to the mulberries, which produce leaves every year; and it is thought that the beauty and fineness of the Spanish wool is in a great measure owing to the use of this kind of food. From these considerations M. Bourgeois infers, that even in countries where, from the nature of the climate, the scarcity of workmen and the high price of labour, or any other particular causes, silk-worms could not be raised to any advantage, the cultivation of mulberry trees ought not be neglected. — The fruit of the white mulberry has a sweetish and very inipid taste. Birds, however, are very fond of it; and it is remarked that those which have been fed with such fruit are excellent eating.

The *papyrifera*, or paper-mulberry, is so called from the paper chiefly used by the Japanzse being made of the bark of its branches; (see the article PAPER.) The leaves of this species also serve for food to the silk worm, and it is now cultivated with success in France. It thrives best in sandy soils, grows faster than the common mulberry, and at the same time is not injured by the cold. M. de la Bouvriere affirms that he procured a beautiful vegetable silk from the bark of the young branches of this species of mulberry, which he cut while the tree was in sap, and afterwards beat and steeped. The women of Louifiana procure the same kind of production from the shoots which issue from the stalk of the mulberry, and which are four or five feet high. After taking off the bark, they dry it in the sun, and then beat it that the external part may fall off; and the internal part, which is fine bark, remains entire. This is again beaten, to make it still finer; after which they bleach it with dew. It is then spun, and various fabrics are made from it, such as nets and fringes; they even sometimes weave it and make it into cloth.—The finest florf of cloth among the inhabitants of Otaheite and others of the South Sea Islands, is made of the bark of this tree, in the manner particularly described under the article BARK.

The *involutia* is a fine timber-tree, and a principal ingredient in most of our yellow dyes, for which it is chiefly imported into Europe. The berries are sweet and wholesome; but not much used, except by the winged tribe, by whose care it is chiefly planted.

Culture of the Mulberry. From the nourishment which it affords to the silk-worm, that valuable insect to which we are indebted for the materials of our finest stuffs, the method of cultivating the mulberry tree must be peculiarly interesting wherever its culture can be undertaken with success. In France and Italy, vast plantations of the trees are made solely for their leaves to feed the little animals we have mentioned, which amply reward the poulwer with the supply of silk which they spin from their bowels. Plantations of the mulberry have at different times been recommend-
ed in England for the same purpose; though nothing has yet been done in that way to any extent, and even the expediency of any such attempt has been doubted by others, upon the ground of its interfering with other branches of rural economics more productive and more congenial to the climate.

In the European silk-countries, a great many varieties of mulberry trees are distinguished, arising from difference of climate, soil, method of culture, and other accidental causes. Among the wild mulberries, we meet with some whose leaves are roundish, and resembling those of a rose; hence they have been called the rose-leaved mulberry.

Mulberry trees were first cultivated in France in the reign of Charles IX. It has been found by experience that this tree is not so peculiar to warm countries, such as Spain, Italy, Provence, Languedoc, and Piedmont; but it may also thrive very well in colder countries, such as Touraine, Poitou, Maine, Anjou, Angoumois near Rochefoucauld, and even in Germany, where it affords very good nourishment for silk-worms. They grow in all kinds of soil: they thrive best in strong and wet lands; but it is alleged that their leaves constitute too coarse food, prejudicial to the worms, and unfavourable to the quality of the silk. — A good light land is the best kind of soil for raising them. White mulberry trees have been found to grow in sandy soils where heat would scarcely vegetate; but their leaves are too dry, and afford not sufficient nourishment for the silk-worms.

Mulberry trees may be propagated either from shoots which have taken root, or by seed, by layers, and by slips. To raise black mulberry trees, the seed must be taken from the largest and most beautiful mulberries: in raising white ones, the seed is taken from the finest mulberries growing on trees with large whitish soft and tender leaves, and as little cut as possible. The best seed is commonly got from Piedmont, Languedoc, &c. According to M. Duhamel, that seed should be preferred which is gathered in counties where the cold is sometimes pretty severe; because in that case the trees are better able to resist the attacks of the frost. It frequently happens in severe winters, as M. Bourgeois observes, that the flanks of the young mulberry trees, especially during the first winter, are destroyed by the frost; but when they are cut close to the earth, they fend forth as beautiful and vigorous flanks as the former. Good seed ought to be large, heavy, light coloured, to produce a great deal of oil when it is pressed, and to crackle when thrown on a red hot flask. This seed must be sown in good land.

In the autumn of the second year, all those trees must be pulled up which have small leaves of a very deep green, rough, and deeply indented, for they would produce no leaves proper for the silk worms. — In the third year, when the mulberry tree is about the thickness of the finger, it must be taken up and put in the nursey. According to M. Bourgeois, mulberries ought to be transplanted in the spring of the second year, which makes them thrive better, and sooner attain their growth. Without this transplantation, they would put forth only one root like a pivot and most of them would be in danger of perishing when they are taken up to be put where they are intended.
tended to remain. Some cultivators of this tree tell us, that all the young trees, whether large or small, straight or crooked, ought to be cut close to the ground in the third year, that they may put forth a greater number of roots. Others never employ this method but with regard to those which are crooked, or in a languishing state.

White mulberries may be raised for the food of silk-worms, either in the form of a copse, or planted in a regular order, by letting them grow to their natural size. Ingrafting is one of the surest methods of producing fine leaves from mulberries. Mulberries ingrafted on wild flocks chosen from a good kind, such as those which are produced from the seed of the Italian mulberry, commonly called the *rofe-mulberry*, or of the Spanish mulberry, produce, as M. Bourgeois observes, much more beautiful leaves, and of a much better quality, for silk-worms, than those which are ingrafted on the common or prickly small-leafed wild-flock. The same observation has been made by a great many cultivators of mulberries, and in particular by M. Thomé of Lyons, whose authority has the greatest weight in whatever regards the cultivation of mulberries and the rearing of silk-worms.

Ingrafted mulberries, it must be confessed, produce a greater number of leaves, and these more nourishing for silk-worms, than wild mulberries. The latter, however, it has been found by experience, may exit for two centuries; whereas the extension of leaves middling size, inclining to a light yellow, and of an excellent size to those of a gourd. The *Laurus*, being of an excellent quality and much esteemed.

Of the white ingrafted mulberry-trees, the rofe, or Italian ingrafted mulberry, which is now the species most cultivated in France, Italy, and Piedmont, produces great abundance of large, thick and smooth leaves. It has now come into great repute, in consequence of the recommendation of M. Thomé, who prefers it to all other species of mulberry-trees for producing indented leaves, oblong, and very slender; but it is worth being attended to, because it thrives very well when planted in a hedge, and in a favourable exposure: it is also earlier in the spring than the other species. The wild mulberry, which is produced from the rofe or Italian ingrafted mulberry, bears a great many leaves, of a roundish shape and middling size, inclining to a light yellow, and of an excellent quality.

MOSA, (anc. geog.) a river of Belgica, rising in mount Vogelas on the borders of the Lingones, and which, after receiving a part of the Rhine called *PalaEURS*, forms the fland of the Batavi, and paffes off into the sea, at no greater distance than 80 miles: its mouth, which is large and broad, is that which Pliny calls *Helius*, denoting *Lower*, according to some German writers. Now called the *Moes", or *MOLF*, rising in Champaign, on the borders of the county of Burgundy, or the Franche Comté, at a village called *Moufl", whence the appellation; and running north through Lorrain and Champaign into the Netherlands: it afterwards directs its course north-east, and then west; and joining the Waal, runs to Dort, and...
falls into the German sea, a little below the Briel.—

According to Baudrand, it twice receives the Waal; by the first junction forming the island Bommel; and again receives it at Worcum, from which place proceeding to Dort, it divides into two branches, which again uniting together form one large mouth discharging itself into the German sea.

MOSÆ Fons (anc. geog.), supposed to be Maestricht, situated on the Maesse. E. Long. 5. 40. N. Lat. 50° 55'

MOSAIC LAW, or the Law of Moses, is the most ancient that we know of in the world, and is of three kinds; the moral law, the ceremonial law, and the judicial law. * The different manner in which each of these was delivered, may perhaps suggest to us a right idea of their different natures. The moral law, or ten commandments, for instance, was delivered on the top of the mountain, in the face of the whole world, as being of universal influence, and obligatory on all mankind. The ceremonial was received by Moses in private in the tabernacle, as being of peculiar concern, belonging to the Jews only, and defined to cease when the tabernacle was down, and the vail of the temple rent. As to the judicial law, it was neither so publicly nor so audibly given as the moral law, nor yet so privately as the ceremonial; this kind of law being of an indifferent nature, to be observed or not observed, as its rites suit with the place and government under which we live. The five books of Moses called the Pentateuch are frequently styled, by way of emphasis, the Law. This was held by the Jews in such a spirit of their different natures. The moral law, or the Law of Moses, is the most severe, as its rites suit with the place and government of an indifferent nature; to be observed or not observed. The MOSAIC LAW, or the Law of Moses, is the most severe, as its rites suit with the place and government of an indifferent nature; to be observed or not observed. The moral law, or the Law of Moses, is the most severe, as its rites suit with the place and government of an indifferent nature; to be observed or not observed. The judicial law

**Class III. The Political Law.**

N. B. The Magistrate is the Keeper of the Precepts of both Tables, and to have respect to human Society:—therefore the Political Laws of the Israelites are referred to both the Tables, and are to be reduced to the several Precepts of the Moral Law.

Laws referred to the first table, namely,

1st. To the first and second commandments, viz.
   Of idolators and apostates,
   Of abolishing idolatry,
   Of diviners and false prophets,
   Of covenants with other gods,

2d. To the third commandment, viz.
   Of blasphemies,

3d. To the fourth commandment, viz.
   Of breaking the sabbath,

Political laws referred to the second table,

1st. To the fifth commandment, viz.
   Of magistrates and their authority,
   Of the power of fathers,

2d. To the sixth commandment, viz.
   Of capital punishments,
   Of wilful murder,
   Of manslaughter unwittingly committed, and of the cities of refuge,
   Of heinous injury,
   Of punishments not capital,
   Of the law of war,

3d. To the seventh commandment, viz.
   Of unlawful marriages,
   Of fornication,
   Of whoredom,
   Of adultery and jealousy,
   Of copulation against nature,
   Of divorcements,

Other matrimonial laws,

4th. To the eighth commandment, viz.
   Of the punishment of thefts,
   Of sacrilege,
   Of not injuring strangers,
   Of not defrauding hirelings,
   Of just weights,
   Of removing the land-mark,
   Of lost goods,
   Of stray cattle,
   Of corrupted judgments,
   Of fire breaking out by chance,
   Of man-slaughtering,
   Of the fugitive servant,

5th. To the ninth commandment, viz.
Of witnesses,
The establishing the political law,
The establishing the divine law in general,

From the dignity of the lawgiver,
From the excellency of the laws,
From the promises,
From the threatenings,

MOSAIC, or MOSAIC-WORK, an assemblage of little pieces of glafs, marble, precious stones, &c. of various colours, cut square, and cemented on a ground of stucco, in such a manner as to imitate the colours and gradations of painting. The critics are divided as to the origin and reason of the name. Some derive it from MOSAICUM, a corruption of MUSAICUM, as that is of MUSIACUM, as it was called among the Romans. Scaliger derives it from the Greek mosaikos, and imagines the name was given to this sort of works as being very fine and ingenious. Nebricienis is of opinion it was so called, because ex hic pistoris ornamuntur musea.

1. The method of performing Mosaic-work of glafs is this: provide little pieces of glafs, of as many different colours and sizes as possible.

Now, in order to apply these several pieces, and out of them to form a picture, they in the first place procure a cartoon or design to be drawn; this is transferred to the ground or plaster by calking, as in painting in fresco. See FRESCO.

As this plaster is to be laid thick on the wall, and therefore will continue fresh and soft a considerable time, so there may be enough prepared at once to serve for as much work as will take up three or four days.

This plaster is composed of lime made of hard stone, with brick-dust very fine, gum tragacanth, and whites of eggs: when this plaster has been thus prepared and laid on the wall, and made the design of what is to be represented, they take out the little pieces of glafs with a pair of pliers, and range them one after another, still keeping strictly to the light, shadow, different tints, and colours represented in the design before; prefilling or flattening them down with a ruler, which serves both to fix them within the ground and to render the surface even.

Thus, in a long time, and with a great deal of labour, they finish the work, which is still the more beautiful, as the pieces of glafs are more uniform, and ranged at an even height.

Some of these pieces of mosaic-work are performed with that exactness, that they appear as smooth as a table of marble, and as finished and mellowly as a painting in fresco; with this advantage, that they have a fine lustre, and will last ages.

The finest works of this kind that have remained till our time, and those by whom the moderns have retrieved the art, which was in a manner lost, are those in the church of St Agnes, formerly the temple of Bacchus, at Rome; and some at Pisa, Florence, and other cities of Italy. The most esteemed among the works of the moderns are those of Joseph Pine and the Chevalier Lanfranc, in the church of St Peter at Rome: there are also very good ones at Venice.

2. The method of performing Mosaic-work of marble is this: The ground of Mosaic-works, wholly marble, is usually a massive marble, either white or black. On this ground the design is cut with a chisel, after it has been first calked. After it has been cut off a considerable depth, i.e. an inch or more, the cavities are filled up with marble of a proper colour, first fashioned according to the design, and reduced to the thickness of the indentures with various instruments. To make the piece thus formed into the indentures cleave fast, whose several colours are to imitate those of the design, they use a stucco, composed of lime and marble-dust; or a kind of mastic, which is prepared by each workman, after a different manner peculiar to himself. The figures being marked out, the painter or sculptor himself draws with a pencil the colors of the figures not determined by the ground, and in the same manner makes strokes or hatchings in the place where shadows are to be: and after he has engraved with the chisel all the strokes thus drawn, he fills them up with a black mastic, composed partly of Burgundy-pitch poured on hot; taking off afterwards what is superfluous with a
piece of soft stone or brick, which together with water and beaten cement, takes away the mastic, polishes the marble, and renders the whole so even that one would imagine it only composed of one piece. This is the kind of Mosaic-work that is seen in the pompous church of the invalids at Paris, and the fine chapel at Versailles, with which every entire apartments of that palace are incrustated.

3. As for Mosaic-work of precious stones, other and finer instruments are required than those used in marble; as drills, wheels, &c., used by lapidaries and engravers on stone. As none but the richest marbles and stones enter this work, to make them go the farther, they are fawn into the thinnest leaves imaginable, scarce exceeding half a line in thickness; the block to be sawn is gradually with cords on the bench, and only raised a little on one side the block and which besides has this convenience, which it admits of continued pieces or framing of the design, they are applied to the ground.

The ground which supports this Mosaic-work is usually of free-stone. The matter with which the stones are joined together is a mastic, or kind of stucco, laid very thin on the leaves as they are fashioned; and this being done, the leaves are applied with plicys.

If any contour, or fide of a leaf, be not either squared or rounded sufficiently, so as to fit the piece exactly into which it is to be inserted, when it is too large, it is to be brought down with a brass file or rasp; and if it be too little, it is managed with a drill and other instruments used by lapidaries.

Mosaic-work of marbles is used in large works, as in pavements of churches, basilicas, and palaces; and in the incrustation and vaneering of the walls of the same edifices.

As for that of precious stones, it is only used in small works, as ornaments for altar pieces, tables for rich cabinets, precious stones being so very dear.

4. Manner of performing Mosaic-work of gypsum. Of this stone calcined in a kiln beating in a mortar, and sifted, the French workmen made a sort of artificial marbles, imitating precious stones; and of these they compose a kind of Mosaic-work, which does not come far short either of the durability or the vivacity of the natural stones; and which besides has this advantage, that it admits of continued pieces or painting of entire compartments without any visible jointing.

Scene make the ground of plaster of Paris, others of free stone. If it be of plaster of Paris they spread it in a wooden frame, of the length and breadth of the work intended, and in thickness about an inch and a half. This frame is so contrived, that the tenons being only joined to the mortises by single pins, they may be taken afunder, and the frame be dismounted when the plaster is dry. The frame is covered on one side with a strong linen cloth, nailed all round; which being placed horizontally with the linen at the bottom, is filled with plaster passed through a wide sieve. When the plaster is half dry, the frame is set up perpendicularly, and left till it is quite dry; then it is taken out, by taking the frame to pieces.

In this Mosaic, the ground is the most important part. Now in order to the preparation of this sifted gypsum, which is to be applied on this ground, it is divided and boiled in the belt English glue, and mixed with the colour that it is to be of; then the whole is worked up together into the usual consistence of plaster, and then is taken and spread on the ground five or six inches thick. If the work be such, as that mouldings are required, they are formed with gouges and other instruments.

It is on this plaster, thus coloured like marble or precious stone, and which is to serve as a ground to a work, either of lapis, agate, alabaster, or the like, that the design to be represented is drawn; having been first pounced or calqued. To hollow or impress the design they use the same instruments that sculptors do; the ground wherein they are to work not being much less hard than the marble itself. The cavities being thus made in the ground, are filled with the same gypsum boiled in glue, only differently coloured, and thus are the different colours of the original represented. In order that the necessary colours and tints may be ready at hand, the quantities of the gypsum are tempered with the several colours in pots. After the design has been thus filled and rendered visible, by half-polishing it with brick and soft stone, they go over it again, cutting such plates as are either to be weaker or more shadowed, and filling them with gypsum; which work they repeat till all the colours are added one after the other, represent the original to the life. When the work is finished, they scour it with soft stone, sand, and water; after that, with a pumice-stone; and in the last place polish it with a wooden mullet and emery. Lastly, they give it a lustre, by fine-sieving it over with oil, and rubbing it a long time with the palm of the hand, which gives it a lustre no ways inferior to that of natural marble.

5. In Clavigero's history of Mexico is described a curious kind of Mosaic-work made by the ancient Mexicans of the most delicate and beautiful feathers of birds. They raised for this purpose various species of birds of fine plumage with which that country abounds, not only in the palaces of the king, where there were all sorts of animals, but likewise in private houses; and at certain times they called them off their feathers to make use of them on this kind of work, or to sell them at market. They set a high value on the feathers of those wonderful little birds which they call Huiafinius, and the Spanish Pliefores, on account of the smallness, the fineness, and the various colours of them. In these other beautiful birds, nature supplied them with all the colours which art can produce, and also some which art cannot imitate. At the undertaking of every Mosaic-work several artists assembled: After having agreed upon a design, and taken their measures and proportions, each artist charged himself with the execution of a certain part of the image; and exerted himself so diligently in it with such patience and application, that he frequently spent a whole day in adorning a feather; first tuning one, then another, viewing it sometimes one way, then another.
MOSCHION, a name common to four different writers, whose compositions, character, and native place, are unknown. Some fragments of their writings remain, some few verses, and a treatise De Mulierum affedibus.

MOSCHUS, a Grecian poet of antiquity, usually coupled with Bion; and they were both of them contemporaries with Theocritus. In the time of the latter Grecians, all the ancient Idyls were collected and attributed to Theocritus; but the claims of Moschus and Bion have been admitted to some few little pieces; and this is sufficient to make us inquisitive about their characters and story; yet all that can be known about them must be collected from their own remains. Moschus, by composing his delicate elegy on Bion, has given the best memorials of Bion's life. See Bion. Moschus and Theocritus have by some critics been supposed the same person; but there are irrefragable evidences against it: others will have him as well as Bion to have lived later than Theocritus, upon the authority of Suidas: while others again suppose him to have been the scholar of Bion, and probably his successor in governing the poetic school; which, from the elegance of Moschus, does not seem unlikely. Their remains are to be found in all the editions of the Poetae Minores.

MOSCHUS, in zoology, a genus of quadrupeds of the order of pecora, having no horns. There are eight small cutting teeth in the lower jaw; in the upper, no cutting or fore teeth; but two long tusks, one on each side, projecting out of the mouth.

1. The mochiferus, or Thibet mule, has a bag or tumour on the belly near the navel, and a very short tail almost hid in the fur. The length of the male is about three feet three inches from the nose to the origin of the tail, and about two feet three inches high at the shoulder; the female is less than the male, has a sharper nose, has no hair on the maxilla hare; and is provided with two teats. The head resembles that of the roe: the fur is coarse like that of the animals of the deer kind; but softer, very smooth, ereft, plentiful, thick, and long: the colour varies according to the age of the animal and time of the year; but is chiefly blackish brown on the upper, and heary, seldom white, on the under parts of the body: the hoofs are long, black, and much divided, and the spurious hoofs of the fore feet are very long: the scrotum is of a bright red colour, and the penis very small. It inhabits the Aftatic Alps, especially the highest rocky mountains from the Aftatic chain to that which divides Thibet from India; likewise in China and Tonquin, and in eastern Siberia about lake Baikal and the rivers Jenisea and Argun. It avoids mankind, dwelling solitarily in the most precipitous places of the mountains, among rocks in the small narrow valleys surrounded by these snowy hills, and the pine forests which grow in their interstices. It is a very gentle and timid animal, excepting in rutting time, when the males fight violently with their tusks for the females; it is exceedingly active in leaping, running, climbing, and swimming, and is very difficultly tamed; the flesh is edible, and that of the younger animals is reckoned delicate. The

[380.]

MOS

Moscow...

Moscow, the chief province of the empire of Russia, deriving its name from the river Muscovy, or Moskva, on which the capital is situated. It was from this duchy that the czars of old took the title of dukes of Moscovy. The province is bounded on the north by the duchies of Tver, Rostow, Sufdal, and Wolodimer; on the south by Rezan, from which it is separated by the river Ocka; on the east by the principality of Cachin, and the same river Ocka parting it from Nisf Novgorod; and on the west by the duchies of Rezva, Biela, and Smolenko. It extends about 200 miles in length, and about 100 in breadth; and is watered by the Moskva, Ocka, and Clefn, by the Wolga; which fall into the Wolga: nevertheless, the soil is not very fertile. The air, however, though sharp, is salubrious; and with this advantage, with the advantage of its being situated in the midst of the best provinces in the empire, induced the czars to make it their chief residence. In the western part of Moscovy is a large forest, from whence flows the celebrated river Nieper, or Borythenes, which, traversing the duchy of Smolensko, winds in a serpentine course to Ukraine, Lithuanian, and Poland.

Moscow, the capital of the above province, and till the beginning of the present century the metropolis of all Russia, is situated in a spacious plain on the banks of the river Moskova. The Russian antiquaries differ considerably in their opinions concerning the first foundation of Moscow. The following relation, Mr. Coxe says, is generally esteemed by the best authors the most probable account. Kiof was the metropolis, when George son of Vladimir Monomakoff ascended in 1154 the Russian throne. That monarch, being infatuated in a progress through his dominions by a rich and powerful nobleman named Stephen Kutchko, put him to death, and confiscated his domains, which contained the lands now occupied by the city of Moscow and the adjacent territory. Kiof was situated near the river of that name. Upon the death of George, the new town was not neglected by his son Andrew, who transferred the seat of empire from Kiof to Vladimir; but it fell into such decay under his immediate successors, that when Daniel, son of Alexander Nevski, received, in the division of the empire, the duchy of Muscovy as his portion, and fixed his residence upon the confluence of the Moskva and Neglin, he may be said to have new founded the town. The spot now occupied by the Kremlin was at that time overspread with a thick wood and a morass, in the midst whereof was a small island containing a single wooden hut. Upon this part Daniel constructed churches and monasteries, and various buildings, and enclosed
Mocov. enclosed it with wooden fortifications; he first assumed the title of duke of Mocov, and so was attached to this situation, that when in 1304 he succeeded his brother Andrew Alexanderovich in the great duchy of Vladimir, he did not remove his court to Vladimir, but continued his residence at Mocov, which then became the capital of the Russian dominions. His successors followed his example; among whom his son Ivan considerably enlarged the new metropolis, and in 1567 his grandson Demetrius Ivanovitch Donfki surrounded the Kremlin with a brick wall. These new fortifications, however, were not strong enough to prevent Tamerlane in 1382 from taking the town, after a short siege. Being soon evacuated by that defeat, it again came into the possession of the Russians; but was frequently invaded and occupied by the Tartars, who in the 14th and 15th centuries over-ran the greatest part of Russia, and who even maintained a garrison in Mocov until they were finally expelled for Ivan Vaflilevitch I. To him Mocov is indebted for its principal splendor, and under him it became the principal and most considerable city of the whole empire.

Mocov continued the metropolis of Russia until the beginning of the present century, when, to the great dissatisfaction of the nobility, but with great advantage probably to the state, the seat of empire, was transferred to Peterburgh.

Notwithstanding the predilection which Peter conceived for Peterburgh, in which all the succeeding sovereigns excepting Peter II. have fixed their residence, Mocov, according to Mr. Coxe, is still the most populous city of the Russian empire. Here the chief nobles who do not belong to the court of the empress reside: they here support a larger number of retainers; they love to gratify their taste for a ruder and more expensive magnificence in the ancient style of feudal grandeur; and are not, as at Peterburgh, eclipsed by the superior splendor of the court.

Mocov is represented as the largest town in Europe; its circumference within the rampart, which encloses the suburbs, being exactly 39 versts or 26 miles; but it is built in a straggling and disjointed manner, that its population in no degree corresponds to its extent. Some Russian authors state its inhabitants at 500,000 souls, a number evidently exaggerated. According to a late computation, which Mr. Coxe may be depended upon, Mocov contains within the ramparts 250,000 souls, and in the adjacent villages 50,000. The streets of Mocov are in general exceedingly long and broad; some of them are paved; others, particularly those in the suburbs, are formed with trunks of trees, or are boarded with planks like the floor of a room; wretched hovels are blended with large palaces; cottages of one story stand next to the most superb and stately mansions. Many brick structures are covered with wooden tops; some of the wooden houses are painted; others have iron doors and roofs. Numerous churches present themselves in every quarter, built in a peculiar style of architecture; some with domes of copper, others of tin, gilt or painted green, and many roofed with wood.

In a word, some parts of this vast city have the look of a deserted fort, other quarters of a populous town; some of a contemptible village, others of a great capital.

Mocov may be considered as a town built upon the Asiatic model, but gradually becoming more and more European, and exhibiting in its present state a motley mixture of discordant architecture. It is distributed into the following divisions. 1. The Kremlin. This stands in the central and highest part of the city; is of a triangular form, and about two miles in circumference; and is surrounded by high walls of stone and brick, which were constructed in the year 1491, under the reign of Ivan Vaflilevitch I. It contains the ancient palace of the czars, several churches, two convents, the patriarchal palace, the arsenal now in ruins, and one private house, which belonged to Boris Godunov before he was raised to the throne. 2. Khitaigorod, or the Chinese town, is enclosed on one side by that wall of the Kremlin which runs from the Mokva to the Neglina; and on the other side by a brick wall of inferior height. It is much larger than the Kremlin, and contains the university, the printing-house, and many other public buildings, and all the trade and manufacturing shops. The edifices are generally stuccoed or white-washed, and it has the only street in Mocov in which the houses stand close to one another without any intervals between them. 3. The Biegorod, or White Town, which runs quite round the two preceding divisions, is supposed to derive its name from a white wall with which it was formerly enclosed, and of which some remains are still to be seen. 4. Semlainogorod, which environs all the three other quarters, takes its denomination from a circular rampart of earth with which it is encompassed. These last-mentioned divisions exhibit a grotesque group of churches, convents, palaces, brick and wooden houses, and mean hovels; and a degree of poverty prevailing that at the present day. The Sloboda, or suburbs, form a vast exterior circle round all the parts already described, and are inhabited by a low rampart and ditch. These suburbs contain, besides buildings of all kinds and denominations, corn fields, much oxen pasture, and some small lakes, which give rise to the Neglina. The river Mokva, from which the city takes its name, flows through it in a winding channel; but, excepting in spring, is only navigable for rafts. It receives the Yaufa in the Semlainogorod, and the Neglina at the western extremity of the Kremlin; the beds of both these last-mentioned rivulets are in summer little better than dry channels.

The places of divine worship at Mocov are exceedingly numerous; including chapels, they amount to above 1000; there are 484 public churches, of which 199 are of brick, and the others of wood; the former are commonly stuccoed or white-washed, the latter painted of a red colour. The most ancient churches of Mocov are generally square buildings, with a cupola and four small domes; some whereof are of copper or iron gilt; others of tin; either plain or painted green. These cupolas and domes for the most part ornamented with croffes entwined with thin chains or wires. The church of the Holy Trinity sometimes called the church of Jerusalem, which stands in the Khitaigorod, close to the gate leading into the Kremlin, has a kind of high steeple and nine or ten domes.
Kremlin, are both in the same elegant. In the cathedral of St. Michael, in chronological order with such manuscripts relative to foreign kingdoms and about two feet in height. When Mr. Coxe visited it, the manu- scripts were expediently to the ceiling and occasionally touching the ground with their heads. The bell, which form no considerable part of public worship in this country, as the length or shortness of their peals affirms the greater or lesser sanctity of the day, are hung in belfries detached from the church: they do not swing like our bells; but are fixed immovably to the beams, and are rung by a rope tied to the clapper and pulled sideways. Some of these bells are of a stupendous size: one in the tower of St. Ivan's church weighs 3551 Russian pounds, or 127,836 English pounds. It has always been esteemed a meritorious act of religion to present a church with bells: and the piety of the donor has been measured by their magnitude. According to this mode of estimation, Boris Godunoff, who gave a bell of 288,000 pounds to the cathedral of Moscow, was the most pious sovereign of Russia; until he was surpassed by the empress Anne, at whose expense a bell was cast weighing 432,000 pounds, and which exceeded in bigness every bell in the known world. The height of this enormous bell is 19 feet, its circumference at the bottom 21 yards 11 inches; its greatest thickness 23 inches. The beam to which this vast machine was fastened being accidentally burnt, the bell fell down, and a fragment was broken off towards the bottom, which left an aperture large enough to admit two persons abreast without stopping.

The palace, inhabited by the ancient czars, stands at the extremity of the Kremlin. Part of this palace is old, and remains in the same state in which it was built under Ivan Vassilievitch I. The remainder has been successively added at different intervals without any plan, and in various styles of architecture, which has produced a motley pile of building, remarkable for nothing but the incongruity of the several structures. The top is thickly set, with numerous little gilded spires and globes; and a large portion of the front is decorated with the arms of all the provinces which compose the Russian empire. The apartments are in general exceedingly small, excepting one single room called the council-chamber, in which the ancient czars used to give audience to foreign ambassadors, and which has been repeatedly defribed by several English travellers who visited Moscow before the imperial residence was transferred to Petersburg. The room is large and vaulted, and has in the centre an enormous pillar of stone which supports the ceiling. In this palace Peter the Great came into the world, in the year 1672. In that part called the treasury are reposited the crown, jewels, and royal robes, used at the coronation of the sovereign, besides several curiosities relative to the history of the country. Of the great number of churches contained in this city, two in particular, namely, that of St. Michael and that of the Assumption of the Virgin Mary, are remarkable; the one for being the place where the sovereigns of Russia were formerly interred, and the other where they are crowned. These edifices, which are situated in the Kremlin, are both in the same style of architecture; and their exterior form, though modelled according to the ancient style of the country, is not absolutely elegant. In the cathedral of St. Michael, which contains the tombs of the Russian sovereigns, the bodies are not, as with us, deposited in vaults, but are entombed in raised pulpits, mostly of brick, in the shape of a coffin, and about two feet in height. When Mr. Coxe visited the cathedral, the most ancient were covered with piles of red cloth, others of red velvet, and that of Peter II with gold tissue, bordered with silver fringe and ermine. Each tomb has at its lower extremity a small silver plate, upon which is engraved the name of the deceased sovereign, and the era of his death.

The cathedral of the Assumption of the Virgin Mary, which has long been appropriated to the coronation of the Russian sovereigns, is the most splendid and magnificent in Moscow. The screen is in many parts covered with plates of solid silver and gold richly worked. From the centre of the roof hangs an enormous chandelier of maffy silver, weighing 2940 pounds; it was made in England, and was a present from Morosoff, prime minister and favourite of Alexey Michaelovitch. The sacred utensils and episcopal vestments are extraordinarily rich, but the taste of the workmanship is in general rude, and by no means equal to the materials. Many of the paintings which cover the inside walls are of a colossal size; none are very ancient, and were executed so early as in the latter end of the 11th century. It contains, amongst the rest, a head of the virgin, supposed to have been delineated by St. Luke, and greatly celebrated in this country for its sanctity and the power of working miracles. Its face is almost black; its head is ornamented with a glory of precious stones and its hands and body are gilded, which gives it a most grotesque appearance. It is placed in the ikreen, and enclosed within a large silver covering, which is only taken off on great festivals, or for the curiosity of strangers. In this cathedral are deposited the remains of the Russian patriarchs.

The place in the Khitaigorod, where the public archives are deposited, is a strong brick building, containing several vaulted apartments with iron floors. These archives consisting of a numerous collection of flat-papers, were crowded into boxes, and thrown aside like common lumber, until the present empress ordered them to be revised and arranged. In conformity to this mandate, Mr. Muller has disposed them in chronological order with such perfect regularity, than any single document may be inspected with little trouble. They are enclosed in separate cabinets with glass doors; those relative to Russia are all clasped according to the several provinces which they concern; and over each cabinet is inscribed the name of the province to which it is appropriated. In the same manner the manuscripts relative to foreign kingdoms are placed in separate divisions under the respective titles of Poland, Sweden, England, France, Germany, Sc.

The university of Moscow, also situated in the Khitaigorod, was founded, at the instance of Count Shuvalof, by the empress Elizabeth, for 600 students; who are clothed,
Moscow is the centre of the inland commerce of Russia, and particularly connects the trade between Europe and Siberia. The only navigation to this city is formed by the Moskva, which falling into the Oka near Columna, communicates by means of that river with the Volga. But as the Moskva is only navigable in spring upon the melting of the snows, the principal merchandise is conveyed to and from Moscow upon flegdes in winter. As to the retail commerce here, the whole of it is carried on in the Khlitagorod, where, according to a custom common in Russia, as well as in most kingdoms of the East, all the shops are collected together in one spot. The place is like a kind of fair, confiting of many rows of low brick buildings; the interval between them resembling alleys. These shops or booths occupy a consider-able space; they do not, as with us, make part of the houses inhabited by the tradesmen, but are quite detached from their dwellings, which for the most part are at some distance in another quarter of the town. The tradesman comes to his shop in the morning, remains there all day, and returns home to his family in the afternoon. Every trade has its separate department; and they who sell the same goods have booths adjoining to each other. Furs and skins form the most considerable article of commerce in Moscow; and the shops which vend those commodities occupy several streets.

Among the curiosities of Moscow, the market for the sale of houses is not the least remarkable. It is held in a large open space in one of the suburbs; and exhibits a great variety of ready-made houses, thickly strewn upon the ground. The purchaser who wants a dwelling, repairs to this spot, mentions the number of rooms he requires, examines the different timbers, which are regularly numbered, and bargains for that which suits him. The house is then painted on the spot and taken away by the purchaser; or sometimes the vender contrives to transport and erect it upon the place where it is designed to stand. It may appear incredible to assert, that a dwelling may be thus bought, removed, raised, and inhabited, within the space of a week; but we shall conceive it practicable by considering that these ready-made houses are in general merely collections of trunks of trees tenanted and mortoiled at each extremity into one another, so that nothing more is required than the labour of transporting and assembling them. But this summary mode of building is not always peculiar to the meaner houses; as wooden structures of very large dimensions and handsome appearance are occasionally formed in Russia with an expedition almost inconceivable to the inhabitants of other countries. A remarkable instance of this dispatch was displayed the last time the embassy came to Moscow. Her ma-

jesty proposed to reside in the mansion of prince Ga-

litzin, which is esteemed the completest edifice in this city; but as it was not sufficiently spacious for her reception, a temporary addition of wood, larger than the original house, and containing a magnificent suite of apartments, was begun and finished within the space of six weeks. This material was like fabric was so handsome and commodious, that the materials which were taken down at her majesty's departure, were to be re-constructed as a kind of imperial villa upon an emi-
nence near the city.

Mr Cox mentions an admirable police in this city for preventing riots, or for fopping the concourse of people in case of fires, which are very frequent and violent in those parts, where the houses are mostly of wood, and the fire is laid with timber. At the entrance of each street there is a chevaux-frize gate, one end whereof turns upon a pivot, and the other rolls upon a wheel; near it is a cen-
y-box in which a man is occasionally stationed. In times of riot or fire the sentinel flusts the gate, and all passage is immediately stopped.

Among the public institutions of Moscow, the most remarkable is the Foundling Hospital, endowed in 1764 by the present empress, and supported by voluntary contributions and legacies, and other charitable gifts. In order to encourage donations, her majesty grants to all benefactors some valuable privileges, and a certain degree of rank in proportion to the extent of their liberality. Among the principal contributors must be mentioned a private merchant named Dimidoff, a person of great wealth, who has expended in favour of this charity above L. 100,000.

The hospital, which is situated in a very airy part of the town upon a gentle ascent near the river Moskva, is an immense pile of building of a quadrangular shape, part of which was only finished when Mr Cox (who account we are transmitting) was at Moscow. It contained, at that time, 3000 foundlings; and, when the whole is completed, will receive 8000. The children are brought to the porter's lodge, and admitted without any recommendation. The rooms are lofty and large; the dormitories, which are separate from the work rooms, are very airy, and the beds are not crowded; each foundling, even each infant has a separate bed; the bead-boards are of iron; the sheets are changed every week, and the linen three times a-week. Through the whole range of building, the whole range is sometimes painted; even the nurseries being uncommonly clean, and without any unwholesome smells. No cradles are allowed, and rocking is particularly forbidden. The infants are not swaddled according to the custom of the country but loosely drefled. — The foundlings are divided into separate classes, according to their respective ages. The children remain two years in the nursery, when they are admitted into the lowest clafs; the boys and girls continue together until they are seven years of age, at which time they are separated. They all learn to read, write, and count accounts. The boys are taught to knit; they occasionally card hemp, flax, and wool, and work in the different manufactories. The girls learn to spin and weave lace; they are employed in cookery, baking, and house-work of all sorts. At the age of 14 the foundlings enter into the first clafs; when they have the liberty of choosing
MOS [384] MOS

there are different species of manufactures established in the hospital, of which the principal are embroidery, silk flossings, ribbons, lace, gloves, buttons, and cabinet work. A separate room is appropriated to each trade. Some boys and girls are instructed in the French and German languages, and a few boys in the Latin tongue; others learn music, drawing, and dancing. About the age of 20, the foundlings receive a sum of money, and several advantages, which enable them to follow their trade in any part of the empire: a very considerable privilege in Russia, where the peasants are slaves, and cannot leave their village without the permission of the master. The girls and boys eat separately. The dining rooms, which are upon the ground-floor are large and vaulted, and distinct from their work-rooms. The first classes sit at table; the little children are attended by servants; but those of the first or second classes alternately wait upon each other. Their victuals are of the most wholesome and nourishing kinds. Each foundling has a napkin, pewter plate, a knife, fork and spoon: the napkin and table-cloth are clean three times in the week. They rise at 6, dine at eleven, and sup at six. The little children have bread at seven and at four. When they are not employed in their necessary occupations, the utmost freedom is allowed, and they are encouraged to be as much in the air as possible.

MOSELLE, a river of Germany, which rises in the mountains of Vauge in Lorrain, and, running through that duchy and the electorate of Trier, falls into the Rhine at Coblenz.

MOSES, the son of Amram and Jochebed, was born in the year 1571 before Christ. Pharaoh king of Egypt, perceiving that the Hebrews were becoming a formidable nation, issued forth an edict commanding all the male children to be put to death. Jochebed, the mother of Moses, having, to avoid this cruel edict, concealed her son for three months, at length made an ark or basket of bulrushes, daubed it with pitch, laid the child in it, and exposed him on the banks of the Nile. Thermuthis the king’s daughter, who happened to be walking by the river’s side, perceived the floating cradle, commanded it to be brought to her, and struck with the beauty of the child, determined to preserve his life. In three years afterwards the princess adopted him for her own son, called his name Mofes, and caused him to be diligently instructed in all the learning of the Egyptians. But his father and mother, to whom he was reared by a fortunate accident, were at still greater pains to teach him the history and religion of his fathers. Many things are related by historians concerning the first period of Mofes’s life, which are not to be found in the Old Testament. According to Josephus and Eusebius, he made war on the Ethiopians, and completely defeated them. They add, that the city Saba, in which the enemy had been forced to take refuge, was betrayed into his hands by the king’s daughter, who became deeply enamoured of him, when the beheld from the top of the walls his valorous exploits at the head of the Egyptian army. But as the truth of this expedition is more than doubtful, we shall therefore confine ourselves to the narrative of sacred writ, which commences at the fortieth year of Mofes’s life. He then left the court of Pharaoh, and went to visit his countrymen the Hebrews, who groaned under the ill-usage and oppression of their unfeeling masters. Having perceived an Egyptian slaying an Hebrew, he slew the Egyptian, and burnt him in the land. But he was obliged, in consequence of this murder, to fly into the land of Midian, where he married Zipporah, daughter of the priest Jethro, by whom he had two sons, Gershom and Eliezer. Here he lived 40 years; during which time his employment was to tend the flocks of his father-in-law. Having one day led his flock towards Mount Horæb, God appeared to him in the midst of a bush which burned with fire but was not consumed, and commanded him to go and deliver his brethren from their bondage. Moses at first refused to go, but was at length prevailed on by two miracles which the Almighty wrought for his conviction. Upon his return to Egypt, he, together with his brother Aaron, went to the court of Pharaoh and told him that God commanded him to let the Hebrews go to offer sacrifices in the desert of Arabia. But the impious monarch disregarded this command, and caused the labour of the Israelites to be doubled. The messengers of the Almighty again returned to the king, and wrought a miracle in his sight, that they might move his heart, and induce him to let the people depart. Aaron having cast down his miraculous rod, it was immediately converted into a serpent; but the same thing being performed by the magicians, the king’s heart was hardened more and more; and his obstinacy at last drew down the judgements of the Almighty on his kingdom, which was afflicted with ten dreadful plagues. The first was the changing of the waters of the Nile and of all the rivers into blood, so that the Egyptians died of thirst. In consequence of the second plague, the land was covered with innumerable swarms of frogs, which entered even into Pharaoh’s palace. By the third plague, the dust was converted into lice, which cruelly tormented both man and beast. The fourth plague was a multitude of destructive flies which spread throughout Egypt, and infected the whole country. The fifth was a sudden pestilence, which destroyed all the cattle of the Egyptians, without injuring those of the Israelites. The sixth produced numberless ulcers and fiery bites upon man and upon beast. The seventh was a dreadful storm of hail, accompanied with thunder and lightning, which destroyed every thing that was in the field, whether man or beast, and spared only the land of Gothen where the children of Israel dwelt. By the eighth plague swarms of locusts were brought into the country, which devoured every green herb, the fruit of the trees and the produce of the harvest. By the ninth plague thick darkness covered all the land of Egypt, except the dwellings of the children of Israel. The tenth and last plague was the death of the first-born in Egypt, who were all in one night cut off by the destroying angel, from the first-born of the king to the first-born of the slaves and of the cattle. This dreadful calamity moved the heart of the hardened Pharaoh, and he at length consented to allow the people of Israel to depart from his kingdom.

Proune authors who have spoken of Moses, seem to have been in part acquainted with these mighty wonders.
the commandments

Moses, who built a house for the God of his fathers after

years. He ed the levites to its service. He likewise gave various

law was inscribed. When Moses descended, his face

sion, and put 23,000 of the transgressors to the

waters thereof being divided, remained suspended on

both sides the Hebrews passed through dry-footed.

—The Egyptians determined to follow the same course; but God caused a violent wind to blow, which brought back the waters to their bed, and the whole army of Pharaoh perished in the waves.

After the miraculous passage of the Red Sea, the army proceeded towards Mount Sinai, and arrived at Marah, where the waters were bitter; but Moses, by casting a tree into them, rendered them fit for drinking. Their tenth encampment was at Rephidim; where Moses drew water from the rock in Horeb, by fmiting it with his rod. Here likewise Amaelek attacked Israel. While Joshua fought against the Amalekites, Moses stood on the top of a hill, and lifted up his hand; in consequence of which the Israelites prevailed and cut their enemies in pieces. They at length arrived at the foot of Mount Sinai on the third day of the ninth month after their departure from Egypt. Moses having ascended several times into the mount, received the law from the hand of God himself in the midst of thunders and lightnings, and concluded the famous covenant betwixt the Lord and the children of Israel. When he descended from the mount, he found that the people had fallen into the idolatrous worship of the golden calf. The mef­ fenger of God, shocked at such ingratitude, broke in pieces the tables of the law which he carried in his hands, and put 23,000 of the transgressors to the sword. He afterwards recended into the mountain, and there obtained new tables of stone on which the law was inscribed. When Moses descended, his face shone so that the Israelites dared not to come nigh unto him, and he was obliged to cover it with a veil. The Israelites were here employed in constructing the tabernacle according to a pattern shown them by God. It was erected and consecrated at the foot of Mount Sinai on the first day of the first month of the second year after their departure from Egypt; and it served the Israelites instead of a temple till the time of Solomon, who built a house for the God of his fathers after a model shown him by David.

Moses having dedicated the tabernacle, he consecrated Aaron and his sons to be its ministers, and appointed the levites to its service. He likewise gave various commandments concerning the worship of God and the political government of the Jews. This was a theocracy in the full extent of the word. God himself governed them immediately by means of his servant Moses, whom he had chosen to be the interpreter of his will to the people; and he required all the honors belonging to his king to be paid unto himself. He dwelt in his tabernacle, which was situated in the middle of the camp, like a monarch in his palace. He gave answers to those who consorted with him, and himself denounced punishments against the transgressors of his laws. This properly was the time of the theocracy, taken in its fullest extent; for God was not only considered as the divinity who was the object of their religious worship, but as the sovereign to whom the honors of supreme majesty were paid. The camp was nearly the same under Joshua; who, being filled with the spirit of Moses, undertook nothing without consulting God. Every measure, both of the leader and of the people, was regulated by the direction of the Almighty, who rewarded their fidelity and obedience by a series of miracles, victories, and successes. After Moses had regulated every thing regarding the civil administration, and the marching of the troops, he led the Israelites to the confines of Canaan, to the foot of Mount Nebo. Here the Lord commanded him to ascend into the mountain; whence he showed him the promised land, whereunto he was not permitted to enter. He immediately after yielded up the ghost, without sickness or pain, in the 120th year of his age, and 145 years before Jesus Christ.

Moses is incontestably the author of the first five books of the Old Testament, which go by the name of the Pentateuch; and which are acknowledged to be inspired, by the Jews and by Christians of every persuasion. Some, however, have denied that Moses was the author of these books; and have found their opinion on this, that he always speaks of himself in the third person. But this manner of writing is by no means peculiar to Moses; it occurs also in several ancient historians such as Xenophon, Caesar, Josephus, &c. who, possessed of more modesty or good sense than some modern historians, whose egotism is altogether disgusting, have not like them left to posterity a spectacle of ridiculous vanity and self conceit. After all it is proper to observe that profane authors have related many falsehoods and absurdities concerning Moses, and concerning the origin and the religion of the Jews, with which they were but little acquainted. Plutarch, in his book concerning Isis and Osiris, says, that Judeus and Hierofoylus were brothers, and descended from Typhon; and that the former gave his name to the country and its inhabitants, and the latter to the capital city. Others say that they came from Mount Ida in Phrygia. Strabo is the only author who speaks any thing like reason and truth concerning them; tho' he too says that they were descended from the Egyptians, and considers Moses their legislator as an Egyptian priest. He acknowledges, however, that they were a people strictly just and sincerely religious. Other authors by whom they are mentioned, seem not to have had the smallest acquaintance either with their laws or their worship. They frequently confound them with the Christians, as is the case with Juvenal, Tacitus, and Quintilian.

MOSEHEIM (John Laurence), an illustrious German divine, was born in 1695, of a noble family, which might seem to open to his ambition a fair path to civil promotion; but his zeal for the interests of
religion, his thirst after knowledge, and particularly his taste for sacred literature, induced him to consecrate his talents to the service of the church. The German universities loaded him with literary honours; the king of Denmark invited him to settle at Copenhagen; the duke of Brunswick called him thence to Halmstadt, where he filled the academical chair of divinity; was honoured with the character of ecclesiastical councillor to the court; and presided over the seminaries of learning in the duchy of Wolfenbuttle and the principality of Blackenburgh. When a design was formed of giving an uncommon degree of lucre to the university of Gottingen, by filling it with men of the first rank in letters, Dr Mosheim was deemed worthy to appear at the head of it, in quality of chancellor; and here he died, universally lamented, in 1755. In depth of judgment, in extent of learning, in purity of taste, in the powers of eloquence, and in a laborious application to all the various branches of erudition and philosophy, he had certainly very few superiors. His Latin translation of Cudworth's Intellectual System, enriched with large annotations, discovered a profound acquaintance with ancient learning and philosophy. His illustrations of the Scriptures, his labours in defence of Christianity, and the light he cast upon religion and philosophy, appear in many volumes of sacred and profane literature; and his Ecclesiastical History, from the birth of Christ to the beginning of the present century, is unquestionably the best that is extant. This work, written in Latin, has been translated into English, and accompanied with notes and chronological tables by Archibald Maclaine, D. D. and from this translator's preface to the second edition, 1758, in 5 vols 8vo, this short account is taken.

MOSQUITO-COUNTRY, is situated in North America, between 85 and 88 degrees of west longitude, and between 13 and 15 degrees of north latitude; having the north sea on the north and east, Nicaragua on the south, and Honduras on the west; and indeed the Spaniards esteem it a part of the principality of Honduras, though they have no colonies in the Mosquito country. When the Spaniards first invaded this part of Mexico, they massacred the greatest part of the natives, which gave those that escaped into the inaccessible part of the country an insuperable aversion to them and they have always appeared ready to join any Europeans that come upon their coasts against the Spaniards, and particularly the English, who frequently come hither; and the Mosquito men being excellent marksmen, the English employ them in striking the maratee sith, &c. and many of the Mosquito Indians come to Jamaica, and fail with the English in their voyages.

These people are so situated between morassies and inaccessible mountains, and a coast full of rocks and fisals, that no attempts against them by the Spaniards whom they mortal hate, could ever succeed. Nevertheless, they are a mild inoffensive people, of great morality and virtue, and will never trufl a man who has once deceived them. They have so great a veneration towards the English, that they have spontaneously put themselves and their lands under the protection and dominion of the crown of England. This was first done when the duke of Albemarle was governor of Jamaica, and the king of the Moskitos received a commission from his grace, under the seal of that island; since which time they have not only been steady in their alliance with the English, but warm in their affections, and very useful to them on many occasions.

When their king dies, the male heir goes to Jamaica, to certify that he is next in blood, and receives a commission in form from the governor of Jamaica to be king of the Moskitos, till which he is not acknowledged as such by his countrymen. So fond are these people of every thing that is English, that the common people are proud of every Christian or surname given them by our seamen, who honour their chief men with the titles of some of our nobility.

MOSQUE, a temple or place of religious worship among the Mahometans.

All mosques are square buildings, generally constructed of stone. Before the chief gate there is a square court paved with marble; and low galleries round it, whose roof is supported by marble pillars. In these galleries the Turks wash themselves before they go into the mosque. In each mosque there is a great number of lamps; and between these hang many crystal rings, ostrich eggs, and other curiosities, which when the lamps are lighted, make a fine show. As it is not lawful to enter the mosque with stockings or shoes on, the pavements are covered with pieces of stuff folded together, each being wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter the mosque, but stay in the porches without. About every mosque there are fix high towers, called minarets, each of which has three little open galleries one above another; these towers, as well as the mosques, are covered with lead, and adorned with gilding and other ornaments; and from thence, instead of a bell, the people are called to prayers by certain officers appointed for that purpose. Most of the mosques have a kind of hospital belonging to them, in which travellers of what religion lower are entertained three days. Each mosque has also a place called tare, which is the burying-place of its founders; within which is a tomb fix or seven feet long, covered with green velvet or satin; at the ends of which are two tapers, and round it several seats for those who read the koran and pray for the souls of the deceased.

Moss (Dr Robert), dean of Ely, was eldest son of Mr Robert Mos, a gentleman in good circumstances; and was born at Gillingham in Norfolk in 1666. He was bred at Benet-college, Cambridge; and acquired great reputation both as a disputant and a preacher. He became preacher to the society of Grays-inn, London, in 1698; and assistant preacher to Dr Wake at St James's, Westminster, 1699. He was sworn chaplain in three succeeding reigns, to King William, Queen Anne, and George I. and being one of the chaplains in waiting when Queen Anne visited the university of Cambridge, April 5, 1705, he was then created D. D. In 1708 he was invited by the parishioners of St Lawrence Jewry, on the resignation of dean Stanhope, to accept of their Tuesday lecture, which he held till 1727, and then resigned it on account.
In the year 1712, on the death of Dr Roderick, he was nominated by the queen to the deanery of Ely, which was the highest, but not the last, promotion he obtained in the church; for in 1716 he was collated, by Robinion bishop of London, to Gildon, a small rectory on the eastern side of Hertfordshire. The poet deprived him of the use of his limbs for some of the last years of his life; and he died March 26, 1729, in his 63rd year, and was buried in the presbytery of his own cathedral, under a plain stone with a simple inscription. His character may be seen in the preface to the eight volumes of his Sermons, which has usually been attributed to Dr Snape, the editor of the sermons; but the credit of it has lately been transferred to Dr Zachary Grey. Dean Moss is also supposed to have been the author of a pamphlet printed in 1717, intitled. "The report vindicated from misreports: being a defence of my lords the bishops, as well as the clergy of the lower house of convocation; in a letter from a member of that house to the preluder concerning their late confusions about the bishop of Bangor's writings." He wrote also some poems, both Latin and English.

Moss, or Mosses, in botany. See Musci.

Moss on Trees, in gardening. The growth of large quantities of moss on any kind of tree is a disturber of very bad consequence to its increase, and much damages the fruit of the trees of our orchards.

The present remedy is the scraping it off from the body and large branches by means of a kind of wooden knife that will not hurt the bark, or with a piece of rough hair cloth, which does very well after a soaking rain. But the most effectual cure is the taking away the cause. This is to be done by draining off all the superfluous moisture from about the roots of the trees, and may greatly be guarded against in the first planting of the trees, by not setting them too deep.

If trees stand too thick in a cold ground, they will always be covered with moss; and the best way to remedy the fault is to thin them. When the young branches of trees are covered with a long and shaggy moss, it will utterly ruin them; and there is no way to prevent it but to cut off the branches near the trunk, and even to take off the head of the tree if necessary; for it will sprout again; and if the caufe be in the mean time removed by thinning the plantation, or draining the land and stirring the ground well, the young shoots will continue clear after this.

If the trees are covered with moss in consequence of the ground's being too dry, as this will happen from either extreme in the soil, then the proper remedy is the laying mud from the bottom of a pond or river pretty thick about the root, opening the ground to some distance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of moss, but it will also prevent the other great mischief which fruit-trees are liable to in dry grounds, which is the falling off of the fruit too early.

The mosses which cover the trunks of trees, as they always are freethelt and moist vigorous on the side which points to the north, if only produced on that, serve to preserve the trunk of the tree from the severity of the north winds, and direct the traveller in his way, by always plainly pointing out that part of the country.

Moss is also a name given by some to the boggy ground in many parts of England, otherwise called a fen and bog.

In many of these grounds, as well in England and Ireland as in other parts of the world, there are found vast numbers of trees standing with their thumps erect, and their roots piercing the ground in a natural posture as when growing. Many of these trees are broken or cut off near the roots, and lie along, and this usually in a north-east direction. People who have been willing to account for this, have usually resolved it into the effect of the deluge in the days of Noah; but this is a very wild conjecture, and is proved false by many unanswerable arguments. The waters of this deluge might indeed have washed together a great number of trees, and buried them under loads of earth; but then they would have lain irregularly and at random; whereas they all lie lengthwise from south-west to north-east, and the roots all stand in their natural perpendicular posture, as close as the roots of trees in a forest.

Beyond these, these trees are not all in their natural state, but many of them have the evident marks of human workmanship upon them, some being cut down with an ax, some split, and the wedges still remaining in them; some burnt in different parts, and some bored through with holes. These things are also proved to be of a later date than the deluge, by other matters found among them, such as utensils of ancient people, and coins of the Roman emperors.

It appears from the whole, that all the trees which we find in this mossy state, originally grew in the very places where we now find them, and have only been thrown down and buried there, not brought from elsewhere. It may appear indeed an objection to this opinion, that most of these mossy trees are of the fir-kind; and that Cæsar says expressly, that no firs grew in Britain in his time: but this is easily answered by observing, that these trees, though of the fir-kind, yet are not the species usually called the fn, but pitch tree; and Cæsar has no where said that pitch-trees did not grow in England. Norway and Sweden yet abound with these trees; and there are at this time whole forests of them in many parts of Scotland, and a large number of them wild upon a hill at Wareton in Staffordshire to this day.

In Hatfield marsh, where such vast numbers of the mossy trees are now found, there has evidently once been a whole forest of them growing. The laft of these was found alive, and growing in that place within 70 years last past, and cut down for some common use.

It is also objected by some to the system of the fir growing where they are found fossil, that these countries are all bogs and moors, whereas these farts of trees grow only in mountainous places. But this is founded on an error; for though in Norway and Sweden, and some other cold countries, the fir kinds all grow upon barren and dry rocky mountains, yet in warmer places they are found to thrive as well on wet plains. Such are found plentifully in Pomerania, Livonia, and Courland, &c. and in the west parts of New England.
England there are vast numbers of fine flatly trees of them in low grounds. The whole truth seems to be, that these trees love a sandy soil; and such as is found at the bottoms of all the mosses where these trees are found fertile. The roots of the fir-kind are always found fixed in these; and those of oaks, where they are found fertile in this manner are usually found fixed in clay; so that each kind of tree is always found rooted in the places where they stand in their proper soil; and there is no doubt to be made but that they originally grew there. When we have thus found that all the fertile trees we meet with once grew in the places where they are now buried, it is plain that in these places there were once noble forests, which have been destroyed at some time; and the question only remains how and by whom they were destroyed. This we have reason to believe, by the Roman coins found among them, was done by the people of that empire, and that at the time when they were established or establishing themselves there.

Their own historian tells us, that when their armies pursued the wild Britons, these people always sheltered themselves in the miry woods and low watery forests. Caesar expressly says this; and observes, that Cassibelain and his Britons, after their defeat, passed the Thames, and fled into such low morasses and woods, that there was no pursuing them; and we find that the Silures secured themselves in the same manner when attacked by Ostorius and Agricola. The same thing is recorded of Venutius king of the Britons, who inhabited this forest and the Roman troops under Ostorius. The Romans slew many of the Britons, and drove the rest back into this forest, which at that time overspread all this low country. On this the conquerors taking advantage of a strong south-westerly wind, set fire to the pitch-trees, of which this forest was principally composed; and when the greater part of the trees were thus destroyed, the Roman soldiers and captive Britons cut down the remainder, except a few large ones which they left standing as memorials of the destruction of the reft. Their fingle trees, however, could not stand long against the winds, and these falling into the rivers which ran through the country, interrupted their currents; and the water then overspreading the level country, made one great lake, and gave origin to the mosses or moorly bogs, which were afterwards formed there, by the workings of the waters, the precipitation of earthy matter from them, and the putrefaction of rotten boughs and branches of trees, and the vast increase of water-mosses and other pitchy plants which grow in prodigious abundance in all these sorts of places. Thus were these burnt and felled trees buried under a new-formed spongy and watery earth, and afterwards found on the draining and digging through this earth again.

Hence it is not strange that Roman weapons and Roman coins are found among these buried trees; and hence it is that among the buried trees found burnt, some chapped and hewn; and hence it is that the bodies of the trees all lie by their proper roots, and with their tops lying north-east, that is, in that direction in which a south-westerly wind would have blown them down: hence also it is, that some of the trees are found with their roots lying flat, thebe being not cut or burned down, but blown up by the roots afterwards when left fingle; and it is not wonderful, that such trees as these should have continued to grow even after their fall, and shoot up branches from their sides which might easily grow into high trees. Phil. Trans. N° 275.

By this system it is also easily explained why the
moss in the country is in some places two or three yards thicker than in others, or higher than it was formerly, since the growing up of peat-earth or bog-ground is well known, and the moss added by overflowing of waters is not a little.

As the Romans were the destroyers of this great and noble forest, so they were probably also of the several other ancient forests; the ruins of which furnish us with the bog-wood of Staffordshire, Lancashire, Yorkshire, and other counties. But as the Romans were not much in Wales, in the Isle of Man, or in Ireland, it is not to be supposed that forests cut down by those people gave origin to the foillie wood found there: but though they did not cut down these forests, others did; and the origin of the bog-wood is the same with them and with us. Holinghead informs us, that Edward I. being not able to get at the Welch because of their hiding themselves in boggy woods, gave orders at length that they should all be destroyed by fire and by the axe; and doubtless the roots and bodies of trees found in Penbrokeshire under ground, are the remains of the execution of this order. The foillie wood in the bogs of the island of Man is doubtless of the same origin, though we have not any accounts extant of the time or occasion of the forests there being destroyed; but as to the foillie trees of the bogs of Ireland, we are expressly told, that Henry II. when he conquered that country, ordered all the woods to be cut down that grew in the low parts of it, to secure his conquests by cutting away the places of resort of rebels.

MOVING-MOSS. We have an account in the Philosophical Transactions of a moving moss near Churchtown in Lancashire, which greatly alarmed the neighbourhood as miraculous. The moss was observed to rise to a surprising height, and soon after funk as much below the level, and moved flowly towards the south.

A very surprising instance of a moving moss is that of Edway in Scotland, which happened in the year 1771, after severe rains which had produced terrible inundations of the rivers in many places. For the better understanding this event, we shall give the following description of the spot of ground where it happened. Along the side of the river Esk there is a vale, about a mile broad, less or more in different places. It is bounded on the south-east by the river Esk, and on the north west by a steep bank 30 feet in height above the level of the vale. From the top of the bank the ground rises in an easy ascent for about a quarter of a mile, where it is terminated by the moss; which extends about two miles north and south, and about a mile and a half east and west, and is bounded on the north-west by the river Sark. It is probable that the solid ground from the top of the bank above the vale was continued in the same direction under the moss, before its eruption, for a considerable space; for the moss at the place where the eruption happened, was inclined towards the sloping ground. From the edge of the moss there was a gully or hollow, called by the country people the gap, and said to be 30 yards deep where it entered the vale; down which ran a small rill of water which was often dry in summer, having no supply but what filtered from the moss. The eruption happened at the head of this gap, on Saturday November 16th 1771, about ten or eleven at night, when all the neighbouring rivers and brooks were prodigiously swelled by the rains. A large body of the moss was forced, partly by the great fall of rain, and partly by some springs below it, into a small beck or burn, which runs within a few yards of its border to the south-east. By the united pressure of the water behind it, and of this beck, which was then very high, it was carried down a narrow glen between two banks about 300 feet high, into a wide and spacious plain, over part of which it spread with great rapidity. The moss continued for some time to send off considerable quantities; which, being borne along by the torrent on the back of the first great body, kept it for many hours in perpetual motion, and drove it still farther on. This night at least 400 acres of fine arable land were covered with moss from 3 to 12 or 15 feet deep. Several houses were destroyed, a good deal of corn lost, &c. but all the inhabitants escaped. When the waters subsided, the moss also ceased to flow; but two pretty considerable streams continued to run from the heart of it, and carried off some pieces of moss matter to the place where it burst. There they joined to the beck already mentioned; which, with this addition, resumed its former channel; and, with a little assistance from the people of the neighbourhood, made its way to the Esk, through the midst of that great body of moss which obstructed its course. Thus, in a great measure drained, the new moss fell several feet, when the fair weather came in the end of November, and settled in a firmer and more solid body on the lands it had over-run. By this inundation about 800 acres of arable ground were overflowed before the moss stopped, and the habitations of 27 families destroyed. Tradition has preferred the memory of a similar inundation in Monkist in Scotland. A moss there altered its course in one night, and covered a great extent of ground.

MOSS of Kincardine: A remarkable tract of ground in the shire of Perth in Scotland, which deserves particular notice, not merely as a topographical curiosity, or as a subject of natural history; but for the information, equally uncommon and important, which it affords, respecting agricultural improvement, and the promotion of industry and population.

The moss of Kincardine is situated in the parish of the same name, comprehended between the rivers Forth and Teith, and in that district of Perthshire called Monticull. The moss begins about a mile above the confluence of these rivers; from thence it extends in length about four miles, and from one to two in breadth; and before the commencement of the operations (an account of which is to be given), comprehend near 2000 Scotch acres, of which about 1500 belong to the estate of Blair Drummond, the property of Lord Kames by his marriage with Mrs Drummond of Blair Drummond.

As mosses are extremely various in their nature, before entering upon the improvements made in Kincardine moss, it will be proper to give a short description of that moss, and of the subjacent foil which is the object of those improvements.

The moss lies upon a field of clay, which is a continuation of those rich, extensive flats in the neighbourhood
MOS [ 390 ]

The brown mould is highly fertile; the other, especially in a dry season, is very unproductive. The crop that had occupied this mould when the trees were felled is found still entire. It consists chiefly of heath; but several other smaller plants are also very distinguishable.

Immediatly above the stratum lies the moss, to the height, upon an average, of seven feet. It is composed of different vegetables arranged in three distinct strata. Of these the first is three feet thick. It is black and heavy, and preferable to the others for the purpose of fuel. It consists of bent-grass (Agrostis), which seems to have grown up luxuriantly among the trees after they were felled. The second stratum also is three feet thick. It is composed of various kinds of mosses, but principally of bog moss (Sphagnum). It is of a fallow or iron colour, and remarkably elastic. It is commonly called white peat; and for fuel is considered as much inferior to that above mentioned. The third stratum is composed of heath and a little bent-grass, but chiefly of the deciduous parts of the former. It is about a foot thick, and black.

Three strata of different vegetables lying above each other, the limits of each distinctly marked, and each distinguishable by a different colour, is certainly a curious natural phenomenon.

An inquiry will here occur, What has occasioned this succession in the vegetables of which the moss is composed?

Every vegetable has a particular foil, more or less moist, peculiarly adapted to its nature. Let a piece of ground be in a mossy state, rushes will introduce themselves; drain the ground sufficiently, the rushes will disappear, and finer vegetables will succeed. It seems reasonable to account for the succession of the different plants that compose the moss on similar principles.

Let us imagine an extensive plain covered with trees lying in all directions, full of branches, and possibly loaded with leaves. This it is evident would produce a great stagnation of water, which, as the crops of bent-grass accumulated, would still increase: and the probability is, that at length it had so increased, as to be the cause why the bent-grasses and other congenial plants of the first stratum ceased to grow. But it is evident that a plant was to be found that could live in such a situation. Accordingly we see that bog-mosses has established itself; a plant that loves even to swim in water.

When the accumulations of bent-grass and the mosses had, in process of time, risen to the height of six feet above the surrounding carse ground, the water that fell upon the surface had by no means an opportunity to discharge itself. It had accordingly formed many channels which are often three feet deep; and the intermediate surface being wholly turned into little hillocks has become dry and firm. By this means it became unfit for mosses, and heath succeeded.

Such seems to have been the process in the formation of what is now called a moss.

By far the greatest part of the moss in question is, upon an average, full seven feet deep, and has in all probability lain undisturbed since its formation; this is called High Moss. The remainder called the Low Moss, lies to a considerable breadth around the extremities of the high; and is, upon an average, not above three feet in depth.
The peats. These are formed of that stratum of the
M., fol. bro.:ught from the adjacent grounds. But what
Many farmers were wont to
acres of which they for that end left unfown. Here
cause in a dry season the superficial covering of clay
the clay was carried, and the softness of the moss, this

DRAINING has also been proposed as another mode of
Draining has also been proposed as another mode of
improvement; and it must be acknowledged, that, by
the means of draining, many mosses have been converted
both into arable and meadow grounds, which, in the
end became interesting improvements. But in a moss,
as that of Kinardine, this method would be
ineffectual; as for several feet deep it is of such a
nature, that upon being dry and divided into parts, it
would blow with the wind like chaff; and when thrown
aside in the operation of digging peats, it lies for years
without producing a single vegetable, except only a
few plants of forrel.

By the methods described from 100 to 200
acres of moss had been removed. When the
present plan was introduced, there still remained covered
with moss from 1300 or 1400 acres of carse clay—a
treasure for which it must be ever interesting to dig.

In the year 1766 Lord Kames entered into posses-
sion of the estate of Blair Drummond. Long before
that period he was well acquainted with the moss, and
often lamented that no attempt had ever been made to
turn it to advantage; Many different plans were now
proposed; at length it was resolved to attempt, by
means of water as the most powerful agent, entirely to
sweep off the whole body of moss.

That moss might be floated in water, was abundantly
obvious; but to find water in sufficient quantity
was difficult, the only stream at hand being employed
to turn a corn-mill. Convinced of the superior con-
sequence of dedicating this stream to the purpose of
floating off the moss, Lord Kames having made an
agreement with the tenant who farmed the mill, and
the tenants thirled confenting to pay the rent, he im-
mediately threw down the mill, and applied the water
to the above purpose.

In order to determine the best manner of condu-
ting the operation, workmen were now employed for
a considerable time upon Law Moss. But both the
day and by the piece, to ascertain the expense for
which a given quantity of moss could be removed.
It was then agreed to operate at a certain rate per
acre; and in this manner several acres were removed.
But this was to be a very expensive process. The
ground gained might, indeed, be afterwards let to ten-
ants; but every acre would require an expenditure
from £12 to £15, before it could be ready for sowing;
so that the acquisition of the whole, computing it at a
medium to be 1350 acres, would flink a capital of near-
ly 20,000l. sterling.

One other method still remained; namely, to at-
tempt letting portions of the moss, as it lay, for a
term of years sufficient to indemnify tenants for the
expenses incurred in removing it. For some time both
these plans were adopted; but several reasons made
the latter preferable. 1. The quantity of water to be
used had been small; and being also uncertain, it was very
inconvenient for an undertaker; neither were there
